Replace	This function returns the specified text string as a *String* value after all or part of it has been replaced with another string.
Right	This function returns a *String* value that presents the specified number of characters from the end of the specified string.
Text	This function returns the specified number as a *String* value after it has been converted to a text string that is formatted according to the server locale settings of the current application instance.
Translate	This function returns a *String* value that contains the result of the replacement the specified text in characters for another provided set of characters.
Trim	This function returns the specified text string as a *String* value after tab, carriage return, line feed, and form feed characters have been replaced by a single space character, after leading and trailing spaces have been truncated, and after multiple spaces between words have been removed.
Upper	This function returns the specified text string as a *String* value after it has been converted to uppercase letters.

CHAR ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `CHAR` function returns a *String* value that presents a single character that is referenced by the specified Unicode number.

Syntax

VB

```
CHAR (number)
```

Arguments

`number`: *Integer*

A number that corresponds to an expected single character.

Return values

String

The resulting text value.

Usage notes

The string that this function returns depends on the encoding that is selected in the parent **FILE** format element. For a list of the supported encodings, see Encoding class.

Example

`CHAR (255)` returns "ÿ".

Additional resources

Text functions

Last updated on 04/08/2026

CONCATENATE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `CONCATENATE` function returns all the specified text strings as a *String* value after they have been joined into one string.

Syntax

VB

```
CONCATENATE (text 1[, text 2, …, text N])
```

Arguments

`text 1`: *String*

A reference to a data source of the *String* data type. This argument is required.

`text N`: *String*

A reference to a data source of the *String* data type. These additional arguments are optional.

Return values

String

The resulting text value.

Example

`CONCATENATE ("abc", "def")` returns "**abcdef**".

Usage notes

The expression `"abc" & "def"` also returns "**abcdef**".

Additional resources

Text functions

Last updated on 04/08/2026

FORMAT ER function

The `FORMAT` function returns the specified string as a *String* value after it formats the string by substituting any occurrences of **%N** with the *N*th argument.

Syntax

```VB
FORMAT (string, argument 1[, argument 2, …, argument N])
```

Arguments

`string`: *String*

A reference to a data source of the *String* type that you want to format. This argument is required.

`argument 1`: *String*

The first argument, which replaces occurrences of **%1**. This argument is required.

`argument N`: *String*

The *N*th argument, which replaces occurrences of **%2**, **%3**, and so on. These additional arguments are optional.

Return values

String

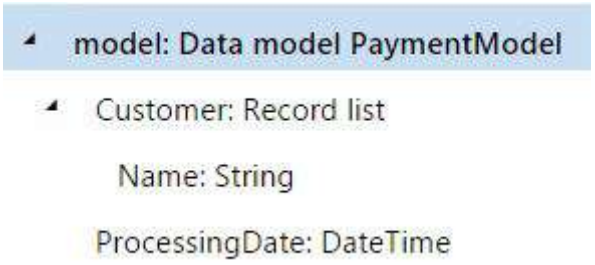
The resulting text value.

Usage notes

If you don't provide an argument for a parameter, the string shows the parameter as **"%N"**. For *Real* type values, the default string conversion rounds the number to two decimal places.

Example

In the following illustration, the **PaymentModel** data source returns a list of customer records by using the **Customer** component. It returns the processing date value by using the **ProcessingDate** field.



In the Electronic reporting (ER) format that is designed to generate an electronic file for selected customers, select **PaymentModel** as a data source. It controls the process flow. If a selected customer is stopped for the date when the report is processed, an exception is thrown to notify the user. The formula that is designed for this type of processing control can use the following resources:

- Label SYS70894, which has the following text:
  - **For the EN-US language:** "Nothing to print"
  - **For the DE language:** "Nichts zu drucken"
- Label SYS18389, which has the following text:
  - **For the EN-US language:** "Customer %1 is stopped for %2."
  - **For the DE language:** "Debitor '%1' wird für %2 gesperrt."

Here's the expression that you can design.

VB

```
FORMAT (CONCATENATE (@"SYS70894", ". ", @"SYS18389"), model.Customer.Name,
DATETIMEFORMAT (model.ProcessingDate, "d"))
```

If you process a report for the **Litware Retail** customer on December 17, 2025, in the **EN-US** culture and the **EN-US** language, this formula returns the following text, which you can present to the user as an exception message:

Nothing to print. Customer Litware Retail is stopped for 12/17/2025.

If you process the same report for the **Litware Retail** customer on December 17, 2025, in the **DE** culture and the **DE** language, the formula returns the following text, which uses a different date format:

Nichts zu drucken. Debitor 'Litware Retail' wird für 17.12.2025 gesperrt.

> **Note**
>
> The following syntax is applied in ER formulas for labels:
>
> - **For labels from resources in the Microsoft Dynamics 365 Finance app: @X**, where **X** is the label ID in the Application Object Tree (AOT)
> - **For labels that reside in ER configurations: @"GER_LABEL:X"**, where **X** is the label ID in the ER configuration

GETENUMVALUEBYNAME ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `GETENUMVALUEBYNAME` function searches for a specific *Enum* value in the specified enumeration data source by using the enumeration name that you specify as a *String* value. If the function finds the *Enum* value, it returns it. Otherwise, the function returns the **null** enumeration value.

Syntax

VB

```
GETENUMVALUEBYNAME (enumeration data source path, enumeration value text)
```

Arguments

`enumeration data source path`: *Enumeration*

The valid path of a data source for one of the following enumeration types:

- Electronic reporting (ER) model enumeration
- ER format enumeration
- Microsoft Dynamics 365 Finance enumeration

`enumeration value text`: *String*

A string value that represents the name of a single enumeration value.

Return values

Nullable *Enum*

The resulting enumeration value.

Usage notes

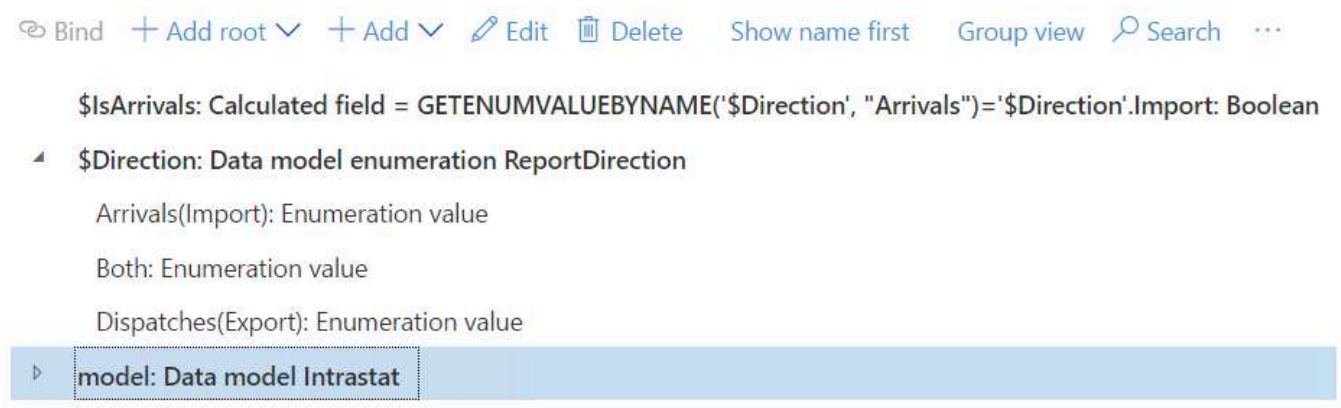
No exception is thrown if an *Enum* value isn't found by using the name of the enumeration value that you specify as a *String* value.

Example 1

In the following illustration, the **ReportDirection** enumeration is introduced in a data model. The labels for the enumeration values are defined.

The following illustration shows these details:

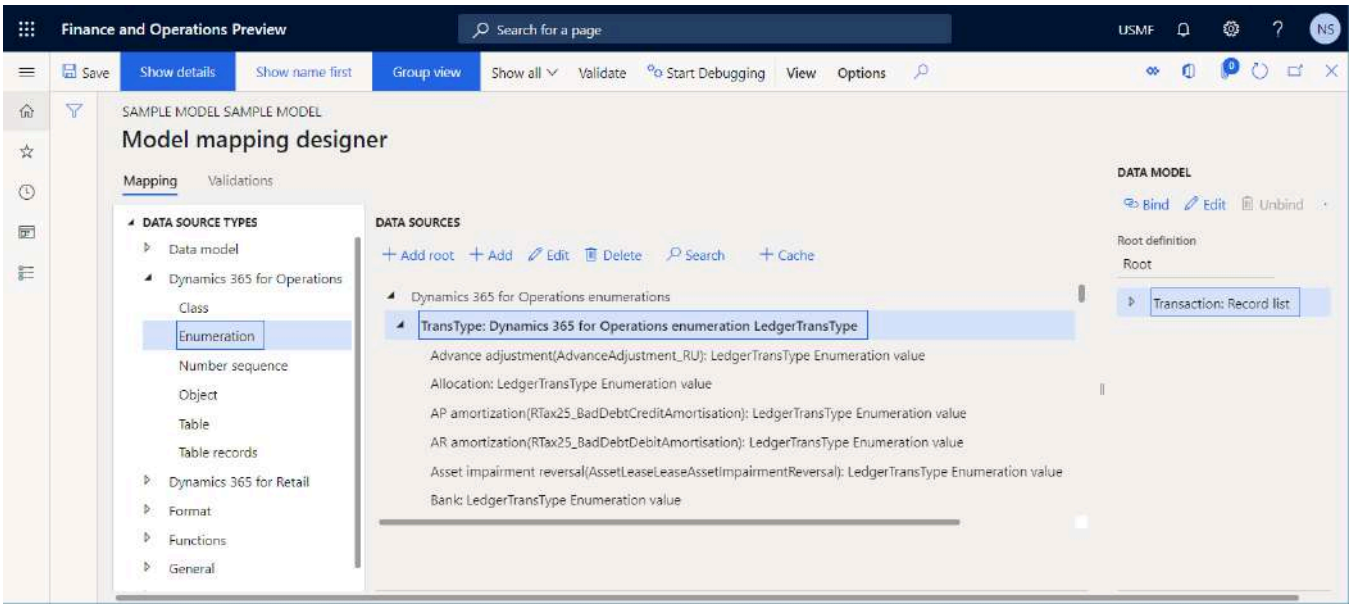
- The **$Direction** data source is configured in an ER report. This data source is configured based on the **ReportDirection** model enumeration.
- The `$IsArrivals` expression uses the model enumeration–based **$Direction** data source as a parameter of this function.
- The value of this comparison expression is **TRUE**.



Example 2

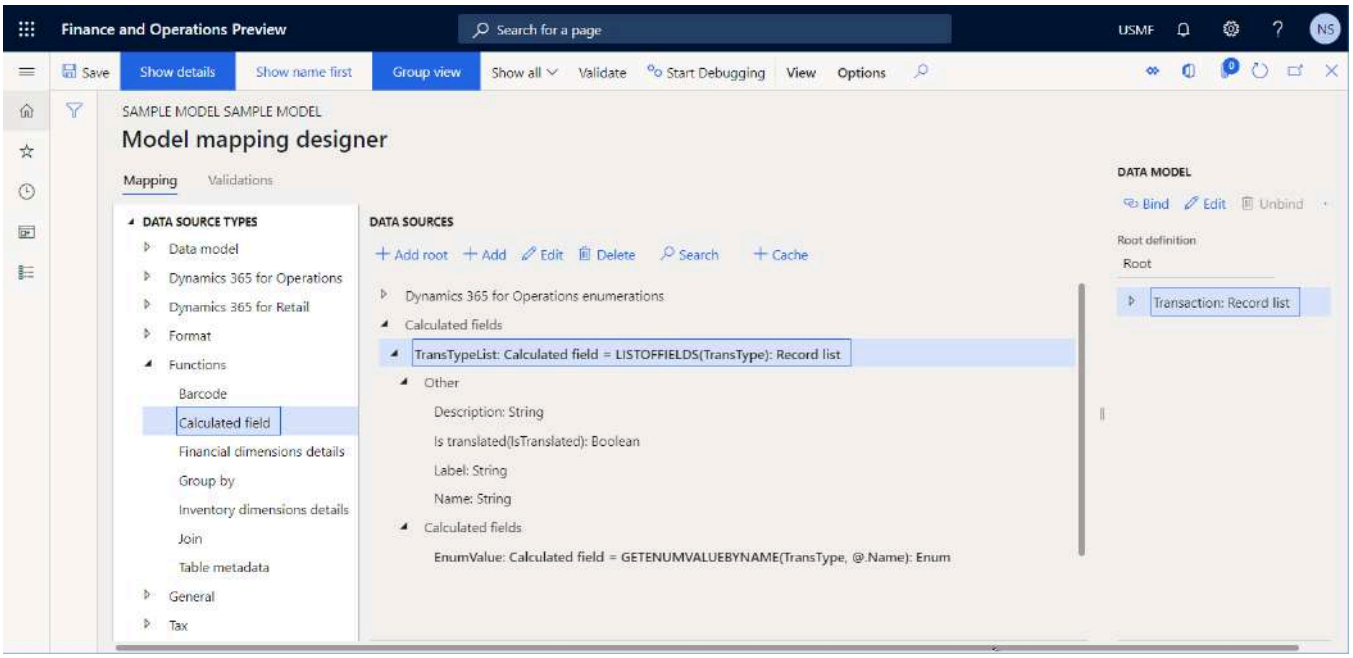
Use the `GETENUMVALUEBYNAME` and LISTOFFIELDS functions to get the values and labels of supported enumerations as text values. Supported enumerations include application enumerations, data model enumerations, and format enumerations.

In the following illustration, you add the **TransType** data source in a model mapping. This data source refers to the **LedgerTransType** application enumeration.



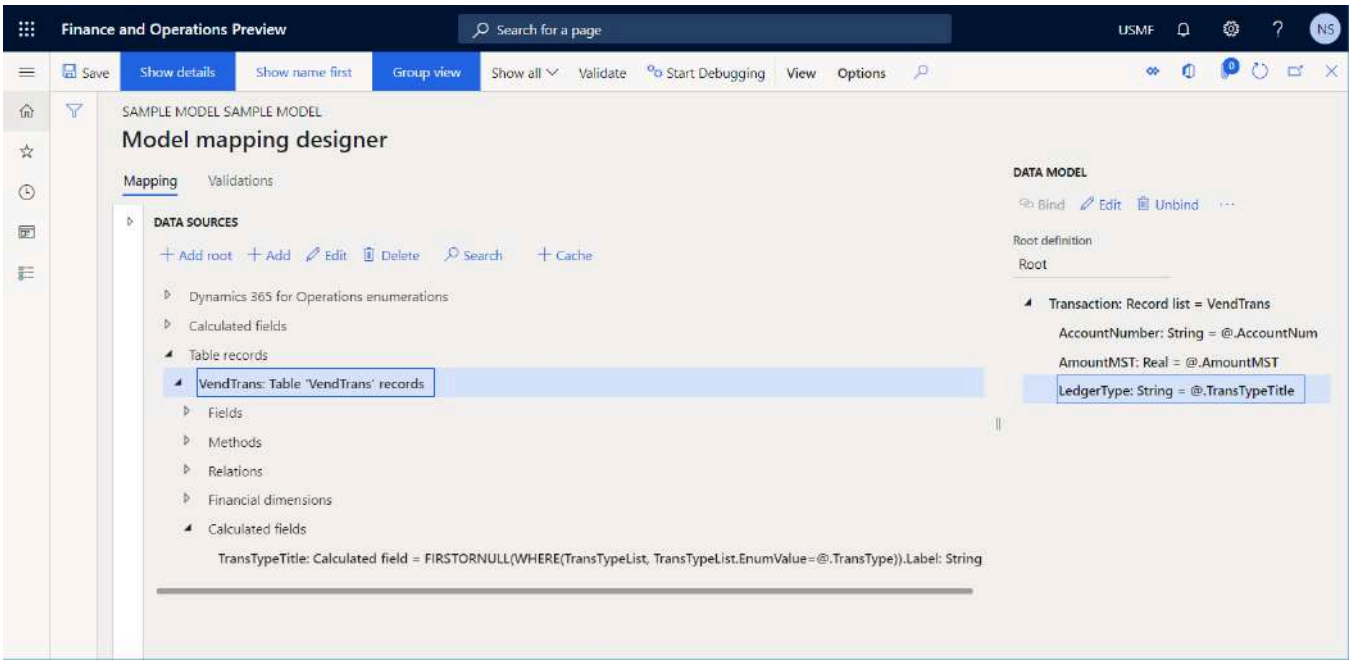
The following illustration shows the **TransTypeList** data source that you configure in a model mapping. You base this data source on the **TransType** application enumeration. Use the `LISTOFFIELDS` function to return all enumeration values as a list of records that contain fields. This approach exposes the details of every enumeration value.

> **Note**
>
> Use the `GETENUMVALUEBYNAME(TransType, TransTypeList.Name)` expression to configure the **EnumValue** field for the **TransTypeList** data source. This field returns an enumeration value for every record in this list.

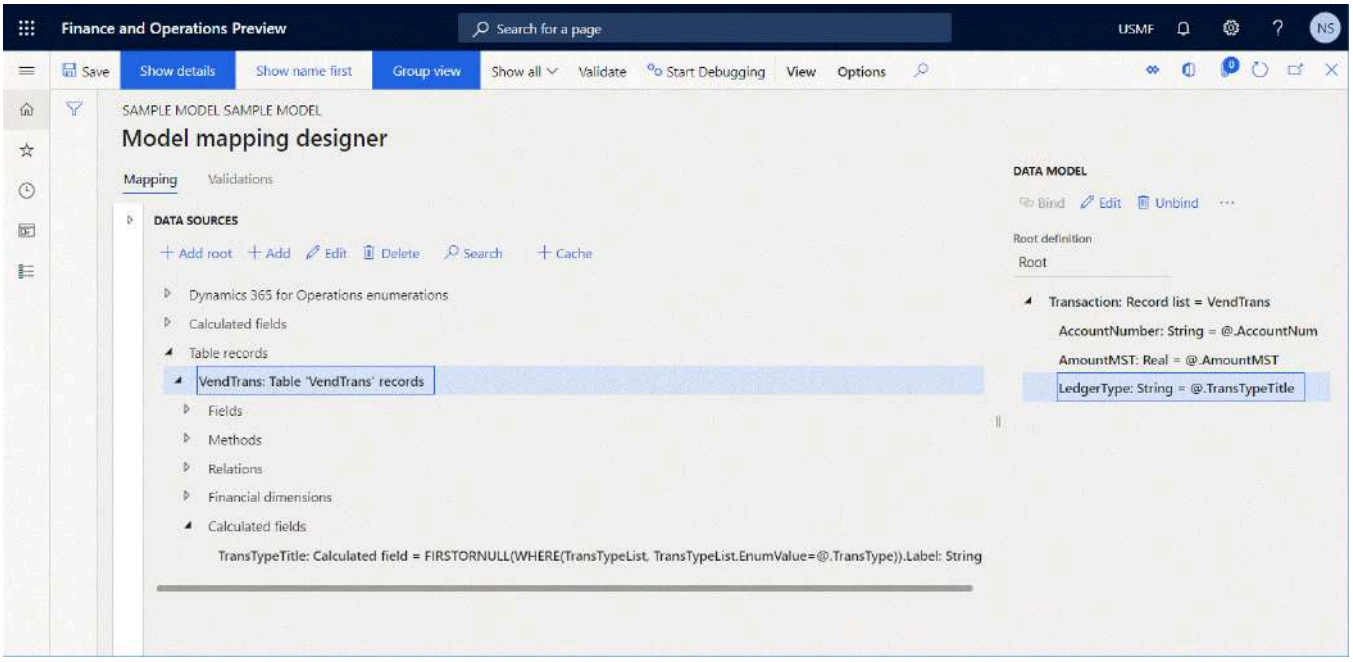


The following illustration shows the **VendTrans** data source that you configure in a model mapping. This data source returns vendor transaction records from the **VendTrans** application table. The ledger type of every transaction is defined by the value of the **TransType** field.

> **Note**
>
> Use the `FIRSTORNULL(WHERE(TransTypeList, TransTypeList.EnumValue = @.TransType)).Label` expression to configure the **TransTypeTitle** field for the **VendTrans** data source. This field returns the label of an enumeration value of the current transaction as text, if this enumeration value is available. Otherwise, it returns a blank string value.
>
> Bind the **TransTypeTitle** field to the **LedgerType** field of a data model. This binding enables you to use the information in every ER format that uses the data model as a source of data.



The following illustration shows how you can use the data source debugger to test the configured model mapping.



The **LedgerType** field of a data model exposes labels of transaction types as expected.

If you plan to use this approach for a large amount of transactional data, consider execution performance. For more information, see Trace the execution of ER formats to troubleshoot performance issues.

Text functions

Trace the execution of ER formats to troubleshoot performance issues

LISTOFFIELDS ER function

FIRSTORNULL ER function

WHERE ER function

Last updated on 04/13/2026

GETLABELTEXT ER function

The `GETLABELTEXT` function searches for a specific label to return a *String* value that represents the translation of the specified label in the specified language.

Syntax

```
VB
GETLABELTEXT (label id, language)
```

Arguments

Label ID

`label id`: *String* or *Label Id*

The valid ID of one of the following label types:

- Electronic reporting (ER) label
- Microsoft Dynamics 365 Finance label

Usage notes

This argument can be defined only as a constant, by using one of the following supported patterns:

- For ER labels:
  - `@"GER_LABEL:<LABEL ID>"`
  - `"GER_LABEL:<LABEL ID>"`
- For Finance labels:
  - `@"<LABEL ID>"`
  - `"<LABEL ID>"`

> **Note**

At design time, a validation error message is shown on the Formula designer page if no label can be found by using the provided label ID.

Language

`language`: *String*

A string that represents a language code.

Usage notes

This argument can be defined either as a text constant or as the path of a data source field that returns a *String* value.

> ⓘ Note
>
> At design time, a validation error message is shown if no language code can be found by using the provided `language` argument when it has been defined as a text constant.
>
> At runtime, the translation for the `EN-US` system language is returned for a specified label if no language code has been found by using the provided `language` argument.

Return values

String

The resulting text value.

Example 1: System label

The expressions `GETLABELTEXT (@"SYS70894", "en-us")` and `GETLABELTEXT ("SYS70894", "en-us")` return the English translation "Nothing to print" for the `@SYS70894` application label.

Example 2: ER label

You start to edit an ER configuration that has been derived from the **ISO20022 Credit transfer (DE)** configuration, enter a new data source of the *Calculated field* type, and configure the expression `GETLABELTEXT(@"GER_LABEL:VendorName", "de")` for this data source. In this case, at runtime, the data source returns the German translation "Kreditorenname" for the

`@GER_LABEL:VendorName` ER label that was initially configured in the base **ISO20022 Credit transfer (DE)** ER configuration.

GUIDVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `GUIDVALUE` function converts the specified input of the *String* type to a data item of the *GUID* type.

Syntax

```
VB

GUIDVALUE (input)
```

Arguments

`input`: *String*

The valid path of a data source of the *String* type.

Return values

GUID

The resulting globally unique identifier (GUID) value.

Usage notes

To do a conversion in the opposite direction (that is, to convert specified input of the *GUID* data type to a data item of the *String* data type), you can use the TEXT function.

Example

You define the following data sources in your model mapping:

- A **myID** data source of the *Calculated field* type that contains the expression `GUIDVALUE ("AF5CCDAC-F728-4609-8C8B- A4B30B0C0AA0")`
- A **Users** data source of the *Table records* type that refers to the UserInfo table

You can then use an expression such as `FILTER (Users, Users.objectId = myID)` to filter the UserInfo table by the **objectId** field of the *GUID* data type.

JSONVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `JSONVALUE` function parses data in JavaScript Object Notation (JSON) format that is accessed at the specified path, and it extracts a scalar value that has the specified ID. It then returns the extracted scalar value as a *String* value.

Syntax

VB

```
JSONVALUE (input, path)
```

Arguments

`input`: *String*

The valid path of a data source of the *String* type that contains JSON data.

`path`: *String*

The identifier of a scalar value of JSON data. Use a forward slash (/) to separate the names of related JSON nodes. Use the bracket ([]) notation to specify the index of a particular value in a JSON array. Note that zero-based numbering is used for this index.

Return values

String

The resulting text value.

Example 1

The **JsonField** data source contains the following data in JSON format: **{"BuildNumber":"7.3.1234.1", "KeyThumbprint":"7366E"}**. In this case, the expression `JSONVALUE (JsonField, "BuildNumber")` returns the following value of the *String* data type: **"7.3.1234.1"**.

Example 2

The **JsonField** data source of the *Calculated field* type contains the following expression: `"{""workers"": [ {""name"": ""Adam"", ""age"": 30, ""emails"": [""AdamS@Contoso.com"", ""AdamS@Hotmail.com"" ]}, { ""name"": ""John"", ""age"": 21, ""emails"": [""JohnS@Contoso.com"", ""JohnS@Aol.com""]}]}"`

This expression configured to return a *String* value that represents the following data in JSON format.

JSON

```
{
    "workers": [
        {
            "name": "Adam",
            "age": 30,
            "emails": [ "AdamS@Contoso.com", "AdamS@Hotmail.com" ]
        },
        {
            "name": "John",
            "age": 21,
            "emails": [ "JohnS@Contoso.com", "JohnS@Aol.com" ]
        }
    ]
}
```

In this case, the expression `JSONVALUE(json, "workers/[1]/emails/[0]")` returns the following value of the *String* data type: `JohnS@Contoso.com`.

LEFT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `LEFT` function returns a *String* value that presents the specified number of characters from the start of the specified string.

Syntax

VB

```
LEFT (text, number)
```

Arguments

`text`: *String*

A *String* value that represents the original text.

`number`: *Integer*

The number of characters that must be returned from the start of the original text.

Return values

String

The resulting text value.

Example

`LEFT ("Sample", 3)` returns "**Sam**".

Additional resources

Text functions

Last updated on 04/08/2026

LEN ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `LEN` function returns the number of characters in the specified string as an *Integer* value.

Syntax

VB

```
LEN (text)
```

Arguments

`text`: *String*

A *String* value that specifies the text.

Return values

Integer

The resulting numeric value.

Example

`LEN ("Sample")` returns **6**.

Additional resources

Text functions

Last updated on 04/08/2026

LOWER ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `LOWER` function returns the specified text string as a *String* value after it has been converted to lowercase letters.

Syntax

VB

```
LOWER (text)
```

Arguments

`text`: *String*

A *String* value that specifies the text.

Return values

String

The resulting text value.

Example

`LOWER ("Sample")` returns **"sample"**.

Additional resources

Text functions

Last updated on 04/08/2026

MID ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `MID` function returns a *String* value that presents the specified number of characters from the specified string, starting at the specified position.

Syntax

```
VB

MID (text, starting position, number of characters)
```

Arguments

`text`: *String*

A *String* value that specifies the text to return characters from.

`starting position`: *Integer*

An *Integer* value that specifies the position of the first character that must be returned from the specified text.

`number of characters`: *Integer*

An *Integer* value that specifies the number of characters that must be returned, starting at the specified starting position.

Return values

String

The resulting text value.

Usage notes

If the value of the `starting position` argument is less than 0 (zero), the characters that are returned are counted from the first position in the specified string.

If the value of the `starting position` argument exceeds length of the specified string, an empty string is returned.

Example

`MID ("Sample", 2, 3)` returns "**amp**".

Additional resources

Text functions

Last updated on 04/08/2026

NEWGUID ER function

The `NEWGUID` function generates a new globally unique identifier (GUID) and returns it as a *GUID* value.

Syntax

```
VB

NEWGUID ()
```

Return values

GUID

The resulting GUID value.

Example

`NEWGUID()` always returns a new *GUID* value, such as **3afcf7ff-af10-ec11-b6e6-000d3a13209e**.

NUMBERFORMAT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `NUMBERFORMAT` function returns a *String* value that presents the specified number in the specified format and in an optionally specified culture. For information about the supported formats, see standard and custom.

Syntax 1

```
VB

NUMBERFORMAT (number, format)
```

Syntax 2

```
VB

NUMBERFORMAT (number, format, culture)
```

Arguments

`number`: *Integer* or *Real*

A numeric value that specifies the number that must be formatted.

`format` : *String*

A *String* value that represents the format.

`culture`: *String*

A *String* value that represents the culture to use for formatting.

Return values

String

The resulting text value.

Usage notes

If the culture isn't defined as an argument of the called function, the context that this function is run in determines the culture that is used to format numbers.

Example 1

For the **EN-US** culture, `NUMBERFORMAT (0.45, "p")` returns "**45.00 %**", and `NUMBERFORMAT (10.45, "#")` returns "**10**".

Example 2

`NUMBERFORMAT (10/3, "F2", "de")` returns **3,33**, whereas `NUMBERFORMAT (10/3, "F2", "en-us")` returns **3.33**.

NUMERALSTOTEXT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `NUMERALSTOTEXT` function returns the specified number as a *String* value after it spells out the number in the specified language.

Syntax

VB

```
NUMERALSTOTEXT (number, language, currency, print currency name flag, decimal points)
```

Arguments

`number`: *Integer* or *Real*

A numeric value that specifies the number to spell out.

`language`: *String*

A *String* value that represents the language code.

`currency`: *String*

A *String* value that represents the currency code.

`print currency name flag`: *Boolean*

A *Boolean* value that indicates whether to add a currency name to the spelled-out text.

`decimal points`: *Integer*

An *Integer* value that indicates the number of decimal places that the spelled-out text should have.

Return values

String

The resulting text value.

Usage notes

The language code is optional. If you define it as an empty string, the language code for the running context is used. The default language code is **EN-US**. The language code for the running context is defined in a **Folder** or **File** element of the Electronic reporting (ER) format that is running.

The currency code is optional. If you define it as an empty string, the company currency for the running context is used.

> **Note**
>
> The `print currency name flag` and `decimal points` arguments are analyzed only for the following language codes: **CS**, **ET**, **HU**, **LT**, **LV**, **PL**, and **RU**. Additionally, the `print currency name flag` argument is analyzed only for companies where the country's or region's context supports declension of currency names.

Example 1

`NUMERALSTOTEXT (1234.56, "EN-US", "", false, 2)` returns "**One Thousand Two Hundred Thirty Four and 56**".

Example 2

`NUMERALSTOTEXT (120, "PL", "", false, 0)` returns "**Sto dwadzieścia**".

Example 3

`NUMERALSTOTEXT (120.21, "RU", "EUR", true, 2)` returns "**Сто двадцать евро 21 евроцент**".

PADLEFT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `PADLEFT` function returns a *String* value of the specified length, where the start of the specified string is padded with the specified characters.

Syntax

VB

```
PADLEFT (text, length, padding chars)
```

Arguments

`text`: *String*

A *String* value that represents the original text.

`length`: *Integer*

An *Integer* value that represents the final number of characters in the padded string.

`padding chars`: *String*

The characters to use for padding.

Return values

String

The resulting text value.

Example

`PADLEFT ("1234", 10, " ")` returns the text string "   1234".

Additional resources

Text functions

Last updated on 04/08/2026

QRCODE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `QRCODE` function returns a *Container* value that presents the Quick Response code (QR code) image for the specified string in binary format.

Syntax

VB

```
QRCODE (text)
```

Arguments

`text`: *String*

A *String* value that represents the original text.

Return values

Container

The resulting binary stream.

Example

You can configure an Electronic reporting (ER) format to generate an outbound document in Microsoft Office format (Excel workbooks or Word documents) by using a predefined template. This template might contain a **Picture** object (Excel workbook) or a **Picture Content Control** (Word document) as a placeholder for a QR code image. Add a **Cell** element to the configured ER format that fills this placeholder. To specify what information the QR code stores, define a

binding for this **Cell** element. For example, you can configure the binding to contain the following expression:

```
VB

QRCODE (model.ListOfShelfLabels.LabelText)`
```

When you run the configured ER format, the text value of the **LabelText** field of the **model.ListOfShelfLabels** data source generates a QR code image. This image replaces a QR code image placeholder in the document template that you use to generate an outbound document. When you scan this image of the generated document, it returns the text that was taken from the **LabelText** field of the **model.ListOfShelfLabels** data source. For more information, see Embed images and shapes in documents that you generate by using ER.

REPLACE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `REPLACE` function returns the specified text string as a *String* value after all or part of it is replaced with another string.

Syntax

VB

```
REPLACE (text, pattern, replacement, regular expression flag)
```

Arguments

`text`: *String*

The valid path of a data source of the *String* type.

`pattern`: *String*

If the `regular expression flag` argument is **FALSE**, this argument contains the text that must be replaced.

If the `regular expression flag` argument is **TRUE**, this argument contains a regular expression that defines both a search pattern and the replacement text.

`replacement`: *String*

If the `regular expression flag` argument is **FALSE**, this argument contains the text to use as a replacement.

If the `regular expression flag` argument is **TRUE**, this argument isn't used.

`regular expression flag`: *Boolean*

A *Boolean* value that indicates whether a regular expression is used to do the replacement.

Return values

String

The resulting text value.

Usage notes

If the `regular expression flag` argument is **TRUE**, this function returns the specified string after it has been changed by applying the regular expression that is specified by the `pattern` argument. The regular expression is used to find the characters that must be replaced.

If the `regular expression flag` argument is **FALSE**, this function returns the specified string after the set of characters that are defined in the `pattern` argument have been replaced by characters of the `replacement` argument.

Example 1

`REPLACE ("+1 923 456 4971", "[^0-9]", "", true)` applies a regular expression that removes all non-numeric symbols, and it returns "**19234564971**".

Example 2

`REPLACE ("abcdef", "cd", "GH", false)` replaces the pattern "**cd**" with the string "**GH**" and returns "**abGHef**".

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `RIGHT` function returns a *String* value that presents the specified number of characters from the end of the specified string.

Syntax

VB

```
RIGHT (text, number)
```

Arguments

`text`: *String*

A *String* value that represents the original text.

`number`: *Integer*

The number of characters that you want to return from the end of the original text.

Return values

String

The resulting text value.

Example

`RIGHT ("Sample", 3)` returns "**ple**".

TEXT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `TEXT` function returns the specified number as a *String* value after it converts the number to a text string that's formatted according to the server locale settings of the current application instance.

Syntax

```
VB

TEXT (number)
```

Arguments

`number`: *Integer* or *Real*

The number to convert to a text string.

Return values

String

The resulting text value.

Usage notes

For *Real* type values, the string conversion includes up to two decimal places.

Example

If the server locale of the Microsoft Dynamics 365 Finance instance is defined as **EN-US**, `TEXT (NOW ())` returns the current Finance session date, December 17, 2015, as the text string "**12/17/2015 07:59:23 AM**". `TEXT (1/3)` returns "**0.33**".

TRANSLATE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `TRANSLATE` function returns a *String* value that contains the result of the character replacement of specified text in characters of another provided set.

Syntax

```
VB

TRANSLATE (text , pattern, replacement)
```

Arguments

`text`: *String*

The valid path of a data source of the *String* type.

`pattern`: *String*

The text that you want to replace.

`replacement`: *String*

The text to use as a replacement.

Return values

String

The resulting text value.

Usage notes

The `TRANSLATE` function replaces one character at a time. The function replaces the first character of the `text` argument with the first character of the `pattern` argument and then the second character and follows the same flow until finished. When a character from the `text` and `pattern` arguments match, the function replaces it with a character from the `replacement` argument that is in the same position as the character from the `pattern` argument. If a character appears multiple times in the `pattern` argument, the function uses the `replacement` argument mapping that corresponds to the first occurrence of this character.

Example 1

`TRANSLATE ("abcdef", "cd", "GH")` replaces the "**c**" character of the specified "**abcdef**" text with the "**G**" character of the `replacement` text due to the following reasons:

- The "**c**" character is presented in the `pattern` text in the first position.
- The first position of the `replacement` text contains the "**G**" character.

Example 2

`TRANSLATE ("abcdef", "ccd", "GH")` returns "**abGdef**".

Example 3

`TRANSLATE ("abccba", "abc", "123")` returns "**123321**".

TRIM ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `TRIM` function returns the specified text string as a *String* value after it replaces tab, carriage return, line feed, and form feed characters with a single space character. It also removes leading and trailing spaces and removes multiple spaces between words.

Syntax

```
VB

TRIM (text)
```

Arguments

`text`: *String*

The valid path of a data source of the *String* type.

Return values

String

The resulting text value.

Usage notes

In some cases, you might want to remove leading and trailing spaces but prefer to keep formatting for the specified text. For example, when this text represents an address that you enter in the multi-line text box and could contain line feed and carriage return formatting. In

this case, use the following expression: `REPLACE(text,"^[ \t]+|[ \t]+$","", true)` where `text` is the argument that refers to the specified text string.

Example 1

`TRIM ("  Sample  text  ")` returns "**Sample text**".

Example 2

`TRIM (CONCATENATE (CHAR(10), "  Sample  ", CHAR(9),"  text  ", CHAR(13)))` returns "**Sample text**".

UPPER ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `UPPER` function returns the specified text string as a *String* value after it converts the text to uppercase letters.

Syntax

VB

```
UPPER (text )
```

Arguments

`text`: *String*

The valid path of a data source of the *String* type.

Return values

String

The resulting text value.

Example

`UPPER ("Sample")` returns **"SAMPLE"**.

List of ER functions in the data collection category

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) data collection functions are used to do counting and summing in an ER format that is being run, based on data of the output that has already been generated in **Text** or **Xml** format. This approach is used to help improve performance of an ER format that is run, to enter values of running totals in generated documents, and for other purposes. This article provides a summary of these functions.

List of supported functions

Expand table

Function	Description
CollectedList	This function returns a *Record list* value that contains the list of values that were returned by the **Collected data key value** property of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.
CountIF	This function returns an *Integer* value that represents the number of format elements that was collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified condition. The condition consists of a key range and a key value.
CountIFs	This function returns an *Integer* value that represents the number of format elements that was collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.
FormatElementName	This function returns a *String* value that represents the name of the current ER format's element.

Function	Description
SumIF	This function returns a *Real* value that represents the sum of values that were returned by bindings of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified condition. The condition consists of a key range and a key value.
SumIFs	This function returns a *Real* value that represents the sum of values that were returned by bindings of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.

COLLECTEDLIST ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `COLLECTEDLIST` function a *Record list* value that contains the list of values that were returned by the **Collected data key value** property of format elements and collected when the format elements were used to generate outbound documents during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.

Syntax

VB

```
COLLECTEDLIST (condition 1 range, condition 1 value[, condition 2 range, condition 2 value, …, condition N range, condition N value])
```

Arguments

`condition 1 range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an Electronic reporting (ER) format component. This argument is mandatory.

`condition 1 value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. This argument is mandatory.

`condition N range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an ER format component. These additional arguments are optional.

`condition N value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Usage notes

The **Collected data key name** and **Collected data key value** properties can be configured for either the **Sequence** component or the **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

This function returns an empty list when the **Collect output details** option of the current **Common\File** component is turned off.

In `condition range` arguments, the wildcard character "*" can be used to represent any multiple characters.

In `condition value` arguments, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the ER Use data of format output for counting and summing task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

COUNTIF ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `COUNTIF` function returns an *Integer* value that represents the number of format elements that was collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified condition. The condition consists of a key range and a key value.

Syntax

```
VB

COUNTIF (condition range, condition value)
```

Arguments

`condition range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an Electronic reporting (ER) format component.

`condition value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component.

Return values

Integer

The resulting numeric value.

Usage notes

The **Collected data key name** and **Collected data key value** properties can be configured for either the **Sequence** component or the **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

This function returns a **0** (zero) value when the **Collect output details** option of the current **Common\File** component is turned off.

In the `condition range` argument, the wildcard character "*" can be used to represent any multiple characters.

In the `condition value` argument, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the ER Use data of format output for counting and summing task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

COUNTIFS ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `COUNTIFS` function returns an *Integer* value that represents the number of format elements that was collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.

Syntax

VB

```
COUNTIFS (condition 1 range, condition 1 value[, condition 2 range, condition 2 value, …, condition N range, condition N value])
```

Arguments

`condition 1 range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an Electronic reporting (ER) format component. This argument is mandatory.

`condition 1 value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. This argument is mandatory.

`condition N range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an ER format component. These additional arguments are optional.

`condition N value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. These additional arguments are optional.

Return values

Integer

The resulting numeric value.

Usage notes

The **Collected data key name** and **Collected data key value** properties can be configured for either the **Sequence** component or the **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

This function returns a **0** (zero) value when the **Collect output details** option of the current **Common\File** component is turned off.

In `condition range` arguments, the wildcard character "*" can be used to represent any multiple characters.

In `condition value` arguments, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the ER Use data of format output for counting and summing task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

FORMATELEMENTNAME ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `FORMATELEMENTNAME` function returns a *String* value that represents the name of the current Electronic reporting (ER) format's element.

Syntax

VB

```
FORMATELEMENTNAME ()
```

Return values

String

The resulting text value.

Usage notes

This function can be called in ER expressions that were configured for the **Collected data key name** and **Collected data key value** properties of an ER format component from the **Text** group that resides under the **Common\File** component where the **Collect output details** option is turned on.

Example

For more information about how to use this function, see the ER Use data of format output for counting and summing task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

SUMIF ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `SUMIF` function returns a *Real* value that represents the sum of values that were returned by bindings of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified condition. The condition consists of a key range and a key value.

Syntax

VB

```
SUMIF (key name for summing, condition range, condition value)
```

Arguments

`key name for summing`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of the Electronic reporting (ER) format component for which the value of the binding must be used for summing purposes.

The **Collected data key value** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

Return values

Real

The resulting numeric value.

Usage notes

This function returns a **0** (zero) value when the **Collect output details** option of the current **Common\File** component is turned off.

In the `condition range` argument, the wildcard character "*" can be used to represent any multiple characters.

In the `condition value` argument, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the ER Use data of format output for counting and summing task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

For more information and examples about using this function, see Defer the execution of sequence elements in ER formats and Defer the execution of XML elements in ER formats.

SUMIFS ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `SUMIFS` function returns a *Real* value that represents the sum of values that were returned by bindings of format elements and collected when the format elements were used to generate an outbound document during the format run, and that satisfies the specified conditions. Each condition consists of a key range and a key value.

Syntax

VB

```
SUMIFS (key name for summing, condition 1 range, condition 1 value[, condition 2 range, condition 2 value, …, condition N range, condition N value])
```

Arguments

`key name for summing`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of the Electronic reporting (ER) format component for which the value of the binding must be used for summing purposes.

The **Collected data key name** property can be configured for either a **Numeric** component or a **String** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

`condition 1 range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an ER format component. This argument is mandatory.

The **Collected data key name** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

`condition 1 value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. This argument is mandatory.

The **Collected data key value** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

`condition N range`: *String*

A value that is returned by the expression that has been configured in the **Collected data key name** property of an ER format component. These additional arguments are optional.

The **Collected data key name** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

`condition N value`: *String*

A value that is returned by the expression that has been configured in the **Collected data key value** property of an ER format component. These additional arguments are optional.

The **Collected data key value** property can be configured for either a **Sequence** component or an **XML Element** component of an ER format that resides under the **Common\File** component where the **Collect output details** option is turned on.

Return values

Real

The resulting numeric value.

Usage notes

This function returns a **0** (zero) value when the **Collect output details** option of the current **Common\File** component is turned off.

In the `condition range` arguments, the wildcard character "*" can be used to represent any multiple characters.

In the `condition value` arguments, the wildcard character "*" can be used to represent any multiple characters.

Example

For more information about how to use this function, see the ER Use data of format output for counting and summing task guide, which is part of the **Acquire/Develop IT service/solution components** business process.

List of ER functions in the business domain–specific category

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) domain-specific functions can be used to perform calculations and data access requests that are specific to the implementation of Microsoft Dynamics 365 Finance. This article provides a summary of these functions.

List of supported functions

Expand table

Function	Description
CH_Bank_Mod_10	This function returns a *String* value that represents a creditor reference as an MOD10 expression, based on the digits of the specified invoice number.
CN_GBT_AdditionalDimensionID	This function returns a *String* value that represents a single financial dimension ID that is taken from the specified string. The specified string presents all dimensions as a comma-separated list of IDs.
ConvertCurrency	This function returns a *Real* value that represents the result of converting the specified monetary amount from the specified source currency to the specified target currency by using the settings of the specified company on the specified date.
CurCredRef	This function returns a *String* value that represents a creditor reference, based on the digits of the specified invoice number.
FA_Balance	This function returns a *Container (record)* value that consists of data for the fixed asset balance for the specified fixed asset item, value model code, reporting year, and reporting date.
FA_Sum	This function returns a *Container (record)* value that consists of data for the fixed asset amounts for the specified fixed asset item, value model

Function	Description
	code, and period of dates.
GetCurrentCompany	This function returns a *String* value that represents the code for the legal entity (company) that a user is currently signed in to.
ISOCredRef	This function returns a *String* value that represents an International Organization for Standardization (ISO) creditor reference, based on the digits and alphabetic symbols of the specified invoice number.
IsValidCharacterISO7064	This function returns a *Boolean* value of **TRUE** if the specified string represents a valid international bank account number (IBAN). Otherwise, it returns a *Boolean* value of **FALSE**.
Mod_97	This function returns a *String* value that represents a creditor reference as a MOD97 expression, based on the digits of the specified invoice number.
NumSeqValue	This function returns a *String* value that represents the new generated value of a number sequence, based on the specified number sequence, scope, and scope ID. The scope ID equals the company code that is supplied by the context that the ER format is run under.
RoundAmount	This function returns a *Real* value that represents the result of rounding the specified amount to the specified number of decimal places according to the specified rounding rule.
TableName2ID	This function returns a numeric representation of the table ID for the specified table name as an *Integer* value.
TaxUnitConversion	This function returns a *Real* value that represents the quantity result of converting the specified unit from a transaction to the specified unit in a tax configuration. This function requires context that's from an original sourcing system. The method `ConverUnit` in interface `IExternalAPIProvider` must be implemented in a sourcing ERP environment.

CH_BANK_MOD_10 ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `CH_BANK_MOD_10` function returns a *String* value that represents a creditor reference as an MOD10 expression, based on the digits of the specified invoice number.

Syntax

VB

```
CH_BANK_MOD_10 (invoice number digits)
```

Arguments

`invoice number digits`: *String*

A text value that represents the digits of an invoice number.

Return values

String

The resulting text value.

Example

`CH_BANK_MOD_10 ("VEND-200002")` returns **3**.

CN_GBT_ADDITIONALDIMENSIONID ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `CN_GBT_ADDITIONALDIMENSIONID` function returns a *String* value that represents a single financial dimension ID that is taken from the specified string. The specified string presents all dimensions as a comma-separated list of IDs.

Syntax

VB

```
CN_GBT_ADDITIONALDIMENSIONID (text, number)
```

Arguments

`text`: *String*

A *String* value that presents all dimensions as a comma-separated list of IDs.

`number`: Integer

An *Integer* value that defines the sequence code of the requested dimension in the specified string.

Return values

String

The resulting text value.

Example

`CN_GBT_AdditionalDimensionID ("AA,BB,CC,DD,EE,FF,GG,HH", 3)` returns "**CC**".

CONVERTCURRENCY ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `CONVERTCURRENCY` function returns a *Real* value that represents the result of converting the specified monetary amount from the specified source currency to the specified target currency by using the settings of the specified company on the specified date.

Syntax

VB

```
CONVERTCURRENCY (amount, source currency, target currency, date, company)
```

Arguments

`amount`: *Integer* or *Real*

A numeric value that represents the monetary amount that must be converted.

`source currency`: *String*

The code of the source currency.

`target currency`: *String*

The code of the target currency.

`date`: *Date*

A *Date* value that represents the date that is used to determine the exchange rate for the conversion.

`company`: *String*

A *String* value that represents the code of a company that supplies the settings that are used for the conversion.

Return values

Real

The resulting numeric value.

Example

`CONVERTCURRENCY (1, "EUR", "USD", TODAY(), "DEMF")` returns the equivalent of one euro in US dollars on the current session date, based on settings for the **DEMF** company.

CURCREDREF ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `CURCREDREF` function returns a *String* value that represents a creditor reference, based on the digits of the specified invoice number.

Syntax

```
VB

CURCREDREF (invoice number digits)
```

Arguments

`invoice number digits`: *String*

A text value that represents the digits of an invoice number.

Return values

String

The resulting text value.

Example

`CURCredRef ("VEND-200002")` returns "**2200002**".

Additional resources

Other (business domain–specific) functions

Last updated on 04/08/2026

FA_BALANCE ER function

The `FA_BALANCE` function returns a *Container (record)* value that consists of data for the fixed asset balance for the specified fixed asset item, value model code, reporting year, and reporting date.

Syntax

VB

```
FA_BALANCE (fixed asset code, value model code, reporting year, reporting date)
```

Arguments

`fixed asset code`: *String*

A *String* value that represents the code of a fixed asset item that the balance is calculated for.

`value model code`: *String*

A *String* value that represents the code of a value model that the balance is calculated for.

`reporting year`: *Enumeration value*

An enumeration value of the **AssetYear** application enumeration that defines a period for the balance calculation.

`reporting date`: *Date*

A *Date* value that defines a date for the balance calculation.

Return values

Container (record)

The resulting record value.

Example

`FA_ BALANCE ("COMP-000001", "Current", AxEnumAssetYear.ThisYear, SESSIONTODAY ())` returns the data container of balances for fixed asset **COMP-000001** that has been prepared for the

Current value model on the current application session date.

Other (business domain–specific) functions

Last updated on 04/13/2026

FA_SUM ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `FA_SUM` function returns a *Container (record)* value that consists of data for the fixed asset amounts for the specified fixed asset item, value model code, and period of dates.

Syntax

VB

```
FA_SUM (fixed asset code, value model code, start date, end date)
```

Arguments

`fixed asset code`: *String*

A *String* value that represents the code of a fixed asset item that the balance is calculated for.

`value model code`: *String*

A *String* value that represents the code of a value model that the balance is calculated for.

`start date`: *Date*

A *Date* value that represents the start date of a period that the fixed asset amounts are calculated for.

`end date`: *Date*

A *Date* value that represents the end date of a period that the fixed asset amounts are calculated for.

Return values

Container (record)

The resulting record value.

Example

`FA_SUM ("COMP-000001", "Current", Date1, Date2)` returns the data container for fixed asset **COMP-000001** that has been prepared for the **Current** value model and for a period from **Date1** to **Date2**.

Other (business domain–specific) functions

Last updated on 04/08/2026

GETCURRENTCOMPANY ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `GETCURRENTCOMPANY` function returns a *String* value that represents the code for the legal entity (company) that a user is currently signed in to.

Syntax

VB

```
GETCURRENTCOMPANY ()
```

Return values

String

The resulting text value.

Example

`GETCURRENTCOMPANY ()` returns **USMF** for a user who is signed in to the **Contoso Entertainment System USA** company.

Additional resources

Other (business domain–specific) functions

Last updated on 04/08/2026

ISOCREDREF ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ISOCREDREF` function returns a *String* value that represents an International Organization for Standardization (ISO) creditor reference, based on the digits and alphabetic symbols of the specified invoice number.

Syntax

```
VB

ISOCREDREF (invoice number digits)
```

Arguments

`invoice number digits`: *String*

A text value that represents the digits of an invoice number.

Return values

String

The resulting text value.

Usage notes

> **Note**
>
> To eliminate symbols from alphabets that are't ISO-compliant, the `invoice number digits` argument must be translated before it's passed to this function.

Example

`ISOCredRef ("VEND-200002")` returns "**RF23VEND-200002**".

ISVALIDCHARACTERISO7064 ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ISVALIDCHARACTERISO7064` function returns a *Boolean* value of **TRUE** if the specified string represents a valid international bank account number (IBAN). Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

VB

```
ISVALIDCHARACTERISO7064 (text)
```

Arguments

`text`: *String*

A text value that represents an IBAN.

Return values

String

The resulting text value.

Example

`ISVALIDCHARACTERISO7064 ("AT61 1904 3002 3457 3201")` returns **TRUE**.

`ISVALIDCHARACTERISO7064 ("AT61")` returns **FALSE**.

MOD_97 ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `MOD_97` function returns a *String* value that represents a creditor reference as a MOD97 expression, based on the digits of the specified invoice number.

Syntax

VB

```
MOD_97 (invoice number digits)
```

Arguments

`invoice number digits`: *String*

A text value that represents the digits of an invoice number.

Return values

String

The resulting text value.

Example

`MOD_97 ("VEND-200002")` returns **"20000285"**.

Additional resources

Other (business domain–specific) functions

Last updated on 04/08/2026

NUMSEQVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `NUMSEQVALUE` function returns a *String* value that represents the new generated value of a number sequence, based on the specified number sequence, scope, and scope ID. The scope ID equals the company code that is supplied by the context that the Electronic reporting (ER) format is run under.

Syntax 1

```
VB

NUMSEQVALUE (number sequence code)
```

Syntax 2

```
VB

NUMSEQVALUE (number sequence record ID)
```

Syntax 3

```
VB

NUMSEQVALUE (number sequence code, scope type, scope ID)
```

Arguments

`number sequence code`: *String*

A text value that represents the code of the number sequence that a new value is required in.

`number sequence record ID`: *Int64*

An *Int64* value that represents the record ID of a record in the NumberSequenceTable table that contains the definition of the number sequence that a new value is required in.

`scope type`: *Enum value*

An enumeration value of the **ERExpressionNumberSequenceScopeType** enumeration that defines the scope of the number sequence that a new value is required in. The available scope types are **Shared**, **Legal entity**, and **Company**.

`scope ID`: *String*

A *String* value that identifies the scope, based on the specified scope type.

Return values

String

The resulting text value.

Usage notes

For the **Shared** scope type, specify an empty string as the scope ID.

For the **Company** and **Legal entity** scope types, specify the company code as the scope ID. If you specify an empty string as the scope ID for these scope types, the current company code is used.

When syntax 1 is used, the number sequence is requested for the **Company** scope type, and the company code is supplied by the context that the ER format is run under.

Example 1

In your ER format, you define the **AskNumSeq** data source of the *User input parameter* type. This data source refers to the **Description** extended data type (EDT). Next, you define the **NumSeq** data source of the *Calculated field* type. This data source contains the expression `NUMSEQVALUE (AskNumSeq)`. When the **NumSeq** data source is called, it returns the new generated value of the number sequence that was specified at runtime by entering its code in the dialog box. The number sequence is requested for the **Company** scope type. The company code is supplied by the context that the ER format is run under.

Example 2

The following data sources are defined in your model mapping:

- The **LedgerParms** data source of the *Table* type. This data source refers to the LedgerParameters table.
- The **NumSeq** data source of the *Calculated field* type. This data source contains the expression `NUMSEQVALUE ( LedgerParameters.'numRefJournalNum()'.NumberSequenceId)`.

When the **NumSeq** data source is called, it returns the new generated value of the number sequence that has been configured in the General ledger parameters for the company that supplies the context that the ER format is run under. This number sequence uniquely identifies journals and acts as a batch number that links the transactions together.

Example 3

The following data sources are defined in your model mapping:

- The **enumScope** data source of the Microsoft Dynamics 365 Finance *enumeration* type. This data source refers to the **ERExpressionNumberSequenceScopeType** enumeration.
- The **NumSeq** data source of the *Calculated field* type. This data source contains the expression `NUMSEQVALUE ("Gene_1", enumScope.Company, "")`.

When the **NumSeq** data source is called, it returns the new generated value of the **Gene_1** number sequence that has been configured for the company that supplies the context that the ER format is run under.

ROUNDAMOUNT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ROUNDAMOUNT` function returns a *Real* value as the result of the rounding of the specified number to the nearest multiple of another number according to the specified rounding rule.

Syntax

VB

```
ROUNDAMOUNT (number, decimals, round rule)
```

Arguments

`number`: *Int* or *Real*

A numeric value that must be rounded.

`decimals`: *Int* or *Real*

The number that the value of the `number` parameter must be rounded to a multiple of.

`round rule`: *Enum value*

An enumeration value of the **RoundOffType** enumeration that defines the rounding rule. This enumeration offers the following values:

- Normal (Ordinary)
- Downward (RoundDown)
- Rounding-up (RoundUp)

Return values

Real

The resulting numeric value is a multiple of the value specified by the `decimals` parameter and is closest to the value specified by the `number` parameter.

Usage notes

When the `number` parameter is zero, this function always returns zero.

When the `decimals` parameter is zero, this function rounds to the default round-off value. When the `round rule` parameter is set to **RoundOffType.Ordinary**, the default round-off value is **0.01**. Otherwise, the default round-off value is **1.0**.

When the `round rule` parameter is set to **RoundOffType.Ordinary**, this function rounds to the nearest round-off amount.

When the `round rule` parameter is set to **RoundOffType.RoundDown**, this function rounds towards zero to the nearest round-off amount.

When the `round rule` parameter is set to **RoundOffType.RoundUp**, this function rounds away from zero to the nearest round-off amount.

When the `round rule` parameter is set to **RoundOffType.Ordinary**, this function behaves like the MROUND Excel function and the ROUND X++ function.

Remarks

To round a numeric value to a specified number of decimal places, use the ROUND function.

Example

If the **model.RoundOff** parameter is set to **RoundOffType.Ordinary**, `ROUNDAMOUNT (7.45, 1.05, model.RoundOff)` returns 7.35.

If the **model.RoundOff** parameter is set to **RoundOffType.RoundDown**, `ROUNDAMOUNT (7.45, 1.05, model.RoundOff)` returns 7.35.

If the **model.RoundOff** parameter is set to **RoundOffType.RoundUp**, `ROUNDAMOUNT (7.45, 1.05, model.RoundOff)` returns 8.4.

TABLENAME2ID ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `TABLENAME2ID` function returns a numeric representation of the table ID for the specified table name as an *Integer* value.

Syntax

```
VB

TABLENAME2ID (text)
```

Arguments

`text`: *String*

A text value that represents a valid table name.

Return values

Integer

The resulting numeric value.

Usage notes

Execution of this function can have different results in different instances of Microsoft Dynamics 365 Finance, even if the same company name is used.

Example

`TABLENAME2ID ("Intrastat")` returns **1510**.

Additional resources

TAXUNITCONVERSION ER function

The `TAXUNITCONVERSION` function returns a *Real* value that represents the quantity result of converting the specified unit from transaction to the specified unit in tax configuration. And it should be noticed that this function requires context that from an original sourcing system. The method `ConverUnit` in interface `IExternalAPIProvider` must be implemented in a sourcing Enterprise resource planning (ERP) environment.

Syntax

VB

```
TAXUNITCONVERSION(itemId, quantity, base unit, tax unit, invent dimension ID,
packaging)
```

Arguments

`itemId`: *String*

The Item ID defined in Finance and Operations Apps.

`quantity`: *Real*

The quantity of the original unit.

`base unit`: *String*

The unit of the original transaction.

`tax unit`: *String*

The unit is defined in the tax configuration.

`invent dimension Id`: *String*

The **invent dimension** is defined in the finance and operations apps transaction.

`packaging`: *Bool*

The packaging parameter is from the tax configuration.

Return values

Real

The converted quantity of the tax unit.

Example

`TAXUNITCONVERSION ("D001", 12, "ea", "dz", "", false)` returns the quantity converted from "**ea**" to "**dz**" which is **1**.

List of ER functions in the type conversion category

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) type conversion functions can be used to convert values between types. This article provides a summary of these functions.

Type conversion functions

Expand table

Function	Description
Int64Value	This function returns an *Int64* value that represents the specified string.
IntValue	This function returns an *Int* value that represents the specified string.
NumberValue	This function returns a *Real* value that is converted from the specified *String* value. During the conversion, the specified decimal and digit grouping separators are considered.
Value	This function returns a *Real* value that is converted from the specified *String* value.

Type conversion functions in the container category

The following table describes the type conversion functions in the container category.

Expand table

Function	Description
Base64StringToContainer	This function converts the specified input of the *String* type to a data item of the *Container* type.

Type conversion functions in the date and time category

The following table describes the type conversion functions in the date and time category.

Expand table

Function	Description
DateTimeValue	This function returns a *DateTime* value that is converted from a given *String* value in the specified format and in an optionally specified culture to a date/time value.
DateToDateTime	This function returns a *DateTime* value that is converted from a given *Date* value to a date/time value in Coordinated Universal Time (Greenwich Mean Time [GMT]).
DateValue	This function returns a *Date* value that is converted from a given *String* value in the specified format and in an optionally specified culture to a date value.

Type conversion functions in the list category

The following table describes the type conversion functions in the list category.

Expand table

Function	Description
List	This function returns a *Record list* value as a new list that is created from specified arguments of the *Container (record)* type.
ListOfFields	This function returns a *Record list* value that is created based on the structure of a given argument of the *Enumeration* or *Container (record)* type.
Split	This function splits the specified *String* value into substrings and returns the result as a new *Record list* value.
StringJoin	This function returns a *String* value that consists of concatenated values of the specified field from the specified *Record list* value. The values can be separated by the specified delimiter.

Type conversion functions in the text category

The following table describes the type conversion functions in the text category.

Expand table

Function	Description
Char	This function returns a *String* value that represents a single character that is referenced by the specified Unicode number.
GuidValue	This function converts the specified input of the *String* type to a data item of the *GUID* type.
NumberFormat	This function returns a *String* value that represents the specified number in the specified format and in an optionally specified culture.
QrCode	This function returns a *Container* value that presents the Quick Response code (QR code) image for the specified string in binary format.
Text	This function returns a *String* value that represents the specified number after it has been converted to a text string that is formatted according to the server locale settings of the current application instance.

INT64VALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `INT64VALUE` function returns an *Int64* value that represents the specified string.

Syntax 1

```
VB

INT64VALUE (text)
```

Syntax 2

```
VB

INT64VALUE (number)
```

Arguments

`text`: *String*

A text value that must be converted to an *Int64* number.

`number`: *Real* or *Integer*

A numeric *Real* or *Integer* value that must be converted to an *Int64* number.

Return values

Int64

The resulting numeric value.

Usage notes

Any decimal places are truncated.

Example 1

`INT64VALUE ("22565422744")` returns the *Int64* value **22565422744**.

Example 2

`INT64VALUE ( VALUE("22565422744.77"))` returns the *Int64* value **22565422744**.

INTVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `INTVALUE` function returns an *Int* value that represents the specified string.

Syntax 1

```
VB

INTVALUE (text)
```

Syntax 2

```
VB

INTVALUE (number)
```

Arguments

`text`: *String*

A text value that must be converted to an *Int* number.

`number`: *Real* or *Integer*

A numeric *Real* or *Integer* value that must be converted to an *Int* number.

Return values

Int

The resulting numeric value.

Usage notes

Any decimal places are truncated.

Example 1

`INTVALUE ("100.77")` returns the *Int* value **100**.

Example 2

`INTVALUE (-100.77)` returns the *Int* value **-100**.

Additional resources

Type conversion functions

Last updated on 04/08/2026

NUMBERVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `NUMBERVALUE` function returns a *Real* value that is converted from the specified *String* value. During the conversion, the specified decimal and digit grouping separators are considered.

Syntax

VB

```
NUMBERVALUE (text, decimal separator, digit grouping separator)
```

Arguments

`text`: *String*

A text value that must be converted to a *Real* number.

`decimal separator`: String

A decimal separator. It's used to separate the integer and fractional parts of a decimal number.

`digit grouping separator`: *String*

A digit grouping separator. It's used as the thousands separator.

Return values

Real

The resulting numeric value.

Example

`NUMBERVALUE( "1 234,56", ",", " ")` returns **1234.56**.

Additional resources

Type conversion functions

Last updated on 04/08/2026

VALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `VALUE` function returns a *Real* value that is converted from the specified string.

Syntax

VB

```
VALUE (text)
```

Arguments

`text`: *String*

A string value that must be converted to a numeric value.

Return values

Real

The resulting numeric value.

Usage notes

Commas and dot characters (.) are considered decimal separators, and a leading hyphen (-) is used as a negative sign. An exception is thrown at runtime if the specified string contains other non-numeric characters.

Example 1

`VALUE ("1 234,56")` throws an exception.

Example 2

`VALUE ("1234,56")` returns **1234.56**.

Additional resources

Type conversion functions

Last updated on 04/08/2026

Base64StringToContainer ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `BASE64STRINGTOCONTAINER` function converts the specified input of the *String* type to a data item of the *Container* type.

Syntax

VB

```
BASE64STRINGTOCONTAINER (input)
```

Arguments

`input`: *String*

The valid path of a data source of the *String* type.

Return values

Container

The resulting binary value in binary large object (BLOB) format.

Usage notes

The "Parameter is not valid" exception is thrown if the input string doesn't provide a correct Base64 group of binary-to-text encoding schemes.

Example

You define the following data sources in your model mapping:

- The root **DocuTypeGroupEnum** data source of the *Dynamics 365 for Operations / Enumeration* type that refers to the **DocuTypeGroup** application enumeration
- The root **Customer** data source of the *Dynamics 365 for Operations / Table records* type that refers to the **CustTable** application table
- The **#Media** data source of the *Calculated field* type that is configured in the following way:
  - It's added as a child data source of the **Customer** data source.
  - It contains the expression `WHERE(@.'<Relations'.'<Documents', @.'<Relations'.'<Documents'.'docuType()'.TypeGroup = DocuTypeGroupEnum.Image)`.
- The **#MediaAsBase64String** data source of the *Calculated field* type that is configured in the following way:
  - It's added as a child data source of the **Customer.'#Media'** data source.
  - It contains the expression `Customer.'#Media'.'getFileContentAsBase64String()'`.
- The **#BlobFomBase64** data source of the *Calculated field* type that is configured in the following way:
  - It's added as a child data source of the **Customer.'#Media'** data source.
  - It contains the expression `Base64StringToContainer(Customer.'#Media'.'#MediaAsBase64String')'`.

In this example, the **#MediaAsBase64String** data source encodes the binary content of the current media attachment as text that represents a Base64 group of binary-to-text encoding schemes. The **#BlobFomBase64** data source decodes the Base64 string and returns a binary value in BLOB format.

Container functions

Last updated on 04/08/2026

DATETIMEVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `DATETIMEVALUE` function returns a *DateTime* value that is converted from a given text value in the specified format and in an optionally specified culture to a date/time value. For information about the supported formats, see standard and custom.

Syntax 1

```
VB

DATETIMEVALUE (text, format)
```

Syntax 2

```
VB

DATETIMEVALUE (text, format, culture)
```

Arguments

`text`: *String*

Text that represents the value to format.

`format`: *String*

The format of the given text. For information about the supported formats, see standard and custom.

`culture`: *String*

The culture that is used for formatting of the given text. For information about the supported cultures, see culture.

Return values

DateTime

The resulting date/time value.

Usage notes

When the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATETIMEVALUE` function is called by using syntax 1 in an Electronic reporting (ER) format for a **FILE** element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

Example 1

`DATETIMEVALUE ("21-Dec-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss")` returns **2:55:00 AM on December 21, 2016**, based on the specified custom format and the default application's **EN-US** culture.

Example 2

`DATETIMEVALUE ("21-Gen-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss", "IT")` returns **2:55:00 AM on December 21, 2016**, based on the specified custom format and culture.

However, `DATETIMEVALUE ("21-Gen-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss", "EN-US")` throws an exception to inform the user that the specified string isn't recognized as a valid date/time value for the specified culture.

Additional resources

Date and time functions

Last updated on 04/08/2026

DATETODATETIME ER function

The `DATETODATETIME` function returns a *DateTime* value that is converted from a given date value to a date/time value in Coordinated Universal Time (Greenwich Mean Time [GMT]).

Syntax

VB

```
DATETODATETIME (date)
```

Arguments

`date`: *Date*

A date value that represents the date to convert.

Return values

DateTime

The resulting date/time value.

Example 1

`DATETODATETIME (CompInfo. 'getCurrentDate()')` returns the date of the current Microsoft Dynamics 365 Finance session, December 24, 2025, as **12/24/2025 12:00:00 AM**. In this example, **CompInfo** is an Electronic reporting (ER) data source of the **finance and operations/Table** type, and it refers to the CompanyInfo table.

Example 2

`DATETODATETIME (DATEVALUE ("2024-11-12T16:00:00.0000000-07:00", "O"))` returns the date and time value **11/12/2024 12:00:00 AM**.

Additional resources

Date and time functions

Last updated on 08/04/2026

DATEVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `DATEVALUE` function returns a *Date* value that is converted from a given text value in the specified format and in an optionally specified culture to a date value. For information about the supported formats, see standard and custom.

Syntax 1

```
VB

DATEVALUE (text, format)
```

Syntax 2

```
VB

DATEVALUE (text, format, culture)
```

Arguments

`text`: *String*

Text that represents the value to format.

`format`: *String*

The format of the given text. For information about the supported formats, see standard and custom.

`culture`: *String*

The culture that is used for formatting of the given text. For information about the supported cultures, see culture.

Return values

Date

The resulting date value.

Usage notes

When the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATEVALUE` function is called by using syntax 1 in an Electronic reporting (ER) format for a **FILE** element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

Example 1

`DATEVALUE ("21-Dec-2016", "dd-MMM-yyyy")` returns the date value **December 21, 2016**, based on the specified custom format and the default application's **EN-US** culture.

Example 2

`DATEVALUE ("21-Gen-2016", "dd-MMM-yyyy", "IT")` returns the date value **January 21, 2016**, based on the specified custom format and culture.

However, `DATEVALUE ("21-Gen-2016", "dd-MMM-yyyy", "EN-US")` throws an exception to inform the user that the specified string isn't recognized as a valid date for the specified culture.

LIST ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `LIST` function returns a *Record list* value that consists of a new list of records that is created from the specified arguments.

Syntax

VB

```
LIST (record 1 [, record 2, …, record N])
```

Arguments

`record 1`: *Container (record)*

A reference to a data source of the *Record* data type. This argument is required.

`record N`: *Container (record)*

A reference to a data source of the *Record* data type. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Usage notes

The structure of the list that is created contains only the fields that are presented in the structure of every record that is mentioned in the arguments.

Example

You enter data source **Record 1** of the *Container* type. This data source contains the following nested fields of the *Calculated field* type:

- **Code:** This field contains an expression that returns a value of the *String* type.
- **Amount:** This field contains an expression that returns a value of the *Real* type.

You then enter data source **Record 2** of the *Container* type. This data source contains the following nested fields of the *Calculated field* type:

- **Amount:** This field contains an expression that returns a value of the *Real* type.
- **IsValid:** This field contains an expression that returns a value of the *Boolean* type.

In this case, the expression `LIST('Record 1', 'Record 2')` returns a new list that contains two records. The structure of this list consists of a single **Amount** field of the *Real* type, because this field is the only field that is presented in every argument of the called function.

Additional resources

List functions

Last updated on 04/08/2026

LISTOFFIELDS ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `LISTOFFIELDS` function returns a *Record list* value that is created based on the structure of the specified argument of the *Enumeration* or *Container (record)* type.

Syntax 1

```
VB

LISTOFFIELDS (path)
```

Syntax 2

```
VB

LISTOFFIELDS (path, language)
```

Arguments

`path`: Data source reference

The valid reference path of a data source of one of the following data types:

- Model enumeration
- Format enumeration
- Application enumeration
- Container (record)

`language`: *String*

Text that represents a language code.

Return values

Record list

The resulting list of records.

Usage notes

The list that is created consists of records that have the following fields:

- **Name** (*String* data type)
- **Label** (*String* data type)
- **Description** (*String* data type)
- **IsTranslated** (*Boolean* data type)

If the `path` argument refers to a data source of the *Container (Record)* type, for every field of the referenced container record, a new record is added to the list that is created. For every record that is created, the **Name** field returns the name of the field of the referenced container record that the current record was created for.

If the `path` argument refers to a data source of one of the *Enumeration* types, for every enumeration value of the referenced enumeration, a new record is added to the list that is created. For every record that is created, the **Name** field returns the value of the referenced enumeration that the current record was created for, the **Description** field returns the description of that enumeration, and the **Label** field returns the label of that enumeration.

At runtime, when syntax 1 is used, the **Label** and **Description** fields must return values that are based on the language settings of the Electronic reporting (ER) format that is running:

- If the labels and descriptions for the requested language are available, the **Label** and **Description** fields return values that are based on that language, and the **IsTranslated** field returns **True**.
- If the labels and descriptions for the requested language aren't available, the **Label** and **Description** fields return values that are based on the default **EN-US** language, and the **IsTranslated** field returns **False**.

At runtime, when syntax 2 is used, the **Label** and **Description** fields must return values that are based on the language that is defined as the second argument of the called function:

- If the labels and descriptions for the requested language are available, the **Label** and **Description** fields return values that are based on that language, and the **IsTranslated**

field returns **True**.

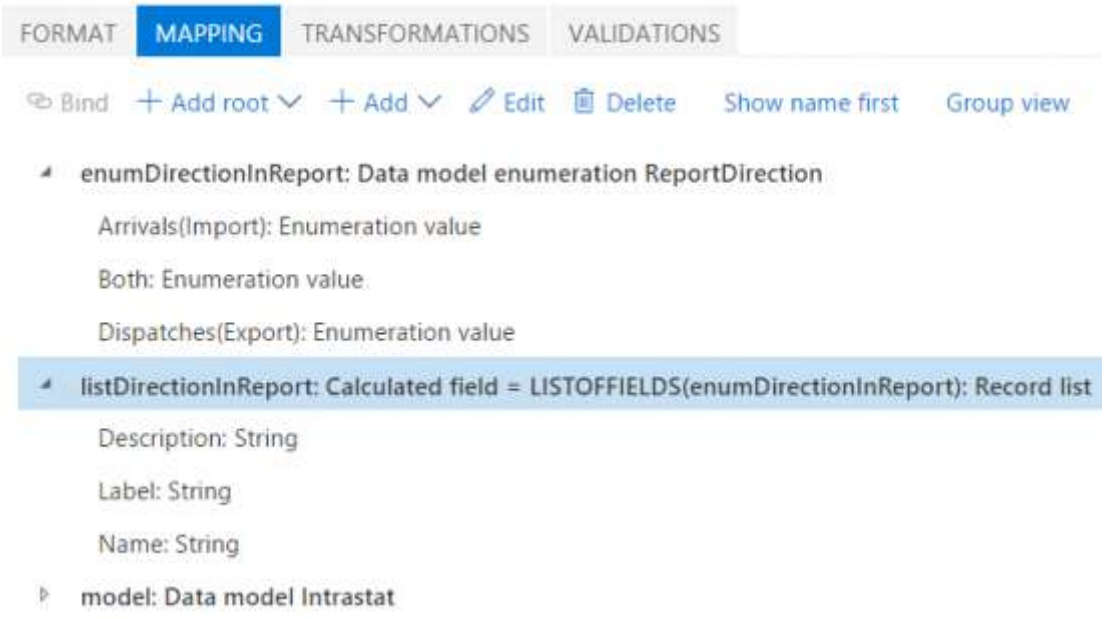
- If the labels and descriptions for the requested language aren't available, the **Label** and **Description** fields return values that are based on the **EN-US** language, and the **IsTranslated** field returns **False**.

Example 1

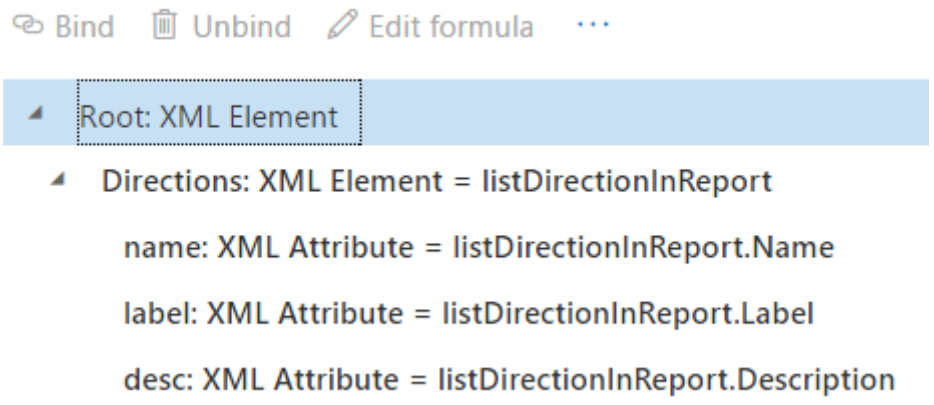
In the following illustration, an enumeration is introduced in an ER data model.

The following illustration shows these details:

- The model enumeration is inserted into a report as a data source.
- An ER expression uses the model enumeration as a parameter of the `LISTOFFIELDS` function.
- A data source of the *Record list* type is inserted into a report by using the ER expression that is created.



The following example shows the ER format elements that are bound to the data source of the *Record list* type that was created by using the `LISTOFFIELDS` function.



The following illustration shows the result when the designed format is run.

```
<?xml version="1.0" encoding="UTF-8"?>
- <Root>
    <Directions desc="" label="Both" name="Both"/>
    <Directions desc="" label="Dispatches" name="Export"/>
    <Directions desc="" label="Arrivals" name="Import"/>
  </Root>
```

> ⓘ Note
>
> Based on the language settings of the parent **FILE** and **FOLDER** format elements, translated text for labels and descriptions is entered in the output of the ER format.

Example 2

You use the *Calculated field* data source type to configure **enumType_de** and **enumType_deCH** data sources for the **enumType** data model enumeration:

- **enumType_de** = `LISTOFFIELDS (enumType, "de")`
- **enumType_deCH** = `LISTOFFIELDS (enumType, "de-CH")`

In this case, you can use the following expression to get the label of the enumeration value in Swiss German, if that translation is available. If the Swiss German translation isn't available, the label is in German.

VB

```
IF (NOT (enumType_deCH.IsTranslated), enumType_de.Label, enumType_deCH.Label)
```

SPLIT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `SPLIT` function splits the specified input string into substrings and returns the result as a new *Record list* value.

Syntax 1

```
VB

SPLIT (input, length)
```

This syntax is used to split the specified input string into substrings, each of which has the specified length.

Syntax 2

```
VB

SPLIT (input, delimiter)
```

This syntax is used to split the specified input string into substrings, based on the specified delimiter.

Arguments

`input`: *String*

The text to split.

`length`: *Integer*

The maximum length of a single substring.

`delimiter`: *String*

A delimiter that is used to separate substrings.

Return values

Record list

The resulting list of records.

Usage notes

The record structure of the list that is returned consists of the **Value** field of the *String* type. Every record of the list that is returned contains generated substrings in this field.

If the `delimiter` argument is empty, the new list that is returned consists of one record that has the **Value** field of the *String* type. This field contains the input text.

If the `input` argument is empty, a new empty list is returned. If either the `input` or `delimiter` argument is unspecified (null), an application exception is thrown.

Example 1

`SPLIT ("abcd", 3)` returns a new list that consists of two records that have the **Value** field of the *String* type. The **Value** field in the first record contains the text "**abc**", and the **Value** field in the second record contains the text "**d**".

Example 2

`SPLIT ("XAb aBy", "aB")` returns a new list that consists of three records that have the **Value** field of the *String* type. The **Value** field in the first record contains the text "**X**", the **Value** field in the second record contains the text " ", and the **Value** field in the third record contains the text "**y**".

Example 3

Yo can use the INDEX function to access individual elements of the specified input string. If you enter the **MyList** data source of the **Calculated field** type and configure for it the `SPLIT("abc", 1)` expression, the expression `INDEX(MyList,2).Value` returns the text "**b**".

Example 4

The ENUMERATE function can also help you access individual elements of the specified input string. If you first enter the **MyList** data source of the **Calculated field** type and configure for it the `SPLIT("abc", 1)` expression, and then enter the **EnumeratedList** data source of the **Calculated field** type and configure for it the `ENUMERATE(MyList)` expression, the expression `FIRSTORNULL(WHERE(EnumeratedList, EnumeratedList.Number=2)).Value` returns the text "**b**".

STRINGJOIN ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `STRINGJOIN` function returns a *String* value that consists of concatenated values of the specified field from the specified list. The values can be separated by the specified delimiter.

Syntax

```
VB

STRINGJOIN (list, field, delimiter)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`field`: *Field*

The valid path of a field of the *String* data type in the specified list.

`delimiter`: *String*

A delimiter that is used to separate substrings.

Return values

String

The resulting text value.

Example

If you enter `SPLIT("abc" , 1)` as data source **DS**, the expression `STRINGJOIN (DS, DS.Value, "-")` returns "**a-b-c**".

CHAR ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `CHAR` function returns a *String* value that presents a single character that is referenced by the specified Unicode number.

Syntax

VB

```
CHAR (number)
```

Arguments

`number`: *Integer*

A number that corresponds to an expected single character.

Return values

String

The resulting text value.

Usage notes

The string that this function returns depends on the encoding that is selected in the parent **FILE** format element. For a list of the supported encodings, see Encoding class.

Example

`CHAR (255)` returns "ÿ".

GUIDVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `GUIDVALUE` function converts the specified input of the *String* type to a data item of the *GUID* type.

Syntax

```
VB

GUIDVALUE (input)
```

Arguments

`input`: *String*

The valid path of a data source of the *String* type.

Return values

GUID

The resulting globally unique identifier (GUID) value.

Usage notes

To do a conversion in the opposite direction (that is, to convert specified input of the *GUID* data type to a data item of the *String* data type), you can use the TEXT function.

Example

You define the following data sources in your model mapping:

- A **myID** data source of the *Calculated field* type that contains the expression `GUIDVALUE ("AF5CCDAC-F728-4609-8C8B- A4B30B0C0AA0")`
- A **Users** data source of the *Table records* type that refers to the UserInfo table

You can then use an expression such as `FILTER (Users, Users.objectId = myID)` to filter the UserInfo table by the **objectId** field of the *GUID* data type.

NUMBERFORMAT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `NUMBERFORMAT` function returns a *String* value that presents the specified number in the specified format and in an optionally specified culture. For information about the supported formats, see standard and custom.

Syntax 1

```
VB

NUMBERFORMAT (number, format)
```

Syntax 2

```
VB

NUMBERFORMAT (number, format, culture)
```

Arguments

`number`: *Integer* or *Real*

A numeric value that specifies the number that must be formatted.

`format` : *String*

A *String* value that represents the format.

`culture`: *String*

A *String* value that represents the culture to use for formatting.

Return values

String

The resulting text value.

Usage notes

If the culture isn't defined as an argument of the called function, the context that this function is run in determines the culture that is used to format numbers.

Example 1

For the **EN-US** culture, `NUMBERFORMAT (0.45, "p")` returns "**45.00 %**", and `NUMBERFORMAT (10.45, "#")` returns "**10**".

Example 2

`NUMBERFORMAT (10/3, "F2", "de")` returns **3,33**, whereas `NUMBERFORMAT (10/3, "F2", "en-us")` returns **3.33**.

QRCODE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `QRCODE` function returns a *Container* value that presents the Quick Response code (QR code) image for the specified string in binary format.

Syntax

VB

```
QRCODE (text)
```

Arguments

`text`: *String*

A *String* value that represents the original text.

Return values

Container

The resulting binary stream.

Example

You can configure an Electronic reporting (ER) format to generate an outbound document in Microsoft Office format (Excel workbooks or Word documents) by using a predefined template. This template might contain a **Picture** object (Excel workbook) or a **Picture Content Control** (Word document) as a placeholder for a QR code image. Add a **Cell** element to the configured ER format that fills this placeholder. To specify what information the QR code stores, define a

binding for this **Cell** element. For example, you can configure the binding to contain the following expression:

```
VB

QRCODE (model.ListOfShelfLabels.LabelText)`
```

When you run the configured ER format, the text value of the **LabelText** field of the **model.ListOfShelfLabels** data source generates a QR code image. This image replaces a QR code image placeholder in the document template that you use to generate an outbound document. When you scan this image of the generated document, it returns the text that was taken from the **LabelText** field of the **model.ListOfShelfLabels** data source. For more information, see Embed images and shapes in documents that you generate by using ER.

TEXT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `TEXT` function returns the specified number as a *String* value after it converts the number to a text string that's formatted according to the server locale settings of the current application instance.

Syntax

```
VB

TEXT (number)
```

Arguments

`number`: *Integer* or *Real*

The number to convert to a text string.

Return values

String

The resulting text value.

Usage notes

For *Real* type values, the string conversion includes up to two decimal places.

Example

If the server locale of the Microsoft Dynamics 365 Finance instance is defined as **EN-US**, `TEXT (NOW ())` returns the current Finance session date, December 17, 2015, as the text string "**12/17/2015 07:59:23 AM**". `TEXT (1/3)` returns "**0.33**".

ER Design a configuration for generating reports in OPENXML format (November 2016)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how a user in the System Administrator or Electronic Reporting Developer role can create a new Electronic reporting (ER) configuration that contains a template for generating electronic documents in OPENXML format. Use this configuration for processing vendor payments.

In this example, you create a configuration for sample company, Litware, Inc. You can perform these steps in GBSI company.

To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure. You must also have an Excel file that you import when creating the template. You can access this file from the Template of Payment Report.

Upload the Payments data model configuration

1. In the navigation pane, go to **Modules** > **Organization administration** > **Workspaces** > **Electronic reporting**.
2. In the list, select the configuration provider for sample company, Litware, Inc. If you don't see this configuration provider, you must first complete the steps in Create configuration providers and mark them as active.
3. Select **Set active**.
4. Select **Repositories**. Select a repository for the Operations Resources type, if available. If it's available, skip the following steps about creating a new repository.
5. Select **Add** to open the drop dialog.
6. In the **Configuration repository type** field, enter `Operations resourcesdd`.

7. Select **Create repository**.
8. Select **OK**.
9. Select **Open**.
10. In the tree, select **Payment model**.
11. Select **Import**. Import this data model. It serves as a data source in a new format configuration. Skip this step if this configuration is already imported.
12. Select **Yes**.
13. Close the pages until you return to the Electronic reporting page.

Create a new format configuration

1. Select **Reporting configurations**.
2. In the tree, select **Payment model**.
3. Select **Create configuration** to open the drop dialog.
4. In the **New** field, enter `Format based on data model PaymentModel`. Create a format that is based on the PaymentModel data model.
5. In the **Name** field, type `Sample worksheet report`. Sample worksheet report
6. In the **Description** field, type `Sample worksheet report for vendors' payments`. Sample worksheet report for vendors' payments.
7. In the **Data model definition** field, enter or select a value. Select the **CustomerCreditTransferInitiation** definition.
8. Select **Create configuration**.

Design a new document in OPENXML worksheet format

1. In the tree, select **Payment model\Sample worksheet report**.
2. Select **Designer**.
3. On the Action Pane, select **Import**.
4. Select **Import from Excel**.
5. Select **Attachments**. Attach the existing Excel document as a template.
6. Select **New**.
7. Select **File**. Point to the existing Excel file.
8. Close the page.
9. In the **Template** field, enter or select a value. Select the attached Excel file to be used as a template.

10. Select **OK**. Note that ER format components are created in the designing format based on the structure of the referring MS Excel document (named ranges).

Create a new data source to calculate totals by currency codes

1. Select the **Mapping** tab.
2. Select **Add root** to open the drop dialog.
3. In the tree, select **Functions\Group by**.
4. In the **Name** field, type `PaymentByCurrency`.
5. Select **Edit group by**.
6. In the tree, expand **model**, and then select **model\Payments**.
7. Select **Add field to**.
8. Select **What to group**.
9. In the tree, expand **model\Payments**, and then select **model\Payments\Currency**.
10. Select **Add field to**.
11. Select **Grouped fields**.
12. In the tree, select **model\Payments\Instructed Amount(InstructedAmount)**.
13. Select **Add field to**, and then select **Aggregation fields**.
14. In the **Method** field, select an option. Select the **SUM aggregation** function.
15. In the **Name** field, type `TotalInstructuredAmount`.
16. Select **Save**.
17. Close the page.
18. Select **OK**.

Map format components to data sources

1. In the tree, select **model\Payments\Initiating Party(InitiatingParty)\Name** and **Excel\ReportHeader\CompanyName**.
2. Select **Bind**.
3. In the tree, select **model\Payments\Creditor\Identification\Source ID(SourceID)** and **Excel\PaymLines\VendAccountName**.
4. Select **Bind**.
5. In the tree, select **model\Payments\Creditor\Name** and **Excel\PaymLines\VendName**.
6. Select **Bind**.
7. In the tree, select **model\Payments\Creditor Agent(CreditorAgent)\Name** and **Excel\PaymLines\Bank**.

8. Select **Bind**.
9. In the tree, select **model\Payments\Creditor Agent(CreditorAgent)\Routing Number(RoutingNumber)** and **Excel\PaymLines\RoutingNumber**.
10. Select **Bind**.
11. In the tree, select **model\Payments\Creditor Account(CreditorAccount)\Identification\Number** and **Excel\PaymLines\AccountNumber**.
12. Select **Bind**.
13. In the tree, select **model\Payments\Instructed Amount(InstructedAmount)** and **Excel\PaymLines\Debit**.
14. Select **Bind**.
15. In the tree, select **model\Payments\Currency** and **Excel\PaymLines\Currency**.
16. Select **Bind**.
17. In the tree, select **PaymentByCurrency\grouped\Currency** and **Excel\SummaryLines\SummaryCurrency**.
18. Select **Bind**.
19. In the tree, select **PaymentByCurrency\aggregated\TotalInstructuredAmount** and **Excel\SummaryLines\SummaryAmount**.
20. Select **Bind**.
21. In the tree, select **PaymentByCurrency** and **Excel\SummaryLines**.
22. Select **Bind**.
23. In the tree, select **model\Payments** and **Excel\PaymLines**.
24. Select **Bind**.
25. Select **Save**, and then close the page.

Use the created configuration for payments processing

1. Select **Change status**.
2. Select **Complete**.
3. Select **OK**.
4. In the navigation pane, go to **Modules** > **Accounts payable** > **Payment setup** > **Methods of payment**.
5. Use the Quick Filter to filter on the **Method of payment** field with a value of **Electronic**.
6. Select **Edit**.
7. Expand the **File formats** section.
8. Select **Yes** in the **Generic electronic reporting** field.

9. In the **Export format configuration** field, enter or select a value. Select the **Sample worksheet report** configuration.
10. Select **Save**.
11. Close the page.

Use the created configuration to test payment journal processing

1. In the navigation pane, go to **Modules** > **Accounts payable** > **Payments** > **Payment journal**.
2. Select **New** to create a new payment journal.
3. In the **Name** field, type **VendPay**.
4. Select **Lines**.
5. In the **Account** field, enter the value `GB_SI_000001`.
6. Set **Debit** to `1000`.
7. Select **New**.
8. In the **Account** field, enter the value `GB_SI_000005`.
9. Set **Debit** to `2000`.
10. In the **Currency** field, type `EUR`.
11. In the **Offset account** field, enter the value `GBSI OPER`.
12. In the **Method of payment** field, type `Electronic`.
13. Select **Save**.
14. Select **Generate payments**.
15. In the **Method of payment** field, type `Electronic`.
16. In the **File name** field, type `Payments`.
17. In the **Bank account** field, type `GBSI OPER`.
18. Select **OK**, and then select **OK** again. Review the created worksheet, including details of payment lines as well as totals for each currency code used in this payment message.

Last updated on 04/13/2026

Design a configuration for generating documents in Excel format

You can design an Electronic reporting (ER) format configuration that has an ER format component that you can configure to generate an outbound document in a Microsoft Excel workbook format. You must use specific ER format components for this purpose.

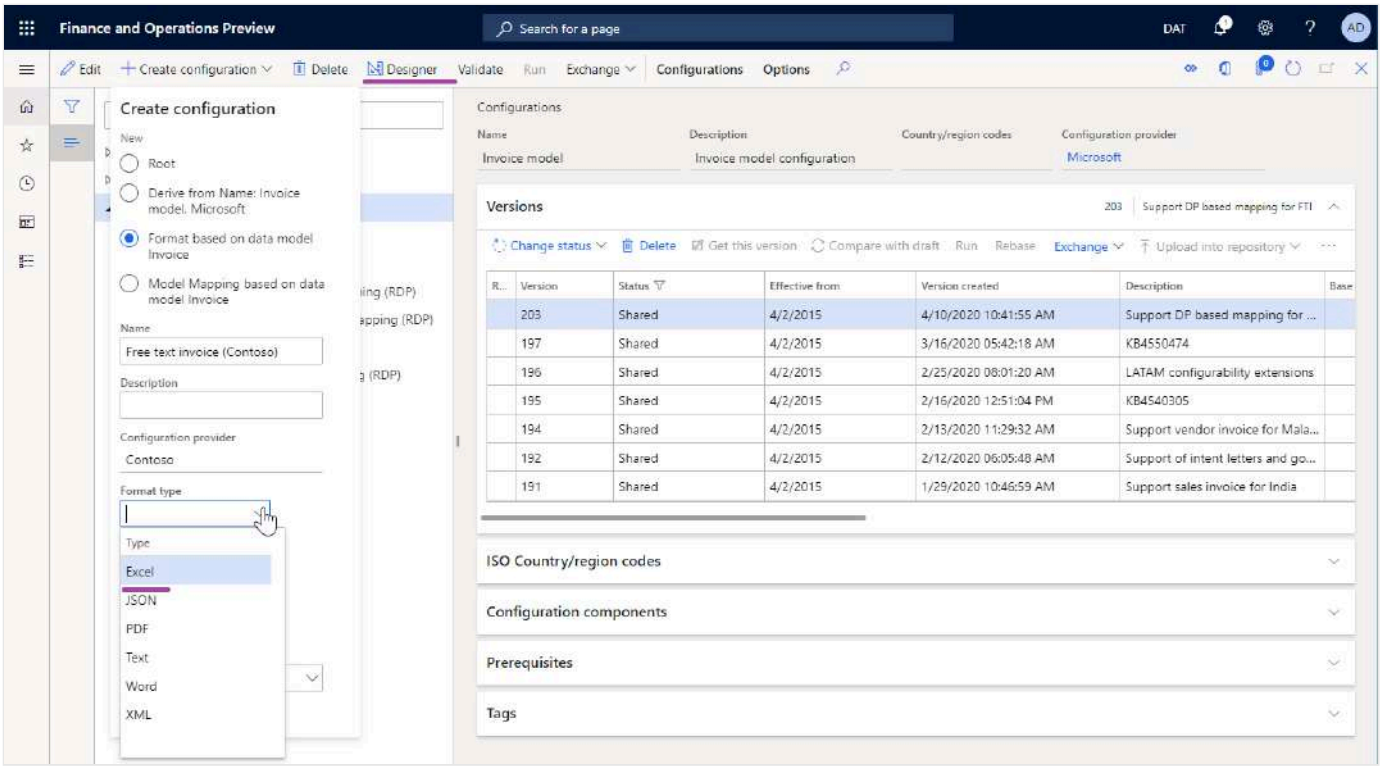
To learn more about this feature, see Design a configuration for generating reports in OPENXML format.

Add a new ER format

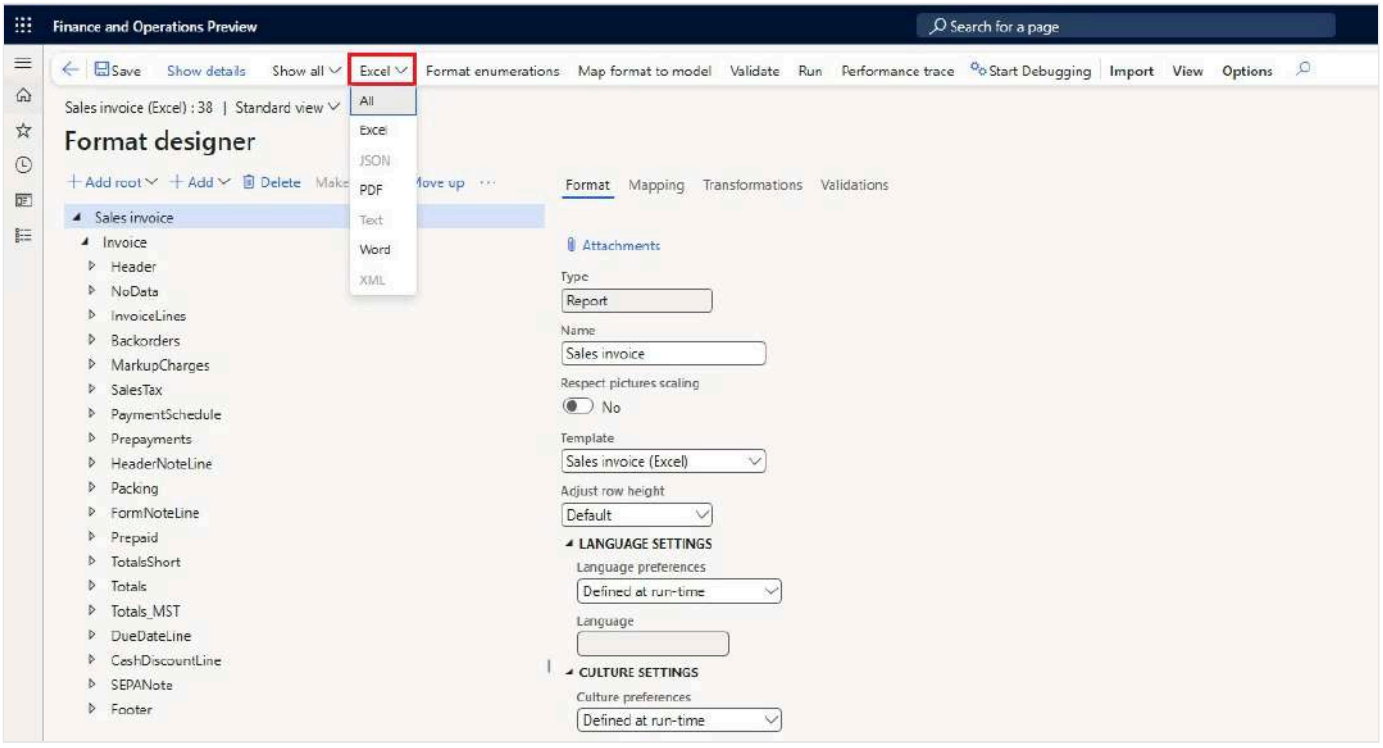
When you add a new ER format configuration to generate an outbound document in an Excel workbook format, select the **Excel** value for the **Format type** attribute of the format or leave the **Format type** attribute blank.

- If you select **Excel**, you can configure the format to generate an outbound document only in Excel format.
- If you leave the attribute blank, you can configure the format to generate an outbound document in any format that the ER framework supports.

To configure the ER format component of the configuration, select **Designer** on the Action Pane, and open the ER format component for editing in the ER Operation designer.



In Finance version **10.0.34**, you can view and change the **Format type** value for the selected format configuration version in the designer.

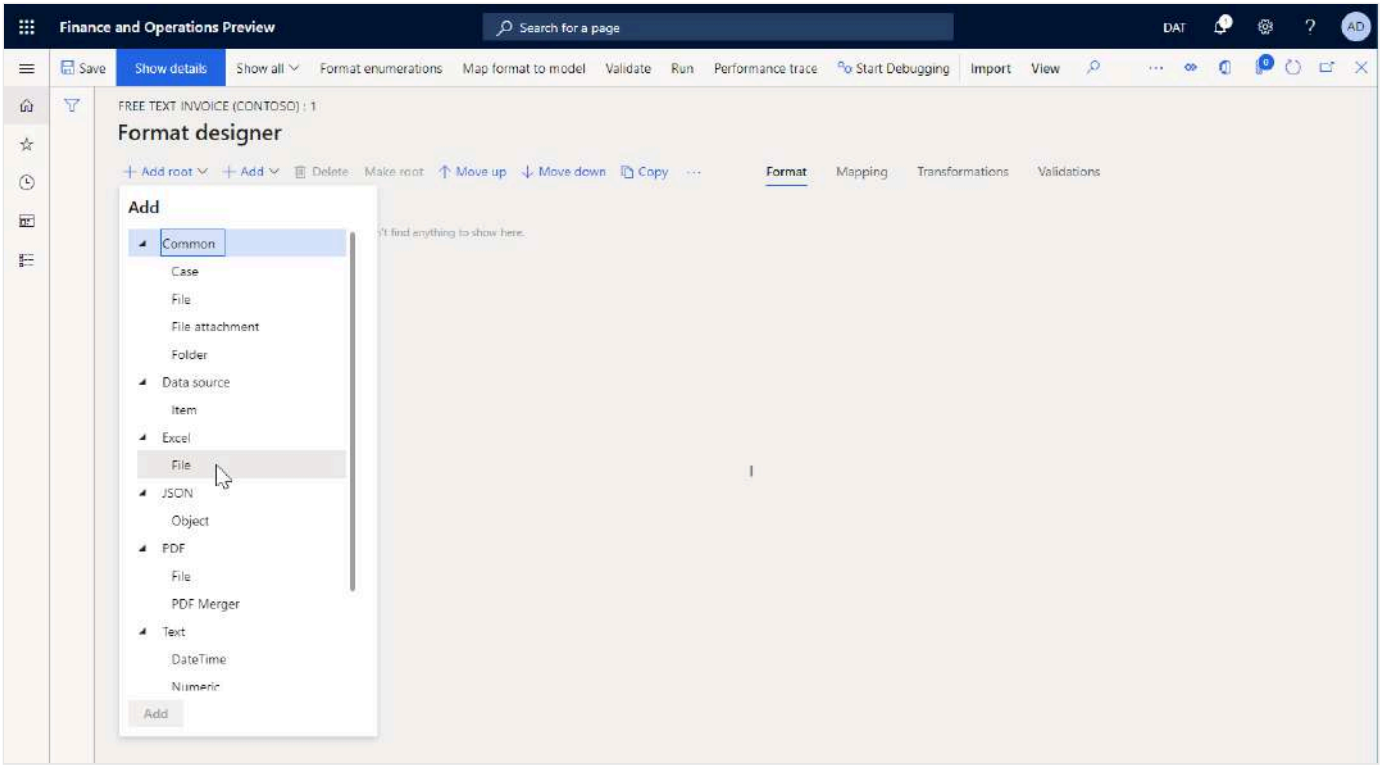


> **Note**
>
> The system suggests a selection of allowed format types, based on the current content of the format configuration.

Excel file component

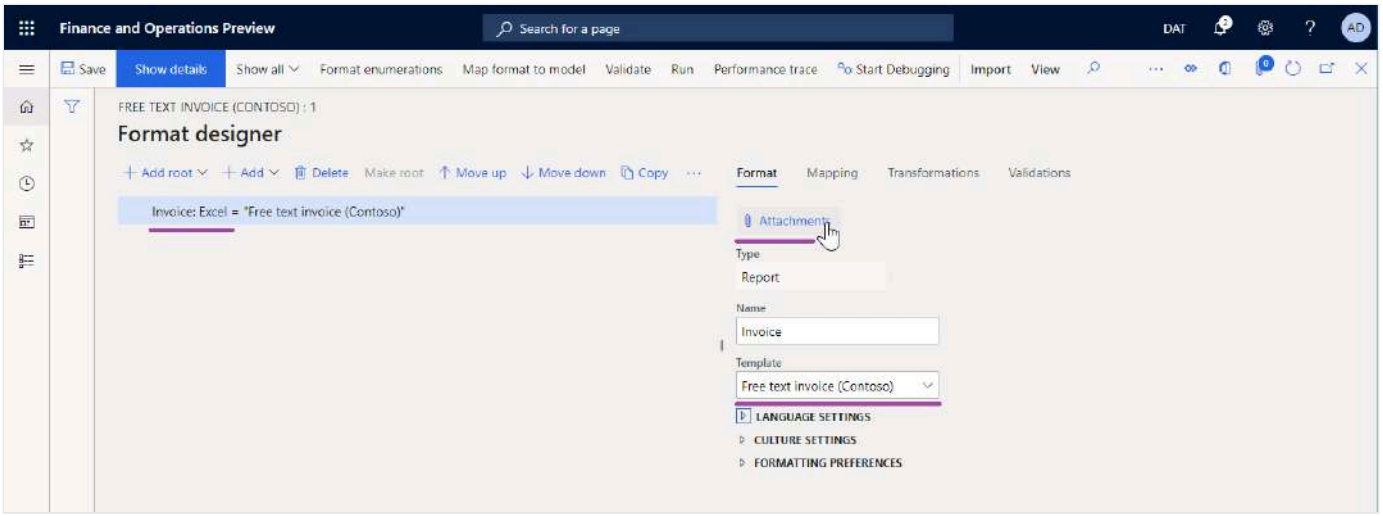
Manual entry

To generate an outbound document in Excel format, add an **Excel\File** component to the configured ER format.



To specify the layout of the outbound document, attach an Excel workbook that has the .xlsx extension to the **Excel\File** component as the template for outbound documents.

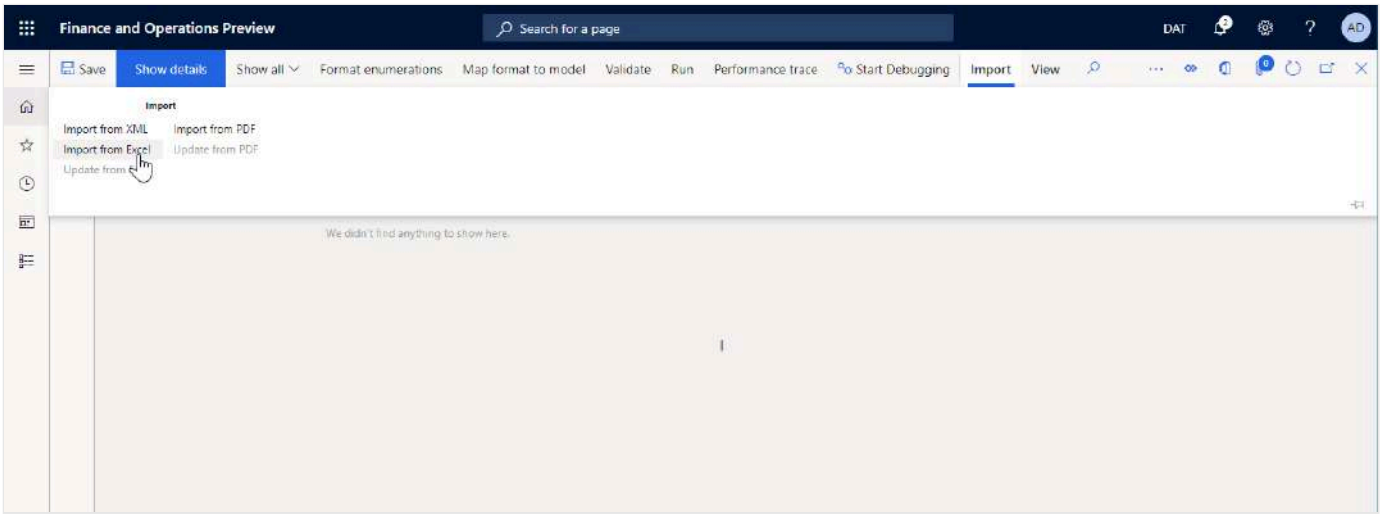
> **Note**
>
> When you manually attach a template, use a document type that's configured for this purpose in the ER parameters.



To specify how the attached template fills in when you run the configured ER format, add nested **Sheet**, **Range**, and **Cell** components to the **Excel\File** component. Associate each nested component with an Excel named item.

Template import

To import a new template into a blank ER format, select **Import from Excel** on the **Import** tab of the Action Pane. In this example, you automatically create an **Excel\File** component and attach the imported template to it. The process also automatically creates all required ER components, based on the list of Excel named items that it discovers.



> **Note**
>
> If you want to create the optional **Sheet** element in the editable ER format, set the **Create Excel Sheet format element** option to **Yes**.

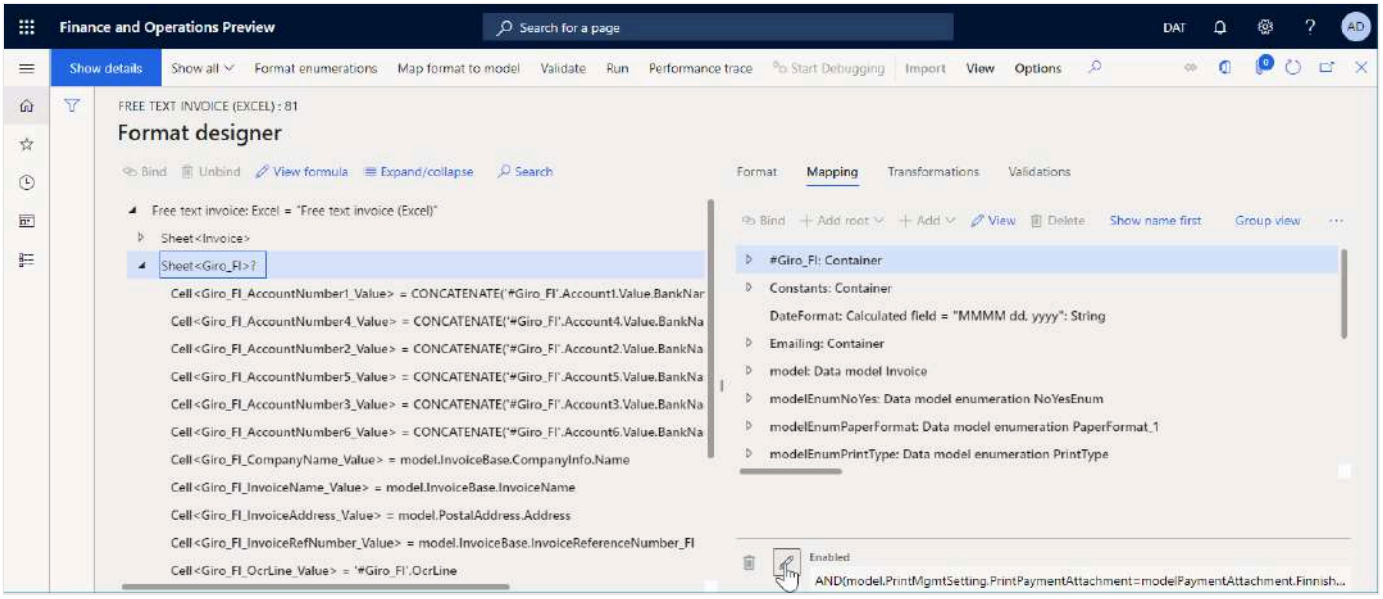
Sheet component

The **Sheet** component represents a worksheet in the attached Excel workbook that you need to fill in. You set the name of the worksheet in an Excel template through the **Sheet** property of this component.

> **Note**
>
> This component is optional for Excel workbooks that contain a single worksheet.

On the **Mapping** tab of the ER Operation designer, you can configure the **Enabled** property for a **Sheet** component to specify whether to include the component in a generated document:

- If you configure an expression for the **Enabled** property that returns **True** at runtime, or if you don't configure an expression, the appropriate worksheet is included in the generated document.
- If you configure an expression for the **Enabled** property that returns **False** at runtime, the generated document doesn't contain the worksheet.



Range component

Nested components

Data typing

The **Range** component can include other nested ER components that you use to enter values in the appropriate ranges.

- If you use any component from the **Text** group to enter values, you enter the value in an Excel range as a text value.

  > ⓘ **Note**
  >
  > Use this pattern to format entered values based on the locale that the application defines.

- If you use the **Cell** component from the **Excel** group to enter values, you enter the value in an Excel range as a value of the data type that the binding of that **Cell** component defines. For example, the data type might be **String**, **Real**, or **Integer**.

  > ⓘ **Note**
  >
  > Use this pattern to enable the Excel application to format entered values based on the locale of the local computer that opens the outbound document.

Row handling

You can configure the **Range** component as vertically replicated, so that it generates multiple rows in an Excel worksheet. The parent **Range** component or its nested **Range** components can generate the rows.

In version 10.0.26 and later, you can force a generated worksheet to keep the generated rows on the same page. In the ER format designer, set the **Keep rows together** option to **Yes** for the parent **Range** component in the editable ER format. ER then tries to keep all the content that it generates by that range on the same page. If the height of the content exceeds the remaining space on the current page, ER adds a page break, and the content starts at the top of the next new page.

> ⓘ **Note**
>
> Configure the **Keep rows together** option only for ranges that span the whole width of a generated document.
>
> The **Keep rows together** option applies only to **Excel** > **File** components that you configure to use an Excel workbook template.

You can use the **Keep rows together** option only when the **Enable usage of EPPlus library in Electronic reporting framework** feature is enabled.

This feature can be used for **Range** components that reside under the **Page** component. However, there's no guarantee that page footer totals are correctly calculated by using Data collection data sources.

To learn how to use this option, follow the example steps in Design an ER format to keep rows together on the same Excel page.

Replication

The **Replication direction** property specifies whether and how a range is repeated in a generated document:

- **No replication** – The appropriate Excel range isn't repeated in the generated document.
- **Vertical** – The appropriate Excel range is repeated vertically in the generated document. Each replicated range is placed below the original range in an Excel template. The number of repetitions is defined by the number of records in a data source of the **Record list** type that is bound to this ER component.
- **Horizontal** – The appropriate Excel range is repeated horizontally in the generated document. Each replicated range is placed to the right of the original range in an Excel template. The number of repetitions is defined by the number of records in a data source of the **Record list** type that is bound to this ER component.

  To learn more about horizontal replication, see Use horizontally expandable ranges to dynamically add columns in Excel reports.

Enabling

On the **Mapping** tab of the ER Operation designer, you can configure the **Enabled** property for a **Range** component to specify whether the component is included in a generated document:

- If you configure an expression for the **Enabled** property to return **True** at runtime, or if you don't configure an expression, the appropriate range is filled in the generated document.
- If you configure an expression for the **Enabled** property to return **False** at runtime, and if this range doesn't represent the entire rows or columns, the appropriate range isn't filled in the generated document.

- If you configure an expression for the **Enabled** property to return **False** at runtime, and this range represents the entire rows or columns, the generated document contains those rows and columns as hidden rows and columns.

Resizing

You can configure your Excel template to use cells to present textual data. To ensure that the whole text in a cell is visible in a generated document, you can configure that cell to automatically wrap the text inside it. You can also configure the row that contains that cell to automatically adjust its height if the wrapped text isn't fully visible. For more information, see the "Wrap text in a cell" section in Fix data that is cut off in cells.

> **Note**
>
> Because of a known Excel limitation, even if you configure cells to wrap text, and you configure the rows that contain those cells to automatically adjust their height to fit the wrapped text, you might not be able to use the **AutoFit** and **Wrap text** Excel features for merged cells and the rows that contain them.

As of Dynamics 365 Finance version 10.0.23, when you're working in a generated document, you can force ER to calculate the height of every row that was configured to automatically fit its height to the content of nested cells whenever that row contains at least one merged cell that was configured to wrap the text inside it. The calculated height is then used to resize the row to ensure that all cells in the row are visible in the generated document.

> **Note**
>
> Be aware that this functionality might not work as expected when a custom font is used to format a merged cell. Because Excel doesn't embed custom fonts, it doesn't provide information about custom font size. Therefore, the size of the merged cell can be incorrectly estimated.

To start to use this functionality when you run any ER formats that were configured to use Excel templates to generate outbound documents, follow these steps:

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization configurations** page, in the **Related links** section, select **Electronic reporting parameters**.

3. On the **Electronic reporting parameters** page, on the **Runtime** tab, set the **Autofit row height** option to **Yes**.

When you want to change this rule for a single ER format, update the draft version of that format by following these steps.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization configurations** page, in the **Configurations** section, select **Reporting configurations**.
3. On the **Configurations** page, in the configurations tree in the left pane, select an ER configuration that is designed to use an Excel template to generate outbound documents.
4. On the **Versions** FastTab, select the configuration version that has a status of **Draft**.
5. On the Action Pane, select **Designer**.
6. On the **Format designer** page, in the format tree in the left pane, select the Excel component that is linked to an Excel template.
7. On the **Format** tab, in the **Adjust row height** field, select a value to specify whether ER should be forced, at runtime, to change the height of rows in an outbound document that is generated by the edited ER format:
    - **Default** – Use the general setting that is configured in the **Autofit row height** field on the **Electronic reporting parameters** page.
    - **Yes** – Override the general setting, and change the row height at runtime.
    - **No** – Override the general setting, and don't change the row height at runtime.

Cell component

Use the **Cell** component to fill in Excel named cells, shapes, and pictures. To indicate an Excel named object that the **Cell** ER component must fill in, specify the name of that object in the **Excel range** property of the **Cell** component.

On the **Mapping** tab of the ER Operation designer, you can configure the **Enabled** property for a **Cell** component to specify whether the object is filled in in a generated document:

- If you configure an expression for the **Enabled** property that returns **True** at runtime, or if you don't configure an expression, the appropriate object is filled in in the generated

document. The binding of this **Cell** component specifies a value that goes in the appropriate object.

- If you configure an expression for the **Enabled** property that returns **False** at runtime, the appropriate object isn't filled in in the generated document.

When you configure a **Cell** component to enter a value in a cell, you can bind it to a data source that returns the value of a primitive data type (for example, **String**, **Real**, or **Integer**). In this case, the value is entered in the cell as a value of the same data type.

When you configure a **Cell** component to enter a value in an Excel shape, you can bind it to a data source that returns a value of a primitive data type (for example, **String**, **Real**, or **Integer**). In this case, the value is entered in the Excel shape as the text of that shape. For values of data types that aren't **String**, the conversion to text is done automatically.

> ⓘ **Note**
>
> You can configure a **Cell** component to fill in a shape only in cases where a shape text property is supported.

When you configure a **Cell** component to enter a value in an Excel picture, you can bind it to a data source that returns a value of the **Container** data type that represents an image in binary format. In this case, the value is entered in the Excel picture as an image.

> ⓘ **Note**
>
> Every Excel picture and shape is anchored by its upper-left corner to a specific Excel cell or range. To replicate an Excel picture or shape, you must configure the cell or range that it's anchored to as a replicated cell or range.

> 💡 **Tip**
>
> If you plan to use an image with custom scaling and aspect ratio at runtime, set the option **Respect pictures scaling** of the parent **Excel file component** to **Yes** to apply the scaling and aspect ratio as a placeholder of that image in the Excel template you're using.

To learn more about how to embed images and shapes, see Embed images and shapes in documents that you generate by using ER.

Page break component

The **PageBreak** component forces Excel to start a new page. This component isn't required when you want to use Excel's default paging, but use it when you want Excel to follow your ER format to structure paging.

Page component

Overview

Use the **Page** component when you want Excel to follow your ER format and structure pagination in a generated outbound document. When an ER format runs components that are under the **Page** component, it automatically adds the required page breaks. During this process, it considers the size of the generated content, the page setup of the Excel template, and the paper size that you select in the Excel template.

If you need to split a generated document into different sections, each with a different pagination, configure several **Page** components in every Sheet component.

Structure

If the first component under the **Page** component is a Range component where you set the **Replication direction** property to **No replication**, the system considers this range the page header for pagination that is based on the settings of the current **Page** component. The Excel range that is associated with this format component repeats at the top of every page that the system generates by using the settings of the current **Page** component.

> **Note**
>
> For correct pagination, if you configure the Rows to repeat at top range in your Excel template, the address of this Excel range must equal the address of the Excel range that is associated with the previously described **Range** component.

If the last component under the **Page** component is a **Range** component where you set the **Replication direction** property to **No replication**, the system considers this range the page footer for pagination that is based on the settings of the current **Page** component. The Excel range that is associated with this format component repeats at the bottom of every page that the system generates by using the settings of the current **Page** component.

> **Note**
>
> For correct pagination, don't resize the Excel ranges that are associated with the **Range** components at runtime. Don't format cells of this range by using the **Wrap text in a cell** and **Autofit row height** Excel options.

You can add multiple other **Range** components between the optional **Range** components to specify how a generated document is filled in.

If the set of nested **Range** components under the **Page** component doesn't comply with the previously described structure, a validation error occurs at design time in the ER format designer. The error message informs you that the issue can cause problems at runtime.

> **Note**
>
> To generate correct output, don't specify a binding for any **Range** component under the **Page** component if you set the **Replication direction** property for that **Range** component to **No replication**, and the range is configured to generate page headers or page footers.

If you want pagination-related summing and counting to compute running totals and totals per page, configure the required Data collection data sources. To learn how to use the **Page** component to paginate a generated Excel document, complete the procedures in Design an ER format to paginate a generated document in Excel format.

Limitations

When you use the **Page** component for Excel pagination, you don't know the final number of pages in a generated document until the pagination is complete. Therefore, you can't calculate the total number of pages by using ER formulas, and you can't print the correct number of pages of a generated document on any page before the last page.

> **Tip**
>
> To achieve this result in an Excel header or footer, use the special Excel formatting for headers and footers.

Dynamics 365 Finance version 10.0.22 doesn't consider configured **Page** components when you update an Excel template in the editable format. This functionality is considered for future

releases of Finance.

If you configure your Excel template to use conditional formatting, it might not work as expected in some cases.

Applicability

The **Page** component works for the Excel file format component only when you configure that component to use a template in Excel. If you replace the Excel template with a Word template and then run the editable ER format, the **Page** component is ignored.

The **Page** component works only when the **Enable usage of EPPlus library in Electronic reporting framework** feature is enabled. An exception is thrown at runtime if ER tries to process the **Page** component while this feature is disabled.

> ⓘ Note
>
> An exception is thrown at runtime if an ER format processes the **Page** component for an Excel template that contains at least one formula that refers to a cell that isn't valid. To help prevent runtime errors, fix the Excel template as described in How to correct a #REF! error.

Footer component

Use the **Footer** component to add footers at the bottom of a generated worksheet in an Excel workbook.

> ⓘ Note
>
> Add this component for every **Sheet** component to specify different footers for different worksheets in a generated Excel workbook.

When you configure an individual **Footer** component, use the **Header/footer appearance** property to specify the pages that the component applies to. The following values are available:

- **Any** – Run the configured **Footer** component for any page of the parent Excel worksheet.
- **First** – Run the configured **Footer** component for only the first page of the parent Excel worksheet.

- **Even** – Run the configured **Footer** component for only the even pages of the parent Excel worksheet.
- **Odd** – Run the configured **Footer** component for only the odd pages of the parent Excel worksheet.

For a single **Sheet** component, you can add several **Footer** components, each of which has a different value for the **Header/footer appearance** property. By using this approach, you can generate different footers for different types of pages in an Excel worksheet.

> ⓘ Note
>
> Make sure that each **Footer** component that you add to a single **Sheet** component has a different value for the **Header/footer appearance** property. Otherwise, a validation error occurs. The error message that you receive notifies you about the inconsistency.

Under the added **Footer** component, add the required nested components of the **Text\String**, **Text\DateTime**, or other type. Configure the bindings for those components to specify how your page footer is filled in.

You can also use special formatting codes to correctly format the content of a generated footer. To learn how to use this approach, follow the steps in Example 1, later in this article.

> ⓘ Note
>
> When you configure ER formats, be sure to consider the Excel limit and the maximum number of characters for a single header or footer.

Header component

Use the **Header** component to add headers at the top of a generated worksheet in an Excel workbook. Use it like the **Footer** component.

Edit an added ER format

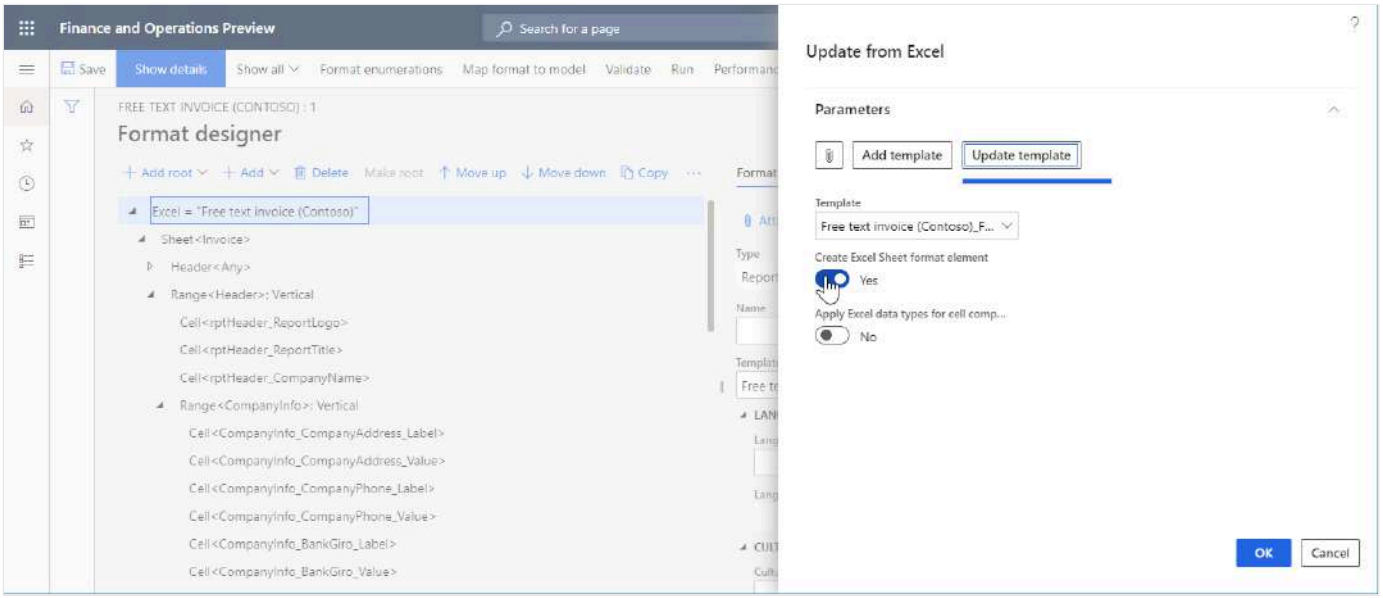
Update a template

Select **Update from Excel** on the **Import** tab of the Action Pane to import an updated template into an editable ER format. During this process, the template for the selected **Excel\File**

component is replaced by a new template. The content of the editable ER format syncs with the content of the updated ER template.

- If the process doesn't find the ER format component in the editable format, it automatically creates a new ER format component for every Excel name.
- If the process doesn't find the appropriate Excel name for an ER format component, it deletes that component from the editable ER format.

> **Note**
>
> Set the **Create Excel Sheet format element** option to **Yes** if you want to create the optional **Sheet** element in the editable ER format.
>
> If the editable ER format originally contained **Sheet** elements, set the **Create Excel Sheet format element** option to **Yes** when you import an updated template. Otherwise, the process creates all nested elements of the original **Sheet** element from scratch. Therefore, all bindings of the re-created format elements are lost in the updated ER format.



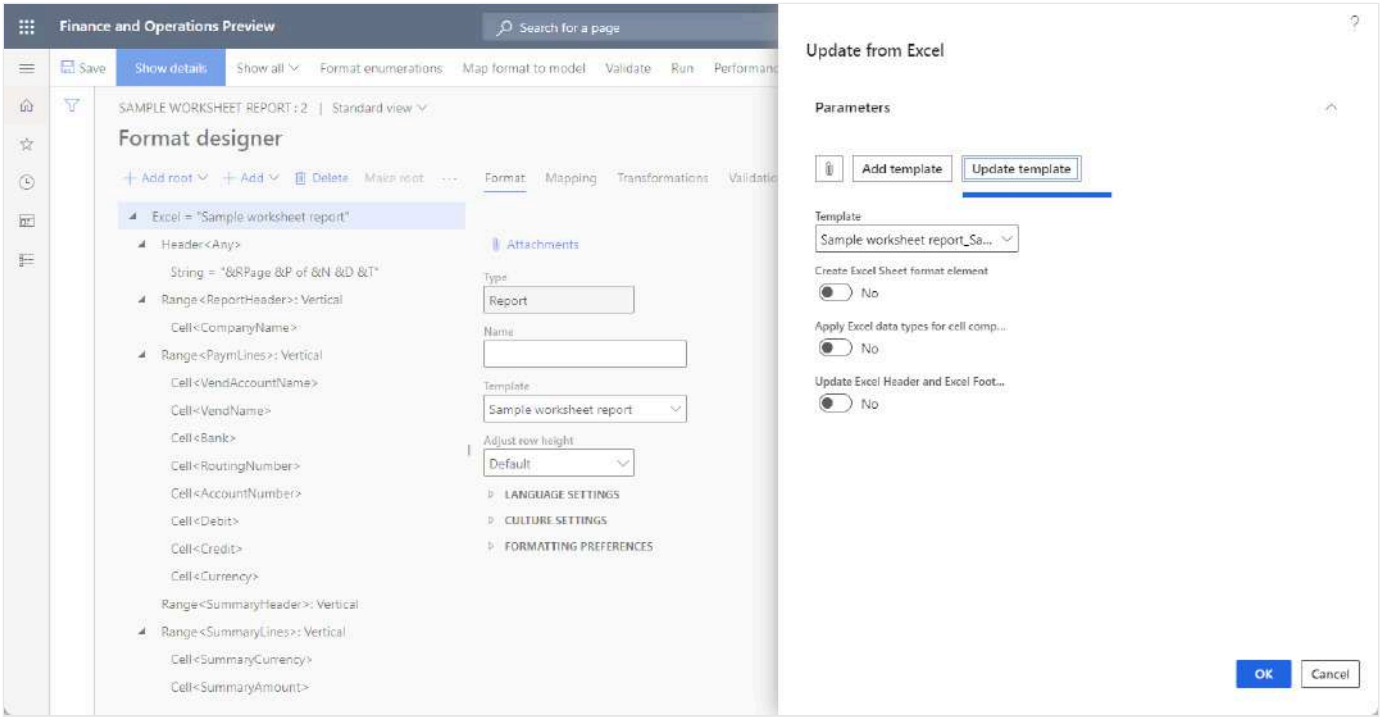
In version 10.0.28 and later, you can use the **Update Excel Header and Excel Footer format elements** option.

- When you set this option to **No**, the Excel Header and Excel Footer format elements remain unchanged, even if the corresponding headers or footers are updated in the worksheets of the imported template in the Excel workbook format.

- When you set this option to **Yes**, Excel Header and Excel Footer format elements change when the corresponding headers or footers are updated in worksheets of the imported

template in the Excel workbook format.

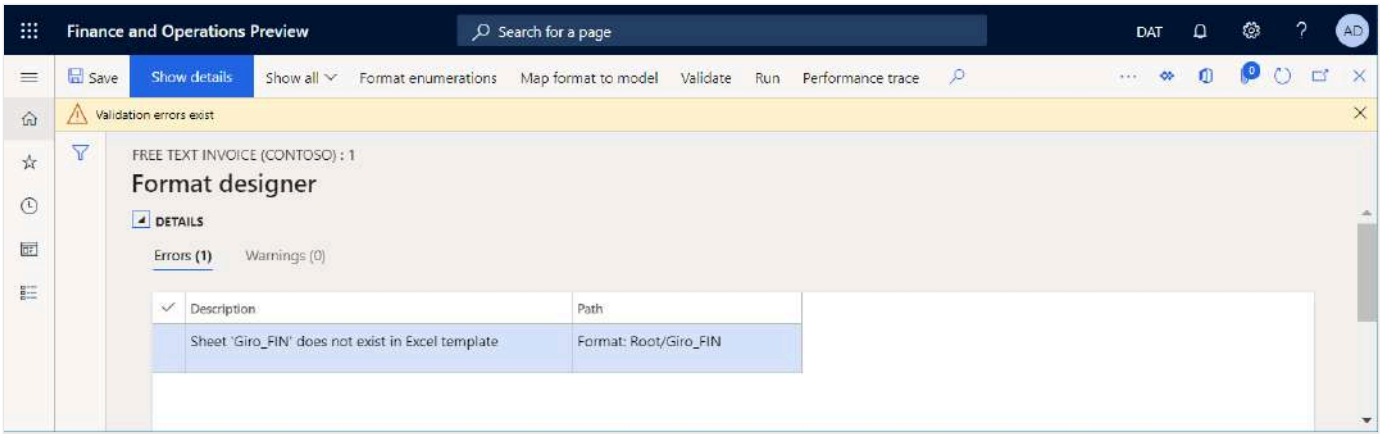
- If the structure of a worksheet header or footer isn't changed, or if it's only appended, the structure of the corresponding Excel Header or Excel Footer format element is updated. Bindings of format elements that are nested under this Excel Header or Excel Footer format element are preserved.
- If the structure of a worksheet header or footer is changed, the corresponding Excel Header or Excel Footer format element is re-created. Bindings of format elements that are nested under this Excel Header or Excel Footer format element are removed.



To learn more about this feature, see Modify Electronic reporting formats by reapplying Excel templates.

Excel-specific validation of ER format

When you validate an ER format that you can edit, the system checks for consistency to make sure that the Excel name exists in the Excel template that you're currently using. The system notifies you about any inconsistencies. For some inconsistencies, the option to automatically fix problems is available.



Control the calculation of Excel formulas

When you generate an outbound document in a Microsoft Excel workbook format, some cells in this document might contain Excel formulas. When you enable the **Enable usage of EPPlus library in Electronic reporting framework** feature, you can control when the formulas are calculated by changing the value of the **Calculation Options** parameter in the Excel template that you're using:

- Select **Automatic** to recalculate all dependent formulas every time new ranges, cells, and other elements are added to a generated document.

  > **Note**
  >
  > This choice might cause a performance problem for Excel templates that contain multiple related formulas.

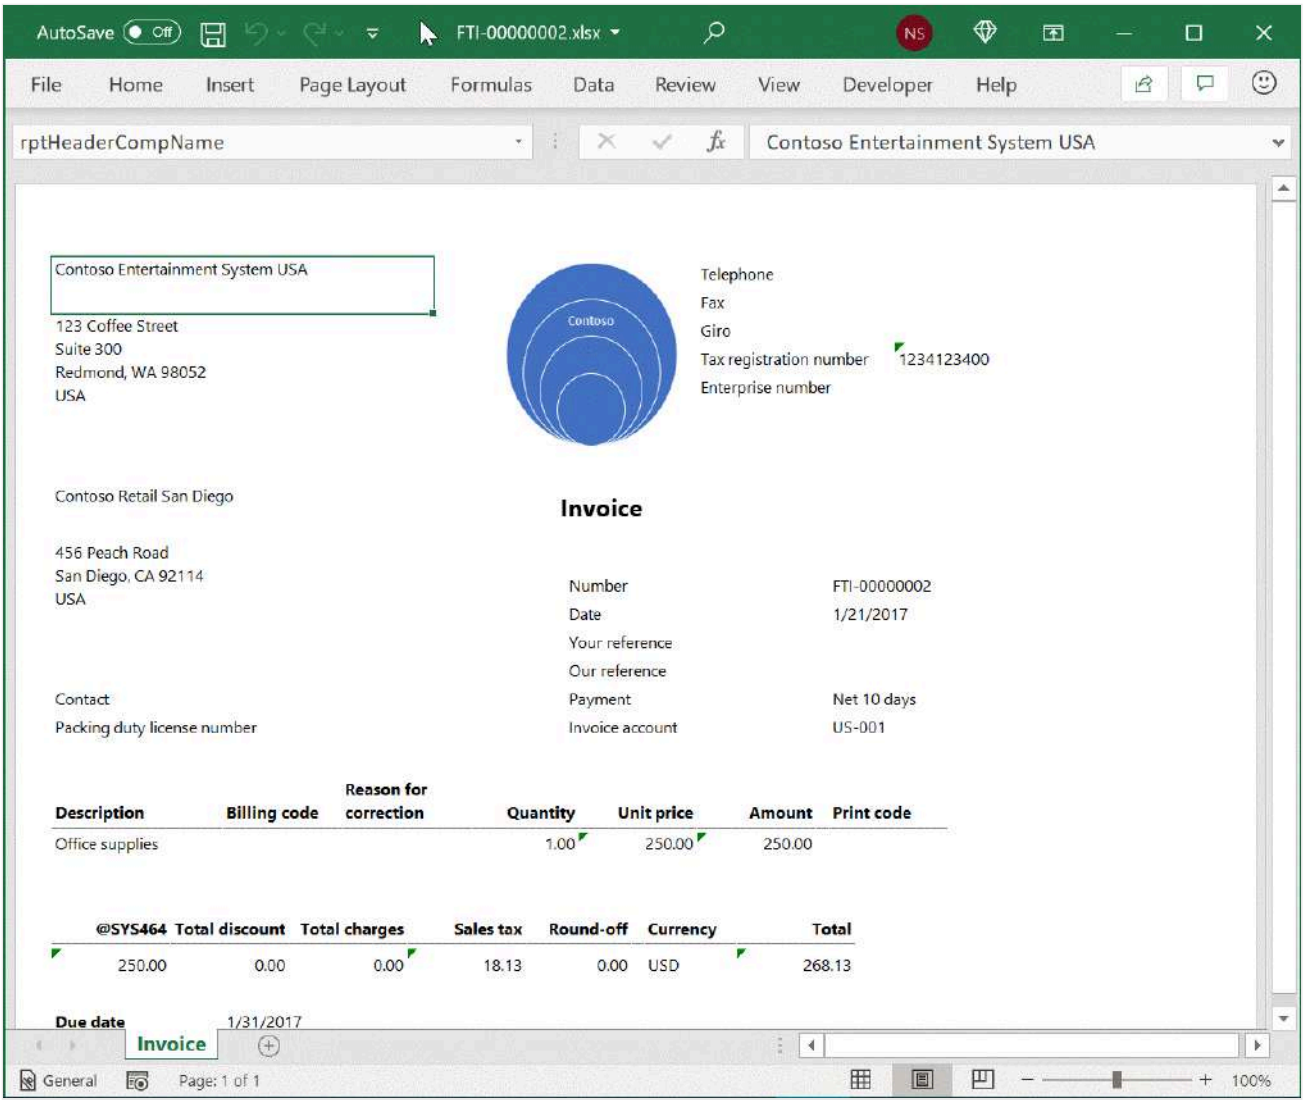
- Select **Manual** to avoid formula recalculation when a document is generated.

  > **Note**
  >
  > Formula recalculation is manually forced when a generated document is opened for preview by using Excel. Don't use this option if you configure an ER destination that assumes the usage of a generated document without its preview in Excel (PDF conversion, emailing, and so on) because the generated document might not contain values in cells that contain formulas.

Example 1: Format footer content

1. Use the provided ER configurations to generate a printable free text invoice (FTI) document.

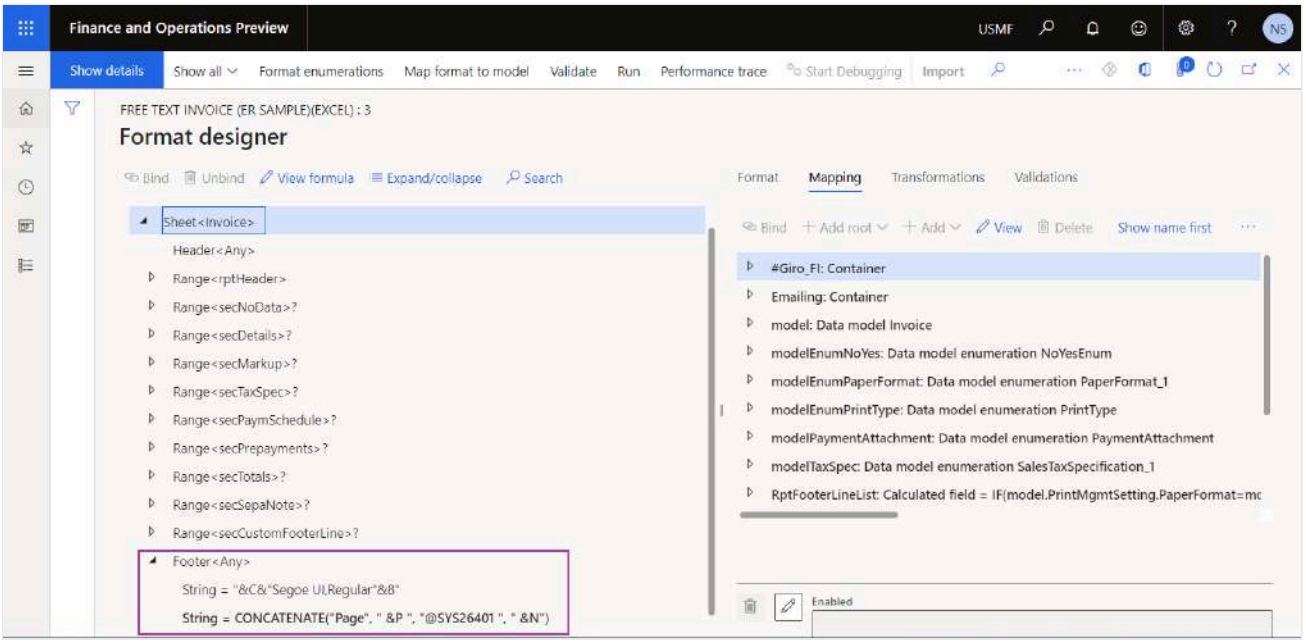
2. Review the footer of the generated document. Notice that it contains information about the current page number and the total number of pages in the document.



3. In the ER format designer, open the sample ER format for review.

   The footer of the **Invoice** worksheet is generated based on the settings of two **String** components that reside under the **Footer** component:

   - The first **String** component fills in the following special formatting codes to force Excel to apply specific formatting:
     - **&C** – Align the footer text in the center.
     - **&"Segoe UI,Regular"&8** – Present the footer text in the "Segoe UI Regular" font at a size of 8 points.
   - The second **String** component fills in the text that contains the current page number and the total number of pages in the current document.



4. Customize the sample ER format to modify the current page footer:

   a. Create a derived **Free text invoice (Excel) custom** ER format that is based on the sample ER format.

   b. Add the first new pair of **String** components for the **Footer** component of the **Invoice** worksheet:

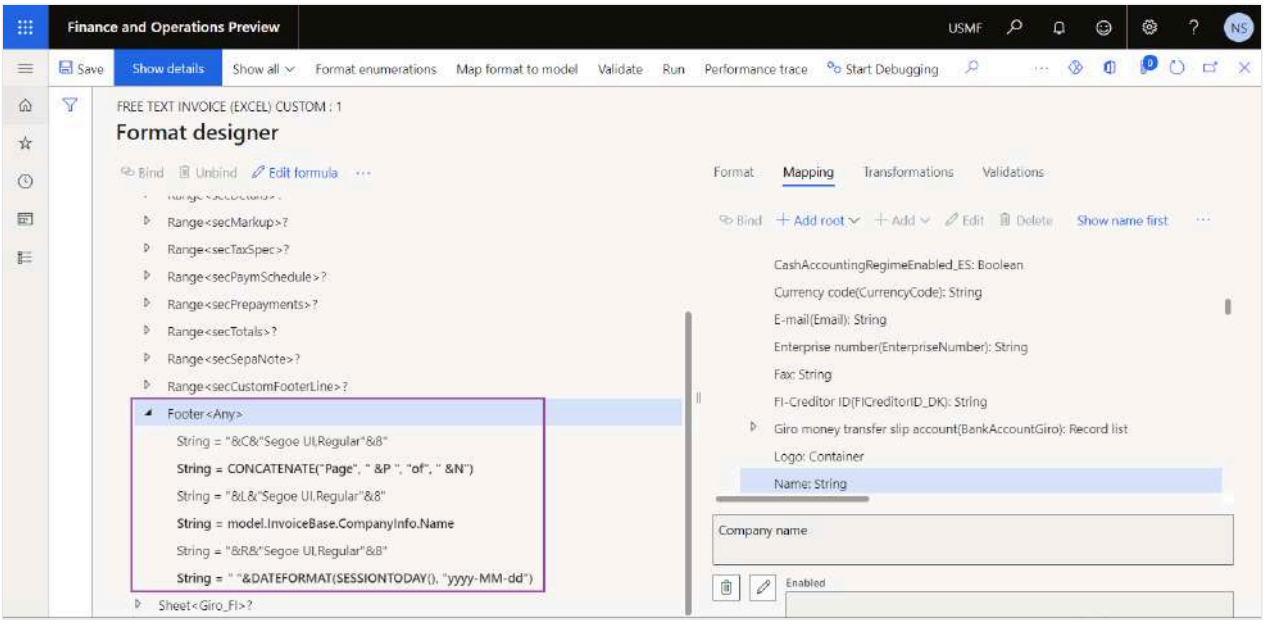
      i. Add a **String** component that aligns the company name on the left and presents it in 8-point "Segoe UI Regular" font (**"&L&"Segoe UI,Regular"&8"**).

      ii. Add a **String** component that fills in the company name (**model.InvoiceBase.CompanyInfo.Name**).

   c. Add the second new pair of **String** components for the **Footer** component of the **Invoice** worksheet:

      i. Add a **String** component that aligns the processing date on the right and presents it in 8-point "Segoe UI Regular" font (**"&R&"Segoe UI,Regular"&8"**).

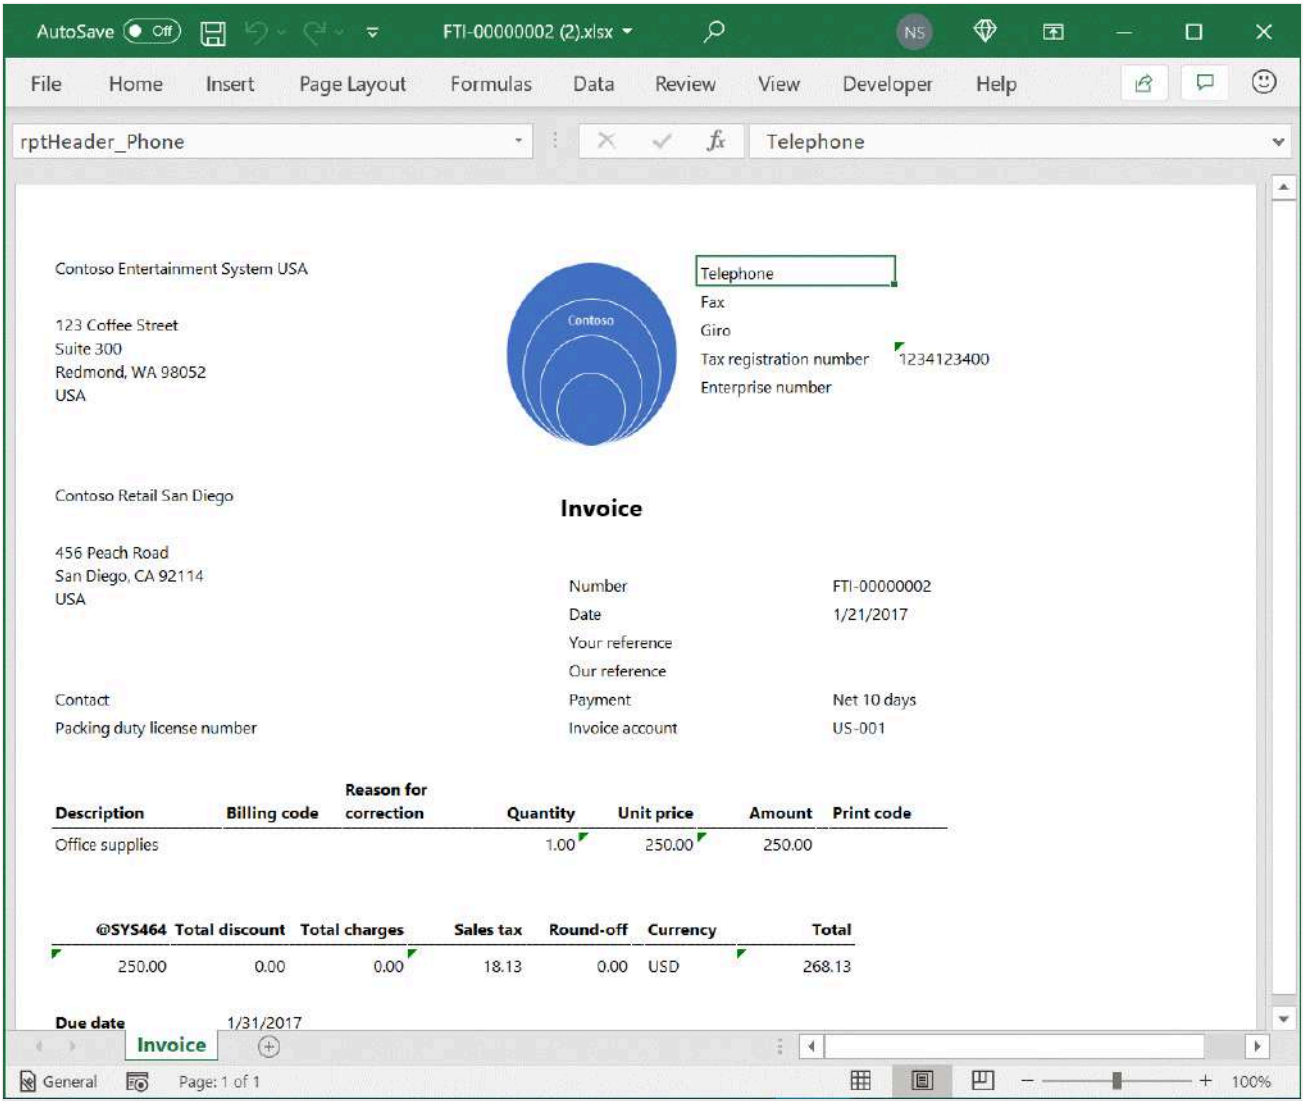
      ii. Add a **String** component that fills in the processing date in a custom format (**" "&DATEFORMAT(SESSIONTODAY(), "yyyy-MM-dd")**).



d. Complete the draft version of the derived **Free text invoice (Excel) custom** ER format.

5. Configure Print management to use the derived **Free text invoice (Excel) custom** ER format instead of the sample ER format.

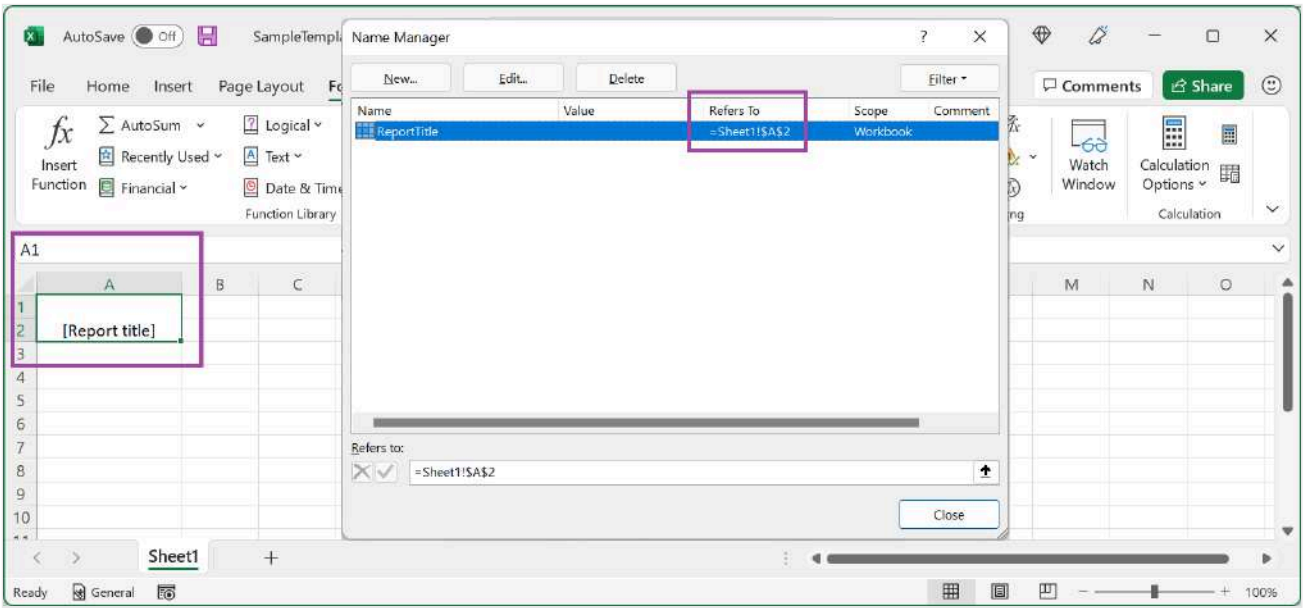
6. Generate a printable FTI document, and review the footer of the generated document.



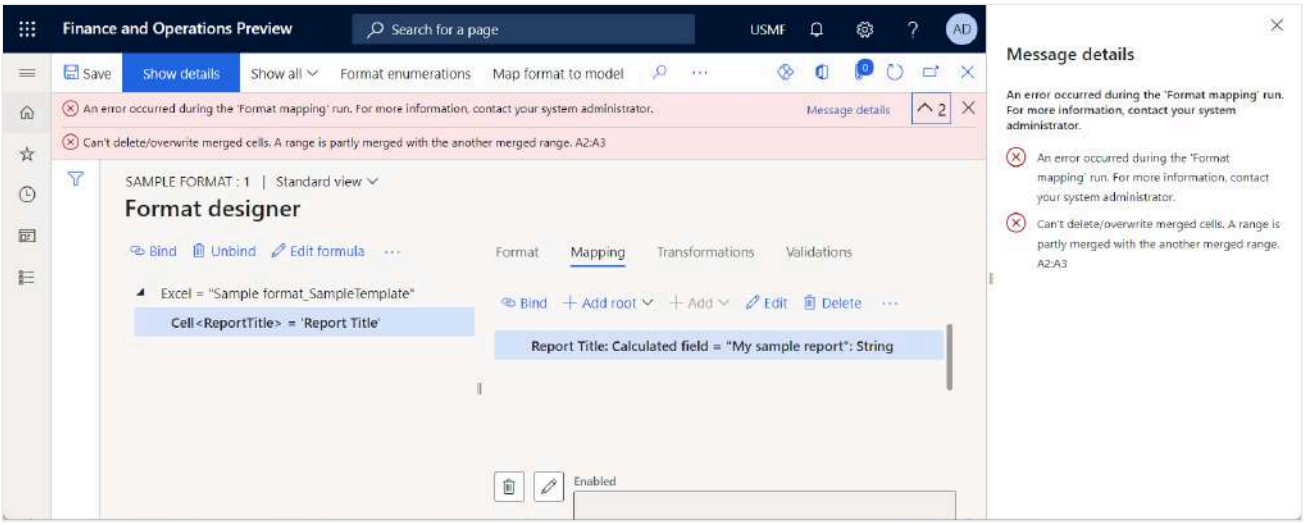
Example 2: Fixing the merged cells EPPlus issue

You can run an ER format to generate an outbound document in an Excel workbook format. When you enable the **Enable usage of EPPlus library in Electronic reporting framework** feature in the **Feature management** workspace, the EPPlus library is used to make Excel output. However, because of known Excel behavior and a limitation of the EPPlus library, you might encounter the following exception: "Can't delete/overwrite merged cells. A range is partly merged with the another merged range." To learn what kind of Excel templates might cause this exception and how you can fix the issue, complete the following example.

1. In the Excel desktop application, create a new Excel workbook.
2. On worksheet **Sheet1**, add the **ReportTitle** name for cell **A2**.
3. Merge cells **A1** and **A2**.



4. On the **Configurations** page, add a new ER format to generate an outbound document in an Excel workbook format.
5. On the **Format designer** page, import the designed Excel workbook into the added ER format as a new template for outbound documents.
6. On the **Mapping** tab, configure the binding for the **ReportTitle** component of the Cell type.
7. Run the configured ER format. Notice that the following exception is thrown: "Can't delete/overwrite merged cells. A range is partly merged with the another merged range."



You can fix the issue in either of the following ways:

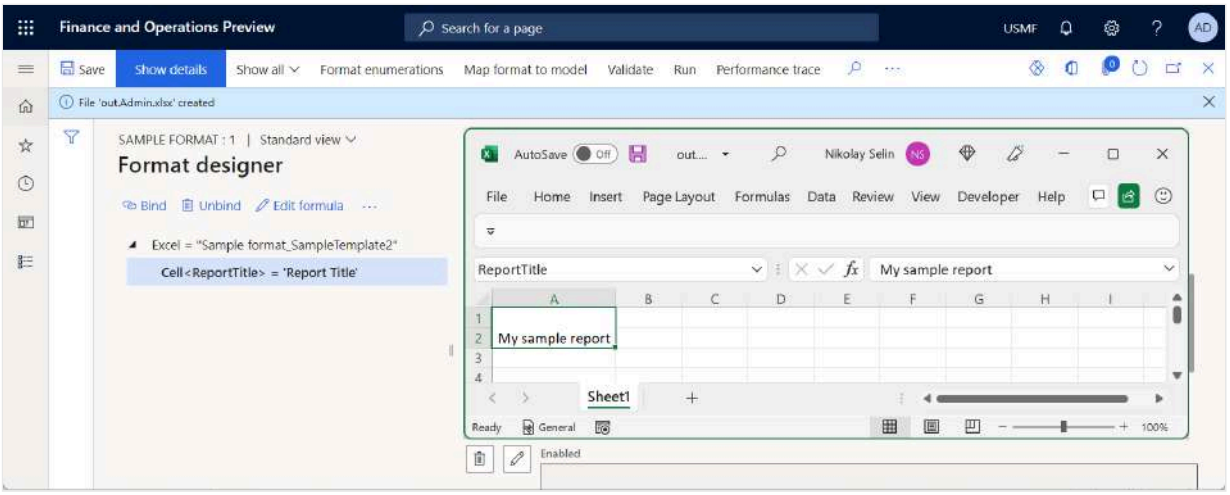
- **Easier but not recommended:** In the **Feature management** workspace, turn off the **Enable usage of EPPlus library in Electronic reporting framework** feature. Although this approach is easier, you might experience other issues if you use it, because some ER functionality is supported only when the **Enable usage of EPPlus library in Electronic reporting framework** feature is enabled.

- **Recommended:** Follow these steps:

    1. In the Excel desktop application, modify the Excel workbook in one of the following ways:
        - On worksheet **Sheet1**, unmerge cells **A1** and **A2**.
        - Change the reference for the **ReportTitle** name from **=Sheet1!$A$2** to **=Sheet1!$A$1**.

    2. On the **Format designer** page, import the modified Excel workbook into the editable ER format to update the existing template.

3. Run the modified ER format.



Limitations

Known EPPlus library limitations

External data sources

If one of your templates contains a PivotTable that is based on a PowerPivot model that refers to an external data source, and you enable the **Enable usage of EPPlus library in Electronic reporting framework** feature, you receive the following error message when you run an ER format that uses that template to generate an outbound document in Excel format: "The cachesource is not a worksheet." To fix this issue, use the following options:

- **Recommended:** Redesign the Excel solution that you're using:

  1. Isolate the part that contains pivots in a separate Excel workbook (workbook A).
  2. Use ER to generate a second Excel workbook (workbook B) from Finance that has the required details.
  3. Refer to workbook B in workbook A as soon as workbook B is generated.

- Turn off the feature, **Enable usage of EPPlus library in Electronic reporting framework** to use an option other than EPPlus.

Modify electronic reporting formats by reapplying Excel templates

Use the Electronic reporting (ER) tool to generate business documents in an electronic format. To generate a business document, create an ER format, and then use the ER designer to define the layout of the business document and specify the data that should be included in it. Then, run the ER format to generate the business document.

Use the ER tool to generate business documents as Microsoft Excel files. You can use an Excel document as a template for these documents. To define the document layout in the ER designer, import the contents of the Excel document that you want to use as a template into the defined ER format. For more details, and to practice this scenario, see the task guide **ER Design a configuration for generating reports in OPENXML format** (part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process). In the task guide step where you import an Excel template, use the initial template of the Payment Report Excel file, SampleVendPaymWsReport.

If you edit the Excel document that you use as a template for a business document, new ER functionality lets you reapply the updated template to the ER format. The ER format is then updated so that it adheres to the updated template. For more details about this functionality, see the task guide **ER Modify a format by reapplying an Excel template** (part of the 7.5.5.3 Acquire/Develop IT service/solution components (10683) business process). In the task guide step where you import an updated template, use the modified template of the Payment Report Excel file, SampleVendPaymWsReport2.

ER Use horizontally expandable ranges to dynamically add columns in Excel reports (Part 1 - Design format)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to generate reports as OPENXML worksheets (Excel) files in which the required columns can be created dynamically as horizontally expandable ranges. These steps can be performed in any company.

To complete these steps, you must first complete these three task guides:

"ER Create a configuration provider and mark it as active"

"ER Use financial dimensions as a data source (Part 1: Design data model)"

"ER Use financial dimensions as a data source (Part 2: Model mapping)"

You must also download and save a local copy of the template with a sample report found here, Sample Financial Dimensions Web Service Report.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Create a new report configuration

1. Go to Organization administration > Electronic reporting > Configurations.
2. In the tree, select `Financial dimensions sample model`.
3. Click Create configuration to open the drop dialog.
4. In the New field, enter `Format based on data model Financial dimensions sample model`.

    - Use the model created in advance as the data source for your new report.

5. In the Name field, type `Sample report with horizontally expandable ranges`.
    - Sample report with horizontally expandable ranges
6. In the Description field, type `To make Excel output with dynamically adding columns`.
    - To make Excel output with dynamically adding columns
7. In the Data model definition field, select Entry.
8. Click Create configuration.

Design the report format

1. Click Designer.
2. Turn on the `Show details` toggle button.
3. On the Action Pane, click Import.
4. Click Import from Excel.
5. Click Attachments.
    - Import the report`s template. Use Excel file that you downloaded for that.
6. Click New.
7. Click File.
8. Close the page.
9. In the Template field, enter or select a value.
    - Select the downloaded template.
10. Click OK.
    - Add a new range to dynamically create Excel output with as many columns as you selected (in the user dialog form) for financial dimensions. Each cell for every column will represent a single financial dimension`s name.
11. Click Add to open the drop dialog.
12. In the tree, select `Excel\Range`.
13. In the Excel range field, type `DimNames`.
    - DimNames
14. In the Replication direction field, select `Horizontal`.
15. Click OK.

16. In the tree, select `Excel = "SampleFinDimWsReport"\Range<DimNames>: Horizontal`.
17. Click Move up.
18. In the tree, select `Excel = "SampleFinDimWsReport"\Cell<DimNames>`.
19. Click Cut.
20. In the tree, select `Excel = "SampleFinDimWsReport"\Range<DimNames>: Horizontal`.
21. Click Paste.
22. In the tree, expand `Excel = "SampleFinDimWsReport"\Range<DimNames>: Horizontal`.
23. In the tree, expand `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical`.
24. In the tree, expand `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical`.
25. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical`.

    - Add a new range to dynamically create Excel output with as many columns as you selected (in the user dialog form) for financial dimensions. Each cell for every column will represent a single financial dimension`s value for each reporting transaction.

26. Click Add Range.
27. In the Excel range field, type `DimValues`.

    - DimValues

28. In the Replication direction field, select `Horizontal`.
29. Click OK.
30. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Cell<DimValues>`.
31. Click Cut.
32. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Range<DimValues>: Horizontal`.
33. Click Paste.
34. In the tree, expand `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Range<DimValues>: Horizontal`.

Map format elements to data sources

1. Click the Mapping tab.
2. In the tree, expand `model: Data model Financial dimensions sample model`.

3. In the tree, expand `model: Data model Financial dimensions sample model\Journal: Record list`.
4. In the tree, expand `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list`.
5. In the tree, expand `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list`.
6. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Range<DimValues>: Horizontal\Cell<DimValues>`.
7. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list\Code: String`.
8. Click Bind.
9. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Range<DimValues>: Horizontal`.
10. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list`.
11. Click Bind.
12. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Cell<Credit>`.
13. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Credit: Real`.
14. Click Bind.
15. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Cell<Debit>`.
16. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Debit: Real`.
17. Click Bind.
18. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Cell<Currency>`.
19. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Currency: String`.
20. Click Bind.
21. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Cell<TransDate>`.
22. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Date: Date`.
23. Click Bind.

24. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Cell<TransVoucher>`.
25. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Voucher: String`.
26. Click Bind.
27. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical\Cell<TransBatch>`.
28. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Batch: String`.
29. Click Bind.
30. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Range<TransactionLine>: Vertical`.
31. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list`.
32. Click Bind.
33. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical\Cell<Batch>`.
34. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list\Batch: String`.
35. Click Bind.
36. In the tree, select `Excel = "SampleFinDimWsReport"\Range<JournalLine>: Vertical`.
37. In the tree, select `model: Data model Financial dimensions sample model\Journal: Record list`.
38. Click Bind.
39. In the tree, expand `model: Data model Financial dimensions sample model\Dimensions setting: Record list`.
40. In the tree, select `model: Data model Financial dimensions sample model\Dimensions setting: Record list\Code: String`.
41. In the tree, select `Excel = "SampleFinDimWsReport"\Range<DimNames>: Horizontal\Cell<DimNames>`.
42. Click Bind.
43. In the tree, select `model: Data model Financial dimensions sample model\Dimensions setting: Record list`.
44. In the tree, select `Excel = "SampleFinDimWsReport"\Range<DimNames>: Horizontal`.
45. Click Bind.
46. In the tree, select `Excel = "SampleFinDimWsReport"\Cell<CompanyName>`.

47. In the tree, select `model: Data model Financial dimensions sample model\Company: String`.
48. Click Bind.
49. Click Save.
50. Close the page.

ER Use horizontally expandable ranges to dynamically add columns in Excel reports (Part 2 - Run format)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to generate reports as OPENXML worksheets (Excel) files in which the required columns can be created dynamically as horizontally expandable ranges. You can perform these steps in the DEMF company.

To complete these steps, you must first complete the steps in the "ER Use horizontally expandable ranges to dynamically add columns in Excel reports (Part 1: Design format)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Find created format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Financial dimensions sample model**.
3. In the tree, select **Financial dimensions sample model\Sample report with horizontally expandable ranges**.

Execute format to create Excel output

1. Select **Run**.
2. In the **Dimension name** field, type `BusinessUnit;CostCenter;Department`.

    - In the **Dimension name** field, enter or select a value. To select all dimensions for the current company, enter the following value:

`BusinessUnit;CostCenter;Department;ItemGroup;MainAccount;Project`

3. Expand the **Records to include** section.
4. Select **Filter**.
5. Select the row for the **Ledger journal** table and the **Journal batch number** field.
6. In the **Criteria** field, type `00057..00058`.

    - 00057..00058

7. Select **OK**.
8. Select **OK**.

    - Review the generated output. The newly created Excel file contains the same number of columns that you selected for financial dimensions. The report header in those columns represents financial dimensions' names. The transactions' lines in those columns represent financial dimensions. Run this report and select different dimensions to see that the report isn't dependent on the number of selected dimensions or the number of dimensions configured for this instance.

Design an ER format to paginate generated documents in Excel

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how a user in the System Administrator or Electronic Reporting Functional Consultant role can configure an Electronic reporting (ER) format to generate outbound documents in Microsoft Excel and manage document pagination.

In this example, you will modify the Microsoft-provided ER format that is used to print the control report when the Intrastat declaration is generated. This report lets you observe reported Intrastat transactions. Your modifications will let you manage the pagination of control reports that are generated.

The procedures in this article can be completed in the **DEMF** company. No coding is required. Before you begin, download and save the following files.

Expand table

Description	File name
Report template 1	ERIntrastatReportDemo1.xlsx
Report template 2	ERIntrastatReportDemo2.xlsx

Configure the ER framework

Follow the steps in Configure the ER framework to set up the minimal set of ER parameters. You must complete this setup before you start to use the ER framework to design a custom version of a standard ER format.

Import the standard ER format configuration

Follow the steps in Import the standard ER format configuration to add the standard ER configurations to your current instance of Dynamics 365 Finance. Import version **1.9** of the **Intrastat report** format configuration. Base version 1 of the base **Intrastat model** configuration is automatically imported from the repository.

Customize the standard ER format

Create the custom ER format

In this scenario, you're the representative of Litware, Inc., which is currently selected as the active ER configuration provider. You must create a new ER format configuration by using the **Intrastat report** configuration as a base.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, in the configuration tree in the left pane, expand **Intrastat model**, and select **Intrastat report**. Litware, Inc. will use version 1.9 of this ER format configuration as the base for the custom version.
3. Select **Create configuration** to open the drop-down dialog box. You can use this dialog box to create a new configuration for a custom payment format.
4. In the **New** field group, select **Derive from Name: Intrastat report, Microsoft**.
5. In the **Name** field, enter **Intrastat report Litware**.
6. Select **Create configuration** to create the new format.

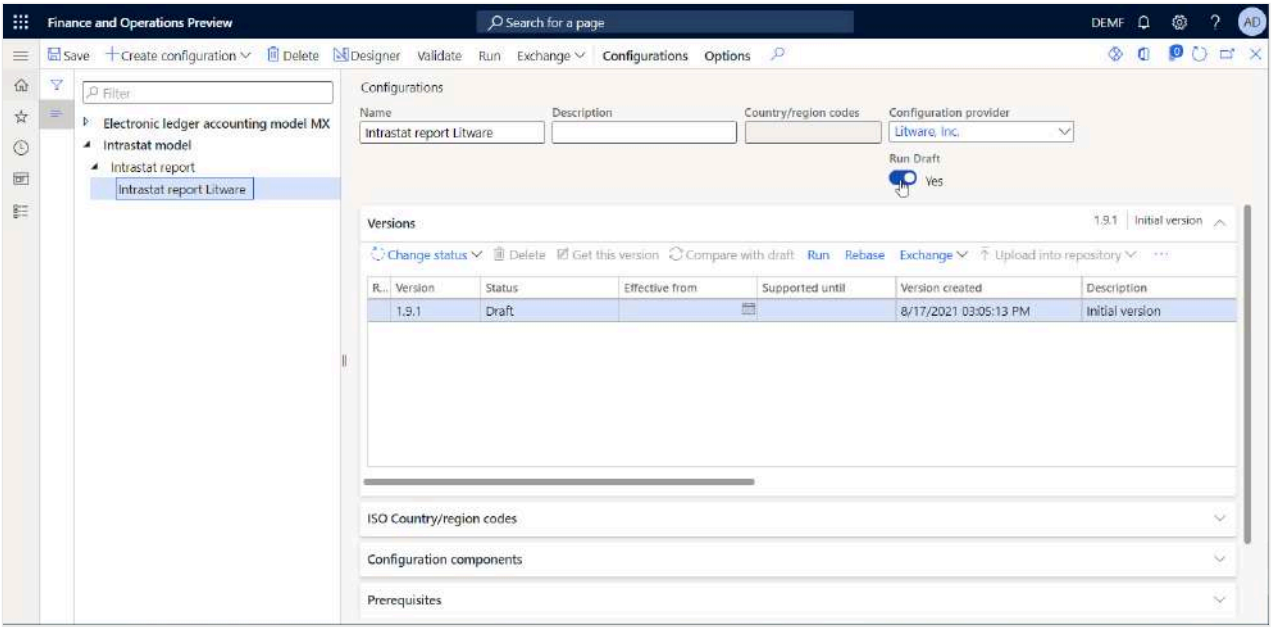
Version 1.9.1 of the **Intrastat report Litware** ER format configuration is created. This version has a status of **Draft** and can be edited. The current content of your custom ER format matches the content of the format that is provided by Microsoft.

Make the custom format runnable

Now that the first version of your custom format has been created and has a status of **Draft**, you can run the format for testing purposes. To run the report, process a vendor payment by using the payment method that refers to your custom ER format. By default, when you call an ER format from the application, only versions that have a status of **Completed** or **Shared** are considered. This behavior helps prevent ER formats that have unfinished designs from being used. However, for your test runs, you can force the application to use the version of your ER format that has a status of **Draft**. In this way, you can adjust the current format version if any modifications are required. For more information, see Applicability.

To use the draft version of an ER format, you must explicitly mark the ER format.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, set the **Run settings** option to **Yes**, and then select **OK**.
4. Select **Edit** to make the current page editable, as required.
5. In the configuration tree in the left pane, select **Intrastat report Litware**.
6. Set the **Run Draft** option to **Yes** and then select **Save**.



Set up Foreign trade parameters to use the custom ER format

Follow these steps to configure Foreign trade parameters so that you can use the custom format.

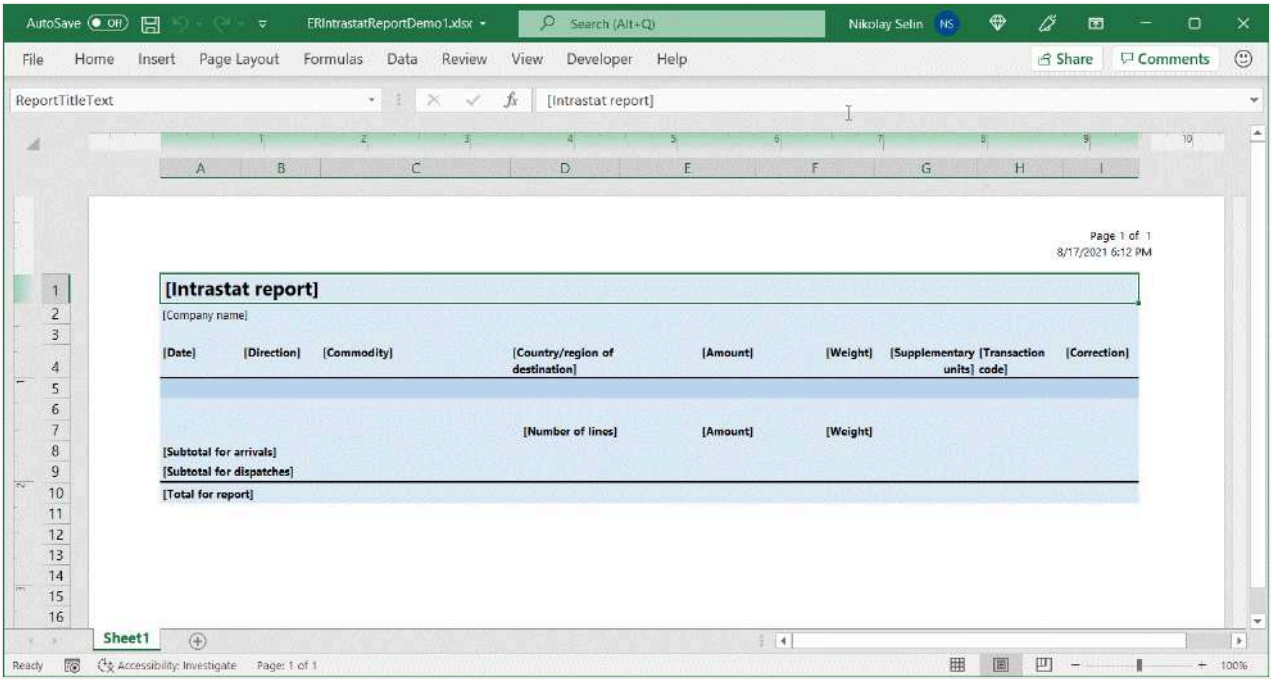
1. Go to **Tax** > **Setup** > **Foreign trade** > **Foreign trade parameters**.
2. On the **Foreign trade parameters** page, on the **Electronic reporting** FastTab, in the **File format mapping** field, select **Intrastat report Litware**.
3. In the **Report format mapping** field, select **Intrastat report Litware**.
4. Select **Save**.

Configure the custom format to use the downloaded report template

Review the first downloaded Excel template

1. In the Excel desktop application, open the **ERIntrastatReportDemo1.xlsx** template file that you downloaded earlier.

2. Verify that the template contains named ranges to create report header, report details, and report footer sections in generated documents.

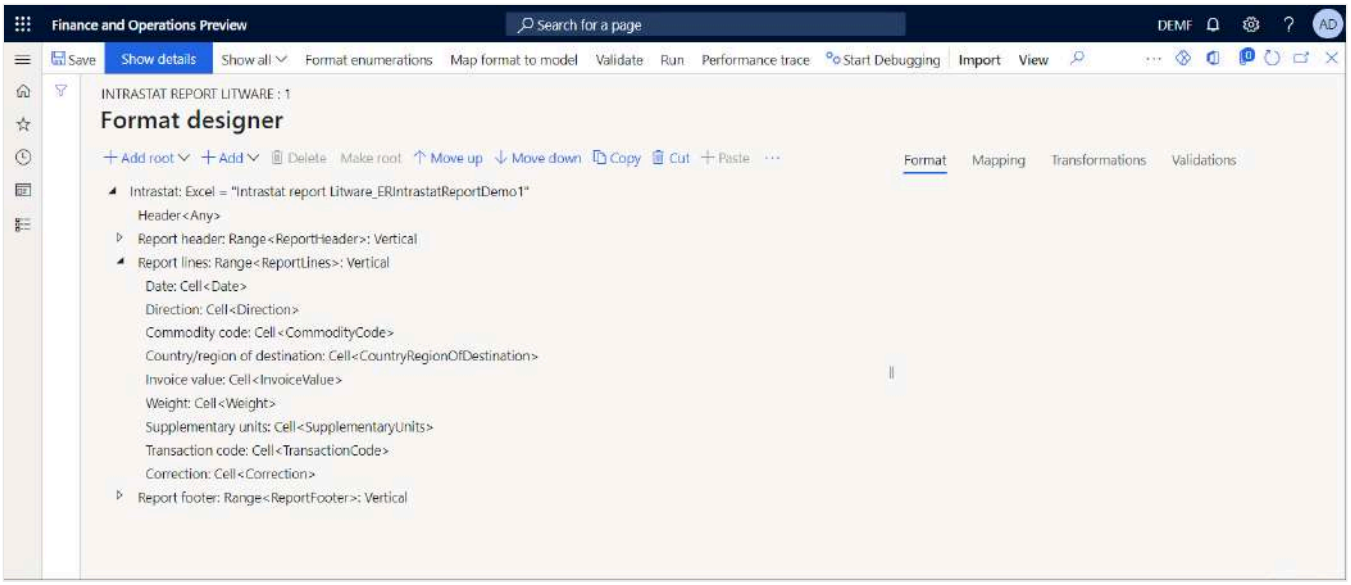


Replace the current Excel template in the custom ER format

You must add a new Excel template to the custom ER format.

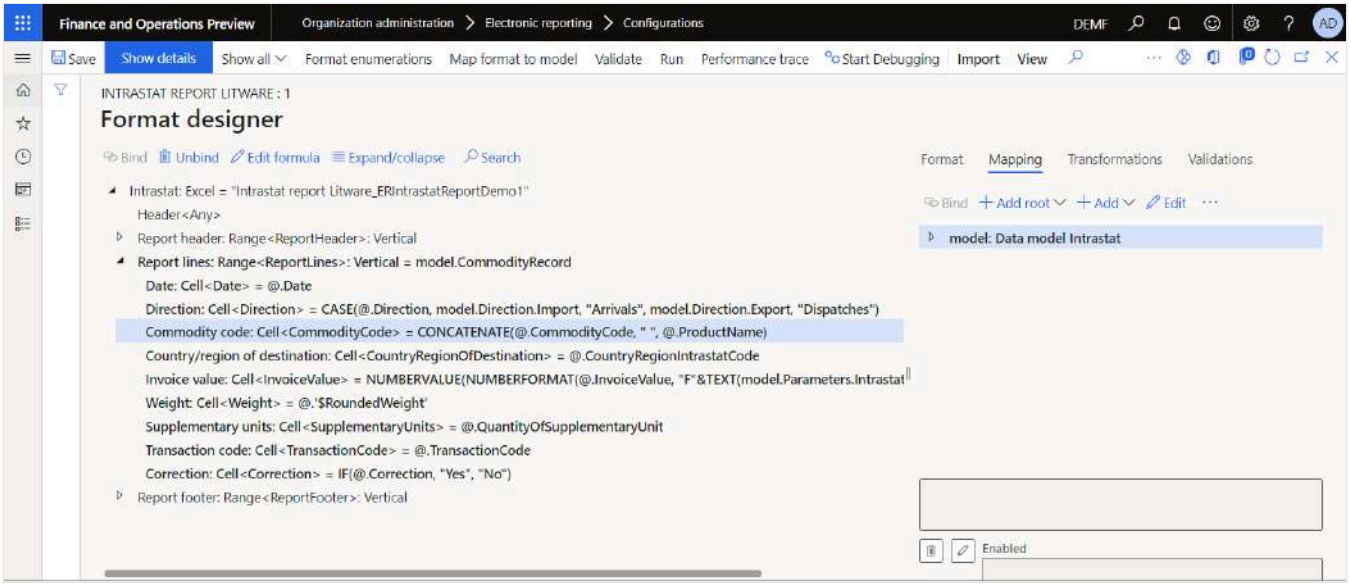
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, in the configuration tree in the left pane, expand **Intrastat model** > **Intrastat report**, and select the **Intrastat report Litware** configuration.
3. Select **Designer**.
4. On the **Format designer** page, on the Action Pane, select **Show details**.
5. Make sure that the **Intrastat: Excel** root format component is selected, and then, on the Action Pane, on the **Import** tab, in the **Import** group, select **Update from Excel**.
6. In the **Update from Excel** dialog box, select **Update template**.
7. In the **Open** dialog box, browse to and select the **ERIntrastatReportDemo1.xlsx** file that you downloaded earlier, and then select **Open**.

8. Select **OK**.
9. Select **Save**.



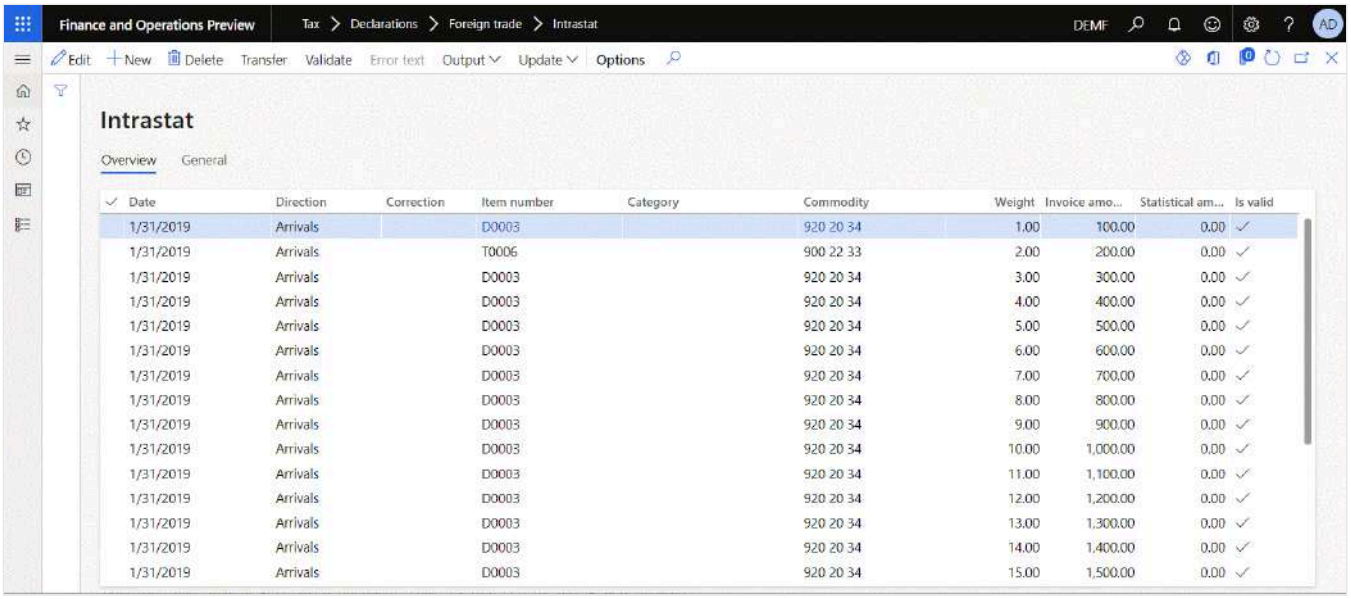
Change the data binding to show the item description on a generated report

1. On the **Format designer** page, select the **Mapping** tab.
2. Expand **Intrastat** > **Report lines**, and select the **Commodity code** component.
3. Select **Edit formula**.
4. Change the binding formula from `@.CommodityCode` to `CONCATENATE(@.CommodityCode, " ", @.ProductName)`.
5. Select **Save**.



Generate an Intrastat declaration control report

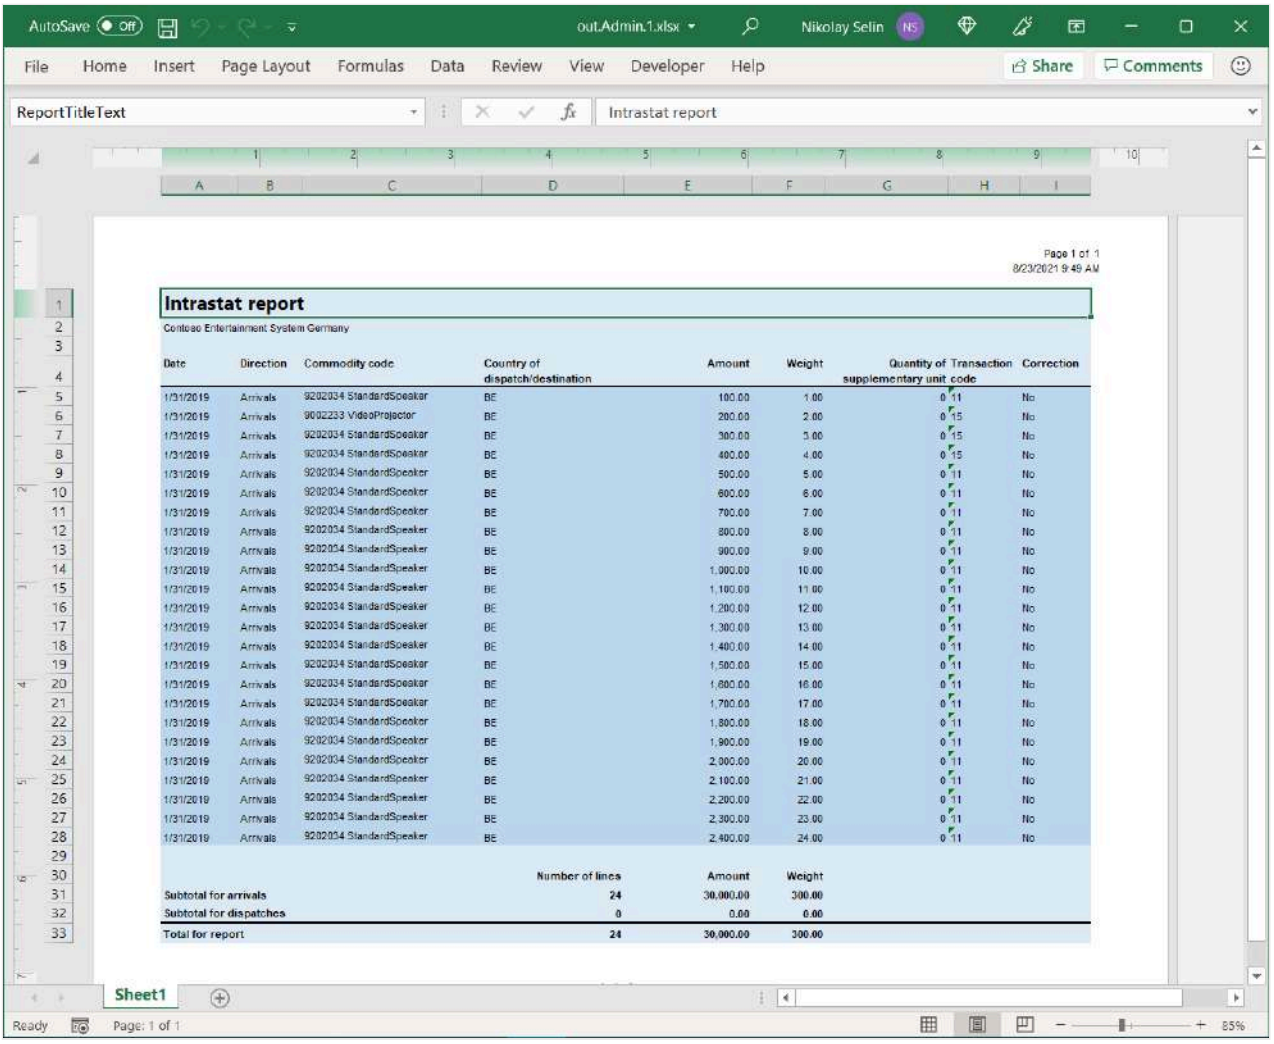
First, make sure that you have Intrastat transactions for reporting on the **Intrastat** page.



Date	Direction	Correction	Item number	Category	Commodity	Weight	Invoice amo...	Statistical am...	Is valid
1/31/2019	Arrivals		D0003		920 20 34	1.00	100.00	0.00	✓
1/31/2019	Arrivals		T0006		900 22 33	2.00	200.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	3.00	300.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	4.00	400.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	5.00	500.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	6.00	600.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	7.00	700.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	8.00	800.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	9.00	900.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	10.00	1,000.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	11.00	1,100.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	12.00	1,200.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	13.00	1,300.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	14.00	1,400.00	0.00	✓
1/31/2019	Arrivals		D0003		920 20 34	15.00	1,500.00	0.00	✓

Then use the custom ER format to generate the control report of the Intrastat declaration.

1. Go to **Tax** > **Declarations** > **Foreign trade** > **Intrastat**.
2. On the **Intrastat** page, on the Action Pane, select **Output** > **Report**.
3. In the **Intrastat Report** dialog box, follow these steps to run the report:
   a. Set the **From date** and **To date** fields to include specific Intrastat transactions to the report.
   b. Set the **Generate file** option to **No**.
   c. Set the **Generate report** option to **Yes**.
   d. Select **OK**.
4. Download and save the document that is generated.
5. Open the document in Excel, and review it.



Configure the custom format to paginate generated documents

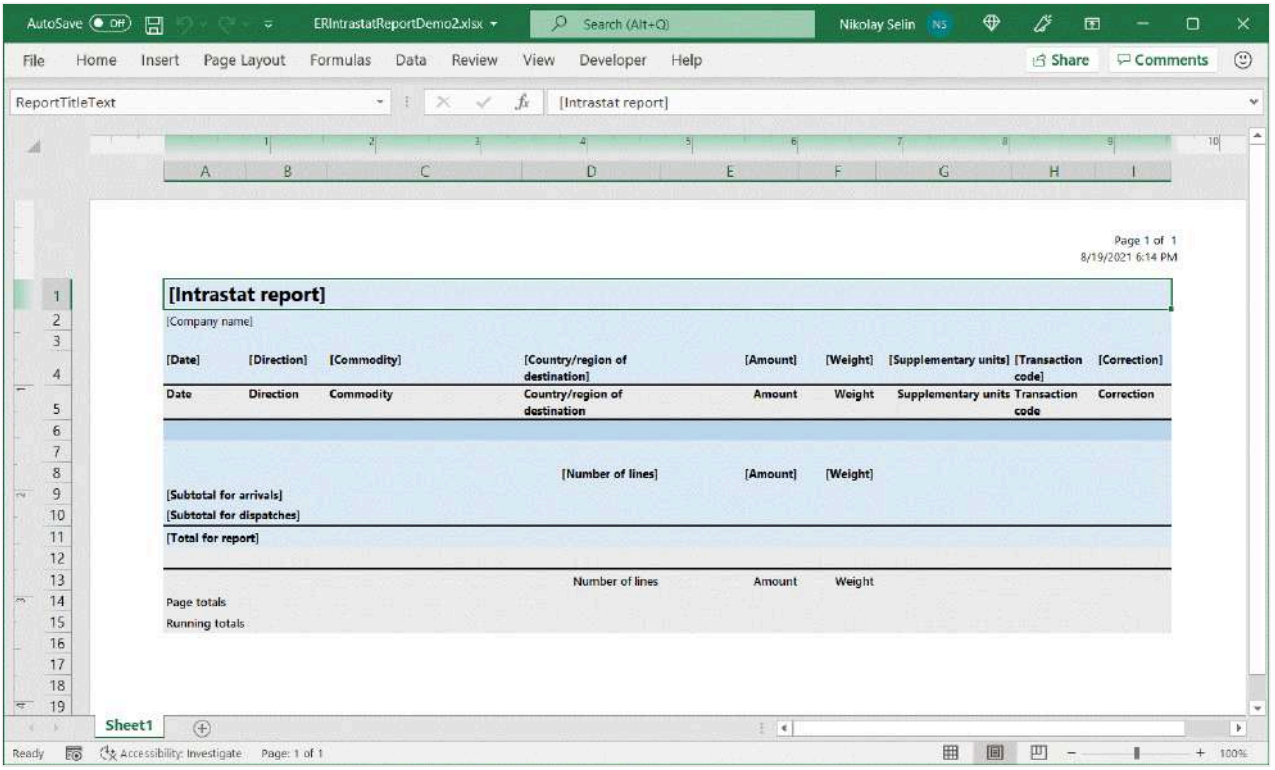
Review the second downloaded Excel template

1. In Excel, open the **ERIntrastatReportDemo2.xlsx** template file that you downloaded earlier.

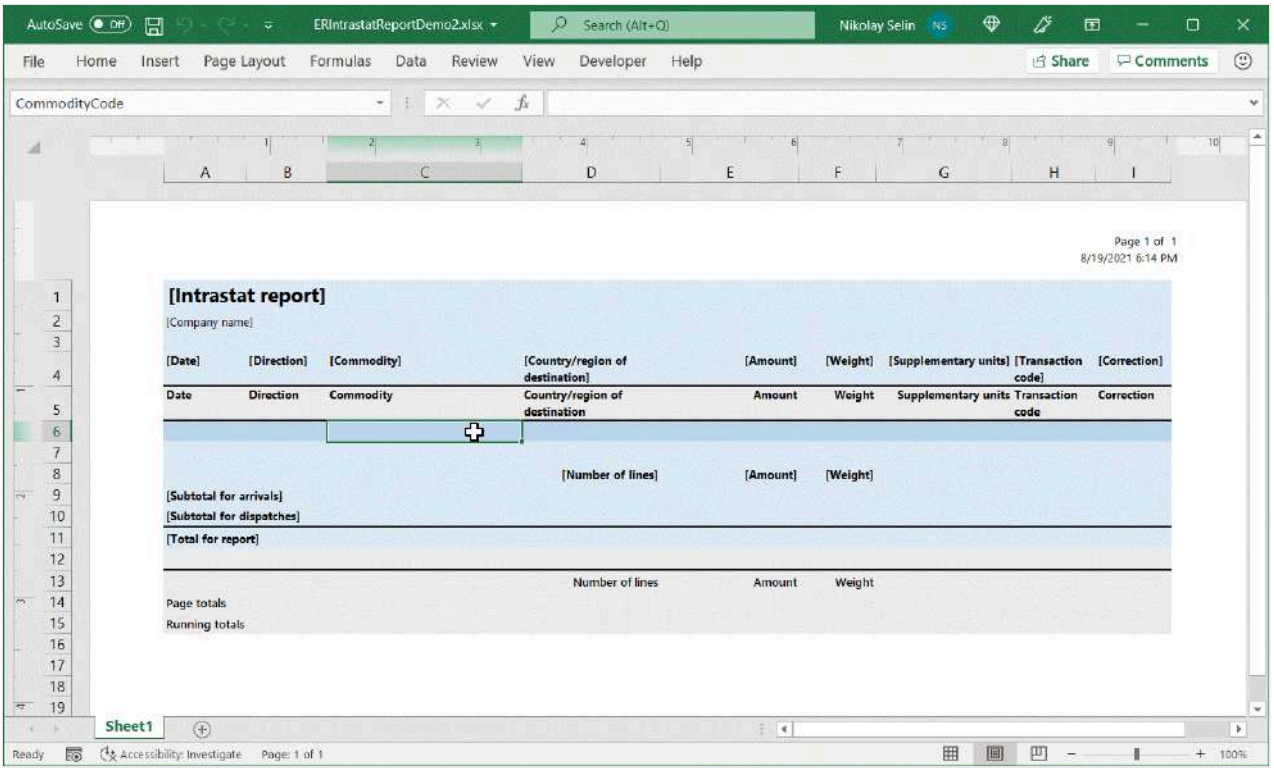
2. Compare this template with the **ERIntrastatReportDemo1.xlsx** template, and verify that it contains several new Excel names to create and fill in page-specific sections in generated documents:

    - The **ReportPageHeader** range is added to create page headers.
    - The **ReportPageFooter** range is added to create page footers.
    - The **ReportPageFooter_PageLines** cell is configured to show the number of transactions per page.
    - The **ReportPageFooter_PageAmount** cell is configured to show the total amount of transactions per page.

- The **ReportPageFooter_PageWeight** cell is configured to show the total weight of transactions per page.
- The **ReportPageFooter_RunningCounterLines** cell is configured to show the running counter of transactions from the beginning of the report through the current page.
- The **ReportPageFooter_RunningTotalAmount** cell is configured to show the amount running total for all transactions from the beginning of the report through the current page.
- The **ReportPageFooter_RunningTotalWeight** cell is configured to show the weight running total for transactions from the beginning of the report through the current page.



The **CommodityCode** cell of this template is configured to wrap cell text. Because the transaction details row is configured so that it will automatically fit the height of a row, the height of the whole row must automatically change when the text in the **CommodityCode** cell is wrapped.



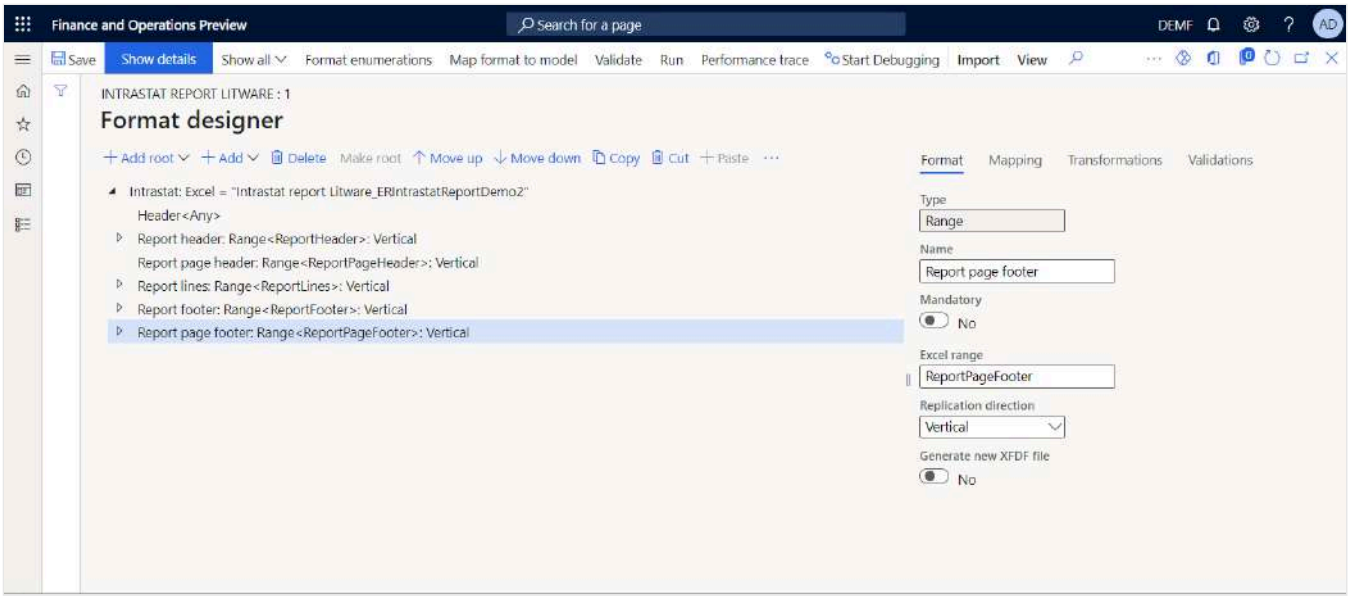
Repeat the replacement of the current Excel template in the custom ER format

1. Follow the steps in the Replace the current Excel template in the custom ER format section of this article. However, in step 7, select the **ERIntrastatReportDemo2.xlsx** file.

2. On the **Format designer** page, expand **Intrastat**.

3. Name the Range format components that have been added to the editable ER format to sync the structure with the structure of the applied Excel template:
   a. Select the **Range** component that is associated with the Excel name **ReportPageHeader**.
   b. On the **Format** tab, in the **Name** field, enter **Report page header**.
   c. Select the **Range** component that is associated with the Excel name **ReportPageFooter**.
   d. On the **Format** tab, in the **Name** field, enter **Report page footer**.

4. Select **Save**.



Change the format structure to implement document pagination

1. On the **Format designer** page, in the format tree in the left pane, select the **Intrastat** root component.

2. Select **Add**.

3. In the **Add** dialog box, select the Page component in the **Excel** group of components.

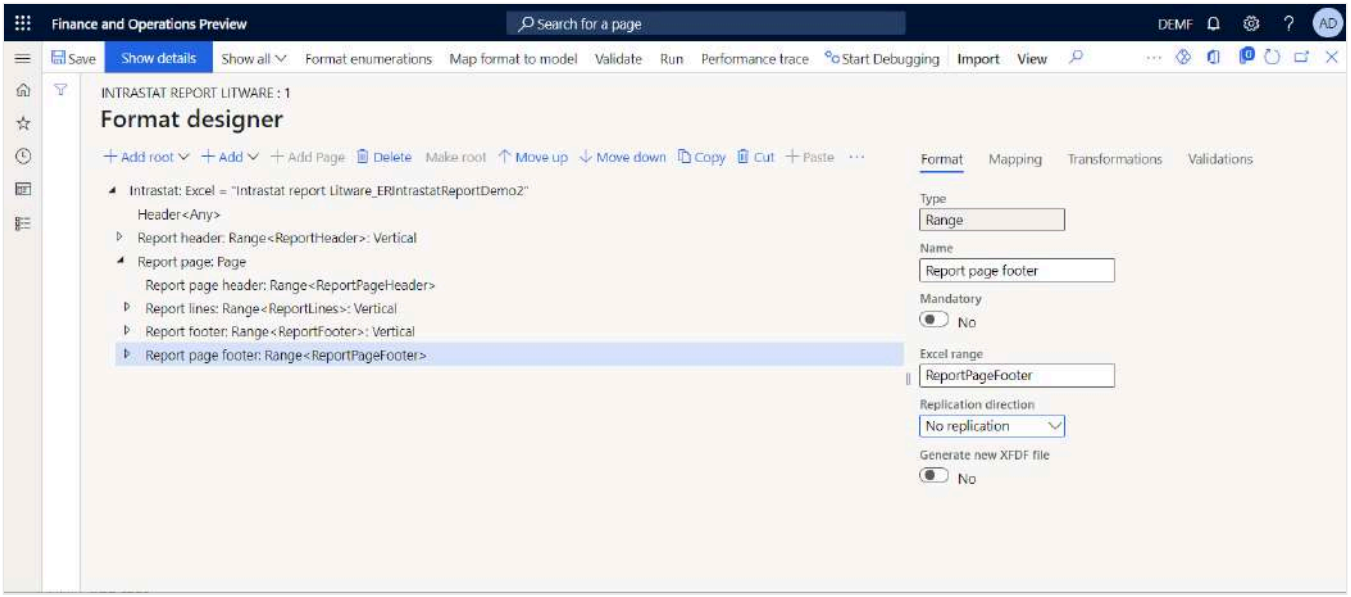
4. In the **Component properties** dialog box, in the **Name** field, enter **Report page**. Then select **OK**.

5. To use the **Report page header** component as a page header on every generated page, follow these steps:
   a. Select the **Report page header** component, and then select **Cut**.
   b. Select the **Report page** component, and then select **Paste**.
   c. Expand **Report page**.
   d. To force the **Page** component to consider this range a page header, select **Report page header**, and then, on the **Format** tab, in the **Replication direction** field, select **No replication**.

6. To paginate a generated document so that the content on report lines is considered, follow these steps:
   a. Select the **Report lines** component, and then select **Cut**.
   b. Select the **Report page** component, and then select **Paste**.

7. To include the report footer after report lines but before the final page footer, follow these steps:
   a. Select the **Report footer** component, and then select **Cut**.
   b. Select the **Report page** component, and then select **Paste**.

8. To use the **Report page footer** component as a page footer on every generated page, follow these steps:
   a. Select the **Report page footer** component, and then select **Cut**.
   b. Select the **Report page** component, and then select **Paste**.
   c. To force the **Page** component to consider this range a page footer, select **Report page footer**, and then, on the **Format** tab, in the **Replication direction** field, select **No replication**.



Add data sources to calculate page footer totals

You must configure new data sources to calculate the page total, the running counter, and the running total values, and to show them in the page footer section. We recommend that you use Data collection data sources for this purpose.

1. On the **Format designer** page, select the **Mapping** tab.

2. Select **Add root**, and then follow these steps:
   a. In the **Add data source** dialog box, in the **General** section, select **Empty container**.
   b. In the **'Empty container' data source properties** dialog box, in the **Name** field, enter **Total**.
   c. Select **OK**.

3. Select the **Total** data source, select **Add**, and then follow these steps:

a. In the **Add data source** dialog box, in the **General** section, select **Empty container**.
b. In the **'Empty container' data source properties** dialog box, in the **Name** field, enter **Page**.
c. Select **OK**.

4. Select **Add** again, and then follow these steps:
   a. In the **Add data source** dialog box, in the **General** section, select **Empty container**.
   b. In the **'Empty container' data source properties** dialog box, in the **Name** field, enter **Running**.
   c. Select **OK**.

5. Select the **Total.Page** data source, select **Add**, and then follow these steps:
   a. In the **Add data source** dialog box, in the **Functions** section, select **Data collection**.
   b. In the **'Data collection' data source properties** dialog box, in the **Name** field, enter **Amount**.
   c. In the **Item type** field, select **Real**.
   d. Set the **Collect all values** option to **Yes**.
   e. Select **OK**.

6. Select **Add** again, and then follow these steps:
   a. In the **Add data source** dialog box, in the **Functions** section, select **Data collection**.
   b. In the **'Data collection' data source properties** dialog box, in the **Name** field, enter **Weight**.
   c. In the **Item type** field, select **Real**.
   d. Set the **Collect all values** option to **Yes**.
   e. Select **OK**.

7. Select the **Total.Running** data source, select **Add**, and then follow these steps:
   a. In the **Add data source** dialog box, in the **Functions** section, select **Data collection**.
   b. In the **'Data collection' data source properties** dialog box, in the **Name** field, enter **Amount**.
   c. In the **Item type** field, select **Real**.
   d. Set the **Collect all values** field to **Yes**.
   e. Select **OK**.

8. Select **Add** again, and then follow these steps:
   a. In the **Add data source** dialog box, in the **Functions** section, select **Data collection**.
   b. In the **'Data collection' data source properties** dialog box, in the **Name** field, enter **Weight**.

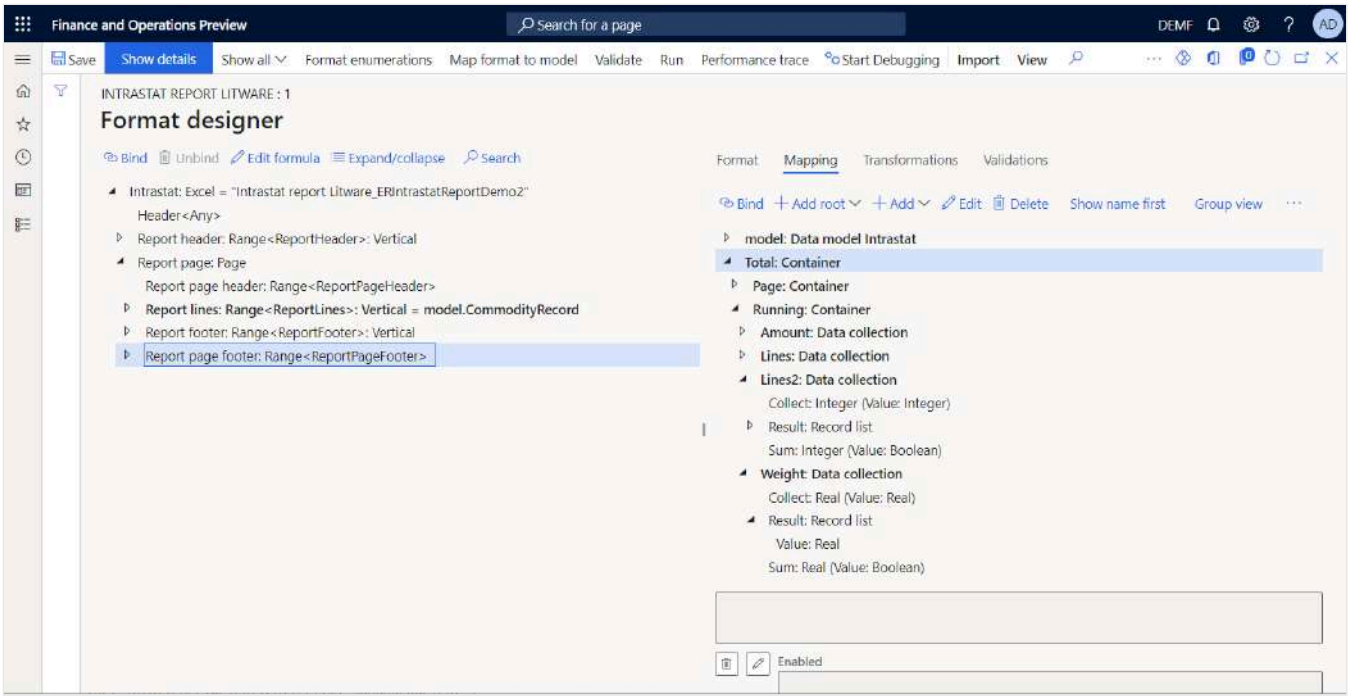
c. In the **Item type** field, select **Real**.
d. Set the **Collect all values** field to **Yes**.
e. Select **OK**.

9. Select **Add** again, and then follow these steps:
   a. In the **Add data source** dialog box, in the **Functions** section, select **Data collection**.
   b. In the **'Data collection' data source properties** dialog box, in the **Name** field, enter **Lines**.
   c. In the **Item type** field, select **Integer**.
   d. Set the **Collect all values** field to **Yes**.
   e. Select **OK**.
10. Select **Save**.

Add data sources to control page footer visibility

If you plan to control page footer visibility, and you don't plan to include the footer on the final page if it contains transactions, configure a new data source to calculate the required running counter.

1. On the **Format designer** page, select the **Mapping** tab.
2. Select the **Total.Running** data source, select **Add**.
3. In the **Add data source** dialog box, in the **Functions** section, select **Data collection**.
4. In the **'Data collection' data source properties** dialog box, in the **Name** field, enter **Lines2**.
5. In the **Item type** field, select **Integer**.
6. Set the **Collect all values** option to **Yes**.
7. Select **OK**.
8. Select **Save**.



Configure bindings to collect total values

1. On the **Format designer** page, in the format tree, expand the **Report lines** component, and select the nested **Invoice value** component.

2. Select **Edit formula**.

3. Change the binding formula from `NUMBERVALUE(NUMBERFORMAT(@.InvoiceValue, "F"&TEXT(model.Parameters.IntrastatAmountDecimals)), ".", "")` to `Total.Page.Amount.Collect(NUMBERVALUE(NUMBERFORMAT(@.InvoiceValue, "F"&TEXT(model.Parameters.IntrastatAmountDecimals)), ".", ""))`.

   > **Note**
   >
   > In addition to putting the amount value in an Excel cell for every iterated transaction, this binding collects the value in the data collection **Total.Page.Amount** data source.

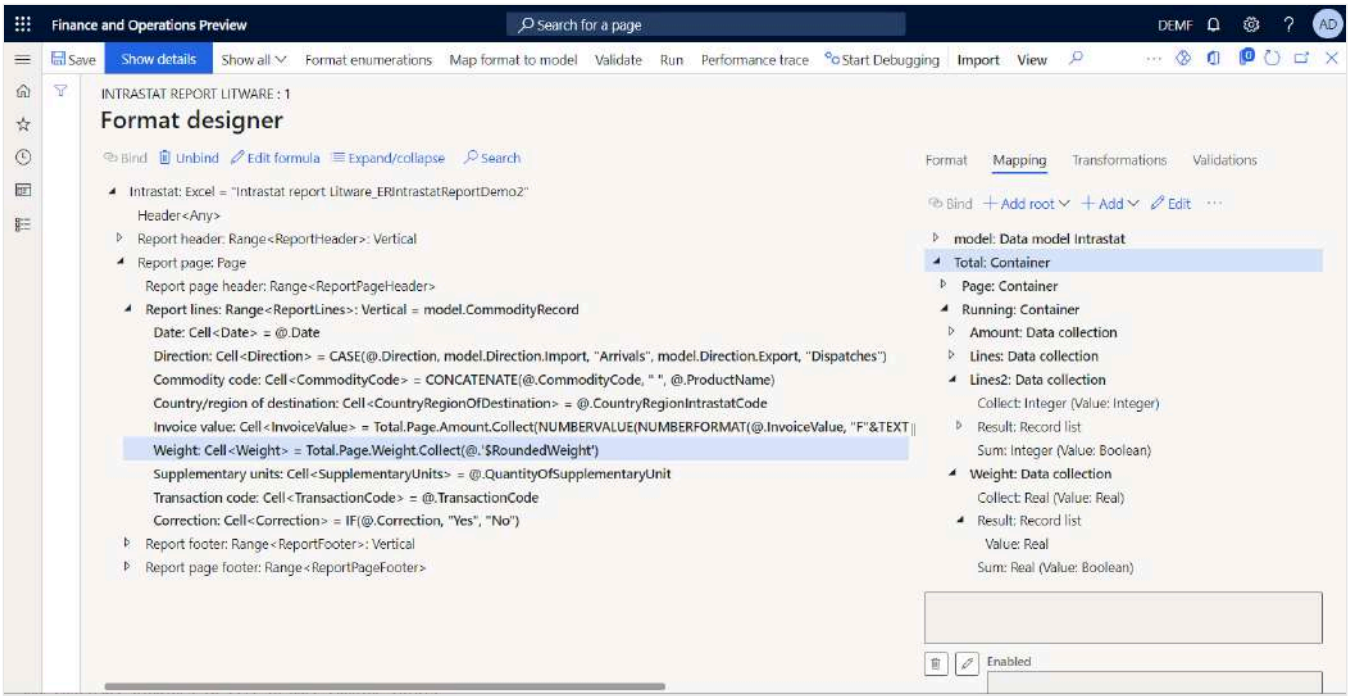
4. Select the nested **Weight** component.

5. Select **Edit formula**.

6. Change the binding formula from `@.'$RoundedWeight'` to `Total.Page.Weight.Collect(@.'$RoundedWeight')`.

   > **Note**

In addition to putting the weight value in an Excel cell for every iterated transaction, this binding collects the value in the **Total.Page.Weight** data source.



Configure bindings to fill in page footer totals

1. On the **Format designer** page, in the format tree, expand the **Report page footer** component, select the nested **Range** component that refers to the Excel **ReportPageFooter_PageAmount** cell, and then follow these steps:
   a. In the data sources tree in the right pane, select the **Total.Page.Amount.Sum()** item.
   b. Select **Bind**.
   c. Select **Edit formula**.
   d. Update the formula to `Total.Page.Amount.Sum(false)`.

> **Note**
>
> You must specify the argument of this function as **False** to keep collected data for the current page, because this data is required to calculate the amount running total, total number of lines per page, and running counter of lines.

2. In the format tree, select the nested **Range** component that refers to the Excel **ReportPageFooter_PageWeight** cell, and then follow these steps:
   a. In the data sources tree in the right pane, select the **Total.Page.Weight.Sum()** item.
   b. Select **Bind**.
   c. Select **Edit formula**.

d. Update the formula to `Total.Page.Weight.Sum(false)`.

Configure bindings to fill in page running totals

1. On the **Format designer** page, in the format tree, expand the **Report page footer** component, select the nested **Range** component that refers to the Excel **ReportPageFooter_RunningTotalAmount** cell, and then follow these steps:
   a. In the data sources tree in the right pane, select the **Total.Running.Amount.Collect()** item.
   b. Select **Bind**.
   c. Select **Edit formula**.
   d. Update the formula to `Total.Running.Amount.Sum(false)+Total.Running.Amount.Collect(Total.Page.Amount.Sum(true))`.

   > ⓘ **Note**
   >
   > The `Total.Running.Amount.Sum(false)` operand returns the previously collected amount running total. The `Total.Running.Amount.Collect(Total.Page.Amount.Sum(true))` operand returns the total amount of the current page. You must specify the argument of the nested function of the second operand as **True** to reset the `Total.Page.Amount` data collection as soon as this value is put in the `Total.Running.Amount` running total collection. The specified argument must start to collect the next page total from a 0 (zero) value.
   >
   > The `Total.Running.Amount.Sum(false)` function is called to enter the amount running total in the Excel **ReportPageFooter_RunningTotalAmount** cell on the current page.

2. In the format tree, select the nested **Range** component that refers to the Excel **ReportPageFooter_RunningTotalWeight** cell, and then follow these steps:
   a. In the data sources tree in the right pane, select **Total.Running.Weight.Collect()** item.
   b. Select **Bind**.
   c. Select **Edit formula**.
   d. Update the formula to `Total.Running.Weight.Sum(false)+Total.Running.Weight.Collect(Total.Page.Weight.Sum(true))`.

Configure bindings to fill in the page running counter

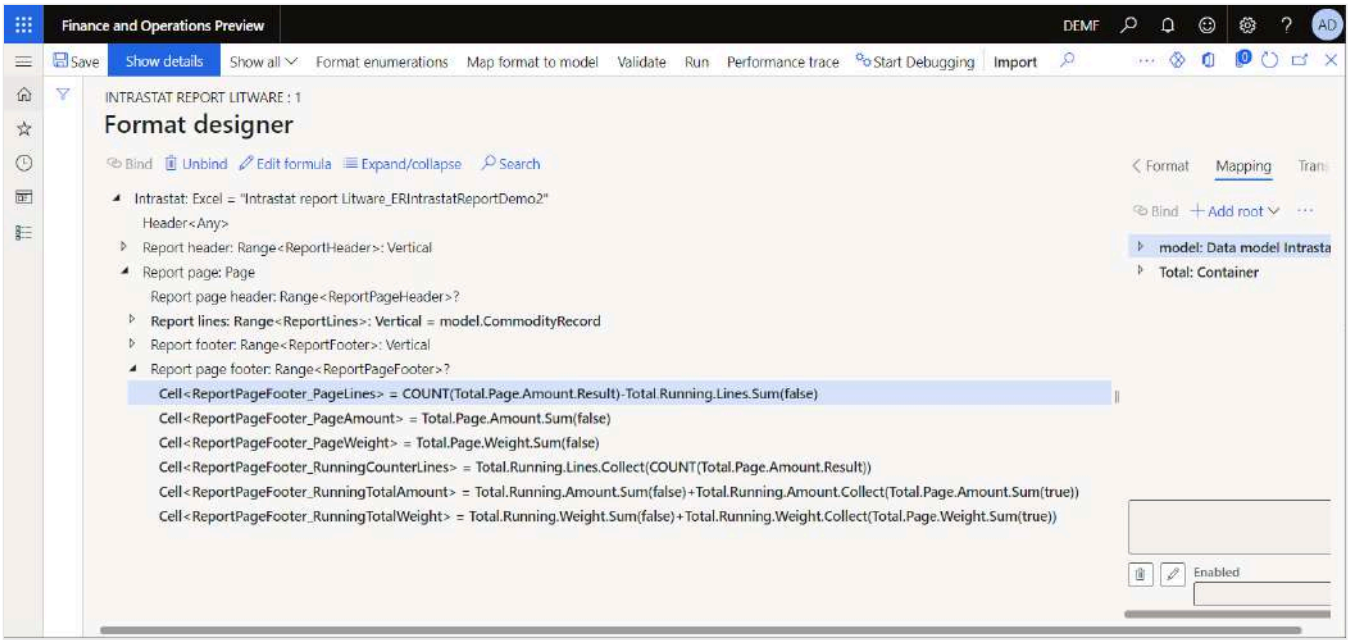
1. On the **Format designer** page, in the format tree, expand the **Report page footer** component, and select the nested **Range** component that refers to the Excel **ReportPageFooter_RunningCounterLines** cell.
2. Select **Edit formula**.
3. Add the formula `Total.Running.Lines.Collect(COUNT(Total.Page.Amount.Result))`.

> ⓘ Note
>
> This formula returns the number of collected amount values for the whole report. This number equals the number of transactions that have been iterated at the current moment. At the same time, the formula collects the returned value in the **Total.Running.Lines** collection.

Configure bindings to fill in the page footer counter

1. On the **Format designer** page, in the format tree, expand the **Report page footer** component, and select the nested **Range** component that refers to the Excel **ReportPageFooter_PageLines** cell.
2. Select **Edit formula**.
3. Add the formula `COUNT(Total.Page.Amount.Result)-Total.Running.Lines.Sum(false)`.

> ⓘ Note
>
> This formula calculates the number of transactions on the current page as the difference between the number of transactions that was collected in **Total.Page.Amount.Result** for the whole report and the number of transactions that has been stored at this stage in **Total.Running.Lines.Sum**. Because the number of transactions for the current page is stored in **Total.Running.Lines** in the binding of the **Range** component that refers to the Excel **ReportPageFooter_RunningCounterLines** cell, the number of transactions on the current page isn't yet included. Therefore, this difference equals the number of transactions on the current page.



Configure component visibility

You can change the visibility of the page header and footer on a specific page of a generated document to hide the following elements:

- The page header on the first page, because the report header already contains column titles
- The page header on any page that doesn't have transactions that can occur for the last page
- The page footer on any page that doesn't have transactions that can occur for the last page

To change the visibility, update the **Enabled** property of the **Report page header** and **Report page footer** components.

1. On the **Format designer** page, in the format tree, expand the **Report page** component, select the nested **Report page header** component, and then follow these steps:

   a. Select **Edit** for the **Enabled** field.

   b. On the **Formula designer** page, in the **Formula** field, enter the following expression:

   ```
   AND(
   COUNT(Total.Page.Amount.Result)<>0,
   COUNT(Total.Page.Amount.Result)<>COUNT(model.CommodityRecord)
   )
   ```

2. In the format tree, select the nested **Report page footer** component, and then follow these steps:

   a. Select **Edit** for the **Enabled** field.

   b. On the **Formula designer** page, in the **Formula** field, enter the following expression:

```
(
COUNT(Total.Page.Amount.Result)-Total.Running.Lines2.Sum(false)+
0*Total.Running.Lines2.Collect(COUNT(Total.Page.Amount.Result))
)<>0
```

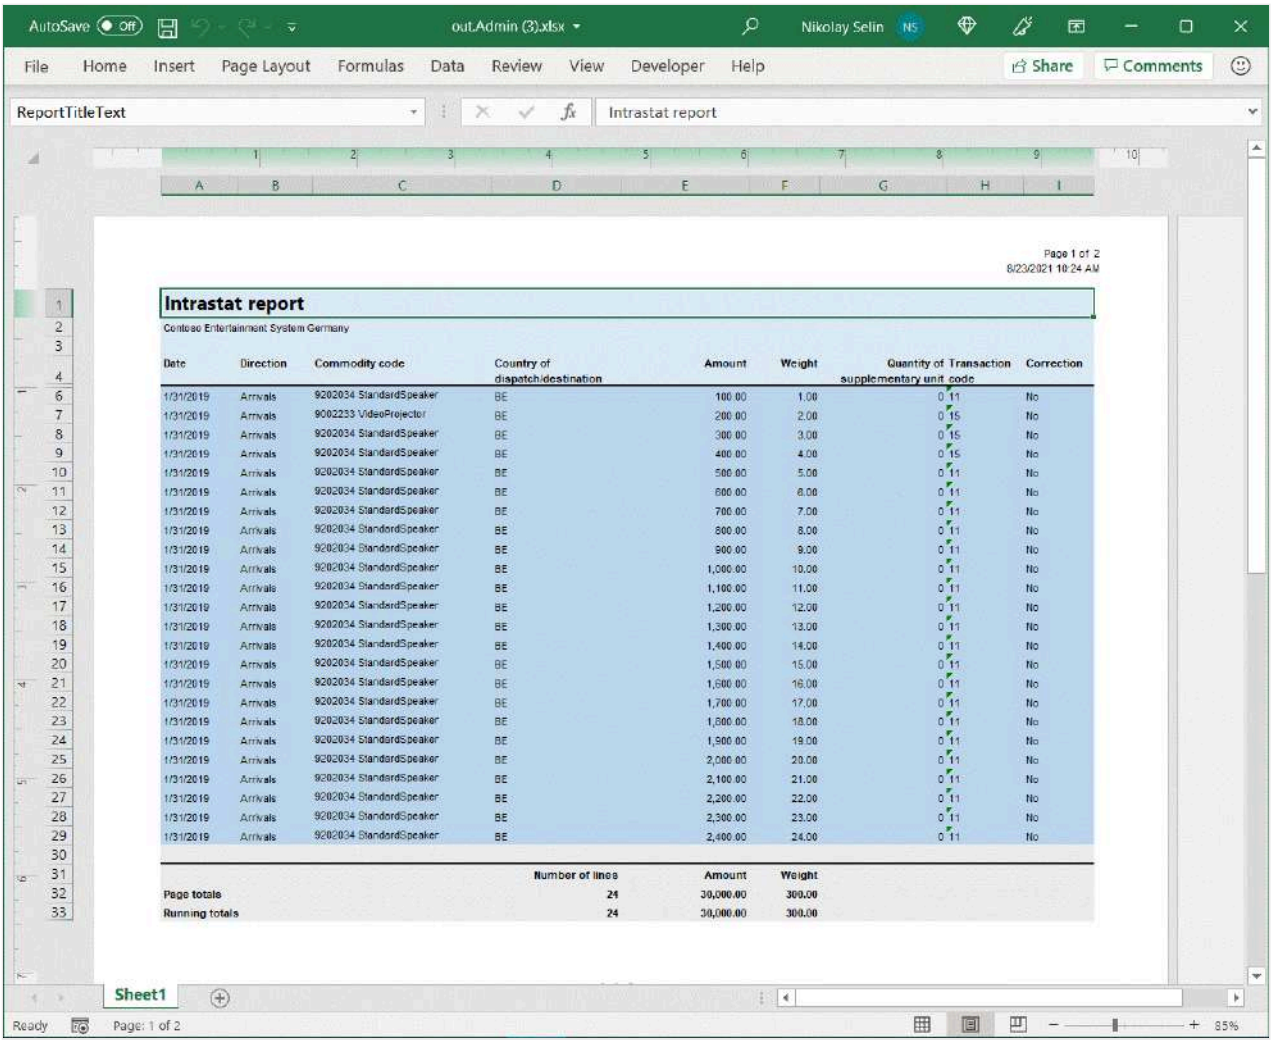
> **Note**
>
> The `COUNT(Total.Page.Amount.Result)-Total.Running.Lines2.Sum(false)` construction is used to calculate the number of transactions on the current page. The `0*Total.Running.Lines2.Collect(COUNT(Total.Page.Amount.Result)` construction is used to add the number of transactions on the current page to the collection, to correctly handle the visibility of the next page footer.
>
> The `Total.Running.Lines` collection can't be reused here, because the **Enabled** property of a base component is processed **after** the bindings of nested components are processed. When the **Enabled** property is processed, the `Total.Running.Lines` collection is already incremented by the number of transactions on the current page.

3. Select **Save**.

Generate an Intrastat declaration control report (updated)

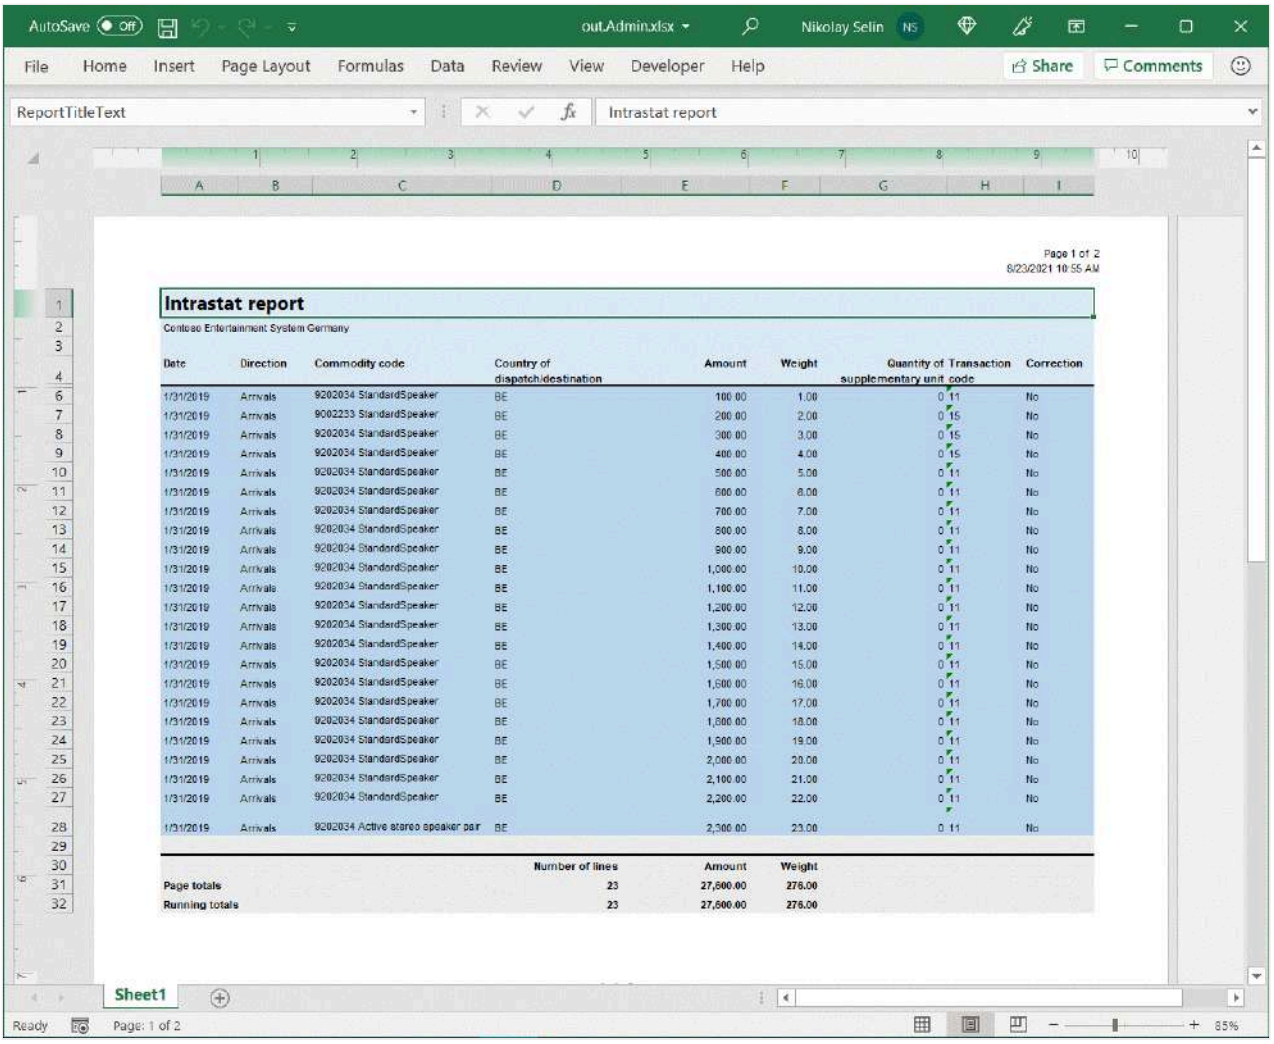
1. Make sure that you have 24 transactions on the **Intrastat** page. Repeat the steps in the Generate an Intrastat declaration control report section of this article to generate and review the control report.

   All transactions are presented on the first page. The page totals and counters equal the report totals and counters. The page header range is hidden on the first page because the report header already contains column titles. The page header and footer are hidden on the second page because that page contains no transactions.



2. Update two transactions on the **Intrastat** page by changing the **Item number** code from **D00006** to **L0010**. Notice that the product name of the new item, **Active stereo speaker pair**, is longer than the product name of the original item, **Standard speaker**. This situation forces text wrapping in the corresponding cell of the generated document. Document pagination, and page-related summing and counting, must now be updated. Repeat the steps in the Generate an Intrastat declaration control report section to generate and review the control report.

   Currently, transactions are presented on two pages, and page totals and counters are correctly calculated. The page header range is correctly hidden on the first page and visible on the second page. The page footer is visible on both pages because they contain transactions.



Frequently asked questions

Is there any way to recognize when the final page is processed by the Page format component?

The **Page** component doesn't expose information about the number of the processed page and the total number of pages in a generated document. Nevertheless, you can configure ER formulas to recognize the final page. Here is an example:

- Calculate the total number of transactions that have already been processed by using the **Report page** component. You can do this calculation by using the formula `COUNT(Total.Page.Amount.Result)`.
- Calculate the total number of transactions that must be processed based on the `model.CommodityRecord` binding that is configured for the **Report lines** component. You can do this calculation by using the formula `COUNT(model.CommodityRecord)`.
- Compare two numbers to recognize the final page. When both values are equal, the final page is generated.

> **Note**
>
> We recommend that you use this approach only when the **Enabled** property of the **Report lines** component contains no formula that might return False at runtime for some of the iterated records of the bound Record list.

Additional resources

- Design a configuration for generating documents in Excel format
- Use DATA COLLECTION data sources in Electronic reporting (ER) formats

Design an ER format to keep rows together on the same Excel page

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how a user in the System Administrator or Electronic Reporting Functional Consultant role can configure an Electronic reporting (ER) format that generates outbound documents in Microsoft Excel and manage document pagination so that rows that are created stay on the same page.

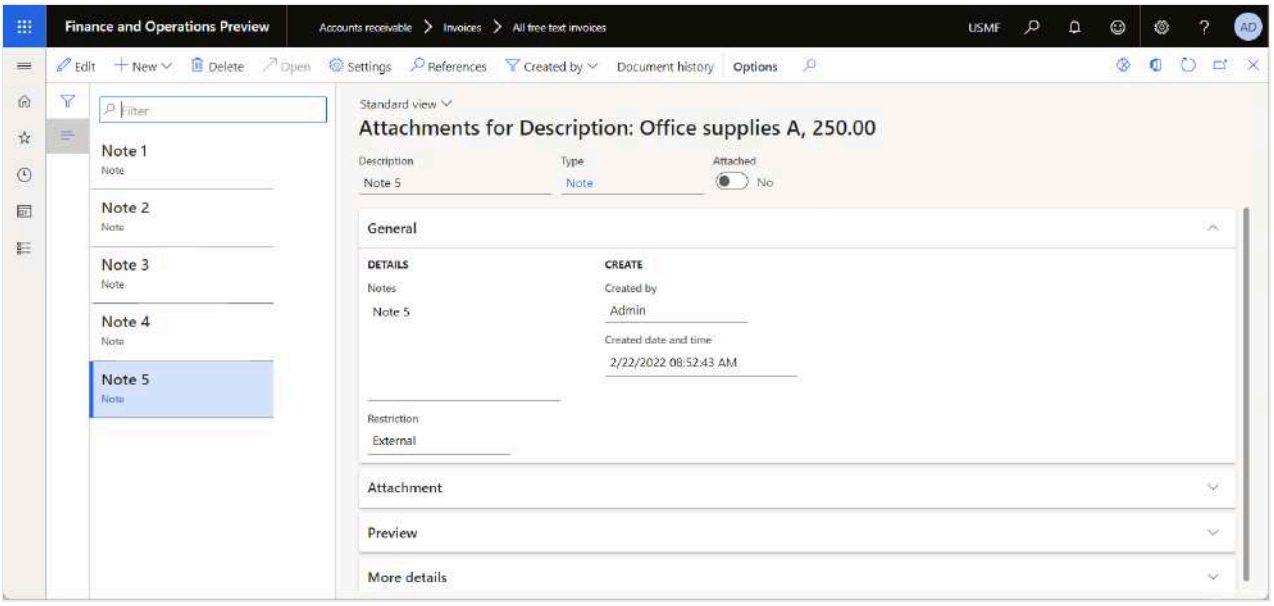
In this example, you modify the Microsoft-provided ER format that's used to print free text invoices in Excel. Your modifications let you manage the pagination of a generated free text invoice report so that all the rows of a single invoice line stay on the same page when possible.

You can complete the procedures in this article in the **USMF** company. No coding is required.

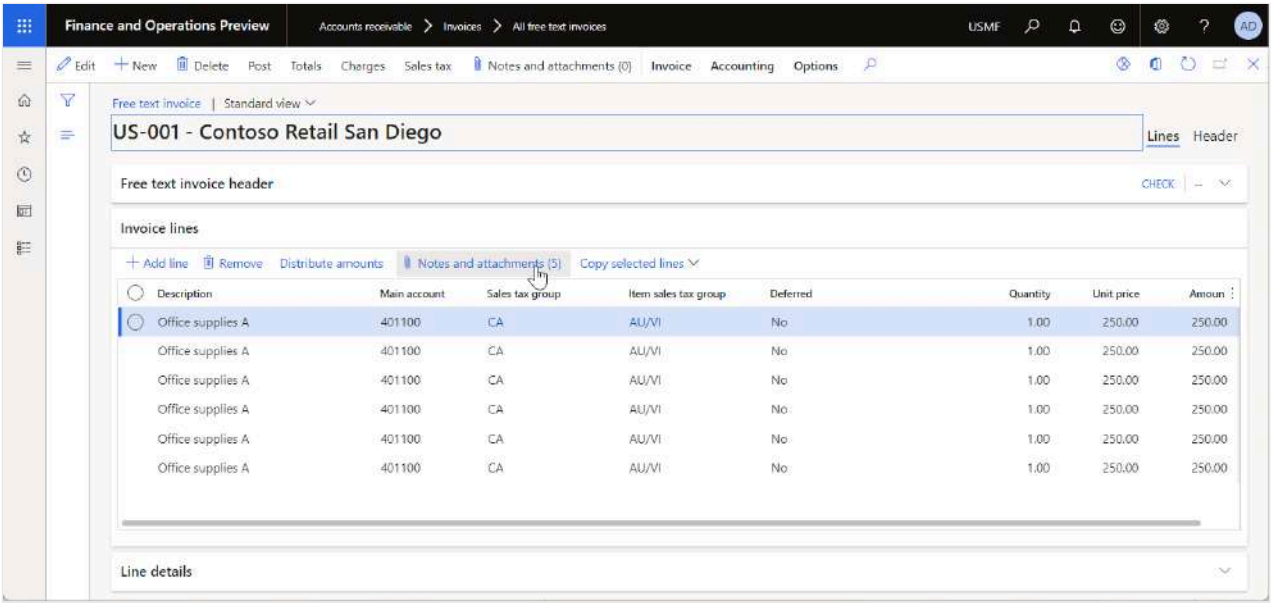
In this example, you create the required ER configurations for the **Litware, Inc.** sample company. Make sure that the configuration provider for the **Litware, Inc.** (`http://www.litware.com`) sample company is listed for the ER framework, and that it's marked as **Active**. If this configuration provider isn't listed, or if it isn't marked as **Active**, follow the steps in Create a configuration provider and mark it as active.

Enter a new free text invoice

1. Follow the steps in Create a free text invoice to add a free text invoice.
   a. Add a single line to the invoice.
   b. Add five notes for the invoice line.



2. Follow the steps in Copy lines to create five additional invoice lines that are copies of the invoice line that you added in the previous step.



Configure the ER framework

Follow the steps in Configure the ER framework to set up the minimal set of ER parameters. You must complete this setup before you start to use the ER framework to design a custom version of a standard ER format.

Import the standard ER format configuration

Follow the steps in Import the standard ER format configuration to add the standard ER configurations to your current instance of Dynamics 365 Finance. For example, import version **252.116** of the **Free text invoice (Excel)** format configuration. The base version **252** of the base

Invoice model configuration is automatically imported from the repository together with the required **Invoice model mapping** configuration.

Set up print management to use the standard ER format

Follow the steps in Set up print management to configure print management for the **Accounts receivable** module so that the standard ER format is used to print free text invoices.

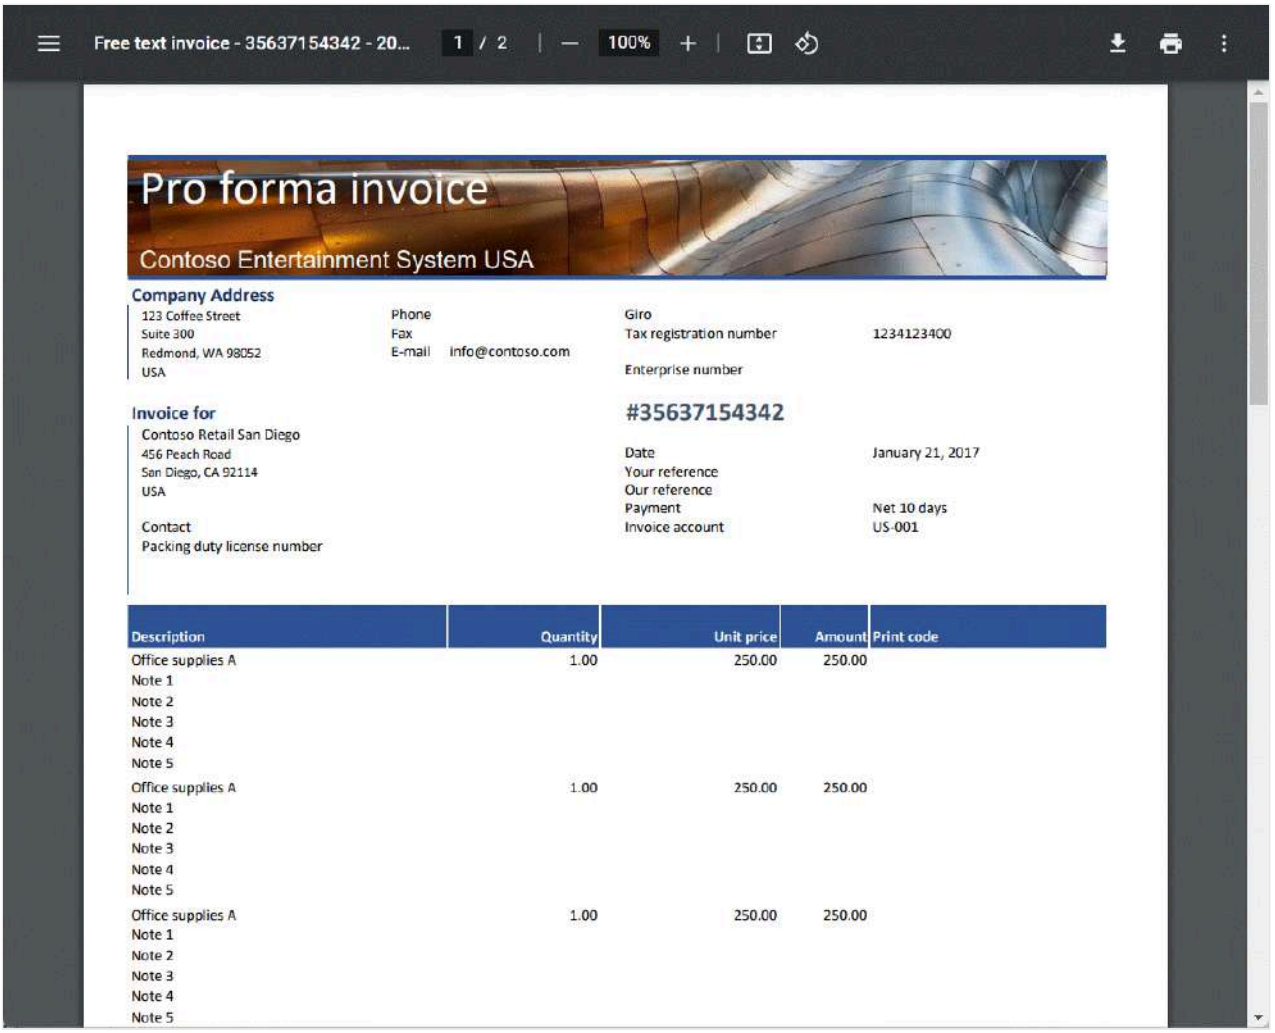
Configure a format destination for the standard ER format

Follow the steps in Configure a format destination for on-screen preview to configure the Screen ER destination of the standard ER format so that generated reports are converted to PDF format and previewed on a new browser tab.

Print a free text invoice by using the standard ER format

1. Follow the steps in Print a free text invoice to use the standard ER format to generate a free text invoice report in Excel format for the added invoice.
2. Download the generated Excel workbook, and review it in the Excel desktop application.

   Notice that the sixth line of the invoice starts on the first page of the report and continues on the second page. The last note appears on the second page, and it isn't obvious that it belongs to the sixth invoice line. Therefore, the page break in the middle of the content for the invoice line makes this document more difficult to read.



The remaining procedures in this article show how you can tune the standard ER format to improve the look and readability of the invoice report by keeping all the content for a single invoice line on the same page.

Create a custom format

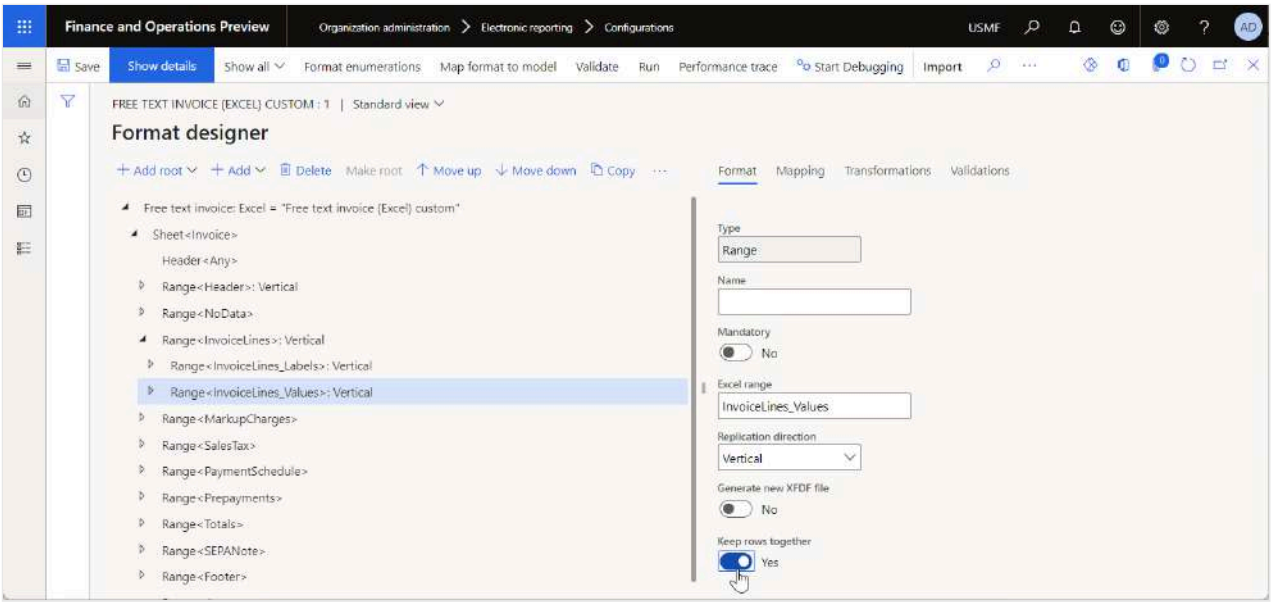
Follow the steps in Create a custom format to derive a format from the imported ER format and create a **Free text invoice (Excel) custom** ER configuration that you can edit and modify.

Edit the custom format

1. Follow the steps in Create a custom format to open the derived ER format for editing in the ER format designer.

2. On the **Format designer** page, in the format component tree in the left pane, expand **Free text invoice** > **Sheet** > **InvoiceLines**, and select the **InvoiceLines_Values** component.

3. On the **Format** tab, set the **Keep rows together** option to **Yes**.



4. Select **Save**, and close the page.

Mark the custom format as runnable

Follow the steps in Mark the custom format as runnable to make the modified version of the custom ER format runnable.

Set up print management to use the custom ER format

Follow the steps in Set up print management to configure print management for the **Accounts receivable** module so that the custom ER format is used to print free text invoices.

Configure a format destination for the custom ER format

Follow the steps in Configure a format destination for on-screen preview to configure the **Screen** ER destination of the custom ER format so that generated reports are converted to PDF format and previewed on a new browser tab.

Print a free text invoice by using the custom ER format

1. Follow the steps in Print a free text invoice to use the custom ER format to generate a free text invoice report in Excel format for the added invoice.

2. Download the generated Excel workbook, and review it in the Excel desktop application.

Notice that the sixth line of the invoice starts on the second page, and all the Excel rows that represent this invoice line appear together on that page.

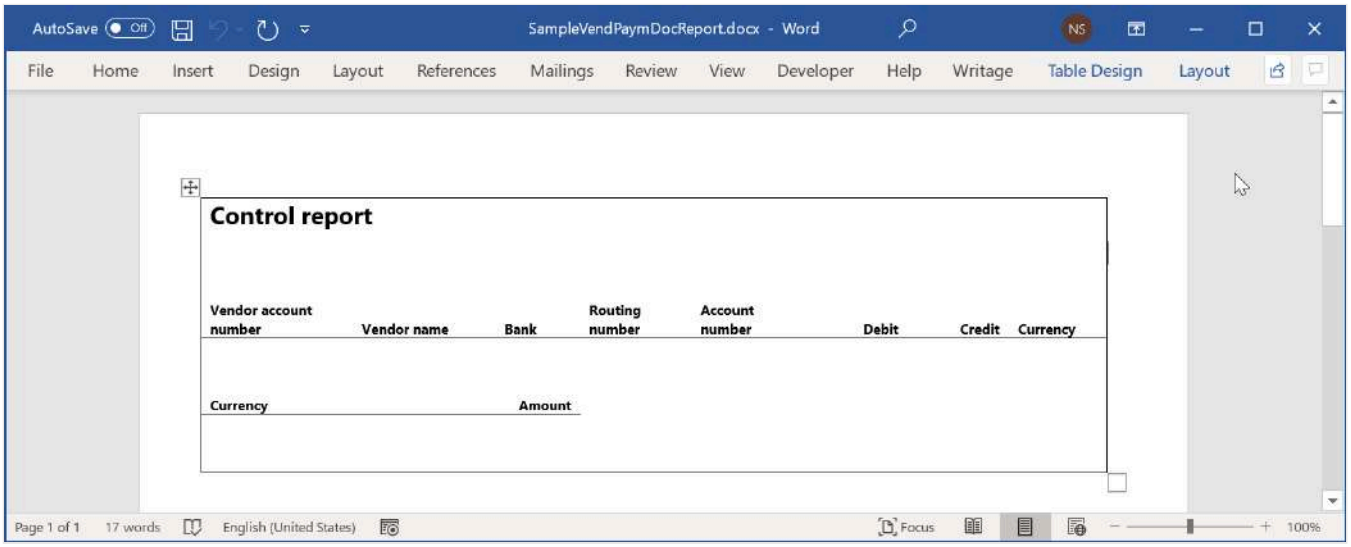
Design a configuration for generating documents in Excel format

Last updated on 04/08/2026

Design a new ER configuration to generate reports in Word format

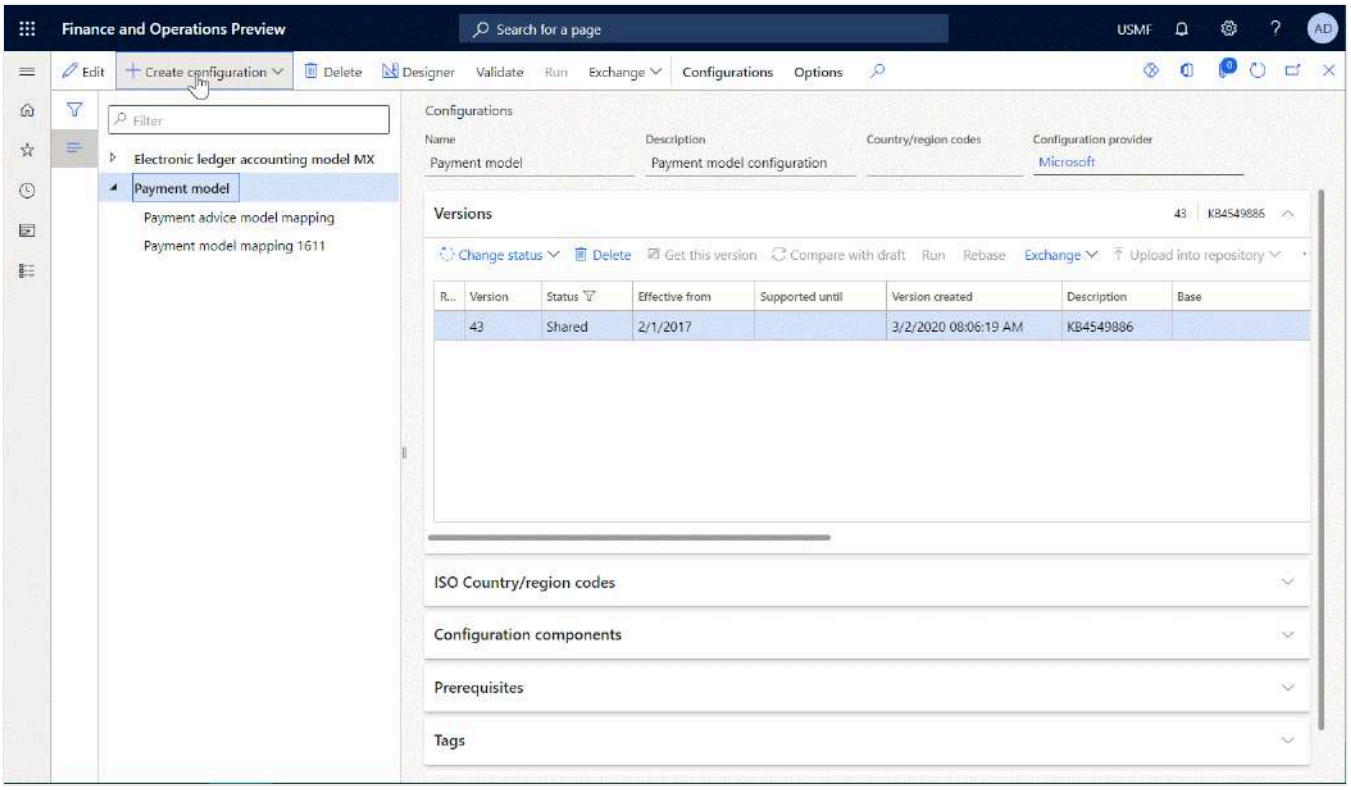
> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To generate reports as Microsoft Word documents, design a template for the reports by using, for example, the Word desktop application. The following illustration shows the sample template for the control report that you can generate to show details of processed vendor payments.



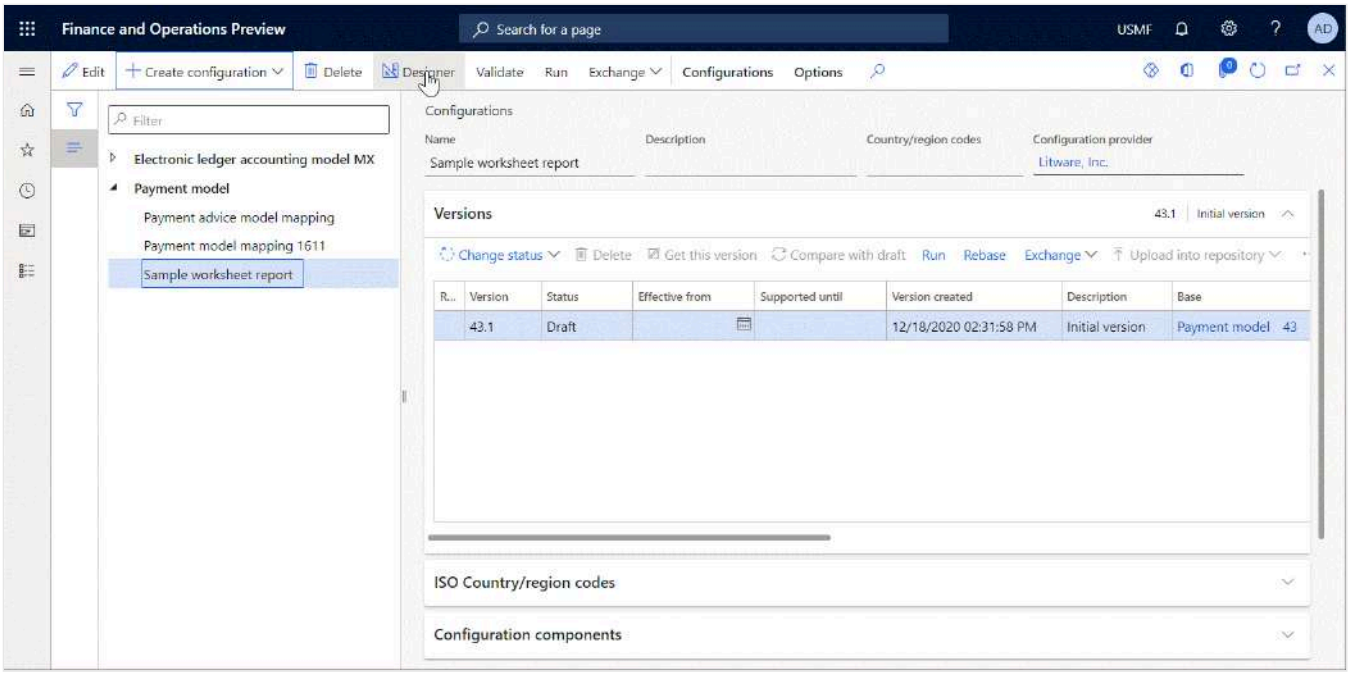
To use a Word document as a template for reports in Word format, configure a new Electronic reporting (ER) solution. This solution must include an ER configuration that contains an ER format component.

> **Note**
>
> When you create a new ER format configuration to generate reports in Word format, select **Word** as the format type in the **Create configuration** dropdown list or leave the **Format type** field blank.

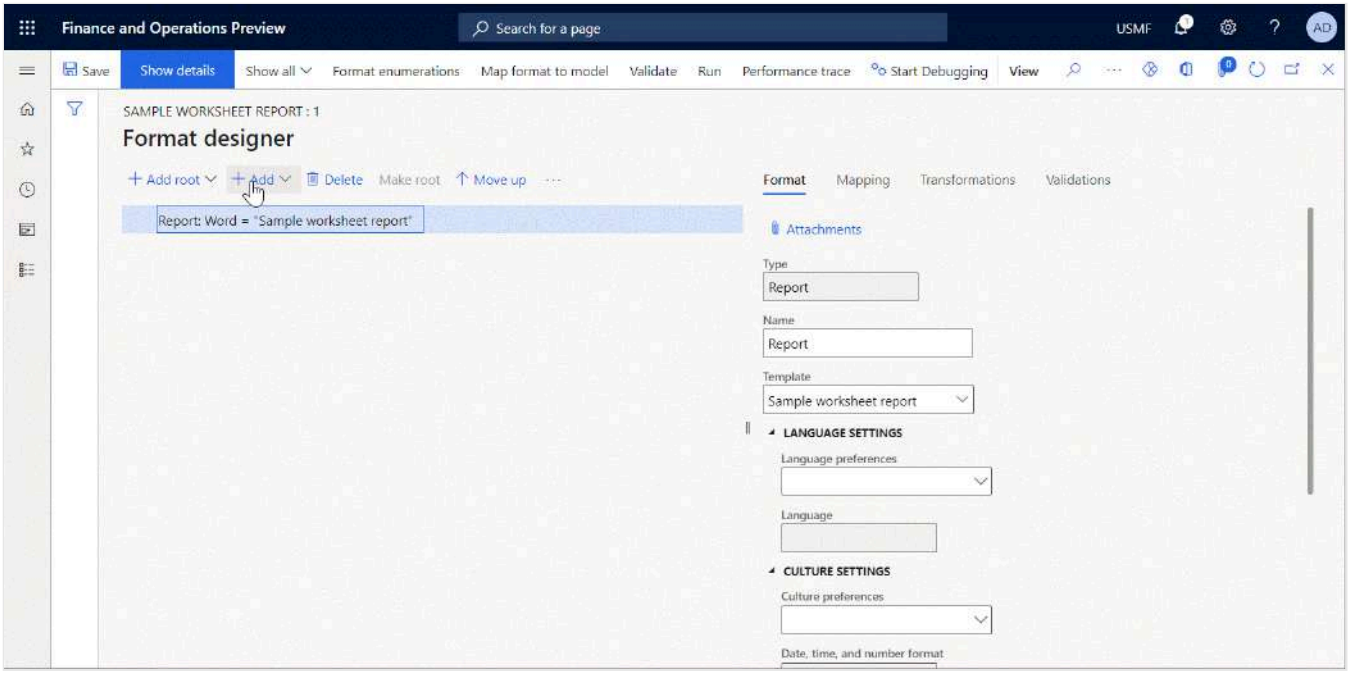


The ER format component of the solution must contain the **Excel\File** format element. Link that format element to the Word document that you use as the template for generated reports at runtime. To configure the ER format component, open the draft version of the created ER configuration in the ER format designer. Then add the **Excel\File** element, attach your Word template to the editable ER format, and link that template to the **Excel\File** element that you added.

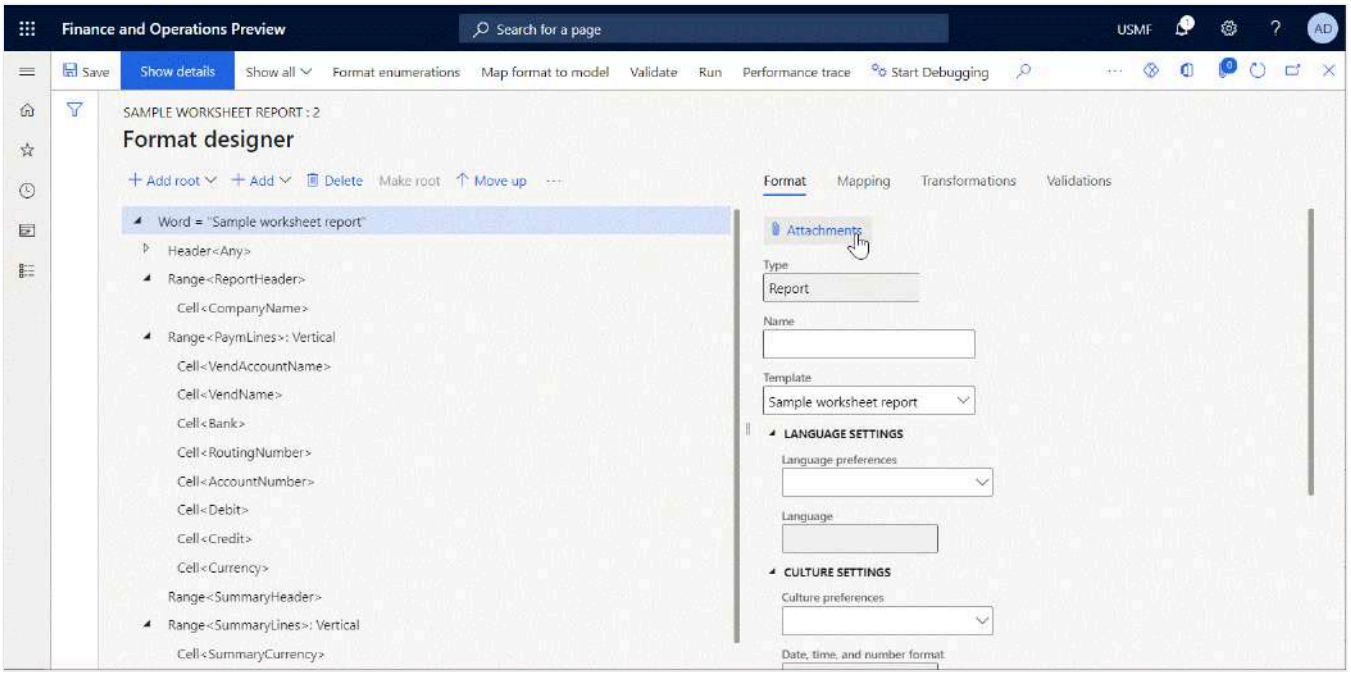
> **Note**
>
> When you attach a template, use a document type that is previously configured in the ER parameters to store templates of ER formats.



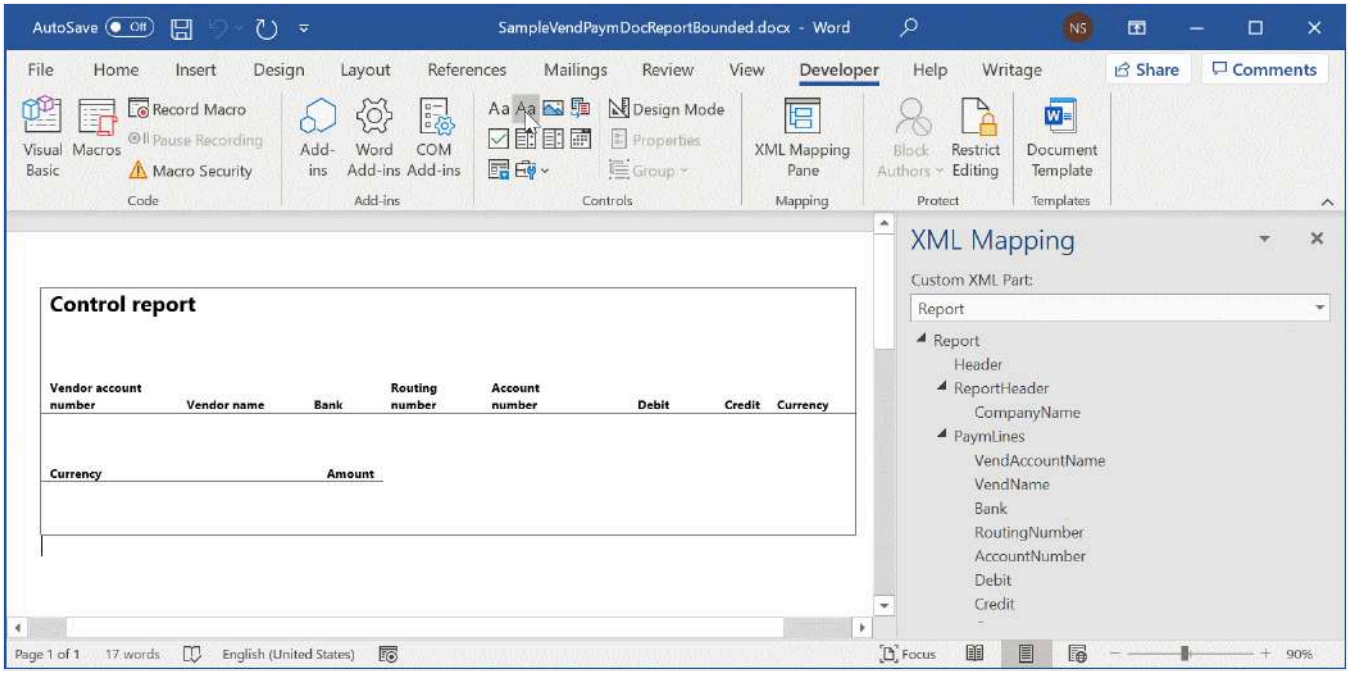
You can add **Excel\Range** and **Excel\Cell** nested elements for the **Excel\File** element to specify the structure of data to enter in generated reports at runtime. You must then bind those elements to data sources of the editable ER format to specify the actual data to enter in generated reports at runtime.



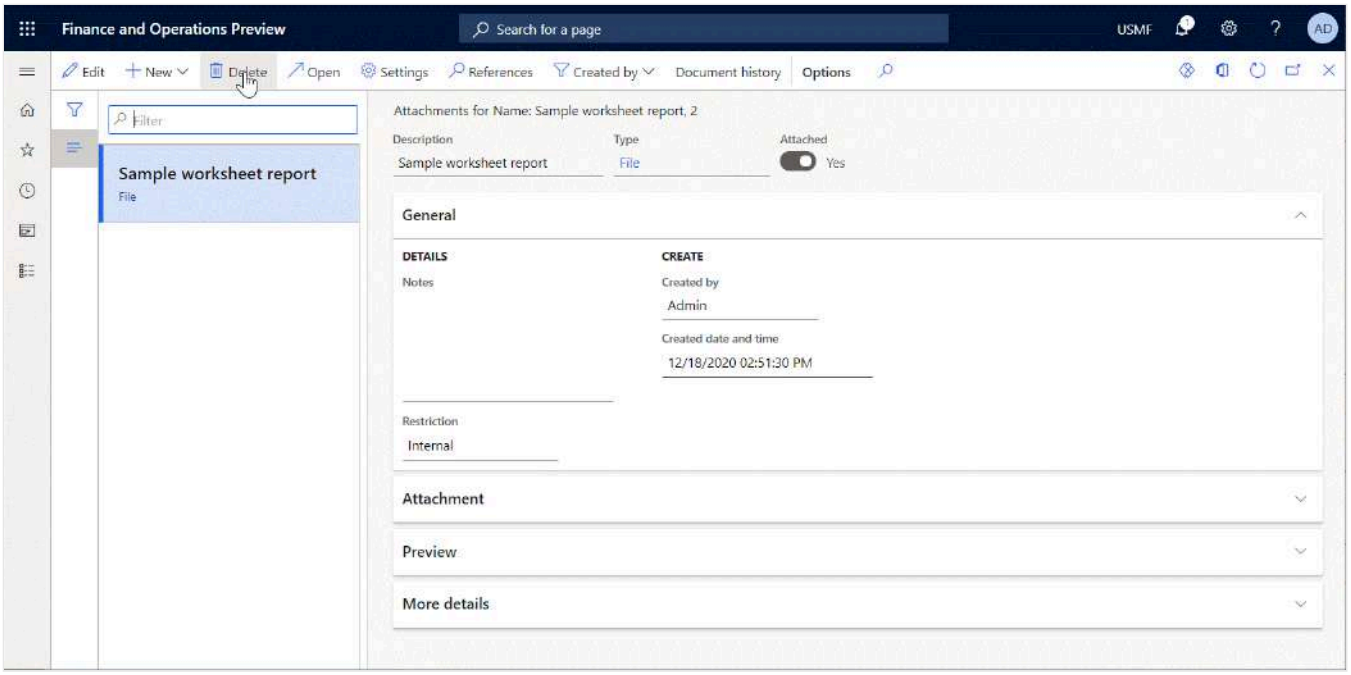
When you save your changes to the ER format at design time, the hierarchical format structure is stored in the attached Word template as a custom XML part that is named **Report**. You must access the modified template, download it from Finance, store it locally, and open it in the Word desktop application. The following illustration shows the locally stored sample template for the control report that contains the **Report** custom XML part.



When bindings of **Excel\Range** and **Excel\Cell** format elements run at runtime, the data that every binding delivers comes into the generated Word document as an individual field of the **Report** custom XML part. To enter the values from the fields of the custom XML part in a generated document, add the appropriate Word content controls to your Word template to serve as placeholders for data that's filled in at runtime. To specify how content controls are filled in, map every content control to the appropriate field of the **Report** custom XML part.



You must then replace the original Word template of the editable ER format with the modified template that now contains Word content controls that were mapped to the fields of the **Report** custom XML part.



When you run the configured ER format, the attached Word template is used to generate a new report. The actual data is stored in the Word report as a custom XML part that is named **Report**. When the generated report is opened, the Word content controls are filled in with data from the **Report** custom XML part.

Frequently asked questions

Question: I configured an ER format to print a Word document that contains a company address. In the Word template for this ER format, I inserted a rich text content control to present a company address. In Finance, I entered the company address as multiline text and selected **Enter** to add a carriage return for every line that I entered. Therefore, I expect the company address to appear as multiline text in generated documents. However, the address appears as a single line of text that contains special symbols instead of carriage returns. What is wrong with my settings?

Answer: Instead of using a rich text content control, use a plain text content control and select the **Allow carriage returns (multiple paragraphs)** check box in the control's properties.

Additional resources

- Reuse ER configurations with Excel templates to generate reports in Word format
- Embed images and shapes in documents that you generate by using ER

Reuse ER configurations with Excel templates to generate reports in Word format

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To generate reports as Microsoft Word documents, you can configure a new Electronic reporting (ER) format. Alternatively, you can reuse an ER format that was originally designed to generate reports as Excel workbooks. In this case, you must replace the Excel template with a Word template.

The following procedures show how a user in either the System administrator role or the Electronic reporting developer role can configure an ER format to generate reports as Word files by reusing an ER format that was designed to generate reports as Excel files.

You can complete these procedures in the GBSI company.

Prerequisites

To complete these procedures, first follow the steps in the Design a configuration for generating reports in OPENXML format task guide.

You must also download and locally save the following templates for the sample report:

- Template of Payment Report (SampleVendPaymDocReport.docx)
- Bounded Template of Payment Report (SampleVendPaymDocReportBounded.docx)

These procedures are for a feature that was added in Dynamics 365 for Operations version 1611 (November 2016).

Select the existing ER report configuration

1. In Dynamics 365 Finance, go to **Organization administration** > **Workspaces** > **Electronic reporting**.

2. Make sure that the **Litware, Inc.** configuration provider is selected as **Active**. If it isn't, follow the steps in the Create configuration providers and mark them as active task guide.

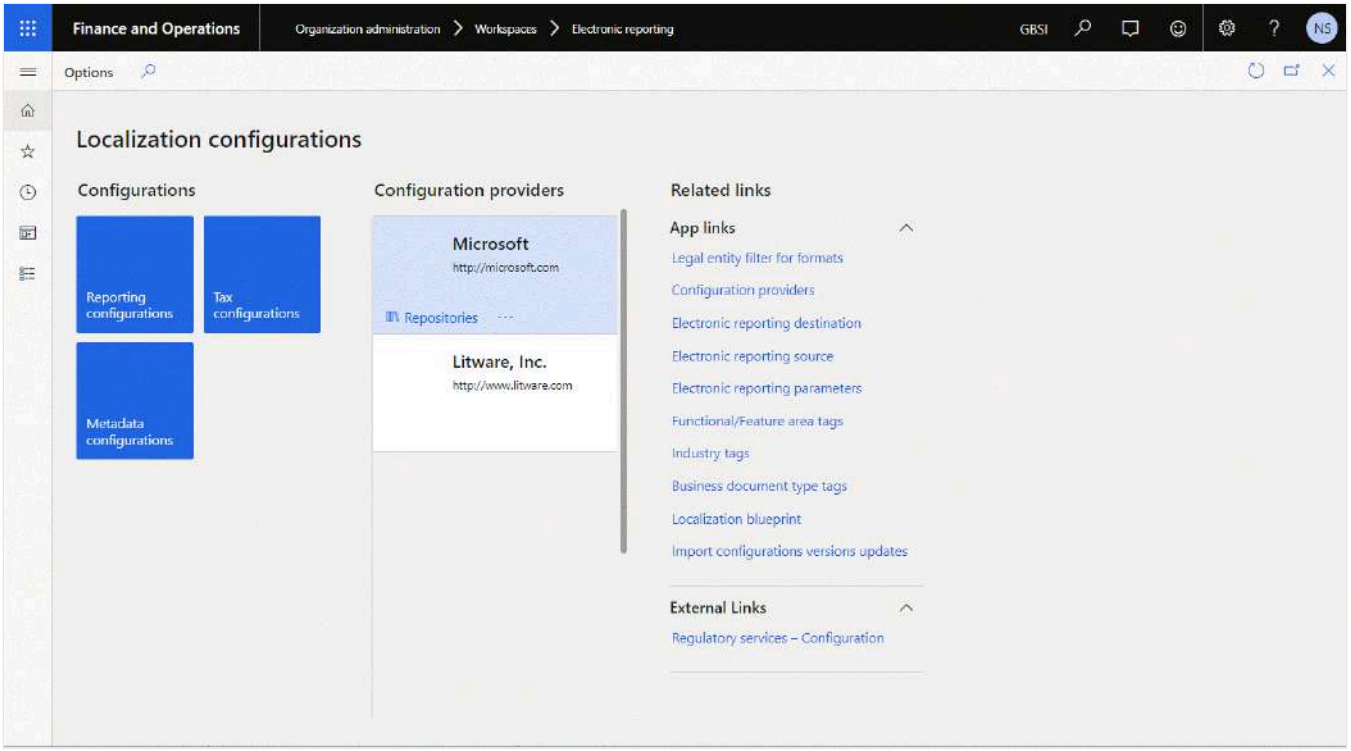
3. Select **Reporting configurations**. You reuse the existing ER configuration that was designed to generate the report output in OPENXML format.

4. On **Configurations**, in the configuration tree in the left pane, expand **Payment model**, and select **Sample worksheet report**.

   > ⓘ **Note**
   >
   > You can edit the draft version of the selected ER format on the **Versions** FastTab.

5. Select **Designer**.

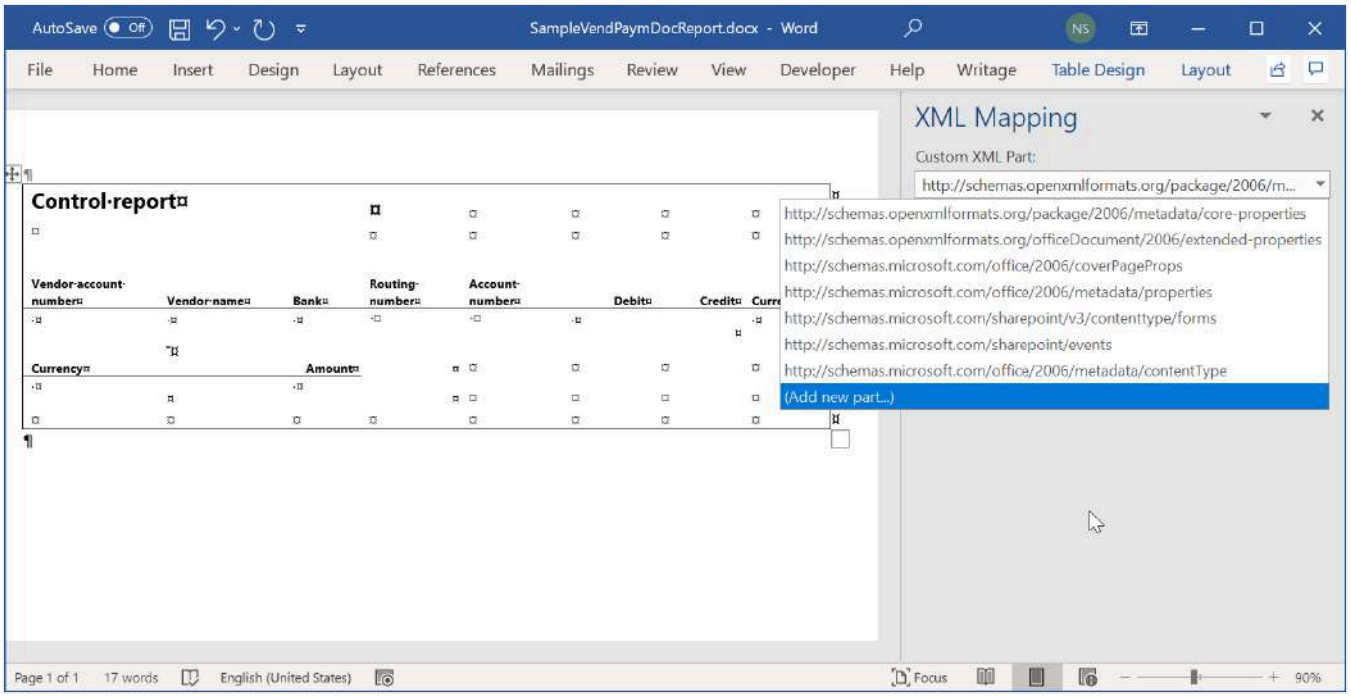
6. On **Format designer**, the title of the root format element indicates that an Excel template is currently used.



Review the downloaded Word template

1. In the Word desktop application, open the **SampleVendPaymDocReport.docx** template file that you downloaded earlier.

2. Verify that the template contains only the layout of the document that you want to generate as ER output.



Replace the Excel template with the Word template and add a custom XML part

Currently, the Excel document is used as a template to generate the output in OPENXML format. Replace this template with the **SampleVendPaymDocReport.docx** Word template file that you downloaded earlier. You can also extend the Word template by adding a custom XML part.

1. In Finance, on the **Format designer** page, on the **Format** tab, select **Attachments**.
2. On the **Attachments** page, select **Delete** to remove the existing Excel template. Select **Yes** to confirm the change.
3. Select **New** > **File**.

> **Note**
>
> To store templates of ER formats, select a document type that is configured in the ER parameters.

4. Select **Browse**, and then browse to and select the **SampleVendPaymDocReport.docx** file that you downloaded earlier.

5. Select **OK**.

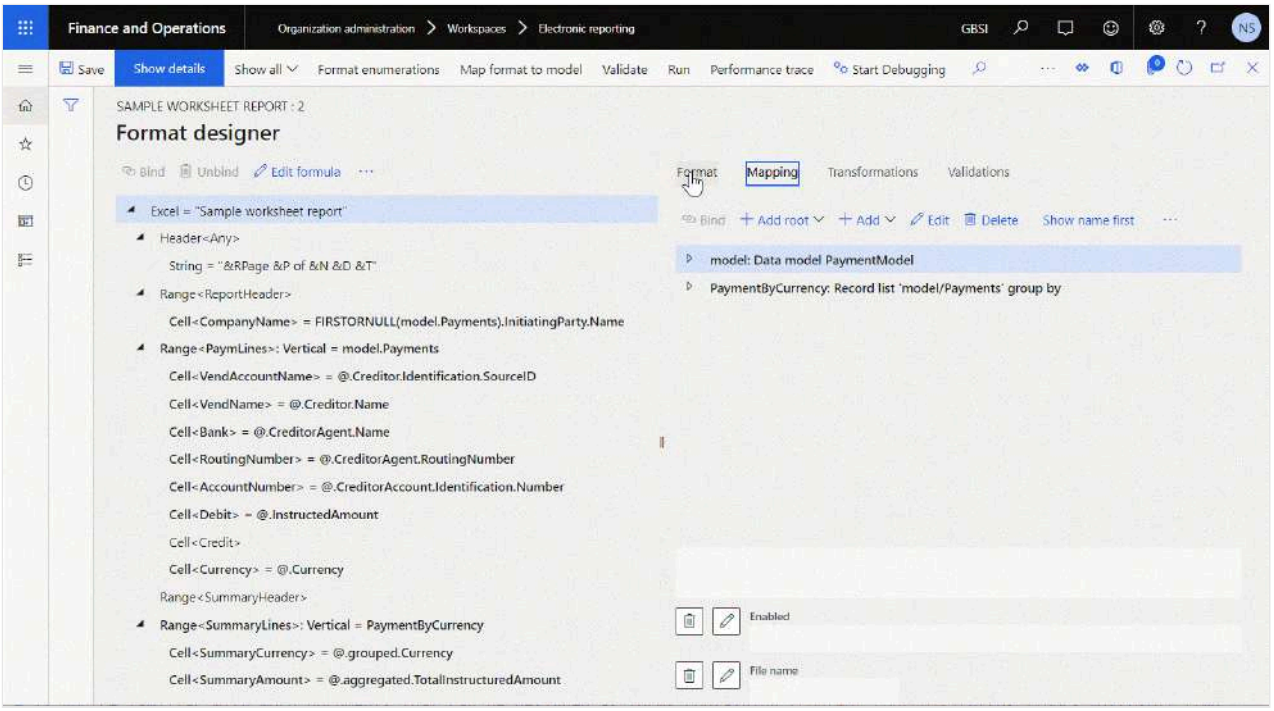
6. Close the **Attachments** page.

7. On the **Format designer** page, in the **Template** field, enter or select the **SampleVendPaymDocReport.docx** file to use that Word template instead of the Excel template that was previously used.

8. Select **Save**.

   In addition to storing configuration changes, the **Save** action updates the attached Word template. The hierarchical structure of the designed format is added to the attached Word document as a new custom XML part that is named **Report**. The attached Word template contains the layout of the document that is generated as ER output and the structure of data that ER enters in that template at runtime.

9. Notice that the title of the root format element indicates that a Word template is currently used.



10. On the **Format** tab, select **Attachments**.

You can now map the elements of the **Report** custom XML part to the content controls of the Word document.

If you're familiar with the process of designing Word documents as forms that contain content controls that are mapped to elements of custom XML parts, complete all steps in the next

procedure to create the document. For more information, see Create forms that users complete or print in Words. Otherwise, skip the next procedure.

Get a Word document that has a custom XML part and do data mapping

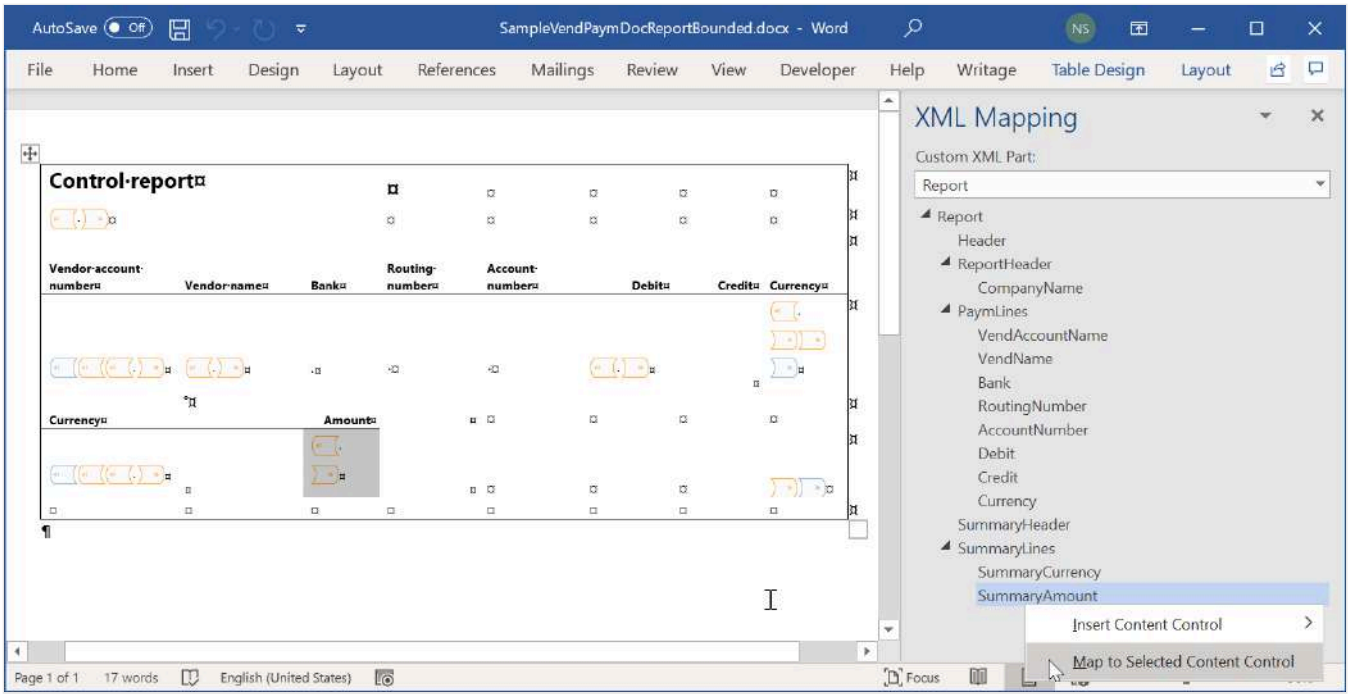
1. In Finance, on the **Attachments** page, select **Open** to download the selected template from Finance and store it locally as a Word document.
2. In the Word desktop application, open the document that you just downloaded.
3. On the **Developer** tab, select **XML Mapping Pane**.

   > **Note**
   >
   > If the **Developer** tab doesn't appear on the ribbon, customize the ribbon to add it.

4. In the **XML Mapping** pane, in the **Custom XML Part** field, select the **Report** custom XML part.
5. Map the elements of the selected **Report** custom XML part and the content controls of the Word document.
6. Save the updated Word document locally as **SampleVendPaymDocReportBounded.docx**.

Review the Word template where the custom XML part is mapped to content controls

1. In the Word desktop application, open the **SampleVendPaymDocReportBounded.docx** template file.
2. Verify that the template contains the layout of the document that you want to generate as ER output. The content controls that are used as placeholders for data that ER enters in this template at runtime are based on the mappings that you configure between elements of the **Report** custom XML part and the content controls of the Word document.



Upload the Word template where the custom XML part is mapped to content controls

1. In Finance, on the **Attachments** page, select **Delete** to remove the Word template that has no mappings between elements of the **Report** custom XML part and content controls. Select **Yes** to confirm the change.

2. Select **New** > **File** to add a new template file that contains mappings between elements of the **Report** custom XML part and content controls.

   > **Note**
   >
   > To store templates of ER formats, select a document type that is **configured** in the ER parameters.

3. Select **Browse**, and then browse to and select the **SampleVendPaymDocReportBounded.docx** file that you downloaded or prepared by completing the procedure in the Get a Word that has a custom XML part to do data mapping section.

4. Select **OK**.

5. Close the **Attachments** page.

6. On the **Format designer** page, in the **Template** field, select the document that you just downloaded.
7. Select **Save**.
8. Close the **Format designer** page.

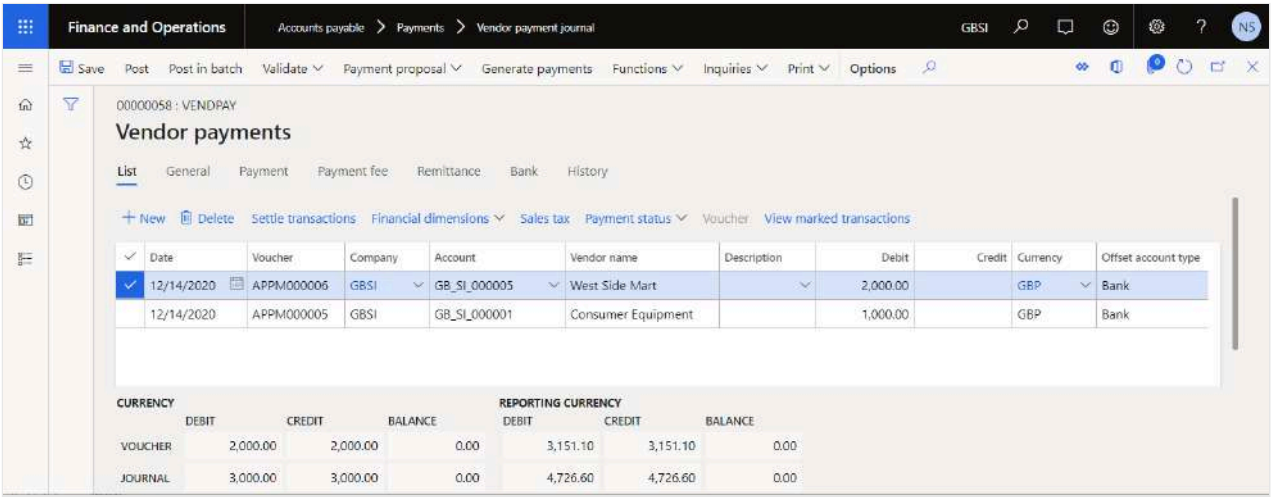
Mark the configured format as runnable

To run the draft version of the editable format, you must make it runnable.

1. In Finance, on the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
2. In the **User parameters** dialog box, set the **Run settings** option to **Yes**, and then select **OK**.
3. Select **Edit** to make the current page editable, as required.
4. For the currently selected **Sample worksheet report** configuration, set the **Run Draft** option to **Yes**.
5. Select **Save**.

Run the format to create output in Word format

1. In Finance, go to **Accounts payable** > **Payments** > **Payment journal**.
2. In a payment journal that you entered earlier, select **Lines**.
3. On the **Vendor payments** page, select all rows in the grid.
4. Select **Payment status** > **None**.



5. On the Action Pane, select **Generate payments**.

6. In the dialog box that appears, follow these steps:
    a. In the **Method of payment** field, select **Electronic**.
    b. In the **Bank account** field, select **GBSI OPER**.
    c. Select **OK**.

7. In the **Electronic report parameters** dialog box, select **OK**.

8. The generated output is presented in Word format and contains the details of the processed payments. Analyze the generated output.

- Design a new ER configuration to generate reports in Word format
- Embed images and shapes in documents that you generate by using ER

Last updated on 04/10/2026

Suppress Word content controls in generated reports

To generate reports as Microsoft Word documents, you must design a template for the reports as a Word document. This template must contain Word content controls as placeholders for data that's filled in at runtime. To use the created Word document as a template for your reports, configure a new Electronic reporting (ER) solution. The solution must include an ER configuration that contains an ER format component. You must configure this ER format to use the designed template for report generation.

In version 10.0.6 and later of Dynamics 365 Finance, you can configure formulas in your ER format to suppress some Word content controls in generated documents.

The following steps explain how a user assigned to the System administrator or Electronic reporting functional consultant role can configure an ER format that generates reports as Word files and suppresses some of the content controls in the generated reports that are configured by using a Word template.

You can complete these steps in the GBSI company.

Prerequisites

To complete these steps, first complete the steps in the following task guides:

- Design a configuration for generating reports in OPENXML format
- Re-use ER configurations with Excel templates to generate reports in Word format

When you complete the steps in these task guides, the following items are prepared:

- A **Sample worksheet report** ER format that is configured to generate a document in Word format
- A draft version of the **Sample worksheet report** ER format that is marked as **Runnable**
- An **Electronic** method of payments that is configured to use the **Sample worksheet report** ER format for vendor payment processing

You must also download and save the following template for the sample report:

- Bounded Template 2 of Payment Report (SampleVendPaymDocReportBounded2.docx)

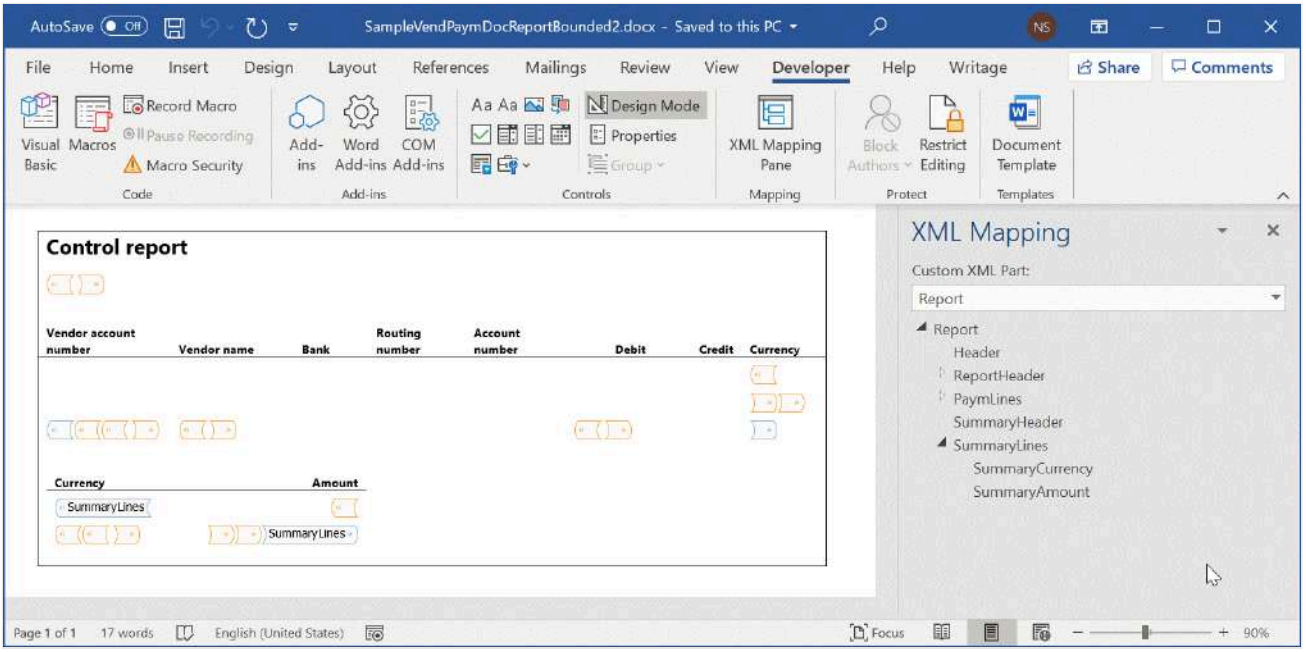
Review the downloaded Word template

1. In the Word desktop application, open the **SampleVendPaymDocReportBounded2.docx** template file that you downloaded earlier.

2. Verify that the template file contains a summary section that shows the total payment amounts for every currency code encountered in the processed payments.

    - The summary section resides in a separate table of the Word document.
    - The first row of this table holds the table columns headings as the section header.
    - The second row of this table holds the repeating content control as the section details.
    - This content control is mapped to the **SummaryLines** field of the **Report** custom XML part.
    - Based on this mapping, the content control is associated with the **SummaryLines** element of the editable ER format.

    > **Note**
    >
    > The repeating content control is tagged by the **SummaryLines** key that matches the field of the custom XML part that it maps to.



Select the existing ER report configuration

For the following steps, reuse the existing ER configuration that you configured when you completed the steps in the previously mentioned task guides.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. On **Configurations**, in the configuration tree, expand **Payment model**, and select **Sample worksheet report**.
4. Select **Designer** to edit the draft version of the selected ER format.

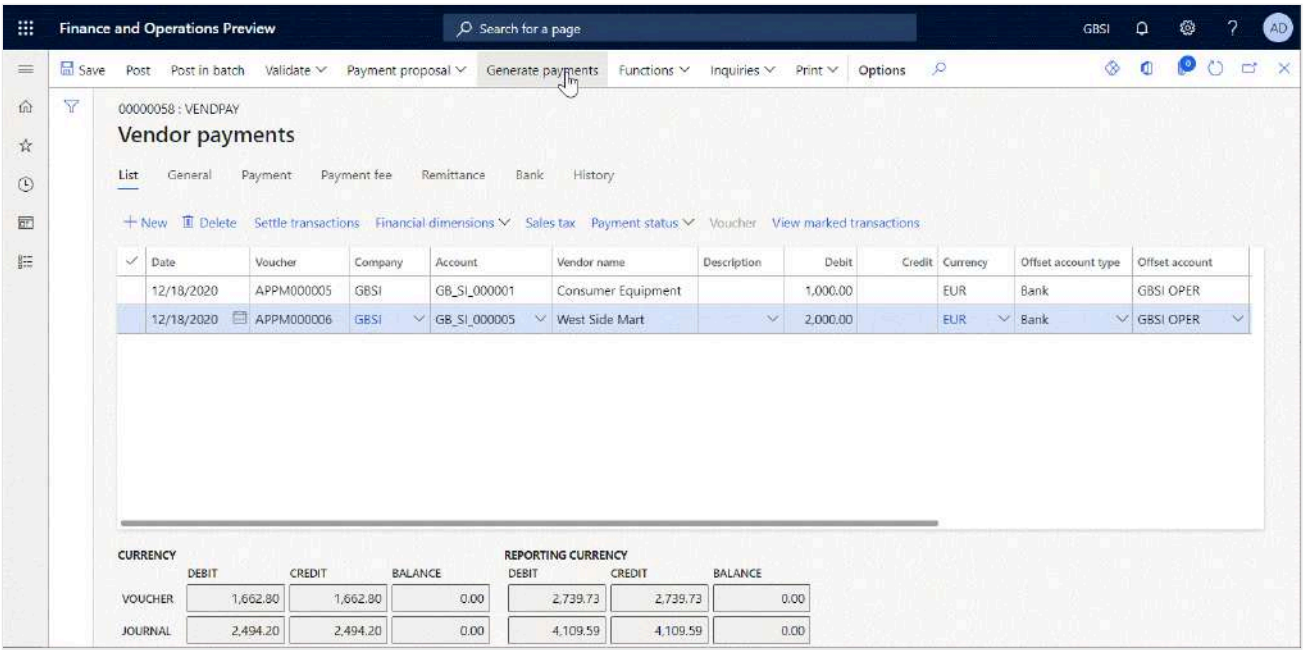
Replace the current template with the new template

Currently, the **SampleVendPaymDocReportBounded.docx** file is used as a template to generate the output in Word format. In the following steps, you replace this Word template with the new Word template, **SampleVendPaymDocReportBounded2.docx**, that you downloaded earlier.

1. On **Format designer**, select **Attachments**.
2. On **Attachments**, select **Delete** to remove the existing template.
3. Select **Yes** to confirm the deletion.
4. Select **New** > **File**.
5. Select **Browse**, and browse to and select the **SampleVendPaymDocReportBounded2.docx** file that you downloaded earlier.
6. Select **OK**.
7. Close **Attachments**.
8. On **Format designer**, in the **Template** field, enter or select the **SampleVendPaymDocReportBounded2.docx** file.

Run the format to create Word output

1. Go to **Accounts payable** > **Payments** > **Payment journal**.
2. On **Vendor payments**, on the **List** tab, select all the payments.
3. Select **Payment status** > **None**.
4. Select **Generate payments**.
5. In the **Method of payment** field, select **Electronic**.
6. In the **Bank account** field, select **GBSI OPER**.
7. Select **OK**.
8. In the **Electronic report parameters** dialog box, select **OK**, and analyze the generated output.



The output is presented in Word format and contains the summary section.

Configure the editable format to suppress the summary section

To suppress the summary section in a generated document, based on the request of a user who runs this ER format, modify the editable ER format.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**, and open the draft version of the ER format for editing.

2. Select **Reporting configurations**.

3. On **Configurations**, in the configuration tree, expand **Payment model** > **Sample worksheet report**.

4. Select **Designer**.

5. On **Format designer**, expand **Word**, and select **SummaryLines**.

6. On the **Mapping** tab, add a new data source to ask the user, at runtime, whether the summary section should be suppressed:
   a. Select **Add root**.
   b. In **Add data source**, select **General\User input parameter** to open **User input parameter data source properties**.
   c. In the **Name** field, enter `uipSuppress`.
   d. In the **Label** field, enter **Suppress summary section**.

e. In the **Operations data type name** field, select or enter **NoYes**.
f. Select **OK**.

7. Add a new data source of the **NoYes** application enumeration type:
   a. Select **Add root**.
   b. In **Add data source**, select **Dynamics 365 for Operations\Enumeration** to open **Enumeration data source properties**.
   c. In the **Name** field, enter `enumNoYes`.
   d. In the **Label** field, enter **Suppress options**.
   e. In the **Operations data type name** field, select or enter **NoYes**.
   f. Select **OK**.

8. For the selected **SummaryLines** format element, configure the formula to specify when the Word content control that is associated with the selected format element should be suppressed:

   a. On the **Mapping** tab, in the **Removed** section, select **Edit** to open the Formula designer.

   b. In the **Formula** field, enter the formula `uipSuppress = enumNoYes.Yes`.

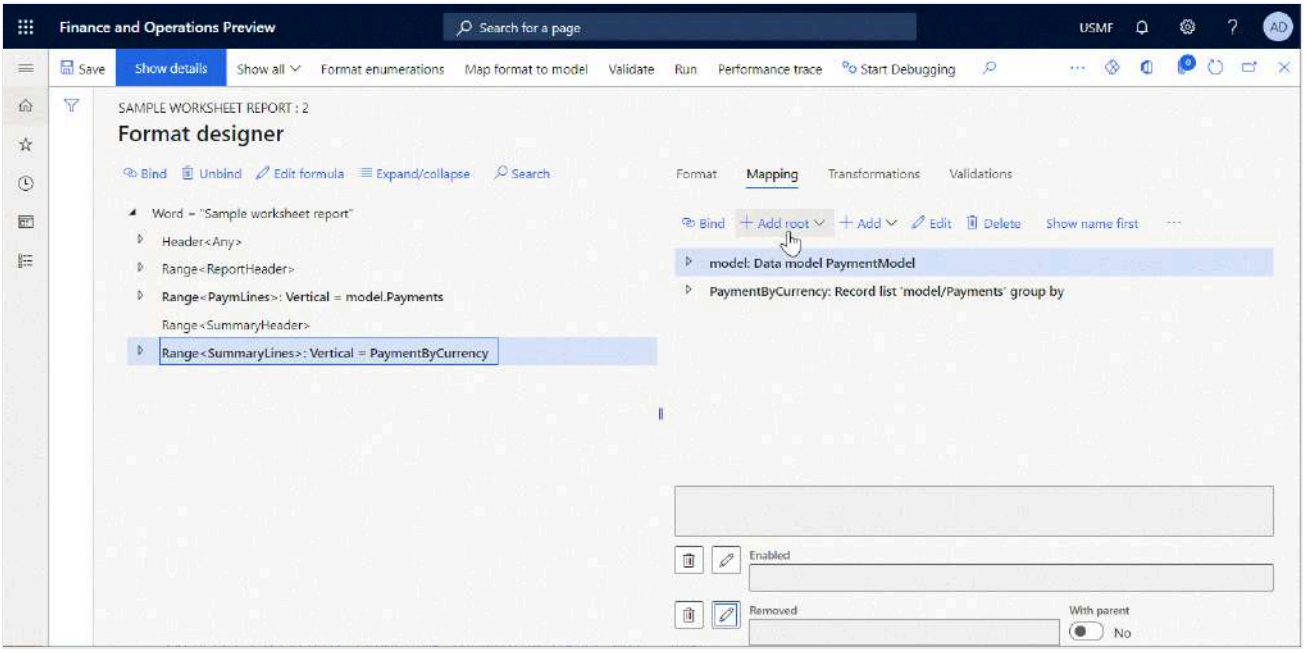
   c. Select **Save**, and close the **Formula designer**.

> ⓘ Note
>
> This formula is applied to a generated document **after all other format elements run**. To apply this formula, a Word content control that is tagged as a format element that the formula is configured for (**SummaryLines** in this case) is found in a generated document. The content control is then completely removed, together with the row in the Word table that holds it. The details row of the summary section is removed from the generated document.
>
> At design time, you might configure the **Removed** formula for a format element, even though no content control in the Word template that you're using has a tag that matches the name of a format element that the **Removed** property is configured for. When you validate the format at design time, you receive a warning about this inconsistency.
>
> At runtime, an exception is thrown if no content control in the Word template that you're using has a tag that matches the name of a format element that the **Removed** property is configured for.

d. On the **Mapping** tab, in the **Removed** section, set the **With parent** option to **Yes**.

> **Note**
>
> You must set this option to **Yes** to remove the whole Word table as the parent object of the row that holds the summary section details. If you set this option to **No**, the section header row remains in the generated document.

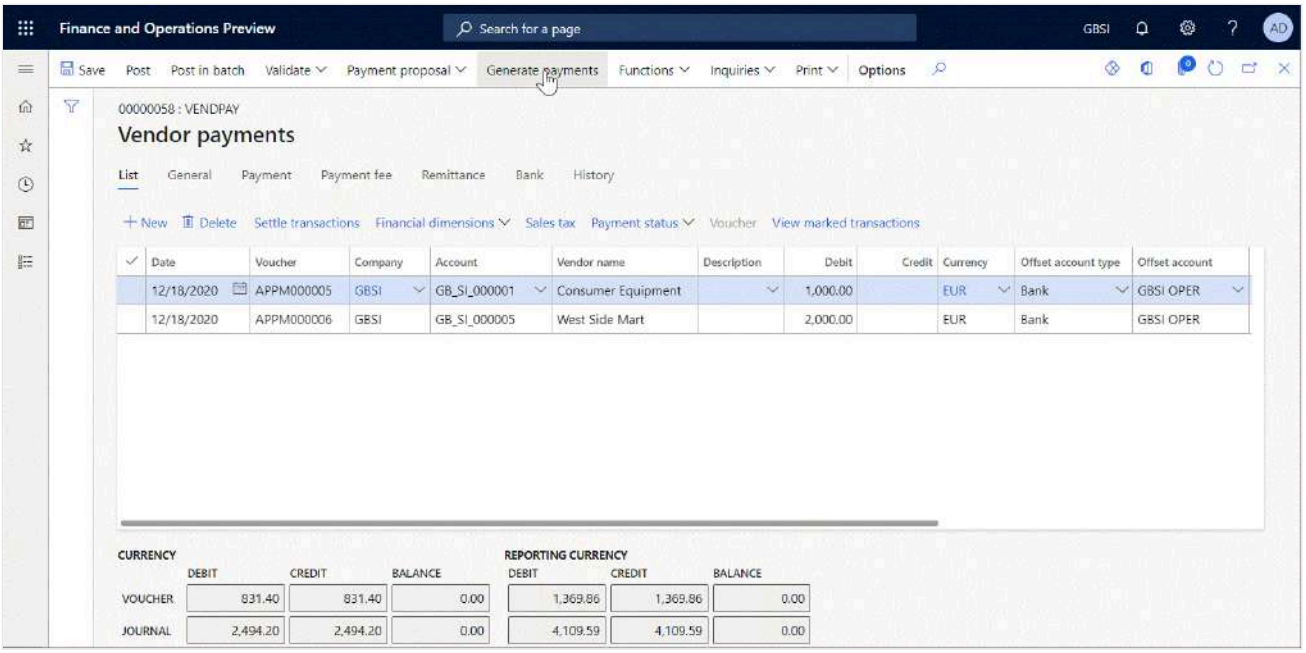
9. Select **Save** to save your changes to the editable format.



Run the modified format to create Word output

1. Go to **Accounts payable** > **Payments** > **Payment journal**.
2. Select the payment journal that you created, and then select **Lines**.
3. On the **Vendor payments** page, select all the rows, and then select **Payment status** > **None**.
4. Select **Generate payments**.
5. In the **Method of payment** field, select **Electronic**.
6. In the **Bank account** field, select **GBSI OPER**.
7. Select **OK**.
8. In the **Electronic report parameters** dialog box, in the **Suppress summary section** field, select **Yes**.

9. Select **OK**, and analyze the generated output.



The output doesn't contain the summary section, because it's suppressed.

Additional resources

- Design a configuration for generating reports in OPENXML format
- Design a new ER configuration to generate reports in Word format
- Re-use ER configurations with Excel templates to generate reports in Word format
- Inspect the configured ER component to prevent runtime issues

Design ER configurations to fill in PDF templates

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The procedures in this article provide examples that show how a user in either the **System administrator** role or the **Electronic reporting developer** role can configure an Electronic reporting (ER) format that generates reports as PDF files by using fillable PDF documents as report templates. You can perform these steps in any company of Dynamics 365 Finance or Regulatory Configuration Services (RCS).

Prerequisites

Before you begin, you must have one of the following types of access, depending on the service that you use to complete the procedures in this article:

- Access to Finance for one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator
- Access to RCS for one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator

You must also complete the Create configuration providers and mark them as active procedure.

Finally, download the following files.

Expand table

Content description	File name
Template for the first page of the report	IntrastatReportTemplate1.pdf
Template for other pages of the report	IntrastatReportTemplate2.pdf
Sample ER format - PDF	Intrastat report (PDF).version.1.1.xml
Sample ER format - Excel	Intrastat (import from Excel).version.1.1.xml
Sample dataset	Intrastat sample data.xlsx

Design the format configuration

Get access to the list of configurations provided by Microsoft

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Make sure that the **Litware, Inc.** provider is available and marked as active.
3. On the tile for the **Microsoft** provider, select **Repositories**.

> ⓘ **Note**
>
> If a repository of the **LCS** type already exists, skip the remaining steps of this procedure.

4. Select **Add**.
5. In the drop-down dialog box, in the **Configuration repository type** field group, select the **LCS** option.
6. Select **Create repository**.
7. Select **OK**.

Get the model configurations provided by Microsoft

1. On the left side of the **Configuration repositories** page, select the **Show filters** button (the funnel symbol).
2. Add a filter for a value of **LCS** in the **Type** field, and use the **begins with** operator.
3. Select **Apply**.

4. Select **Open**.
5. In the tree, select **Intrastat model**.
6. On the **Versions** FastTab, select version **1**.

> ⓘ Note
>
> If the **Import** button on the **Versions** FastTab is unavailable, skip the remaining steps of this procedure.

7. Select **Import**.
8. Select **Yes** to confirm the import of the selected version of the **Intrastat model** model configuration.

Create a new format configuration

1. In the **Electronic reporting** workspace, select the **Reporting configurations** tile.
2. In the tree, select **Intrastat model**.
3. Select **Create configuration**.

> ⓘ Note
>
> If the **Create configuration** button isn't available, you must turn on design mode on the **Electronic reporting parameters** page that can be opened from the **Electronic reporting** workspace.

4. In the drop-down dialog box, in the **New** field group, select the **Format based on data model Intrastat** option.
5. In the **Name** field, enter **Intrastat report (PDF)**.
6. In the **Description** field, enter **Intrastat report in PDF format**.

> ⓘ Note
>
> The active configuration provider is automatically entered. This provider will be able to maintain this configuration. Although other providers can use this configuration,

they won't be able to maintain it.

7. Optional: In the **Format type** field, you can select a specific format of electronic document. If you select **PDF**, at design time, the ER Operations designer will offer just the format elements that are applicable only to documents that are generated in PDF format (**PDF\File**, **PDF\PDF Merger**, etc.). If you leave this field blank, a format of electronic document will be specified at design time in the ER Operations designer when a first format element will be added. For example, if you add the **Excel\File** as the first format element, the ER Operations designer will offer you just the format elements that are applicable only to documents that are generated in Excel format (**Excel\Cell**, **Excel\Range**, etc.). format.

8. Select **Create configuration**.

A new ER format configuration is created. You can use the draft version of this configuration to store the ER format component that is designed to generate electronic documents in PDF format.

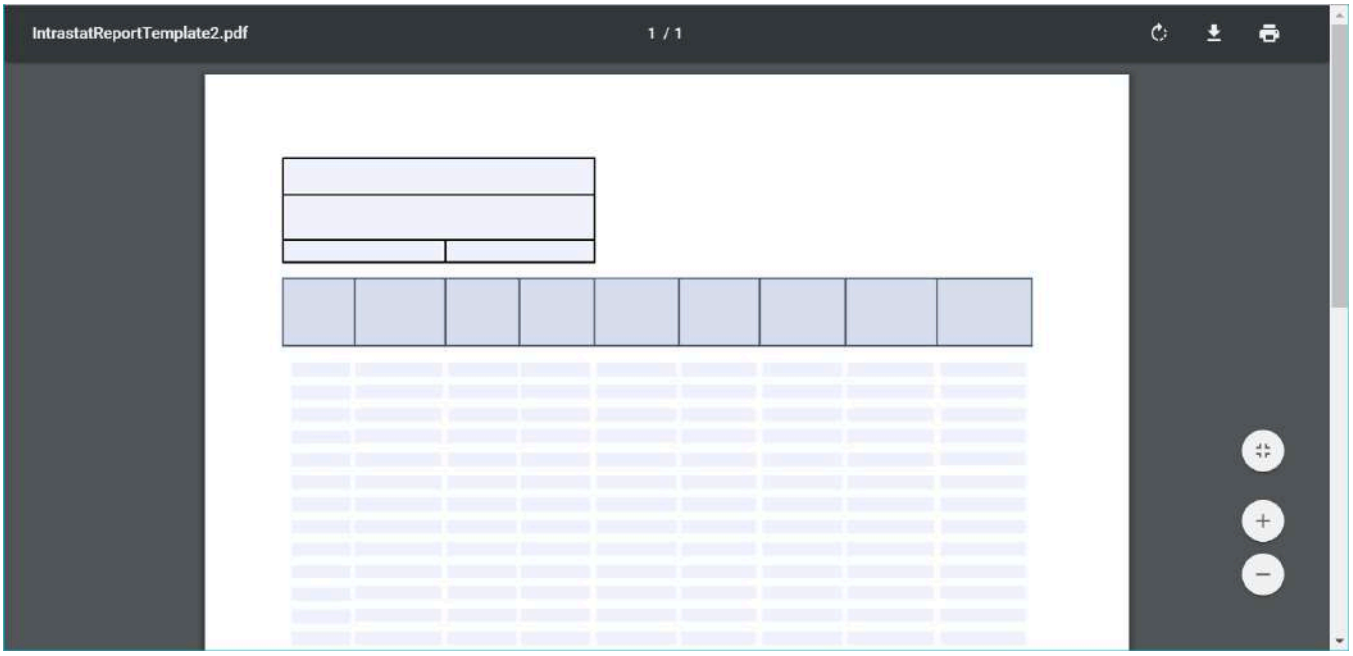
Design the format of an electronic document

Next, in the ER format configuration that you created, design the ER format that generates the **Intrastat control** report in PDF format. The first page of this report must show a summary of the report and details of the foreign trade transactions that are reported on. The other pages must show only details of the foreign trade transactions that are reported on. Because the report pages that are generated must have different layouts, the ER format uses two different templates in PDF format.

In any PDF viewer, open the PDF templates that you downloaded. Each template contains multiple fields that you fill in. In each template, details of foreign trade transactions are presented as 42 rows, each of which has nine fields. The row number appears at the end of each field's name (for example, **Date 1**...**Date 42** and **Commodity 1**...**Commodity 42**).

The following illustration shows the PDF template for the first page of the report.

The following illustration shows the PDF template for other pages of the report.



1. On the **Configurations** page, select **Designer**.
2. Select **Add root**.
3. In the tree, select **PDF** > **PDF Merger**.

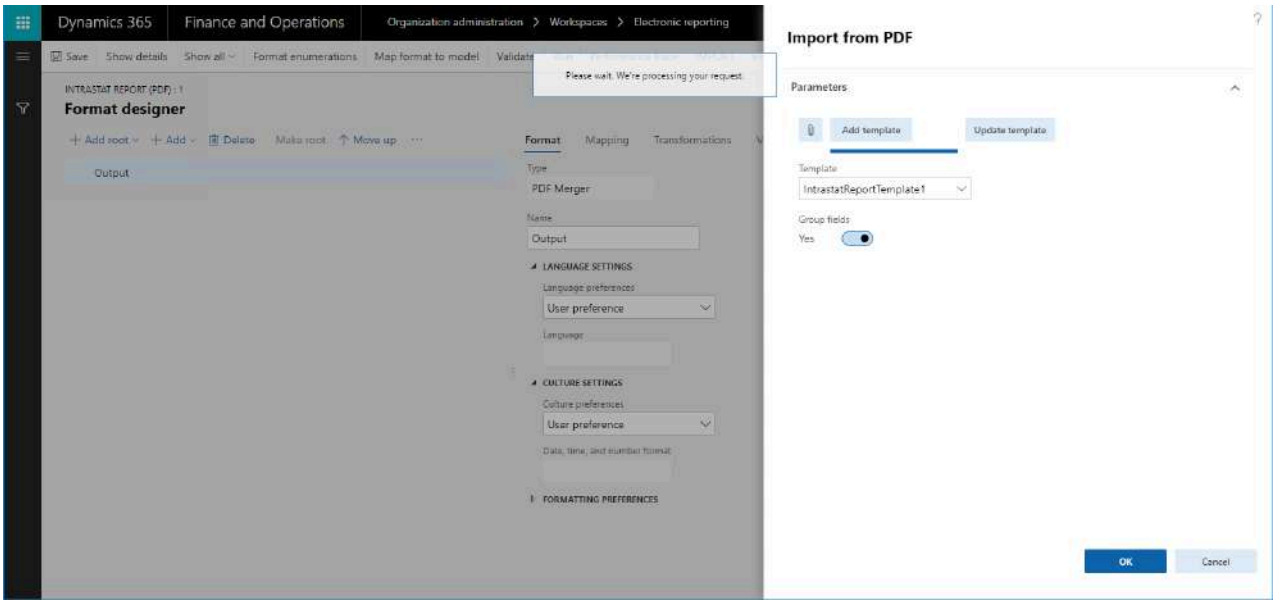
   When you select the **PDF Merger** element as the root element of the format, all PDF documents that are generated at run time are merged into a single final PDF document. If you need only one PDF template to generate all the required documents by using the ER format that you design, select **PDF file** as the root element.
4. In the **Name** field, enter **Output**.

5. In the **Language preferences** field, select **User preference**. The report is generated in the preferred language of the user who runs it.
6. In the **Culture preferences** field, select **User preference**. Values and dates that are presented on the pages of the report are formatted based on the preferred locale of the user who runs the report.
7. Select **OK**.
8. On the Action Pane, on the **Import** tab, select **Import from PDF**.

   When you import a fillable PDF document as a template for this ER format, the system automatically creates all the required ER format elements (**PDF file**, **Field group**, and **Field** elements) in the format that you design, based on the structure of the PDF document that you import.
9. Select **Browse**. Go to and select the **IntrastatReportTemplate1.pdf** file that you downloaded earlier as a prerequisite.
10. Select **OK**.

    The selected file is loaded, and the **Template** field in the **Import from PDF** dialog box is filled in.
11. Set the **Group fields** option to **Yes**. If the selected PDF document contains any field groups, the system uses them to group the ER format elements that it creates. The system creates a **Field group** format element for this purpose.

    If you set this option to **No**, the system creates the required ER format elements as a flat list of elements that are nested under the **PDF File** format element that it creates.
12. Select **OK**.



13. In the tree, expand **Output**.

    The **PDF File** component is automatically created to manage the creation of the first page of the report that is generated at run time.

14. In the tree, expand **Output** > **PDF File**.

    The structured list of format elements is automatically created in this ER format, based on the structure of the fillable PDF document that you imported earlier.

15. In the tree, select **Output** > **PDF File**.

16. In the **Name** field, enter **Page 1**.

    This format element generates the first page of the **Intrastat control** report. That page shows a summary of the report and details of foreign trade transactions.

    If you leave the **Language preferences** field blank, the **Language preferences** setting of the parent **PDF Merger** element determines the language of the report that is generated by using this format element. You can select another value to override the setting of the parent element.

    If you leave the **Culture preferences** field blank, the **Culture preferences** setting of the parent **PDF Merger** element determines the locale of the report that is generated by using this format element. The locale determines the format of values and dates on the pages of the report. You can select another value to override the setting of the parent element.

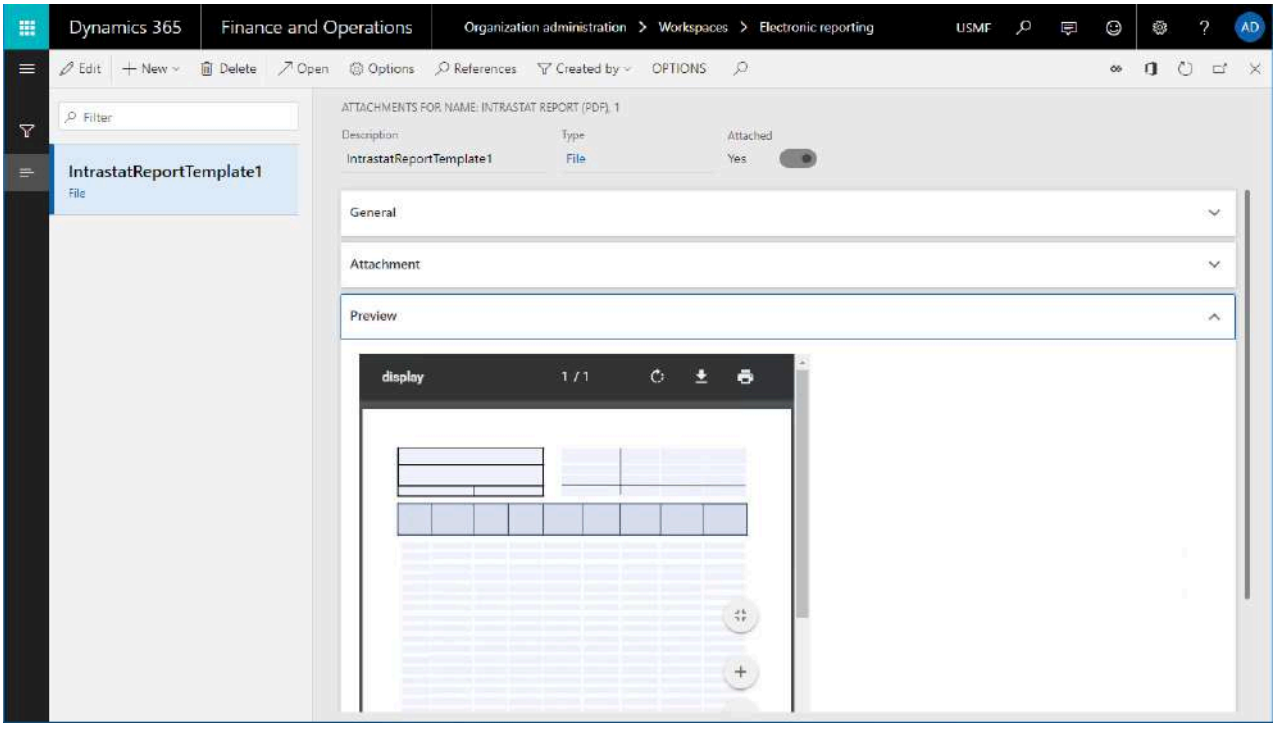
17. On the Action Pane, select the **Import** tab. Notice that the **Update from PDF** button is available for selected format element, **PDF File**.

    Use this button to import the updated PDF template to the edited format. When you import the updated PDF template, the list of format elements changes accordingly:

    - For any new fields in the updated PDF template, the system creates new format elements in the edited ER format.
    - If the updated PDF template no longer includes fields that correspond to any existing format elements in the edited ER format, the system deletes those format elements from the ER format.

18. On the **Format** tab, select **Attachments**.

    The imported PDF document is attached to the edited ER format.



19. Continue to design this format by importing the second PDF template, adding necessary bindings to data sources, and so on.

20. Select **Save**.

21. Close the page.

22. Select **Delete**.

23. Select **Yes**.

To learn how new **PDF Merger**, **PDF File**, **Field group**, and **Field** format elements can be used to generate documents in PDF format, import and analyze the sample ER format.

Import the format configuration

Next, import the sample ER format that you previously downloaded to generate the **Intrastat control** report in PDF format. The first page of the report shows a summary of the report and details of the foreign trade transactions that are reported on. The other pages show only details of the foreign trade transactions that are reported on.

1. On **Configurations**, select **Exchange** > **Load from XML file**.
2. Select **Browse**. Go to and select the **Intrastat report (PDF).version.1.1.xml** file that you downloaded earlier as a prerequisite.
3. Select **OK**.

Analyze the format configuration

Format layout

1. On **Configurations**, in the tree, select **Intrastat model** > **Intrastat report (PDF)**.
2. Select **Designer**.
3. Select **Show details**.
4. In the tree, expand **Output: PDF Merger**.

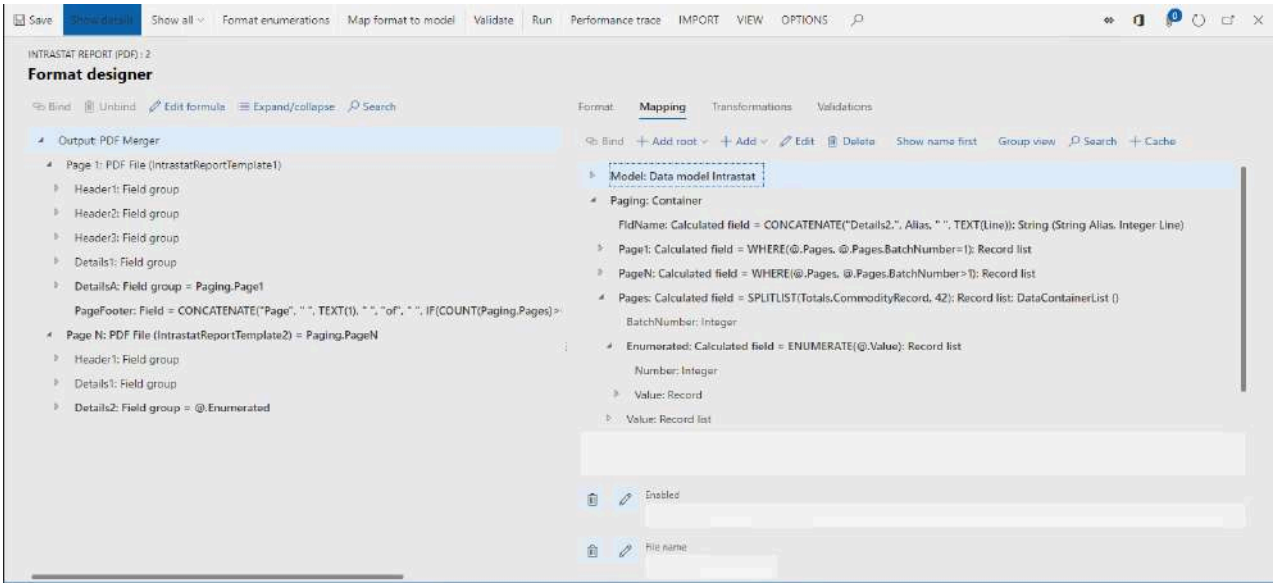
   This ER format contains two **PDF File** elements, each of which uses a different PDF template. One template generates the first page of the report in PDF format, and the other template generates the other pages.
5. In the tree, expand **Output: PDF Merger** > **Page 1: PDF File (IntrastatReportTemplate1)**.
6. In the tree, expand **Output: PDF Merger** > **Page N: PDF File (IntrastatReportTemplate2)**.

   Because the content of the two PDF templates differs, the structure of the nested format elements for the two **PDF File** elements also differs.

Format mapping

1. On **Format designer**, select the **Mapping** tab.

2. In the tree, expand **Paging** > **Pages**.



Note the following details:

- The **Output** > **Page 1** format element of the **PDF File** type isn't bound to any data source, and the **Enabled** expression of this format element is empty. Therefore, at run time, the **IntrastatReportTemplate1** PDF template is filled in only one time when an individual PDF document is generated.

- The **Output** > **Page N** format element of the **PDF File** type is bound to the **Paging.PageN** data source of the **Record list** type, and the **Enabled** expression of this format element is empty. Therefore, at run time, the **IntrastatReportTemplate2** PDF template is filled in for each record from the bound record list when an individual PDF document is generated.

- Because the **Page 1: PDF File** and **Page N: PDF File** format elements are children of the **Output: PDF Merger** format element, all PDF documents that are filled in are merged into a single final PDF document.

- The **Paging.Page1** and **Paging.PageN** data sources are configured as filters of records from the **Paging.Pages** data source. This data source is configured to split the whole set of foreign trade transactions into batches. Each batch contains up to 42 records. The following ER expression is used to split the transactions into batches:

  SPLITLIST(Totals.CommodityRecord,42)

- The **Paging.Pages** data source contains the **Paging.Pages.Enumerated** element that returns the details of each record that is included in a batch. These details include

the record's sequence in the current batch (the **Paging.Pages.Enumerated.Number** field). The **Paging.Pages.Enumerated.Number** field is used in the **Name** expression of **PDF Field** format elements to dynamically generate a field name that is based on the transaction number in a batch. The field name that is generated is then used to fill in the correct PDF field in the PDF template that is used.

- The **Output** > **Page N** > **Details 2** format element of the **PDF Group** type is bound to the **Paging.PageN.Enumerated** data source (or **@.Enumerated** if the **Relative path** view mode is used) of the **Record list** type. Therefore, at run time, the nested elements of this PDF group are filled in for each record from the bound record list. In this way, individual PDF lines are virtually generated when for each Nth of 42 records of the **Paging.PageN.Enumerated** list the following PDF fields are filled in: Date N, Direction N, Commodity N, and so on. Therefore, in this respect, the behavior of this **Field group** format element resembles the behavior of the **XML** > **Sequence** and **Text** > **Sequence** format elements.

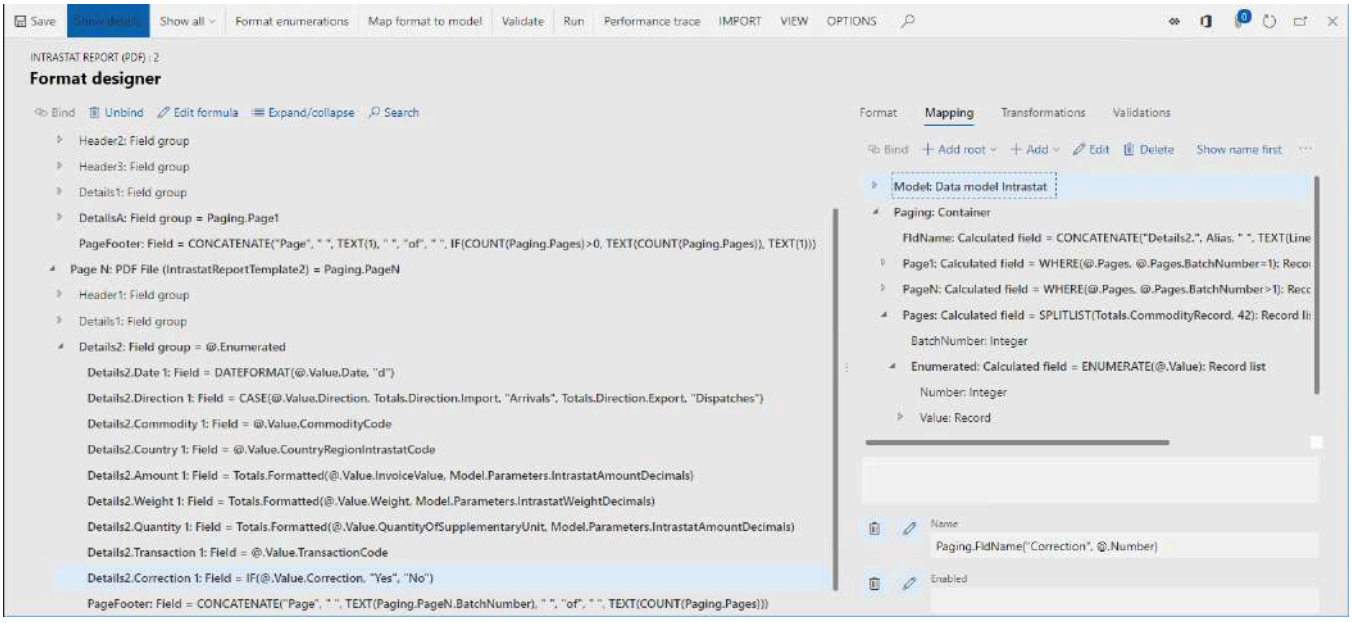
3. In the tree, expand **Output** > **Page N** > **Details2**.

4. In the tree, select **Output** > **Page N** > **Details2** > **PageFooter**.

   Notice that the **Name** attribute of this format element is defined as **PageFooter**. Also notice that the **Name** expression of the format element is empty.

5. In the tree, select **Output** > **Page N** > **Details2** > **Correction 1**.

   Notice that the **Name** attribute of this format element is defined as **Correction 1**. Also notice that the **Name** expression is defined as **Paging.FldName("Correction",@.Number)**.



Note that the **Field** format element is used to fill in an individual field of a fillable PDF document that is defined as a template of the parent **PDF File** format element. The binding of the **PDF File** format element or its nested elements, if it has any nested elements, specifies the value that is entered in corresponding PDF fields. Different properties of the **Field** format element can be used to specify which PDF field is filled in by an individual format element:

- On the **Format** tab, the **Name** attribute of the format element
- On the **Mapping** tab, the **Name** expression of the format element

Because both properties are optional for a **Field** format element, the following rules are applied to specify the target PDF field:

- If the **Name** attribute is blank, and the **Name** expression returns an empty string at run time, an exception is thrown at run time to notify the user that a PDF field can't be found in the PDF template that is being used to fill in the PDF document.
- If the **Name** attribute is defined, and the **Name** expression is blank, the PDF field that has the same name as the **Name** attribute of the format element is filled in.
- If the **Name** attribute is defined, and the **Name** expression is configured, the PDF field that has the same name as the value that is returned by the **Name** expression of the format element is filled in.

> ⓘ **Note**
>
> When a checkbox in the PDF template doesn't belong to a group of checkboxes, it's represented in the editable ER format as a **Field** element that is nested under the **PDF File** element. This type of PDF checkbox can be set as selected in the following ways:
>
> - The corresponding **Field** format element is bound to a data source field of the ***Boolean*** data type that has a value of **True**.
> - The corresponding **Field** format element contains a nested **String** format element that is bound to a data source field that has a text value of **1**, **True**, or **Yes**.
>
> Your template can contain a group of checkboxes where only one checkbox can be selected at a time. Those checkboxes are represented in a PDF template as multiple form fields of the *CHECKBOX* type. Each field has the same name but a different export value. When you import the template into the editable ER format, each checkbox is represented in the format hierarchical structure as a **Check box group item** element that is nested under the same **Check box group** element. The name of the **Check box group** element equals the name of the checkbox fields in the PDF template. The name of each **Check box**

group item element equals the export value of the corresponding checkbox field in the PDF template.

You can bind a **Check box group item** element to a data source field of the *Boolean* data type only.

Run the format configuration

Import the format configuration

Next, load the **Intrastat (import from Excel)** sample ER format. This format is designed to parse a user-selected Microsoft Excel workbook that simulates foreign trade transactions.

1. On **Configurations**, select **Exchange** > **Load from XML file**.
2. Select **Browse**. Go to and select the **Intrastat (import from Excel).version.1.1.xml** file that you downloaded earlier as a prerequisite.
3. Select **OK**.
4. In the tree, select **Intrastat model** > **Intrastat (import from Excel)**.
5. Select **Edit**.
6. Set the **Default for model mapping** option to **Yes**.

   > ⓘ **Note**
   >
   > If you previously set the **Default for model mapping** option to **Yes** for the **Intrastat model** configuration or another configuration that is nested under the **Intrastat model** configuration, set this option to **No**.

   When you set the **Default for model mapping** option to **Yes**, the imported **Intrastat (import from Excel)** ER format becomes the default data source for the **Intrastat report (PDF)** format configuration. Then, when you run the **Intrastat report (PDF)** format configuration, the content of the Excel workbook that the **Intrastat (import from Excel)** ER format parses simulates foreign trade transactions that you must report. The following illustration shows an example of an Excel workbook.

	A	B	C	D	E	F	G	H	I	J	K	L	M	N	O	P

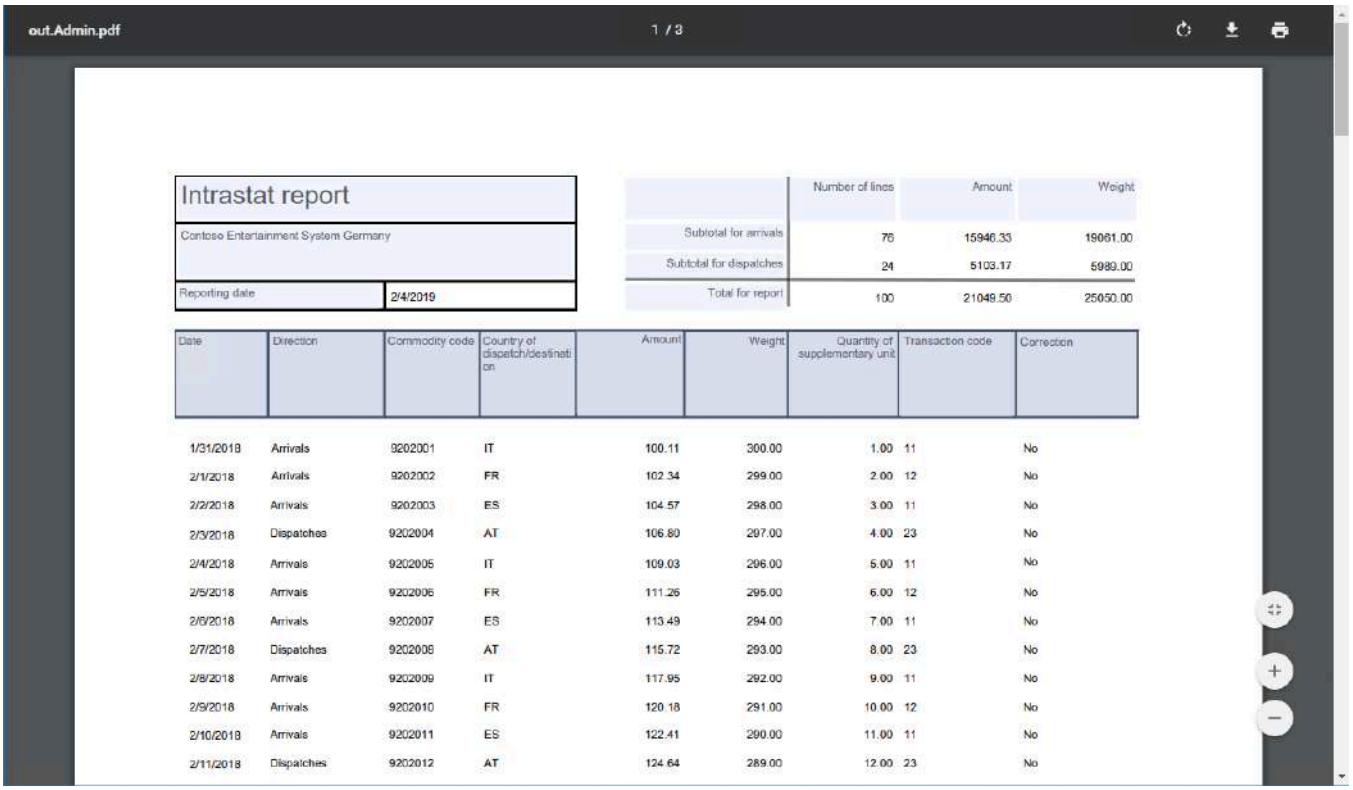
28	9202028	FALSE	2/27/2018	Export	AT	IT	160.32	GRM	28	Notebook	160.00	160.00	23	5	273	
29	9202029	FALSE	2/28/2018	Import	IT	DE	162.55	GRM	29	Speaker	163.00	163.00	11	2	272	

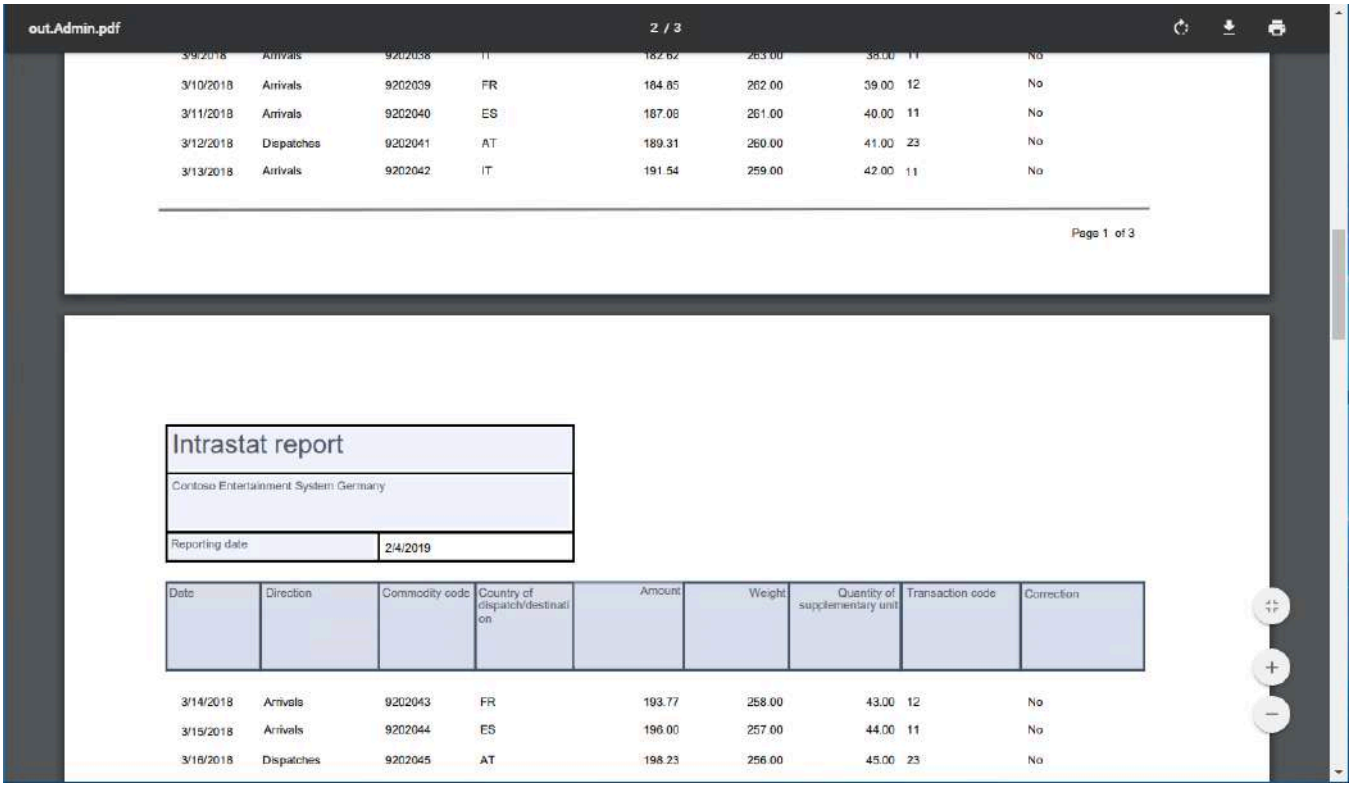
Run the format configuration

1. On **Configurations**, in the tree, select **Intrastat model** > **Intrastat report (PDF)**.
2. Select **Run**.
3. Select **Browse**. Go to the **Intrastat sample data.xlsx** file that you downloaded earlier as a prerequisite, and select it.
4. Select **OK**.
5. In the **Report direction** field, select **Both** to include all transactions from the imported Excel workbook in the generated PDF report.
6. Select **OK**.
7. Review the generated PDF document.

The following illustration shows an example of the first page of the generated report.



The following illustration shows an example of another page of the generated report.



Limitations

The names of fillable fields need to be unique in the PDF form that you plan to use as a report template. When you import a PDF form, the editable ER format creates an individual format element with the corresponding name for every such field. If a PDF form contains several fields

with the same name, the import process creates a single format element for those fields. This single format element doesn't allow you to fill in the fields individually at runtime.

Frequently asked questions

When I run the ER format to generate a report in PDF format, why do I get the following errors: Cannot handle iref streams. The current implementation of PDFSharp cannot handle this PDF feature introduced with Acrobat 6. and A PDF name must start with a slash (/).

The ER framework uses version 1.5 of the PDFSharp library to generate these PDF reports. Some features of PDF 1.5 (Adobe Reader 6.0) aren't yet implemented in this library. Therefore, PDFSharp can't yet open some files that are marked as **for PDF 1.5 or higher** and can result in the errors received. Use one of the following solutions to resolve the issue:

- When you use your own PDF template: Downgrade the template to an earlier Adobe version and start using a new template in your ER format.
- When you use an ER format template that another configuration provider shared with you as part of an ER solution: Contact the owner of this ER solution and provide a description of the issue.
- When you use the ISV solution that contains an earlier version of the PDFSharp library: Contact the owner of the solution and suggest an upgrade to the newer PDFSharp version.

Embed images and shapes in documents that you generate by using ER

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can use the Electronic reporting (ER) tool to design reports that you can run to generate required electronic documents. Use Microsoft Excel or Microsoft Word documents to specify the layout of a report. The ER Operations designer lets you attach the Excel or Word document as a template for the report. The named elements in the attached template are associated with the format elements of the ER report. Format elements of the report are bound to data sources. These elements specify the data that will be entered, at runtime, in the documents that are generated.

This new functionality goes beyond existing ER capabilities for creating documents in Microsoft Office formats. For more information, see the following task guides. You can find these task guides under the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process.

- ER Design a configuration for generating reports in OPENXML format
- ER Design a configuration for generating reports in Microsoft WORD format

Embed an image in an Excel document

Embed an image in an Excel worksheet

First, add a placeholder for the image in an Excel document. Open an Excel workbook, and add a picture as a placeholder for the image that you add later. Then use the ER tool to add a new ER format configuration to include the report that you're designing. Attach the Excel workbook as a template for the format of the report, and then import the content of the workbook into the ER format. The format definition is created automatically. The image placeholder that you added is included in the ER format definition as a **CELL** element.

> **Note**

You can manually specify the format definition instead of importing it. When you save your changes, the format is validated.

Next, bind the **CELL** element of the ER format to the field from the format's data source that provides the picture's data in binary format at runtime. When an ER data model is used as a format's data source, the data type of the field must be Container. Currently, an ER data model field that has the Container data type can be bound to several types of data sources that return images in binary format. You can access a field in a data table and a file that is attached to the data table's record by using the Document management framework.

Important

- To fill the image placeholder in the document that you're creating by using the Excel template, the ER format must contain the **CELL** element that refers to the named picture element in the Excel template. Otherwise, no image placeholder appears in the report's output. If the binding of a **CELL** element returns no data at runtime, the generated document shows the image placeholder from the template. To hide an image in the document that you're generating, define a **CELL** element, and specify that the **Enabling** expression returns **FALSE**.
- In the Excel template, use a unique name for every element. These elements include pictures and cells. If you duplicate an element name, the content of the generated report is ambiguous and confusing.

Embed images in the header and footer of an Excel worksheet

Use the Excel workbook document as a template to specify the layout of a report. The workbook can contain multiple worksheets, each of which can be designed to have a header and a footer. Excel supports up to three images in the header and footer of every worksheet. The images can be aligned to the left, right, or center.

In Finance release 10.0.21, you can manage the header and footer images generated by an ER solution that has an Excel template.

If you want a default picture to appear in the header or footer of a generated document, add an image to the header or footer of a worksheet of an ER template. To access this image in your ER format, add the **Picture** component under the Header or Footer component of the format. Configure the alignment of the **Picture** component as appropriate.

You can also use the **Picture** component to put an image into the header or footer of a generated document at runtime, even if the template contains no default image. To specify the media content that you want to put into the header or footer of a generated document as either a new image or a replacement for a default image, bind the **Picture** component to a data source of the Container type that represents an image in binary format.

Every **Header** or **Footer** component can hold one **Picture** component for each supported alignment: **Left**, **Center**, and **Right**.

The **Scale the height** property of the **Picture** component lets you use the configured binding to control the size of an image:

- Select **Original** to keep the initial size of the image.
- Select **Relative** to scale the height of the image in proportion to the height of the header or footer that holds that image.
  - In this case, define the height of the image as a percentage of the parent header or footer.
  - If the scaling value exceeds 100 percent, the image might overlap the data area of the corresponding worksheet.
  - If the scaling changes the height of the image, the width also changes to maintain the image's original aspect ratio.
- Select **Absolute** to resize the image according to the height and width values (in pixels) provided at design time.
  - If the specified height exceeds the height of the parent header or footer, the image might overlap the data area of the corresponding worksheet.

You can also use the **Enabled** property of the **Picture** component to control the visibility of an image that you put into a generated document by using this component.

> ⓘ **Note**
>
> You must use the ER format designer to add a **Picture** component to the editable ER format. You can't add the component when you use the Business document management workspace to edit the template of a business document.

To learn more about this functionality, see Design an ER format to generate a report in Excel format with embedded images in page headers or footers.

Embed a shape in an Excel document

First, add a placeholder for the shape in an Excel document. Open an Excel workbook, and select **Shape**, **Text box**, or **WordArt** as a placeholder for the shape. Then use the ER tool to add a new ER format configuration to include the report that you're designing. Attach the Excel workbook as a template for the format of the report, and then import the content of the workbook into the ER format. The format definition is created automatically. The shape placeholder that you added is included in the ER format definition as a **CELL** element that refers to the named Excel shape element.

> ⓘ **Note**
>
> You can manually specify the format definition instead of importing it. When you save your changes, the format is validated.

Next, bind the **CELL** element in the ER format to the field from the format's data source that provides the data at runtime. You can convert this data to a text string. When the **CELL** element in the ER format refers to a shape element in the Excel template that supports text, the text provided through this binding at runtime appears in a shape in the generated document.

> ⓘ **Important**
>
> - To use the Excel template that includes the shape placeholder to generate a new document, the ER format must contain a **CELL** element that refers to the Excel shape element. Otherwise, no shape placeholder appears in the report's output. If the binding of a **CELL** element that refers to the named Excel shape element returns no data at runtime, the generated document shows the text of the shape placeholder from the Excel template. To hide a shape in the generated document, define a **CELL** element that refers to the named Excel shape element, and specify that the **Enabling** expression returns **FALSE**.
> - In the Excel template, use a unique name for every element. These elements include shapes and cells. If you duplicate an element name, the content of the generated report is ambiguous and confusing.

Embed an image in a Word document

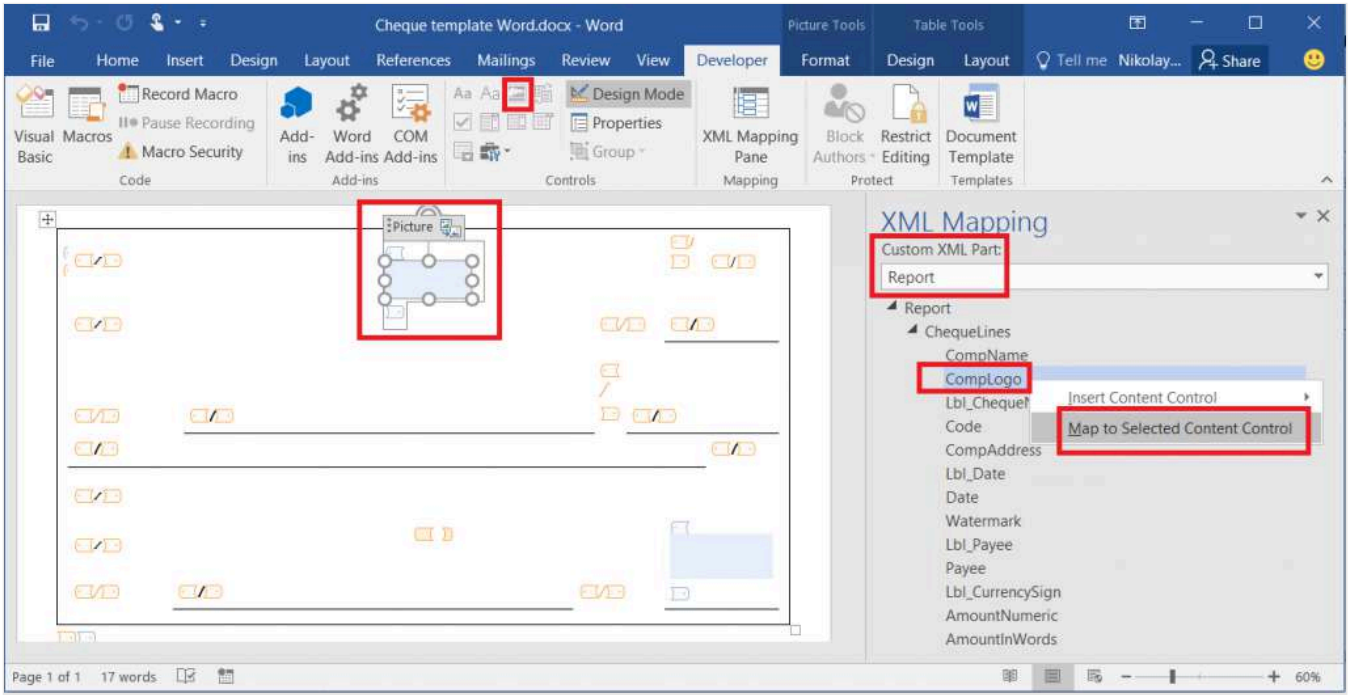
> ⓘ **Important**
>
> You can reuse the ER format that uses an Excel template to create documents that include embedded images. In the ER format, make sure that a name is specified for the **CELL**

element that refers to a named picture element in Excel, and that is bound to a data source that returns a picture at runtime.

First, configure the Word document's layout. Use the **Picture Content** control to create a placeholder for the embedded image. To access this control, you must first make the **Developer** tab visible on the Word Ribbon.

Next, delete the Excel template from the ER format, and attach the Word template document. Update the reference to the template, and save your changes. The structure of the current ER format is saved to the Word template as a new custom XML part that is named **Report**.

Next, save the Word template for the current ER format to your local computer. Open the template, and open the **XML Mapping** pane. Find the custom XML part that is named **Report**, and then point to the **CELL** element in the ER report that is bound to a data source that returns an image in binary format. Map this XML part's item to the selected **Picture Content** control, and save your changes.



Finally, delete the Word template from the ER format, and attach the Word document that includes the mapped custom XML parts. Update the format reference to the template, and save the changes that you made to this ER format.

More information

To learn more about this feature, play the set of task guides, **ER Make reports in MS Office formats with embedded images**. These task guides show how you can embed the images of a company logo and an authorized person's signature in the payment checks that the ER tool generates in Excel and Word documents.

The following table lists the files that you need to complete the **ER Make reports in MS Office formats with embedded images** task guides. Download and save the files to your local computer.

Expand table

Description	File name
ER data model configuration	Model for cheques.xml
ER format configuration	Cheques printing format.xml
Company logo image	Company logo.png
Signature image	Signature image.png
Alternative signature image	Signature image 2.png
Microsoft Word template for printing payment checks	Cheque template Word.docx
Microsoft Excel template for printing payment checks	Cheque template.xlsx

The following graphic provides an example of the test printout for a payment check that is generated from the Excel template.

Design configurations to generate reports in Office format that have embedded images

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To complete the steps in this procedure, first complete the procedure, "ER Create a configuration provider and mark it as active." This procedure explains how to design Electronic reporting (ER) configurations to generate a Microsoft Excel or Word document that contains embedded images. In this procedure, you create the required ER configurations for the sample company, Litware, Inc. You can complete these steps by using the USMF dataset. This procedure is created for users with the assigned role of system administrator or electronic reporting developer. Before you begin, download and save the following files:

Expand table

Description	File name
ER data model configuration	Model for cheques.xml
ER format configuration	Cheques printing format.xml
Company logo image	Company logo.png
Signature image	Signature image.png
Alternative signature image	Signature image 2.png
Microsoft Word template for printing payment checks	Cheque template Word.docx

Verify prerequisites

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure, "Create a configuration provider and mark it as active."
3. Select **Reporting configurations**.

Add a new ER model configuration

1. Instead of creating a new model, load the ER model configuration file (`Model for cheques.xml`) that you saved earlier. This file contains the sample data model for payment cheques and the mapping of the data model to the data components of the Dynamics 365 for Operations application.
2. On the **Versions** FastTab, click **Exchange**.
3. Click **Load from XML file**.
4. Click **Browse**, and then select `Model for cheques.xml`.
5. Click **OK**.
6. Use the loaded model as a data source of information to generate documents that contain images in Excel and Word.

Add a new ER format configuration

1. Instead of creating a new format, load the ER format configuration file (`Cheques printing format.xml`) that you saved earlier. This file contains the sample layout of the format to print cheques using the pre-printed form and the mapping of this format to the **Model for cheques** data model.
2. Click **Exchange**.
3. Click **Load from XML file**.
4. Click **Browse** and select the `Cheques printing format.xml` file.
5. Click **OK**.
6. In the tree, expand **Model for cheques**.
7. In the tree, select **Model for cheques\Cheques printing format**.
8. Use the loaded format to generate documents that contain images in Excel and Word.

Configure ER user parameters

1. On the Action Pane, click **Configurations**.
2. Click **User parameters**.
3. Select **Yes** in the **Run settings** field.
   Turn on the **Run draft** flag to start the draft version of the selected format instead of the

completed one.
4. Click **OK**.

Configure Cash and bank management parameters

1. Go to **Cash and bank management** > **Bank accounts** > **Bank accounts**.
2. Use the Quick Filter to filter on the **Bank account** field with a value of `USMF OPER`.
3. On the Action Pane, select **Set up**.
4. Select **Check**.
5. Expand the **Setup** section.
6. Select **Edit**.
7. Select **Yes** in the **Company logo** field.
8. Select **Company logo**.
9. Select **Change**.
10. Select **Browse** and select the file that you downloaded earlier, **Company logo.png**.
11. Select **Save**.
12. Close the page.
13. Expand the **Signature** section.
14. Select **Yes** in the **Print first signature** field.
15. Select **Change**.
16. Select **Browse** and select the file that you downloaded earlier, **Signature image.png**.
17. Expand the **Copies** section.
18. In the **Watermark** field, select an option.
19. Select **Yes** in the **Generic electronic Export format** field.
20. Select **Cheques printing form** configuration.
21. Now the selected ER format is used for printing cheques.
22. Select **Attach**.
23. Select **New**.
24. Select **File**.
25. Select **Browse** and select the file that you downloaded earlier, **Signature image 2.png**.
26. Close the page.
27. Close the page.
28. Close the page.
29. Go to **Cash and bank management** > **Setup** > **Cash and bank management parameters**.
30. Select **Yes** in the **Allow prenote creation on inactive bank accounts:** field.
31. Select **Save**.
32. Close the page.

Review configurations to generate reports in Office format that have embedded images

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To complete these steps, you must first complete the steps in the "ER Make reports in MS Office formats with embedded images (Part 1: Set up parameters)" task guide.

This procedure shows how to design Electronic reporting (ER) configurations to generate electronic documents that contain embedded images in Microsoft Excel and Microsoft Word. In this example, you review ER configurations for the sample company Litware, Inc.

This procedure is intended for users who have the System administrator or Electronic reporting developer role assigned to them. You can complete the steps by using the USMF data set.

Review the imported data model

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, select **Model for cheques**.
3. Select **Designer**. * This model represents payment cheques from the business standpoint and the mapping of this model to the application's data sources. Review this model by the ER Operations designer. The attributes of the model elements include structure, name, description, data type, and more.
4. In the tree, expand **root**.
5. In the tree, select **root\cheques**.
6. In the tree, expand **root\cheques**.
7. In the tree, expand **root\cheques\attributes**.
8. In the tree, expand **root\payer**.
9. In the tree, select **root\istestrun**.
10. In the tree, select **root\layout**.

    - The layout element of this model represents the details of the printing cheque form layout for the selected bank account. It also includes two nodes of the Container

data type to store images.
11. In the tree, expand **root\layout**.
12. In the tree, select **root\layout\company logo**.
13. In the tree, expand **root\layout\company logo**.
14. In the tree, select **root\layout\company logo\image**.
15. In the tree, select **root\layout\company logo\isprinted**.
16. In the tree, select **root\layout\signature**.
17. In the tree, expand **root\layout\signature**.
18. In the tree, select **root\layout\signature\image**.
19. In the tree, select **root\layout\signature\isprinted**. * Two image data model elements are bound to the fields of the tables that contain images of the company logo and the authorized person's signature in binary format.
20. In the tree, expand **root\layout\watermark**.
21. Select **Map model to datasource**.
22. Select **Designer**.
23. In the tree, expand **chequesselected**.
24. In the tree, expand **layout**.
25. In the tree, expand **layout\company logo**.
26. In the tree, expand **layout\signature**.
27. In the tree, expand **layout\watermark**.
28. Toggle **Show details** on. * The cheques data model element is bound to the TmpChequePrintout table that, at runtime, contains records for cheques that the user selects for printing.
29. Close the page.
30. Close the page.
31. Close the page.

Review the imported format

1. In the tree, expand **Model for cheques**.
2. In the tree, select **Model for cheques\Cheques printing format**.
3. Select **Designer**.
4. Select **Attachments**.
5. Select **Open**.

- Open the attached report's template in Excel.
  - Review the attached report's Excel template that you use to print cheques. The template contains two cheques per page and is designed to print cheques to the preprinted form. Two blank images are embedded. These blank images are for the company logo and the signature of the person who is authorizing a payment.

Verify that the images are named **CompLogo** and **SignatureImage**, respectively, in Excel.

6. Close the page.
7. In the tree, expand **Report**.
8. In the tree, expand **Report\ChequeLines**.
9. In the tree, select **Report\ChequeLines\CompLogo**.
10. Toggle **Show details** on.

    - The **CompLogo** format's cell element represents the Excel item that populates the company logo image in the report. This format element is bound to the image data model element that, at runtime, contains a company logo image in binary format.

11. Select the **Mapping** tab.
12. Select **Edit enabled**. * You can make the **CompLogo** format's cell element so that it's no longer enabled. In this case, the associated Excel image element hides a company logo in the generated report. If the enabled expression returns **TRUE** and the defined binding brings no image, the associated Excel image element shows an image saved in the Excel template.
13. Close the page.
14. In the tree, expand **labels: Container**. * Some labels presented in the preprinted cheque form are included in the report when you create it for testing purposes. However, the preprinted form already includes these labels, so the labels don't print during real printing.
15. Close the page.

Last updated on 03/17/2026

Generate reports in Office format that have embedded images

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user playing either 'System administrator' or 'Electronic reporting developer' role can design Electronic reporting (ER) configurations to generate electronic documents in MS office formats (Excel and Word) containing embedded images.

In this example, you use the created ER configurations for sample company, 'Litware, Inc.'. To complete these steps, you must first complete the steps in the "ER Make reports in MS Office formats with embedded images (Part 2: Review configurations)" task guide. You can perform these steps in 'USMF' company.

Run format with initial model mapping

1. Go to **Cash and bank management** > **Bank accounts** > **Bank accounts**.
2. Use the Quick Filter to filter on the Bank account field with a value of **USMF OPER**.
3. On the Action Pane, select **Set up**.
4. Select **Check**.
5. Select **Print test**.

    - Run the format for testing purposes.

6. Select **Yes** in the Negotiable check format field.
7. Select **OK**.

    - Review the created output. The company logo is presented in the report as well as the authorized person's signature. The signature image is taken from the field of the 'Container' data type of the cheque layout record that is associated with the selected bank account.

8. Expand the Copies section.
9. Select **Edit**.
10. In the Watermark field, enter **Print watermark as Void**.

- Change the watermark layout setting to show the watermark text in generating document in an Excel shape element.

11. Select **Print test**.
12. Select **OK**.

    - Review the created output. The watermark is shown in the created report in accordance to the selection option.

13. Close the page.
14. On the Action Pane, select **Manage payments**.
15. Select **Checks**.
16. Select **Show filters**.
17. Apply the following filters: Enter a filter value of "381","385","389" on the "Check number" field using the "is one of" filter operator.
18. In the list, mark all rows.
19. Select **Print check copy**.

    - Run the format to reprint the selected cheques.
    - Review the created output. The selected cheques are reprinted. The company logo and labels don't print out since they appear on the pre-printed form.

Modify the mapping of the imported data model

1. Close the page.
2. Close the page.
3. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
4. In the tree, select *Model for cheques*.
5. Select **Designer**.
6. Select **Map model to datasource**.
7. Select **Designer**. * Change the binding of the data model's signature item to get the signature image from the file that's attached to the cheque layout record associated with the selected bank account.
8. Turn off **Show details**.
9. In the tree, expand *layout*.
10. In the tree, expand *layout\signature*.
11. In the tree, select *layout\signature\image = chequesaccount.'<Relations'.BankChequeLayout.Signature1Bmp'*.
12. In the tree, expand *chequesaccount*.
13. In the tree, expand *chequesaccount.'<Relations'*.
14. In the tree, expand *chequesaccount.'<Relations'.BankChequeLayout'*.
15. In the tree, expand *chequesaccount.'<Relations'.BankChequeLayout.'<Relations'*.

16. In the tree, expand *chequesaccount.'<Relations'.BankChequeLayout.'<Relations'.<Documents'*.
17. In the tree, select *chequesaccount.'<Relations'.BankChequeLayout.'<Relations'.<Documents.getFileContentAsContainer()*.
18. Select **Bind**.
19. Select **Save**.
20. Close the page.
21. Close the page.
22. Close the page.
23. Close the page.

Run format using the adjusted model mapping

1. Go to **Cash and bank management** > **Bank accounts** > **Bank accounts**.
2. Use the Quick Filter to find records. For example, filter on the **Bank account** field with a value of `USMF OPER`.
3. On the Action Pane, select **Set up**.
4. Select **Check**.
5. Select **Print test**.
6. Select **OK**.

    - Review the created output. The image from the Document Management attachment is presented as the signature of an authorized person.

Use MS Word document as a template in the imported format

1. Close the page.
2. Close the page.
3. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
4. In the tree, expand *Model for cheques*.
5. In the tree, select *Model for cheques\Cheques printing format*.
6. Select **Designer**.
7. Select **Attachments**.
8. Select **Delete**.
9. Select **Yes**.
10. Select **New**.
11. Select **File**.

    - Select **Browse** and select the downloaded in advance *Cheque template Word.docx* file.
12. Close the page.
13. In the **Template** field, enter or select a value.
14. Select **Save**.
15. Close the page.
16. Select **Edit**.
17. Select **Yes** in the **Run Draft** field.
18. Close the page.
19. Go to **Cash and bank management** > **Bank accounts** > **Bank accounts**.
20. Use the **Quick Filter** to filter on the **Bank account** field with a value of *USMF OPER*.
21. Select **Check**.
22. Select **Print test**.
23. Select **OK**.

    - Review the created output. The output is generated as a Word document with embedded images presenting the company logo, the signature of an authorized person, and the selected text of the watermark.

Design an ER format to generate a report in Excel format with embedded images in page headers or footers

This article explains how a user in the System Administrator or Electronic Reporting Functional Consultant role can perform these tasks:

- Configure parameters for the Electronic reporting (ER) framework.
- Import ER configurations that Microsoft provides and are used to generate free text invoices, based on a template in Microsoft Excel format.
- Create a custom (derived) version of a standard ER format configuration that Microsoft provides.
- Modify the custom ER format configuration so that it generates a free text invoice report that has a company logo image in the footer.

You can complete the procedures in this article in the **USMF** company. No coding is required. Before you begin, download and save the following file.

Expand table

Description	File name
Company logo image	Company logo.png

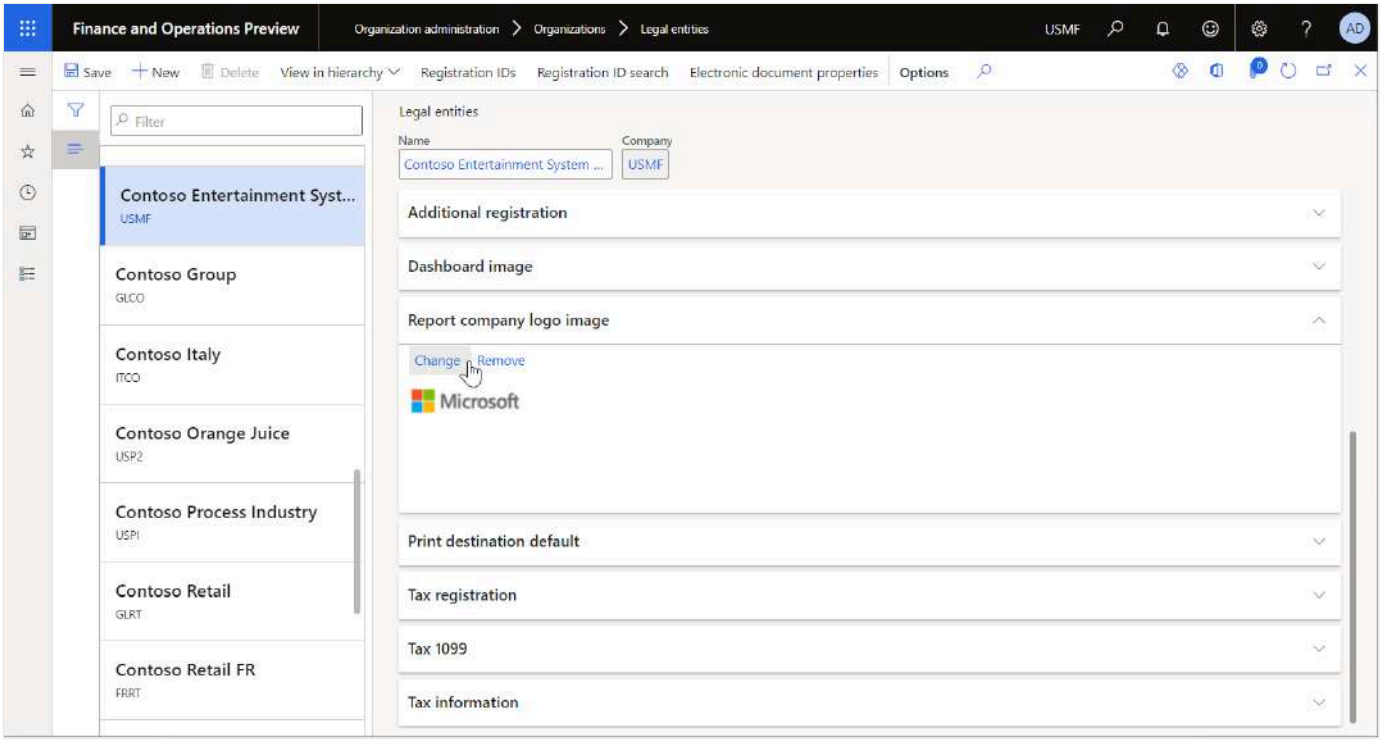
Content

- Configure the legal entity
- Configure the ER framework
  - Configure ER parameters
  - Activate an ER configuration provider
    - Review the list of ER configuration providers
    - Add a new ER configuration provider
    - Activate the new ER configuration provider
- Import the standard ER format configurations

    - Import the standard ER configurations
    - Review the imported ER configurations
- Print a free text invoice by using the standard ER format
    - Set up print management
    - Print a free text invoice
- Customize the standard ER format
    - Create a custom format
    - Edit the custom format
    - Mark the custom format as runnable
- Print a free text invoice by using the custom ER format
    - Set up print management
    - Print a free text invoice
- Additional resources

Configure the legal entity

1. Go to **Organization administration** > **Organizations** > **Legal entities**.
2. On **Legal entities**, on the **Report company logo image** FastTab, select **Change**.
3. In **Select image file to upload**, select **Browse**, and select the **Company logo.png** file that you downloaded earlier.
4. Select **Save**, and then close **Legal entities**.



Configure the ER framework

As a user in the Electronic Reporting Functional Consultant role, you must configure the minimal set of ER parameters before you can start to use the ER framework to design a custom version of a standard ER format.

Configure ER parameters

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Related links** section, select **Electronic reporting parameters**.
3. On **Electronic reporting parameters**, on the **General** tab, set the **Enable design mode** option to **Yes**.
4. On the **Attachments** tab, set the following parameters:
    - In the **Configurations** field, select the **File** type for the **USMF** company.
    - In the **Job archive**, **Temporary**, **Baseline**, and **Others** fields, select the **File** type.

For more information about ER parameters, see Configure the ER framework.

Activate an ER configuration provider

Every ER configuration that you add is marked as owned by an ER configuration provider. Use the ER configuration provider activated in the **Electronic reporting** workspace for this purpose. Therefore, you must activate an ER configuration provider in the **Electronic reporting** workspace before you start to add or edit ER configurations.

> ⓘ **Note**
>
> You can only edit an ER configuration if you are the configuration owner. Before you can edit an ER configuration, you must activate the appropriate ER configuration provider in the **Electronic reporting** workspace.

Review the list of ER configuration providers

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Related links** section, select **Configuration providers**.

3. On **Configuration provider table**, each provider record has a unique name and URL. Review the contents of this page. If a record for **Litware, Inc.** (`https://www.litware.com`) already exists, skip the next procedure, Add a new ER configuration provider.

Add a new ER configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Related links** section, select **Configuration providers**.
3. On **Configuration providers**, select **New**.
4. In the **Name** field, enter **Litware, Inc.**
5. In the **Internet address** field, enter `https://www.litware.com`.
6. Select **Save**.

Activate the new ER configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configuration providers** section, select the **Litware, Inc.** tile, and then select **Set active**.

For more information about ER configuration providers, see Create configuration providers and mark them as active.

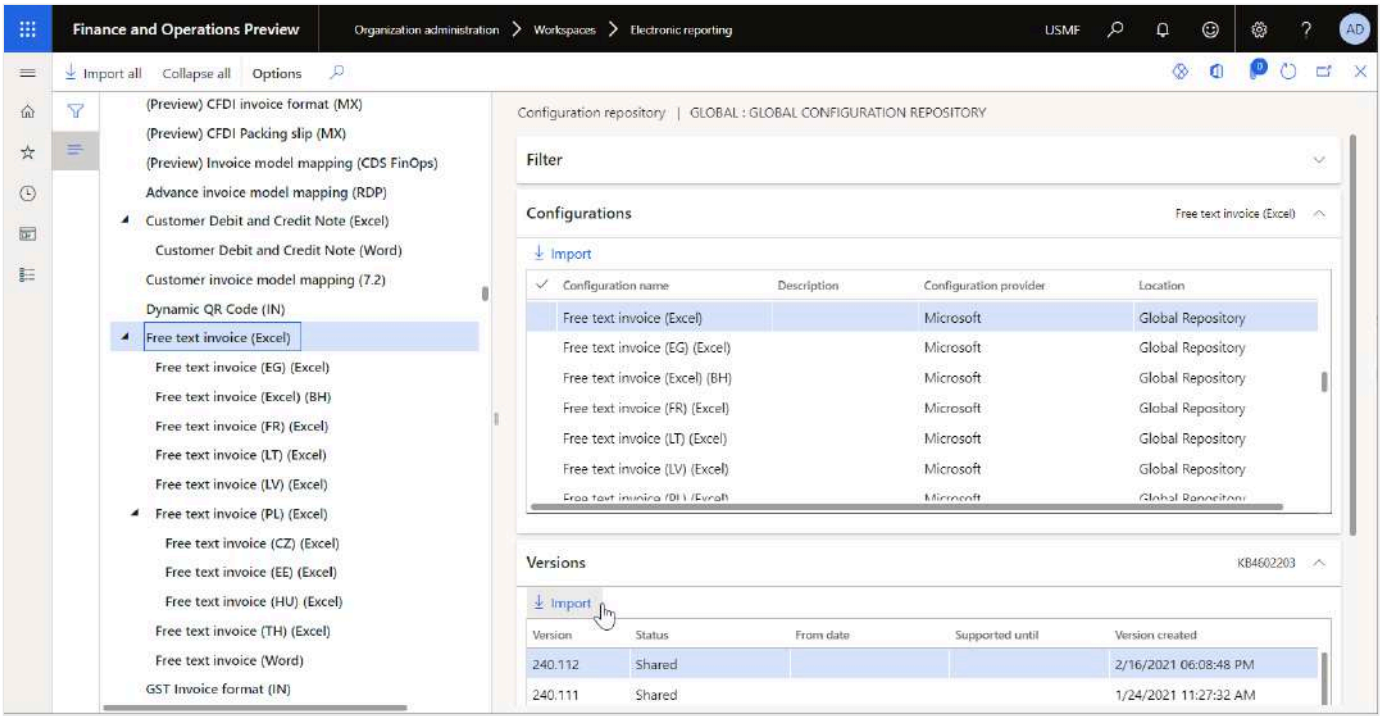
Import the standard ER format configurations

Import the standard ER configurations

To add the standard ER configurations to your current instance of Dynamics 365 Finance, you must import them from the ER repository that was configured for that instance.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configuration providers** section, select the **Microsoft** tile, and then select **Repositories** to view the list of repositories for the **Microsoft** provider.
3. On **Configuration repositories**, select the repository of the **Global** type, and then select **Open**. If you're prompted for authorization to connect to Regulatory Configuration Service, follow the authorization instructions.
4. On **Configuration repository**, in the configuration tree in the left pane, select the **Free text invoice (Excel)** format configuration.
5. On the **Versions** FastTab, select the latest version (for example, **240.112**) of the selected ER format configuration.

6. Select **Import** to download the selected version from the Global repository to the current Finance instance.



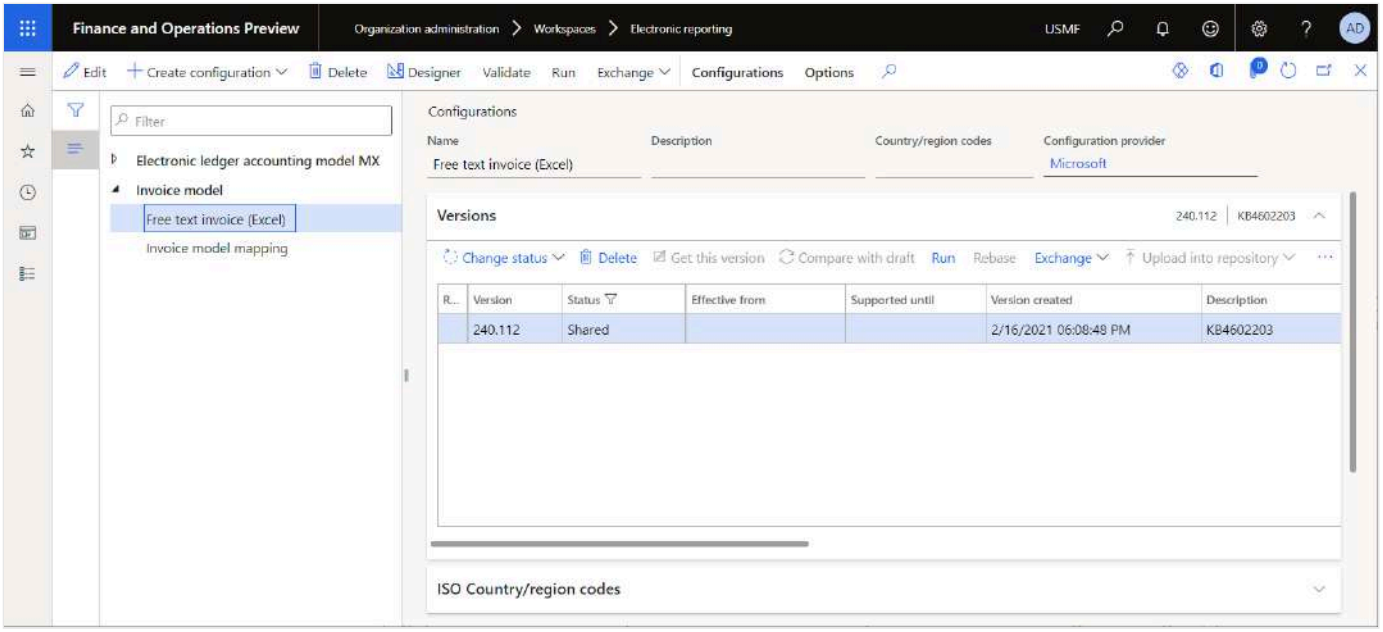
> **Tip**
>
> If you have trouble accessing the Global repository, you can download configurations from Microsoft Dynamics Lifecycle Services (LCS) instead.

Review the imported ER configurations

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configurations** section, select the **Reporting configurations** tile.
3. On **Configurations**, in the configuration tree in the left pane, expand **Invoice model**.
4. In addition to the selected **Free text invoice (Excel)** ER format, other required ER configurations were imported. Make sure that the following ER configurations are available in the configuration tree:
    - **Invoice model** – This configuration contains the data model ER component that represents the data structure of the invoicing business domain.
    - **Invoice model mapping** – This configuration contains the model mapping ER component that describes how the data model is filled in with application data at

runtime.

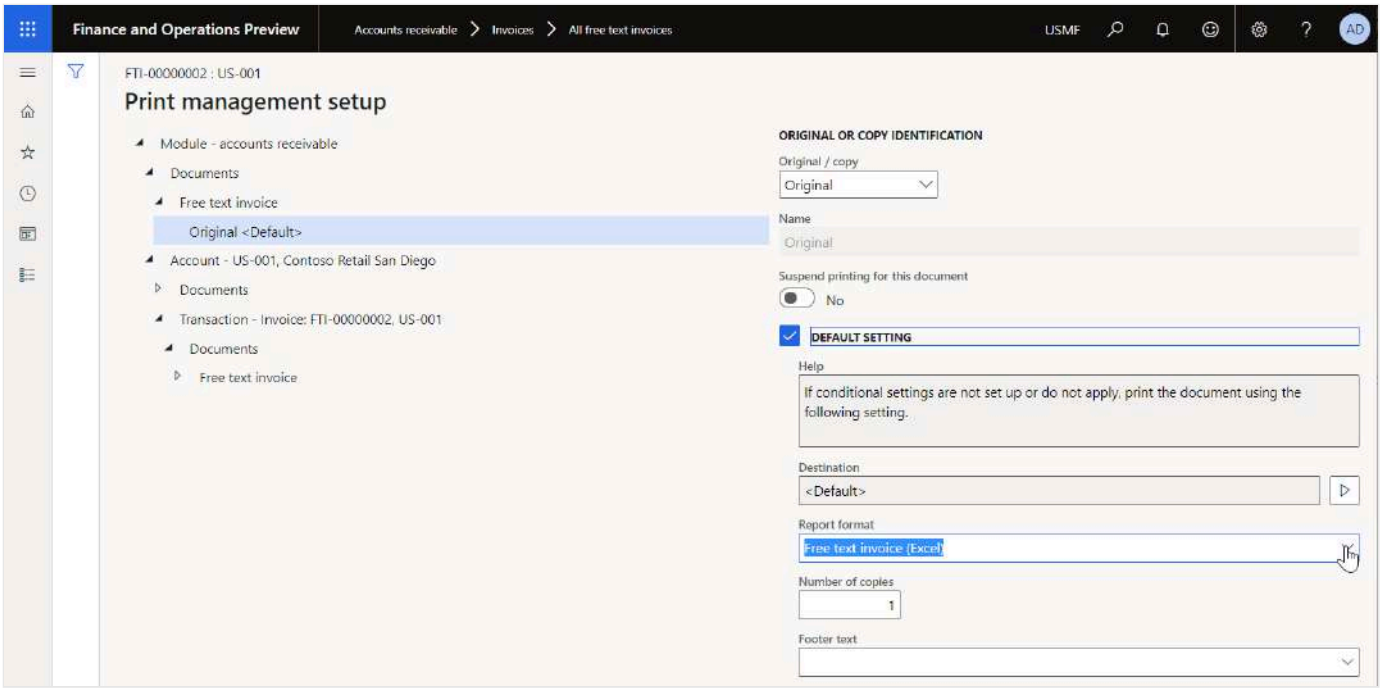
- **Free text invoice (Excel)** – This configuration contains the format and format mapping ER components. The format component specifies the report layout, based on a template in Excel format. The format mapping component contains the model data source and specifies how this data source is used to fill in the report layout at runtime.



Print a free text invoice by using the standard ER format

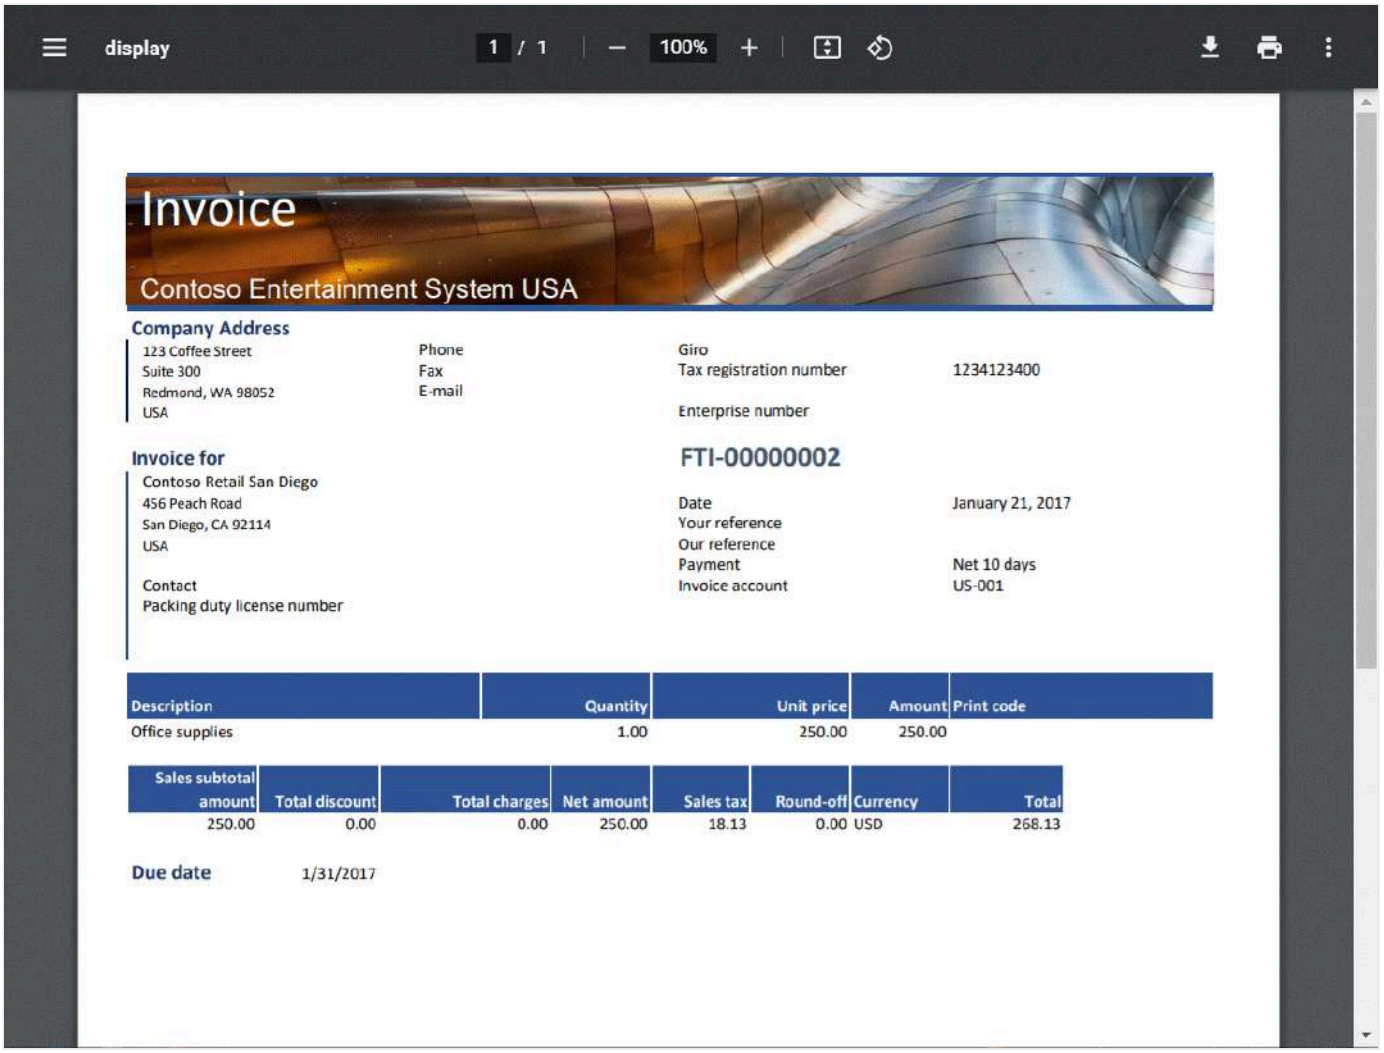
Set up print management

1. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.
2. On **Free text invoice**, select the **FTI-00000002** invoice. Then, on the Action Pane, on the **Invoice** tab, in the **Print management** group, select **Print management**.
3. On **Print management setup**, in the tree on the left, expand **Module - accounts receivable** > **Documents** > **Free text invoice**, and then select the **Original *Default*** item.
4. In the **Report format** field, select **Free text invoice (Excel)**.
5. Select the **Esc** key to leave **Print management setup** and return to **Free text invoice**.



Print a free text invoice

1. On **Free text invoice**, make sure that the **FTI-00000002** invoice is still selected. Then, on the Action Pane, on the **Invoice** tab, in the **Document** group, select **Print** > **Selected**.
2. Download the generated invoice in Excel format, and open it for preview.
3. Notice that, in accordance with the structure of the Excel template for the provided ER format, the page footer of the generated invoice contains information about the current page number and the total number of pages in the report.



Customize the standard ER format

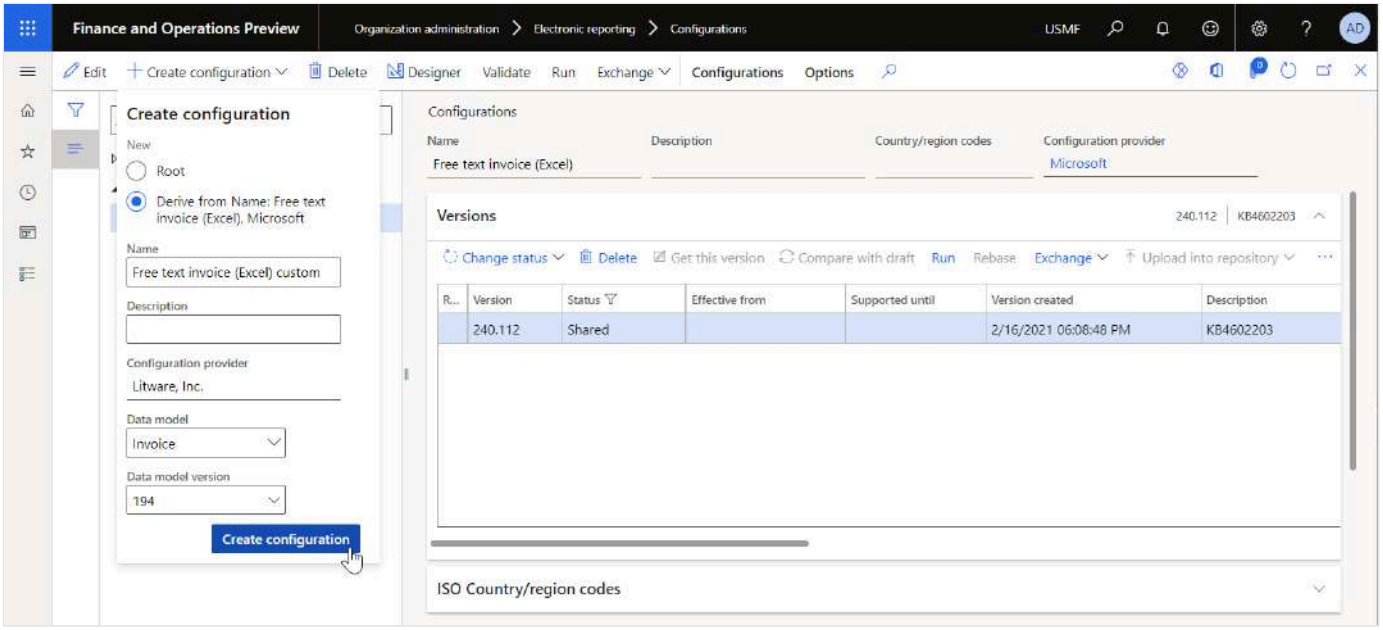
For the example in this section, use the ER configurations that Microsoft provides to generate a free text invoice in Excel format. However, you must add a customization to put a company logo image in the page footer of generated invoices.

In this case, as the representative of Litware, Inc., you must create (derive) a new ER format configuration based on the Microsoft-provided **Free text invoice (Excel)** configuration.

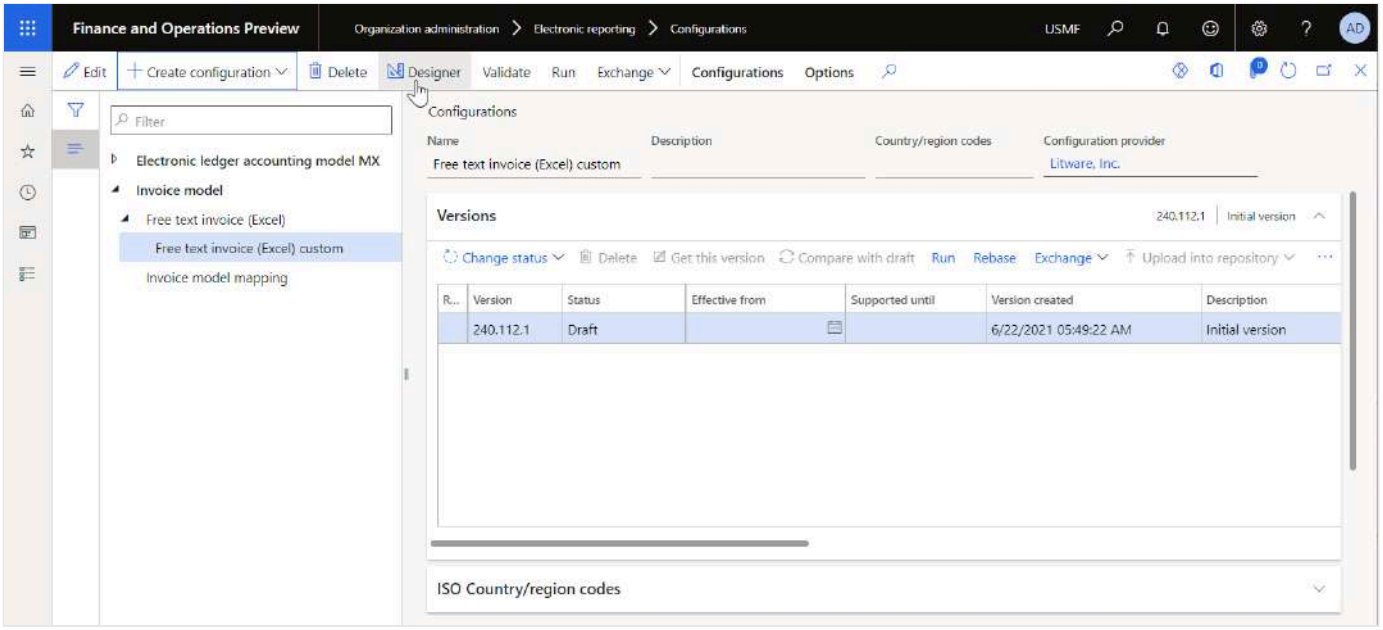
Create a custom format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Invoice model**, and then select **Free text invoice (Excel)**. Litware, Inc. uses the imported version (for example, **240.112**) of this ER format configuration as the base for the custom version.
3. Select **Create configuration** to open the drop-down dialog box. Use this dialog box to create a new configuration for a custom payment format.

4. In the **New** field group, select the **Derive from Name: Free text invoice (Excel), Microsoft** option.
5. In the **Name** field, enter **Free text invoice (Excel) custom**.
6. Select **Create configuration**.



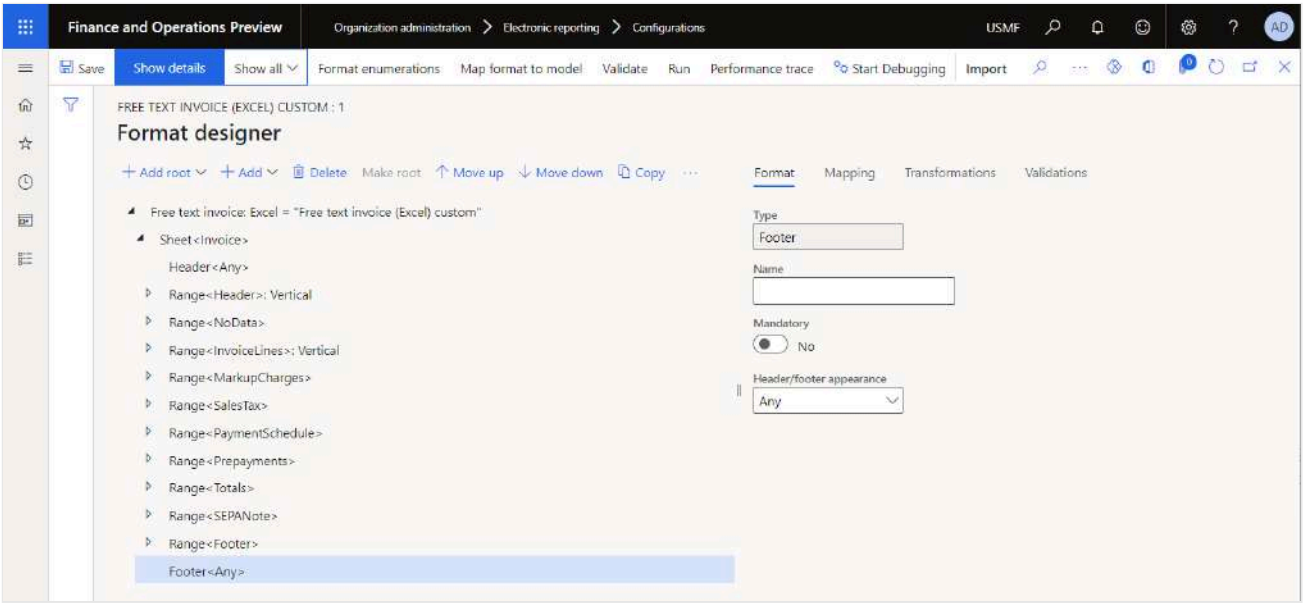
Version 240.112.1 of the **Free text invoice (Excel) custom** ER format configuration is created. This version has a status of **Draft** and can be edited. The current content of your custom ER format matches the content of the format that Microsoft provides.



Edit the custom format

Configure your custom format so that a company logo image appears in the footer on every page of the report.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Payment model**, and then select **Free text invoice (Excel) custom**.
3. On the **Versions** FastTab, select version **240.112.1** of the selected configuration.
4. Select **Designer**.
5. On **Format designer**, select **Show details** to view more information about the format elements.
6. Expand and review the following elements:
    - The **Free text invoice** element of the **Excel** type. This element generates an invoice in Excel workbook format.
    - The **Free text invoice \ Invoice** element of the **Sheet** type. This element generates a worksheet of the generated Excel workbook.
    - The **Free text invoice \ Invoice \ Footer** element of the **Footer** type. This element fills in an invoice footer.
7. Select the **Free text invoice \ Invoice \ Footer** element.



> **Note**
>
> Every page footer of a generated invoice contains information about the current page number and the total number of pages in the report. As you can see, the **Free text invoice \ Invoice \ Footer** element contains no child elements. Therefore, the Excel

template that you're using is configured to show paging details in the center of every report's footer.

8. Select **Add**, and then select the **Excel \ Picture** type of the format element that you're adding:

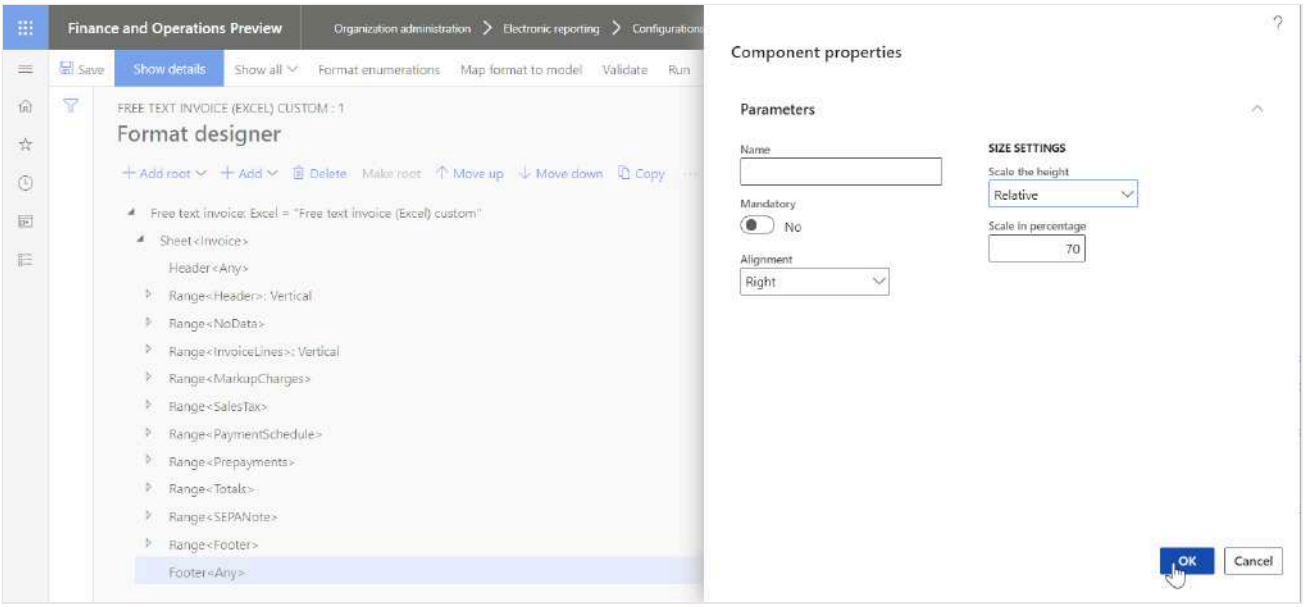
   a. In the **Alignment** field, select **Right**.

   b. In the **Scale the height** field, select **Relative**.

   c. In the **Scale in percentage** field, enter **70**.

   d. Select **OK**.

   > **Note**
   >
   > The **Excel \ Picture** element is used to add a company logo image and align it on right side of the page footer.

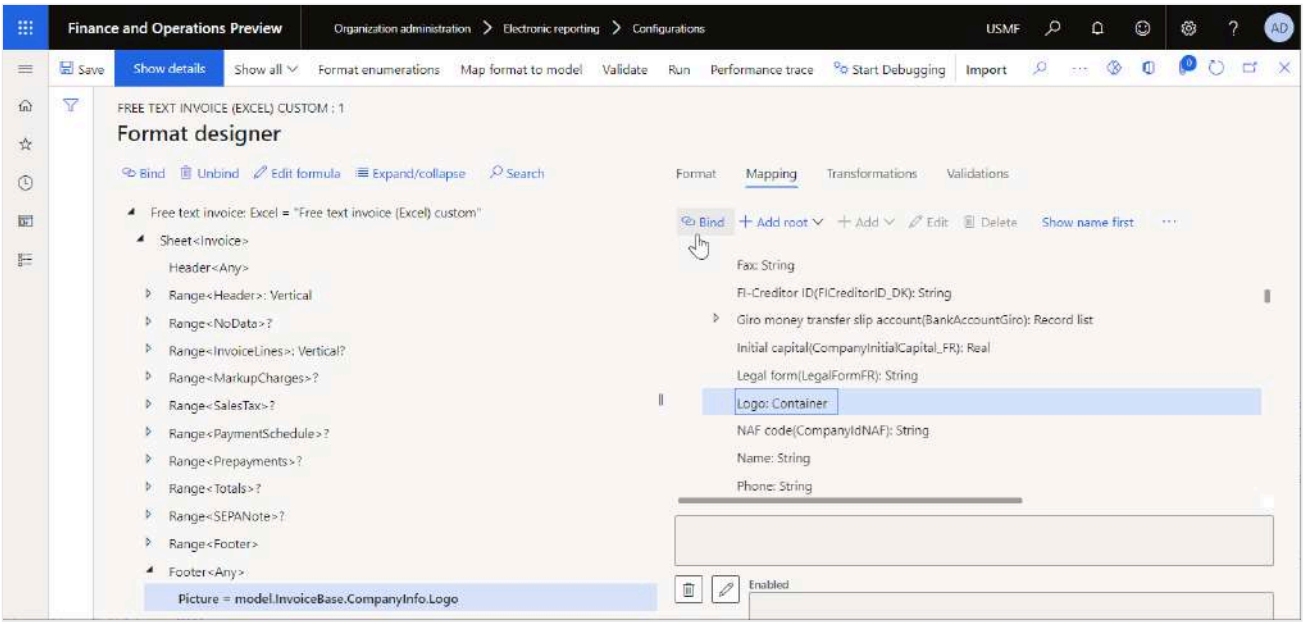


9. In the format structure tree on the left, select the **Picture** element that you just added. On the **Mapping** tab, expand the **model** data source.

10. Expand **model.Payment** > **model.InvoiceBase** > **model.InvoiceBase.CompanyInfo**, and then select the **model.InvoiceBase.CompanyInfo.Logo** data source field. The data source field of the Container type exposes the company logo image as media content.

11. Select **Bind**. The **Picture** format element is now bound with the **model.InvoiceBase.CompanyInfo.Logo** data source field. Therefore, at runtime, a company

logo image appears in the footer of generated invoices.



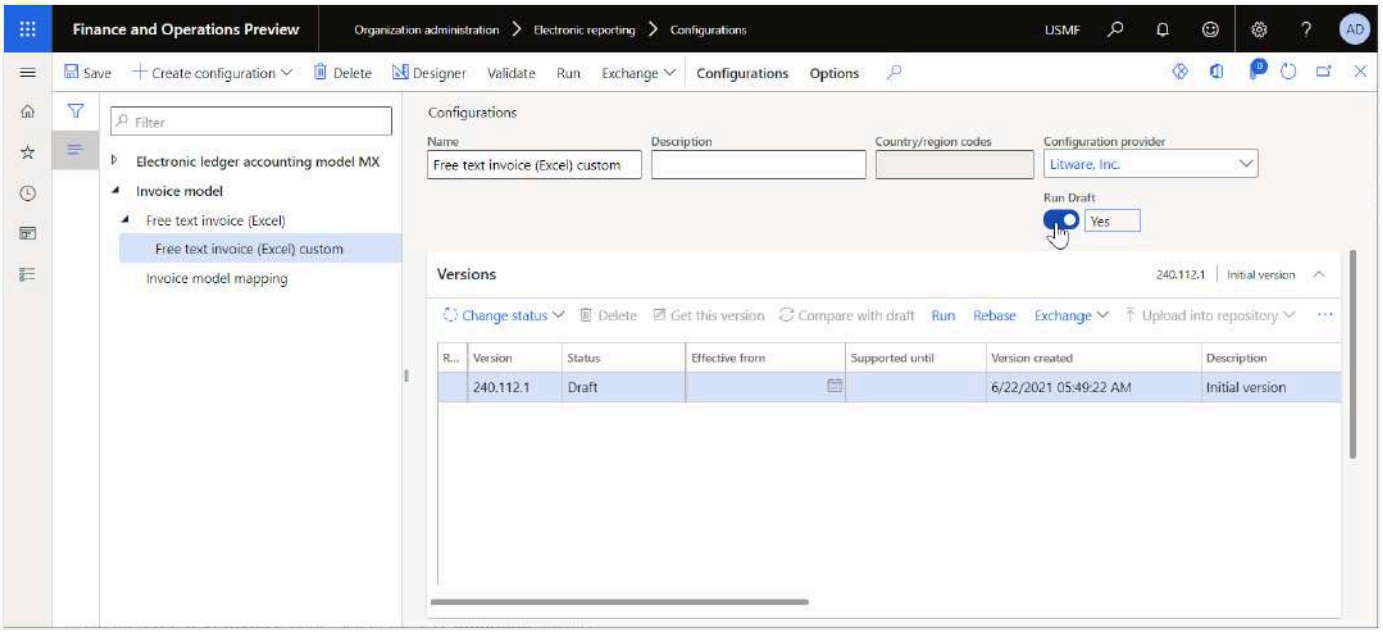
12. Select **Save**, and then close the **Designer** page.

Mark the custom format as runnable

After you create the first version of the custom format, it has a status of **Draft**. You can run the format to test it. To run the report, process a vendor payment by using the payment method that refers to your custom ER format. By default, when you call an ER format from the application, only versions that have a status of **Completed** or **Shared** are considered. This behavior helps prevent ER formats that have unfinished designs from being used. However, for your test runs, you can force the application to use the version of your ER format that has a status of **Draft**. In this way, you can adjust the current format version if any modifications are required. For more information, see Applicability.

To use the draft version of an ER format, you must explicitly mark the ER format.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, set the **Run settings** option to **Yes**, and then select **OK**.
4. Select **Edit** to make the current page editable. In the configuration tree in the left pane, select **Free text invoice (Excel) custom**.
5. Set the **Run Draft** option to **Yes**.



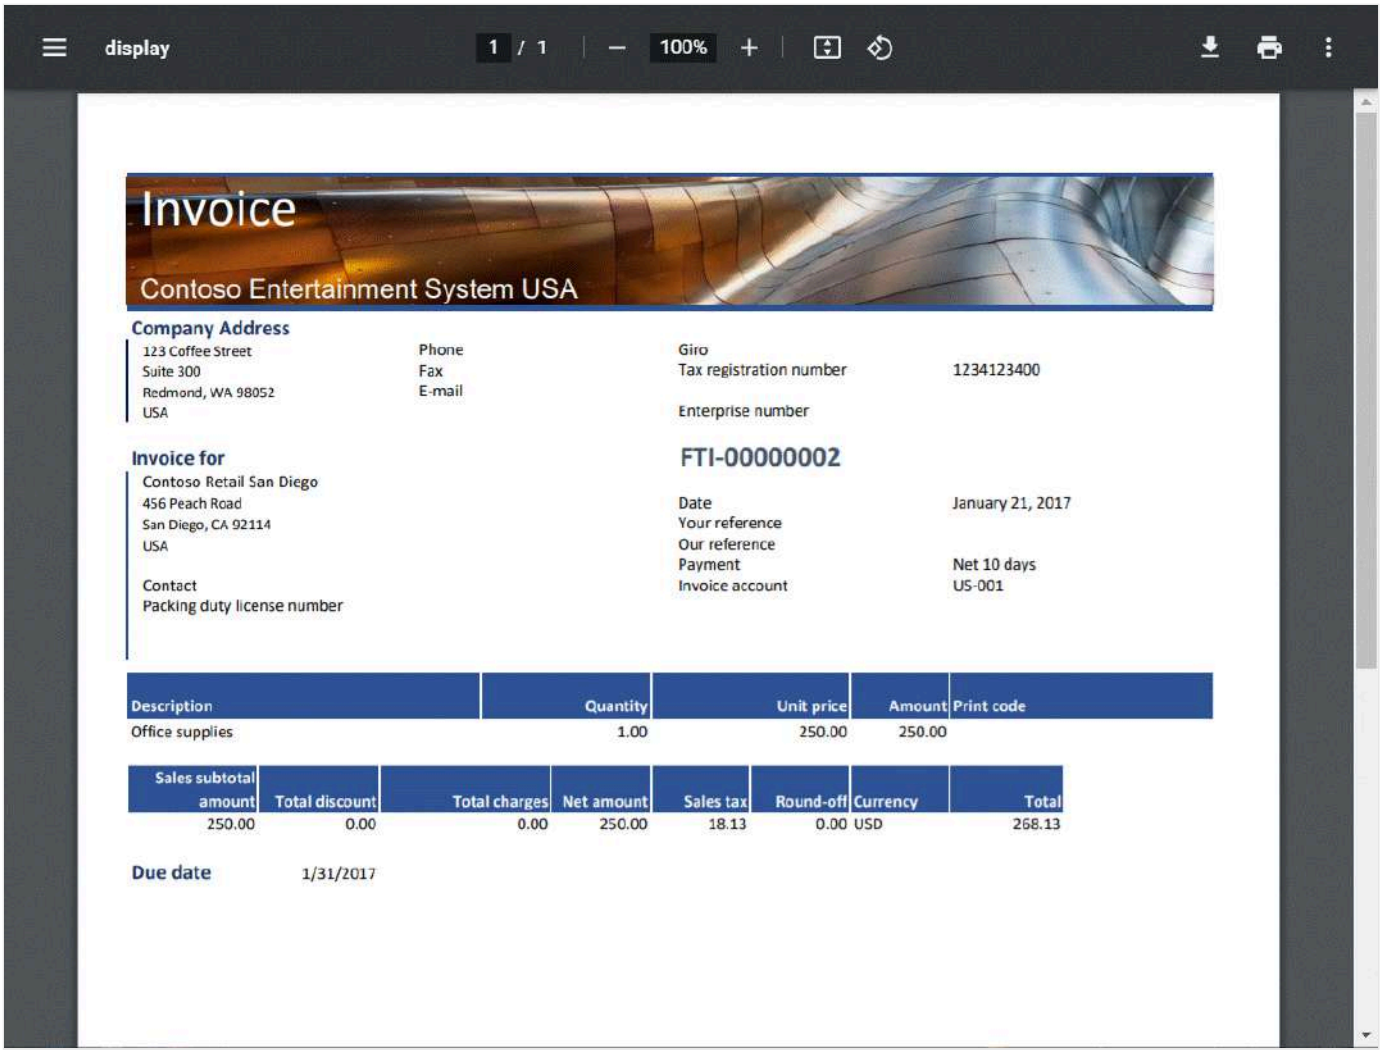
Print a free text invoice by using the custom ER format

Set up print management

1. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.
2. On **Free text invoice**, select the **FTI-00000002** invoice. Then, on the Action Pane, on the **Invoice** tab, in the **Print management** group, select **Print management**.
3. On **Print management setup**, in the tree on the left, expand **Module - accounts receivable** > **Documents** > **Free text invoice**, and then select the **Original <Default>** item.
4. In the **Report format** field, select **Free text invoice (Excel) custom**.
5. Select **Esc** to leave **Print management setup** and return to **Free text invoice**.

Print a free text invoice

1. On **Free text invoice**, make sure that the **FTI-00000002** invoice is still selected. Then, on the Action Pane, on the **Invoice** tab, in the **Document** group, select **Print** > **Selected**.
2. Download the generated invoice in Excel format, and open it for preview.
3. In accordance with the structure of the custom ER format, the page footer of the generated invoice contains a company logo image in addition to information about the report's paging.



Additional resources

- Design a configuration for generating documents in Excel format
- Embed images and shapes in documents that you generate by using ER

Last updated on 04/13/2026

Split generated XML files based on file size and content quantity

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can design Electronic reporting (ER) formats to generate outgoing documents in XML format. Sometimes, recipients accept those documents only when they meet specific criteria, such as a maximum file size or a maximum number of some XML nodes. You can design ER formats to generate electronic documents that satisfy the requirements that the recipients of those documents specify.

- For the FILE format element, you can define a limit on the file size as an ER expression. If the defined limit is exceeded when an ER report is generated, ER finishes creating the current file and then moves on to create the next file.
- For any XML ELEMENT format, you can define a limit on the number of elements as an ER expression. If the number of XML nodes in the file that is generated exceeds the defined limit when an ER report is run, ER finishes creating the current file and then moves on to create the next file.
- For any XML SEQUENCE format element, you can define a limit on the number of child elements as an ER expression. If the number of nested XML nodes of the format element in the generated file exceeds the defined limit when an ER report is run, ER finishes creating the current file and then moves on to create the next file.
- You can mark any XML ELEMENT format element as non-breakable. In this way, you keep the nested items of XML nodes that are generated under the format element in a single generated file.

In addition to using the XML ELEMENT and XML SEQUENCE format elements to add XML nodes to the generated file, you can use the RAW XML format element. However, nodes that you add by using the RAW XML format element aren't considered when the number of nodes is calculated to evaluate the limits on the number of elements.

If you configure file destinations for a FILE format element that you configure to split the generated output whenever specific limits are exceeded, each piece of generated output is sent to the configured file destination as an individual file. To uniquely name the files that are created by splitting the output, you must configure an ER expression for the FILE format element. If you include an ER data source of the NUMBER SEQUENCE type, the number sequence increments for each piece of the split output.

To learn more about this feature, play the **ER Split XML files based on the file size or content item quantity** task guide, which is part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process and can be downloaded from the Microsoft Download Center. This task guide walks you through the process of configuring an ER format to split generated files based on limits on the file size and content item quantity. To complete the task guide, you must download the following files:

- ER model configuration - XmlFilesSplittingModel.xml
- ER format configuration - XmlFilesSplittingFormat.xml

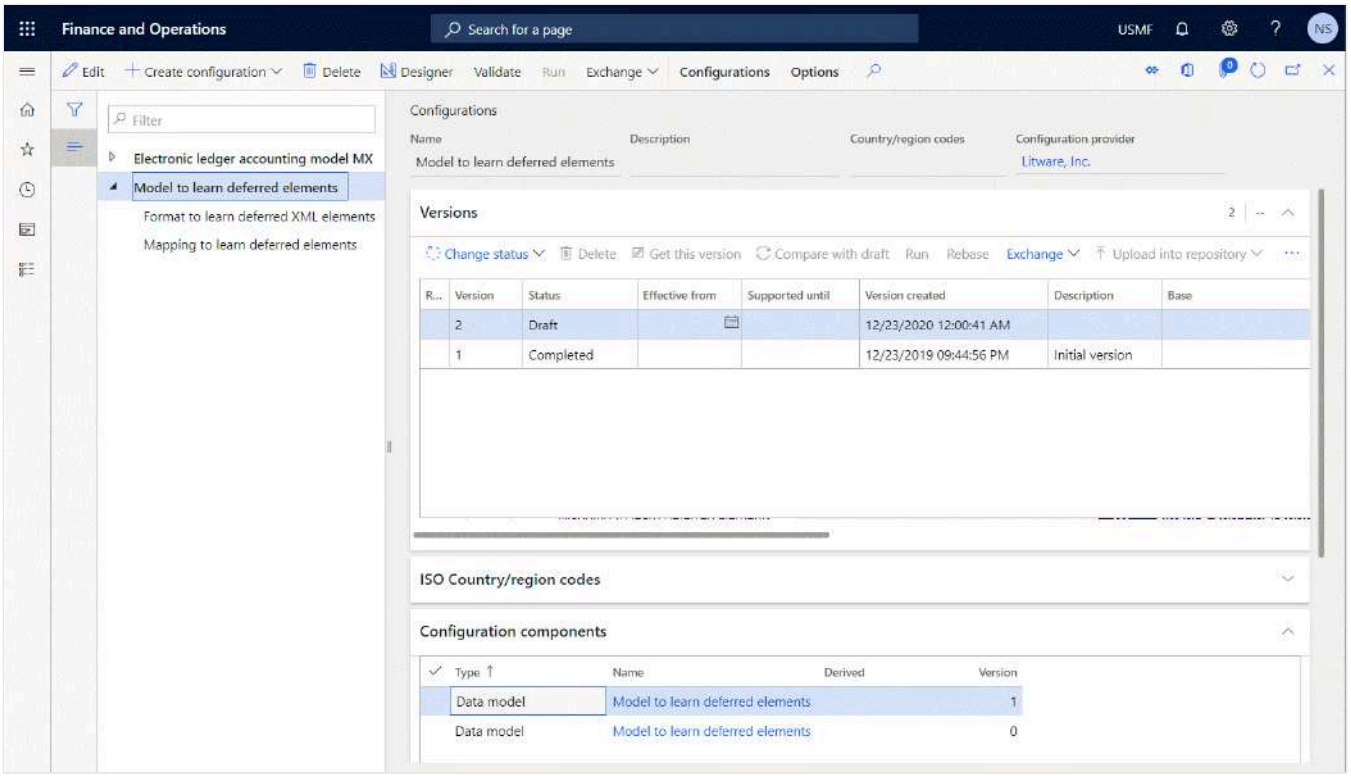
Design ER configurations to suppress BOM characters in generated files

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

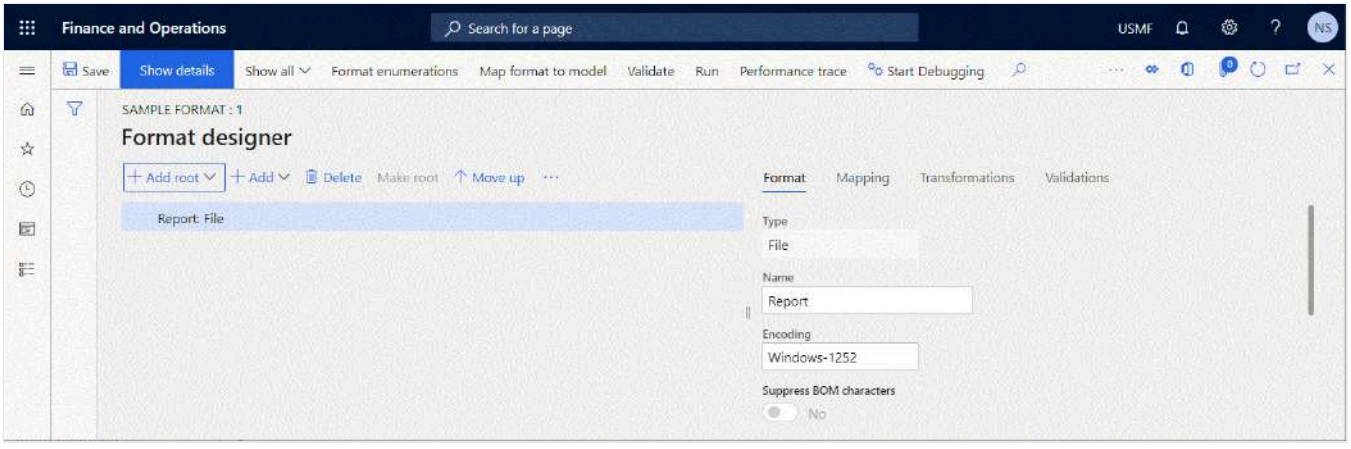
You can design an Electronic reporting (ER) solution to generate outgoing documents. To generate the documents as text or XML files, the solution must include an ER configuration that contains an ER format component. To specify the character encoding that represents the set of characters in generated files, the ER format must contain the **Common\File** format element. To configure the ER format component, open the draft version of the ER configuration in the ER format designer, and add the **Common\File** element. In the **Encoding** field, specify the encoding of outbound files that are generated at runtime by using this component.

> **Note**
>
> If the format contains an incorrect encoding name, an error is thrown when you save your changes to the format's settings.



If you specify **UTF-8**, **UTF-16**, or **UTF-32** as the encoding, the **Suppress BOM characters** option becomes available. Set this option to **Yes** to suppress byte order mark (BOM) characters in outbound files that are generated at runtime when the editable ER format is run.

> **Note**
>
> If you leave the **Encoding** field blank, the default **UTF-8** encoding is used.



To review the functionality at runtime, complete the appropriate procedure. For example, complete the steps in the Defer the execution of XML elements in ER formats article. After you complete the steps in the Modify the format so that the calculation is based on generated output section of that article, follow these additional steps.

1. Specify the UTF encoding:

a. Select the **Report** element of the **Common\File** type.
b. In the **Encoding** field, specify the **UTF-8** encoding.

2. Generate an XML file that includes a BOM character:
   a. Set the **Suppress BOM characters** option to **No** to include BOM characters in generated XML files.
   b. Complete the steps in the Defer the execution of the summary XML element so that the calculated total is used section of the Defer the execution of XML elements in ER formats article, and save the generated file as **SampleXmlReport.xml**.

3. Generate an XML file that doesn't include a BOM character:
   a. Set the **Suppress BOM characters** option to **Yes** to suppress BOM characters in generated XML files.
   b. Complete the steps in the Defer the execution of the summary XML element so that the calculated total is used section of the Defer the execution of XML elements in ER formats article, and save the generated file as **SampleXmlReport (1).xml**.

4. In a file comparison utility, compare the generated files.

   The first difference that you notice is in the file header. The **SampleXmlReport.xml** file contains a BOM character, where the **SampleXmlReport (1).xml** file doesn't.

Generate electronic documents and update application data by using ER

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can design Electronic reporting (ER) formats that the application uses to generate outgoing electronic documents. You can also design ER formats that parse incoming electronic documents and use the content in those documents to update application data.

By using this functionality, you can use a single ER format to generate outgoing electronic documents and then update the application data. Use this feature in the following scenarios:

- To prevent repeated usage of application data in subsequent processes, mark an application's data immediately after you use it to generate electronic documents. For example, mark payment transactions as already processed immediately after you include them in a generated payment message.
- To store the processing details of electronic documents that you generate by using ER logic. For example, a unique payment message identification that is generated by using the ER expression. The expression is based on information entered in the ER dialog box when the ER format is run to generate documents.

To learn more about this feature, watch the set of ER Generate documents with application data update Task guides (part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process). The guides walk you through the details of Intrastat reporting and archiving. The following files are required to complete certain steps in these Task guides. Download and save these files to your local machine.

- ER data model configuration: Intrastat (model)
- ER model mapping configuration: Intrastat (mapping)
- ER format configuration: Intrastat (format)

Import configurations to generate documents that have application data

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To complete the steps in this procedure, you must first complete the procedure, "ER Create a configuration provider and mark it as active".

The steps in this procedure explain how to design Electronic reporting (ER) configurations to generate an electronic document. In this procedure, you import the required ER configurations that are created for the sample company, Litware, Inc., and use them to generate electronic documents. This procedure is created for users with the assigned role of system administrator or electronic reporting developer. You can complete these steps by using the DEMF dataset. Before you begin, download and save the files listed in the Help article, "Generate electronic documents and update application data with ER tool" (generate-electronic-documents-update-application-data/). The files are Intrastat (model).xml, Intrastat (mapping).xml, and Intrastat (format).xml.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

    - Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure, Create a configuration provider and mark it as active.
    - The steps in this procedure show how to use ER capabilities to complete an application data update and how to generate an Intrastat report. The details of the reporting process are archived in the application tables. Currently, when you activate the Intrastat reporting process from the Intrastat form, archiving is done based on the logic programmed in the existing source code. In this procedure, you configure a similar yet simplified logic of application data by using only the ER framework. You make no changes to the source code.

Import ER configurations

1. Select **Reporting configurations**.
2. Select **Exchange**.
3. Select **Load from XML file**.

    - Import the ER model configuration that contains the data model designed to be used as the data source for generating the Intrastat report. Later, you can extend this data model definition to use it for an application data update to archive details of the Intrastat reporting process.
    - Select **Browse** and select the Intrastat (model).xml file.

4. Select **OK**.
5. In the tree, select **Intrastat (model)**.
6. Select **Designer**.
7. In the tree, expand **For outgoing document**.
8. In the tree, expand **For outgoing document\Transactions**.

    - Review the structure of the imported data model. The root item **For outgoing document** specifies the data flow for getting data from the application and using it as the data source to generate the Intrastat report. The **Transactions (Record list)** represents the list of Intrastat transactions that you must report. Because you archive reported commodity codes, the unique identifier of a single commodity code **Commodity rec id (Int64)** is needed in this data flow.

9. Close the page.
10. Select **Exchange**.
11. Select **Load from XML file**.

    - Import the ER mapping configuration that specifies the data flow for getting data from the application and then using it to generate the Intrastat report. Later, you can extend this model mapping definition to get data from the Intrastat report and use it for the application data update to archive details of Intrastat reporting process.
    - Select **Browse** and select the Intrastat (mapping).xml file.

12. Select **OK**.
13. In the tree, expand **Intrastat (model)**.
14. In the tree, select **Intrastat (model)\Intrastat (mapping)**.
15. Select **Designer**.

- The current model mapping contains the value **To model** in the Direction field. This value means that this model mapping is designed for getting data from the application and storing it in the data model.

16. Select **Designer**.
17. In the tree, expand **List**.
18. In the tree, expand **Transactions= List**.

    - Review the structure of the model mapping that uses the data model filtered based on the root item, **For outgoing document**. The added data source, **List** provides access to the required application data, which is the list of records from the Intrastat table.

19. Close the page.
20. Close the page.
21. Select **Exchange**.
22. Select **Load from XML file**.

    - Import the ER format configuration that specifies the layout of the Intrastat report and the process of populating data to the report. Later, you can extend this format definition to put data from the Intrastat report into the data model and then use it to update application data to archive the details of Intrastat reporting process.
    - Click Browse and select the Intrastat (format).xml file.

23. Select **OK**.
24. In the tree, select 'Intrastat (model)\Intrastat (format)'.
25. Select **Designer**.
26. Click Expand/collapse.
27. In the tree, select 'File\Declaration'.
28. Click the Mapping tab.
29. In the tree, select 'File'.

    - Review the structure of the format used to generate the Intrastat report. Note that it is designed to generate an XML file by populating data from the data model, which is based on the root item 'For outgoing document'. Verify that the name for generated file is defined on the user dialog form ('fn' data source is used for that).

30. Close the page.

Design configurations to generate documents that have application data

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To complete the steps in this procedure, you must first complete the procedure, Import configurations to generate documents that have application data.

The steps in this procedure explain how to design Electronic reporting (ER) configurations to generate an electronic document. In this procedure, you run the ER imported format configuration that you created for the sample company, Litware, Inc. to generate electronic documents.

This procedure is created for users with the assigned role of system administrator or electronic reporting developer. You can complete these steps by using the DEMF dataset.

Before you begin, change the country/region context for the DEMF company from DEU (Germany) to BEL (Belgium). Select **Organization administration** > **Organizations** > **Legal entities** to update the country/region code in the primary address of the legal entity DEMF. Restart your application.

Run imported ER format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Intrastat (model)**.
3. In the tree, select **Intrastat (model)\Intrastat (format)**.
4. Select **Run**.
    - Run the draft version of the ER format configuration to generate the Intrastat report.
5. In the **Enter file name** field, type `intrastat.xml`.
    - Specify the name of the file.
6. Select **OK**.
    - Review the generated XML file.

7. Close the page.
8. Go to **Tax** > **Declarations** > **Foreign trade** > **Intrastat**.
    - Open this form to view the Intrastat transactions that are included in the generated electronic document.
9. Select **Intrastat archive**.
    - Because the executed ER format doesn't contain any settings for application data update, the details of the completed Intrastat report aren't archived.
10. Close the page.
11. Close the page.

Modify models and mappings to generate documents that have application data

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To complete the steps in this procedure, you must first complete the procedure, Design configurations to generate documents that have application data.

This procedure explains how to design Electronic reporting (ER) configurations to generate an electronic document and update application data. In this procedure, you modify the ER configurations to start using them to generate electronic documents and update application data. This procedure is for users assigned the role of system administrator or electronic reporting developer. You can complete these steps by using the DEMF dataset.

Modify data model

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, select **Intrastat (model)**. * You can extend how you use the data model. Besides using it as data source to generate the Intrastat report, the data model collects details about the Intrastat reporting process. These details help to update the application data.
3. Select **Designer**.
4. Select **New** to open the **Drop** dialog.
5. In the **New node as a field** box, enter **Model root**.
6. In the **Name** field, type **For application data update**.

    - For application data update

7. Select **Add**.
8. In the tree, select **For application data update**.

    - This new root item is added to specify the data flow for moving data from the Intrastat report (used as a data source) to the application tables (the update destination). Different root items must be used for getting data that is posted to the

outgoing document and for getting data from the document that is used to update application data.

9. Select **New** to open the **Drop** dialog.
10. In the **Name** field, type **Archive header**.

    - Archive header

11. In the **Item type** field, select **Record list**.
12. Select **Add**.

    - Create a new item because you're creating a record for each generated Intrastat report.

13. Select **New** to open the **Drop** dialog.
14. In the **Name** field, type **File name**.

    - File name

15. In the **Item type** field, select **String**.
16. Select **Add**.
17. Select **New** to open the **Drop** dialog.
18. In the **Name** field, type **Number of lines**.

    - Number of lines

19. In the **Item type** field, select **Integer**.
20. Select **Add**.

    - Add this item to represent the number of Intrastat transactions reported during the current reporting process.

21. Select **New** to open the **Drop** dialog.
22. In the **Name** field, type **Archive lines**.

    - Archive lines

23. In the **Item type** field, select **Record list**.
24. Select **Add**.

    - Add this item to represent the list of Intrastat transactions reported during the current reporting process.

25. Select **New** to open the **Drop** dialog.
26. In the **Name** field, type **Amount**.

    - Amount

27. In the **Item type** field, select **Real**.
28. Select **Add**.
29. Select **New** to open the **Drop** dialog.
30. In the **Name** field, type **Commodity rec id**.

    - Commodity rec id

31. In the **Item type** field, select **Int64**.
32. Select **Add**.
33. Select **New** to open the **Drop** dialog.
34. In the **Name** field, type **Item number**.

    - Item number

35. In the **Item type** field, select **String**.
36. Select **Add**.
37. Select **Save**.
38. Close the page.

Modify model mapping

1. In the tree, expand **Intrastat (model)**.
2. In the tree, select **Intrastat (model)\Intrastat (mapping)**.

    - Modify the existing model mapping to start using it for the application data update and to archive Intrastat reporting details.

3. Select **Designer**.
4. Select **New**.
5. In the **Name** field, type **Update archive**.

    - Update archive

6. In the **Direction** field, select **To destination**.
7. Select **Save**.

    - This new mapping specifies the data flow for moving data (Intrastat reporting details) from the data model to the application tables (the update destination). Use the root items of different models to get data from the application for the reporting process. Then, use the data from the data model for the application data update.

8. Select **Designer**.
9. In the tree, select **Data model\Data model**.

- Add the required data source. This source is the data model that contains details of the reported Intrastat transactions to archive.

10. Select **Add root**.
11. In the **Name** field, type **model**.

    - model

12. In the **Definition** field, enter or select the value **For application data update**.

    - For application data update

13. Select **OK**.
14. In the tree, expand **model**.
15. In the tree, select **Functions\Calculated field**.
16. In the tree, select **model\Archive header**.
17. Select **Add**.

    - Because you want to enumerate reported Intrastat transactions for archiving, ensure that you add the appropriate data source.

18. In the **Name** field, type **Enumerated lines**.

    - Enumerated lines

19. Select **Edit** formula.
20. In the tree, select **List\ENUMERATE**.
21. Select **Add** function.
22. In the tree, expand **model**.
23. In the tree, expand **model\Archive header**.
24. In the tree, select **model\Archive header\Archive lines**.
25. Select **Add data source**.
26. In the **Formula** field, enter **ENUMERATE(model.'Archive header'.'Archive lines')**.

    - ENUMERATE(model.'Archive header'.'Archive lines')

27. Select **Save**.
28. Close the page.
29. Select **OK**.
30. Select **Add destination**.

    - Add application tables as required destinations that require updates to archive details of reported Intrastat transactions.

31. In the **Name** field, type **Archive**.

- Archive

32. In the **Table name** field, type **IntrastatArchiveGeneral**.

    - IntrastatArchiveGeneral
    - Keep the record action **Insert** so you can add records during the detail archiving of each Intrastat reporting process.

33. In the **Record infolog** field, select **Yes**.

    - To get information about issues with the application data update, select **Yes**.

34. In the **Skip record action validation** field, select **Yes**.

    - To suppress validation errors about the empty **Intrastat archive ID** field, select **Yes**. These errors are suppressed after the addition of records, based on the sequence number settings configured for this table in the **Foreign trade parameters** form.

35. Select **OK**.

    - Bind elements of the added data source (the filtered model based on the selected root item) with elements from the added destination.

36. In the tree, expand **Archive**.
37. In the tree, expand **Archive<Relations**.
38. In the tree, expand **Archive<Relations\IntrastatArchiveDetail**.
39. In the tree, select **Archive<Relations\IntrastatArchiveDetail\Amount(AmountMST)**.
40. In the tree, expand **model\Archive header\Enumerated lines**.
41. In the tree, expand **model\Archive header\Enumerated lines\Value**.
42. In the tree, select **model\Archive header\Enumerated lines\Value\Amount**.
43. Select **Bind**.
44. In the tree, select **Archive<Relations\IntrastatArchiveDetail\Commodity(IntrastatCommodity)**.
45. In the tree, select **model\Archive header\Enumerated lines\Value\Commodity rec id**.
46. Select **Bind**.
47. In the tree, select **Archive<Relations\IntrastatArchiveDetail\Item number(ItemId)**.
48. In the tree, select **model\Archive header\Enumerated lines\Value\Item number**.
49. Select **Bind**.
50. In the tree, select **Archive<Relations\IntrastatArchiveDetail\Line number(LineNumber)**.
51. In the tree, select **model\Archive header\Enumerated lines\Number**.
52. Select **Bind**.
53. In the tree, select **Archive<Relations\IntrastatArchiveDetail**.
54. In the tree, select **model\Archive header\Enumerated lines**.
55. Select **Bind**.
56. In the tree, select **Archive\File name(FileName)**.

57. In the tree, select **model\Archive header\File name**.
58. Select **Bind**.
59. In the tree, select **Archive\Number of lines(NumberOfLines)**.
60. In the tree, select **model\Archive header\Number of lines**.
61. Select **Bind**.
62. In the tree, select **Archive**.
63. In the tree, select **model\Archive header**.
64. Select **Bind**.
65. Select **Save**.
66. Close the page.
67. Close the page.

Last updated on 03/17/2026

Modify formats to generate documents that have application data

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Before you start, complete the procedure, Modify models and mappings to generate documents that have application data.

This procedure shows how to design Electronic reporting (ER) configurations to generate an electronic document and update application data. Change the ER configurations so they generate electronic documents and update application data. This procedure is for users with the system admin or electronic reporting developer role. Use the DEMF dataset for these steps.

Modify format to collect details of reporting

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Intrastat (model)**.
3. In the tree, select **Intrastat (model)\Intrastat (format)**.
4. Select **Designer**.
5. In the tree, expand **File**.
6. In the tree, expand **File\Declaration**.
7. In the tree, select **File\Declaration\Data**.
8. In the **Multiplicity** field, select **One many**.

    - Configure this format element to archive details of the Intrastat reporting process. This item represents the archive's header record.

9. In the tree, expand **File\Declaration\Data**.
10. In the tree, select **File\Declaration\Data\Item**.
11. In the **Multiplicity** field, select **Zero many**.

    - Configure this format element to archive details of the Intrastat reporting process. This item represents the list of archived lines.

12. In the tree, expand **File\Declaration\Data\Item**.
13. In the tree, select **File\Declaration\Data\Item\Dim1**.

14. Select **Yes** in the **Excluded** field.

    - Don't archive this data, so you can exclude this format element from the data source of Intrastat reporting details.

15. In the tree, expand **File\Declaration\Data\Item\Dim1**.
16. In the tree, select **File\Declaration\Data\Item\Dim1\property**.
17. Select **Yes** in the **Excluded** field.
18. In the tree, select **File\Declaration\Data\Item\Dim1\date**.
19. Select **Yes** in the **Excluded** field.
20. In the tree, select **File\Declaration\Data\Item\Dim2**.
21. Select **Yes** in the **Excluded** field.
22. In the tree, expand **File\Declaration\Data\Item\Dim2**.
23. In the tree, select **File\Declaration\Data\Item\Dim2\property**.
24. Select **Yes** in the **Excluded** field.
25. In the tree, select **File\Declaration\Data\Item\Dim2\code**.
26. Select **Yes** in the **Excluded** field.
27. In the tree, select **File\Declaration\Data\Item\Dim3**.

    - Several format elements can have the same name. For example, Dim. You can't explicitly recognize them when you use this format as a data source for archiving Intrastat reporting details, so you need to define the alternative names for these format elements.

28. In the **Name** field, type **Amount**.

    - Amount

29. In the **Multiplicity** field, select **Exactly one**.
30. In the tree, select **File\Declaration\Data\Item\Dim4**.
31. In the **Name** field, type **Item**.

    - Item

32. In the **Multiplicity** field, select **Exactly one**.

    - In addition to the design format elements, archive the following Intrastat reporting details: unique record identification of each reported commodity item, and the name of the generated file. Because this data isn't in the Intrastat report, add the format related to these detail elements as data source items.

33. In the tree, select **File\Declaration\Data**.
34. Select **Add** to open the **Drop** dialog.
35. In the tree, select **Data source\Item**.

36. In the **Name** field, type **File name**.

    - File name

37. In the **Data type** field, select **String**.
38. Select **OK**.
39. In the tree, select **File\Declaration\Data\Item**.
40. Select **Add Item**.
41. In the **Name** field, type **Commodity rec ID**.

    - Commodity rec ID

42. In the **Data type** field, select **Int64**.
43. Select **OK**.
44. Select the **Mapping** tab.
45. In the tree, select **File\Declaration\Data\File name**.
46. Select **Bind**.
47. In the tree, expand **model**.
48. In the tree, expand **model\Transactions**.
49. In the tree, select **File\Declaration\Data\Item = model.Transactions\Commodity rec ID**.
50. In the tree, select **model\Transactions\Commodity rec ID**.
51. Select **Bind**.
52. Select **Save**.

Modify format to memorize details of reporting

1. Select **Map format to model**.
2. Select **New**.
3. In the **Definition** field, enter or select the **For application data update** root item.

    - For application data update.

4. In the **Name** field, type **Mapping to update data**.

    - Mapping to update data

5. Select **Save**.

    - This mapping defines how the details of the Intrastat report are collected in the data model, which uses the selected root item 'For application data update'. These details, the model mapping with the same root item 'For application data update', and the direction 'To destination' are used for the application data update. The application data update starts immediately after the outgoing Intrastat report is

generated. You can skip the application data update at run time, but the data model must be empty (containing an empty record list).

6. Select **Designer**.

    - The outgoing Intrastat report format is added by default as a data source for this model mapping.
    - Bind elements of the designed report (presented as data source) to elements of the data model, which is filtered based on the selected model's root item.

7. In the tree, expand **Archive header**.
8. In the tree, expand **Archive header\Archive lines**.
9. In the tree, expand `format`.
10. In the tree, expand `format\Declaration: XML Element(Declaration)`.
11. In the tree, expand `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)`.
12. In the tree, expand `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)`.
13. In the tree, expand `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Dim3: XML Element 1..1 (Amount)`.
14. In the tree, expand `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Dim4: XML Element 1..1 (Item)`.
15. In the tree, select **Archive header\Number of lines**.
16. Select **Edit**.
17. In the tree, select **List\COUNT**.
18. Select **Add function**.
19. In the tree, expand `format`.
20. In the tree, expand `format\Declaration: XML Element(Declaration)`.
21. In the tree, expand `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)`.
22. In the tree, select `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)`.
23. Select **Add data source**.
24. In the **Formula** field, enter `COUNT(format.Declaration.Data.Item)`.

    - COUNT(format.Declaration.Data.Item)

25. Select **Save**.
26. Close the page.
27. In the tree, select **Archive header\File name**.
28. In the tree, select `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\File name: Item String(File name)`.

29. Select **Bind**.
30. In the tree, select `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Dim4: XML Element 1..1 (Item)\number: String(number)`.
31. In the tree, select **Archive header\Archive lines\Item number**.
32. Select **Bind**.
33. In the tree, select `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Dim3: XML Element 1..1 (Amount)\value: Numeric Real(value)`.
34. In the tree, select **Archive header\Archive lines\Amount**.
35. Select **Bind**.
36. In the tree, select `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)\Commodity rec ID: Item Int64(Commodity rec ID)`.
37. In the tree, select **Archive header\Archive lines\Commodity rec ID**.
38. Select **Bind**.
39. In the tree, select **Archive header\Archive lines**.
40. In the tree, select `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)\Item: XML Element 0..* (Item)`.
41. Select **Bind**.
42. In the tree, select **Archive header**.
43. In the tree, select `format\Declaration: XML Element(Declaration)\Data: XML Element 1..* (Data)`.
44. Select **Bind**.
45. Select **Save**.

Generate documents that have application data

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To complete the steps in this procedure, you must first complete the procedure, Modify formats to generate documents that have application data.

The steps in this procedure explain how to design Electronic reporting (ER) configurations to generate an electronic document and update application data. In this procedure, you execute the ER format configuration to generate the Intrastat report and update application data for archiving details of the reporting process.

This procedure is created for users with the assigned role of system administrator or electronic reporting developer. You can complete these steps by using the DEMF dataset. Before you begin, make sure that the country/region context for the DEMF company is BEL (Belgium).

Set up foreign trade parameters

1. Go to **Tax** > **Setup** > **Foreign trade** > **Foreign trade parameters**.
2. Select the **Number sequences** tab.

   To archive details of the Intrastat reporting process, you need to identify records of each archive. You must configure a special number sequence for this process.
3. Select the **Intrastat archive ID** reference.
4. In the **Number sequence code** field, type a value.

   In the **Number sequence code** field, enter or select the value **Fore_2**.
5. Resolve changes to the Number sequence code.
6. Select **Save**.
7. Close the page.

Run modified ER format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Intrastat (model)**.
3. In the tree, select **Intrastat (model)\Intrastat (format)**.
4. Select **Run**.
5. In the **Enter file name** field, type **intrastat2.xml**.
6. Select **OK**.

Review ER format execution results

Review the generated XML file.

1. Close the page.
2. Go to **Tax** > **Declarations** > **Foreign trade** > **Intrastat**.

   Open this form containing the Intrastat transactions included in the generated electronic document.
3. Select **Intrastat archive**.

   Since the executed ER format now contains settings for application data update, the details of the completed Intrastat reporting are archived. In this form, you can see the header record of the created archive.
4. Select **Details**.

   In this form, you can see the details for the created archive.
5. Close the page.
6. Close the page.
7. Close the page.

Parse incoming documents

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article covers the following three tasks:

- Parse incoming documents to update application data
- Parse incoming documents in Excel format
- Parse incoming documents in CSV format

Parse incoming documents to update application data

You can design Electronic reporting (ER) formats and run them in the application to parse incoming electronic documents and then use their content to update application data.

The following new ER functionality improves the parsing of incoming electronic documents in XML format:

- Use the **CASE** format element as a root element of the ER format to parse incoming electronic documents in XML format. The **FILE** format element is supported as a nested element of the **CASE** element. Therefore, you can configure a single ER format to parse incoming electronic documents that might contain different root XML elements.

- A **Parsing order of nested elements** attribute is available for XML format elements in ER formats. Use this attribute to define a single XML element that you expect in the incoming file. There are two valid sequences of the nested elements:
  - **As in format** – The incoming file is valid when the sequence of nested elements in the file is the same as the order that is described in the ER format.
  - **Any** – The incoming file is valid when all nested elements in the ER format are present in the parsing file, regardless of their sequence in that file.

To become more familiar with the details of this feature, play the task guide, **ER - Parse incoming documents to update application data** (part of the 7.5.4.3 Acquire/Develop IT

service/solution components (10677) business process). This task guide shows how the responses from a web service can be parsed by using an ER format.

To complete some steps of the task guide, you must download the following files:

Expand table

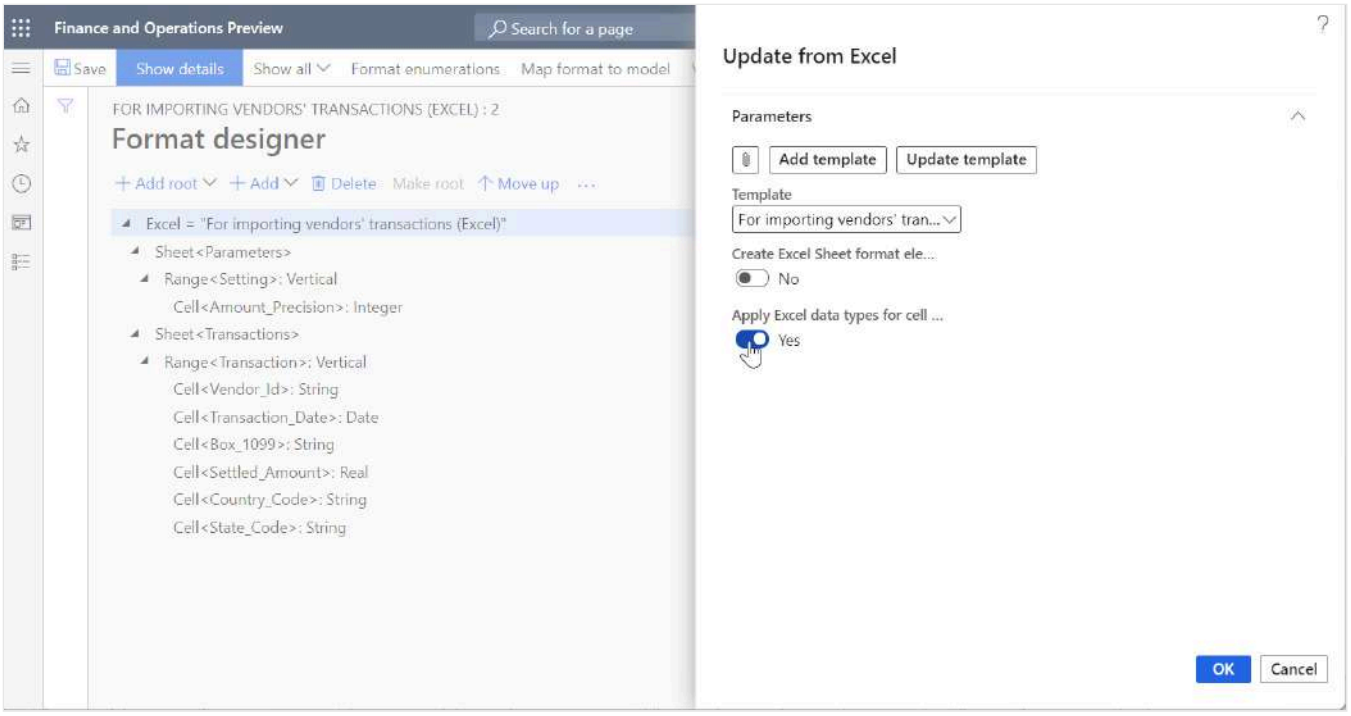
Content description	File
ER data model configuration	EFSTAmodel.xml
ER format configuration	EFSTAformat.xml
Web service response sample 1	Response1.xml
Web service response sample 2	Response2.xml
Web service response sample 3	Response3.xml
Web service response sample 4	Response4.xml

Parse incoming documents in Excel format

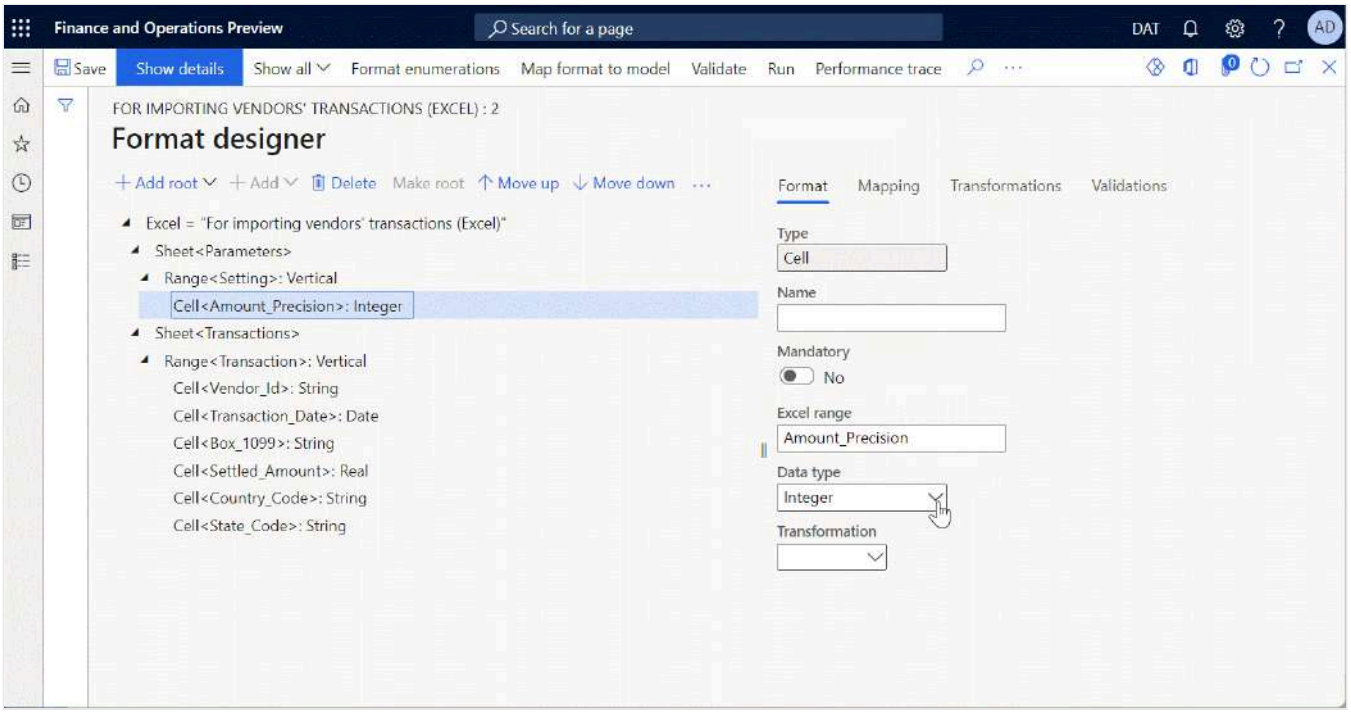
You can design Electronic reporting (ER) formats to parse incoming Microsoft Excel files that represent data in Microsoft Excel workbooks (files in XLSX format). You can then use the content from these files to update application data. This approach is useful if you:

- Design a new model and format and want to test them at run-time. In this case, Excel simulates the actual application data.
- Manage data beyond your application in Excel and want to import this data to submit a specific report.

When you design a new ER format to parse inbound documents, you can import an Excel workbook into it as a template for inbound files. To automatically detect the data type that is stored in Excel named cells, set the **Apply Excel data types for cell components** option to **Yes** in the **Update from Excel** dialog box.



You can manually change the cells later in the **Data type** field on the **Format** tab, if either no data type (void) or an incorrect data type is automatically detected for a single Cell component of the edited ER format. These data types are used in the format model mapping when you specify how data from an inbound file is used to fill in a data model.



By default, when you run this format to parse a real inbound file, ER tries to detect the data type of each cell, just as it did when you imported an Excel template. In some cases, an incorrect data type might be detected and cause incorrect data conversion or a runtime exception. In Finance version 10.0.25 and later, you can force the ER framework at runtime to use the data conversion data types that you specify for each cell component in the **Data type**

field on the **Format** tab of the edited ER format. To force this behavior, enable the **Forcing to use for data parsing only cell data types that are defined in an ER format** feature in the **Feature management** workspace.

To learn more about this feature, watch the task guides **ER Import data from a Microsoft Excel file (Part 1: Design format)** and **ER Import data from a Microsoft Excel file (Part 2: Import data)** (parts of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process). These task guides walk through how the incoming Excel file can be parsed by using the ER format to import information from incoming documents and update application data. You can download the task guide files from the Microsoft Download Center.

Download the following files to complete the task guides mentioned earlier.

Expand table

Content description	File
Incoming file in .XLSX format - template	1099import-template.xlsx
Incoming file in .XLSX format - sample data	1099import-data.xlsx

If you didn't already, to learn how to create the required configurations to import data from an external file, see ER Create required configurations to import data from an external file in the current finance and operations application. To download the file, see the following table.

Expand table

Content description	File
ER model configuration	1099model.xml

Parse incoming documents in CSV format

You can design Electronic reporting (ER) formats to parse incoming electronic documents that represent tabular data in plain text (files in CSV format). Then, use the content from these documents to update application data. Use the following approach:

- Begin your format design by adding a new root sequence element to specify that each line in the parsing file is a separate record.
  - In the added sequence element, select the appropriate value, such as **New line - Windows (CR LF)**, in the **Special characters** field in the **Sequence element delimiter** field group.

- Continue your format design by adding a nested sequence element of the added root sequence element to specify that each line in the parsing file is a set of fields.
  - Specify the character in the **Custom delimiter** field that the parser recognizes in the parsing line as a fields separator.

    > ⓘ **Note**
    > - You can define different field separators for different sequence elements to parse specific file lines in which fields are separated by different characters.
    > - You can leave the **Custom delimiter** field blank for certain sequence elements. An empty field means that any file line that the parser uses this sequence to parse is like a .txt (fixed length text) file line.

  - In the **Quotation application** field, select the value when you expect that some fields of any line that the parser uses this sequence element to parse are enclosed by certain characters. The following options are available:
    - **All** – Include quotation characters in the parsing line for any field of any data type. If you select this option, define the desired characters in the **Quotation mark** field that the parser uses for fields quotation. For example, the double quotes character.
    - **Text only** – Include quotation characters in the parsing line for any field of the **String** data type. If you select this option, define the desired characters in the **Quotation mark** field that the parser uses for fields quotation.
    - **Derive from parent only** – Use the same **Quotation application** field settings that you define for the parent sequence element. The **Quotation mark** field setting comes from the settings of the parent sequence element as well.
    - **None** – Exclude quotation characters in the parsing line for any field of any data type.

- Complete your format design by adding nested elements for the added sequence element that represents the set of fields of the parsing line. Add the required elements of the **Text** group, such as **String**, **DateTime**, and **Numeric**, to describe the structure of the parsing line as a set of individual fields of different data types.
  - For each format element that represents an individual field of the parsing line, by default, nothing is selected in the **Multiplicity** field. This default means that the value of the field in the parsing line is required. In the **Multiplicity** field, select **Zero one** to make the value of this field in the parsing line optional.

> **Note**
>
> The data source item **isMatch** is available when you map this format to ER data model for each **String**, **DateTime**, or **Numeric** format element with the option **Zero one** selected in the **Multiplicity** field. When this field contains a value, **isMatch** returns **True**. If there's no value in the field, it returns **False**.

To learn more about this feature, watch the task guide, **ER Create a format configuration to import data from an external CSV file** (part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process). The guide walks through how the incoming CSV file can be parsed by using the ER format to update application data.

Download the following files to complete the task guide mentioned earlier.

Expand table

Title	File name
ER format configuration	1099formatcsv.xml
Sample of incoming file in .csv format	1099entriescsv.csv

Download the following file to complete the task guide mentioned earlier if you didn't watch the task guide, **ER Create required configurations to import data from an external file for electronic reporting**, in the current finance and operations application.

Title	File name
ER model configuration	1099model.xml

Last updated on 04/13/2026

ER Create required configurations to import data from an external file

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user in the System administrator or Electronic reporting developer role can design Electronic reporting (ER) configurations to import data into the application from an external file. In this example, you create the required ER configurations for the sample company, Litware, Inc. To complete these steps, you must first complete the steps in the task guide, "ER Create a configuration provider and mark it as active." You can complete these steps by using the USMF data set. You must also download and save the following files locally:

Expand table

Content description	File name
ER data model configuration - 1099	1099model.xml
ER format configuration - 1099	1099format.xml
Sample of the incoming document in XML format	1099entries.xml
Sample of the workbook to manage data of incoming document	1099entries.xlsx

ER offers business users the ability to configure the process of importing external data files to tables in either .XML or .TXT format. First, you must design an abstract data model and an ER data model configuration to represent the data that you're importing. Next, you need to define the structure of the file that you're importing and the method that you use to port the data from the file to the abstract data model. You must create the ER format configuration that maps to the designed data model for that abstract data model. Then, you must extend the data model configuration with a mapping that describes how the imported data is persisted as abstract data model data and how it is used to update tables. You must append the ER data

model configuration with a new model mapping that describes the binding of the data model to the application's destinations.

The following scenario shows the ER data import capabilities. This scenario includes vendor transactions that are tracked externally and then imported to be reported later in Vendor's settlement for 1099's.

Add a new ER model configuration

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

   Verify that the configuration provider for sample company **Litware, Inc.** is available and marked as active. If you don't see this configuration provider, first complete the steps in the procedure, "Create a configuration provider and mark it as active."

2. Select **Reporting configurations**.

   Instead of creating a new model to support data import, load the file, `1099model.xml`, that you previously downloaded. This file contains the custom data model of vendors' transactions. You map this data model to the data components that are in the AOT data entity.

3. Select **Exchange**.

4. Select **Load from XML file**.

   Select **Browse** and go to the `1099model.xml` file that you previously downloaded.

5. Select **OK**.

6. In the tree, select **1099 Payments model**.

Review data model settings

1. Select **Designer**.

   This model represents vendors' transactions from the business standpoint. It's separate from the implementation.

2. In the tree, expand **1099-MISC**.

3. In the tree, select **1099-MISC\Transactions**.

4. In the tree, expand **1099-MISC\Transactions**.

   The **Transactions** element of this model represents individual transactions. Use the child elements to specify required details, such as vendor account and transaction date, for each transaction.

5. Close the page.

Add a new ER format configuration that supports data import

The steps in this subtask show you how to create a new format configuration to manage data import from external files.

1. Select **Create configuration** to open the drop dialog.
2. In the **New** field, enter *Format based on data model 1099 Payments model*.
3. Select **Yes** in the **Supports data import** field.
4. Press **ESC** key to close this page.

   Instead of creating a new format to support data import, load the 1099format.xml file that you previously downloaded. This file contains the defined structure of the file you are importing and the mapping of the structure to the custom data model of vendors' transactions.

5. Select **Exchange**.
6. Select **Load from XML file**. Select **Browse** and go to the 1099format.xml file that you previously downloaded.
7. Select **OK**.
8. In the tree, expand *1099 Payments model*.
9. In the tree, select *1099 Payments model\Format for importing vendors' transactions*.

Review format settings

1. Select **Designer**.
2. Toggle **Show details** on.

3. Select **Expand/collapse**.
4. Select **Expand/collapse**.

   The designed format represents the expected structure of the external file. This file must be in XML format and have the settlement root element. Each vendor's transaction is represented by the transaction element that is defined as having zero-to-many multiplicity. This definition means that the incoming file can contain zero to multiple transactions. Nested elements of the *transaction* element represent a single transaction's attributes. All attributes, except country/region, are mandatory, so the importing file must include them.

Review the settings of the format mapping to the data model

1. Select **Map format to model**.

   The mapping **For importing vendors' transactions** contains the data transfer rules from the incoming XML file to the selected part of the custom data model, which you define by selecting the 1099-MISC definition.
2. Select **Designer**.
3. Toggle **Show details** on.
4. In the tree, expand **format: Record**.
5. In the tree, select **format: Record**.

   You see the designed format as a data source component.
6. In the tree, expand `format: Record*settlement: XML Element 1..1 (settlement): Record`.
7. In the tree, expand `format: Record*settlement: XML Element 1..1 (settlement): Record\transaction: XML Element 0..* (transaction): Record list`.
8. In the tree, expand `format: Record*settlement: XML Element 1..1 (settlement): Record\transaction: XML Element 0..* (transaction): Record list*vendor: XML Element 1..1 (vendor): Record`.
9. In the tree, expand `format: Record*settlement: XML Element 1..1 (settlement): Record\transaction: XML Element 0..1 (country): Record`.

10. In the tree, select `format: Record*settlement: XML Element 1..1 (settlement): Record\transaction: XML Element 0..* (transaction): Record list*vendor: XML Element 1..1 (vendor): Record`.

    The predefined **format** data source component presents mandatory and optional format elements differently.

11. In the tree, expand **Transactions: Record list= format.settlement.'$enumerated'**.

    The elements of the format that defines the structure of the imported file are bound to the elements of the custom data model. Based on these bindings, the content of the imported XML file is stored at run-time in the existing data model. Pay attention to the binding of the country element. For any transaction element in the incoming file that has no such element, the default country code **USA** is populated in the data model.

12. Select the **Validations** tab.

    This format mapping can contain user-defined logic to validate the accuracy of the imported data from a business standpoint. For example, based on the setting, for any transaction in the importing file without a defined country code, a warning message is generated in the Infolog that informs the user about the case and indicates the transaction's sequence number.

13. Close the page.

Run the format mapping to the data model

Run this format mapping for testing purposes. Use the `1099entries.xml` file that you previously downloaded. You can export this file from the `1099entries.xlsx` workbook that you use to manage vendor transactions. The generated output imports from the selected XML file and populates the custom data model at real import.

1. Select **Run**.

    Select **Browse** and go to the `1099entries.xml` file that you previously downloaded.

2. Select **OK**.

    Note the warning message about a missing country code for a transaction in the imported file.

Review the output in XML format, which represents the data that you imported from the selected file and ported to the data model.

3. Close the page.

4. Close the page.

Review the settings for the model mapping to the destinations

1. In the tree, select **1099 Payments model**.

2. Select **Designer**.

3. Select **Map model to datasource**.

   The mapping **For 1099 manual transactions import** is defined with the **To destination** direction type. This mapping supports data import and contains the setting of rules that define how the imported external file and persisted abstract data model data are used to update tables in the application.

4. Select **Designer**.

5. In the tree, expand **model: Data model 1099 Payments model**.

6. In the tree, expand **model: Data model 1099 Payments model\Transactions: Record list**.

   The designed model appears as a data source element. At runtime, it contains the data that you import from the external file. Add several tables as data source elements to ensure that the imported data is compliant with the data of the current application, including whether the importing transaction vendor account is available in the system, whether the combination of the importing country/region and state codes exists, and other checks.

7. In the tree, select `model: Data model 1099 Payments model\Transactions: Record list\$failed: Calculated field = IF(OR(ISEMPTY(model.Transactions.'$refs'.vendor), ISEMPTY(model.Transactions.'$refs'.vendor1099), ISEMPTY(model.Transactions.'$refs'.box1099), ISEMPTY(model.Transactions.'$refs'.country), ISEMPTY(model.Transactions.'$refs'.state), ISEMPTY(model.Transactions.'$refs'.location)), true, false): Boolean`.

8. Select **Edit**.
9. Select **Edit formula**.

   When at least one validation fails for a single imported transaction, the data source attribute `$failed` marks this transaction as failed.
10. Close the page.
11. Select **Cancel**.
12. In the tree, select `tax1099trans: Table 'VendSettlementTax1099' records= model.Validated`.
13. Select **Edit destination**.

    Add this ER destination to specify how the imported data updates the application tables. In this case, select the data table `VendSettlementTax1099`. Because the record action `Insert` is selected, the imported transactions are inserted in the table `VendSettlementTax1099`. A single model mapping can contain several destinations. This design means that the imported data can update multiple application's tables at once. You can use tables, views, and data entities as ER destinations.

    If you call the mapping from a point in the application (such as button or menu item) that you specifically designed for this action, mark the ER destination as the integration point. In this example, this point is `ERTableDestination#VendSettlementTax1099`.
14. Select **Cancel**.
15. Select **Show all**.
16. Select **Show mapped only**.
17. In the tree, expand `tax1099trans: Table 'VendSettlementTax1099' records= model.Validated`.

    The data source element that contains only validated transactions is bound to the created destination. You can filter the imported transactions to skip the ones that are incompatible with the applications' data.
18. In the tree, select `failed: Table 'VendSettlementTax1099Entity' records= model.Failed`.
19. Select the **Validations** tab.

This model mapping can contain user-defined logic to validate the correctness of the imported data from the existing application data. For example, based on the present setting, for any transaction in the imported file with a vendor account that isn't in the system, a warning message is generated that informs the user and indicates the incorrect vendor account code.

Use the **Post validation action** option for each validation to specify whether the import process must continue or stop, and if the already performed inserts or updates can be kept or rolled back.

20. Select **Show mapped only**.
21. Select **Show all**.
22. Close the page.

    Execute this model mapping to test the designed format and model mappings. Use the file `1099entries.xml`. The data from the selected file is imported into the system.

23. Select **Run**.

    The dialog box contains no additional questions about the format mapping that must be used to parse the imported file and then port the data to the data model. This condition exists because there's currently only one format that uses this model, which is marked as designed to support data import.

    Define the voucher ID to differentiate the imported transactions from other transactions that you might already entered manually or imported.

24. In the **Enter voucher id** field, type `IMPORT-001`.

    Browse to get the `1099entries.xml` file.

25. Select **OK**.

    The list of generated warnings provides information about incorrect vendor accounts, an incorrect tax 1099 box code, missing country codes, and other issues. Compare this list of warnings to the content that the execution XML file includes.

26. Close the page.
27. Close the page.

28. Close the page.
29. Close the page.
30. Go to **Accounts payable** > **Periodic tasks** > **Tax 1099** > **Vendor settlement for 1099s**.

    This form shows the cumulative transactions in the **Tax1099Summary** table that the system created based on imported transactions.
31. In the **From date** field, set the date to 2000-01-01.
32. Select **Manual 1099 transactions**.

    This form contains the list of transactions that you added manually and those that you just imported.
33. Open **Voucher** column filter.
34. Enter a filter value of `IMPORT-001` on the **Voucher** field by using the **begins with** filter operator.

Review the relationship between model and format mappings

1. Close the page.
2. Close the page.
3. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
4. Select **Reporting configurations**.
5. In the tree, select **1099 Payments model**.

    Assume that you want to support importing the same data but from a .TXT file format.
6. Select **Create configuration** to open the dialog box.
7. In the **New** field, enter *Format based on data model 1099 Payments model*.
8. In the **Name** field, type *Import data from TXT file*.
9. Select **Yes** in the **Supports data import** field.
10. Select **Create configuration**.

11. Select **Designer**.
12. Select **Map format to model**.
13. Select **New**.
14. In the **Definition** field, enter or select a value.

    Select **1099-MISC** option.
15. In the **Name** field, type *Import data from TXT file*.
16. In the **Description** field, type *Import data from TXT file*.
17. Select **Save**.
18. Close the page.
19. Close the page.
20. Select **Edit**.

    If you installed the hotfix "KB 4012871 Support of GER model mappings in separated configurations with an ability to specify different kinds of prerequisites for deploying them on different versions of Dynamics 365 Finance" (KB 4012871), execute the next step **Turn the flag 'Default for model mapping' on** for the entered format configuration. Skip the next step otherwise.
21. Select **Yes** in the **Default for model-mapping** field.
22. In the tree, select **1099 Payments model**.
23. Select **Designer**.
24. Select **Map model to datasource**.
25. Select **Run**.

    If you installed the hotfix, KB 4012871 Support of GER model mappings in separated configurations with an ability to specify different kinds of prerequisites for deploying them on different versions (KB 4012871), select the preferred model mapping in the lookup field. If you didn't install the hotfix, skip to the next step as the mapping is already selected by the definition of the default format configuration.

If you didn't install the hotfix, KB 4012871, the dialog box contains an additional model-mapping question that is used to parse the file that you're importing. The data is then ported from the dialog box to the data model. Currently, you can choose which format mapping to use depending on the type of file that you plan to import.

If you plan to call this model mapping from a point in the application that is specifically designed for the action, the ER destination and the format mapping must be marked as part of the integration.

26. Select **Cancel**.
27. Close the page.
28. Close the page.

Import data from manually selected files in batch mode

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To use the Electronic reporting (ER) framework to import data from manually selected inbound files in batch mode, configure an ER format that supports the import. Then run a model mapping of the **To destination** type that uses that format as a data source. To import data, browse to the file that you want to import, and manually select it.

The new ER capability that supports data import in batch mode enables you to configure this process as unattended. You can use ER configurations to perform data import by scheduling a new batch job from the ER user interface (UI).

This article explains how to complete data import from a manually selected file in batch mode. The examples use vendor transactions as business data. You can complete the steps of these examples in the **USMF** company. No coding is required.

Prerequisites

To complete the examples in this article, you must have the following access:

- One of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator
- ER format and model configurations for 1099 payments

Create the required ER configurations

To create the required ER configurations and obtain other prerequisites, follow one of these steps:

- Play the **ER Import data from a Microsoft Excel file** task guides, which are part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process. These task guides walk you through the process of designing and using ER configurations that interactively import vendor transactions from Microsoft Excel files. For more information, see Parse incoming documents in Excel format.
- Complete the examples in Configure data import from SharePoint. These examples walk you through the process of designing and using ER configurations that interactively import vendor transactions from Excel files that are stored in a SharePoint folder.

Download the required ER configurations

1. Download the following ER configurations, and save them locally.

Expand table

Content description	File
1099 Payments model ER data model configuration	1099model.xml
For importing vendors' transactions (Excel) ER format configuration	1099format-import-from-excel.xml

2. Use the Load from XML file ER option to import the downloaded ER configurations into your instance of Dynamics 365 Finance in the following order:
   a. ER data model configuration
   b. ER format configuration

Download the required Excel files

- Download the following sample data set, and save it locally.

Expand table

Content description	File
Inbound **1099import-data.xlsx** file that contains sample data for import	1099import-data.xlsx

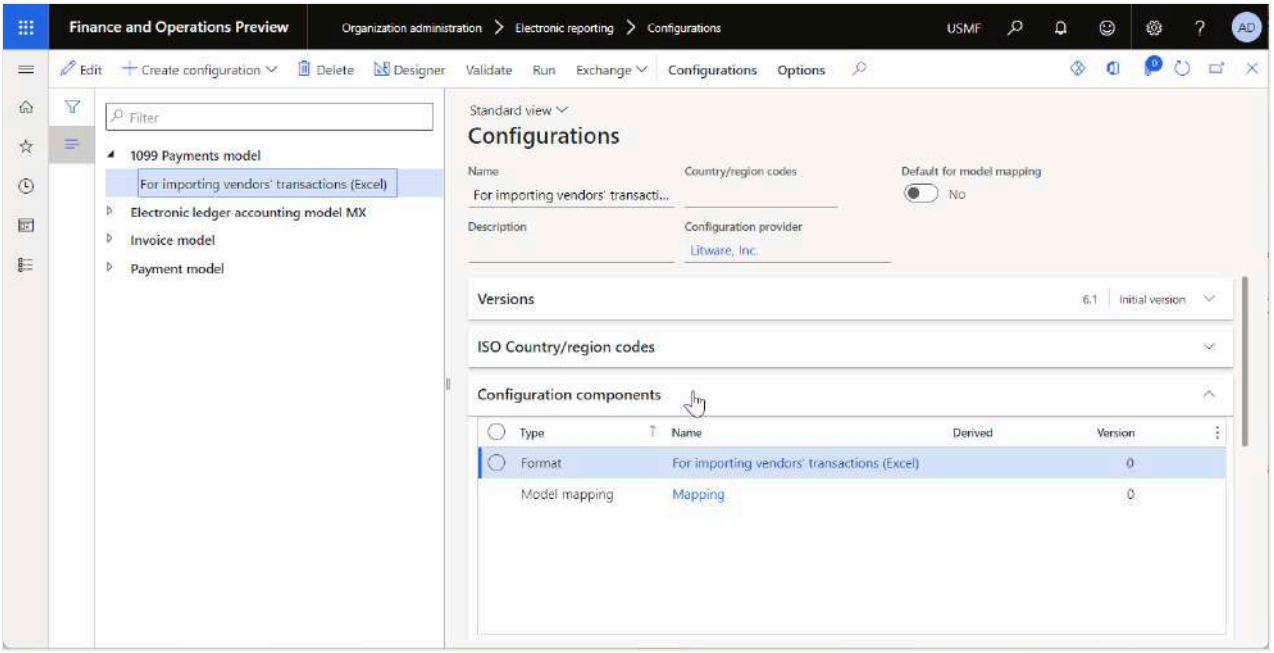
Review the prerequisites

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.

2. On **Configurations**, review the prepared ER solution for data import in batch mode.

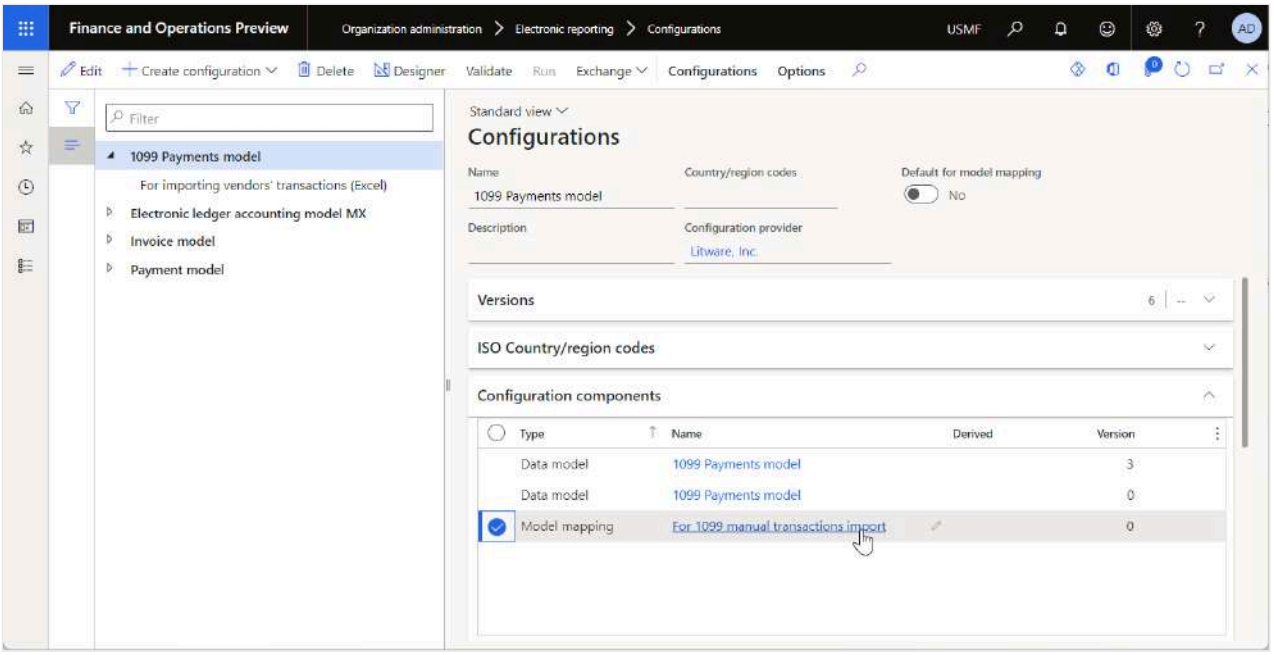
3. Review the **For importing vendors' transactions (Excel)** format configuration.

    - The format component of this configuration is designed to parse an inbound Excel file.
    - The model mapping component of this configuration is used to fill in the base data model by using data from the parsed Excel file.

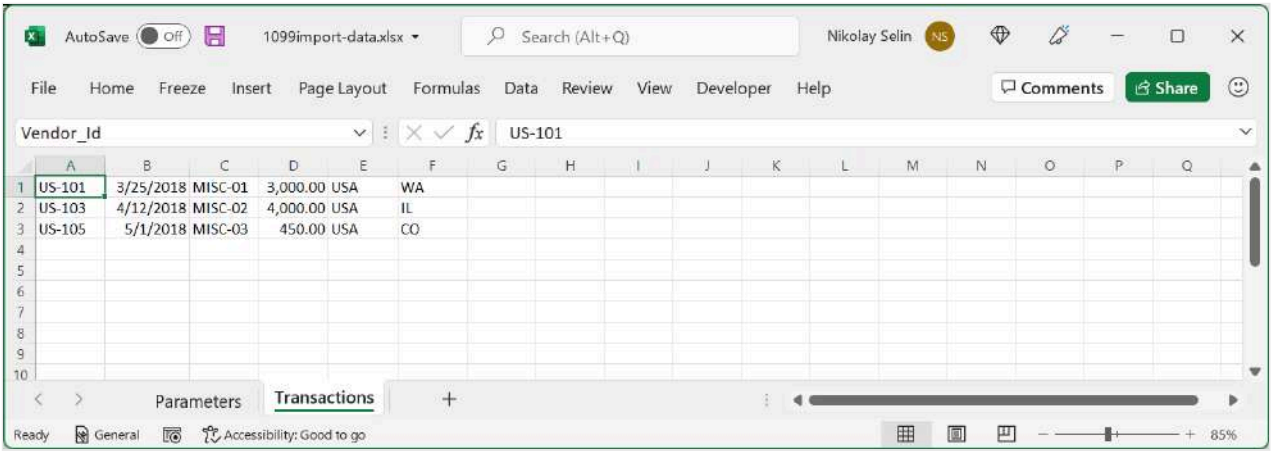


4. Review the **1099 Payments model** data model configuration.

    - The model component of this configuration represents the structure of the data model that is used to pass data between running ER components.
    - The model mapping component of this configuration is used to pull data from the executed format component and then update application tables.



5. Open the **1099import-data.xlsx** file in Excel.



Enable batch data import for ER from the UI

1. Go to **System administration** > **Workspaces** > **Feature management**.
2. In **Feature management**, select the **Run ER import of manually uploaded documents in batch** feature, and then select **Enable now**.

Import data from manually selected Excel files

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, select the **1099 Payments model** data model configuration.
3. On the **Configuration components** FastTab, select the **For 1099 manual transactions import** link.

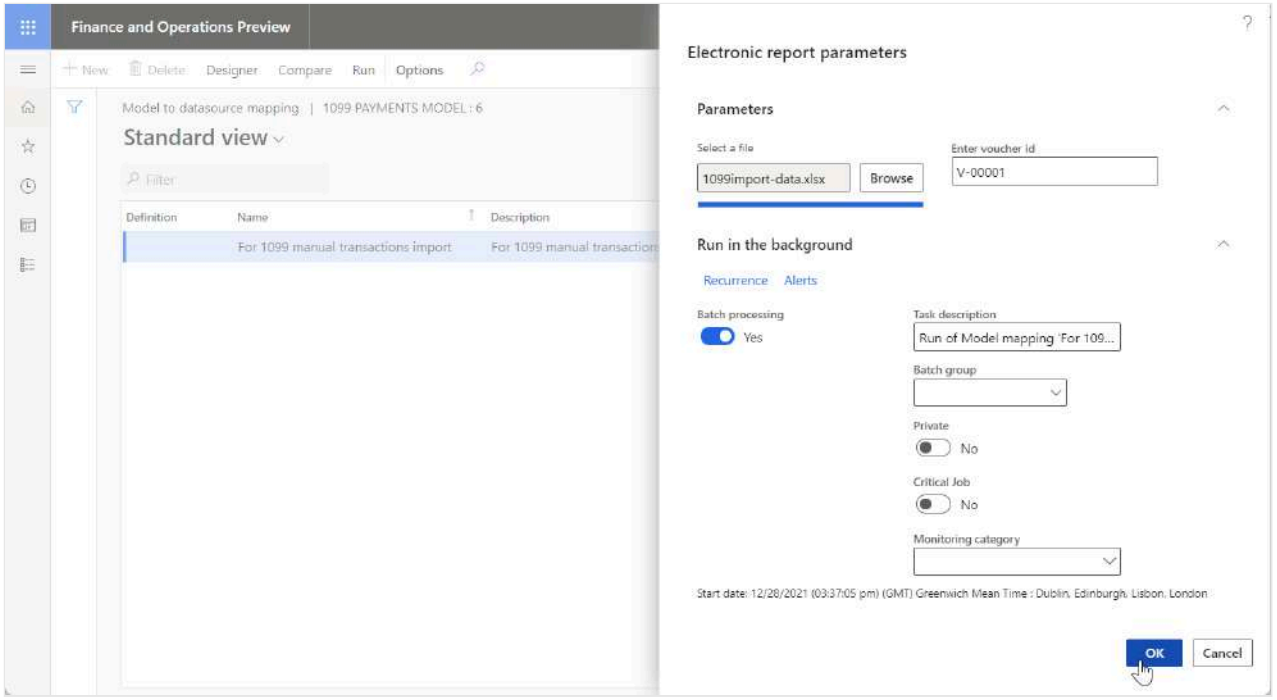
4. On **Model to datasource mapping**, the **For 1099 manual transactions import** model mapping is preselected. Select **Run**.

5. On the **Parameters** tab, select **Browse**. Find and select the **1099import-data.xlsx** file, and then select **OK**.

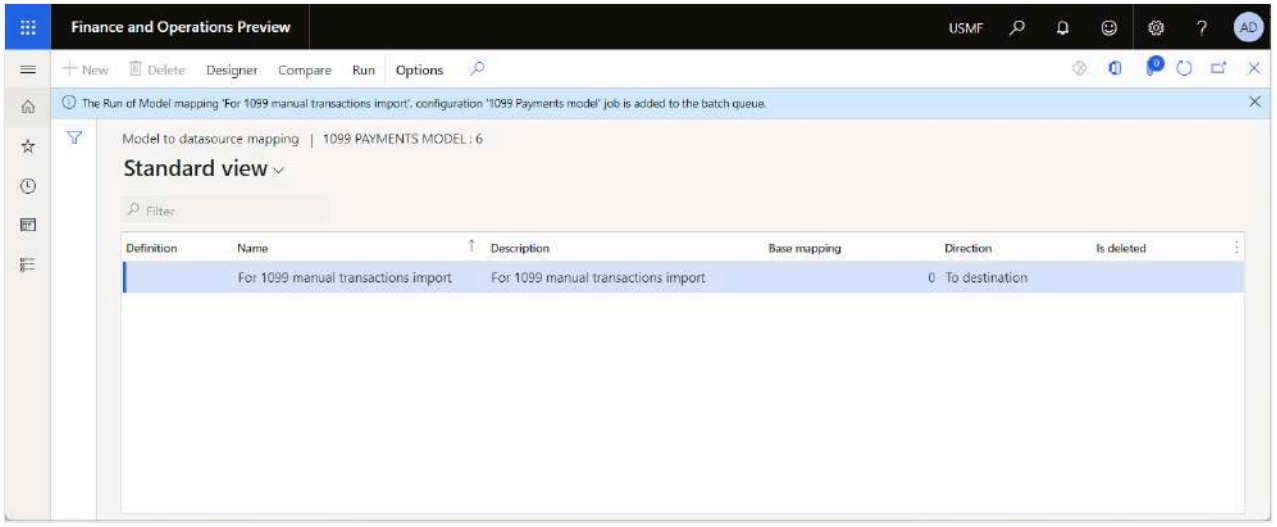
6. In the **Enter voucher id** field, enter **V-00001**.

7. On the **Run in the background** tab, set the **Batch processing** option to **Yes**.

   Notice that the **Task description** field is set to **Run of Model mapping 'For 1099 manual transactions import', configuration '1099 Payments model'**. This value indicates that the execution of the selected model mapping is scheduled as a new batch job.

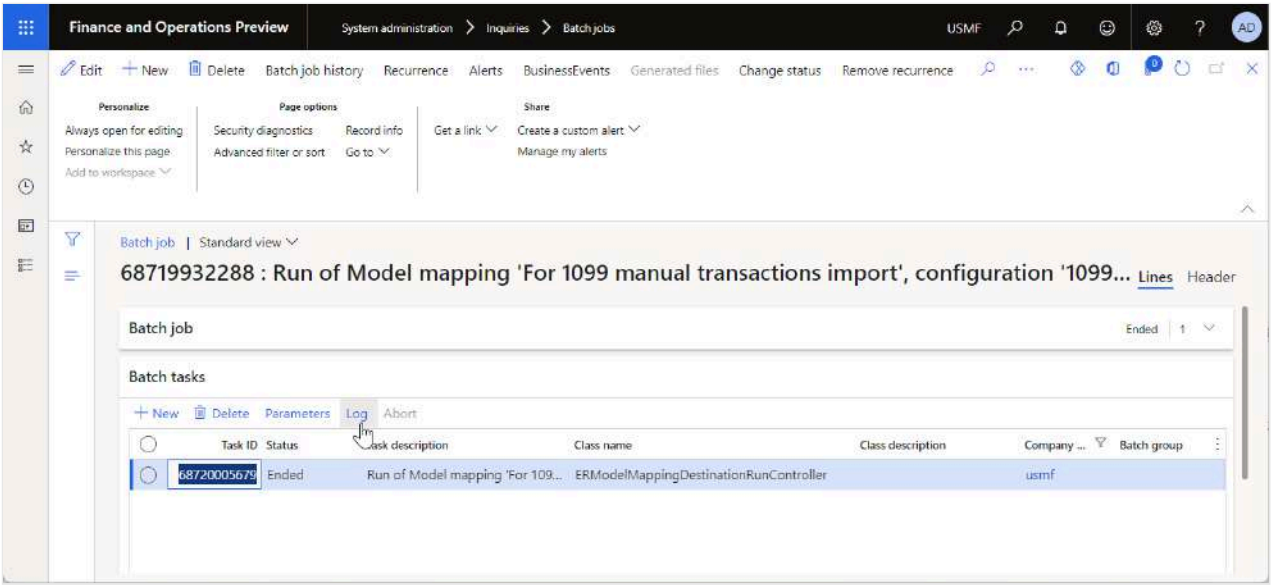


8. Select **OK**. A message notifies you that a new batch job is scheduled.

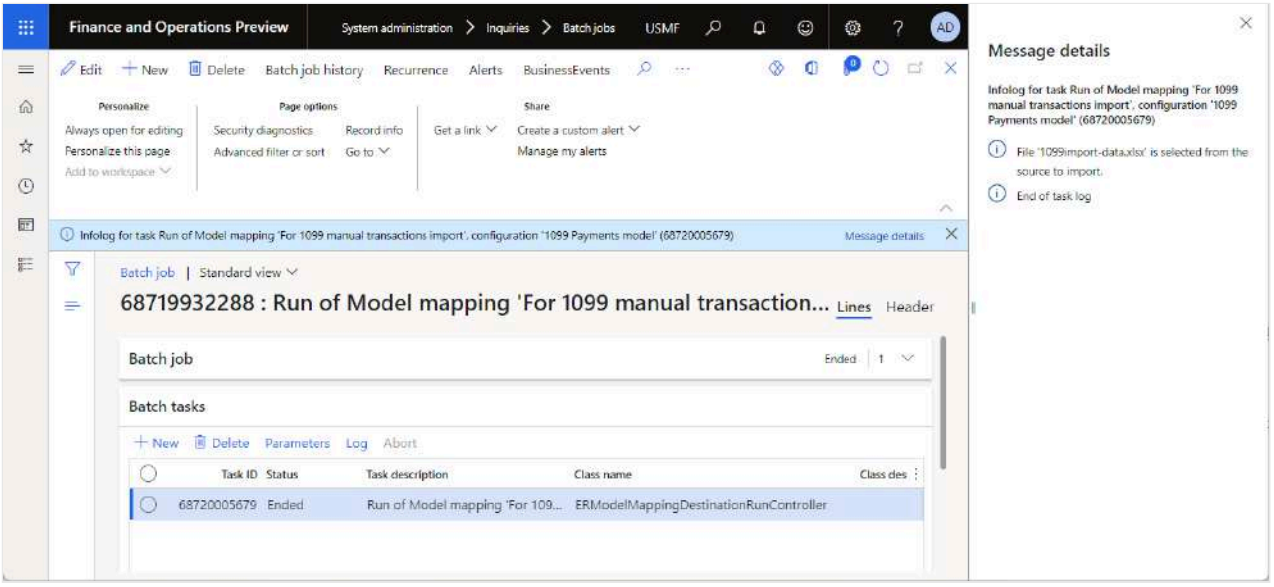


Review the data import results on the Batch job page

1. Go to **Common** > **Inquiries** > **Batch jobs** > **My batch jobs**.
2. On the **Batch job** page, filter the list of batch jobs to find the scheduled batch, and then select it.
3. Select the **Job ID** link to review job details.
4. On the **Batch tasks** FastTab, select **Log**.



5. Review the execution details.



Change the data import parameters

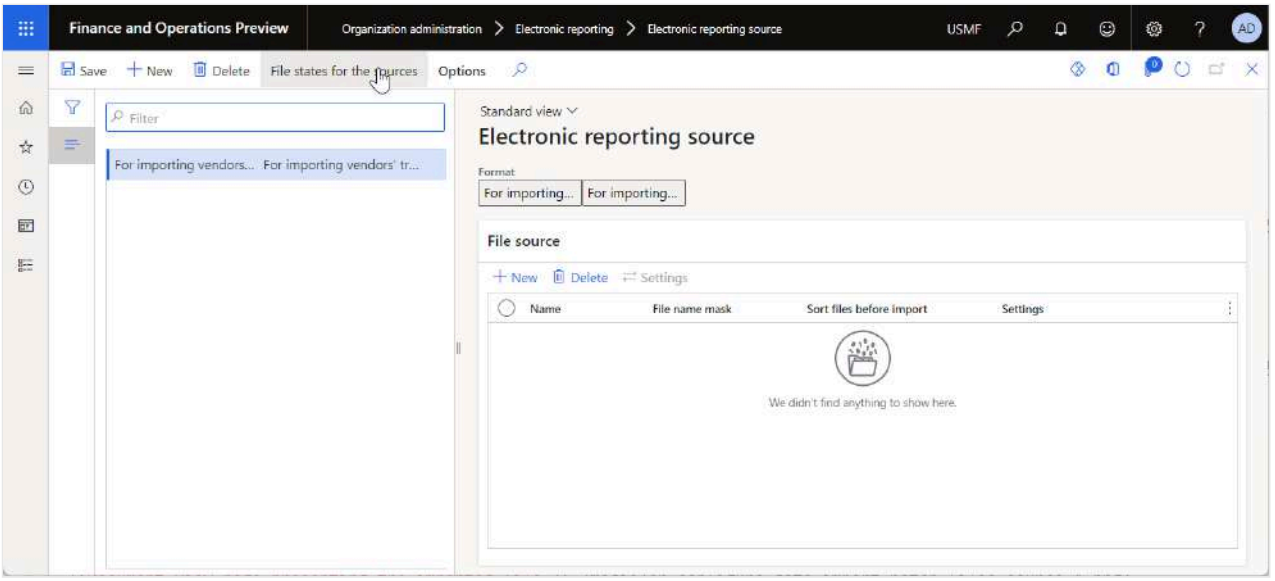
After your batch is scheduled but before it runs, you can change the parameters of the scheduled data import.

1. Go to **Common** > **Inquiries** > **Batch jobs** > **My batch jobs**.
2. On the **Batch job** page, filter the list of batch jobs to find the scheduled batch, and then select it.
3. Select **Change status**.
4. In the **Select new status** dialog box, select **Withhold**, and then select **OK**.
5. Select the **Job ID** link to access the job details.
6. On the **Batch tasks** FastTab, select **Parameters**.
7. In the **Electronic report parameters** dialog box, follow these steps:
    a. Select **Browse** to select the alternative file for data import.
    b. Select **Enter voucher id** to change the voucher number for importing vendor transactions.

    c. Select **OK**.
8. Make sure that the batch is still selected, and then select **Change status** again.
9. In the **Select new status** dialog box, select **Waiting**, and then select **OK**.

Review the data import results on the ER source page

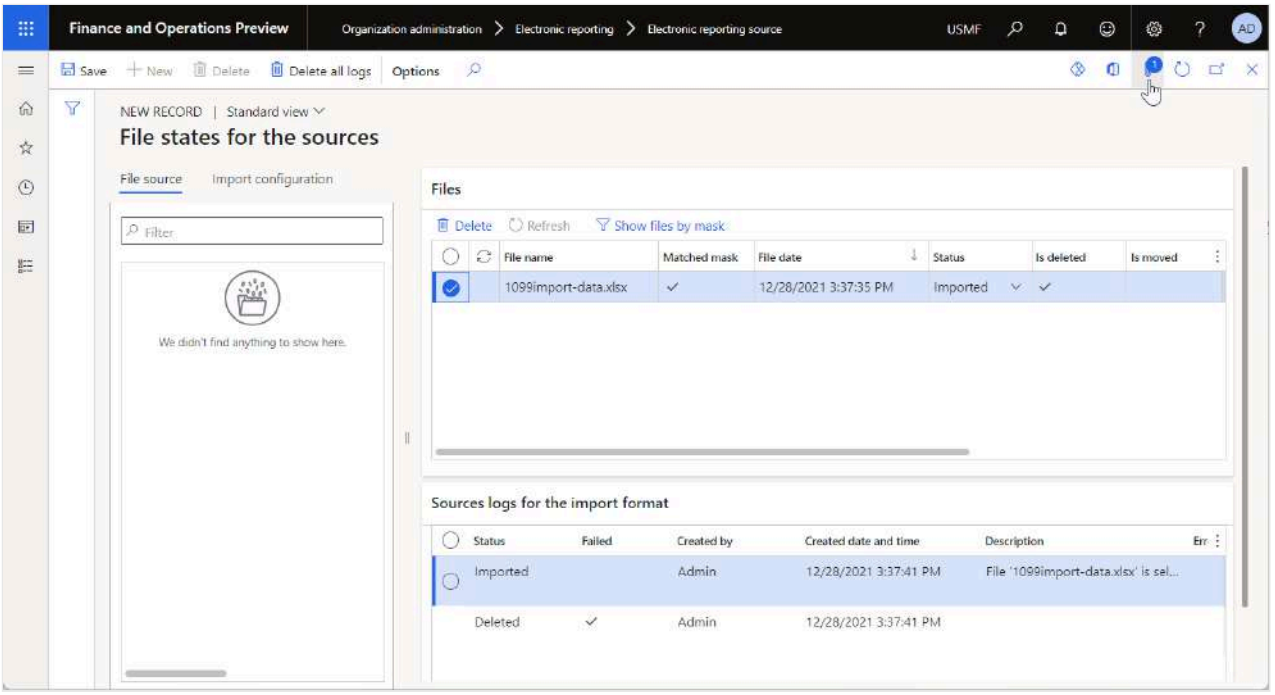
1. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting source**.
2. Select the **For importing vendors' transactions (Excel)** record. This record is created automatically during the data import.



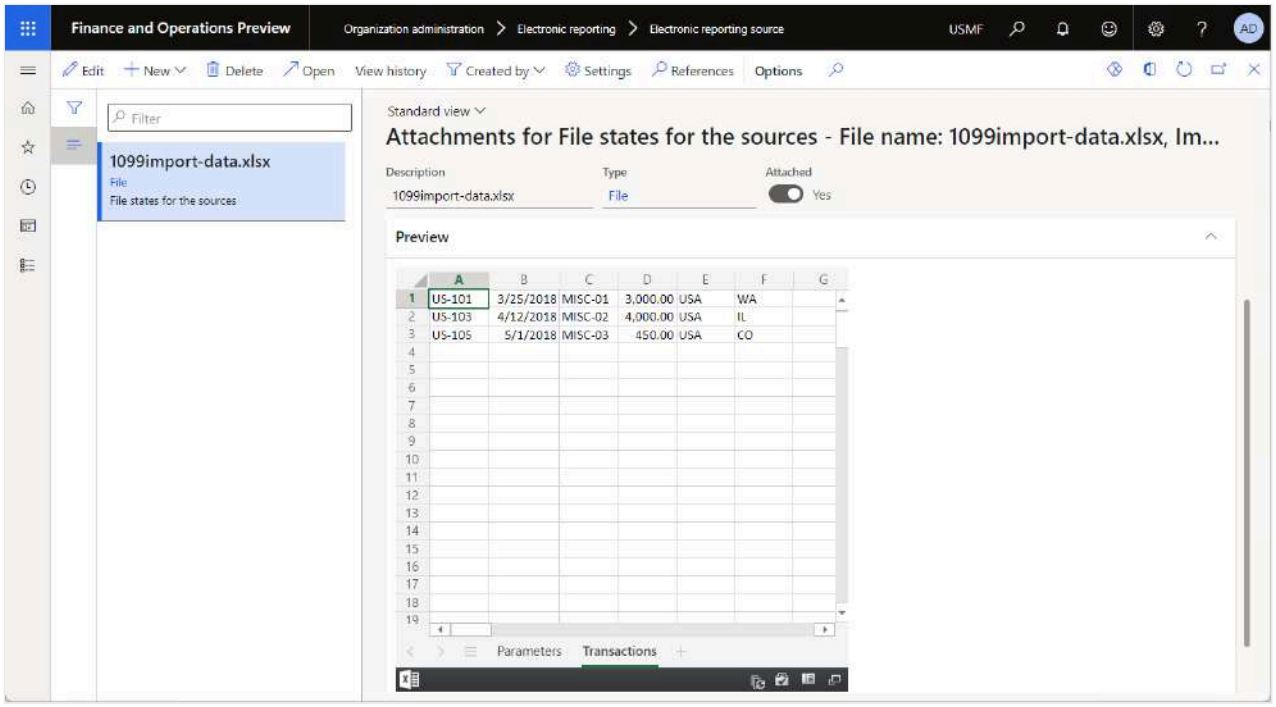
3. Select **File states for the sources**.

4. On the **Files** and **Source logs for the import format** FastTabs, review the import details.

5. On the **Files** FastTab, select the record. The imported file is attached to this record.



6. Select **Attachments** to review the imported file.



> **Tip**
>
> To keep these attachments, the ER framework uses a document type that is **set** for the current company in the **Others** field of the ER parameters.

Review the data import results on the Vendor settlement for 1099s page

1. Go to **Accounts payable** > **Periodic tasks** > **Tax 1099** > **Vendor settlement for 1099s**.
2. In the **From date** field, enter **12/31/2017** (December 31, 2017).
3. Select **Manual 1099 transactions**.

Configure data import from SharePoint

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To import data from an incoming file by using the Electronic reporting (ER) framework, you must configure an ER format that supports the import and then run a model mapping of the **To destination** type that uses that format as a data source. To import data, you must navigate to the file that you want to import. You can manually select the incoming file. By using the new ER capability to support importing data from Microsoft SharePoint, you can configure this process as unattended. You can use ER configurations to perform data import from files that are stored in Microsoft SharePoint folders. This article explains how to complete the import from SharePoint. The examples use vendor transactions as business data.

Prerequisites

To complete the examples in this article, you must have the following access:

- Access one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator
- Access to the instance of Microsoft SharePoint Server that is configured for use with the application.
- ER format and model configurations for 1099 payments.

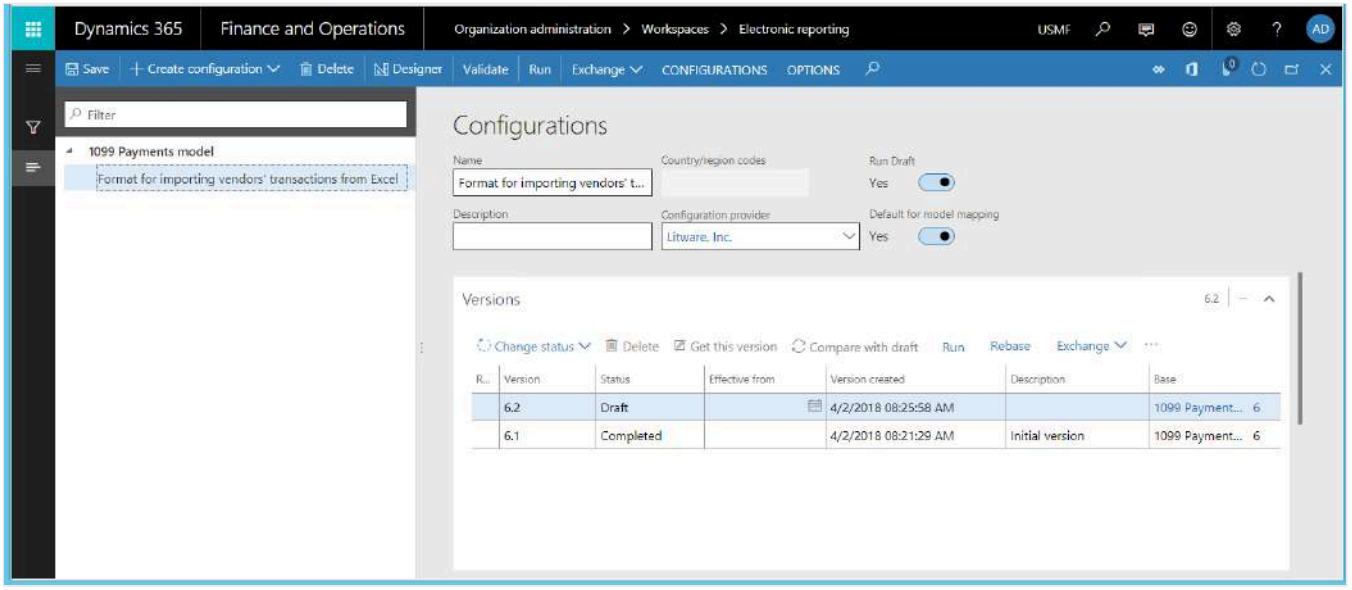
Create required ER configurations

The **ER Import data from a Microsoft Excel file** task guide is part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process. This task guide walks you through the process of designing and using ER configurations to interactively import

vendor transactions from Microsoft Excel files. For more information, see Parse incoming documents in Excel format. When you complete the task guide, you have the following setup.

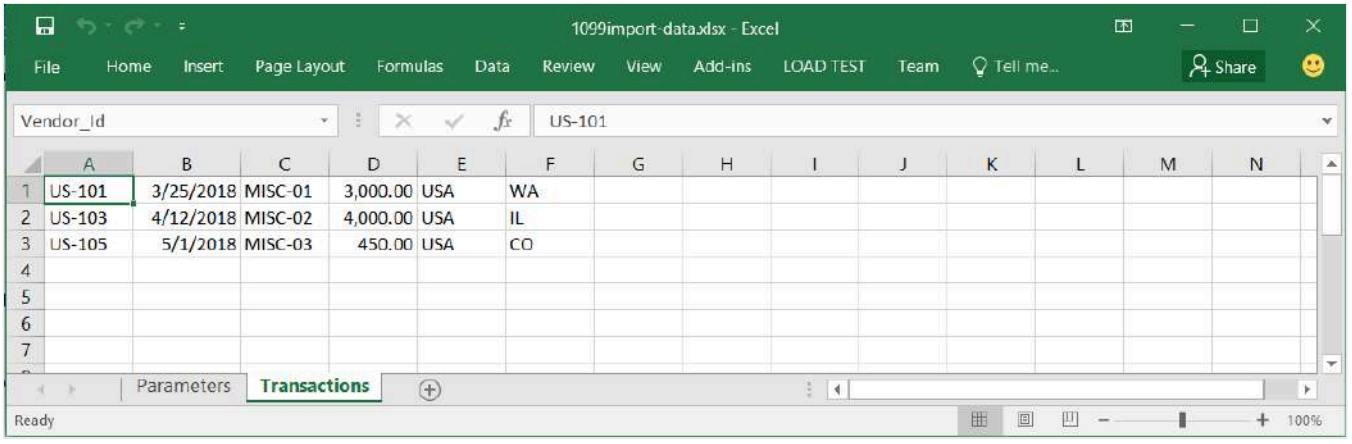
ER configurations

- ER model configuration, **1099 Payments model**
- ER format configuration, **Format for importing vendors' transactions from Excel**



Sample of the incoming file for data import

- Excel file **1099import-data.xlsx**, with vendor transactions that you want to import.

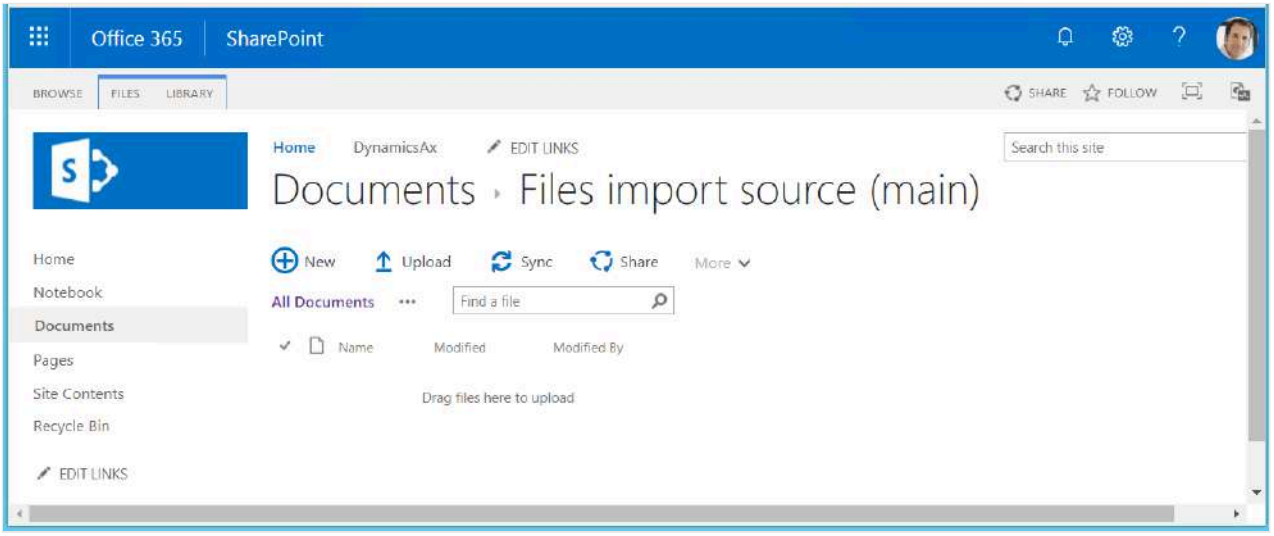


> **Note**
>
> The format for importing vendor transactions is the default model mapping. Therefore, if you run a model mapping of the **1099 Payments model**, and that model mapping is of the **To destination** type, the model mapping runs this format to import data from external files. It then uses that data to update application tables.

Configure access to SharePoint for file storage

To store electronic report files in a SharePoint location, you must configure access to the SharePoint Server instance used by the current company. In this example, the company is USMF. For instructions, see Configure SharePoint storage.

1. Complete the steps in Configure SharePoint storage.
2. Open the configured SharePoint site.
3. Create the following folders where you can store incoming electronic reporting files:
    - Files import source (main) (Example shown in screenshot below)
    - Files import source (alternative)

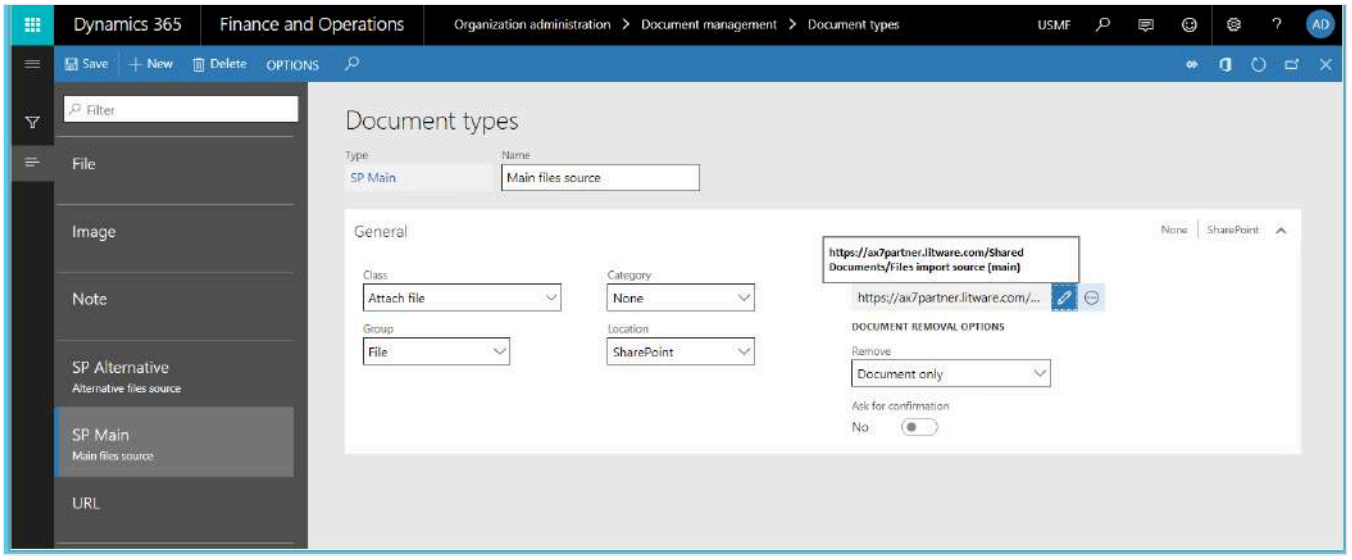


4. (Optional) Create the following folders where you can store files after import.
    - Files archive folder - This folder is for successfully imported files.
    - Files warning folder - This folder is for files that were imported with a warning.
    - Files error folder - This folder is for files that failed to import.
5. Go to **Organization administration** > **Document management** > **Document types**.
6. Create the following document types that help to access the SharePoint folders that you created. For instructions, see Configure document types.

Expand table

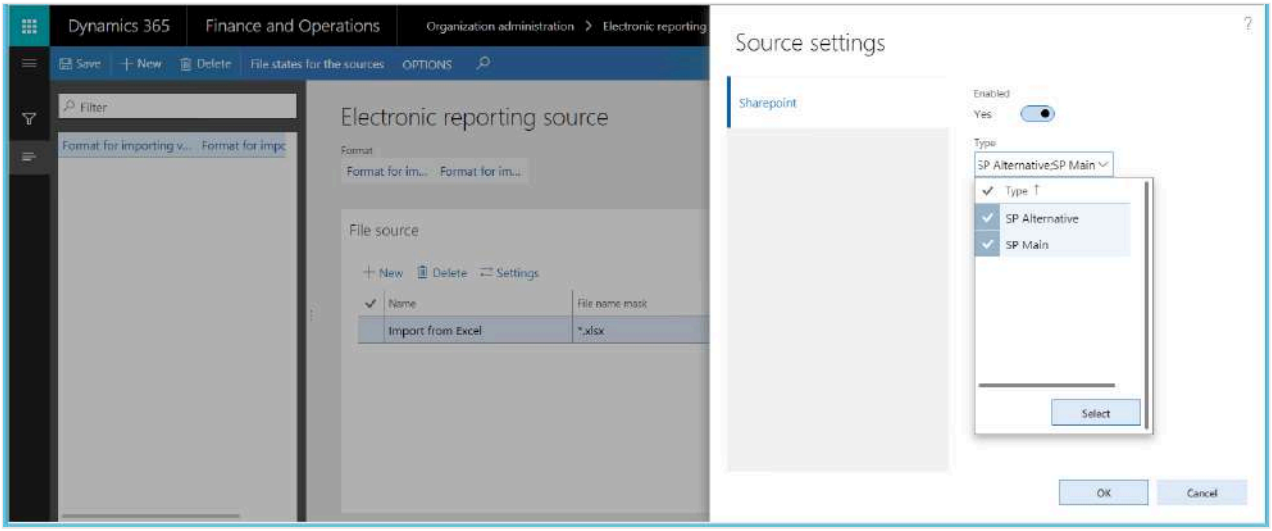
Document type	Group	Location	SharePoint folder
SP Main	File	SharePoint	Files import source (main)

Document type	Group	Location	SharePoint folder
SP Alternative	File	SharePoint	Files import source (alternative)
SP Archive	File	SharePoint	Files archive folder
SP Warning	File	SharePoint	Files warning folder
SP Error	File	SharePoint	Files error folder



Configure ER sources for the ER format

1. Select **Organization administration** > **Electronic reporting** > **Electronic reporting source**.
2. On **Electronic reporting source**, configure the source files for data import by using the configured ER format.
3. Define a file name mask so that only files with the `.xlsx` extension are imported. The file name mask is optional and works only it's defined. You can define only one mask for each ER format.
4. Change **Sort files before import** to **Do not sort** if there are several files for import and the import order isn't important.
5. Select all SharePoint folders that you created earlier.



> **Note**
>
> - The ER *source* is defined for each application company individually. By contrast, ER *configurations* are shared across companies.
> - When you delete an ER source setting for an ER format, all the connected file states are also deleted by confirmation. (see the following section).

Review the file states for the ER format

1. On **Electronic reporting source**, select **File states for the sources** to review the content of the configured file sources for the current ER format.

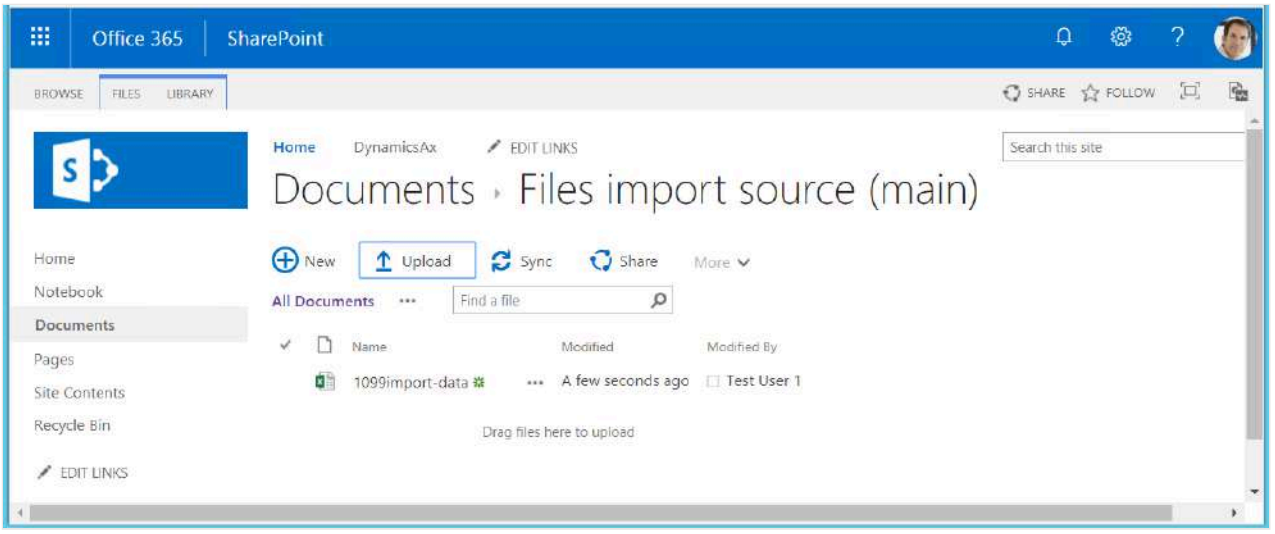
2. In the **Files** section, review the list of files. This list presents the following information:

    - Source files that are applicable, based on the file name mask (if you define one), and that are ready for data import. For these files, the **Sources log for the import format** section is blank.
    - Previously imported files. For each of these files, in the **Sources log for the import format** section, you can review the history of import for this file.

You can also open **File states for the sources** by selecting **Organization administration** > **Electronic reporting** > **File states for the sources**. In this case, the page provides information about file sources for all ER formats with configured file sources in the company that you're currently signed in to.

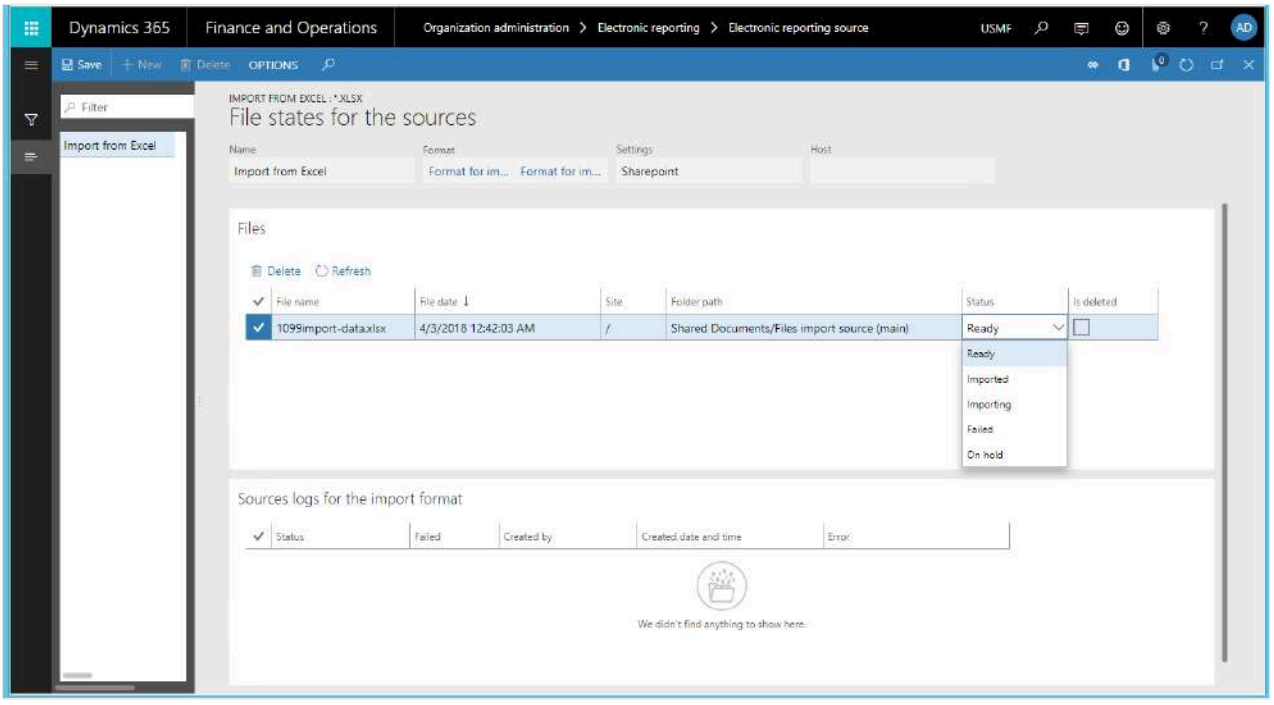
Import data from Excel files in a SharePoint folder

1. In SharePoint, upload the Microsoft Excel file **1099import-data.xlsx** that contains vendor transactions to the **Files import source (main)** SharePoint folder that you created earlier.



2. On **File states for the sources**, select **Refresh** to refresh the page. The Excel file that you uploaded to SharePoint appears on this page with the status **Ready**. The following statuses are currently supported:

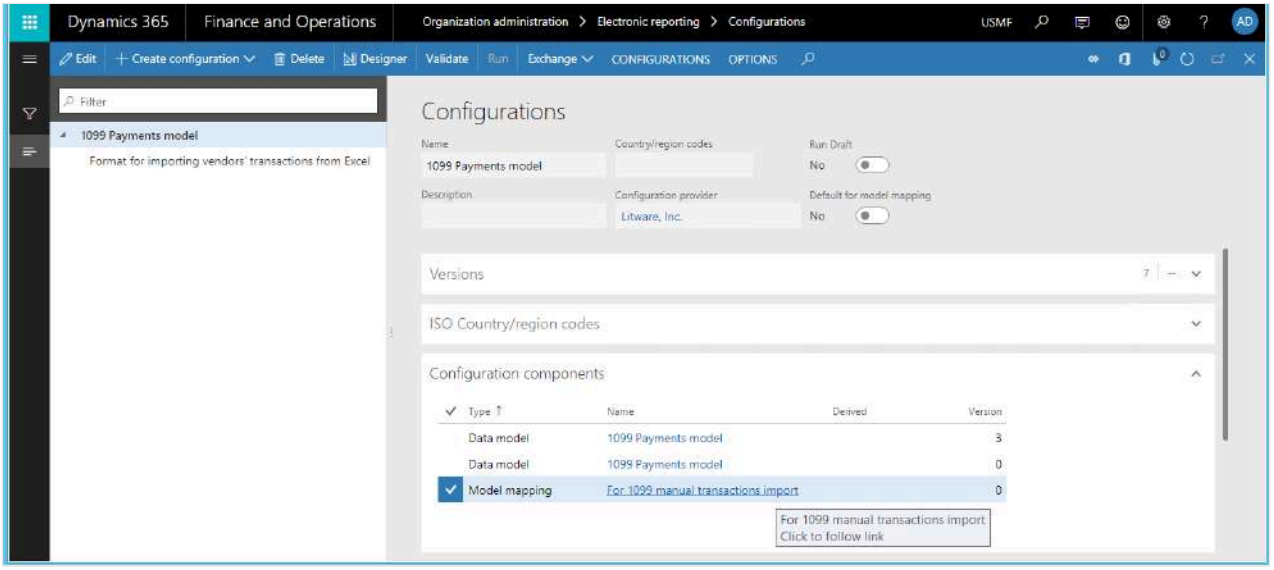
    - **Ready** – Assigned automatically for each new file in a SharePoint folder. This status means that the file is ready for import.
    - **Importing** – Assigned automatically by an ER report when the file is locked by the import process to prevent its usage by other processes (if many of them are running simultaneously).
    - **Imported** – Assigned automatically by an ER report when the file import is successfully completed. This status means that the imported file is deleted from the configured files source (SharePoint folder).
    - **Failed** – Assigned automatically by an ER report when the file import completes with errors or exceptions.
    - **On hold** – Assigned manually by user on this page. This status means that the file isn't imported for now. Use this status to postpone the import of some files.



Import data from SharePoint files

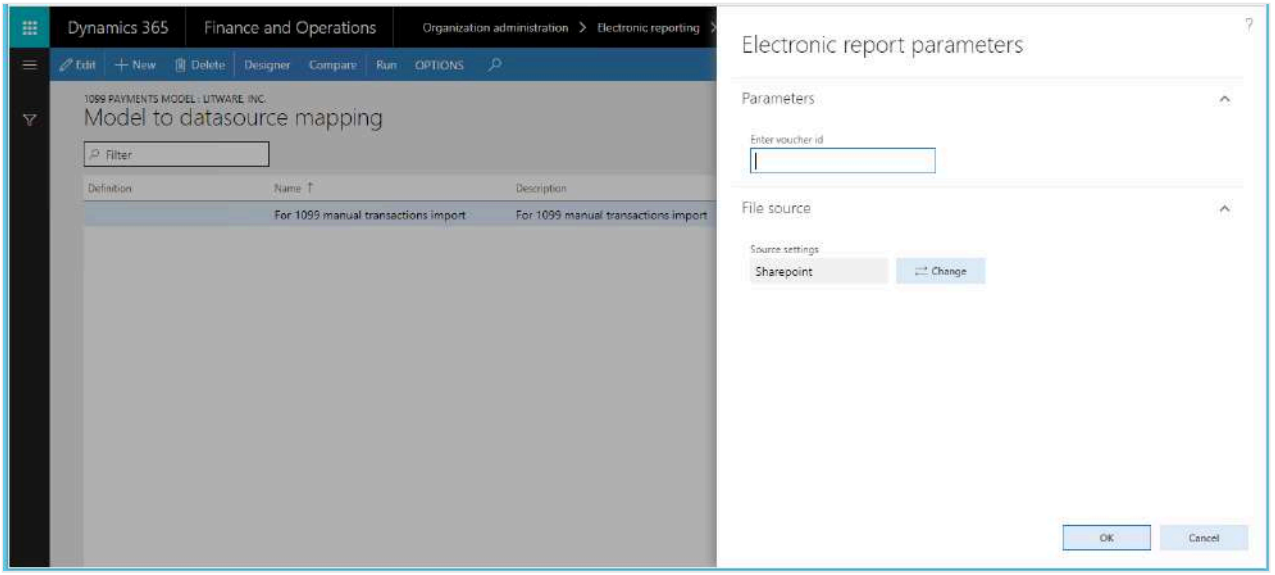
1. Open the ER configurations tree, select the **1099 Payment model**, and expand the list of ER model components.

2. Select the name of the model mapping to open the list of model mappings for the selected ER model configuration.



3. Select **Run** to run the selected model mapping. Because you configured file sources for the ER format, you can change the setting of the **File source** option, if needed. If you keep the setting of this option, the .xslx files are imported from the configured sources (the SharePoint folders, in this example).

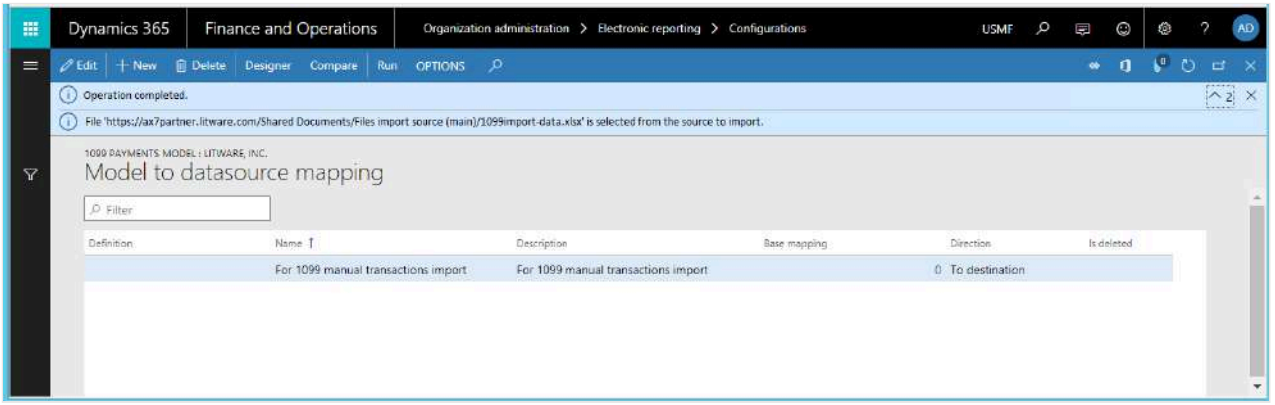
In this example, you're importing only one file. However, if there are multiple files, the files are selected for importing in the order in which you added them to the SharePoint folder. Every run of an ER format imports a single selected file.



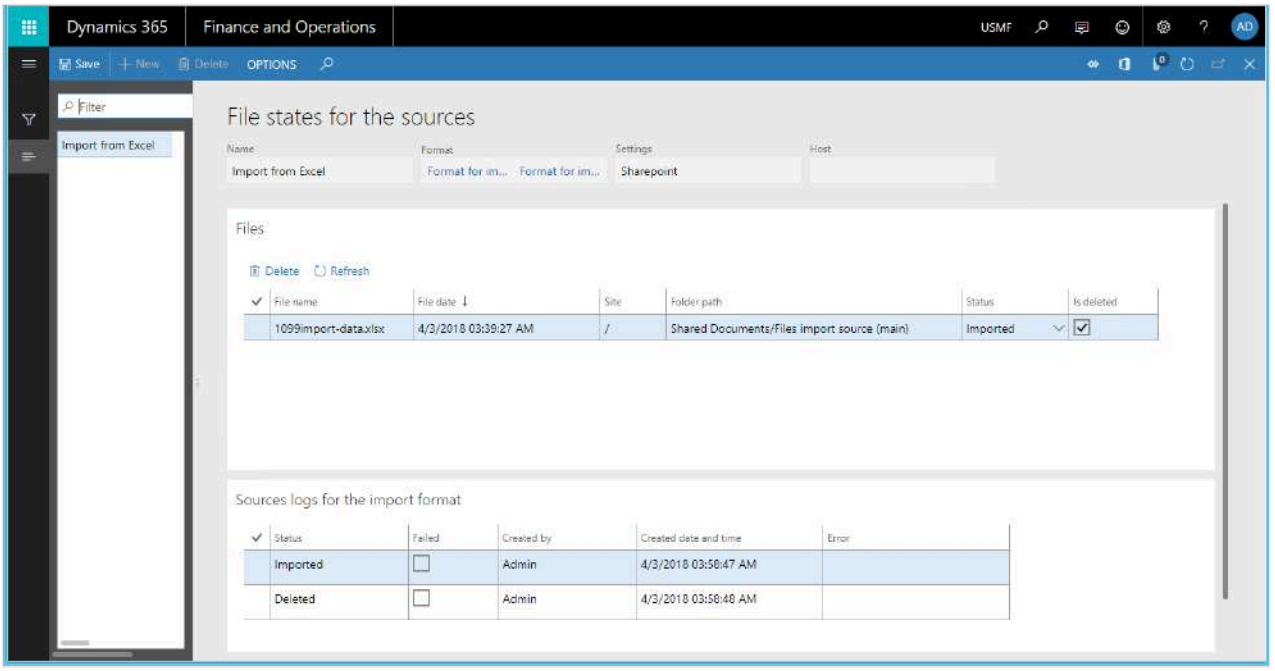
4. The model mapping can run unattended in batch mode. In this case, every time a batch runs this ER format, a single file is imported from the configured file sources.

   When a file is successfully imported from the SharePoint folder, it's deleted from that folder and moved to folder for successful imported files or to the folder to imported files with warnings. Otherwise, it's moved to folder for failed files or stays in this folder if the folder for failed files isn't set up.

5. Enter the voucher ID, such as **V-00001**, and then select **OK**.



6. On the **File states for the sources** page, select **Refresh** to refresh the page.



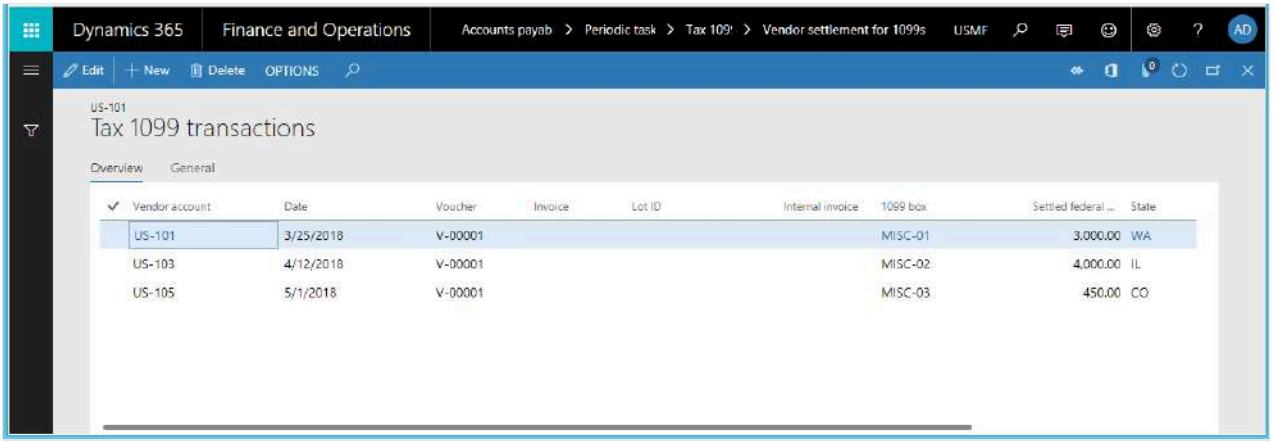
7. In the **Files** section, review the list of files. The **Sources log for the import format** section provides the history of the Excel file import. Because this file was successfully imported, it's marked as **Deleted** in the SharePoint folder.

8. Review the **Files import source (main)** SharePoint folder. The Excel files that were successfully imported are deleted from this folder.

9. Select **Accounts payable** > **Periodic tasks** > **Tax 1099** > **Vendor settlement for 1099s**.

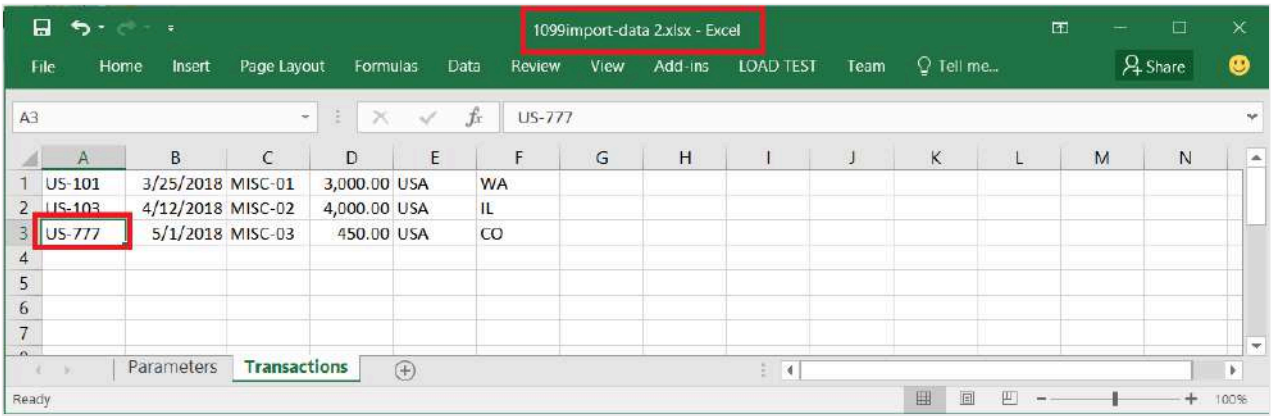
10. In the **From date** and **To date** fields, enter appropriate values. Then select **Manual 1099 transactions**.

    The vendor transactions imported from the Excel files on SharePoint for voucher **V-00001**, are presented on the page.



Prepare an Excel file for import

1. Open the Excel file that you previously used. In row 3, column 1, add a vendor code that doesn't exist in the application. Add additional false vendor information to the row.



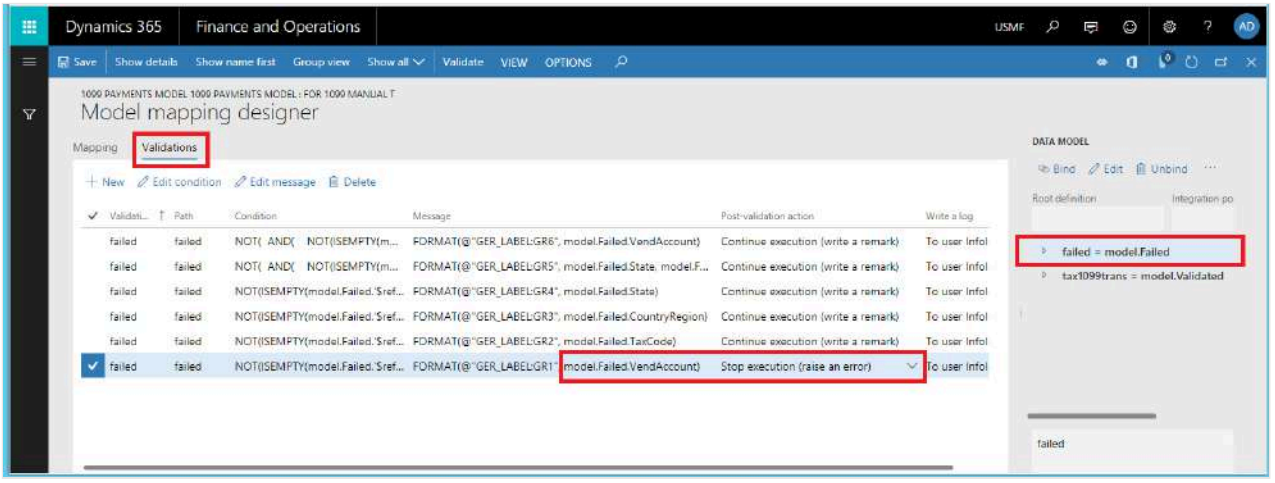
2. Upload the updated Excel file that contains vendor transactions to the **Files import source (main)** SharePoint folder.

3. Open the ER configurations tree, select the **1099 Payment model**, and expand the list of ER model components.

4. Select the name of the model mapping to update the model mapping so that the incorrect vendor code is considered an error during the data import process.

5. Select **Designer**.

6. On the **Validations** tab, change the post-validation action for the validation rule that checks whether the vendor account exists in the application. Update the value of the **Post-validation action** field to **Stop execution**, save your changes, and close the page.

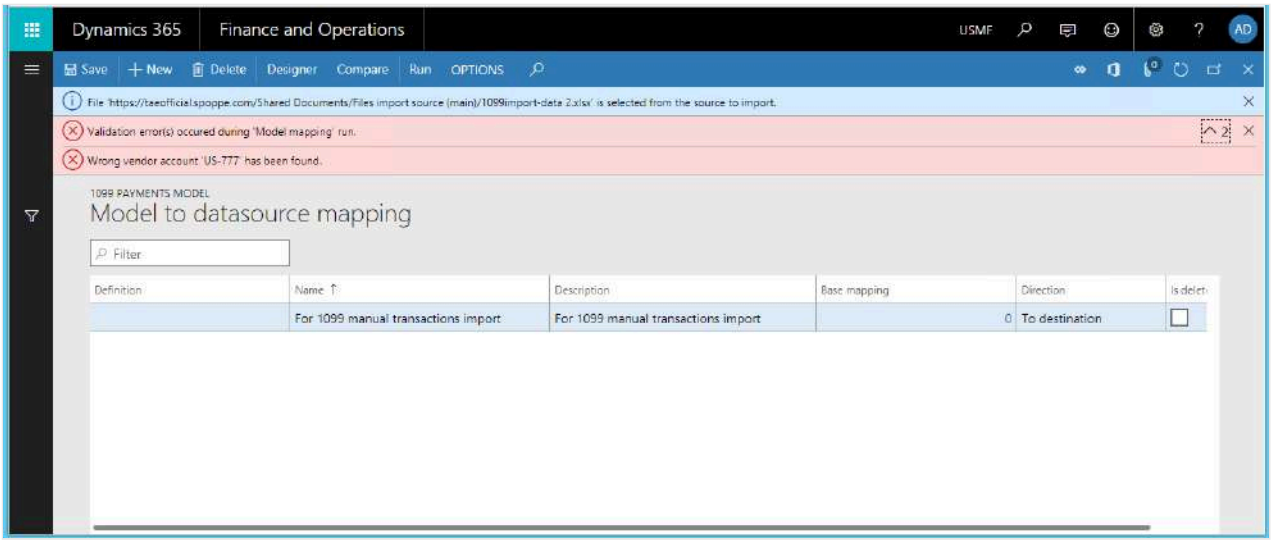


7. Save your changes, and close the ER model mapping designer.

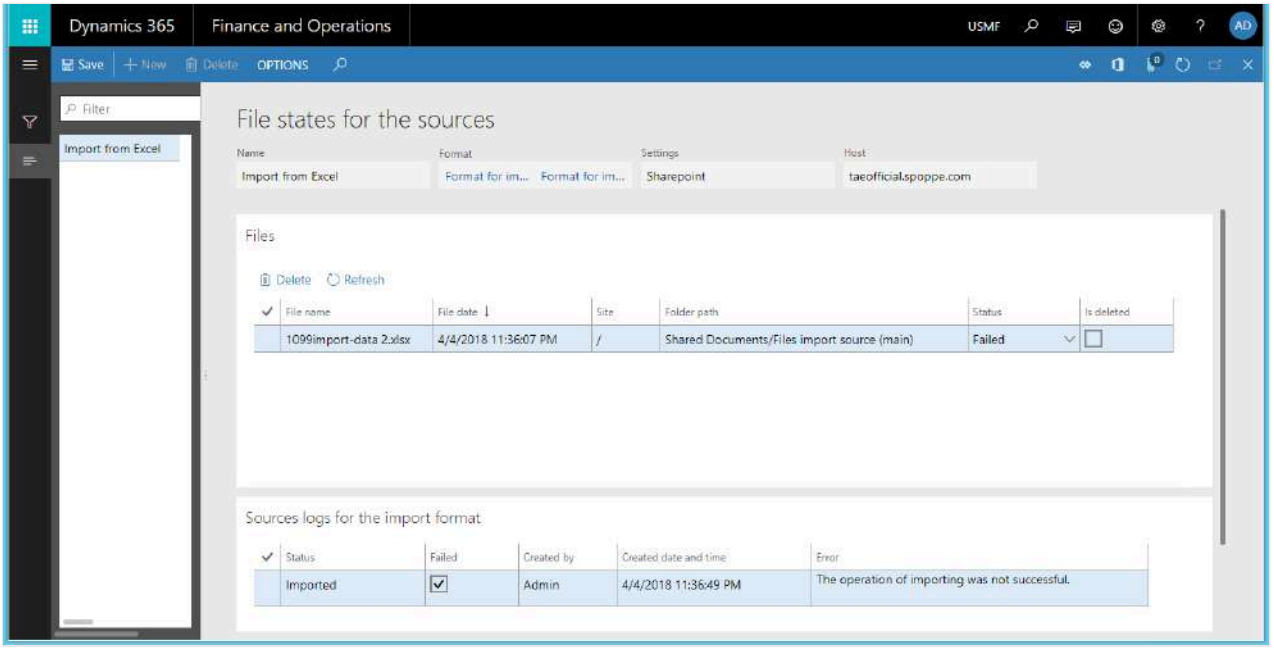
8. Select **Run** to run the modified ER model mapping.

9. Enter the voucher ID, such as **V-00002**, and then select **OK**.

The Infolog contains a notification that there's a file in the SharePoint folder that contains incorrect vendor account and can't be imported.



10. On the **File states for the sources** page, select **Refresh**, and then, in the **Files** section, review the list of files.



The **Sources log for the import format** section indicates that the import process failed and that the file is in the **Files error** SharePoint folder (the **Is deleted** check box isn't selected). If you fix this file on SharePoint by adding the proper vendor code and then move it to the **Files import source (main)** SharePoint folder, you can import the file again.

11. Select **Accounts payable** > **Periodic tasks** > **Tax 1099** > **Vendor settlement for 1099s**, enter appropriate values in the **From date** and **To date** fields, and then select **Manual 1099 transactions**.

Only transactions for voucher V-00001 are available. No transactions for voucher V-00002 are available even though the error for the last imported transaction is found in the Excel file.

Limitations

In versions of Dynamics 365 Finance before version 10.0.25, the user interface (UI) of the ER framework doesn't offer the capability to initiate a new batch job that runs a model mapping for data import in unattended mode. Instead, you must develop new logic so that the configured ER model mapping can be called from the application UI to import data from inbound files. To develop this logic, some engineering work is required.

For more information about the relevant ER API, see the Code to run a format mapping for data import section in ER framework API changes for Application update 7.3. Review the code in the `BankImport_RU` class of the `Application Suite` model to see how you can implement your custom logic. The `BankImport_RU` class extends the `RunBaseBatch` class. In particular, review the `runER()` method, where the `ERIModelMappingDestinationRun` object is created as the runner of an ER model mapping.

In Finance version 10.0.25 and later, the ER framework UI offers the capability to initiate a new batch job that runs a model mapping for data import in unattended mode. For more information about this process, see Import data in batch mode from manually selected files.

Import files in XML format with optional attributes

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can design Electronic reporting (ER) formats to parse incoming electronic documents in XML format. You can specify certain attributes of XML elements as optional in the designed ER format. This option allows you to handle incoming files with and without these XML attributes properly. You can then use the content from these files to update application data.

To learn more about this feature, complete the steps in the article, (RCS) Import files in XML format with optional attributes, which is part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process. You can download this task guide and associated sample files from the Microsoft Download Center.

Expand table

Content description	File
Sample file in XML format	IncomingDocumentToLearnHowToHandleOptionalAttributes.xml
Task guide	RCS Import files in XML format with optional attributes.axtr

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can design ER format configuration to import files in XML format containing optional attributes. To complete these steps, you must first complete the steps in the procedure, Create configuration providers and mark them as active. Before you begin, download and save locally the IncomingDocumentToLearnHowToHandleOptionalAttributes.xml file from Microsoft Download Center (https://go.microsoft.com/fwlink/?linkid=874684).

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the article, Create configuration providers and mark them as active.
3. Click **Reporting configurations**.

Create a new data model configuration

1. Select **Create configuration** to open the form.
2. In the **Name** field, enter *Model to import xml file*.
3. Select **Create configuration**.
4. Select **Designer**.
5. Select **New** to open the form.
6. In the **Name** field, enter *Root*.
7. Select **Add**.
8. Select **New** to open the form.
9. In the **Name** field, enter *List*.
10. In the **Item type** field, select **Record list**.
11. Select **Add**.
12. Select **New** to open the form.
13. In the **Name** field, enter *Code*.
14. In the **Item type** field, select **String**.
15. Select **Add**.
16. Select **Save**.
17. Close the page.
18. Select **Change status**.
19. Select **Complete**.
20. Select **OK**.

Create a format for data import

1. Select **Create configuration** to open the form.
2. In the **New** field, enter *Format based on data model Model to import xml file*.
3. In the **Name** field, type *Format to import xml file*.
4. Select **Yes** in the **Supports data import** field.
5. Select **Create configuration**.

Design a format to parse incoming file in XML format

1. Select **Designer**.
2. Select **Add root** to open the form.
3. In the tree, select **XML\Element**.
4. In the **Name** field, type *root*.
5. Select **OK**.
6. Select **Add** to open the form.
7. In the tree, select **XML\Element**.
8. In the **Name** field, type *document*.
9. In the **Multiplicity** field, select **One many**.
10. Select **OK**.
11. In the tree, select **root\document**.
12. Select **Add** to open the form.
13. In the tree, select **XML\Attribute**.
14. In the **Name** field, type *id*.
15. Select **OK**.
16. Select **Save**.

Design a format mapping to save parsed information to data model

1. Select **Map format to model**.
2. Select **New**.
3. In **Definition**, enter or select a value.
4. In **Name**, type `Mapping`.
5. Select **Save**.
6. Select **Designer**.
7. In the tree, expand **format**.
8. In the tree, expand **format\root: XML Element(root)**.
9. In the tree, select **format\root: XML Element(root)\document: XML Element 1.. (document)**.
10. Select **Bind**.
11. In the tree, expand **format\root: XML Element(root)\document: XML Element 1.. (document)**.
12. In the tree, select *format\root: XML Element(root)\document: XML Element 1.. (document)\id*.
13. In the tree, expand **List = format.root.document**.
14. In the tree, select **List = format.root.document\Code**.

15. Select **Bind**.
16. Select **Save**.
17. Close the page.

Run format mapping

1. Select **Run**.
2. Select **Browse**, and select the file **IncomingDocumentToLearnHowToHandleOptionalAttributes.xml**.
3. Select **OK**.

> **Note**
>
> The selected file isn't imported as the format design assumes the existence of `id` attribute for the `document` element, but the imported file contains no such attribute.

Modify format structure to handle XML attribute as optional

1. Close the page.
2. In the tree, expand **root\document**.
3. In the tree, select **root\document\id**.
4. In the **Empty string for missing attribute** field, select **Yes**.
5. Select **Save**.

Run format mapping to test changes

1. Select **Map format to model**.
2. Select **Run**.
3. Select **Browse**, and select the file **IncomingDocumentToLearnHowToHandleOptionalAttributes.xml**.
4. Select **OK**.
5. Review the generated file. The same file is imported as the format design now considers the `id` attribute for the `document` element as optional.

Last updated on 04/13/2026

(RCS) Import files in XML format with optional attributes

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can design ER format configuration to import files in XML format containing optional attributes. To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure. Before you begin, download and save locally the IncomingDocumentToLearnHowToHandleOptionalAttributes.xml file from Microsoft Download Center.

1. Go to **All workspaces** > **Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure Create configuration providers and mark them as active.
3. Click **Reporting configurations**.

Create a new data model configuration

1. Select **Create configuration** to open the form.
2. In the **Name** field, enter *Model to import xml file*.
3. Select **Create configuration**.
4. Select **Designer**.
5. Select **New** to open the form.
6. In the **Name** field, enter *Root*.
7. Select **Add**.
8. Select **New** to open the form.
9. In the **Name** field, enter *List*.
10. In the **Item type** field, select **Record list**.

11. Select **Add**.
12. Select **New** to open the form.
13. In the **Name** field, enter *Code*.
14. In the **Item type** field, select **String**.
15. Select **Add**.
16. Select **Save**.
17. Close the page.
18. Select **Change status**.
19. Select **Complete**.
20. Select **OK**.

Create a format for data import

1. Select **Create configuration** to open the form.
2. In the **New** field, enter *Format based on data model Model to import xml file*.
3. In the **Name** field, type *Format to import xml file*.
4. Select **Yes** in the **Supports data import** field.
5. Select **Create configuration**.

Design a format to parse incoming file in XML format

1. Select **Designer**.
2. Select **Add root** to open the form.
3. In the tree, select **XML\Element**.
4. In the **Name** field, type *root*.
5. Select **OK**.
6. Select **Add** to open the form.
7. In the tree, select **XML\Element**.
8. In the **Name** field, type *document*.
9. In the **Multiplicity** field, select **One many**.
10. Select **OK**.
11. In the tree, select **root\document**.
12. Select **Add** to open the form.
13. In the tree, select **XML\Attribute**.
14. In the **Name** field, type *ID*.
15. Select **OK**.
16. Select **Save**.

Design a format mapping to save parsed information to data model

1. Select **Map format to model**.
2. Select **New**.
3. In the **Definition** field, enter or select a value.
4. In the list, select the link in the selected row.
5. In the **Name** field, type `Mapping`.
6. Select **Save**.
7. Select **Designer**.
8. In the tree, expand **format**.
9. In the tree, expand **format\root: XML Element(root)**.
10. In the tree, select **format\root: XML Element(root)\document: XML Element 1.. (document)**.
11. Select **Bind**.
12. In the tree, expand **format\root: XML Element(root)\document: XML Element 1.. (document)**.
13. In the tree, select *format\root: XML Element(root)\document: XML Element 1.. (document)\id*.
14. In the tree, expand **List = format.root.document**.
15. In the tree, select **List = format.root.document\Code**.
16. Select **Bind**.
17. Select **Save**.
18. Close the page.

Run format mapping

1. Select **Run**.
2. Select **Browse** and select **IncomingDocumentToLearnHowToHandleOptionalAttributes.xml**.
3. Select **OK**.

> **Note**
>
> The selected file isn't imported as the format design assumes the existence of `id` attribute for the `document` element, but the imported file contains no such attribute.

Modify format structure to handle xml attribute as optional

1. Close the page.
2. In the tree, expand **root\document**.
3. In the tree, select **root\document\id**.
4. Select **Yes** in the **Empty string for missing attribute** field.
5. Select **Save**.

Run format mapping to test changes

1. Select **Map format to model**.
2. Select **Run**.
3. Click **Browse** and select the **IncomingDocumentToLearnHowToHandleOptionalAttributes.xml** file.
4. Select **OK**.
5. Review the generated file.

> **Note**
>
> The same file is imported as the format design now considers the 'id' attribute for the 'document' element as optional.

Manage the Electronic reporting (ER) configuration lifecycle

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to manage the lifecycle of Electronic reporting (ER) configurations for Dynamics 365 Finance.

Overview

Electronic reporting (ER) is an engine that supports statutory required and country/region-specific electronic documents. In general, ER assumes an ability to perform the following tasks for a single electronic document. For more details, see Electronic reporting (ER) overview.

- Design a template for an electronic document:
  - Identify the required sources of data that you can present in the document:
    - Underlying data, such as data tables, data entities, and classes.
    - Process-specific properties, such as execution date and time, and time zone.
    - User input parameters, specified by the end user at run time.
  - Define the required document elements and their topology to specify a final document format.
  - Configure the desired flow of data from selected data sources to defined document elements (via data source bindings to document format components), and specify process control logic.
- Make a template available so that you can use it in other instances:
  - Transform a document template that you created into an ER configuration, and export the configuration from the current application instance as an XML package that you can store either locally or in Microsoft Dynamics Lifecycle Services.

    - Transform an ER configuration into an application document template.
    - Import an XML package that you store either locally or in Lifecycle Services into the current instance.

- Customize the template of an electronic document:
    - Bring a template from Lifecycle Services into the current instance as an ER configuration.
    - Design a custom version of an ER configuration, and keep a reference to the base version.

- Integrate a template with a particular business process, so that it's available in the application:
    - Configure settings so that the application starts to use an ER configuration, by referring to that configuration in a process-related parameter. For example, refer to the ER configuration in a specific Accounts payable payment method to generate an electronic payment message for processing invoices.

- Use a template in a specific business process:
    - Run an ER configuration in a specific business process. For example, to generate an electronic payment message for processing invoices when a payment method that references the ER configuration is selected.

Concepts

The following roles and related activities are associated with the ER configuration lifecycle.

Expand table

Role	Activities	Description
Electronic reporting functional consultant	Create and manage ER components (models and formats).	A business person who designs ER domain–specific data models, designs the required templates for electronic documents, and binds them accordingly.
Electronic reporting developer	Create and manage data model mappings.	A specialist who selects the required Finance data sources and binds them to ER domain–specific data models.
Accounting supervisor	Configure process-related settings that reference ER artifacts.	For example, an **Accounting supervisor** role that allows the settings of an ER configuration to be used in a particular Accounts payable payment method to generate an electronic payment message for processing invoices.

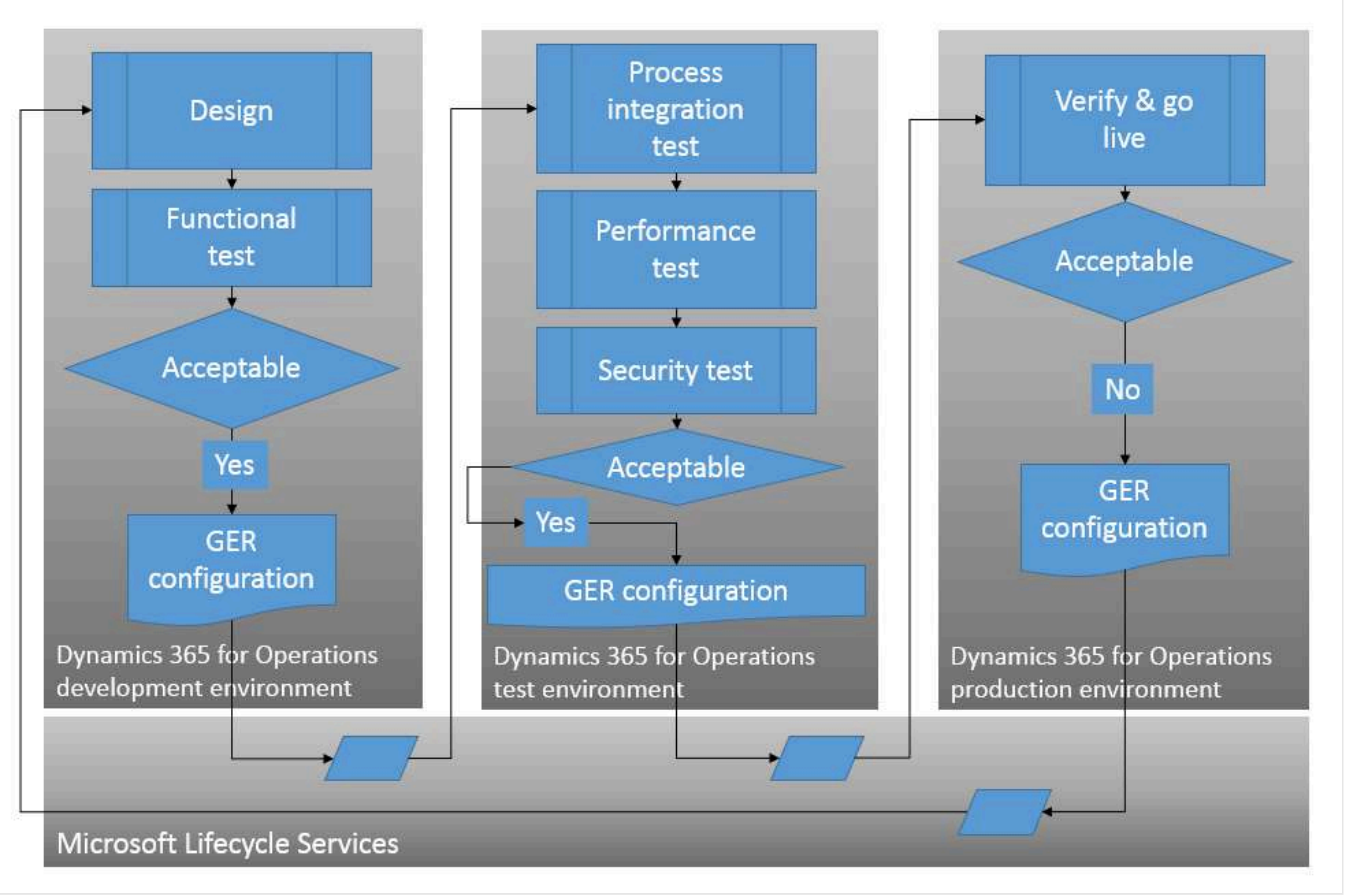
Role	Activities	Description
Accounts payable payments clerk	Use ER artifacts in a specific business process.	For example, an **Accounts payable payments clerk** role that allows electronic payment messages to be generated for processing invoices, based on the ER format that is configured for a specific payment method.

ER configuration development lifecycle

For the following ER-related reasons, design ER configurations in the development environment, as a separate instance of finance and operations:

- Users in either the **Electronic reporting developer** role or the **Electronic reporting functional consultant** role can edit configurations and run them for testing purposes. This scenario can cause calls to methods of classes and tables that might harm business data and the performance of the instance.
- Calls to methods of classes and tables as ER data sources of ER configurations aren't restricted by entry points and logged company content. Therefore, users in either the **Electronic reporting developer** role or the **Electronic reporting functional consultant** role can access business-sensitive data.

You can upload ER configurations that you design in the development environment to the test environment for configuration evaluation (proper process integration, correctness of results, and performance) and quality assurance, such as correctness of role-driven access rights and segregation of duties. Use the features that enable ER configuration interchange for this purpose. Proven ER configurations can be uploaded to Lifecycle Services to share them with service subscribers, or they can be imported to the production environment for internal use.



Data persistence consideration

You can individually import different versions of an ER configuration to your Finance instance. When you import a new version of an ER configuration, the system controls the content of the draft version of this configuration:

- If the imported version is lower than the highest version of this configuration in the current Finance instance, the content of the draft version of this configuration remains unchanged.
- If the imported version is higher than any other version of this configuration in the current Finance instance, the content of the imported version is copied to the draft version of this configuration so you can continue editing the last completed version.

If the configuration belongs to the configuration provider that you currently activate, you can view the draft version of this configuration on the **Versions** FastTab of the **Configurations** page (**Organization administration** > **Electronic reporting** > **Configurations**). You can select the draft version of the configuration and modify its content by using the relevant ER designer. When you edit the draft version of an ER configuration, its content no longer matches the content of the highest version of this configuration in the current Finance instance. To prevent the loss of your changes, the system displays an error that the import can't continue because the version of this configuration is higher than the highest version of this configuration in the

current Finance instance. When this error occurs, for example with the format configuration **X**, the **Format 'X' version is not completed** error is displayed.

To undo the changes that you introduced in the draft version, select the highest completed or shared version of your ER configuration in Finance on the **Versions** FastTab, and then select the **Get this version** option. The content of the selected version is copied to the draft version.

Applicability consideration

When you design a new version of an ER configuration, you can define its dependency on other software components. This step is a prerequisite for controlling the download of this configuration's version from an ER repository or an external XML file, and for any further use of the version. When you try to import a new version of an ER configuration, the system uses the configured prerequisites to control whether the version can be imported.

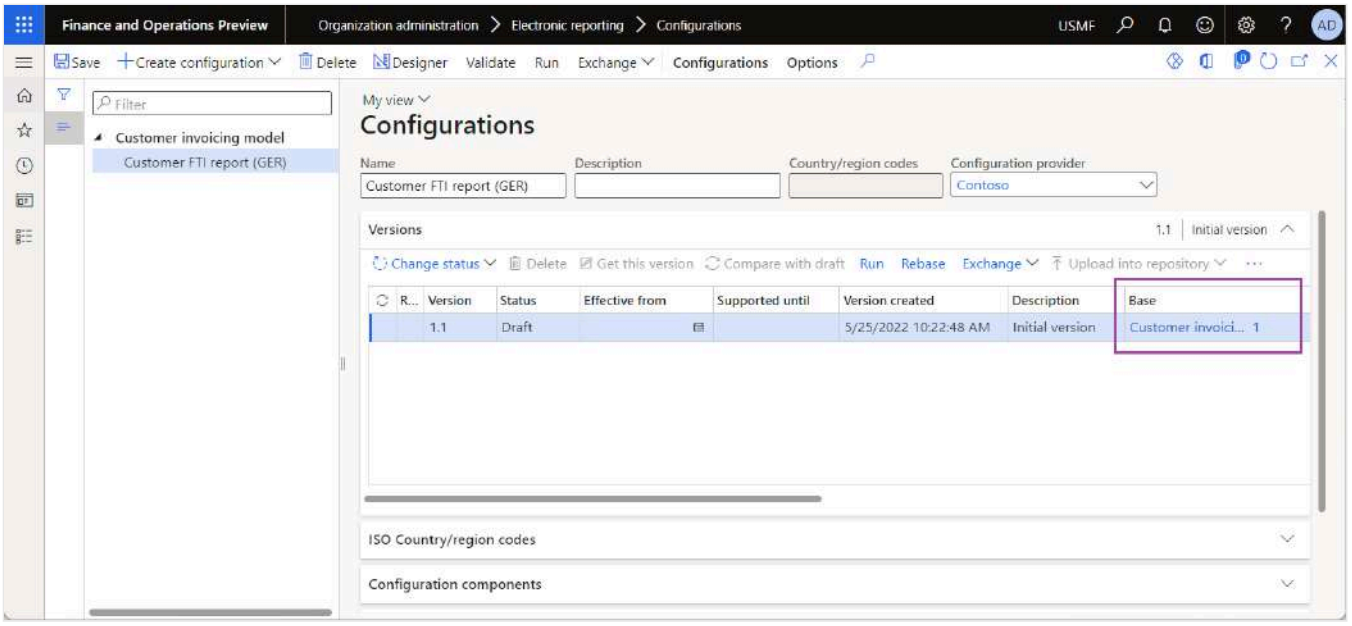
In some cases, you might require that the system ignore the configured prerequisites when you import new versions of ER configurations. To have the system ignore the prerequisites during import, follow these steps:

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. Set the **Skip product updates and version prerequisite check during import** option to **Yes**.

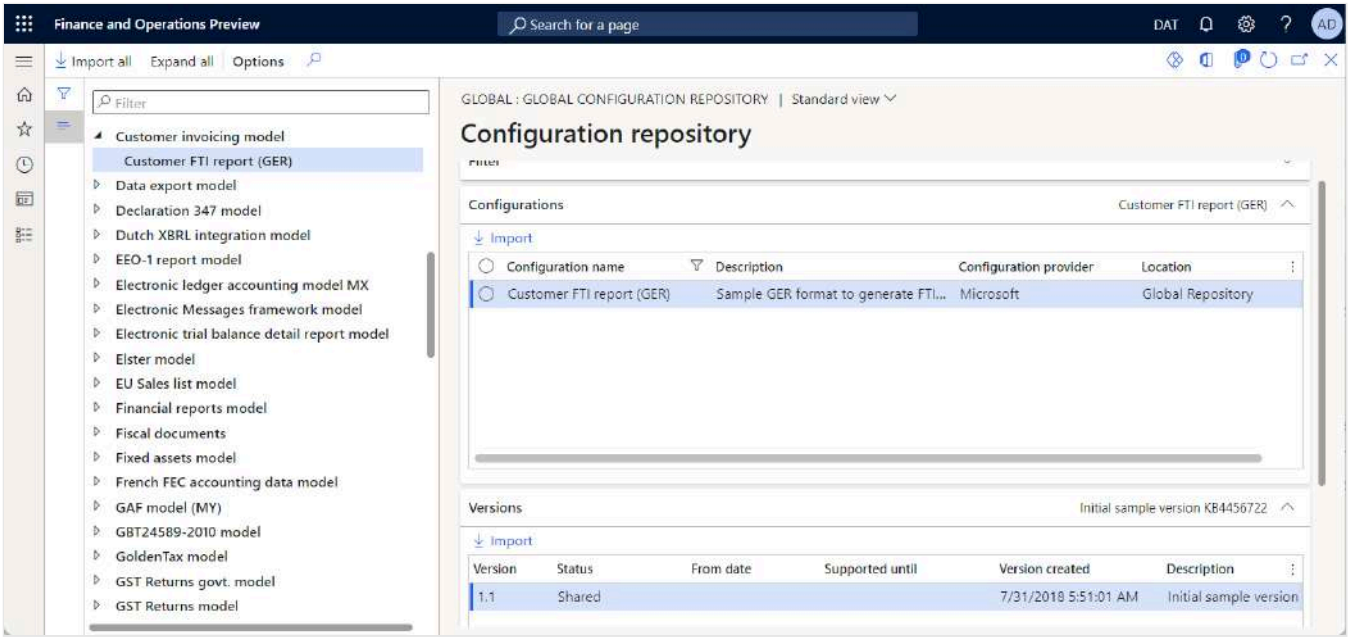
> **Note**
>
> This parameter is user-specific and company-specific.

Dependencies on other components

You can configure ER configurations as dependent on other configurations. For example, you can import an ER data model configuration from the Global repository into your Microsoft Regulatory Configuration Services (RCS) or Dynamics 365 Finance instance. Then, you can create a new ER format configuration that is derived from the imported ER data model configuration. The derived ER format configuration depends on the base ER data model configuration.

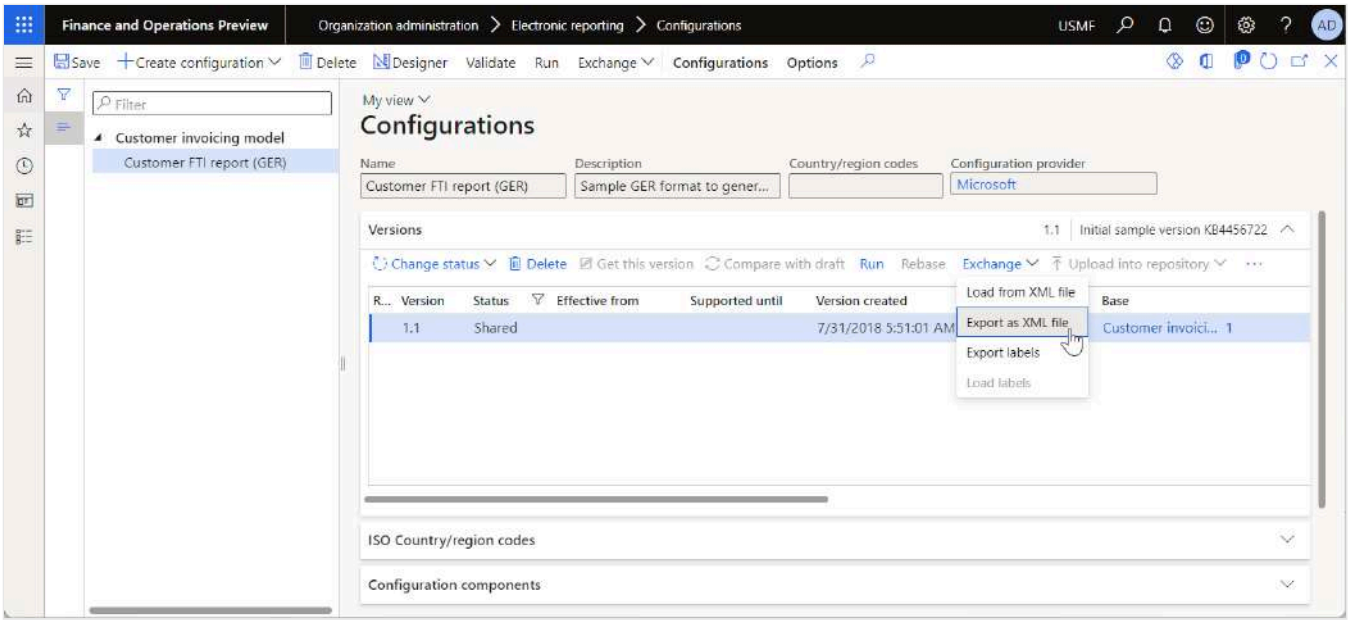


When you finish designing the format, change the status of your initial version of the ER format configuration from **Draft** to **Completed**. Then, share the completed version of the ER format configuration by publishing it to the Global repository. Next, you can access the Global repository from any RCS or Finance cloud instance. You can then import any ER configuration version that is applicable to the application from the Global repository into that application.



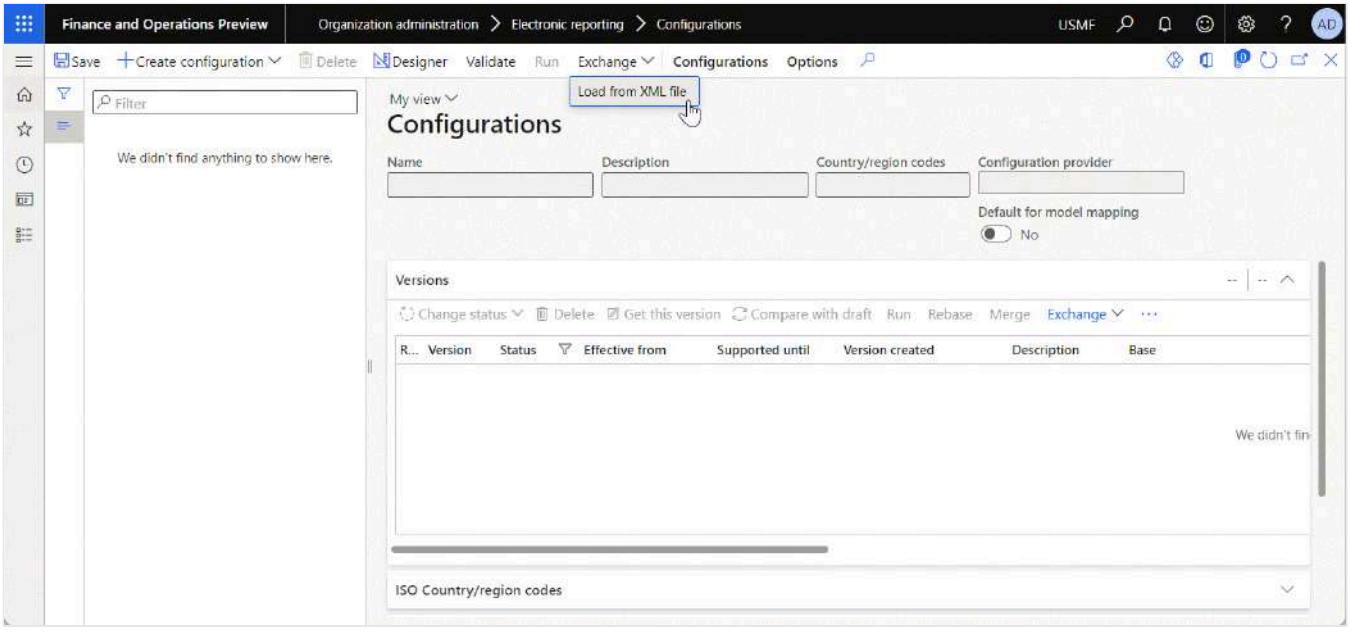
Based on the configuration dependency, when you select the ER format configuration in the Global repository to import it into a newly deployed RCS or Finance instance, the base ER data model configuration is automatically found in the Global repository and imported together with the selected ER format configuration as the base configuration.

You can also export your ER format configuration version out of your current RCS or Finance instance, and store it locally as an XML file.



In versions of Finance **before version 10.0.29**, when you try to import the ER format configuration version from that XML file or from any repository other than the Global repository into a newly deployed RCS or Finance instance that doesn't yet contain any ER configurations, the following exception is thrown to inform you that a base configuration can't be obtained:

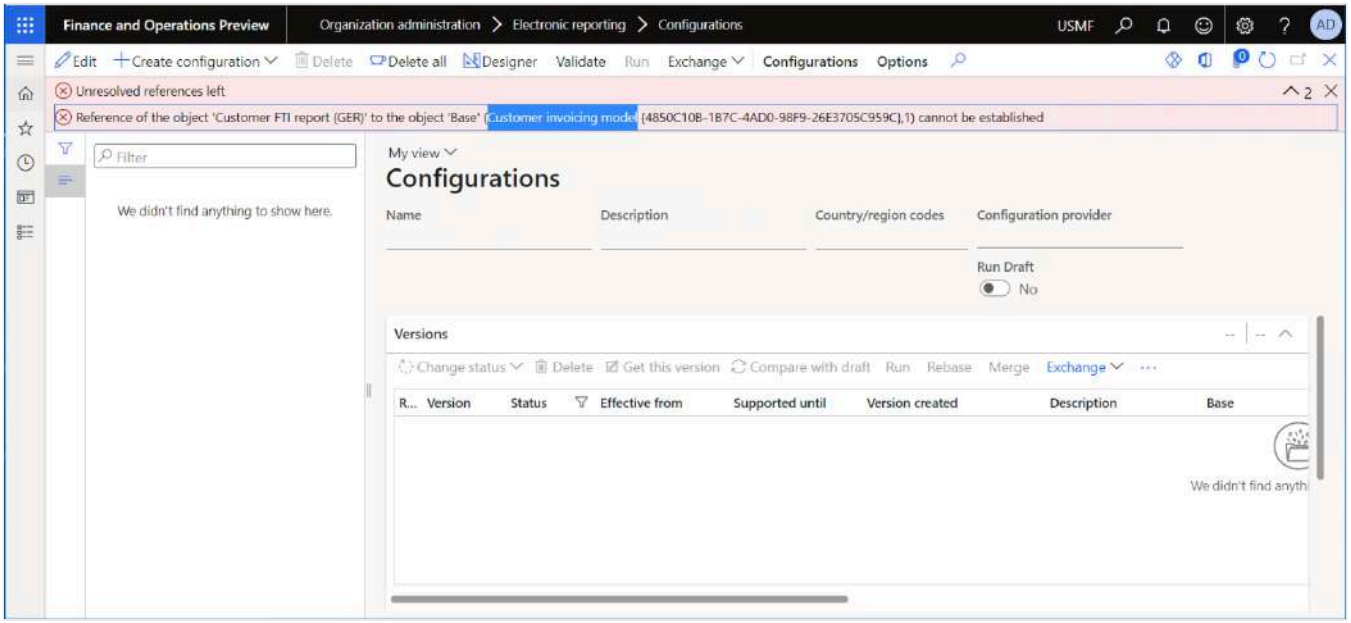
> Unresolved references left
> Reference of the object '<imported configuration name>' to the object 'Base' (<globally unique identifier of the missed base configuration>,<version of the missed base configuration>) can't be established



In version **10.0.29 and later**, when you try to do the same configuration import, if a base configuration can't be found in the current application instance or in the source repository that

you're currently using (if applicable), the ER framework automatically tries to find the name of the missing base configuration in the Global repository cache. It then presents the name and globally unique identifier (GUID) of the missing base configuration in the text of the exception that is thrown.

> Unresolved references left
> Reference of the object '<imported configuration name>' to the object 'Base' (<name of the missed base configuration> <globally unique identifier of the missed base configuration>,<version of the missed base configuration>) can't be established



You can use the provided name to find the base configuration and then manually import it.

> **Note**
>
> This new option works only when at least one user already signs in to the Global repository by using the **Configuration repositories** page or one of the Global repository **lookup** fields in the current Finance instance, and when the Global repository content is cached.

Upload a configuration into Lifecycle Services

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how a user in the System administrator or Electronic reporting developer role can create a new Electronic reporting (ER) configuration and upload it into the project-level Asset library in Microsoft Dynamics Lifecycle Services.

> **Important**
>
> The use of Lifecycle Services as a storage repository for ER configurations is being deprecated. For more information, see Regulatory Configuration Service (RCS) – Lifecycle Services storage deprecation.

In this example, you create a configuration and upload it into Lifecycle Services for a sample company named Litware, Inc. You can complete these steps in any company, because ER configurations are shared among companies. To complete these steps, you must first complete the steps in Create configuration providers and mark them as active. You also need access to Lifecycle Services.

1. Sign in to the application by using one of the following roles:
    - Electronic reporting developer
    - System administrator
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. Select **Litware, Inc.**, and mark it as **Active**.
4. Select **Configurations**.

> **Note**
>
> Make sure that the current Dynamics 365 Finance user is a member of the Lifecycle Services project that contains the **Asset library** that is used to import ER configurations.
>
> You can't access an Lifecycle Services project from an ER repository that represents a different domain than the domain that is used in Finance. If you try, an empty list of Lifecycle Services projects is shown, and you can't import ER configurations from the project-level Asset library in Lifecycle Services. To access project-level Asset libraries from an ER repository that is used to import ER configurations, sign in to Finance by using the credentials of a user who belongs to the tenant (domain) that the current Finance instance is provisioned for.

Create a new data model configuration

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, select **Create configuration** to open the drop-down dialog box.

   In this example, you create a configuration that contains a sample data model for electronic documents. You upload this data model configuration into Lifecycle Services later.
3. In the **Name** field, enter **Sample model configuration**.
4. In the **Description** field, enter **Sample model configuration**.
5. Select **Create configuration**.
6. Select **Model designer**.
7. Select **New**.
8. In the **Name** field, enter **Entry point**.
9. Select **Add**.
10. Select **Save**.
11. Close the page.
12. Select **Change status**.

13. Select **Complete**.
14. Select **OK**.
15. Close the page.

Register a new repository

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. In the **Configuration providers** section, select the **Litware, Inc.** tile.
3. On the **Litware, Inc.** tile, select **Repositories**.

   You can now open the list of repositories for the Litware, Inc. configuration provider.
4. Select **Add** to open the drop-down dialog box.

   You can now add a new repository.
5. In the **Configuration repository enter** field, select **LCS**.
6. Select **Create repository**.
7. In the **Project** field, enter or select a value.

   For this example, select the desired Lifecycle Services project. You must have access to the project.
8. Select **OK**.

   Complete a new repository entry.
9. In the list, mark the selected row.

   For this example, select the **LCS** repository record.

   Note that the current provider marks a registered repository. In other words, only configurations that the provider owns can go in this repository and be uploaded into the selected Lifecycle Services project.
10. Select **Open**.

    You open the repository to view the list of ER configurations. If the selected project isn't yet used for ER configurations sharing, the list is empty.

11. Close the page.
12. Close the page.

Upload a configuration into Lifecycle Services

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configurations tree, select **Sample model configuration**.

   Select a configuration that you created and completed.
3. In the list, find and select the desired record.

   For this example, select the version of the selected configuration that has a status of **Completed**.
4. Select **Change status**.
5. Select **Share**.

   When you publish the configuration in Lifecycle Services, the status changes from **Completed** to **Shared**.
6. Select **OK**.
7. In the list, find and select the desired record.

   For this example, select the configuration version that has a status of **Shared**.

   The status of the selected version changes from **Completed** to **Shared**.
8. Close the page.
9. Select **Repositories**.

   You can now open the list of repositories for the Litware, Inc. configuration provider.
10. Select **Open**.

    For this example, select the **LCS** repository, and open it.

    The selected configuration appears as an asset of the selected Lifecycle Services project.
11. Open Lifecycle Services by going to https://lcs.dynamics.com.

12. Open a project that you used earlier for repository registration.
13. Open the Asset library of the project.
14. Select the **GER configuration** asset type.

    The ER configuration that you uploaded appears in the list.

    If providers have access to this Lifecycle Services project, they can import the uploaded Lifecycle Services configuration into another instance.

Import a configuration from Lifecycle Services

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how a user in the System administrator or Electronic reporting developer role can import a new version of an Electronic reporting (ER) configuration from the project-level Asset library in Microsoft Dynamics Lifecycle Services.

> **Important**
>
> The use of Lifecycle Services as a storage repository for ER configurations is being deprecated. For more information, see Regulatory Configuration Service (RCS) – Lifecycle Services storage deprecation.

In this example, you select the desired version of the ER configuration and import it for a sample company named Litware, Inc. You can complete these steps in any company, because ER configurations are shared among companies. To complete these steps, you must first complete the steps in Upload a configuration into Lifecycle Services. You also need access to Lifecycle Services.

1. Sign in to the application by using one of the following roles:
    - Electronic reporting developer
    - System administrator
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. Select **Configurations**.

> **Note**

Make sure that the current Dynamics 365 Finance user is a member of the Lifecycle Services project that contains the Asset library that you want to access to import ER configurations.

You can't access an Lifecycle Services project from an ER repository that represents a different domain than the domain that is used in Finance. If you try, an empty list of Lifecycle Services projects is shown, and you can't import ER configurations from the project-level Asset library in Lifecycle Services. To access project-level Asset libraries from an ER repository that is used to import ER configurations, sign in to Finance by using the credentials of a user who belongs to the tenant (domain) that the current Finance instance is provisioned for.

Delete a shared version of a data model configuration

1. On **Configurations**, in the configurations tree, select **Sample model configuration**.

   You created the first version of a sample data model configuration and published it to Lifecycle Services when you completed the steps in Upload a configuration into Lifecycle Services. In this procedure, you delete that version of the ER configuration. You can import that version from Lifecycle Services later in this article.

2. In the list, find and select the desired record.

   For this example, select the version of the configuration that has a status of **Shared**. This status indicates that the configuration is published to Lifecycle Services.

3. Select **Change status**.

4. Select **Discontinue**.

   When you change the status of the selected version from **Shared** to **Discontinued**, you make the version available for deletion.

5. Select **OK**.

6. In the list, find and select the desired record.

   For this example, select the version of the configuration that has a status of **Discontinued**.

7. Select **Delete**.

8. Select **Yes**.

The only draft version 2 of the selected data model configuration is now available.

9. Close the page.

Import a shared version of a data model configuration from Lifecycle Services

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. In the **Configuration providers** section, select the **Litware, Inc.** tile.
3. On the **Litware, Inc.** tile, select **Repositories**.

   You can now open the list of repositories for the Litware, Inc. configuration provider.
4. Select **Open**.

   For this example, select the **Lifecycle Services** repository, and open it. You must have access to the Lifecycle Services project and to the Asset library that the selected ER repository accesses.
5. In the list, select the row.

   For this example, select the first version of **Sample model configuration** in the version list.
6. Select **Import**.
7. Select **Yes** to confirm the import of the selected version from Lifecycle Services.

   An informational message confirms that the selected version was successfully imported.
8. Close the page.
9. Close the page.
10. Select **Configurations**.
11. In the tree, select **Sample model configuration**.
12. In the list, find and select the desired record.

    For this example, select the version of the configuration that has a status of **Shared**.

Notice that shared version 1 of the selected data model configuration is also available now.

Last updated on 04/13/2026

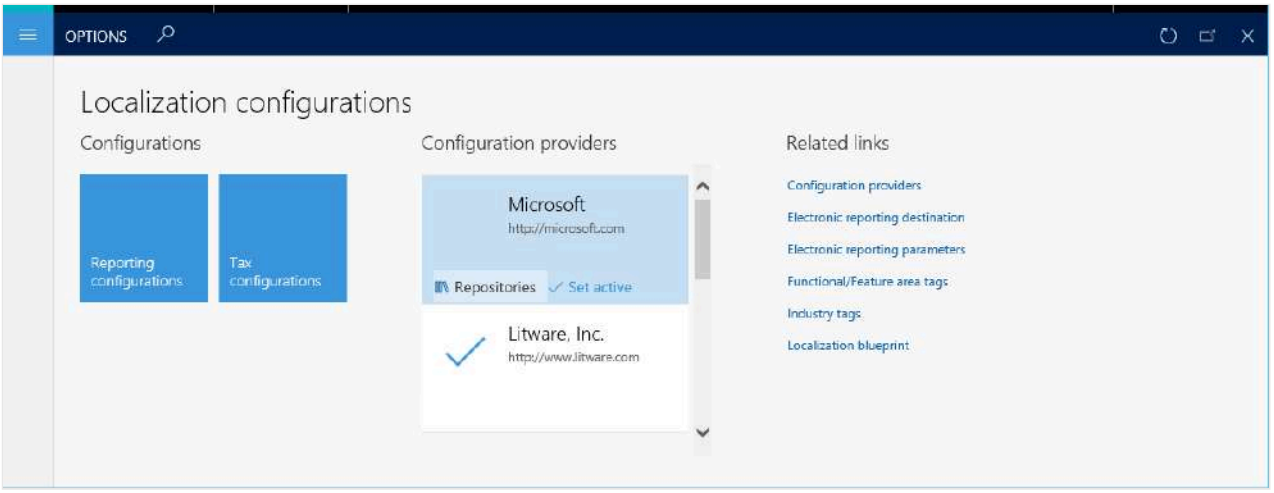
Download electronic reporting configurations from Lifecycle Services

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to download the newest version of Electronic reporting (ER) configurations from the Shared asset library in Microsoft Dynamics Lifecycle Services.

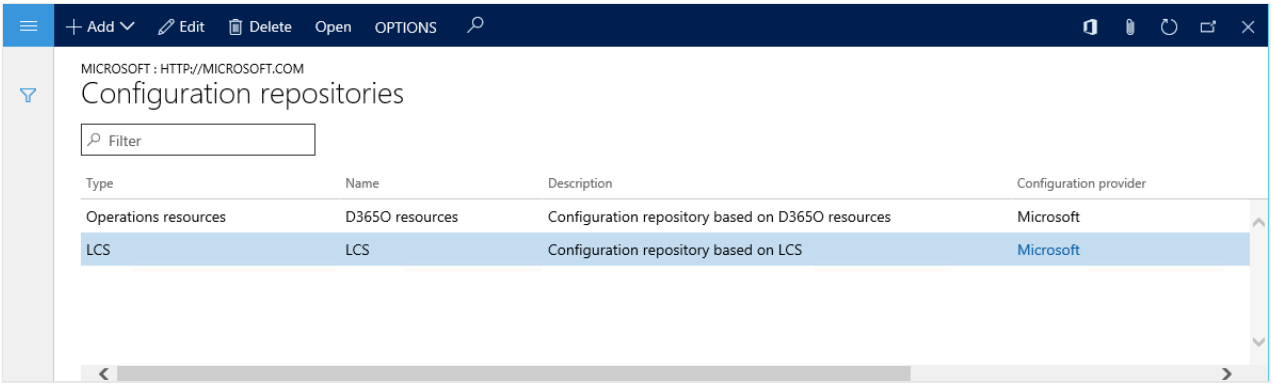
> **Important**
>
> The use of Lifecycle Services as a storage repository for ER configurations is being deprecated. For more information, see Regulatory Configuration Service (RCS) – Lifecycle Services storage deprecation.

1. Sign in to the application by using one of the following roles:
    - Electronic reporting developer
    - Electronic reporting functional consultant
    - System administrator
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. In the **Configuration providers** section, select the **Microsoft** tile.
4. On the **Microsoft** tile, select **Repositories**.



5. On the **Configuration repositories** page, in the grid, select the existing repository of the **LCS** type. If this repository doesn't appear in the grid, follow these steps:
   a. Select **Add** to add a repository.
   b. Select **LCS** as the repository type.
   c. Select **Create repository**.
   d. If you're prompted about authorization, follow the on-screen instructions.
   e. Enter a name and description for the repository.
   f. Select **OK** to confirm the new repository entry.
   g. In the grid, select the new repository of the **LCS** type.

6. Select **Open** to view the list of ER configurations for the selected repository.



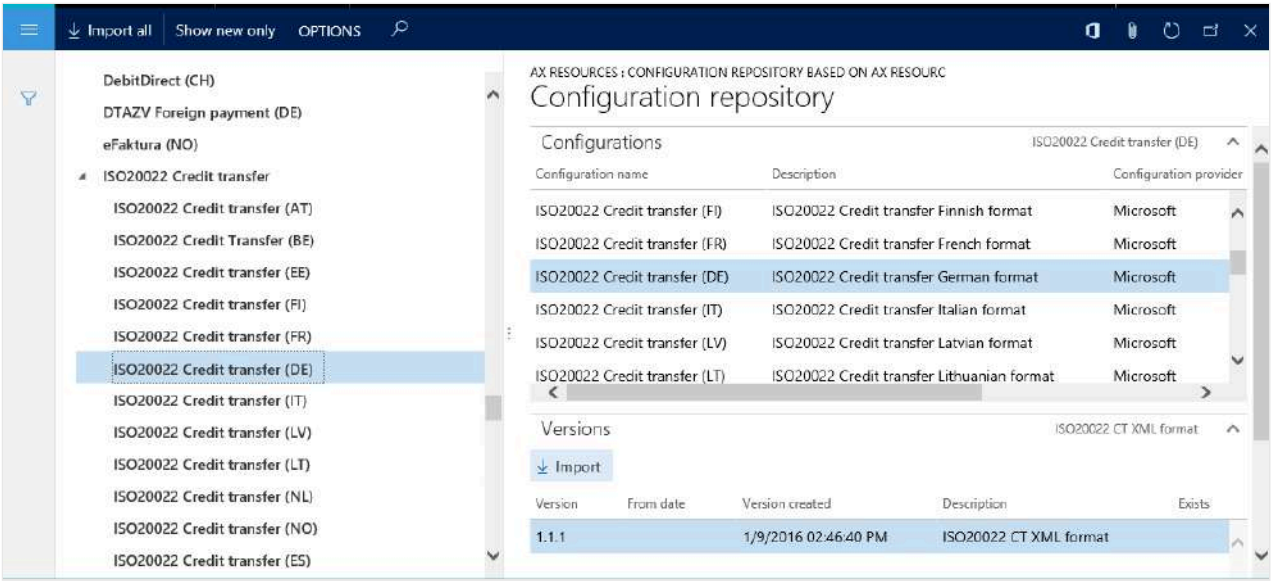
> **Tip**
>
> If you have trouble accessing the Lifecycle Services repository to download configurations from the Shared asset library in Lifecycle Services, you can download configurations from the Global repository instead.

7. In the configurations tree in the left pane, select the required ER configuration.

8. On the **Versions** FastTab, select the required version of the selected ER configuration.

9. Select **Import** to download the selected version from Lifecycle Services to the current instance.

> **Note**
>
> The **Import** button is unavailable for ER configuration versions that are already present in the current instance.



> **Note**
>
> Depending on the ER settings, configurations are validated after they are imported. You might be notified about any inconsistency issues that are discovered. You must resolve those issues before you can use the imported configuration version. For more information, see the list of related topics for this article.

Import Electronic reporting (ER) configurations

> ⓘ Note
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to download Electronic reporting (ER) configurations from Microsoft Dynamics Lifecycle Services to a local business data application or Tier-1 environment.

1. Sign in to your application by using one of the following roles:
    - Electronic reporting developer
    - Electronic reporting functional consultant
    - System administrator
2. Go to **Organization administration** > **Electronic reporting**.
3. In the **Configuration providers** section, select the card for the ER provider that is associated with your company.

    > ⓘ Note
    >
    > To learn how to register a new ER solution provider, see the **Create a configuration provider and mark it as active** task guide.

4. On the selected tile, select **Repositories**.
5. On the **Configuration repositories** page, in the grid, select the existing repository of the **File system** type. If the repository doesn't appear in the grid, follow these steps:
    a. Select **Add** to add a new repository.
    b. Select **FILE SYSTEM** as the repository type.
    c. Select **Create repository**.
    d. Enter a name and description for the repository.

e. Enter the path of the working directory for this repository. This path should point to a folder of the local file system where the ER configurations that belong to the repository are stored.
f. Select **OK** to confirm and save the new repository.
g. In the grid, select the new repository of the **File system** type.

6. In your browser, open another tab, and sign in to Lifecycle Services.
7. In the Shared asset library, select the **GER Configuration** asset type, and then download file **GER Configurations - All**.

> ⓘ **Note**
>
> All the ER configurations are in a zip file for download.

8. Open the file, select all the ER configurations, and then copy them to the working directory for the repository of the **File system** type.
9. On the **ER repositories** page, on the **Dynamics 365 Finance** tab, select **Open** to view the list of ER configurations for the selected repository.
10. In the **Configurations** tree in the left pane, select an ER configuration.
11. On the **Versions** FastTab, select the required version of the ER configuration.
12. Select **Import** to download the selected version from this repository to the current instance.

> ⓘ **Note**
>
> The **Import** button is unavailable for existing ER configuration versions.

> ⓘ **Note**
>
> Depending on the ER settings, configurations are validated after they are imported. You might see a notification about inconsistencies or issues that are discovered. You must resolve these inconsistencies or issues before you can use the imported configuration version.

Adjust an ER format to generate a custom electronic document

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The procedures in this article explain how a user in the System Administrator or Electronic Reporting Functional Consultant role can perform these tasks:

- Configure parameters for the Electronic reporting (ER) framework.
- Import ER configurations that Microsoft provides and that are used to generate a payment file while a vendor payment is being processed.
- Create a custom version of a standard ER format configuration that Microsoft provides.
- Modify the custom ER format configuration so that it generates payment files that meet the requirements of a specific bank.
- Adopt changes that are made to the standard ER format configuration in the custom ER format configuration.

You can perform all the following procedures in the **GBSI** company. No coding is required.

- Configure the ER framework
  - Configure ER parameters
  - Activate an ER configuration provider
    - Review the list of ER configuration providers
    - Add a new ER configuration provider
    - Activate an ER configuration provider
- Import the standard ER format configurations
  - Import the standard ER configurations
  - Review the imported ER configurations

- Prepare a vendor payment for processing
  - Add bank information for a vendor account
  - Enter a vendor payment
- Process a vendor payment by using the standard ER format
  - Set up the electronic payment method
  - Process a vendor payment
- Customize the standard ER format
  - Create a custom format
  - Edit a custom format
  - Mark a custom format as runnable
- Process a vendor payment by using the custom ER format
  - Set up the electronic payment method
  - Process a vendor payment
- Import new versions of the standard ER format configurations
  - Import new versions of the standard ER configurations
  - Review the imported ER format configurations
- Adopt the changes in the new version of an imported format in a custom format
  - Complete the current draft version of a custom format
  - Rebase a custom format to a new base version
  - Process a vendor payment by using a rebased ER format
- Additional resources

Configure the ER framework

As a user in the Electronic Reporting Functional Consultant role, you must configure the minimal set of ER parameters before you can start to use the ER framework to design a custom version of a standard ER format.

Configure ER parameters

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Related links** section, select **Electronic reporting parameters**.

3. On **Electronic reporting parameters**, on the **General** tab, set the **Enable design mode** option to **Yes**.

4. On the **Attachments** tab, set the following parameters:

    - In the **Configurations** field, select the **File** type for the **USMF** company.
    - In the **Job archive**, **Temporary**, **Baseline**, and **Others** fields, select the **File** type.

For more information about ER parameters, see Configure the ER framework.

Activate an ER configuration provider

Each ER configuration that you add is owned by an ER configuration provider. The ER configuration provider that you activate in the **Electronic reporting** workspace serves this role. Therefore, you must activate an ER configuration provider in the **Electronic reporting** workspace before you start to add or edit ER configurations.

> ⓘ **Note**
>
> Only the owner of an ER configuration can edit it. Therefore, before you can edit an ER configuration, you must activate the appropriate ER configuration provider in the **Electronic reporting** workspace.

Review the list of ER configuration providers

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Related links** section, select **Configuration providers**.
3. On **Configuration provider table**, each provider record has a unique name and URL. Review the contents of this page. If a record for **Litware, Inc.** (`https://www.litware.com`) already exists, skip the next procedure, Add a new ER configuration provider.

Add a new ER configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Related links** section, select **Configuration providers**.
3. On **Configuration providers**, select **New**.
4. In the **Name** field, enter **Litware, Inc.**
5. In the **Internet address** field, enter `https://www.litware.com`.

6. Select **Save**.

Activate an ER configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configuration providers** section, select the **Litware, Inc.** tile, and then select **Set active**.

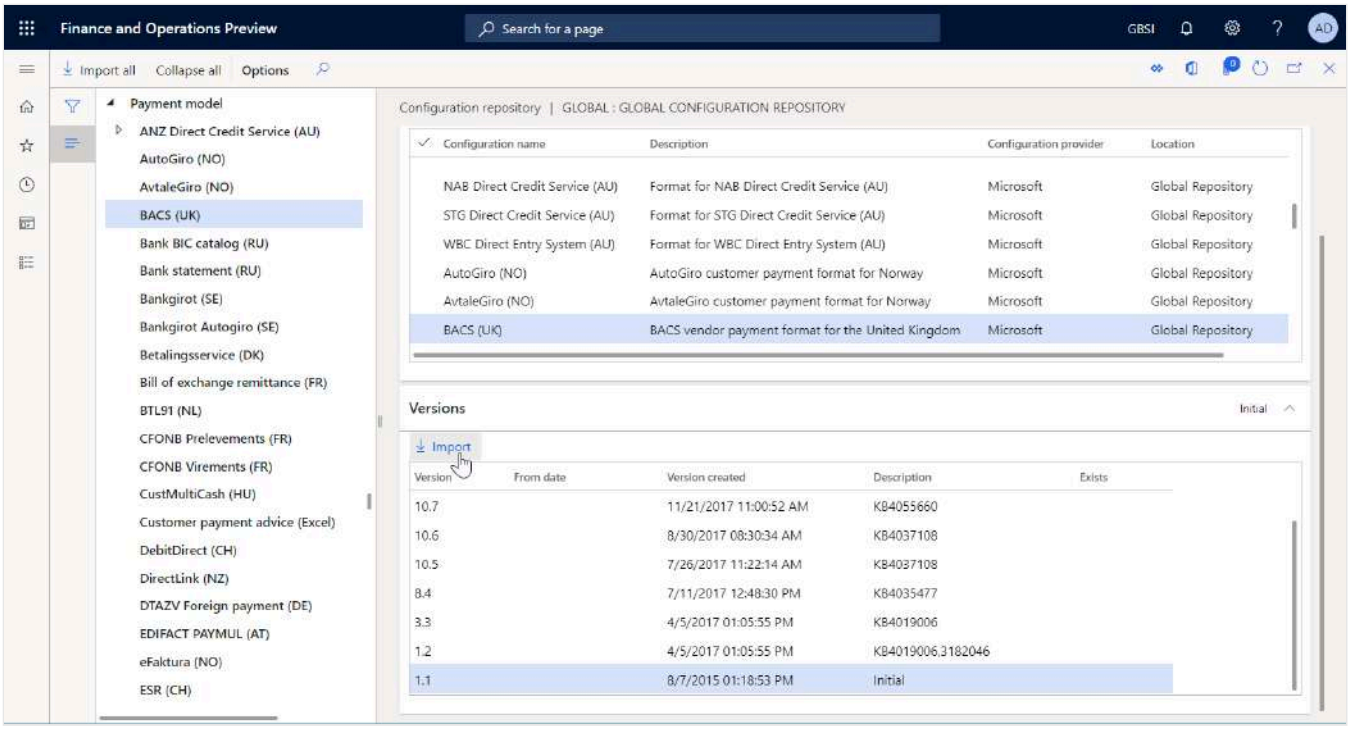
For more information about ER configuration providers, see Create configuration providers and mark them as active.

Import the standard ER format configurations

Import the standard ER configurations

To add the standard ER configurations to your current instance of Microsoft Dynamics 365 Finance, import them from the ER repository that you configured for that instance.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configuration providers** section, select the **Microsoft** tile, and then select **Repositories** to view the list of repositories for the Microsoft provider.
3. On **Configuration repositories**, select the repository of the **Global** type, and then select **Open**. If you're prompted for authorization to connect to Regulatory Configuration Service, follow the authorization instructions.
4. On **Configuration repository**, in the configuration tree in the left pane, select the **BACS (UK)** format configuration.
5. On the **Versions** FastTab, select version **1.1** of the selected ER format configuration.
6. Select **Import** to download the selected version from the Global repository to the current Finance instance.



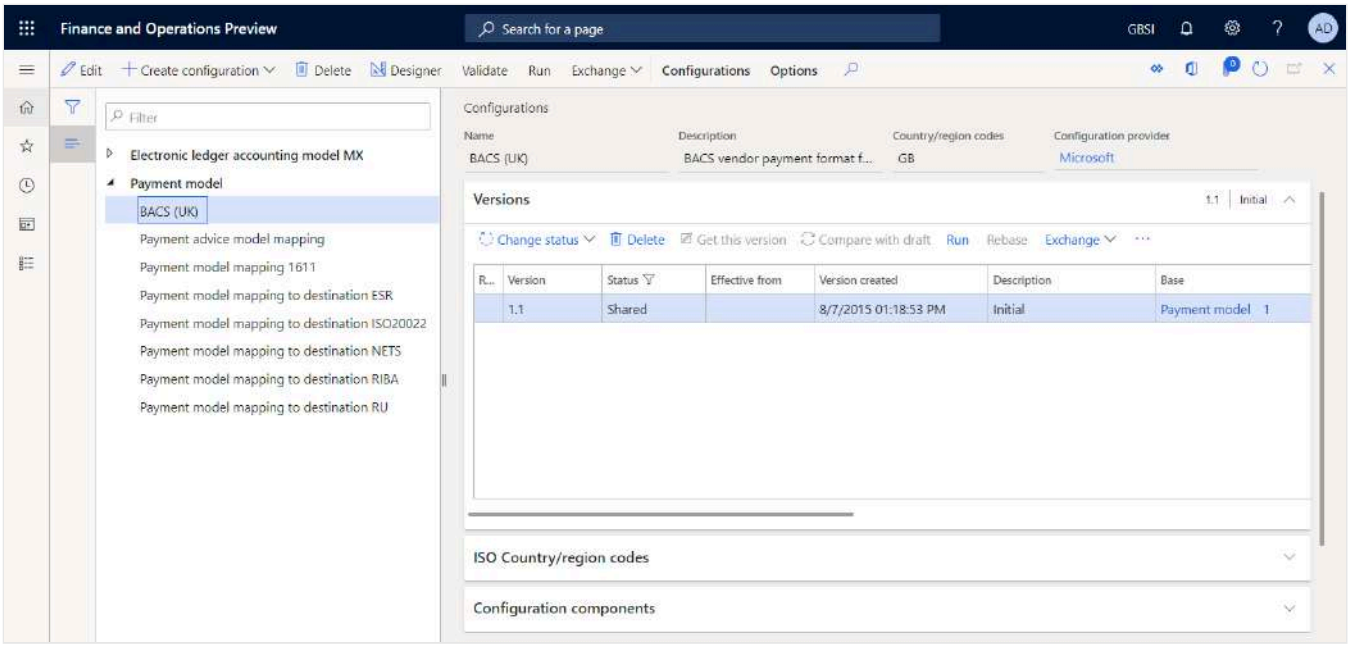
> **Tip**
>
> If you have trouble accessing the Global repository, you can download configurations from Microsoft Dynamics Lifecycle Services instead.

Review the imported ER configurations

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configurations** section, select the **Reporting configurations** tile.
3. On **Configurations**, in the configuration tree in the left pane, expand **Payment model**.
4. In addition to the selected **BACS (UK)** ER format, the import process adds other required ER configurations. Make sure that the following ER configurations are available in the configuration tree:

    - **Payment model** – This configuration contains the data model ER component that represents the data structure of the payment business domain.
    - **Payment model mapping 1611** – This configuration contains the model mapping ER component that describes how the data model is filled in with application data at runtime.
    - **BACS (UK)** – This configuration contains the format and format mapping ER components. The format component specifies the report layout. The format

mapping component contains the model data source and specifies how the report layout is filled in by using this data source at runtime.

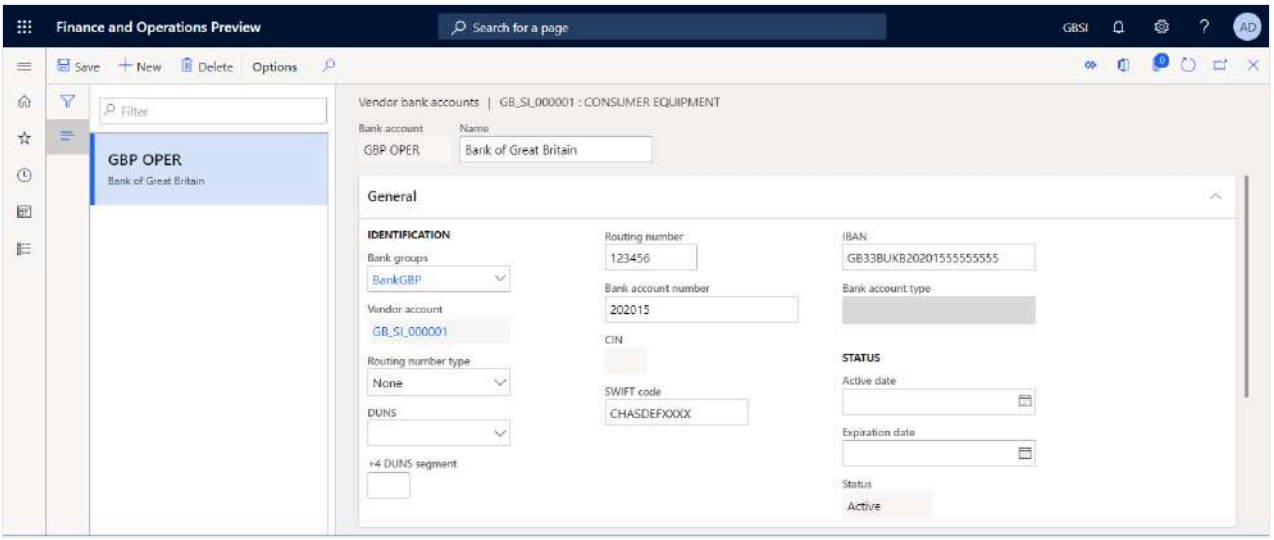


Prepare a vendor payment for processing

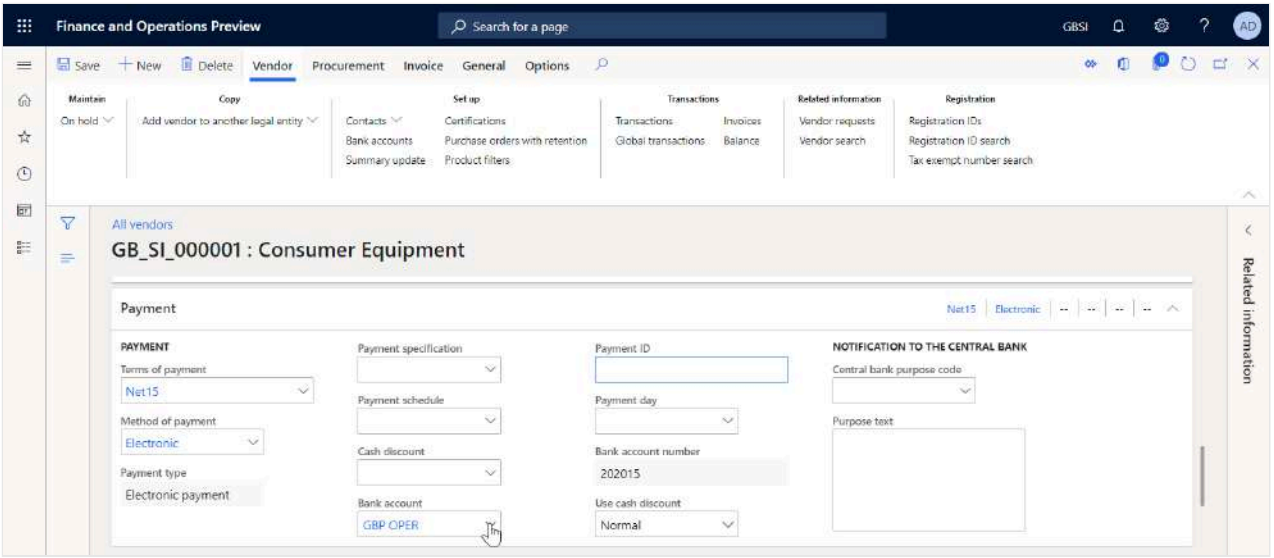
Add bank information for a vendor account

Add bank information for a vendor account that you refer to later in a registered payment.

1. Go to **Accounts payable** > **Vendors** > **All vendors**.
2. On **All vendors**, select the **GB_SI_000001** vendor account. On the Action Pane, on the **Vendor** tab, in the **Set up** group, select **Bank accounts**.
3. On **Vendor bank accounts**, select **New**, and then enter the following information:
   a. In the **Bank account** field, enter **GBP OPER**.
   b. In the **Bank groups** field, select **BankGBP**.
   c. In the **Bank account number** field, enter **202015**.
   d. In the **SWIFT code** field, enter **CHASDEFXXXX**.
   e. In the **IBAN** field, enter **GB33BUKB20201555555555**.
   f. In the **Routing number** field, keep the default value, **123456**.



4. Select **Save**.
5. Close the page.
6. On **All vendors**, open the **GB_SI_000001** vendor account.
7. On the vendor details page, select **Edit** to make the page editable, if required.
8. On the **Payment** FastTab, in the **Bank account** field, select **GBP OPER**.



9. Select **Save**.
10. Close the page.

Enter a vendor payment

Enter a new vendor payment by using a payment proposal.

1. Go to **Accounts payable** > **Payments** > **Vendor payment journal**.

2. On the **Vendor payment journal** page, select **New**.

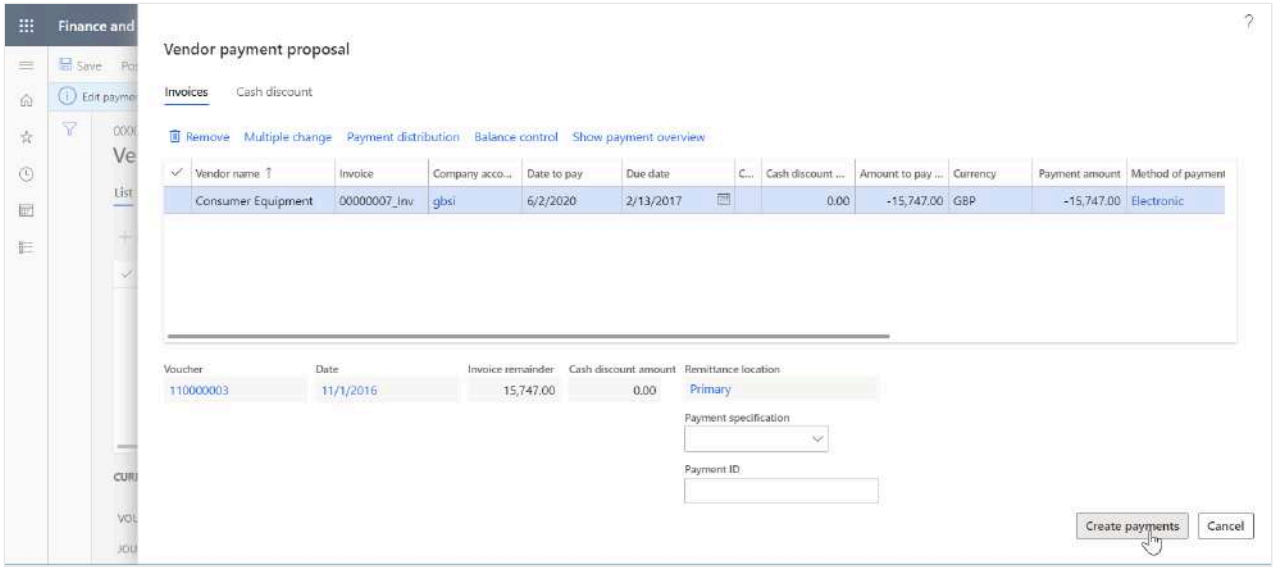
3. In the **Name** field, select **VendPay**.

4. Select **Lines**.

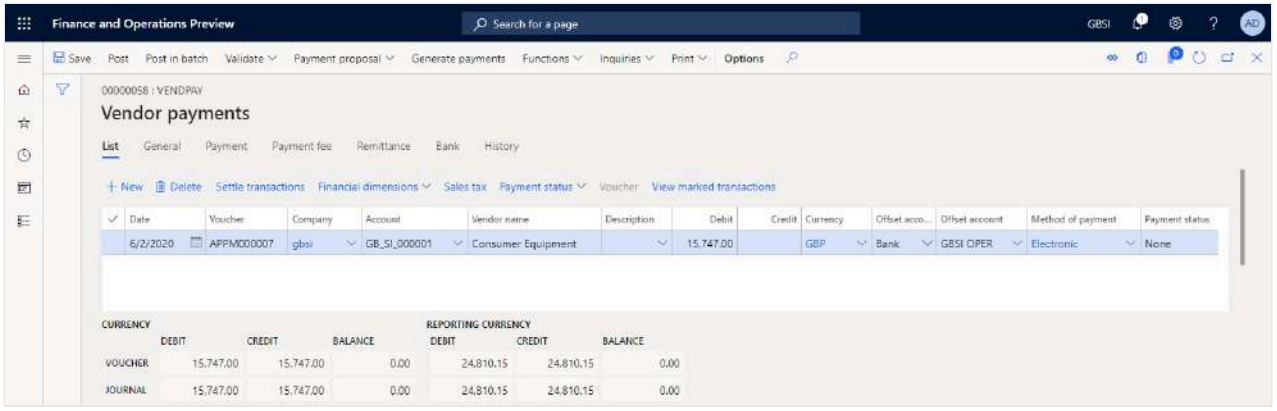
5. Select **Payment proposal** > **Create payment proposal**.

6. In the **Vendor payment proposal** dialog box, set conditions to filter for records for the **GB_SI_000001** vendor account only, and then select **OK**.

7. Select the line for the **00000007_Inv** invoice, and then select **Create payment**.



8. Verify that the payment that you entered is configured to use the **Electronic** method of payment.

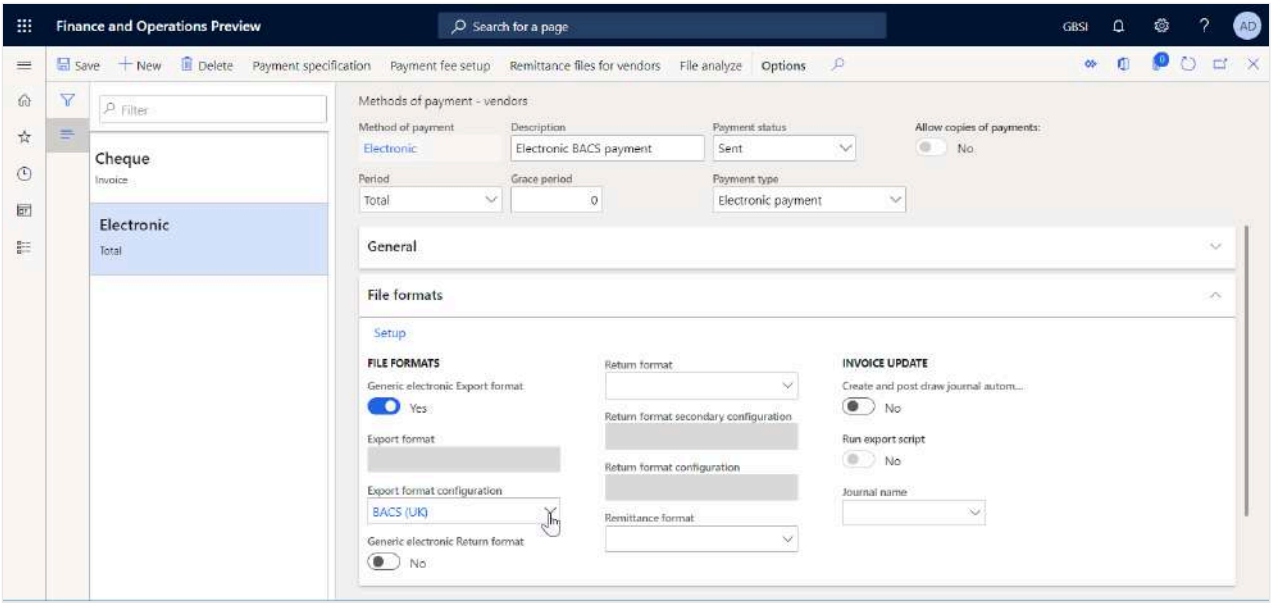


Process a vendor payment by using the standard ER format

Set up the electronic payment method

You must configure the electronic method of payment so that it uses the imported ER format configuration.

1. Go to **Accounts payable** > **Payment setup** > **Methods of payment**.
2. On **Methods of payment - vendors**, select the **Electronic** method of payment in the left pane.
3. Select **Edit**.
4. On the **File formats** FastTab, set the **General electronic Export format** option to **Yes**.
5. In the **Export format configuration** field, select the **BACS (UK)** format configuration.

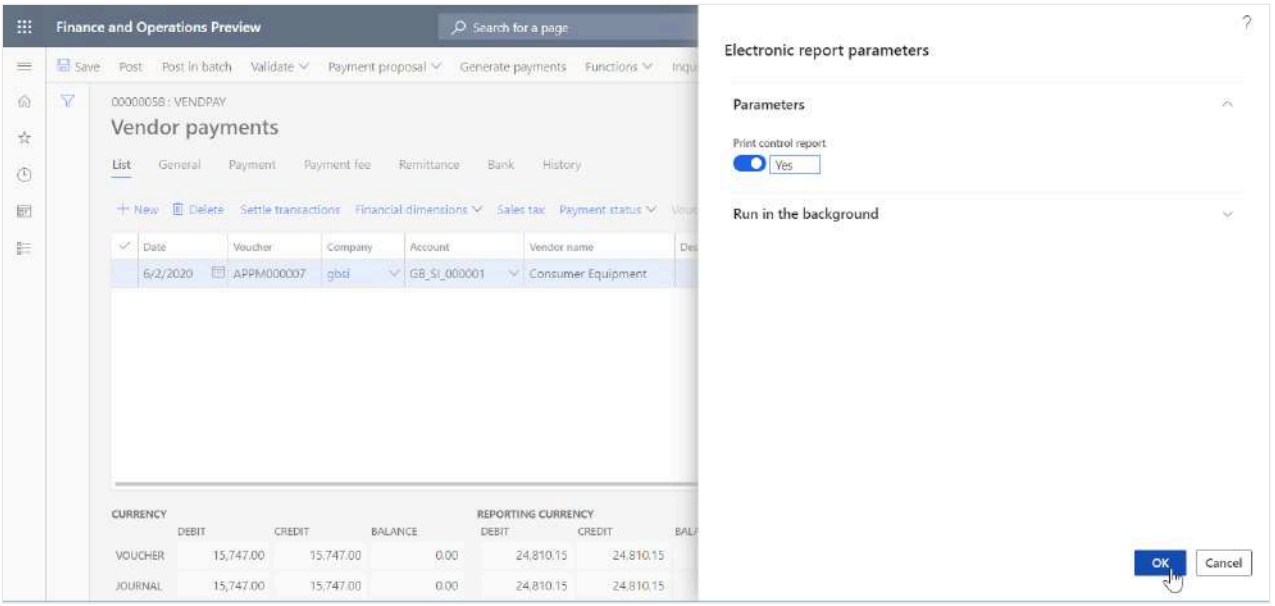


6. Select **Save**.

Process a vendor payment

1. Go to **Accounts payable** > **Payments** > **Vendor payment journal**.
2. On **Vendor payment journal**, select the payment journal that you added earlier, and then select **Lines**.
3. On **Vendor payments**, select **Generate payments**.
4. In **Generate payments**, enter the following information:
    - In **Method of payment**, select **Electronic**.
    - In **Bank account**, select **GBSI OPER**.
5. Select **OK**.

6. In **Electronic report parameters**, set the **Print control report** option to **Yes**, and then select **OK**.



> **Note**
>
> In addition to the payment file, you can now generate the control report.

7. Download the ZIP file, and then extract the following files from it:

   - The control report in Excel format
   - The payment file in TXT format

     Notice that, in accordance with the structure of the provided ER format, the payment line in the generated file starts with the routing number that you defined for the configured bank account.

Customize the standard ER format

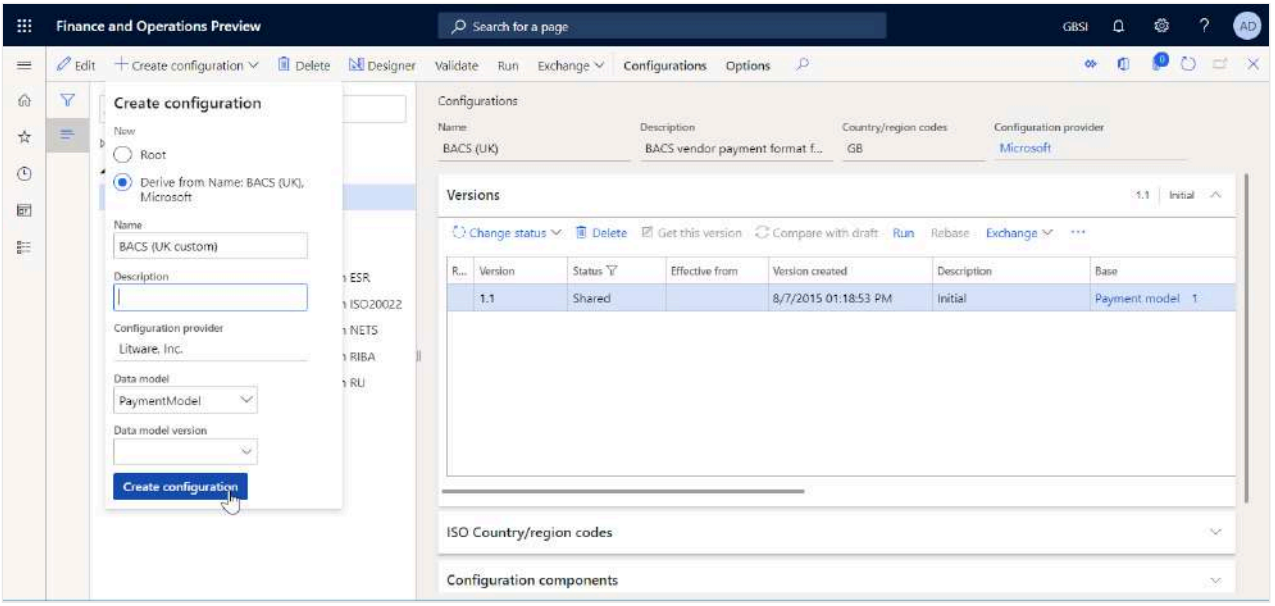
For the example in this section, you want to use the ER configurations that Microsoft provides to generate vendor payment files in BACS format, but you must add a customization to support the requirements of a specific bank. You also want to be able to upgrade your custom

format when new versions of ER configurations become available. However, you want to do the upgrade at the lowest cost.

In this case, as the representative of Litware, Inc., you must create (derive) a new ER format configuration by using the **BACS (UK)** Microsoft-provided configuration as a base.

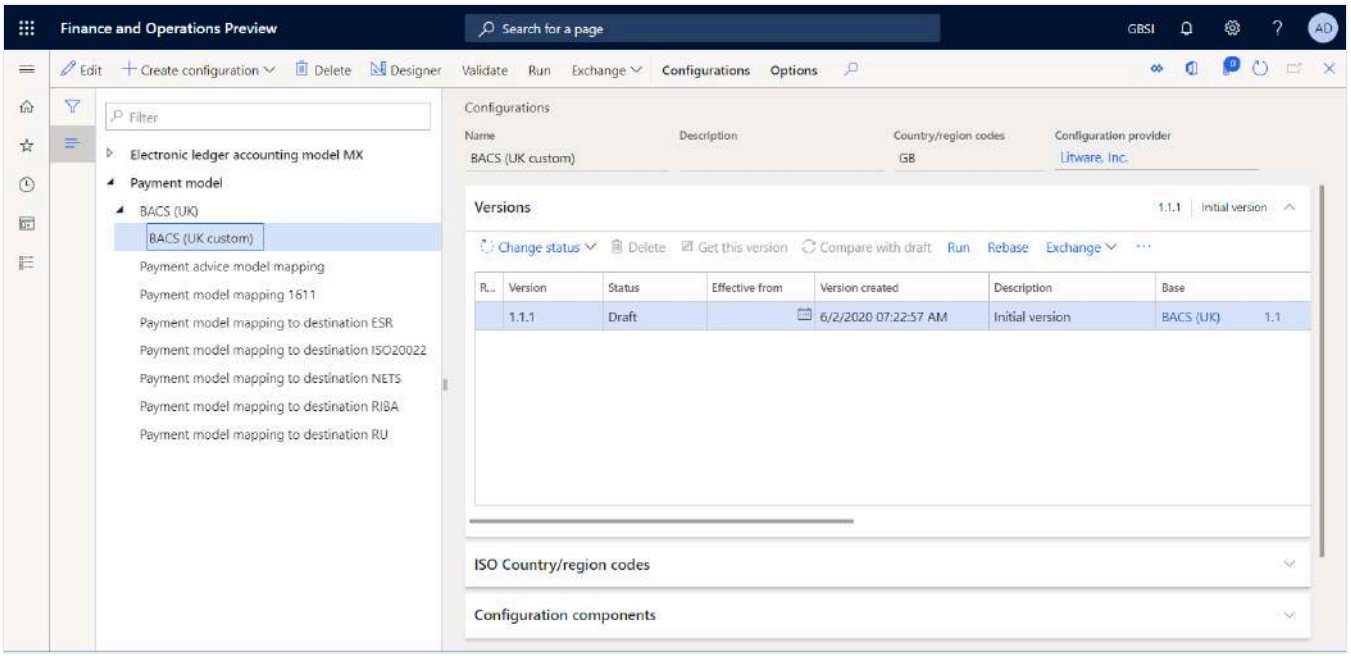
Create a custom format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Payment model**, and then select **BACS (UK)**. Litware, Inc. uses version 1.1 of this ER format configuration as the base for the custom version.
3. Select **Create configuration** to open the drop-down dialog box. Use this dialog box to create a new configuration for a custom payment format.
4. In the **New** field group, select the **Derive from Name: BACS (UK), Microsoft** option.
5. In the **Name** field, enter **BACS (UK custom)**.



6. Select **Create configuration**.

Version 1.1.1 of the **BACS (UK custom)** ER format configuration is created. This version has a status of **Draft** and can be edited. The current content of your custom ER format matches the content of the format that Microsoft provides.



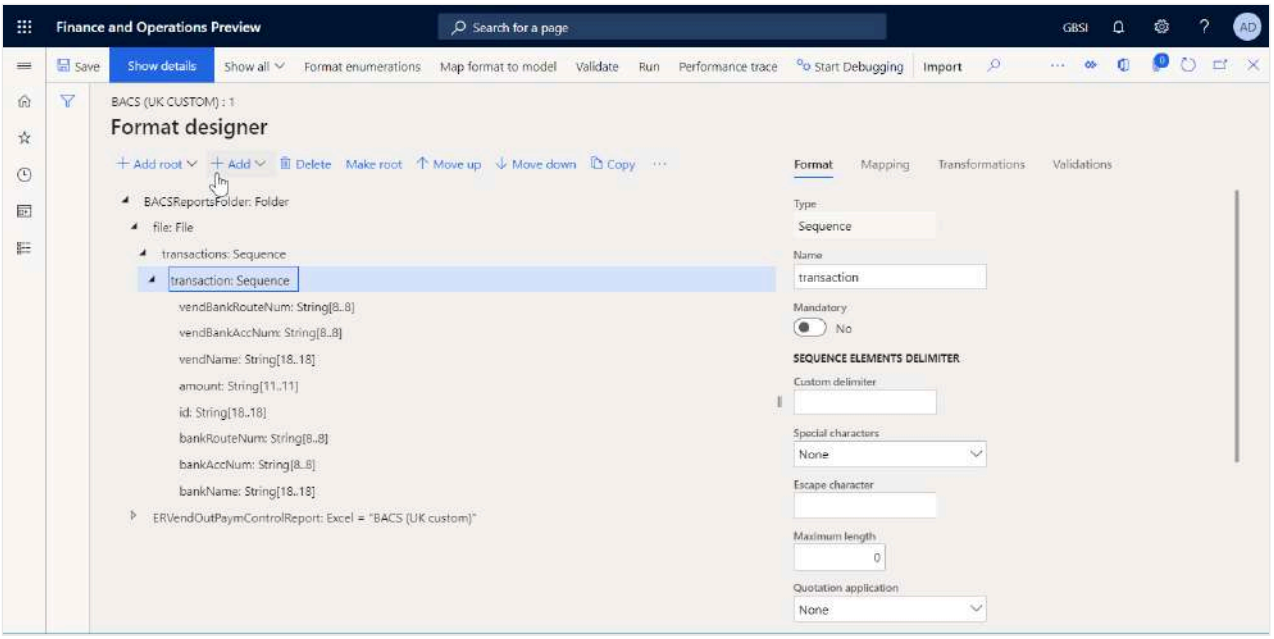
Edit a custom format

You must configure your custom format so that it meets bank-specific requirements. For example, a bank might require that generated payment files include the Society for Worldwide Interbank Financial Telecommunication (SWIFT) code of a bank that is assigned the agent role in the processed vendor payment. SWIFT codes are international bank codes that identify specific banks worldwide. They're also known as Bank Identifier Codes (BICs). The SWIFT code must be 11 characters long, and it must be entered at the beginning of every payment line in a generated payment file.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Payment model**, and then select **BACS (UK custom)**.
3. On the **Versions** FastTab, select version **1.1.1** of the selected configuration.
4. Select **Designer**.
5. On **Format designer**, select **Show details** to view more information about the format elements.
6. Expand and review the following elements:
    - The **BACSReportsFolder** element of the **Folder** type. This element generates output in ZIP format.
    - The **file** element of the **File** type. This element generates a payment file in TXT format.

- The **transactions** element of the **Sequence** type. This element generates a single payment line in a payment file.
- The **transaction** element of the **Sequence** type. This element generates individual fields of a single payment line.

7. Select the **transaction** element.



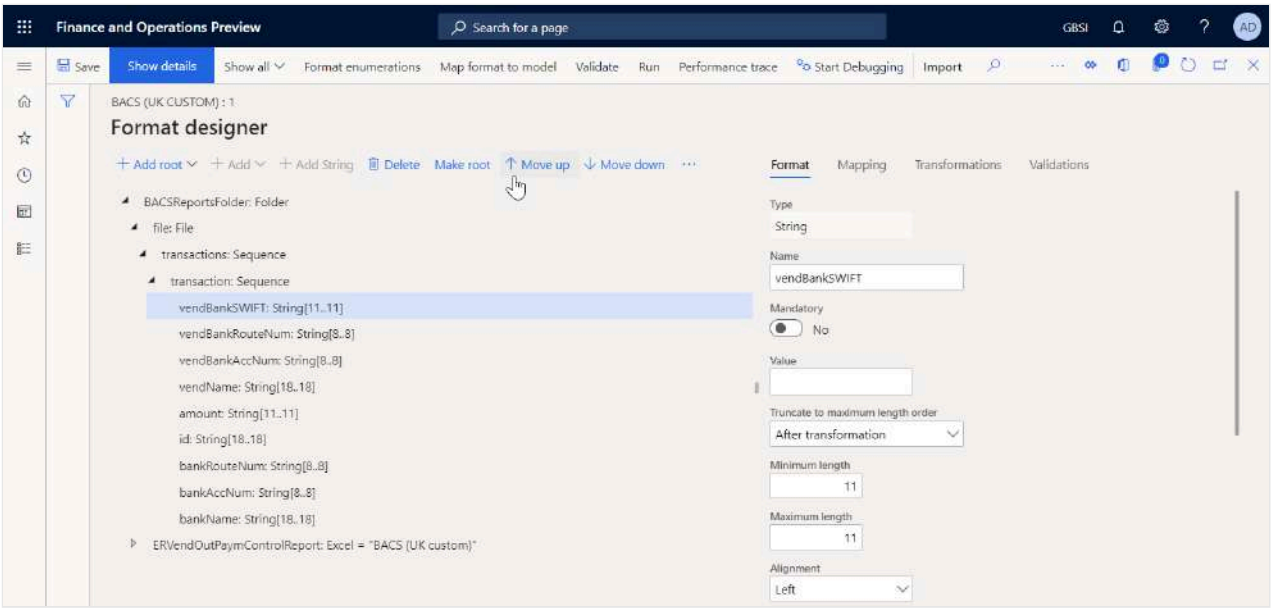
> ⓘ **Note**
>
> The provided report is configured so that every payment line starts with the bank routing number. The **vendBankRouteNum** format element is used for this purpose.

8. Select **Add**, and then select the **Text\String** type of the format element that you're adding:
   a. In the **Name** field, enter **vendBankSWIFT**.
   b. In the **Minimum length** field, enter **11**.
   c. In the **Maximum length** field, enter **11**.
   d. Select **OK**.

> ⓘ **Note**
>
> Use the **vendBankSWIFT** element to enter the SWIFT code of a vendor bank in generated files.

9. In the format structure tree, select **vendBankSWIFT**.

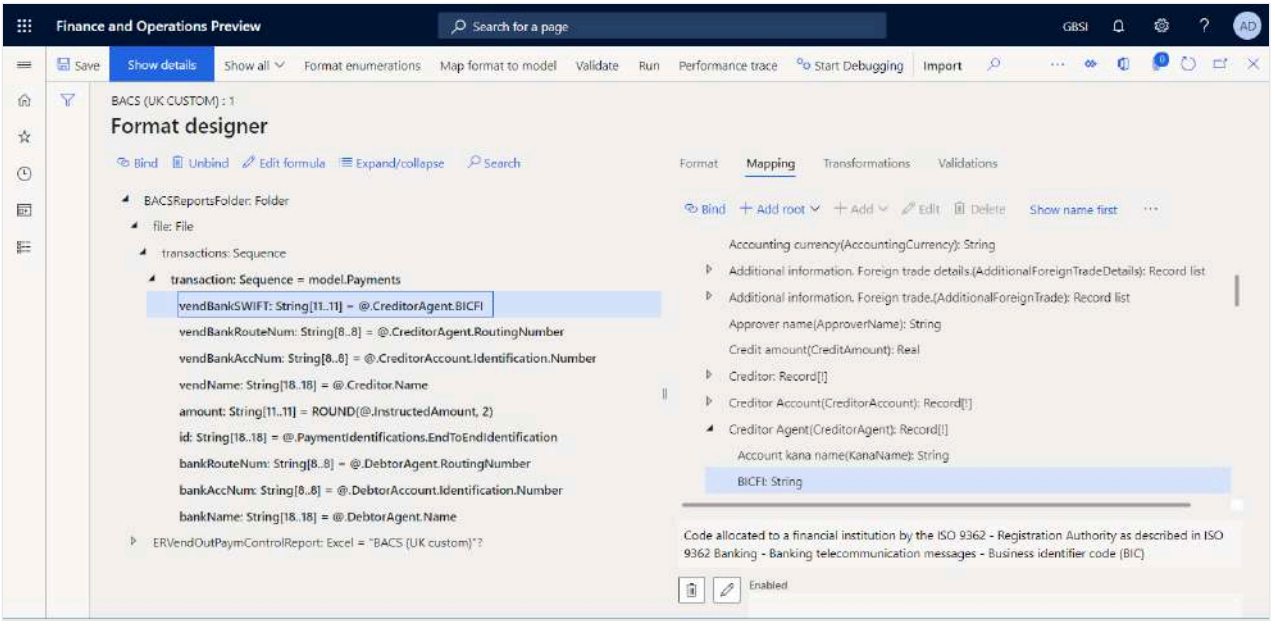
10. Select **Move up** to move the selected format element up one level. Repeat this step until the **vendBankSWIFT** element is the first element under the parent **transaction** element.



11. While the **vendBankSWIFT** is still selected in the format structure tree, select the **Mapping** tab, and then expand the **model** data source.

12. Expand **model.Payment** > **model.Payment.CreditorAgent**, and select the **model.Payment.CreditorAgent.BICFI** data source field. This data source field exposes the SWIFT code of a vendor bank that is assigned the agent role in the processed vendor payment.

13. Select **Bind**. The **vendBankSWIFT** format element is now bound with the **model.Payment.CreditorAgent.BICFI** data source field, so that SWIFT codes are entered in generated payment files.



14. Select **Save**.

15. Close the designer page.

Mark a custom format as runnable

After you create the first version of your custom format and set its status to **Draft**, you can run it for testing purposes. To run the report, you must process a vendor payment by using the payment method that refers to your custom ER format. By default, when you call an ER format from the application, only versions that have a status of **Completed** or **Shared** are considered. This behavior helps prevent ER formats that have unfinished designs from being used. However, for your test runs, you can force the application to use the version of your ER format that has a status of **Draft**. By using this approach, you can adjust the current format version if any modifications are required. For more information, see Applicability.

To use the draft version of an ER format, you must explicitly mark the ER format.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.

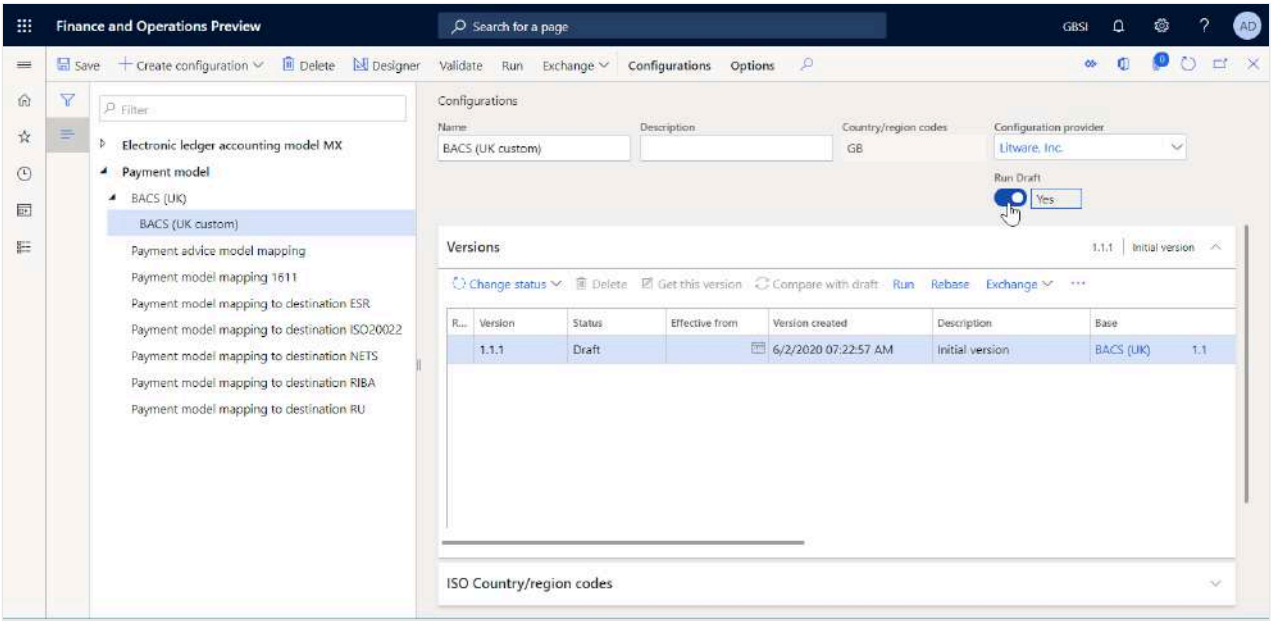
2. On **Configurations**, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.

3. In **User parameters**, set the **Run settings** option to **Yes**, and then select **OK**.

4. Select **Edit** to make the current page editable, as required.

5. In the configuration tree in the left pane, select **BACS (UK custom)**.

6. Set the **Run Draft** option to **Yes**.

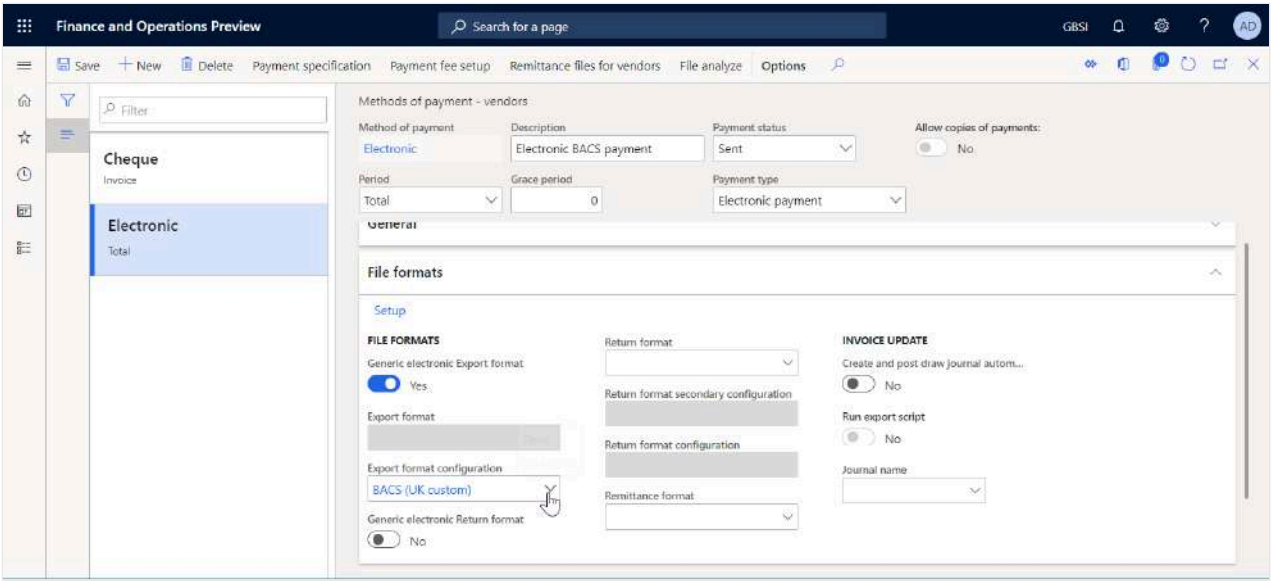


Process a vendor payment by using the custom ER format

Set up the electronic payment method

You must configure the electronic method of payment so that your custom ER format is used to process vendor payments.

1. Go to **Accounts payable** > **Payment setup** > **Methods of payment**.
2. On **Methods of payment - vendors**, select the **Electronic** method of payment in the left pane.
3. Select **Edit**.
4. On the **File format** FastTab, set the **General electronic export format** option to **Yes**.
5. In the **Export format configuration** field, select the **BACS (UK custom)** format configuration.



6. Select **Save**.

Process a vendor payment

1. Go to **Accounts payable** > **Payments** > **Vendor payment journal**.
2. On **Vendor payment journal**, select the payment journal that you created earlier.
3. Select **Lines**.

4. On **Vendor payments**, above the grid, select **Payment status** > **None**.

5. Select **Generate payment**.

6. In **Generate payments**, enter the following information:

    - In **Method of payment**, select **Electronic**.
    - In **Bank account**, select **GBSI OPER**.

7. Select **OK**.

8. In **Electronic report parameters**, set the **Print control report** option to **Yes**, and then select **OK**.

    > **Note**
    >
    > In addition to the payment file, you can generate only the control report.

9. Download the ZIP file, and then extract the following files from it:

    - The control report in Excel format
    - The payment file in TXT format

      Notice that, in accordance with the structure of your custom ER format, the payment line in the generated file now starts with the SWIFT code that you entered for the bank account of the vendor whose payment you processed.

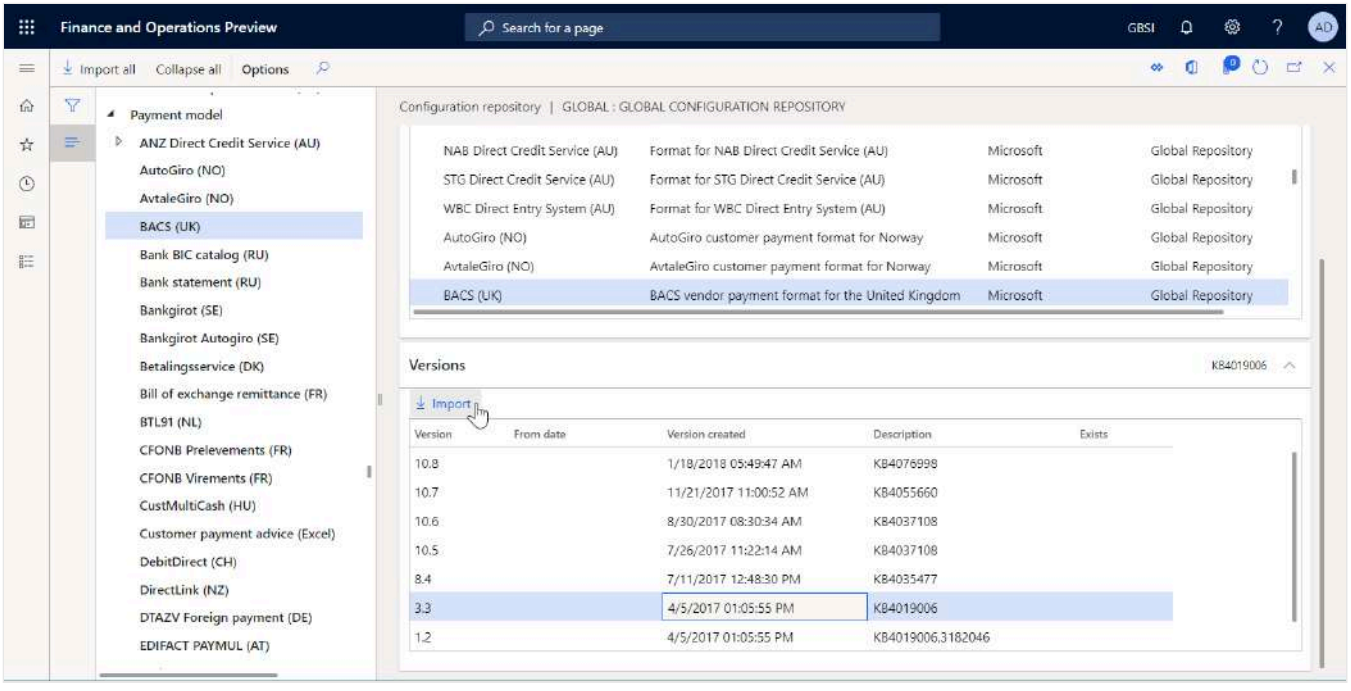
Import new versions of the standard ER format configurations

In the following example, you receive a notification about Knowledge Base article KB3763330. This notification informs you about the new version of the **BACS (UK)** ER format that Microsoft published. In addition to the control report, this new version lets users generate the payment advice report and the attending note report while a vendor payment is being processed. You want to start using that functionality.

Import new versions of the standard ER configurations

To add new versions of the ER configurations to the current Finance instance, import them from the ER repository that you configured.

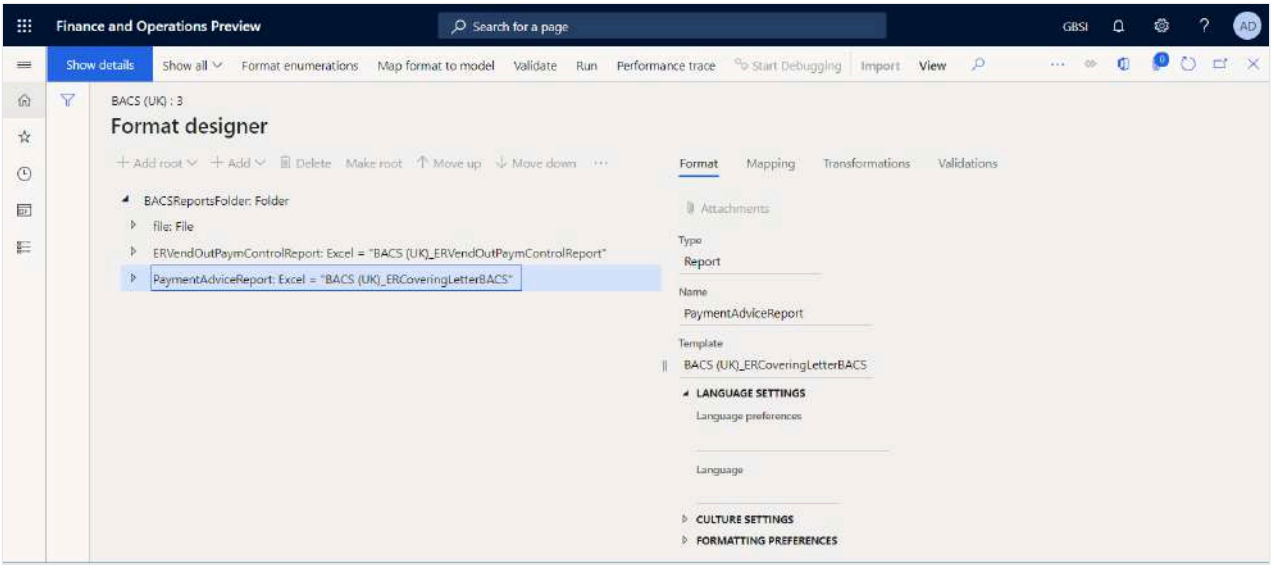
1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configuration providers** section, select the **Microsoft** tile, and then select **Repositories** to view the list of repositories for the Microsoft provider.
3. On **Configuration repositories**, select the repository of the **Global** type, and then select **Open**. If you're prompted for authorization to connect to Regulatory Configuration Service, follow the authorization instructions.
4. On **Configuration repository**, in the configuration tree in the left pane, select the **BACS (UK)** format configuration.
5. On the **Versions** FastTab, select version **3.3** of the selected ER format configuration.
6. Select **Import** to download the selected version from the Global repository to the current Finance instance.



> **Tip**
>
> If you have trouble accessing the Global repository, you can download configurations from Lifecycle Services instead.

Review the imported ER format configurations

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configurations** section, select the **Reporting configurations** tile.
3. On **Configurations**, in the configuration tree in the left pane, expand **Payment model**, and then select **BACS (UK)**.
4. On the **Versions** FastTab, select version **3.3**.
5. Select **Designer**.
6. On **Format designer**, expand the **BACSReportsFolder** format element.
7. Notice that version 3.3 contains the **PaymentAdviceReport** format element that you use to generate a payment advice report when a vendor payment is processed.



8. Close the designer page.

Adopt the changes in the new version of an imported format in a custom format

Complete the current draft version of a custom format

If you want to keep the current state of your custom format, complete the draft version 1.1.1 by changing its status from **Draft** to **Completed**.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configurations** section, select the **Reporting configurations** tile.

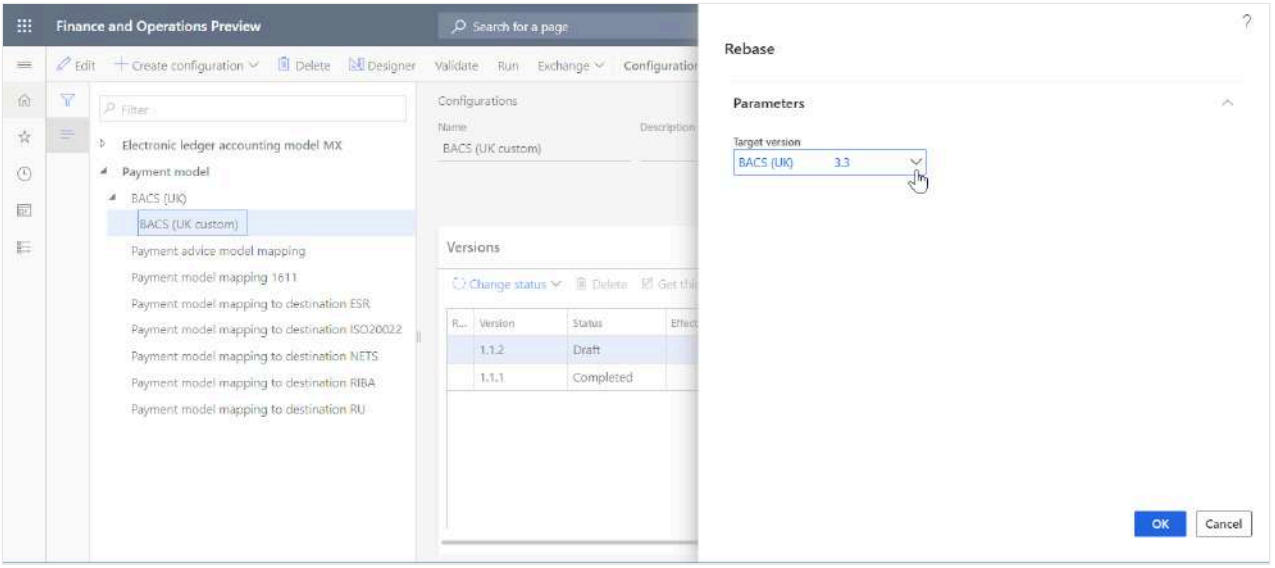
3. On **Configurations**, in the configuration tree in the left pane, expand **Payment model**, expand **BACS (UK)**, and then select **BACS (UK custom)**.
4. On the **Versions** FastTab, select **Change status** > **Complete**, and then select **OK**.

The status of version 1.1.1 changes from **Draft** to **Completed**, and the version becomes read-only. A new editable version, 1.1.2, is added and has a status of **Draft**. Use this version to make further changes in your custom ER format.

Rebase a custom format to a new base version

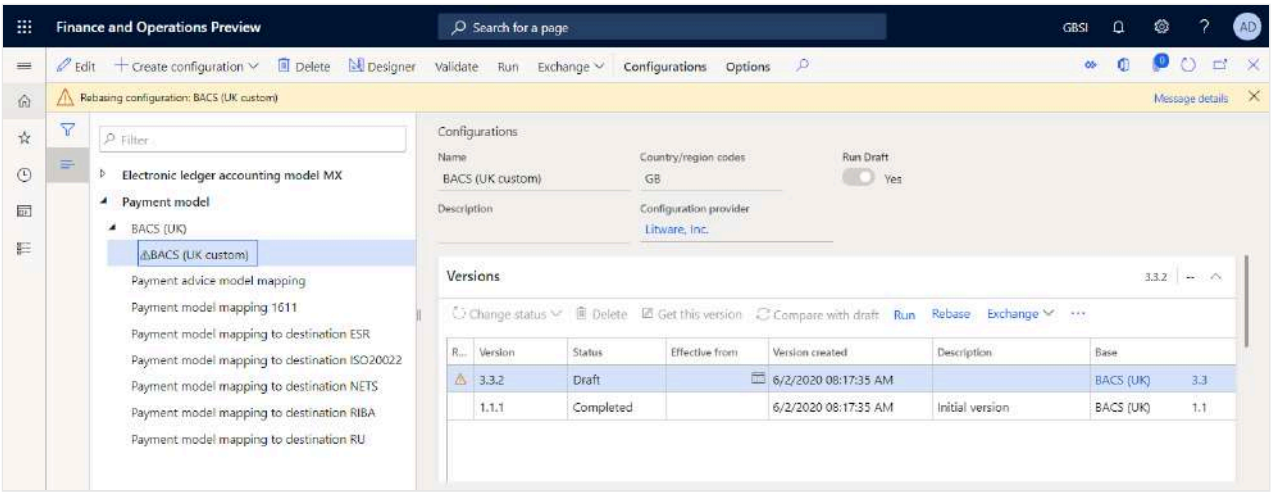
To use the new functionality of version 3.3 of the **BACS (UK)** format in your customization, change the base configuration version for the custom configuration, **BACS (UK custom)**. This process is known as rebasing. Instead of version 1.1 of **BACS (UK)**, use version 3.3.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Payment model**, and then select **BACS (UK custom)**.
3. On the **Versions** FastTab, select version **1.1.2**, and then select **Rebase**.
4. In **Rebase**, in the **Target version** field, select version **3.3** of the base configuration to apply it as the new base and use it to update the configuration.



5. Select **OK**.
6. The number of the draft version changes from **1.1.2** to **3.3.2** to reflect the change in the base version.

When the custom version and a new base version merge, some conflicts might be discovered because of format changes that can't be merged automatically.

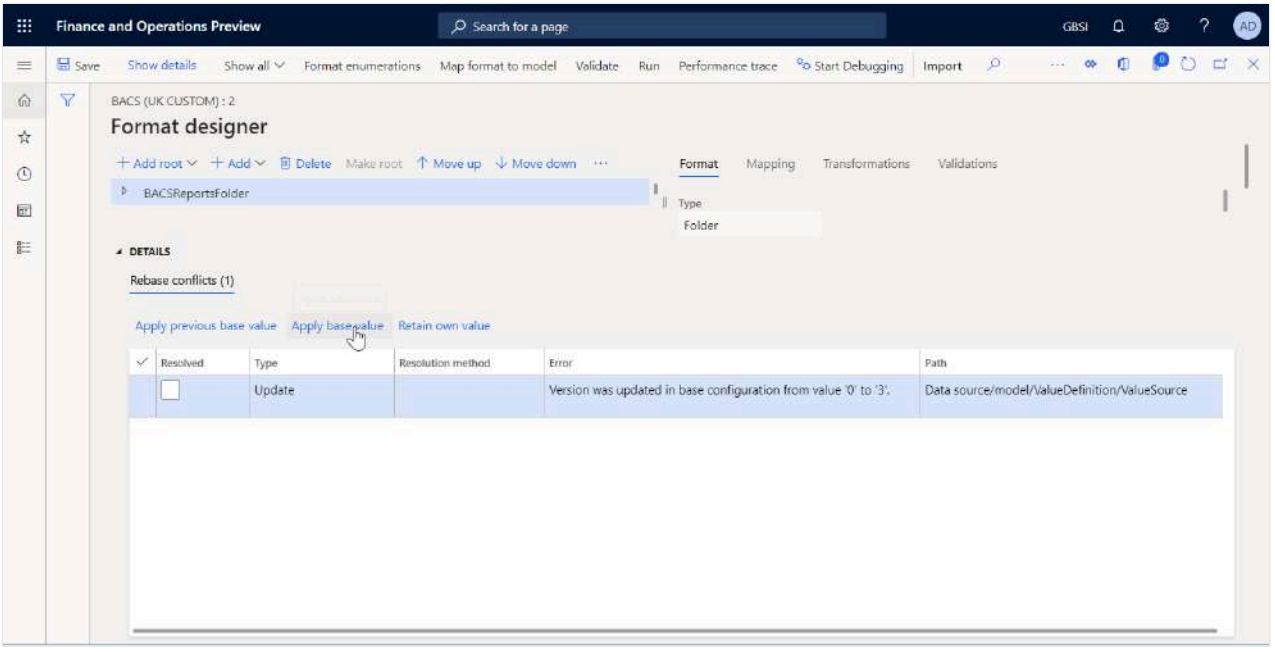


If conflicts are discovered, you must resolve them manually in the format designer.

7. On the **Versions** FastTab, select version **3.3.2**.

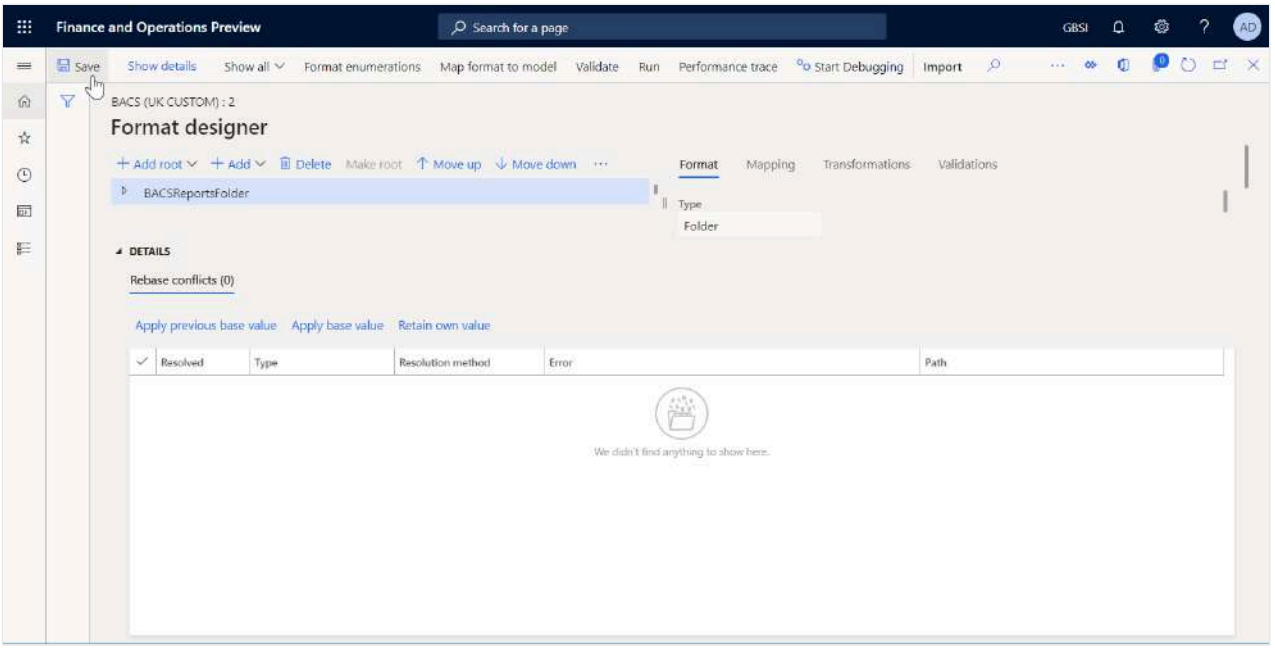
8. Select **Designer**.

9. On **Format designer**, on the **Details** FastTab, select a rebase conflict record, and then select **Apply base value**.



10. Select **Save**.

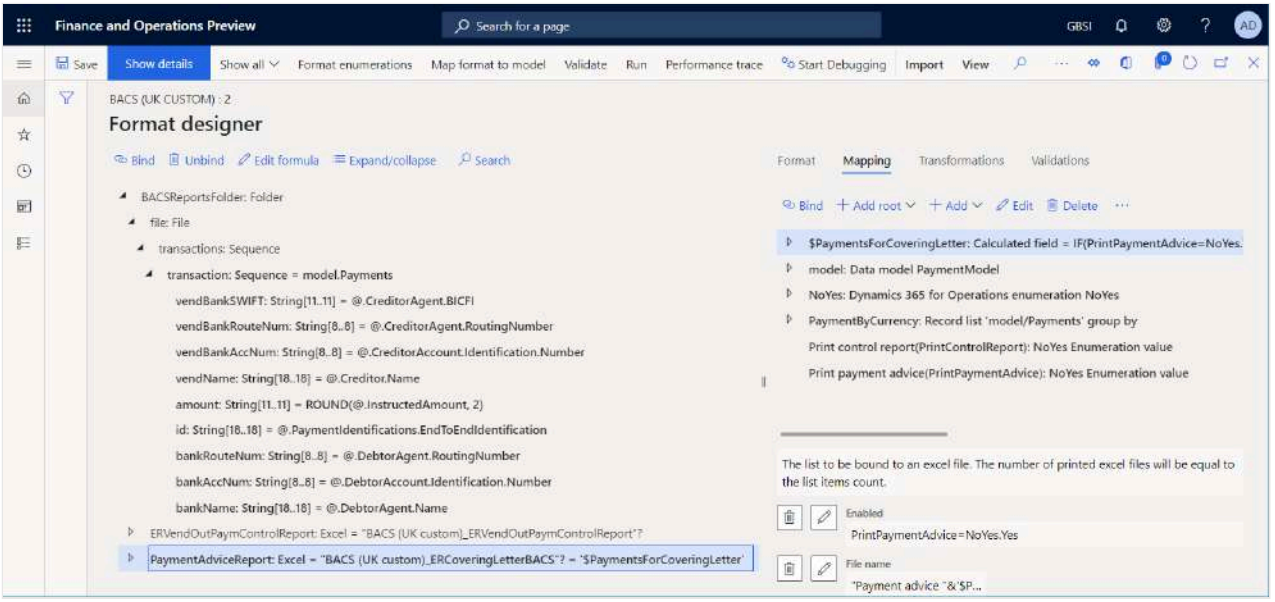
The rebase conflict record no longer appears on the **Details** FastTab.



> **Note**
>
> You resolved the conflict by confirming that version 3 of the base model must be used in this ER format.

11. Expand **BACSReportsFolder** > **file** > **transactions** > **transaction**.

12. On the **Mapping** tab, version 3.3.2 of your custom ER format contains both your customization (the **vendBankSWIFT** format element and its binding) and the new functionality of version 3.3 of the base ER format that Microsoft provides (the **PaymentAdviceReport** format element together with its nested elements and configured bindings). In just a few mouse clicks, you adopted the modifications of a new base version by merging them with your customization.

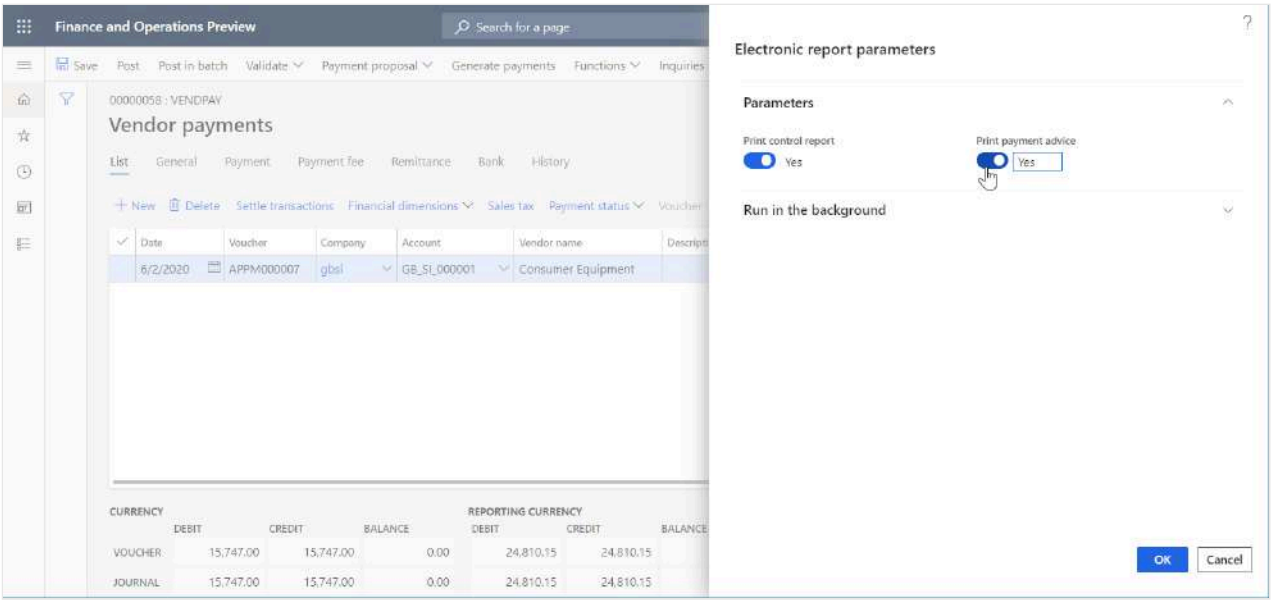


13. Close the designer page.

> ⓘ **Note**
>
> The rebase action is reversible. To cancel this rebase, select version **1.1.1** of the **BACS (UK custom)** format on the **Versions** FastTab, and then select **Get this version**. Version 3.3.2 is renumbered 1.1.2, and the content of draft version 1.1.2 matches the content of version 1.1.1.

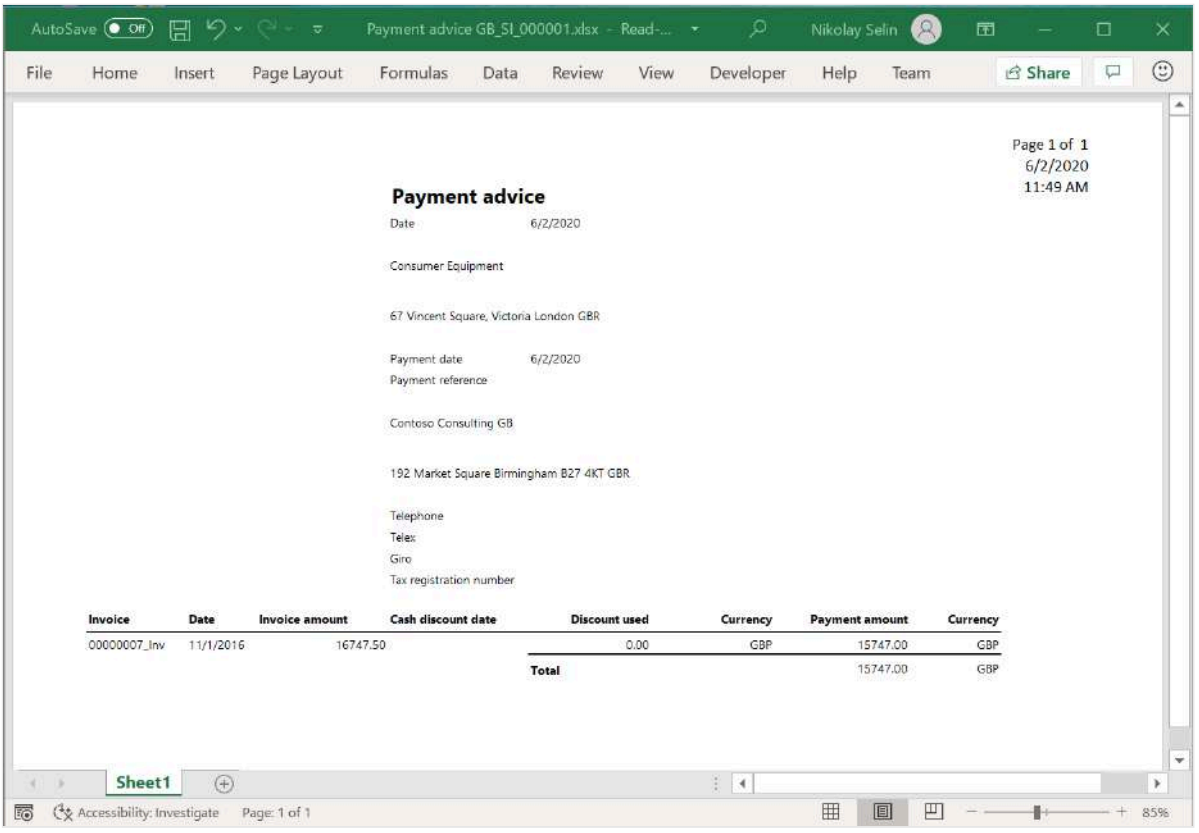
Process a vendor payment by using a rebased ER format

1. Go to **Accounts payable** > **Payments** > **Vendor payment journal**.
2. On **Vendor payment journal**, select the payment journal that you created earlier.
3. Select **Lines**.
4. On **Vendor payments**, above the grid, select **Payment status** > **None**.
5. Select **Generate payment**.
6. In **Generate payments**, enter the following information:
    - In **Method of payment**, select **Electronic**.
    - In **Bank account**, select **GBSI OPER**.
7. Select **OK**.
8. In **Electronic report parameters**, enter the following information:
    - Set the **Print control report** option to **Yes**.
    - Set the **Print payment advice** option to **Yes**.



> **Note**
>
> In addition to the payment file, you can now generate both the control report and the payment advice report.

9. Select **OK**.
10. Download the ZIP file, and then extract the following files from it:
    - The control report in Excel format
    - The payment advice report in Excel format



- The payment file in TXT format

  Notice that the payment line in the generated file starts with the SWIFT code that you entered for the bank account of a vendor whose payment you processed.

Design a new ER solution to print a custom report

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user in the System Administrator, Electronic Reporting Developer, or Electronic Reporting Functional Consultant role can configure parameters of the ER framework, design the required ER configurations of a new ER solution to access the data of a particular business domain, and generate a custom report in Microsoft Office format. You can complete these steps in the **USMF** company.

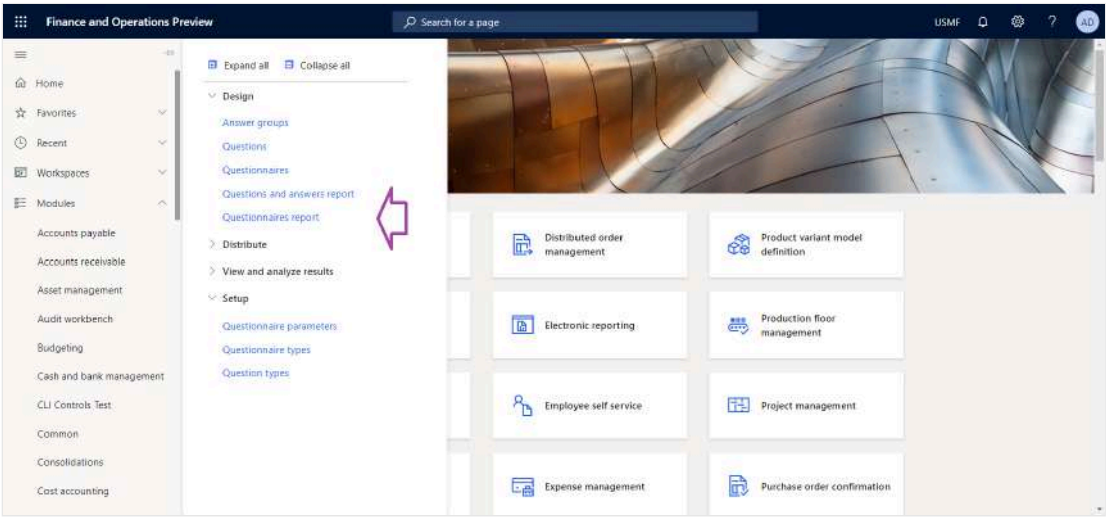
- Configure the ER framework
  - Configure ER parameters
  - Activate an ER configuration provider
    - Review the list of ER configuration providers
    - Add a new ER configuration provider
    - Activate an ER configuration provider
- Design a domain-specific data model
  - Import a new data model configuration
  - Create a new data model configuration
    - Name the data model
    - Add data model fields
    - Complete the design of the data model
- Design a model mapping for the configured data model
  - Import a new model mapping configuration
  - Create a new model mapping configuration
    - Design a new model mapping component
    - Add data sources to access application tables
    - Add data sources to access application enumerations
    - Add ER labels to generate a report in a specified language

        - Add a data source to transform the results of comparing enumeration values to a text value
        - Bind data sources to data model fields
        - Complete the design of the model mapping
- Design a template for a custom report
- Design a format
    - Import a designed format configuration
    - Create a new format configuration
        - Import a report template
        - Configure a format
        - Define the data binding for a report title
        - Review the model data source
        - Bind format elements to data source fields
    - Run a designed format from ER
- Tune a designed format
    - Modify a format to change the name of a generated document
    - Modify a format to change the order of questions
    - Run a modified format from ER
    - Complete the format design
- Develop application artefacts to call the designed report
    - Modify source code
        - Add a data contract class
        - Add a UI builder class
        - Add a data provider class
        - Add a labels file
        - Add a report service class
        - Add a report controller class
        - Add a menu item
        - Add a menu item to a menu
        - Build a Visual Studio project
    - Run a format from the application
- Tune a designed ER solution
    - Modify a model mapping
        - Add data sources to access a data contract object
        - Add a data source to access ER format mapping records
        - Add a data source to access a format mapping record of a running ER format

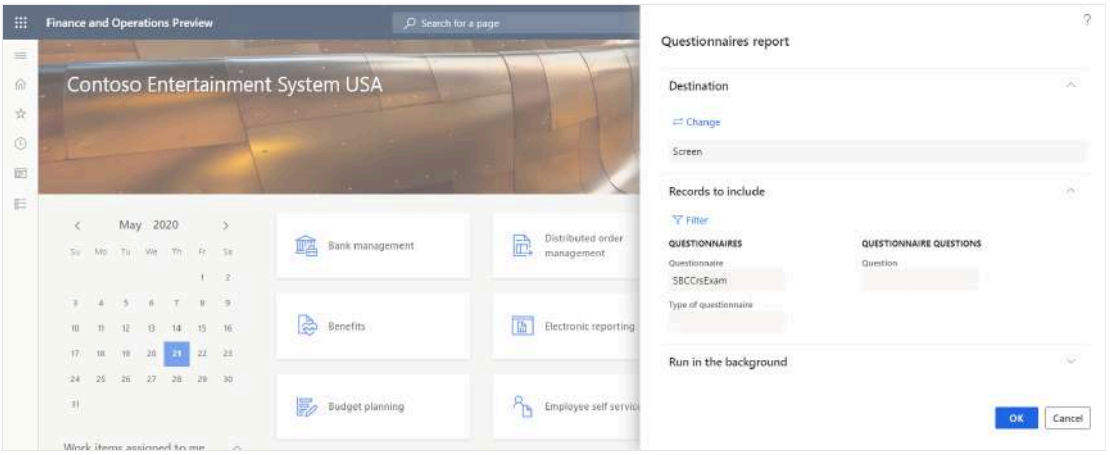
    - Enter the name of the running ER format in the data model
    - Complete the design of the model mapping
  - Modify a format
    - Add a new format element
    - Bind the added format element
    - Complete the format design
  - Run a format from the application
  - Run a format from ER
  - Configure a format destination for on-screen preview
  - Run a format from the application to preview it as a PDF document
- Additional resources

In this example, you create a new ER solution for the Questionnaire module. This new ER solution lets you design a report by using a Microsoft Excel worksheet as a template. You can then generate the **Questionnaire** report in Excel or PDF format, in addition to generating the existing SQL Server Reporting Services (SSRS) report. You can also modify the new report later, upon request. No coding is required.

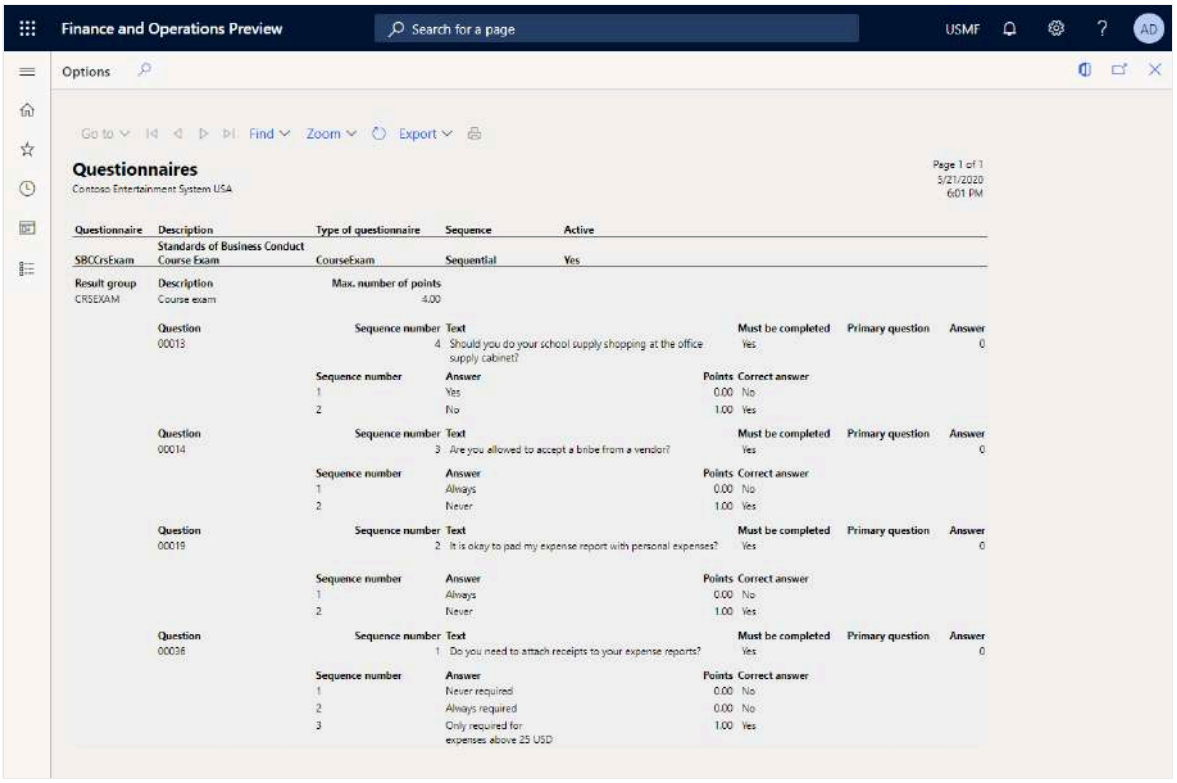
1. To run the existing report, go to **Questionnaire** > **Design** > **Questionnaires report**.



2. In the **Questionnaires report** dialog box, specify selection criteria. Apply a filter so that the report includes only the **SBCCrsExam** questionnaire.



The following illustration shows the generated version of the SSRS report for the **SBCCrsExam** questionnaire.



Configure the ER framework

As a user in the Electronic Reporting Developer role, you must configure the minimal set of ER parameters before you can start to use the ER framework to design your new ER solution.

Configure ER parameters

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. In the **Electronic reporting** workspace, select **Electronic reporting parameters**.
3. On the **Electronic reporting parameters** page, on the **General** tab, set the **Enable design mode** option to **Yes**.
4. On the **Attachments** tab, set the following parameters:

- Set the **Configurations** field to **File** for the **USMF** company.
- Set **Job archive**, **Temporary**, **Baseline**, and **Others** fields to **File**.

For more information about ER parameters, see Configure the ER framework.

Activate an ER configuration provider

Each ER configuration belongs to an ER configuration provider. Therefore, you must activate an ER configuration provider in the **Electronic reporting** workspace before you can add or edit any ER configurations.

> ⓘ **Note**
>
> Only the owner of an ER configuration can edit it. Therefore, before you can edit an ER configuration, activate the appropriate ER configuration provider in the **Electronic reporting** workspace.

Review the list of ER configuration providers

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. In the **Electronic reporting** workspace, in the **Related links** section, select **Configuration providers**.
3. On the **Configuration providers** page, each configuration provider record has a unique name and URL. Review the contents of this page. If a record for **Litware, Inc.** (`https://www.litware.com`) already exists, skip the next procedure, Add a new ER configuration provider.

Add a new ER configuration provider

1. On the **Configuration providers** page, select **New**.
2. In the **Name** field, enter **Litware, Inc.**
3. In the **Internet address** field, enter `https://www.litware.com`.
4. Select **Save**.

Activate an ER configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. In the **Electronic reporting** workspace, select the **Litware, Inc.** configuration provider.
3. Select **Set active**.

For more information about ER configuration providers, see Create configuration providers and mark them as active.

Design a domain-specific data model

You must create a new ER configuration that contains a data model component for the **Questionnaire** business domain. You use this data model as a data source when you design an ER format to generate the **Questionnaire** report.

By completing the steps in the Import a new data model configuration section, you can import the required data model from the provided XML file. Alternatively, you can complete the steps in the Create a new data model configuration section to design this data model from scratch.

Import a new data model configuration

1. Download the Questionnaires model.version.1.xml file, and save it to your local computer.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. In the **Electronic reporting** workspace, select **Reporting configurations**.
4. On the Action Pane, select **Exchange** > **Load from XML file**.
5. Select **Browse**, and then find and select the **Questionnaires model.version.1.xml** file.
6. Select **OK** to import the configuration.

To continue, skip the next procedure, Create a new data model configuration.

Create a new data model configuration

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. In the **Electronic reporting** workspace, select **Reporting configurations**.
3. Select **Create configuration**.
4. In the drop-down dialog box, in the **Name** field, enter **Questionnaire model**.
5. Select **Create configuration** to create the configuration.

Name the data model

1. On **Configurations**, in the configuration tree, select **Questionnaire model**.
2. Select **Designer**.
3. On **Data model designer**, on the **General** FastTab, in the **Name** field, enter **Questionnaires**.

Add new data model fields

1. On **Data model designer**, select **New**.

2. In the drop-down dialog box for adding a data model node, follow these steps:
   a. Select **Model root** as the type of the new node.
   b. In the **Name** field, enter **Root**.
   c. Select **Add** to add the new node.

   This root descriptor provides data for the **Questionnaire** report. A single data model can have multiple descriptors. Each descriptor can be specified for a single ER format, to

identify data that is required to generate the report.

3. Select **New** again. In the drop-down dialog box for adding a data model node, follow these steps:
   a. Select **Child of an active node** as the type of the new node.
   b. In the **Name** field, enter **CompanyName**.
   c. In the **Item type** field, select **String**.
   d. Select **Add** to add the new field.

   This field passes the name of the current company to an ER report that consumes this data model as a data source.

4. Select **New** again. In the drop-down dialog box for adding a data model node, follow these steps:
   a. Select **Child of an active node** as the type of the new node.
   b. In the **Name** field, enter **Questionnaire**.
   c. In the **Item type** field, select **Record list**.
   d. Select **Add** to add the new field.

   This field passes the list of questionnaires to an ER report that consumes this data model as a data source.

5. Select the **Questionnaire** node.

6. Continue to add the required fields of the editable data model in the same manner until you complete the following data model structure.

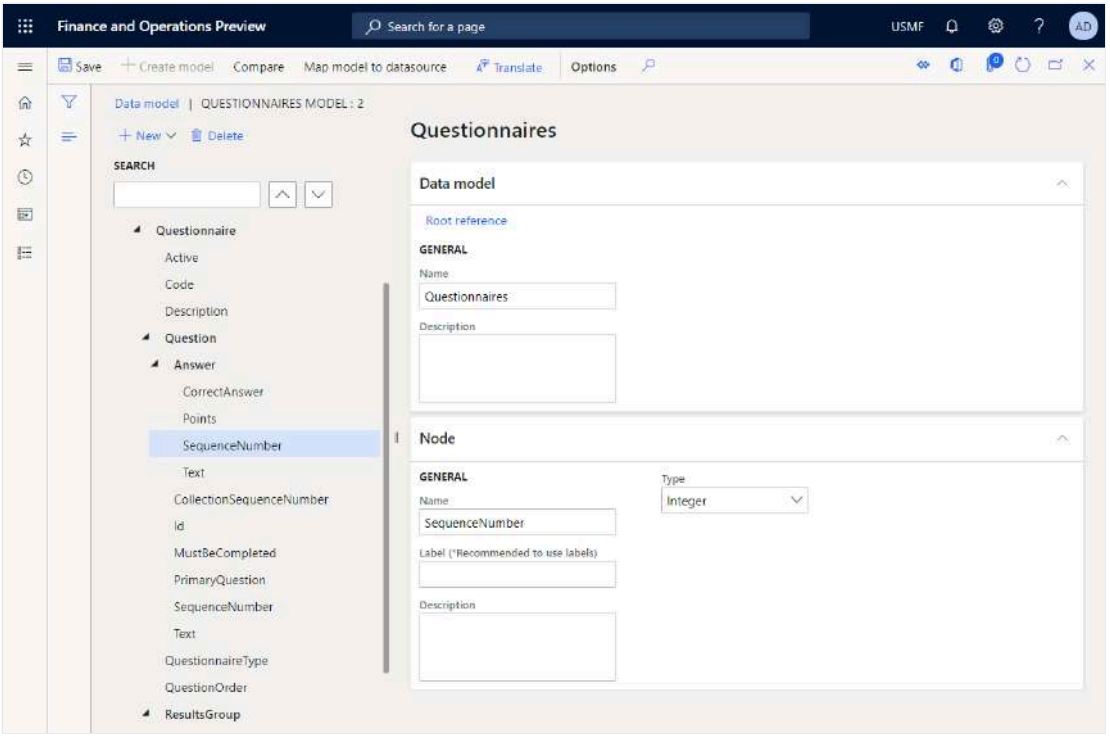
Expand table

Field path	Data type	Field designation/returned value
Root		The reference point to request questionnaire data.
Root\CompanyName	String	The name of the current company.
Root\ExecutionContext	Record	Format execution details.
Root\ExecutionContext\FormatName	String	The name of the ER format that is being run.
Root\Questionnaire	Record list	The list of questionnaires
Root\Questionnaire\Active	String	The status of the current questionnaire.
Root\Questionnaire\Code	String	The code of the current questionnaire.

Field path	Data type	Field designation/returned value
Root\Questionnaire\Description	String	The description of the current questionnaire.
Root\Questionnaire\QuestionnaireType	String	The type of the current questionnaire.
Root\Questionnaire\QuestionOrder	String	The numerical order of the current questionnaire.
Root\Questionnaire\ResultsGroup	Record	The result parameters of the current questionnaire.
Root\Questionnaire\ResultsGroup\Code	String	The identification code of the current result group.
Root\Questionnaire\ResultsGroup\Description	String	The description of the current result group.
Root\Questionnaire\ResultsGroup\MaxNumberOfPoints	Real	The maximum number of points that can be earned.
Root\Questionnaire\Question	Record list	The list of questions for the current questionnaire.
Root\Questionnaire\Question\CollectionSequenceNumber	Integer	The sequence number of the current answer collection.
Root\Questionnaire\Question\Id	String	The identification code of the current question.
Root\Questionnaire\Question\MustBeCompleted	String	A flag that indicates whether the current question must be answered.
Root\Questionnaire\Question\PrimaryQuestion	String	A flag that indicates whether the current question is primary.
Root\Questionnaire\Question\SequenceNumber	Integer	The sequence number of the current question.
Root\Questionnaire\Question\Text	String	The text of the current question.
Root\Questionnaire\Question\Answer	Record list	The list of answers for the current question.
Root\Questionnaire\Question\Answer\CorrectAnswer	String	A flag that indicates whether the current answer is correct.
Root\Questionnaire\Question\Answer\Points	Real	The points that are earned when the current answer is selected.

Field path	Data type	Field designation/returned value
Root\Questionnaire\Question\Answer\SequenceNumber	Integer	The sequence number of the current answer.
Root\Questionnaire\Question\Answer\Text	String	The text of the current answer.

The following illustration shows the completed editable data model on the **Data model designer** page.



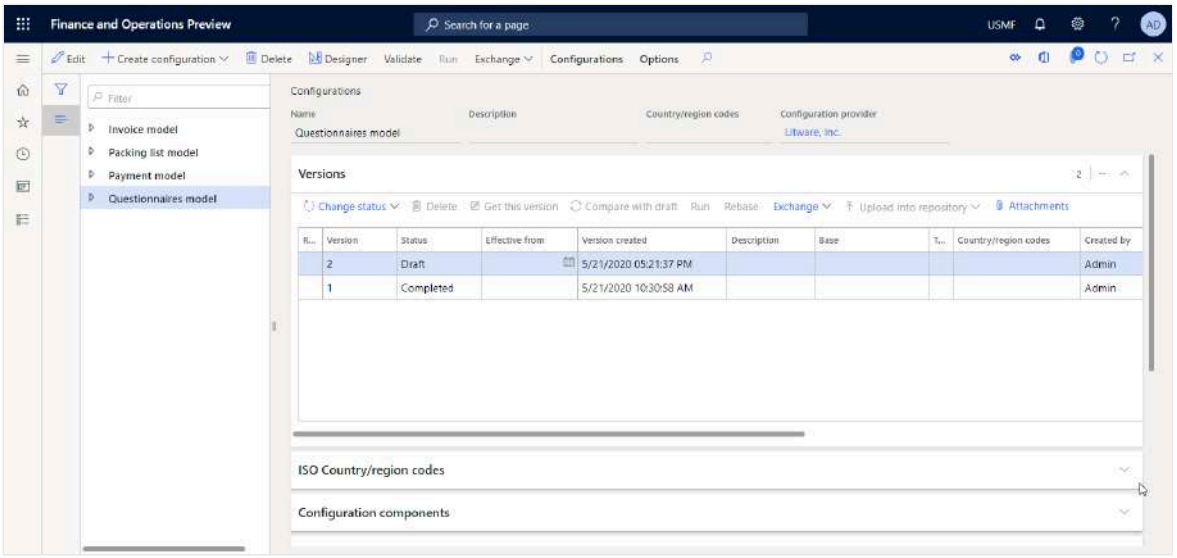
7. Save your changes.

8. Close the **Data model designer** page.

Complete the design of the data model

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, select **Questionnaire model**.
3. On the **Versions** FastTab, select the configuration version that has a status of **Draft**.
4. Select **Change status** > **Complete**.

The status of version 1 of this configuration changes from **Draft** to **Completed**. You can't change version 1 anymore. This version contains the configured data model and can be used as the basis for other ER configurations. Version 2 of this configuration is created and has a status of **Draft**. You can edit this version to adjust the **Questionnaire** data model.



For more information about versioning for ER configurations, see Electronic reporting (ER) overview.

> **Note**
>
> The configured data model is your abstract representation of the **Questionnaire** business domain and contains no relations to artifacts that are specific to Microsoft Dynamics 365 Finance.

Design a model mapping for the configured data model

As a user in the Electronic Reporting Developer role, you must create a new ER configuration that contains a model mapping component for the **Questionnaire** data model. Because this component implements the configured data model for Finance, it's Finance-specific. You must configure the model mapping component to specify the application objects that fill the configured data model with application data at runtime. To complete this task, you must be aware of the implementation details of the data structure of the **Questionnaire** business domain in Finance.

By completing the steps in the Import a new model mapping configuration section, you can import the required model mapping configuration from the provided XML file. Alternatively, you can complete the steps in the Create a new model mapping configuration section to design this model mapping from scratch.

Import a new model mapping configuration

1. Download the Questionnaires mapping.version.1.1.xml file, and save it to your local computer.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. In the **Electronic reporting** workspace, select **Reporting configurations**.

4. On the Action Pane, select **Exchange** > **Load from XML file**.
5. Select **Browse**, and then find and select the **Questionnaires mapping.version.1.1.xml** file.
6. Select **OK** to import the configuration.

To continue, skip the next procedure, Create a new model mapping configuration.

Create a new model mapping configuration

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, select **Questionnaire model**.
3. Select **Create configuration**.
4. In the drop-down dialog box, follow these steps:
   a. In **New**, select **Model Mapping based on data model Questionnaires**.
   b. In **Name**, enter **Questionnaire mapping**.
   c. In **Data model definition**, select the **Root** definition.
   d. Select **Create configuration** to create the configuration.

Design a new model mapping component

1. On **Configurations**, in the configuration tree, select **Questionnaire mapping**.
2. Select **Designer** to open the list of mappings.
3. Select the **Questionnaires mapping** mapping that was automatically added for the **Root** definition.
4. Select **Designer** to start to configure the selected mapping.

A new mapping is automatically added for the **Root** definition. This mapping has the **To model** direction. Therefore, you can use this mapping to fill in a data model with required data.

Add data sources to access application tables

You must configure data sources to access the application tables that contain questionnaire details.

1. On **Model mapping designer**, in the **Data source types** pane, select **Dynamics 365 for Operations\Table records**.
2. Add a new data source that you use to access the KMCollection table, where every record represents a single questionnaire:
   a. In the **Data sources** pane, select **Add root**.
   b. In the dialog box, in **Name**, enter **Questionnaire**.
   c. In **Table**, enter **KMCollection**.
   d. Set the **Ask for query** option to **Yes**. You can then specify filtering options for this table in the system query dialog box at runtime.
   e. Select **OK** to add the new data source.

3. In the **Data source types** pane, select **Dynamics 365 for Operations\Table records**.

4. Add a new data source that you use to access the KMQuestion table, where every record represents a single question in a questionnaire:
   a. In the **Data sources** pane, select **Add root**.
   b. In the dialog box, in **Name**, enter **Question**.
   c. In **Table**, enter **KMQuestion**.
   d. Select **OK** to add the new data source.

5. In the **Data source types** pane, select **Dynamics 365 for Operations\Table records**.

6. Add a new data source that you use to access the KMAnswer table, where every record represents a single answer to a question in a questionnaire:
   a. In the **Data sources** pane, select **Add root**.
   b. In **Name**, enter **Answer**.
   c. In **Table**, enter **KMAnswer**.
   d. Select **OK** to add the new data source.

7. In the **Data source types** pane, select **Functions\Calculated field**.

8. Add a new calculated field that you use to access a record of the KMQuestionResultGroup table from every record of the parent KMCollection table:
   a. In the **Data sources** pane, select **Questionnaire**.
   b. Select **Add**.
   c. In the dialog box, in **Name**, enter **$ResultGroup**.
   d. Select **Edit formula**.
   e. In the ER formula editor, in **Formula**, enter **FIRSTORNULL(@.'<Relations'.KMQuestionResultGroup)** to use the path of the one-to-many relation between the KMCollection and KMQuestionResultGroup tables.
   f. Select **Save**, and close the formula editor.
   g. Select **OK** to add the new calculated field.

9. In the **Data source types** pane, select **Functions\Calculated field**.

10. Add a new calculated field that you use to access question records of the KMQuestion table from every record of the parent KMCollectionQuestion table:
    a. In the **Data sources** pane, select **Questionnaire**.
    b. Expand the **<Relations** node that contains one-to-many relations of the KMCollection table.
    c. Select the related **KMCollectionQuestion** table, and then select **Add**.
    d. In the dialog box, in the **Name** field, enter **$Question**.
    e. Select **Edit formula**.
    f. In the formula editor, in the **Formula** field, enter **FIRSTORNULL (FILTER(Question, Question.kmQuestionId = @.kmQuestionId))** to return the appropriate question records from the KMQuestion table.
    g. Select **Save**, and close the formula editor.

h. Select **OK** to add the new calculated field.

11. In the **Data source types** pane, select **Functions\Calculated field**.

12. Add a new calculated field that you use to access answer records of the KMAnswer table from every record of the parent KMQuestion table:
    a. In the **Data sources** pane, select **Questionnaire.<Relations.KMCollectionQuestion.$Question**, and then select **Add**.
    b. In the dialog box, in the **Name** field, enter **$Answer**.
    c. Select **Edit formula**.
    d. In the formula editor, in the **Formula** field, enter **FILTER (Answer, Answer.kmAnswerCollectionId = @.kmAnswerCollectionId)** to return the appropriate answer records from the KMAnswer table.
    e. Select **Save**, and close the formula editor.
    f. Select **OK** to add the new calculated field.

13. In the **Data source types** pane, select **Dynamics 365 for Operations\Table**.

14. Add a new data source that you use to access methods of the CompanyInfo table. Note that the **find()** method of this table returns a record that represents a company of the current Finance instance that this mapping is called in the context of.
    a. In the **Data sources** pane, select **Add root**.
    b. In the dialog box, in the **Name** field, enter **CompanyInfo**.
    c. In the **Table** field, enter **CompanyInfo**.
    d. Select **OK** to add the new data source.

Add data sources to access application enumerations

You must configure data sources to access application enumerations and compare their values with values of fields of the **Enumeration** type in the application tables. Use the result of the comparison to fill in appropriate fields of the data model.

1. On the **Model mapping designer** page, in the **Data source types** pane, select **Dynamics 365 for Operations\Enumeration**.

2. Add a new data source that you use to access values of the **EnumAppNoYes** enumeration:
    a. In the **Data sources** pane, select **Add root**.
    b. In the dialog box, in the **Name** field, enter **EnumAppNoYes**.
    c. In the **Enumeration** field, enter **NoYes**.
    d. Select **OK** to add the new data source.

3. In the **Data source types** pane, select **Dynamics 365 for Operations\Enumeration**.

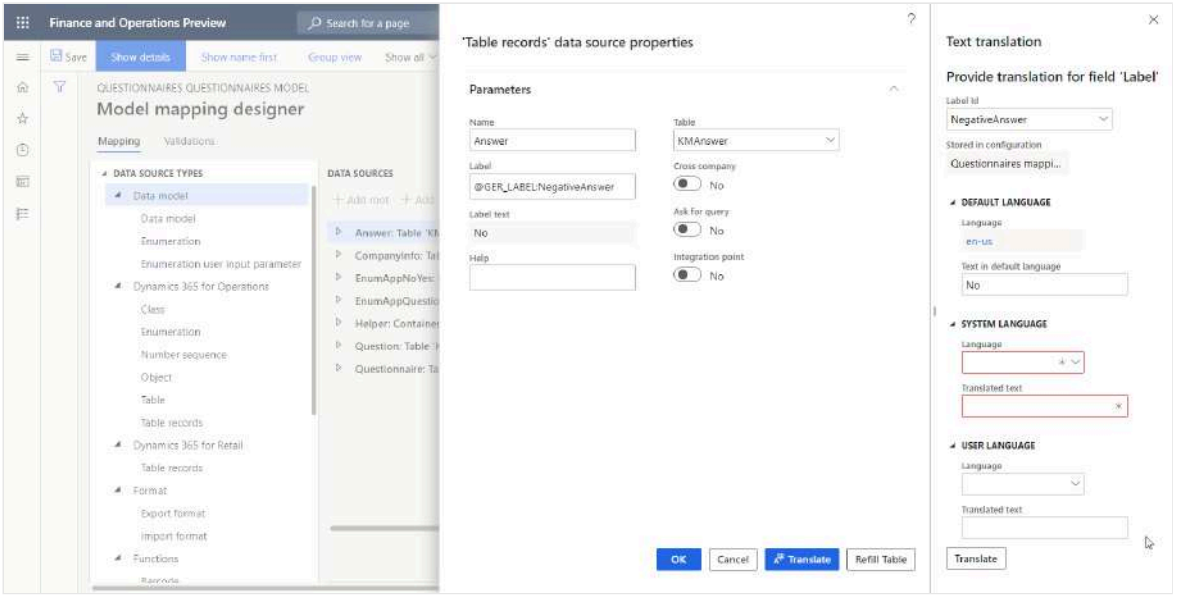
4. Add a new data source that you use to access the values of the **KMCollectionQuestionMode** enumeration:
    a. In the **Data sources** pane, select **Add root**.

b. In the dialog box, in the **Name** field, enter **EnumAppQuestionOrder**.
c. In the **Enumeration** field, enter **KMCollectionQuestionMode**.
d. Select **OK** to add the new data source.

Add ER labels to generate a report in a specified language

You can add ER labels to configure some of your data sources to return values that depend on the language that is defined in the context of the model mapping's call.

1. On the **Model mapping designer** page, in the **Data sources** pane, select **Answer**, and then select **Edit**.
2. Activate the **Label** field.
3. Select **Translate**.
4. In the **Text translation** dialog box, follow these steps:
   a. In the **Label Id** field, enter **PositiveAnswer**.
   b. In the **Text in default language** field, enter **Yes**.
   c. Select **Translate**.
   d. In the **Label Id** field, enter **NegativeAnswer**.
   e. In the **Text in default language** field, enter **No**.
   f. Select **Translate**.
5. Close the **Text translation** dialog box.
6. Select **Cancel**.

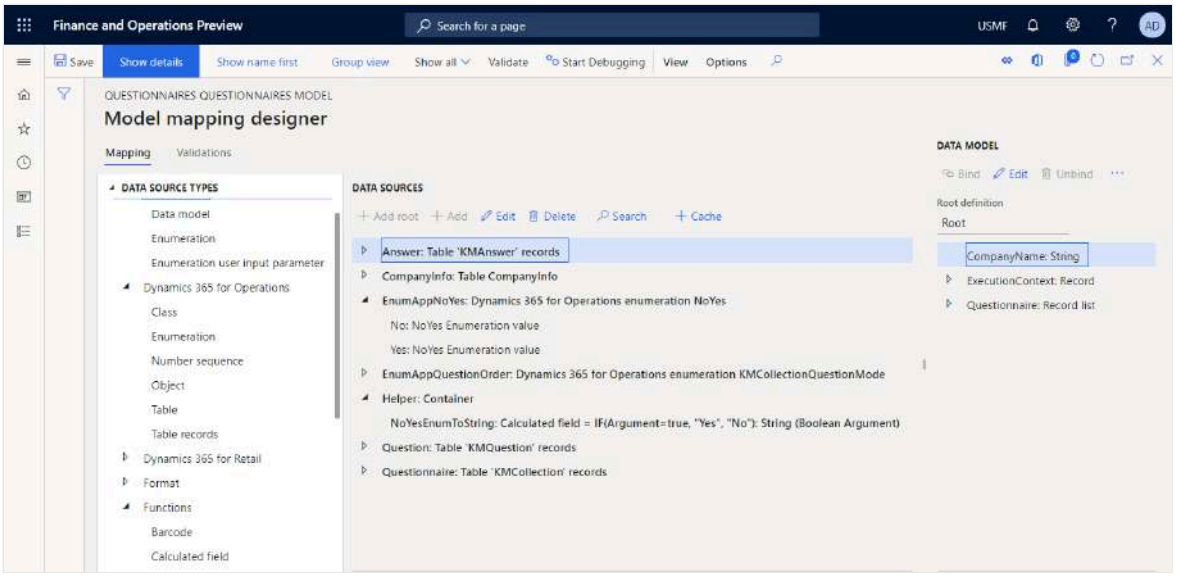


You entered ER labels only for the default language. For information about how to translate ER labels into other languages, see Design multilingual reports.

Add a data source to transform the results of comparing enumeration values to a text value

Because you must transform the results of the comparison between enumeration values and text values several times for different sources, it's a good idea to configure this logic as a single data source. However, to make this data source reusable, you must then configure it as the parameterized data source. For more information, see Support parameterized calls of ER data sources of the Calculated field type.

1. On the **Model mapping designer** page, in the **Data source types** pane, select **General\Empty container**.
2. Add a new container data source:
   a. In the **Data sources** pane, select **Add root**.
   b. In the dialog box, in the **Name** field, enter **Helper**.
   c. Select **OK** to add the new container data source.
3. In the **Data source types** pane, select **Functions\Calculated field**.
4. Add a new data source:
   a. In the **Data sources** pane, select **Helper**.
   b. Select **Add**.
   c. In the dialog box, in the **Name** field, enter **NoYesEnumToString**.
   d. Select **Edit formula**.
   e. In the formula editor, select **Parameters**.
   f. Follow these steps to specify parameters for the configured expression:
      i. Select **New**.
      ii. In the dialog box, in the **Name** field, enter **Argument**.
      iii. In the **Type** field, select the **Boolean** data type.
      iv. Select **OK**.
   g. In the **Formula** field, enter **IF (Argument = true, @"GER_LABEL:PositiveAnswer", @"GER_LABEL:NegativeAnswer")** to return the text of the appropriate ER label, depending on the language of the execution context and value of the specified parameter.
   h. Select **Save**, and close the formula editor.
   i. Select **OK** to add the new data source.



Bind data sources to data model fields

You must bind the configured data sources to the fields of the data model to specify how the data model is filled in with application data at runtime.

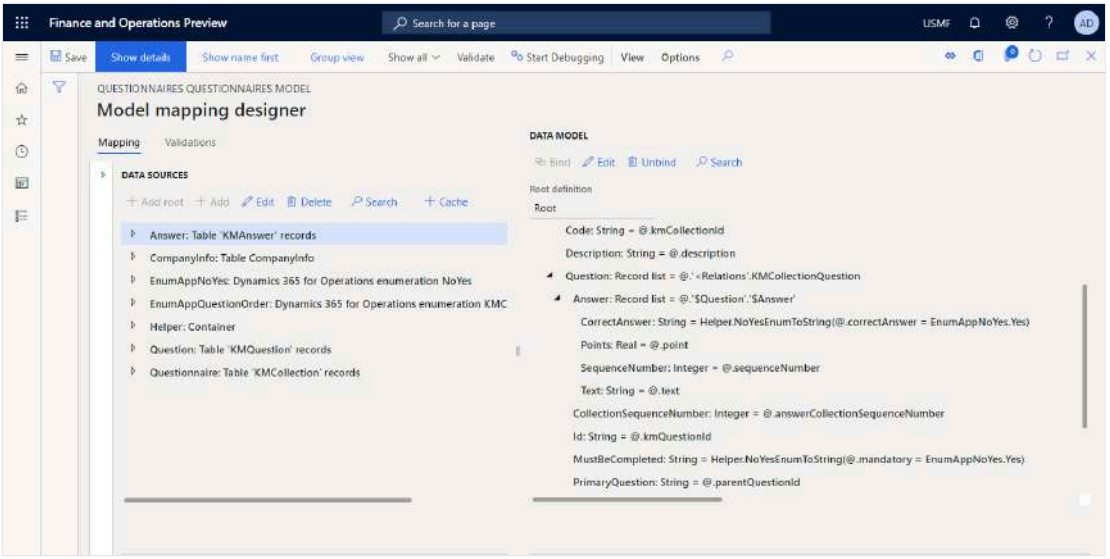
1. On the **Model mapping designer** page, in the **Data model** pane, select **CompanyName**.
2. In the **Data sources** pane, expand **CompanyInfo**, and then follow these steps:
   a. Expand the **CompanyInfo.find()** node that represents the **find()** method of the CompanyInfo table.
   b. Select **CompanyInfo.find().Name**.
   c. Select **Bind** to fill in the name of the company that the configured model mapping is called in the context of at runtime.
3. In the **Data model** pane, select **Questionnaire**.
4. In the **Data sources** pane, select **Questionnaire**, and then select **Bind** to fill in questionnaire records.
5. In the **Data model** pane, expand **Questionnaire**, and then follow these steps:
   a. In the **Data model** pane, select **Active**.
   b. In the **Data model** pane, select **Edit**.
   c. In the **Formula** field, enter **Helper.NoYesEnumToString (@.Active = EnumAppNoYes.Yes)** to fill the text-dependent and language-dependent result of the comparison between enumeration values.
6. Continue to bind data sources to data model fields in the same manner until you achieve the following result.

Expand table

Field path	Data type	Action	Binding expression
CompanyName	String	Bind	CompanyInfo.'find()'.Name
Questionnaire	Record list	Bind	Questionnaire
Questionnaire\Active	String	Edit	Helper.NoYesEnumToString(@.active = EnumAppNoYes.Yes)
Questionnaire\Code	String	Bind	@.kmCollectionId
Questionnaire\Description	String	Bind	@.Description
Questionnaire\QuestionnaireType	String	Bind	@.'>Relations'.kmCollectionTypeId.Desc
Questionnaire\QuestionOrder	String	Edit	CASE (@.questionMode, EnumAppQuestionOrder.Conditional, "Conditional", EnumAppQuestionOrder.Random, "Ran (percentage in questionnaire)", EnumAppQuestionOrder.RandomGroup "Random (percentage in result groups)" EnumAppQuestionOrder.Sequence, "Sequential", "")
Questionnaire\ResultsGroup	Record		
Questionnaire\ResultsGroup\Code	String	Bind	@.'$ResultGroup'.kmQuestionResultGrc
Questionnaire\ResultsGroup\Description	String	Bind	@.'$ResultGroup'.description
Questionnaire\ResultsGroup\MaxNumberOfPoints	Real	Bind	@.'$ResultGroup'.maxPoint
Questionnaire\Question	Record list	Bind	@.'<Relations'.KMCollectionQuestion
Questionnaire\Question\CollectionSequenceNumber	Integer	Bind	@.answerCollectionSequenceNumber
Questionnaire\Question\Id	String	Bind	@.kmQuestionId
Questionnaire\Question\MustBeCompleted	String	Edit	Helper.NoYesEnumToString(@.mandatc EnumAppNoYes.Yes)
Questionnaire\Question\PrimaryQuestion	String	Bind	@.parentQuestionId
Questionnaire\Question\SequenceNumber	Integer	Bind	@.SequenceNumber
Questionnaire\Question\Text	String	Bind	@.'$Question'.text
Questionnaire\Question\Answer	Record list	Bind	@.'$Question'.'$Answer'
Questionnaire\Question\Answer\CorrectAnswer	String	Edit	Helper.NoYesEnumToString(@.correctA = EnumAppNoYes.Yes)
Questionnaire\Question\Answer\Points	Real	Bind	@.point

Field path	Data type	Action	Binding expression
Questionnaire\Question\Answer\SequenceNumber	Integer	Bind	@.sequenceNumber
Questionnaire\Question\Answer\Text	String	Bind	@.text

The following illustration shows the final state of the configured model mapping on the **Model mapping designer** page.

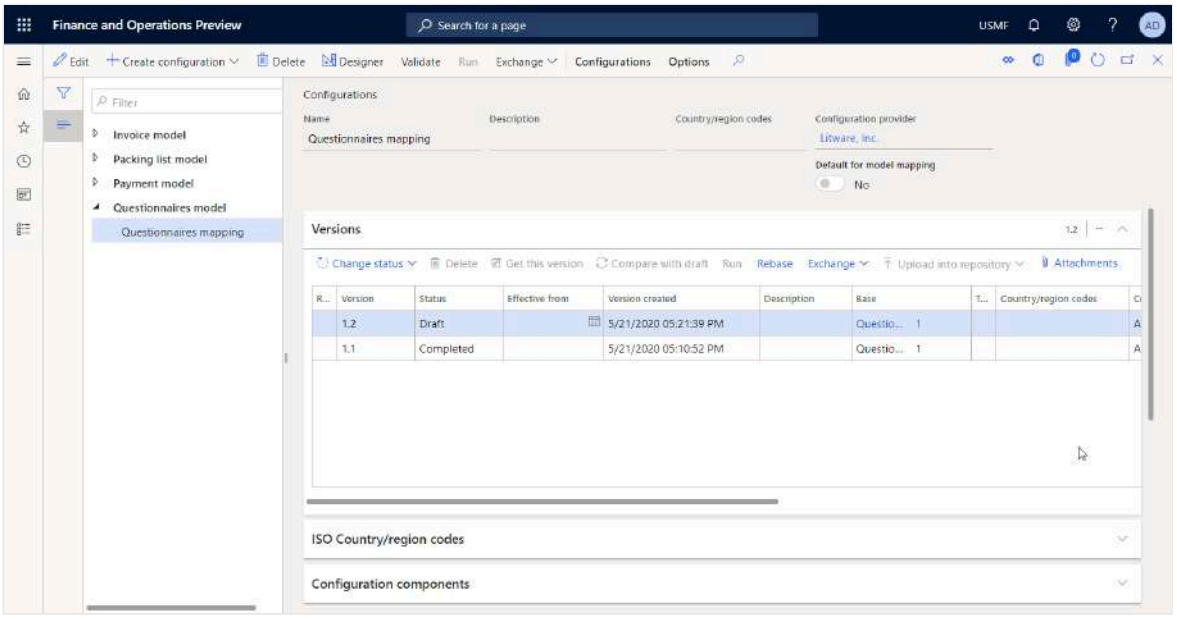


7. Save your changes.
8. Close the **Model mapping designer** page.

Complete the design of the model mapping

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, select **Questionnaire mapping**.
3. On the **Versions** FastTab, select the configuration version that has a status of **Draft**.
4. Select **Change status** > **Complete**.

The status of version 1.1 of this configuration changes from **Draft** to **Completed**. You can no longer change version 1.1. This version contains the configured model mapping and can be used as the basis for other ER configurations. Version 1.2 of this configuration is created and has a status of **Draft**. You can edit this version to adjust the **Questionnaire mapping** configuration.



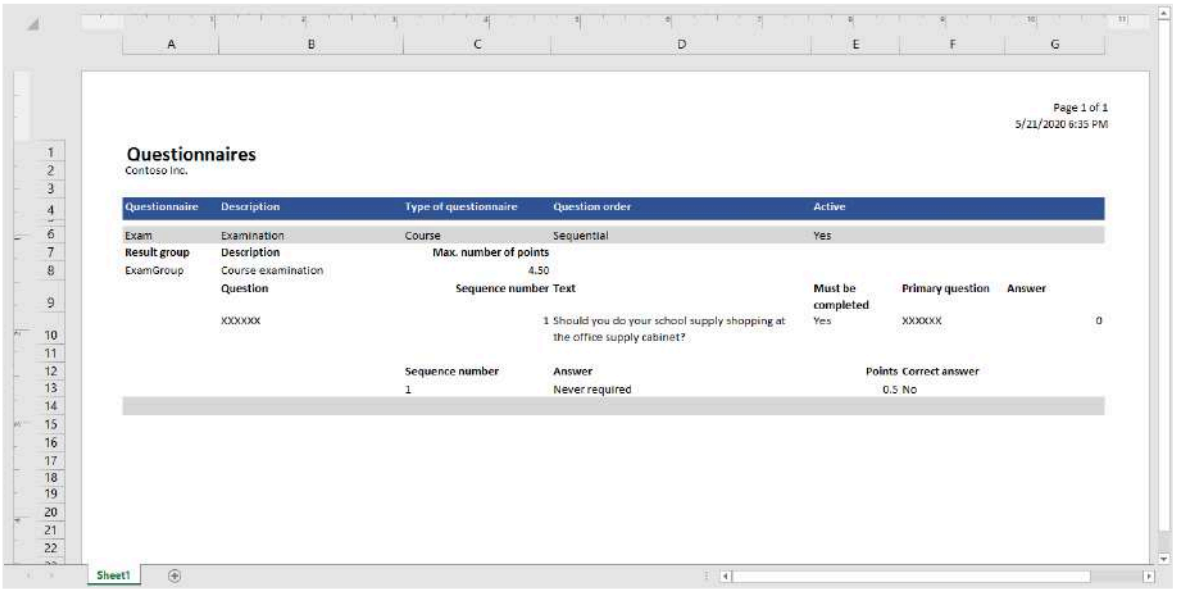
> **Note**
>
> The configured model mapping is your Finance-specific implementation of the abstract data model that represents the **Questionnaire** business domain.

Design a template for a custom report

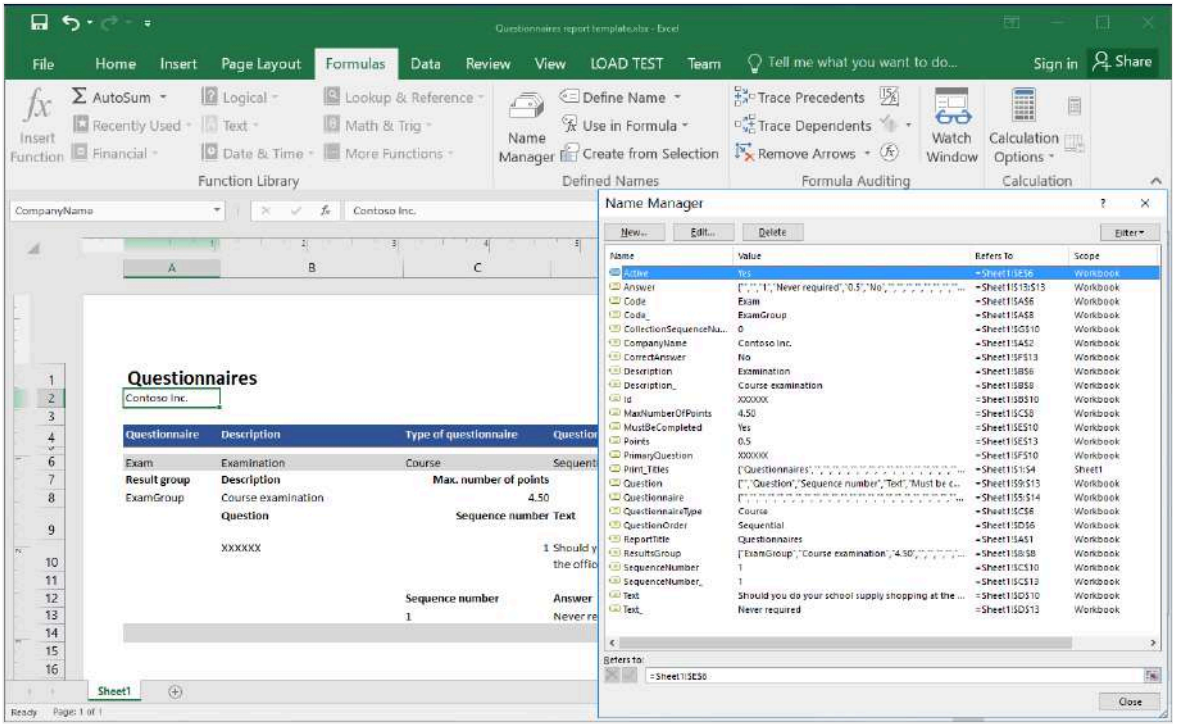
The ER framework uses predefined templates to generate reports in Microsoft Office formats (Excel workbooks or Word documents). While generating the required report, the framework fills the template with the required data according to the configured dataflow. Therefore, you must first design a template for your custom report. Design this template as an Excel workbook, the structure of which represents the layout of a custom report. Name every Excel item that you plan to fill with required data.

1. Download the Questionnaires report template.xlsx file, and save it to your local computer.
2. Open the file in Excel, and review the structure of the workbook.

As the following illustration shows, the downloaded template is designed to print specified questionnaires that present a questionnaire's questions together with appropriate answers.

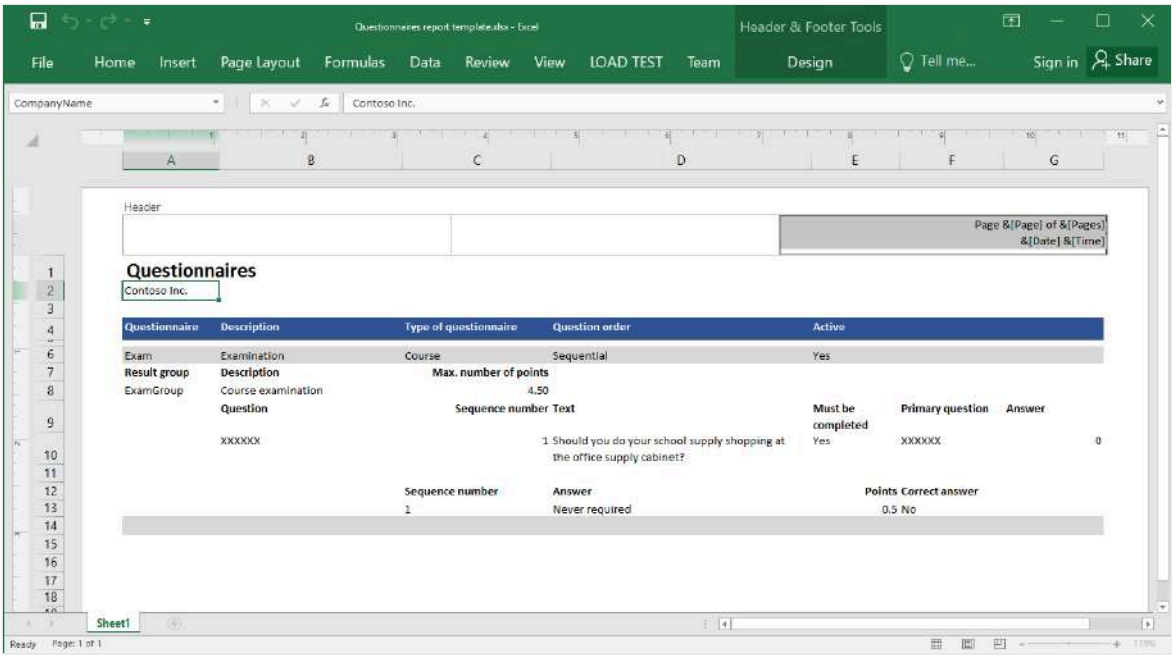


Excel names are added to this template to fill in the questionnaire details. Use Name Manager to review the Excel names.



Report labels are added as fixed text in the English language. You can replace the report labels with new Excel names that fill in the labels with language-dependent text by using the ER format labels, as you did for language-dependent expressions in the configured model mapping. In this case, ER labels must be added in the editable ER format.

As the following illustration shows, the custom report header is specified to enable Excel to do paging.



Design a format

As a user in the Electronic Reporting Functional Consultant role, you must create a new ER configuration that contains a format component. You must configure the format component to specify how a report template is filled with required data at runtime.

By completing the steps in the Import a designed format configuration section, you can import the required format from the provided XML file. Alternatively, you can complete the steps in the Create a new format configuration section to design this format from scratch.

Import a designed format configuration

1. Download the Questionnaires format.version.1.1.xml file, and save it to your local computer.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. In the **Electronic reporting** workspace, select **Reporting configurations**.
4. On the Action pane, select **Exchange** > **Load from XML file**.
5. Select **Browse**, and then find and select the **Questionnaires format.version.1.1.xml** file.
6. Select **OK** to import the configuration.

To continue, skip the next procedure, Create a new format configuration.

Create a new format configuration

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, select **Questionnaire model**.
3. Select **Create configuration**.
4. In the drop-down dialog box, follow these steps:

a. In **New**, select **Format based on data model Questionnaires**.

b. In **Name**, enter **Questionnaire report**.

c. In **Data model version**, select **1**.

> **Note**
>
> - If you select a specific version of the base data model, the structure of the corresponding version of the data model appears as the structure of the **Model** data source in the format that you create.
> - You can leave this field blank. In that case, the structure of the **Draft** version of the data model appears as the structure of the **Model** data source in the format that you create. You can then adjust your model and immediately see those adjustments in your format. This approach might improve the efficiency of ER solution design when you configure your data model, model mapping, and format simultaneously.
> - If you select a specific version of the base data model, you can switch to using the **Draft** version later, when you start to edit a format.

d. In **Data model definition**, select the **Root** definition.

5. Select **Create configuration** to create the configuration.

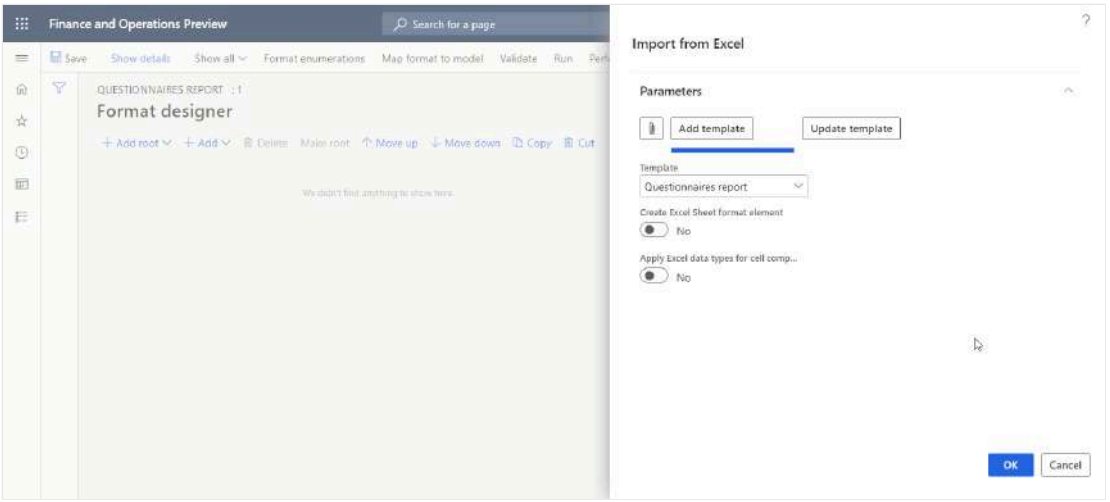
Import a report template

1. On **Configurations**, in the configuration tree, select **Questionnaire report**.

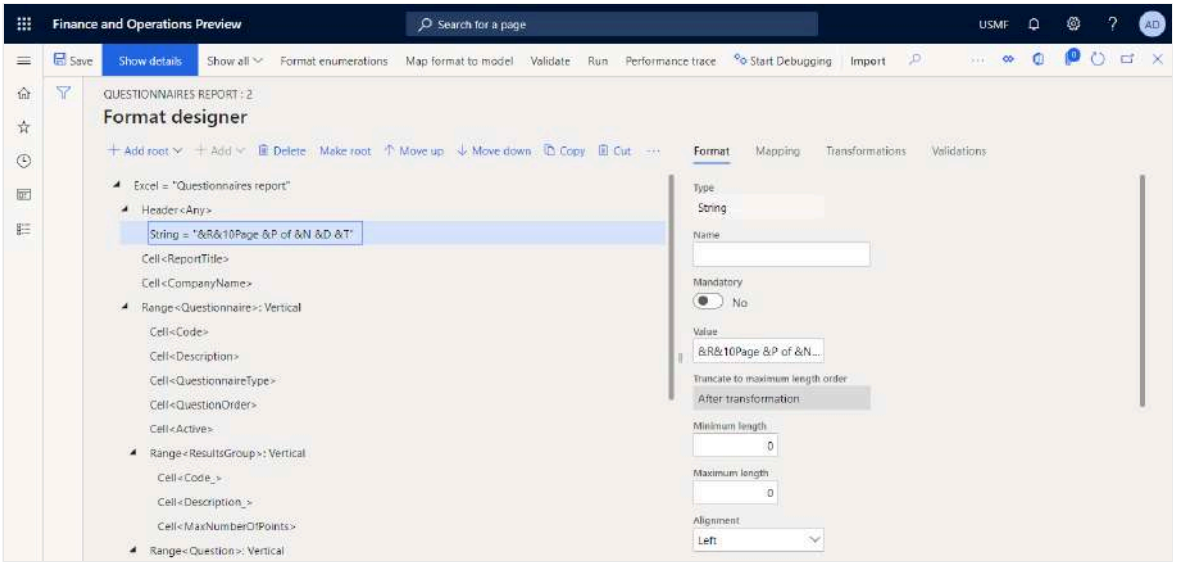
2. Select **Designer** to start to configure a custom format.

3. On **Format designer**, on the Action Pane, select **Import** > **Import from Excel**.

4. In the dialog box, follow these steps:
   a. Select **Add template**.
   b. Find and select the locally saved **Questionnaires report template.xslx** file, and then select **Open**.
   c. Select **OK** to import the template.



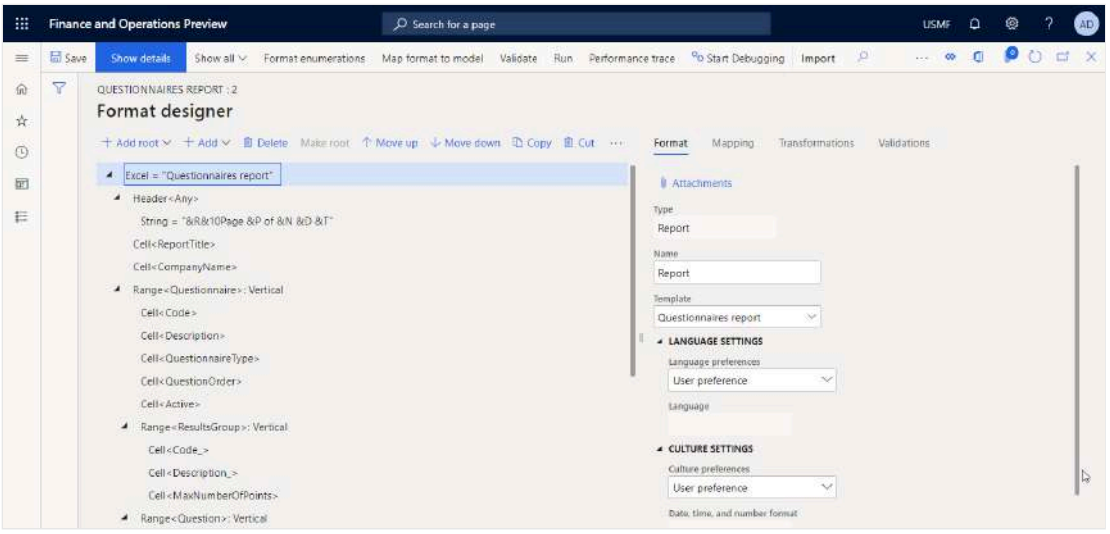
The **Excel\File** format element is automatically added to the editable format as a root element. Additionally, either the **Excel\Range** format element or the **Excel\Cell** format element is automatically added for every recognized Excel name of the imported template. The **Excel\Header** format that has the nested **String** element is automatically added to reflect the header settings of the imported template.



Configure a format

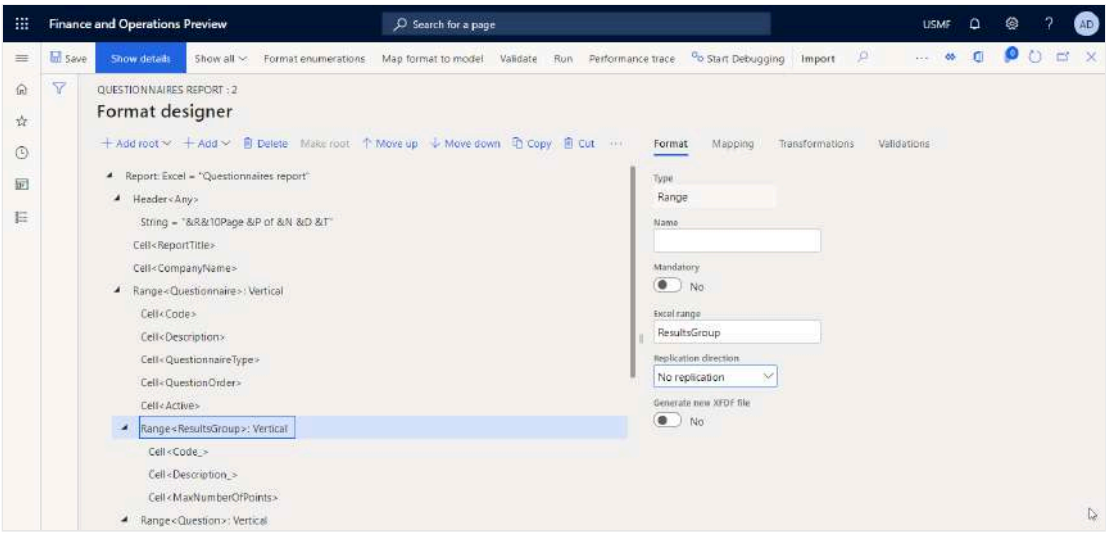
1. On **Format designer**, in the format tree, select the **Excel** root element.
2. On the **Format** tab, in the **Name** field, enter **Report**.
3. In the **Language preference** field, select **User preference** to run the report in the user's preferred language.
4. In the **Culture preference** field, select **User preference** to run the report in the user's preferred culture.

   For information about how to specify the language and culture contexts for an ER process, see Design multilingual reports.



5. In the format tree, expand the root node, and then select **ResultsGroup**.

6. On the **Format** tab, in the **Replication direction** field, select **No replication**, because you don't expect to have multiple result groups for a single questionnaire.



7. Select **Save**.

Define the data binding for a report title

You must specify a data binding for a format element that fills in the title of a generated report.

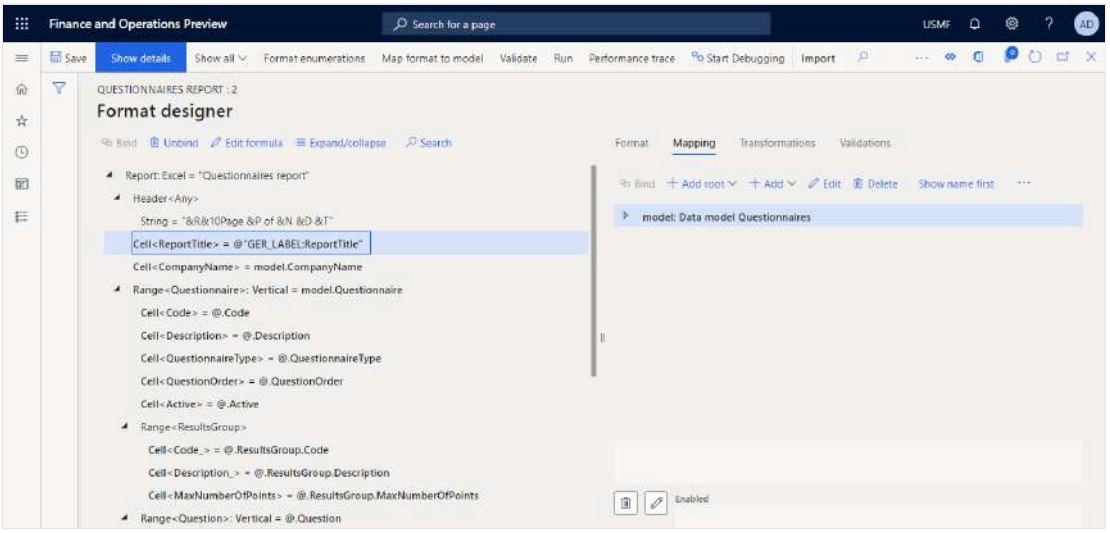
1. On **Format designer**, on the **Mapping** tab, select the **Report\ReportTitle** element.

2. Select **Edit formula**.

3. In the formula editor, select **Translate**.

4. In the **Text translation** dialog box, follow these steps:
   a. In the **Label ID** field, enter **ReportTitle**.
   b. In the **Text in default language** field, enter **Questionnaires report**.
   c. Select **Translate**, and then select **Save**.
   d. Select **Translate** to close the **Text translation** dialog box.

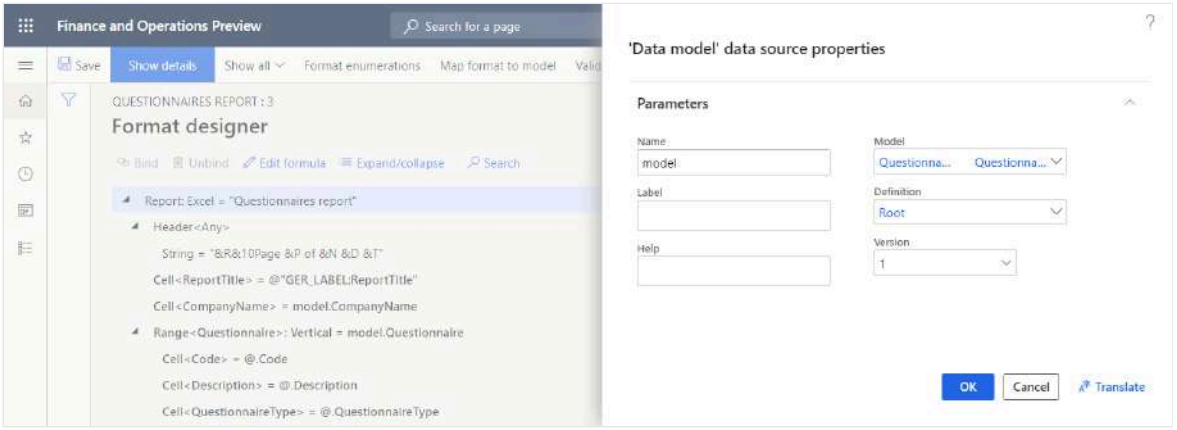
5. Close the formula editor.



Use this technique to make all other labels of the current template language-dependent. For information about how to translate the added labels of a single ER configuration into all supported languages, see Design multilingual reports.

Review model data source

1. On the **Format designer** page, on the **Mapping** tab, select the **model** data source that represents the base data model of this ER format.
2. Select **Edit**.
3. Review the information in the **Data source properties** dialog box. This data source represents version 1 of the **Questionnaires** data model component that resides in the **Questionnaires model** ER configuration.



Bind format elements to data source fields

To specify how a template is filled in at runtime, bind every format element that is associated with an appropriate Excel name to a single field of this format's data source.

1. On the **Format designer** page, in the format tree, select the **Report\CompanyName** format element.

2. On the **Mapping** tab, select the **model.CompanyName** data source field of the **String** type.

3. Select **Bind** to enter a company name in a template.

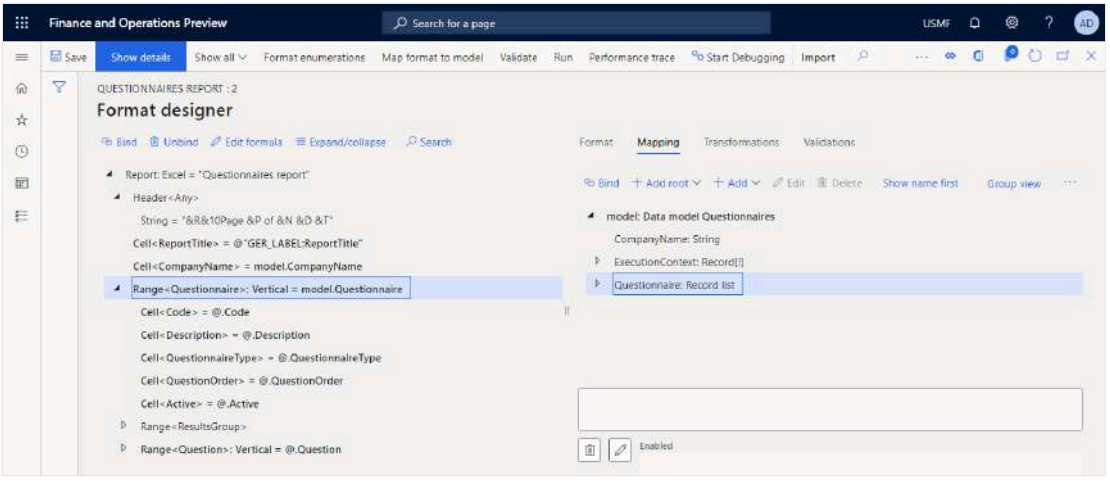
4. In the format tree, select the **Report\Questionnaire** element.

5. On the **Mapping** tab, select the **model.Questionnaire** data source field of the **Record list** type.

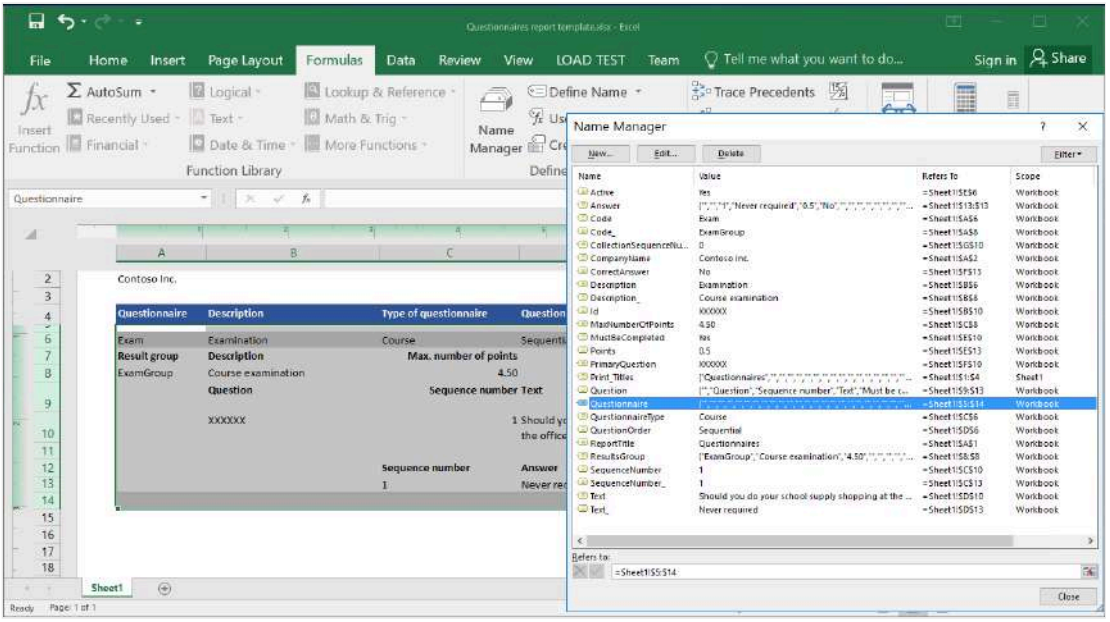
6. Select **Bind**.

7. Select **Show details** to see more details for format elements.

   The **Questionnaire** range format element is configured as vertically replicated. When it's bound to a data source of the **Record list** type, the appropriate **Questionnaire** range of the Excel template is repeated for every record of the bound data source.



Because the **Questionnaire** range of the Excel template is defined between rows 5 through 14, these rows are repeated for every reported questionnaire.



8. Configure similar bindings for the remaining format elements, as described in the following table.

> **Note**
>
> In this table, the information in the "Data source path" column assumes that the relative path ER feature is turned on.

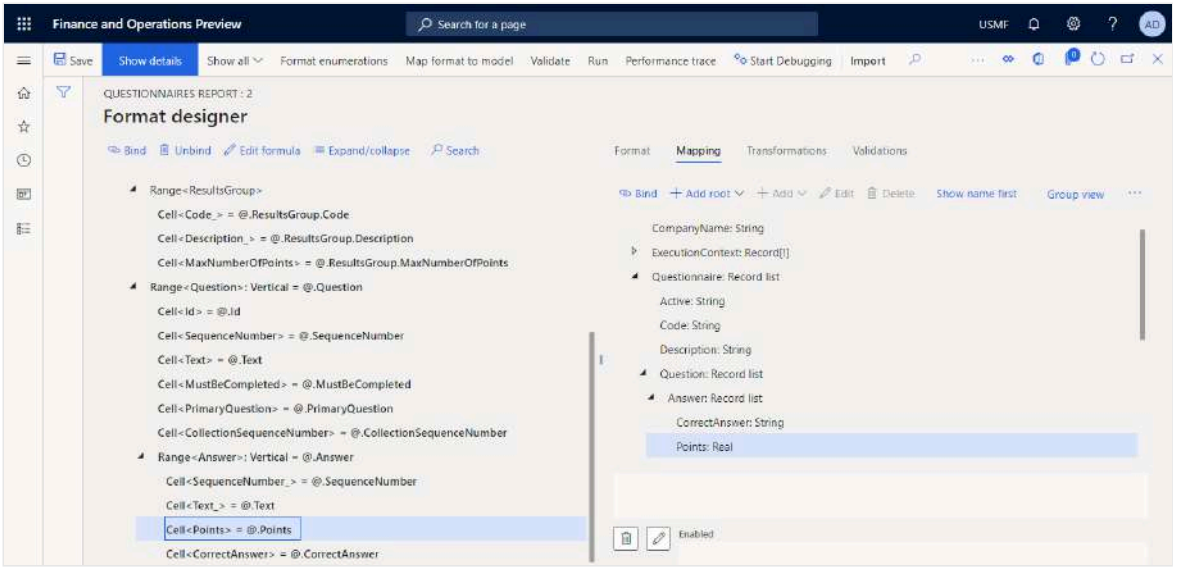
Expand table

Format element path	Data source path
Excel\ReportTitle	**@"GER_LABEL:ReportTitle"**
Excel\CompanyName	**model.CompanyName**
Excel\Questionnaire	**model.Questionnaire**
Excel\Questionnaire\Active	**@.Active**, where @ is **model.Questionnaire**
Excel\Questionnaire\Code	**@.Code**
Excel\Questionnaire\Description	**@.Description**
Excel\Questionnaire\QuestionnaireType	**@.QuestionnaireType**
Excel\Questionnaire\QuestionOrder	**@.QuestionOrder**
Excel\Questionnaire\ResultsGroup\Code_	**@.ResultsGroup.Code**
Excel\Questionnaire\ResultsGroup\Description_	**@.ResultsGroup.Description**
Excel\Questionnaire\ResultsGroup\MaxNumberOfPoints	**@.ResultsGroup.MaxNumberOfPoint**
Excel\Questionnaire\Question	**@.Question**
Excel\Questionnaire\Question\CollectionSequenceNumber	**@.CollectionSequenceNumber**, where @ is **model.Questionnaire.Question**
Excel\Questionnaire\Question\Id	**@.Id**
Excel\Questionnaire\Question\MustBeCompleted	**@.MustBeCompleted**
Excel\Questionnaire\Question\PrimaryQuestion	**@.PrimaryQuestion**
Excel\Questionnaire\Question\SequenceNumber	**@.SequenceNumber**
Excel\Questionnaire\Question\Text	**@.Text**
Excel\Questionnaire\Question\Answer	**@.Answer**
Excel\Questionnaire\Question\Answer\CorrectAnswer	**@.CorrectAnswer**, where @ is **model.Questionnaire.Answer**
Excel\Questionnaire\Question\Answer\Points	**@.Points**

Format element path	Data source path
Excel\Questionnaire\Question\Answer\Text	**@.Text**

9. When you finish, select **Save**.

The following illustration shows the final state of the configured data bindings on the **Format designer** page.



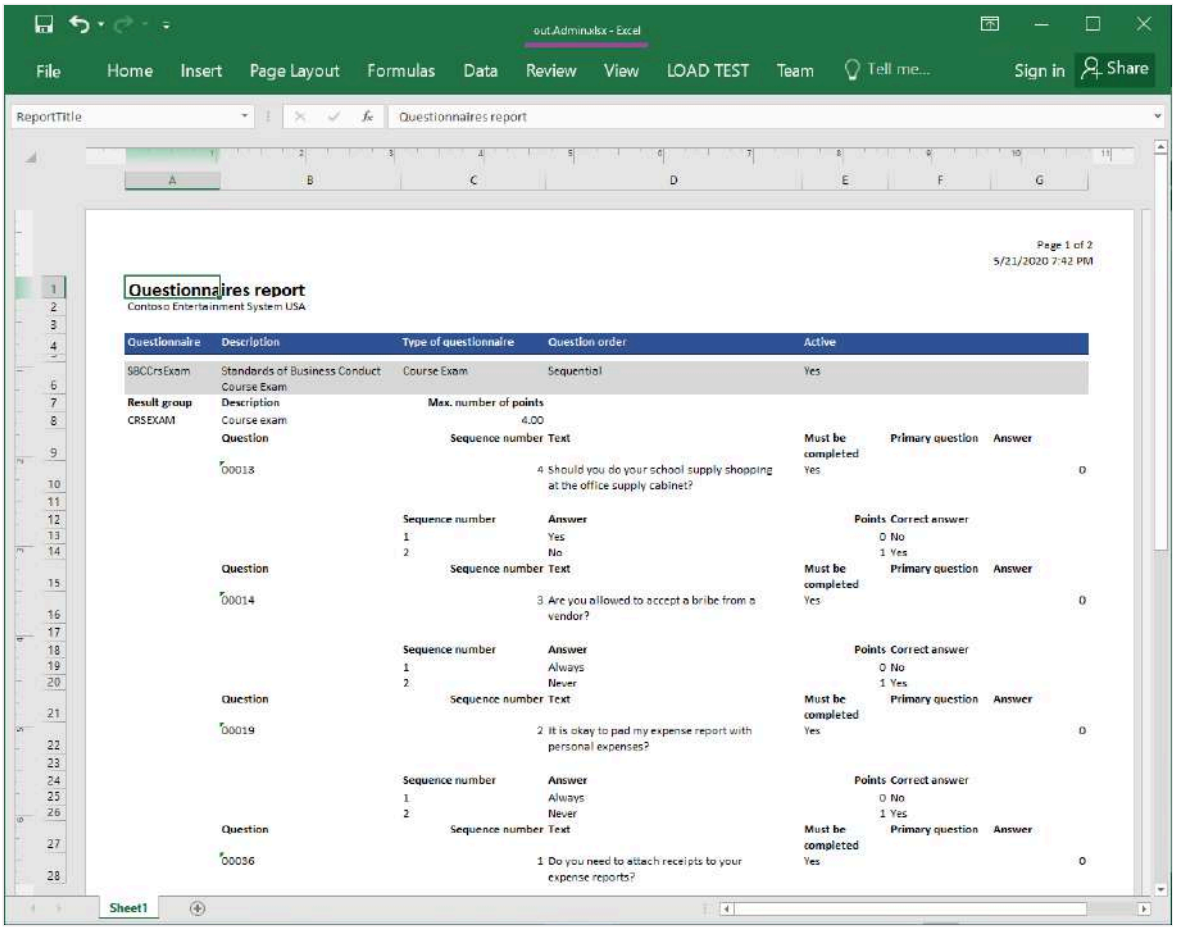
> **Important**
>
> The whole collection of specified data sources and bindings represents a format mapping component of the configured format. This format mapping is called when you run the configured format for report generation.

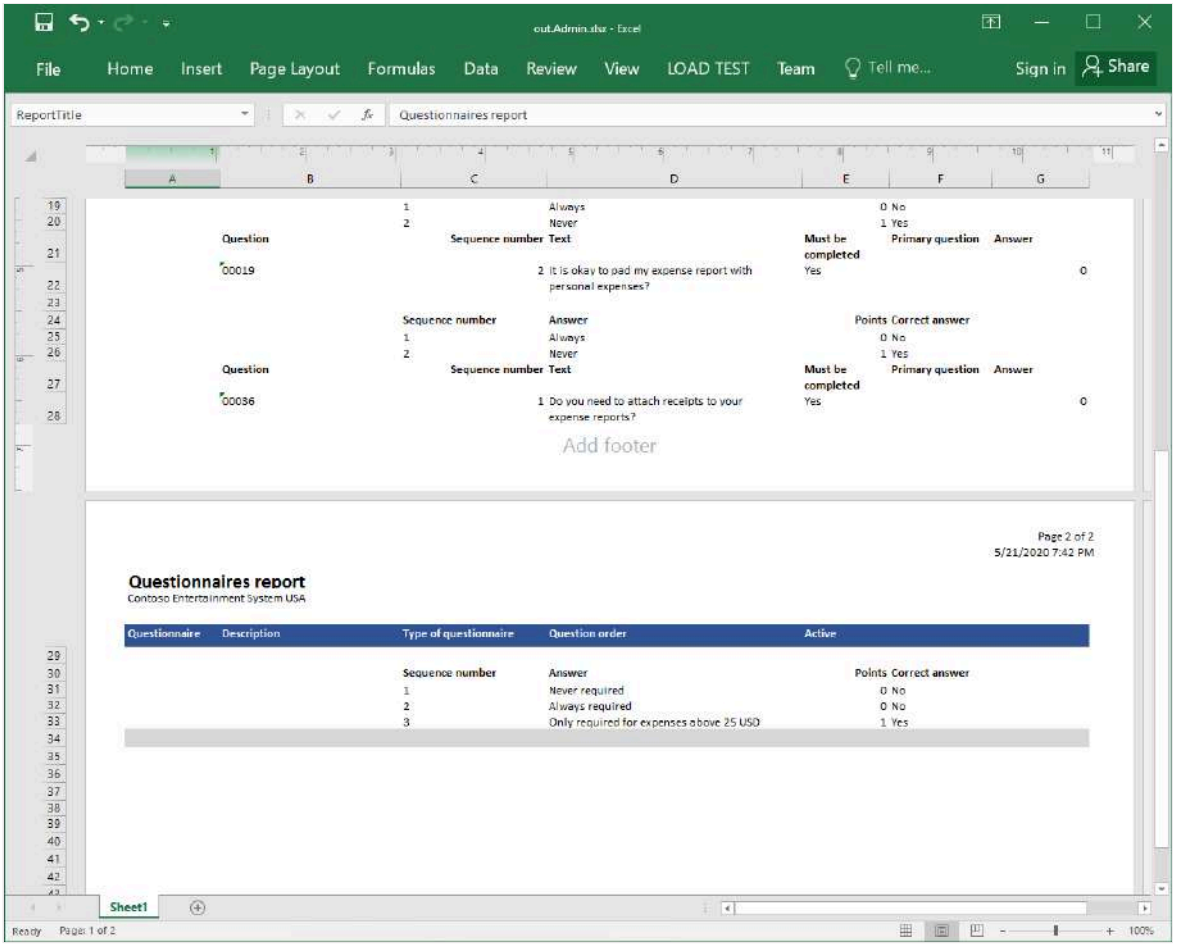
Run a designed format from ER

You can now run a designed format for testing purposes from the **Configurations** page.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configuration** page, in the configuration tree, expand **Questionnaire model**, and then select **Questionnaire report**.
3. Select **Designer** for the format version that has a status of **Draft**.
4. On the **Format designer** page, select **Run**.
5. In the **ER parameters** dialog box, on the **Records to include** FastTab, configure the filtering option so that only the **SBCCrsExam** questionnaire is included.
6. Select **OK** to confirm the filter.
7. Select **OK** to run the report.
8. Review the generated report.

By default, a generated report is delivered as an Excel file that you can download. The following illustrations show two pages of the generated report in Excel format.





Tune a designed format

Modify a format to change the name of a generated document

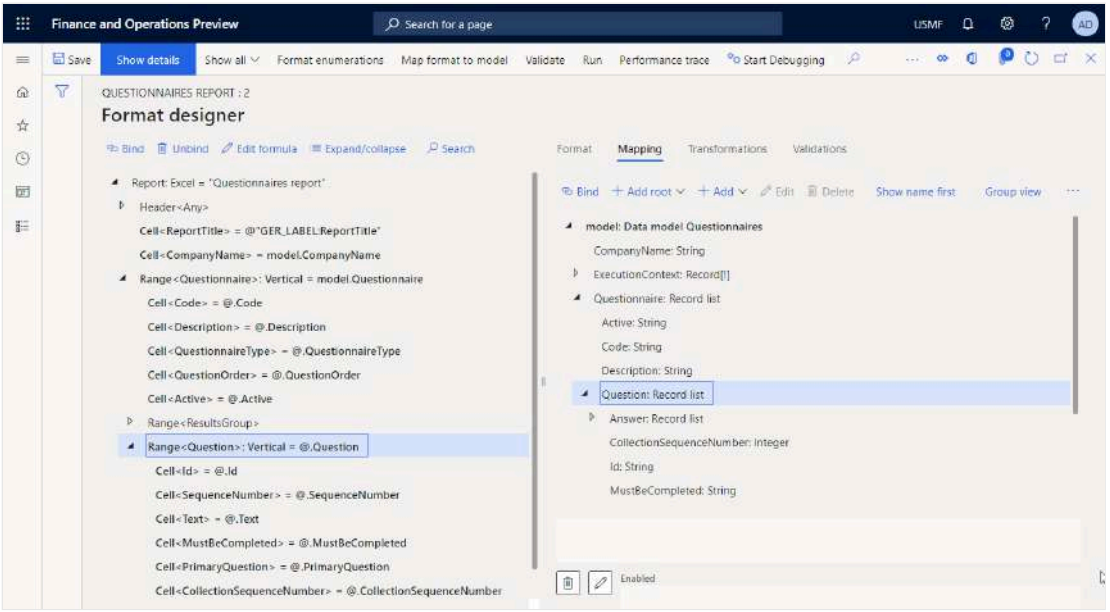
By default, the alias of the current user names a generated document. When you modify the format, you can change this behavior so that a generated document is named based on your custom logic. For example, the name of a generated document can be based on the current session date and time, and on the report's title.

1. On **Format designer**, select the **Report** root item.
2. On the **Mapping** tab, select **Edit file name**.
3. In the **Formula** field, enter `CONCATENATE (\@"GER_LABEL:ReportTitle", " - ", DATETIMEFORMAT(SESSIONNOW(), "yyyy-MM-dd hh-mm-ss"))`.
4. Select **Save**, and close the formula editor.
5. Select **Save**.

Modify a format to change the order of questions

The questions don't appear in the correct order in a generated report. You can change the order by modifying the format.

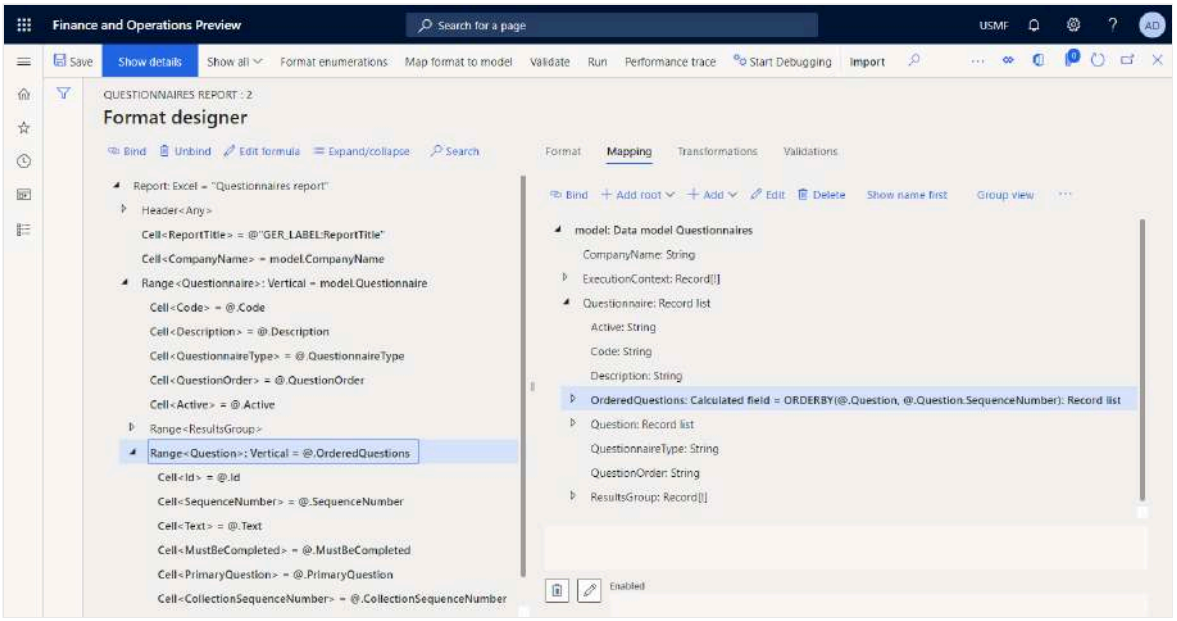
1. On **Format designer**, select the **Report** root item.
2. On the **Mapping** tab, in the format tree, expand **Report\Questionnaire\Question**.



3. On the **Mapping** tab, select **model.Questionnaire**.
4. Select **Add** > **Functions\Calculated field**, and then, in the **Name** field, enter **OrderedQuestions**.
5. Select **Edit formula**.
6. In the formula editor, in the **Formula** field, enter **ORDERBY (model.Questionnaire.Question, model.Questionnaire.Question.SequenceNumber)** to

order the list of questions of the current questionnaire by the sequence order number.

7. Select **Save**, and close the formula editor.
8. Select **OK** to complete the entry of a new calculated field.
9. On the **Mapping** tab, select **model.Questionnaire.OrderedQuestions**.
10. In the format tree, select **Excel\Questionnaire\Question**.
11. Select **Bind**, and then confirm that the current **model.Questionnaire.Questions** path is replaced by the new **model.Questionnaire.OrderedQuestions** path in all bindings of nested elements.
12. Select **Save**.

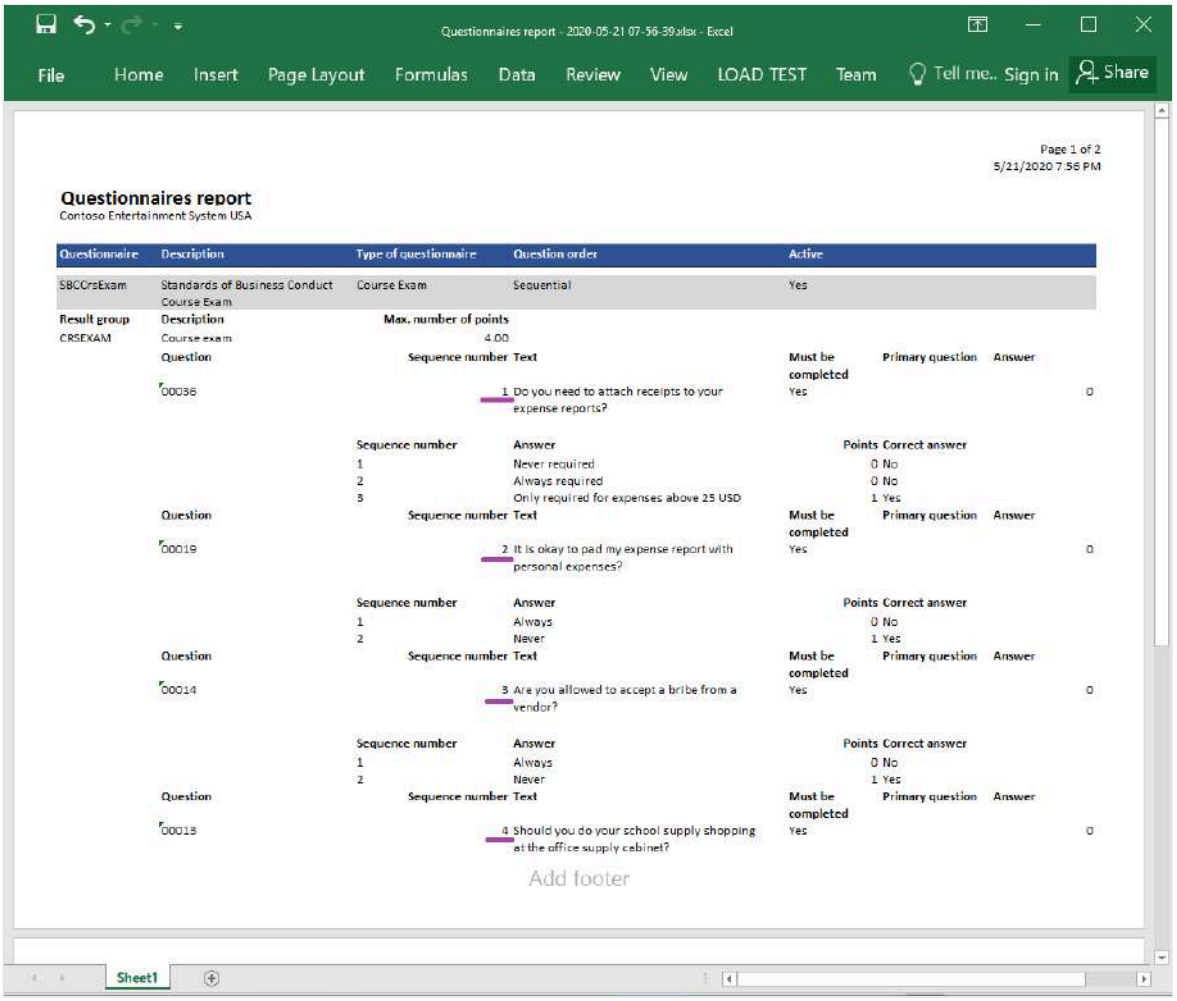


Run a modified format from ER

You can now run a modified format for testing purposes from the ER framework.

1. On the **Format designer** page, select **Run**.
2. In the **ER parameters** dialog box, on the **Records to include** FastTab, configure the filtering option so that only the **SBCCrsExam** questionnaire is included.
3. Select **OK** to confirm the filter.
4. Select **OK** to run the report.
5. Review the generated report.

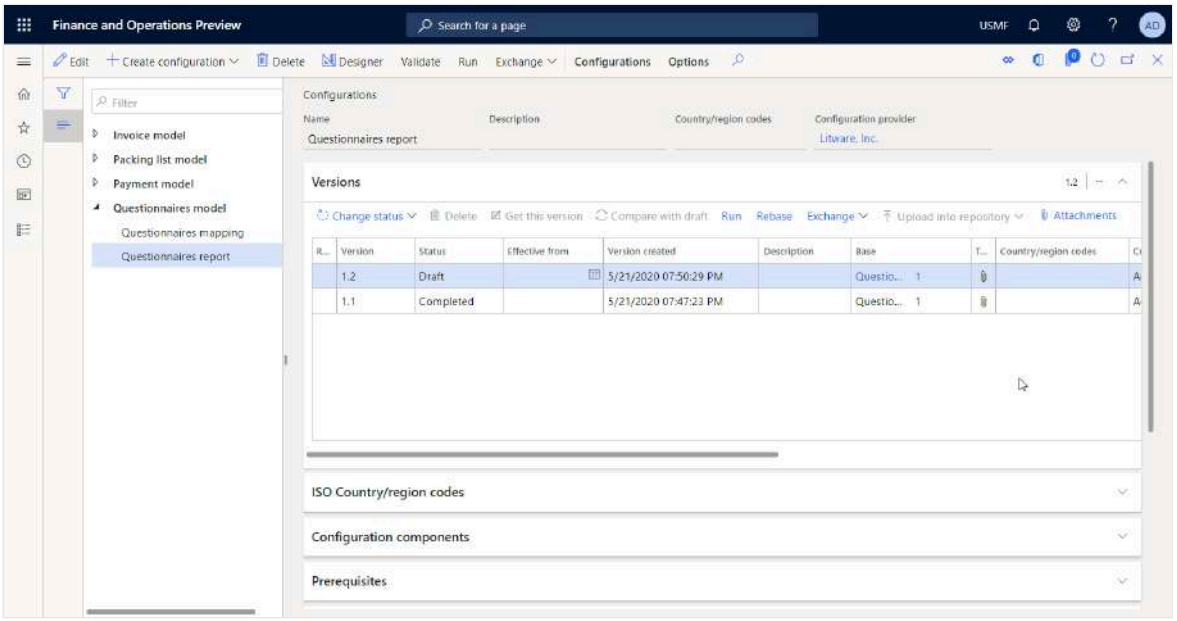
The following illustration shows a generated report in Excel format where the questions are correctly ordered.



Complete the format design

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, expand **Questionnaire model**, and then select **Questionnaire report**.
3. On the **Versions** FastTab, select the configuration version that has a status of **Draft**.
4. Select **Change status** > **Complete**.

The status of version 1.1 of this configuration changes from **Draft** to **Completed**. You can no longer change version 1.1. This version contains the configured format and can be used to print your custom report. Version 1.2 of this configuration is created and has a status of **Draft**. You can edit this version to adjust the format of your **Questionnaire** report.



> **Note**
>
> The configured format is your design of the **Questionnaire** report and contains no relations to the Finance-specific artefacts.

Develop application artifacts to call the designed report

As a user in the System Administrator role, you must develop new logic so that the configured ER format can be called from the application user interface (UI) to generate your custom report. Currently, ER doesn't offer any capability for configuring this type of logic. Therefore, some engineering work is required.

To develop the new logic, you must deploy a topology that supports continuous build. For more information, see Deploy topologies that support continuous build and test automation. You must also have access to the development environment for this topology. For more information about the available ER API, see ER framework API.

Modify source code

Add a data contract class

Add the new **QuestionnairesErReportContract** class to your Visual Studio project. Write code that specifies the data contract to use for running the configured ER format.

X++

```
/// <summary>
///     This class is the data contract class for the
<c>QuestionnairesErReportDP</c> class.
/// </summary>
/// <remarks>
```

```
///    This is the data contract class for the Questionnaires ER report.
/// </remarks>
[
    DataContractAttribute,

SysOperationContractProcessingAttribute(classStr(QuestionnairesErReportUIBuilder))
    ]
    public class QuestionnairesErReportContract extends
ERFormatMappingRunBaseContract implements SysOperationValidatable
{
    ERFormatMappingId formatMapping;

    /// <summary>
    ///    Validates the report parameters.
    /// </summary>
    /// <returns>
    ///    true if no errors; otherwise, false.
    /// </returns>
    public boolean validate()
    {
        boolean ret = true;
        if (!formatMapping)
        {
            ret = checkFailed(strFmt("@SYS26332", new
SysDictType(extendedTypeNum(ERFormatMappingId)).label()));
        }
        return ret;
    }
    [
        DataMemberAttribute('FormatMapping'),

SysOperationLabelAttribute(literalstr("@ElectronicReporting:FormatMapping")),

SysOperationHelpTextAttribute(literalstr("@ElectronicReporting:FormatMapping"))
    ]
    public ERFormatMappingId parmFormatMapping(ERFormatMappingId _formatMapping =
formatMapping)
    {
        formatMapping = _formatMapping;
        return formatMapping;
    }
}
```

Add a UI builder class

Add the new **QuestionnairesErReportUIBuilder** class to your Visual Studio project. Write code to generate a runtime dialog box that looks up the format mapping ID of the ER format to run. The provided code looks up only ER formats that contain a data source of the **Data model** type that refers to the **Questionnaires** data model by using the **Root** definition.

> ⓘ Note
>
> Alternatively, you can use ER integration points to filter ER formats. For more information, see API to show a format mapping lookup.

```
X++
```

```
/// <summary>
/// The UIBuilder class for Questionnaires ER report
/// </summary>
class QuestionnairesErReportUIBuilder extends SysOperationAutomaticUIBuilder
{
    public const str ERQuestionnairesModel = 'Questionnaires';
    public const str ERQuestionnairesDataContainer = 'Root';

    /// <summary>
    /// Action after build of the dialog UI.
    /// </summary>
    public void postBuild()
    {
        DialogField formatMapping;
        super();
        formatMapping = this.bindInfo().getDialogField(this.dataContractObject(),
            methodStr(QuestionnairesErReportContract, parmFormatMapping));
        formatMapping.registerOverrideMethod(
            methodStr(FormReferenceControl, lookupReference),
            methodStr(QuestionnairesErReportUIBuilder, formatMappingLookup),
            this);
    }

    /// <summary>
    /// Performs the lookup form for format mapping.
    /// </summary>
    /// <param name="_referenceGroupControl">
    /// The control to perform lookup form.
    /// </param>
    public void formatMappingLookup(FormReferenceControl _referenceGroupControl)
    {
        ERObjectsFactory::createFormatMappingTableLookupForControlAndModel(
            _referenceGroupControl,
            ERQuestionnairesModel,
            ERQuestionnairesDataContainer).performFormLookup();
    }
}
```

Add a data provider class

Add the new **QuestionnairesErReportDP** class to your Visual Studio project. Write code that introduces the data provider to use for running the configured ER format. The provided code includes only the data contract for this data provider.

X++

```
/// <summary>
/// Data provider class for Questionnaires ER report.
/// </summary>
public class QuestionnairesErReportDP
{
    QuestionnairesErReportContract contract;
    public static QuestionnairesErReportDP construct()
    {
        QuestionnairesErReportDP  dataProvider;
        dataProvider = new QuestionnairesErReportDP();
        return dataProvider;
```

```
    }
}
```

Add a labels file

Add the new **QuestionnairesErReportLabels_en-US** labels file to your Visual Studio project. Specify the following labels for new UI resources:

- The **@QuestionnairesReport** label for a new menu item that contains the following text in US English (en-US): **Questionnaires report (powered by ER)**
- The **@QuestionnairesReportBatchJobDescription** label for a batch job title if a selected ER format is scheduled for execution as a batch job

Add a report service class

Add the new **QuestionnairesErReportService** class to your Visual Studio project. Write code that calls an ER format, identifies it by a format mapping ID, and provides a data contract as a parameter.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
/// <summary>
/// The electronic reporting service class for Questionnaires ER report
/// </summary>
class QuestionnairesErReportService extends SysOperationServiceBase
{
    public const str ERModelDataSourceName = 'model';
    public const str DefaultExportedFileName = 'Questionnaires report';
    public const str ParametersDataSourceName = 'RunTimeParameters';

    /// <summary>
    /// Generates report by using Electronic reporting framework
    /// </summary>
    /// <param name = "_contract">The Questionnaires report contract</param>
    public void generateReportByGER(QuestionnairesErReportContract _contract)
    {
        ERFormatMappingId formatMappingId;
        QuestionnairesErReportDP  dataProvider;
        dataProvider = QuestionnairesErReportDP::construct();
        formatMappingId = _contract.parmFormatMapping();
        if (formatMappingId)
        {
            try
            {
                ERIModelDefinitionParamsAction parameters = new
ERModelDefinitionParamsUIActionComposite()
                    .add(new
ERModelDefinitionObjectParameterAction(ERModelDataSourceName,
ParametersDataSourceName, _contract, true));

                // Call ER to generate the report.
                ERIFormatMappingRun formatMappingRun =
ERObjectsFactory::createFormatMappingRunByFormatMappingId(formatMappingId,
DefaultExportedFileName);
                if (formatMappingRun.parmShowPromptDialog(true))
```

```
                {
                    formatMappingRun.withParameter(parameters);

formatMappingRun.withFileDestination(_contract.getFileDestination());
                    formatMappingRun.run();
                }
            }
            catch
            {
                // An error occurred while exporting data.
                error("@SYP4861341");
            }
        }
        else
        {
            // There is no data available.
            info("@SYS300117");
        }
    }
}
```

When you use an ER format that runs application data, you must configure a data source of the **Data model** type in the format mapping. This data source refers to a specific part of the specified data model by using a single root definition. When the ER format runs, it calls this data source to access the appropriate ER model mapping that is configured for a given model and root definition.

You can pass all the information you prepare in the source code and store as part of the data contract to the running ER format by using an ER model mapping of this type. In the ER model mapping, you must configure a data source of the **Object** type that refers to the QuestionnairesErReportContract class. To identify a model mapping, you must specify a data source that calls this model mapping. In the provided code, this data source is specified by the **ERModelDataSourceName** constant that has the model value. To identify which data source is used to expose the data contract in the model mapping, you must specify a data source name. In the provided code, this name is specified by the **ParametersDataSourceName** constant that has **RunTimeParameters** value.

> ⓘ Note
>
> In a new environment, you might have to refresh the ER metadata so that this type of class is available in the ER model mapping designer. For more information, see Configure the ER framework.

Add a report controller class

Add the new **QuestionnairesErReportController** class to your Visual Studio project. Write code that runs an ER format in either synchronous mode or batch mode, as you prefer, in the dialog box that is built based on the logic of the provided **QuestionnairesErReportUIBuilder** class.

X++

```
/// <summary>
/// The controller for Questionnaires ER report
/// </summary>
class QuestionnairesErReportController extends ERFormatMappingRunBaseController
{
    /// <summary>
    /// The main entrance of the controller
    /// </summary>
    /// <param name = "args">The arguments</param>
    public static void main(Args args)
    {
        QuestionnairesErReportController operation;
        operation = new QuestionnairesErReportController(
            classStr(QuestionnairesErReportService),
            methodStr(QuestionnairesErReportService, generateReportByGER),
            SysOperationExecutionMode::Synchronous);
        operation.startOperation();
    }

    /// <summary>
    /// Gets caption of the dialog.
    /// </summary>
    /// <returns>Caption of the dialog</returns>
    public ClassDescription defaultCaption()
    {
        ClassDescription batchDescription;
        batchDescription = "Questionnaires report (powered by ER)";
        return batchDescription;
    }
}
```

Add a menu item

Add the new **QuestionnairesErReport** menu item to your Visual Studio project. In the **Object** property, this menu item refers to the **QuestionnairesErReportController** class. Use it to specify a user permission to select and run an ER format. In the **Label** property, this menu item refers to the **@QuestionnairesReport** label that you created earlier, so that correct text is presented in the application UI.

Add a menu item to a menu

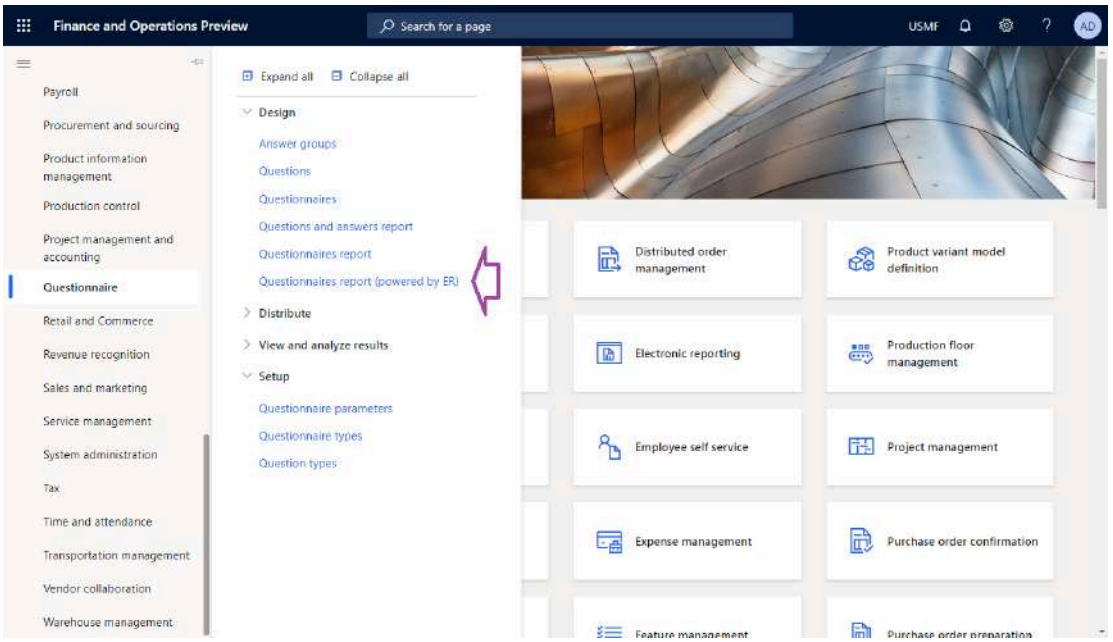
Add the existing **KM** menu to your Visual Studio project. Add a new **QuestionnairesErReport** item of the **Output** type to this menu. This item must refer to the **QuestionnairesErReport** menu item that is described in the previous section.

Build a Visual Studio project

Build your project to make the new menu item available to users.

Run a format from the application

1. Go to **Questionnaire** > **Design** > **Questionnaires report (powered by ER)**.



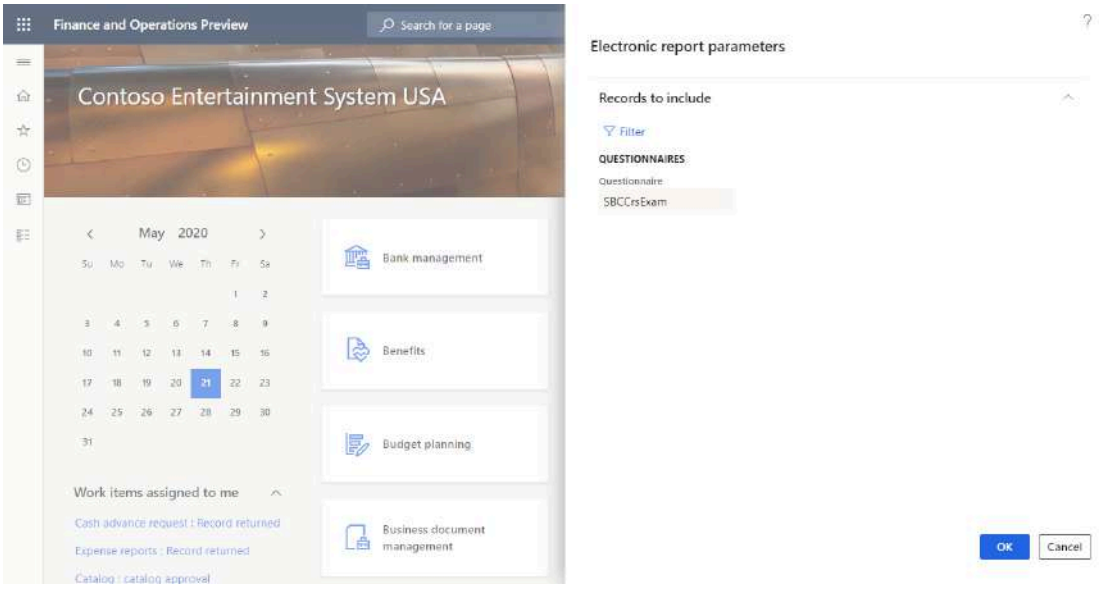
2. In the dialog box, in the **Format mapping** field, select **Questionnaires report**.

3. Select **OK**.

4. In the **Electronic report parameters** dialog box, on the **Records to include** FastTab, set the filter so that it includes only the **SBCCrsExam** questionnaire.

5. Select **OK** to confirm the filter.

6. Select **OK** to run the report.



7. Review the generated report.

Tune a designed ER solution

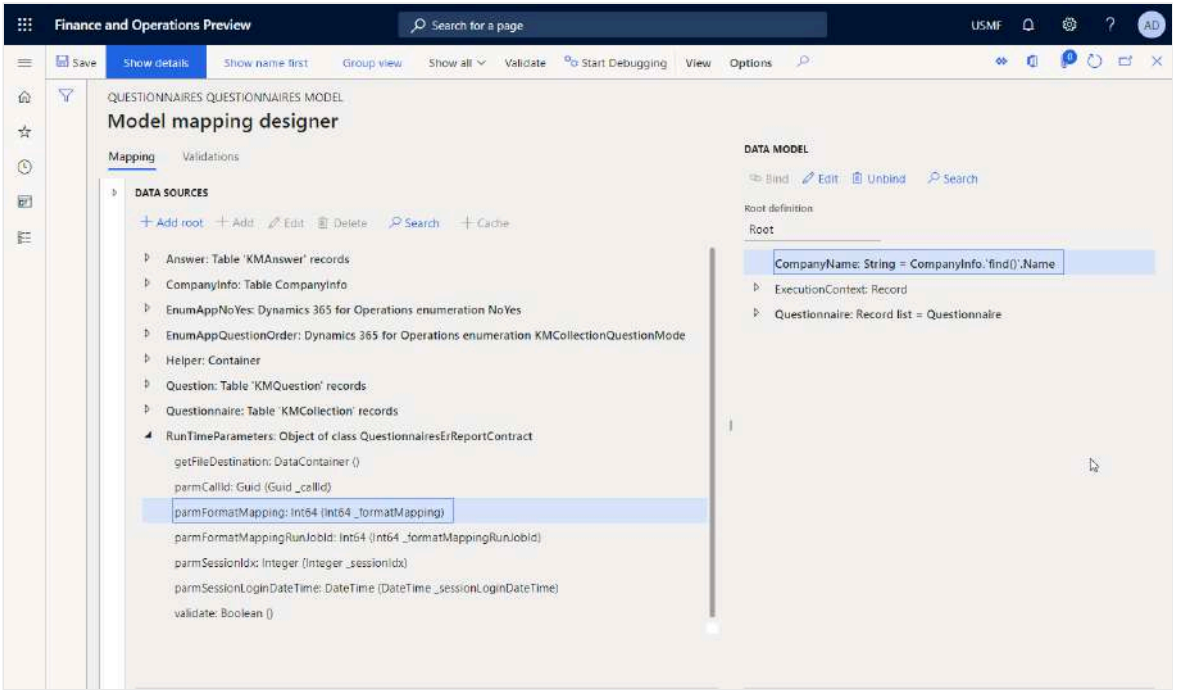
Modify the configured ER solution so that it uses the data provider class you developed to access details of the running ER format. Also, make it enter the name of this ER format in a generated report.

Modify a model mapping

Add data sources to access a data contract object

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, expand **Questionnaire model**, and then select **Questionnaire mapping**.
3. Select **Designer** to open **Model to datasource mapping**.
4. Select **Designer** to open the selected mapping in the model mapping designer.
5. On **Model mapping designer**, in the **Data source types** pane, select **Dynamics 365 for Operations\Object**.
6. In the **Data sources** pane, select **Add root**.
7. In the dialog box, in the **Name** field, enter RunTimeParameters, as defined in the source code of the **QuestionnairesErReportService** class.
8. In the **Class** field, enter QuestionnairesErReportContract, which you coded earlier.
9. Select **OK**.
10. Expand **RunTimeParameters**.

The added data source provides information about the record ID of the running ER format mapping.



Add a data source to access ER format mapping records

Continue to edit the selected model mapping by adding a data source to access ER format mapping records.

1. On **Model mapping designer**, in the **Data source types** pane, select **Dynamics 365 for Operations\Table records**.
2. In the **Data sources** pane, select **Add root**.

3. In the dialog box, in the **Name** field, enter **ER1**.
4. In the **Table** field, enter **ERFormatMappingTable**.
5. Select **OK**.

Add a data source to access a format mapping record of a running ER format

Continue to edit the selected model mapping by adding a data source to access the format mapping record of the running ER format.

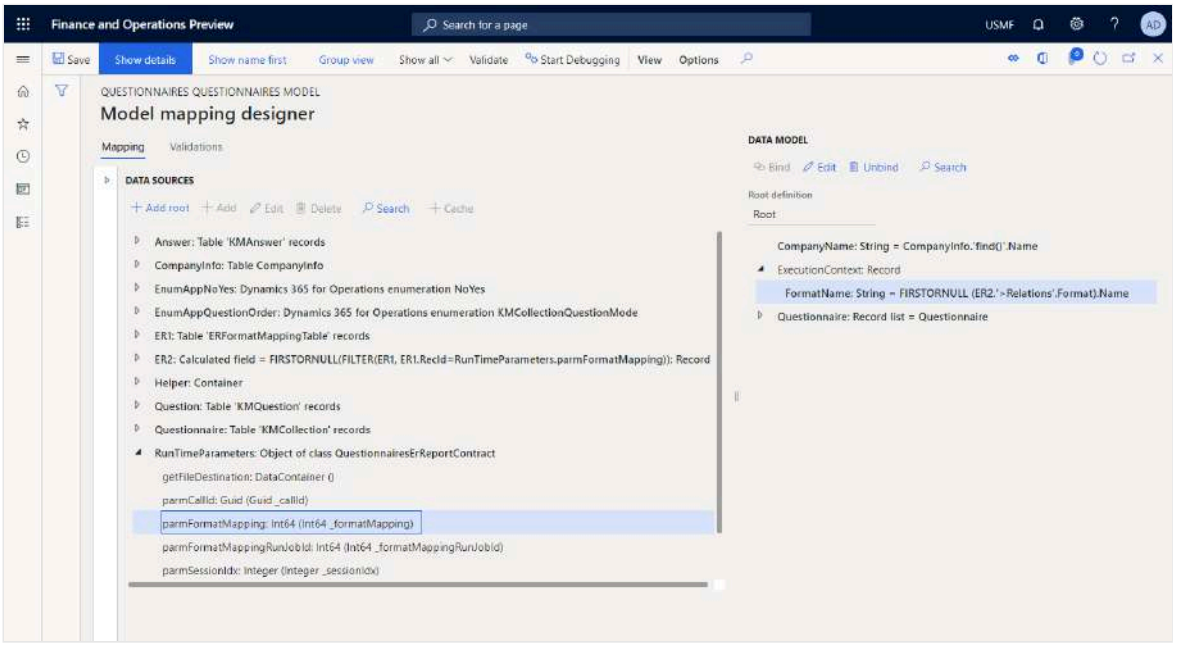
1. On **Model mapping designer**, in the **Data source types** pane, select **Functions\Calculated field**.
2. In the **Data sources** pane, select **Add root**.
3. In the dialog box, in the **Name** field, enter **ER2**.
4. Select **Edit formula**.
5. In the formula editor, in the **Formula** field, enter **FIRSTORNULL (FILTER(ER1, ER1.RecId = RunTimeParameters.parmFormatMapping))**.
6. Select **Save**, and close the formula editor.
7. Select **OK**.

Enter the name of the running ER format in the data model

Continue to edit the selected model mapping so that the name of the running ER format is entered in the data model.

1. On **Model mapping designer**, in the **Data model** pane, expand **ExecutionContext**, and then select **ExecutionContext\FormatName**.
2. In the **Data model** pane, select **Edit** to configure a data binding for the selected data model's field.
3. In the formula editor, in the **Formula** field, enter **FIRSTORNULL (ER2.'>Relations'.Format).Name**.
4. Select **Save**, and close the formula editor.

Because you used the **FormatName** field, the configured model mapping now exposes the name of an ER format that calls this model mapping during execution.



Complete the design of the model mapping

1. On **Model mapping designer**, select **Save**.
2. Close the page.
3. Close the model mappings page.
4. On **Configurations**, in the configuration tree, make sure that the **Questionnaire mapping** configuration is still selected. Then, on the **Versions** FastTab, select the configuration version that has a status of **Draft**.
5. Select **Change status** > **Complete**.

The status of version 1.2 of this configuration changes from **Draft** to **Completed**. You can't change version 1.2 anymore. This version contains the configured model mapping and can be used as the basis for other ER configurations. Version 1.3 of this configuration is created and has a status of **Draft**. You can edit this version to adjust the **Questionnaire** model mapping.

Modify a format

You can modify the configured ER format so that its name appears in the footer of a report that is generated when the ER format runs.

Add a new format element

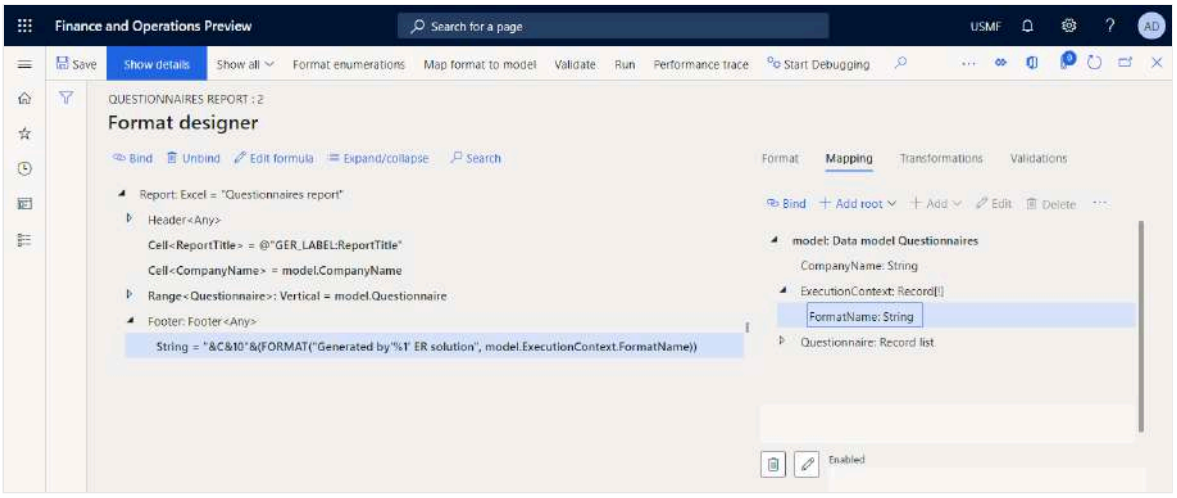
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, expand **Questionnaire model**, and then select **Questionnaire report**.
3. Select **Designer**.
4. On **Format designer**, select the **Report** root item.
5. Select **Add** to add a new nested format element for the selected **Report** root item.
6. Select **Excel\Footer**.
7. In the **Name** field, enter **Footer**.

8. Select **Report\Footer**, and then select **Add**.
9. Select **Text\String**.

Bind the added format element

1. On **Format designer**, on the **Mapping** tab, in the format tree, for the active **Footer\String** element, select **Edit formula**.
2. In the formula editor, in the **Formula** field, enter `CONCATENATE ("\&C\&10", FORMAT("Generated by'\%1' ER solution", model.ExecutionContext.FormatName))`.
3. Select **Save**, and close the formula editor.
4. Select **Save**.

You modified the configured format so that its name is entered in the footer of a generated report by using the **Footer\String** element.



Complete the format design

1. Close **Format designer**.
2. On **Configurations**, in the configuration tree, make sure that the **Questionnaire report** configuration is still selected. Then, on the **Versions** FastTab, select the configuration version that has a status of **Draft**.
3. Select **Change status** > **Complete**.

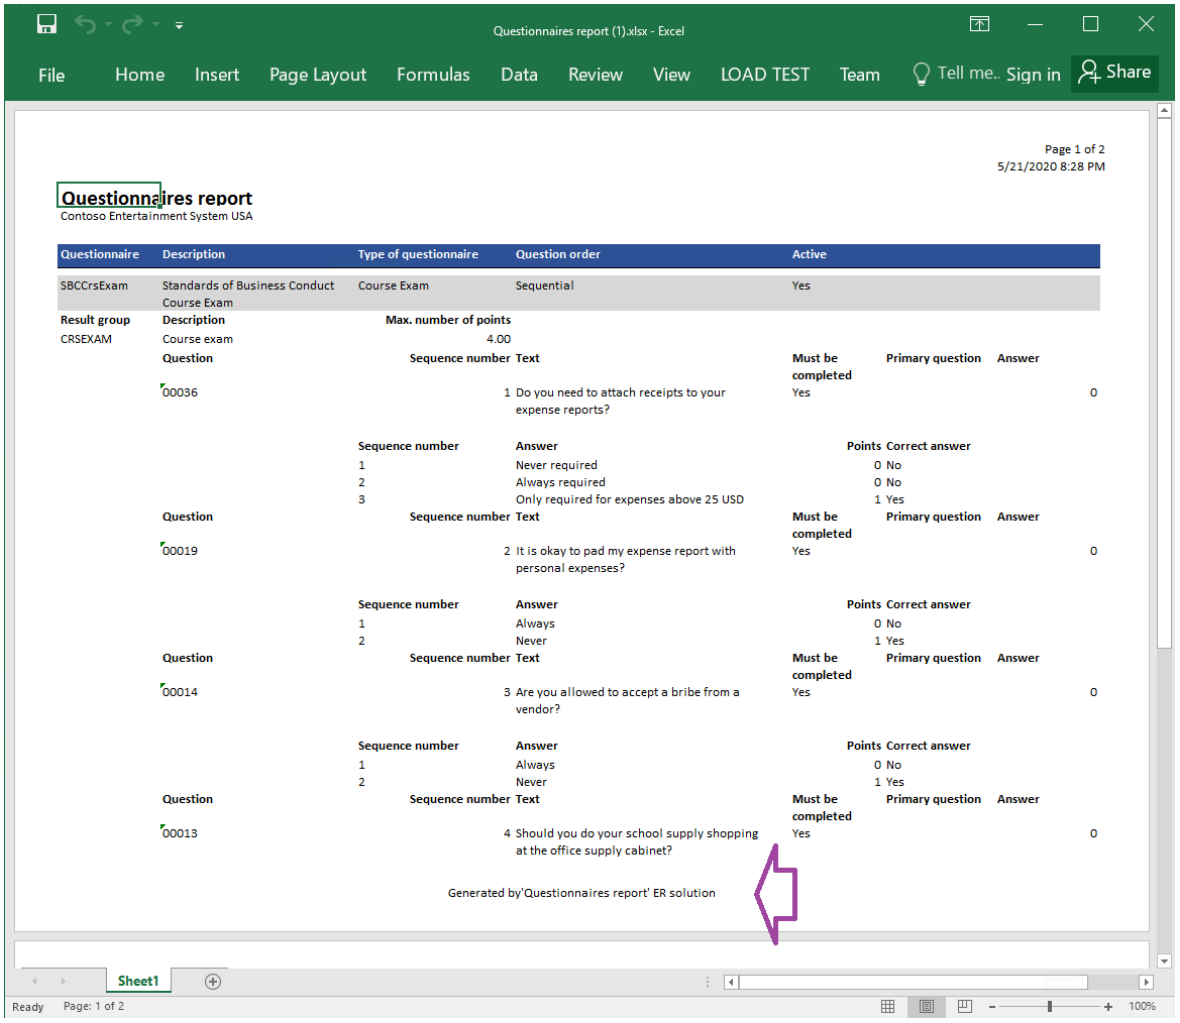
The status of version 1.2 of this configuration changes from **Draft** to **Completed**. You can no longer change version 1.2. This version contains the configured format and can be used as the basis for other ER configurations. Version 1.3 of this configuration is created and has a status of **Draft**. You can edit this version to adjust the **Questionnaire** report.

Run a format from the application

1. Go to **Questionnaire** > **Design** > **Questionnaires report (powered by ER)**.
2. In the dialog box, in the **Format mapping** field, select **Questionnaires report**.
3. Select **OK**.

4. In the **ER parameters** dialog box, on the **Records to include** FastTab, set the filter so that it includes only the **SBCCrsExam** questionnaire.
5. Select **OK** to confirm the filter.
6. Select **OK** to run the report.
7. Review the generated report in Excel format.

The footer of the generated report contains the name of the ER format that was used to generate it.



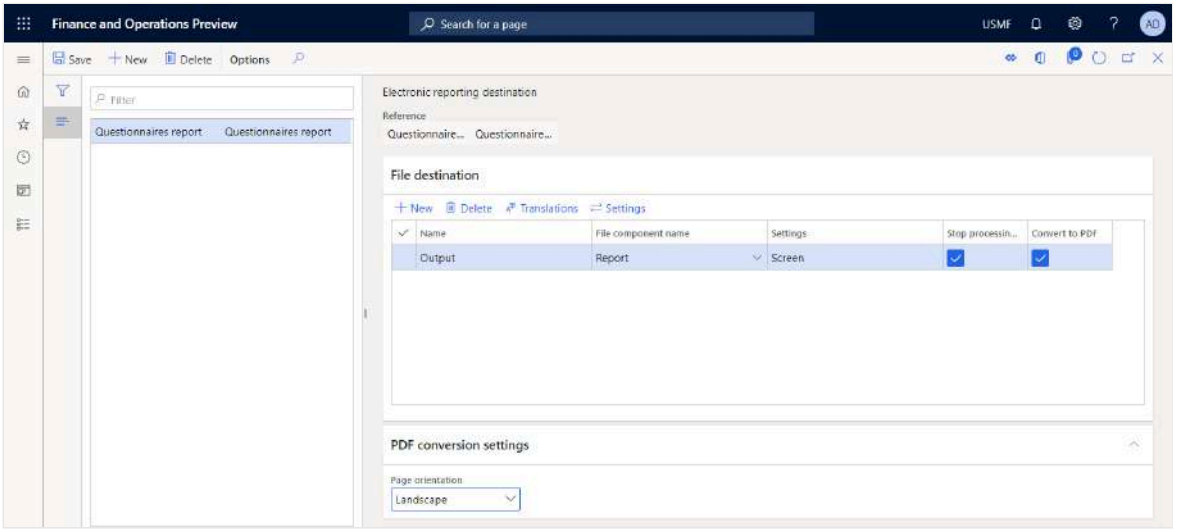
Run a format from ER

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, expand **Questionnaire model**, and then select **Questionnaire report**.
3. On the Action Pane, select **Run**.
4. In the **Electronic report parameters** dialog box, on the **Records to include** FastTab, set the filter so that it includes only the **SBCCrsExam** questionnaire.
5. Select **OK** to confirm the filter.
6. Select **OK** to run the report.
7. Review the generated report in Excel format.

The footer of the generated report doesn't contain the name of ER format that was used to generate it, because the running model mapping wasn't passed the data contract object when the ER format called it.

Configure a format destination for on-screen preview

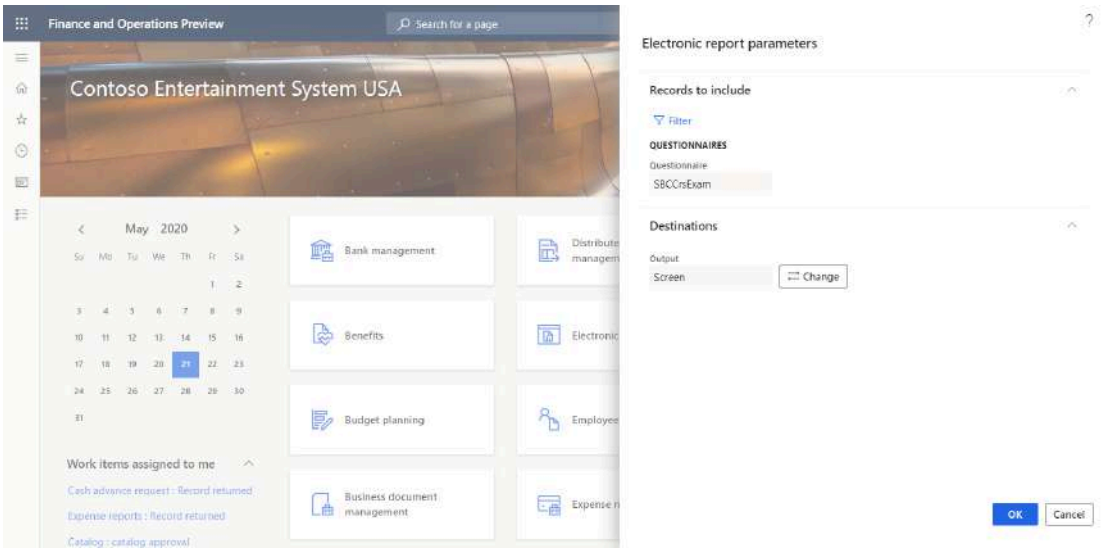
1. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting destination**.
2. On **Electronic reporting destination**, add a destination record for the configured **Questionnaire report** ER format.
3. On the **File destination** FastTab, set up the **Screen** destination for the **Report** format component that you added as the root element of the configured **Questionnaire report** ER format.
4. On the **PDF conversion settings** FastTab, configure the destination to convert a report to PDF format that uses the **Landscape** page orientation.



Run a format from the application to preview it as a PDF document

1. Go to **Questionnaire** > **Design** > **Questionnaires report (powered by ER)**.
2. In the dialog box, in the **Format mapping** field, select **Questionnaires report**.
3. Select **OK**.
4. In the **Electronic report parameters** dialog box, on the **Records to include** FastTab, set the filter so that it includes only the **SBCCrsExam** questionnaire.
5. Select **OK** to confirm the filter.

   On the **Destinations** FastTab, notice that the **Output** field is set to **Screen**. If you want to change the configured destination, select **Change**.



6. Select **OK** to run the report.

7. Review the generated report in PDF format.

Customize Electronic reporting configurations to generate an electronic document

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The Electronic reporting (ER) framework lets you upload the ER configurations that Microsoft provides into your Microsoft Dynamics 365 Finance instance. By using these Microsoft-provided configurations, you can generate electronic customer invoices (e-invoices). Use this ER solution to configure your custom ER solution to access your custom database fields and generate e-invoices that comply with your specific requirements, without editing the source code.

Overview

For the example in this article, you must specify a federal tax identification code as a new custom attribute for every customer that you electronically invoice. Therefore, you must customize the structure of the invoice that is currently used by adding a new item that you fill with the tax code in every e-invoice that you generate.

The procedures in this article explain how a user in the System Administrator, Electronic Reporting Developer, or Electronic Reporting Functional Consultant role can perform the following tasks in your Finance instance:

- Configure the minimal set of ER parameters that is required to start to use the ER framework.
- Import the initial versions of the standard ER configurations that are provided to generate e-invoices.
- Configure the Accounts receivable parameters to start to use the standard ER configurations.

- Configure the legal entity parameters to invoice customers.
- Prepare a customer record for electronic invoicing.
- Add, post, and send a customer invoice by using the standard ER configurations.
- Add a custom database field to manage a federal tax identification code for customers.
- Refresh the ER metadata to enable database changes for the ER model mapping designer.
- Design the custom ER configurations to generate e-invoices that contain the new tax code.
- Configure the Accounts receivable parameters to start to use the custom ER configurations.
- Update a customer record for electronic invoicing.
- Add, post, and send a customer invoice by using the custom ER configurations.
- Import the new versions of the standard ER configurations that are provided to generate e-invoices.
- Adopt the changes to the new versions of the standard ER configurations in your custom ER configurations.
- Add, post, and send a customer invoice by using the new versions of the custom ER configurations.

You can complete all these procedures in the **DEMF** company.

Configure the ER framework

As a user in the Electronic Reporting Functional Consultant or Electronic Reporting Developer role, you must configure the minimal set of ER parameters. You can then start to use the ER framework to design custom versions of the standard configurations of the ER solution that is used to generate e-invoices.

Configure ER parameters

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization blueprint** page, in the **Related links** section, select **Electronic reporting parameters**.
3. On the **Electronic reporting parameters** page, on the **General** tab, set the **Enable design mode** option to **Yes**.
4. On the **Attachments** tab, in the **Configurations** field, select **File**.
5. In the **Job archive**, **Temporary**, **Baseline**, and **Others** fields, select the **File** type.

For more information about ER parameters, see Configure the ER framework.

Activate an ER configuration provider

Each ER configuration you add is owned by an ER configuration provider. The ER configuration provider that you activate in the **Electronic reporting** workspace is used for this purpose. Therefore, you must activate an ER configuration provider in the **Electronic reporting** workspace before you start to add or edit ER configurations.

> ⓘ **Note**
>
> Only the owner of an ER configuration can edit it. Therefore, before you can edit an ER configuration, you must activate the appropriate ER configuration provider in the **Electronic reporting** workspace.

Review the list of ER configuration providers

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization blueprint** page, in the **Related links** section, select **Configuration providers**.
3. On the **Configuration provider table** page, each provider record has a unique name and URL. Review the contents of this page. If a record for **Litware, Inc.** (`https://www.litware.com`) already exists, skip the next procedure, Add a new ER configuration provider.

Add a new ER configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization blueprint** page, in the **Related links** section, select **Configuration providers**.
3. On the **Configuration providers** page, select **New**.
4. In the **Name** field, enter **Litware, Inc.**
5. In the **Internet address** field, enter `https://www.litware.com`.
6. Select **Save**.

Activate an ER configuration provider

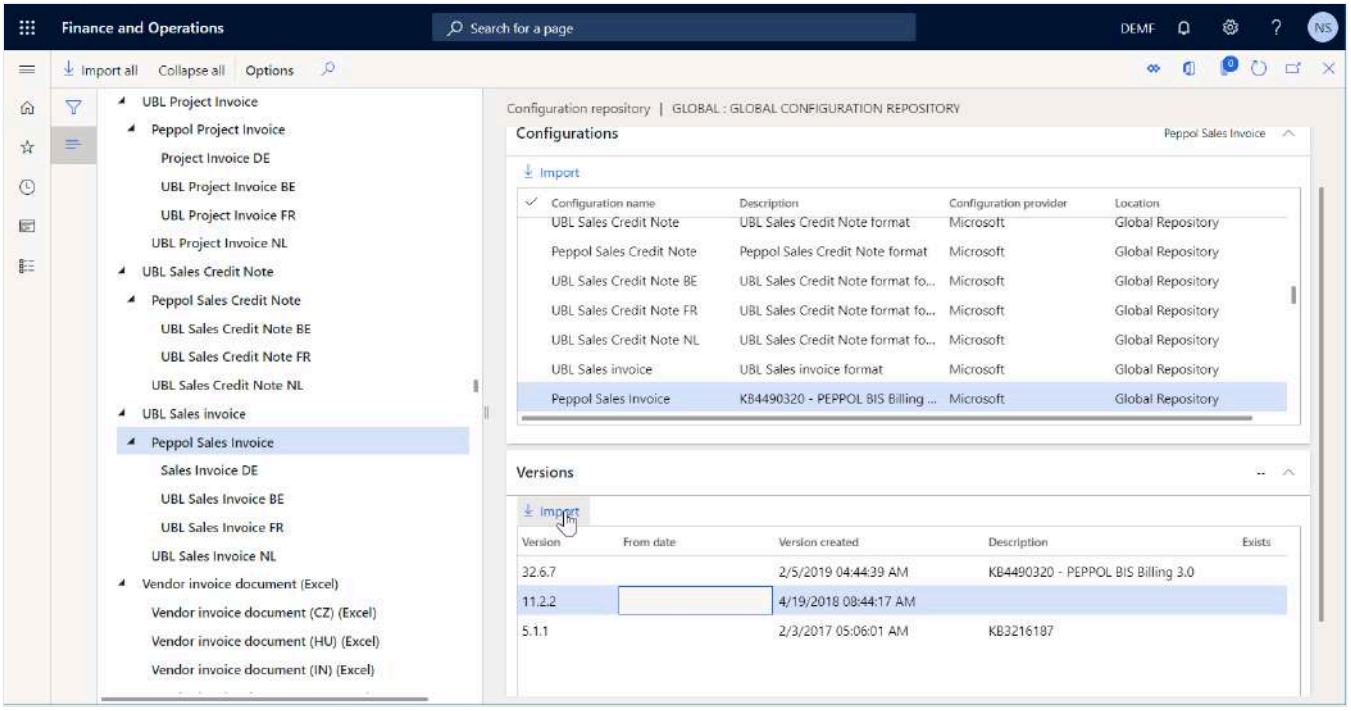
1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization blueprint** page, in the **Configuration providers** section, select the **Litware, Inc.** tile, and then select **Set active**.

For more information about ER configuration providers, see Create configuration providers and mark them as active.

Import the initial versions of standard ER configurations

To add the standard ER configurations to your current Finance instance, import them from the ER repository that you configured for that instance.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization blueprint** page, in the **Configuration providers** section, select the **Microsoft** tile, and then select **Repositories** to view the list of repositories for the Microsoft provider.
3. On **Configuration repositories**, select the repository of the **Global** type, and then select **Open**. If you're prompted for authorization to connect to Regulatory Configuration Service, follow the authorization instructions.
4. On **Configuration repository**, in the configuration tree in the left pane, select the **Peppol Sales Invoice** format configuration.
5. On the **Versions** FastTab, select version **11.2.2**.
6. Select **Import** to download the selected version from the Global repository.



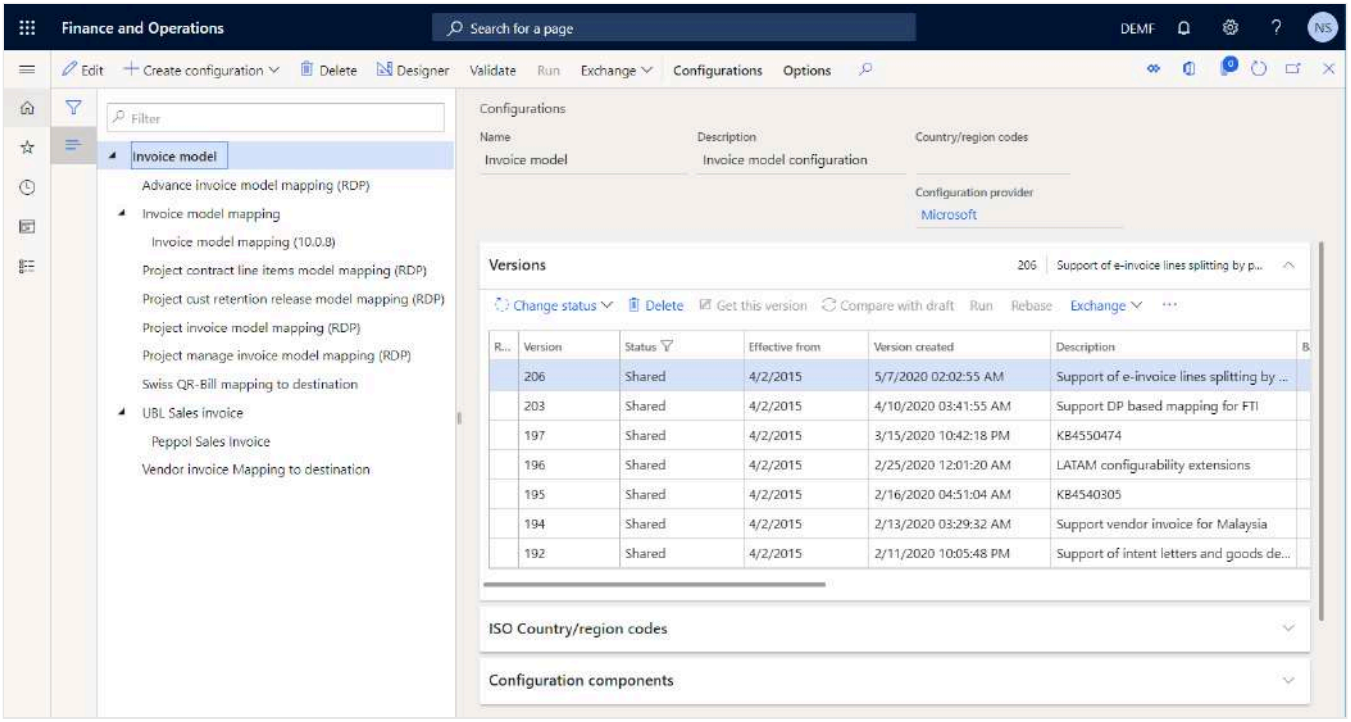
> **Tip**

If you have trouble accessing the Global repository, you can download configurations from Microsoft Dynamics Lifecycle Services instead.

Review the imported ER configurations

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization blueprint** page, in the **Configurations** section, select the **Reporting configurations** tile.
3. On the **Configurations** page, expand the **Configuration components** FastTab.
4. In the configuration tree in the left pane, expand **Invoice model**, and then expand **UBL Sales invoice**.

You see that, in addition to the selected **Peppol Sales Invoice** ER format, the import process brings in other required ER configurations. Because new versions of ER configurations are constantly published to the Global repository and Lifecycle Services to keep the corresponding solutions compliant with new requirements, the latest versions of the required data model configuration and its model mapping configurations are imported.



To simulate the state that ER configurations in the current Finance instance would be in if you imported version **11.2.2** of the **Peppol Sales Invoice** ER format in the past (for example, on August 7, 2019), follow these steps:

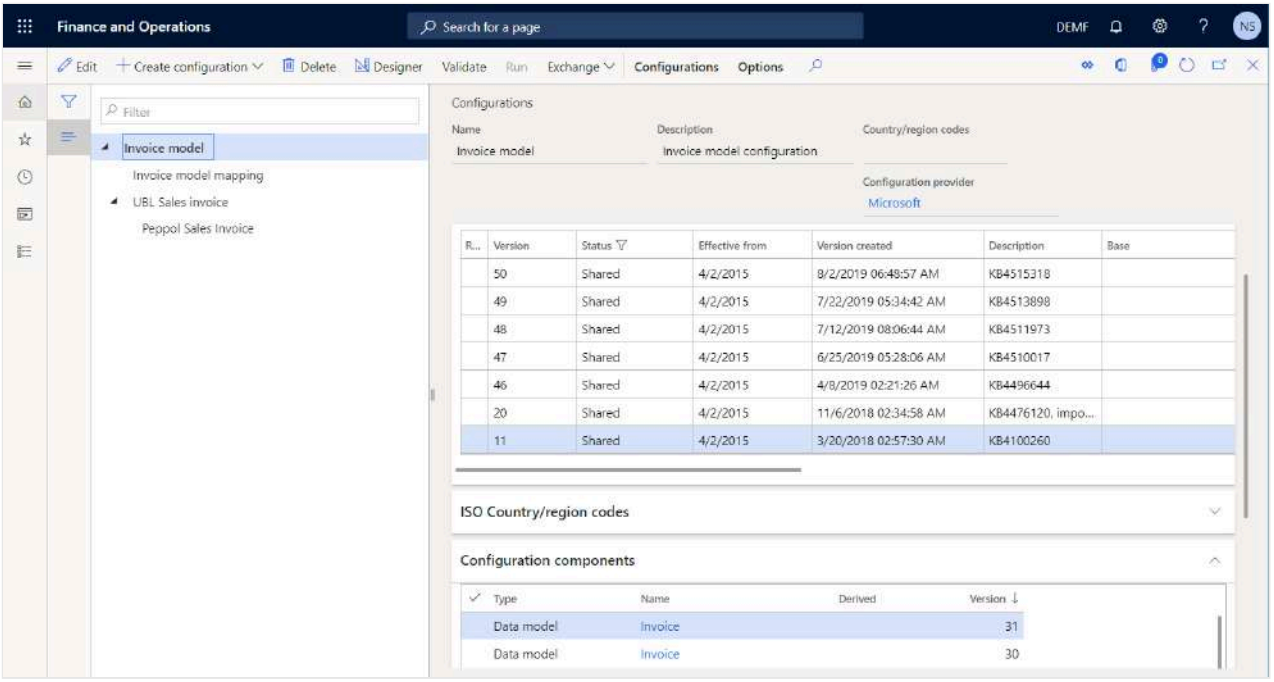
- On the Action Pane, select **Delete** to delete all ER configurations that were published after August 7, 2019. The only **Invoice model**, **Invoice model mapping** (initially named

Customer invoice model mapping), **UBL Sales invoice**, and **Peppol Sales Invoice** configurations remain.

- For the remaining ER configurations, on the **Versions** FastTab, select **Delete** to delete all versions of ER configurations that were published after August 7, 2019.

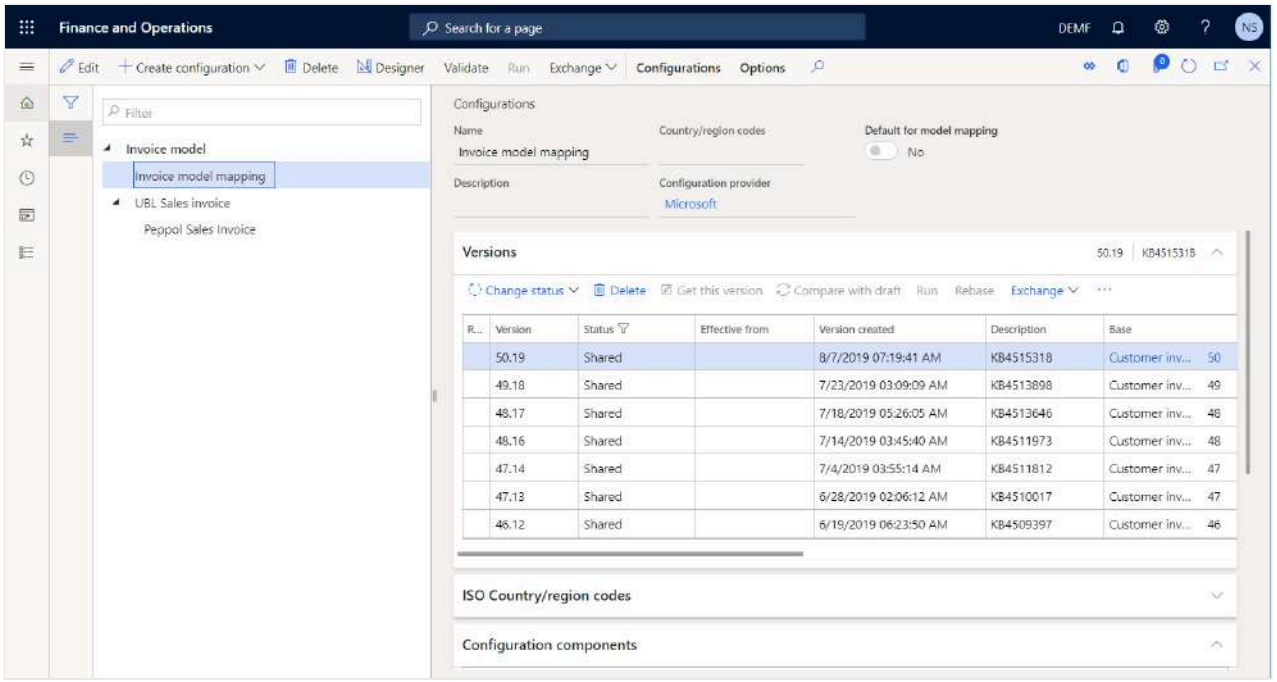
Then verify that the following configurations are available in the configuration tree:

- **Invoice model** ER data model configuration (initially named **Customer invoice model**):
  - Version 11 contains version 10 of the data model ER component that represents the data structure of the invoicing business domain. This ER configuration is imported as an ancestor of the **Peppol Sales Invoice** ER format that you selected for import.
  - Version 50 contains version 31 of the data model ER component. This ER configuration is imported as an ancestor of the August 7, 2019, version of the **Invoice model mapping** ER model mapping configuration.



> **Tip**
>
> If you don't see version 50 of this data model, open the Global repository, and import version 50.19 of the **Invoice model mapping** ER configuration.

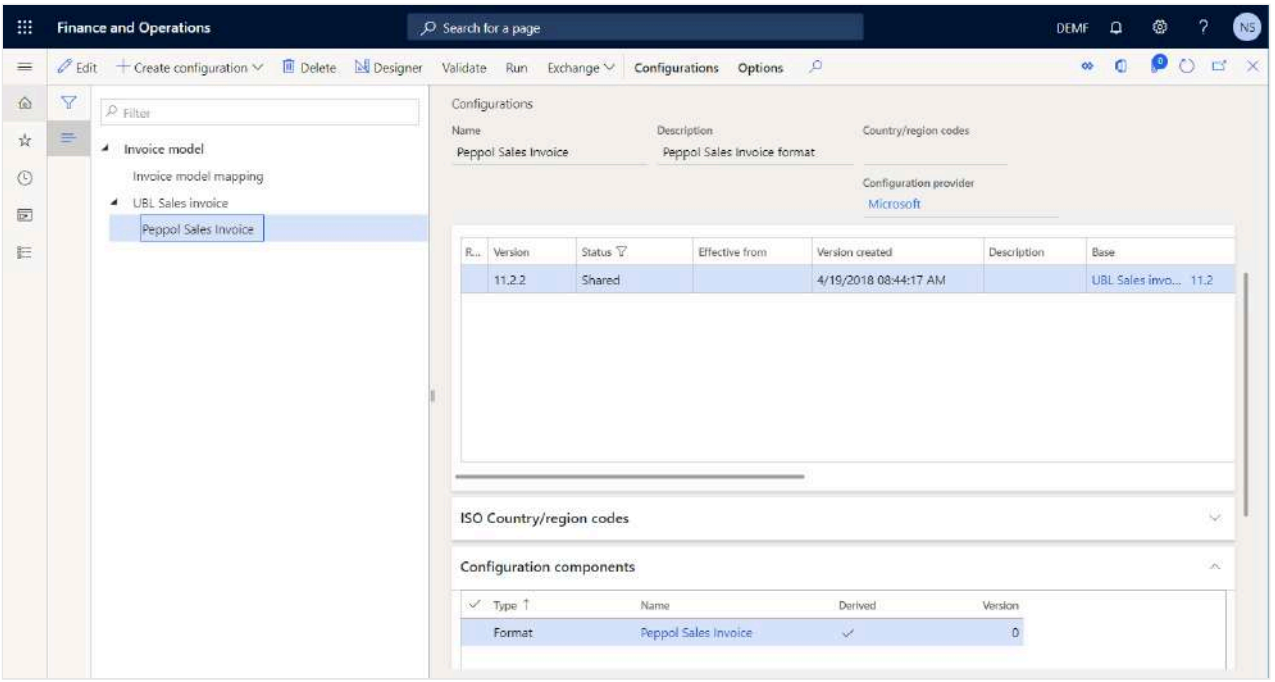
- **Invoice model mapping** ER model mapping configuration (initially named **Customer invoice model mapping**):
  - Version 50.19 is imported as the latest implementation of version 50 of the **Invoice model** ER data model configuration. It contains two model mapping ER components that describe how the data model is filled in with application data at runtime.



> **Tip**
>
> If you don't see version 50.19 of this model mapping, open the Global repository, and import version 50.19 of the **Invoice model mapping** ER configuration.

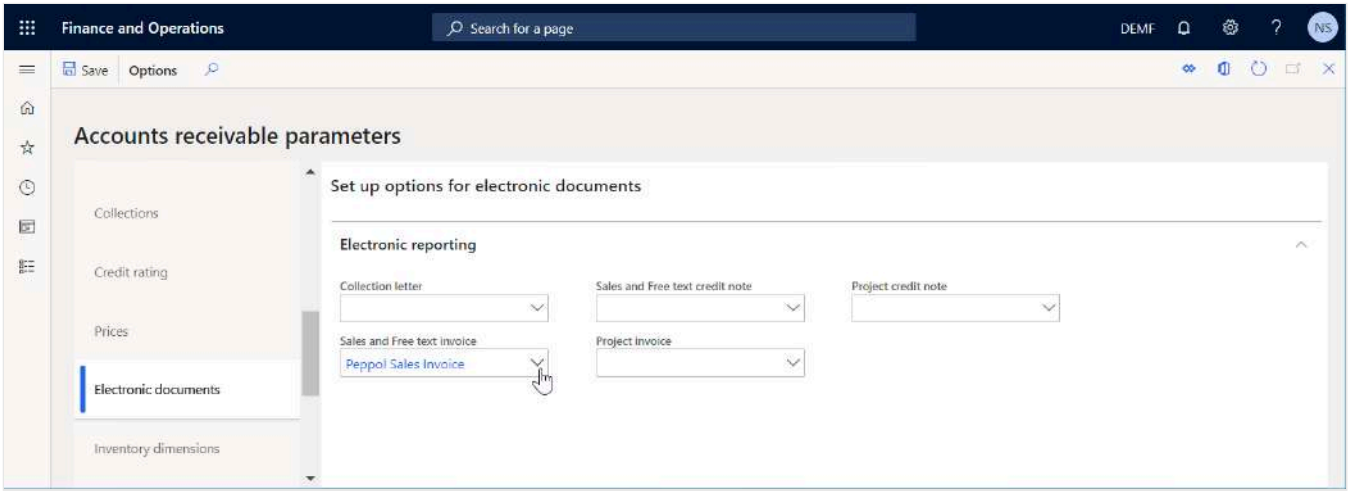
- **UBL Sales invoice** ER format configuration:
  - Version 11.2 contains the format and format mapping ER components. The format component specifies the report layout. The format mapping component contains the model data source and specifies how this data source is used to fill in the report layout at runtime. This ER format is configured to generate e-invoices in Universal Business Language (UBL) format. It's imported as a parent of the **Peppol Sales Invoice** ER format that you selected for import.

- **Peppol Sales Invoice** ER format configuration:
  - Version 11.2.2 contains the format and format mapping ER components that are configured to generate e-invoices in Pan-European Public Procurement OnLine (PEPPOL) format.



Configure the Accounts receivable parameters

1. Go to **Accounts receivable** > **Setup** > **Accounts receivable parameters**.
2. On the **Electronic documents** tab, in the **Electronic reporting** section, select **Peppol Sales Invoice** in the **Sales and Free text invoice** field.
3. Select **Save**.



Configure the legal entity parameters

1. Go to **Organization administration** > **Organizations** > **Legal entities**.
2. For the selected **DEMF** company, in the **Bank account information** section, enter **1234** in the **Routing number** field.
3. Select **Save**.
4. Close the **Legal entities** page.

Prepare a customer record

1. Go to **Accounts receivable** > **Customers** > **All customers**.
2. On the **All customers** page, select the **DE-014** customer account link.

Add a customer contact

1. Go to **Accounts receivable** > **Customers** > **All customers**.
2. On the Action Pane, on the **Customer** tab, in the **Accounts** group, select **Contacts**.
3. Select **Add contacts**.
4. On the **Contacts** page, in the **First name** field, open the lookup, select **Adam Carter**, and then select **Select** to close the lookup.
5. Select **Save**.
6. Close the **Contacts** page.

Define a primary contact

1. Go to **Accounts receivable** > **Customers** > **All customers**.
2. On the **Sales demographics** FastTab, in the **Primary contact** field, select **Adam Carter**.

Set the e-invoicing option

1. Go to **Accounts receivable** > **Customers** > **All customers**.
2. On the **Invoice and delivery** FastTab, set the **eInvoice** option to **Yes**.
3. Select **Save**.
4. Close the **All customers** page.

Process a customer invoice by using the standard ER configurations

Use the standard ER configurations that you imported to electronically send a free text invoice to a customer.

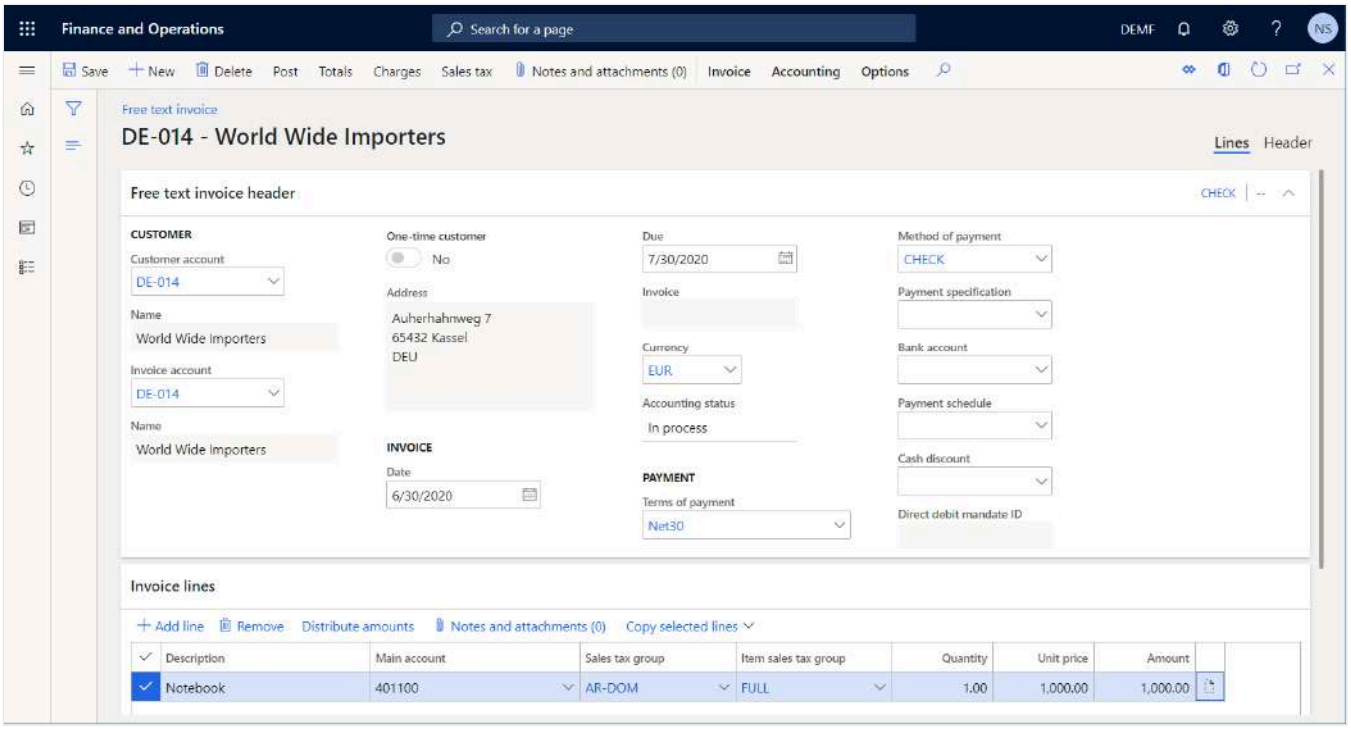
Add a new invoice

1. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.
2. On **Free text invoice**, select **New**.
3. On the **Free text invoice header** FastTab, in the **Customer account** field, select **DE-014**.

4. On the **Invoice lines** FastTab, an invoice line is automatically added. On this line, set the following fields:

    - In the **Description** field, enter **Notebook**.
    - In the **Main account** field, select **401100**.
    - In the **Unit price** field, enter **1000**.

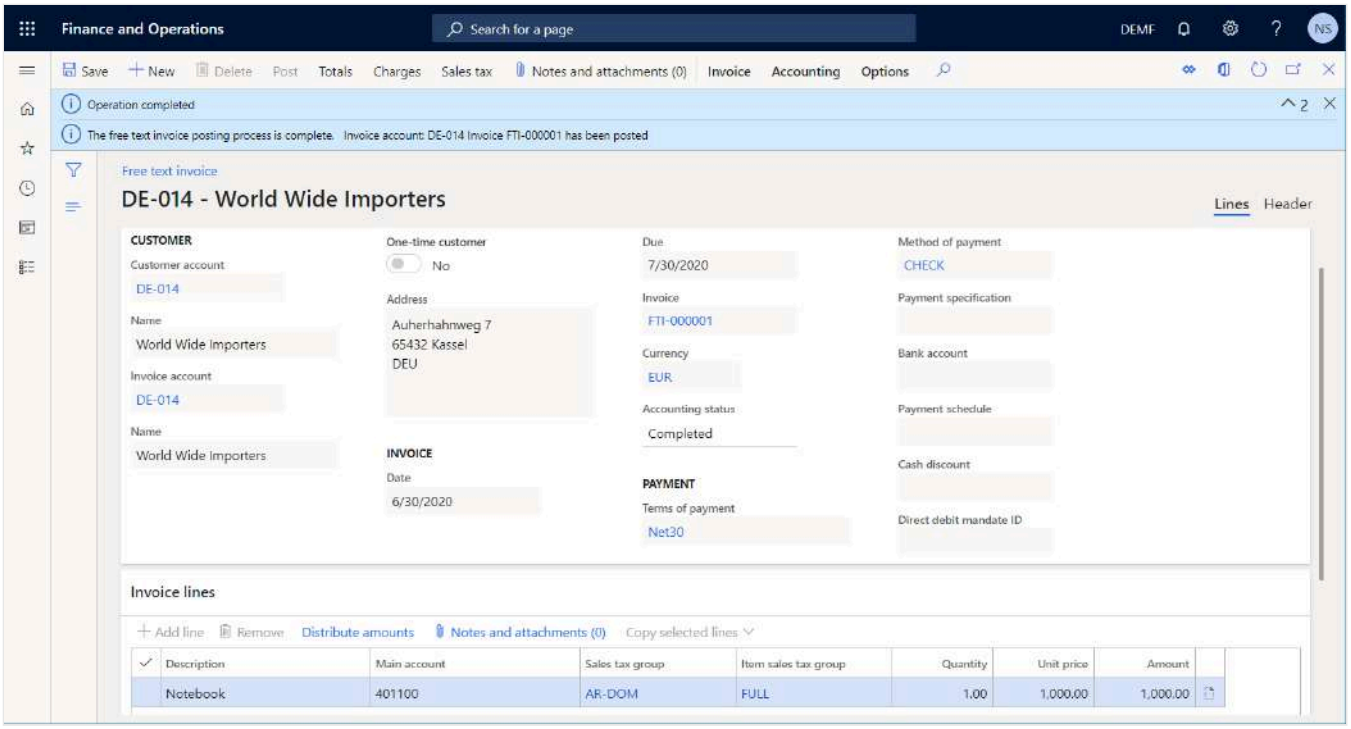
5. Select **Save**.



For more information, see Create a free text invoice.

Post a new invoice

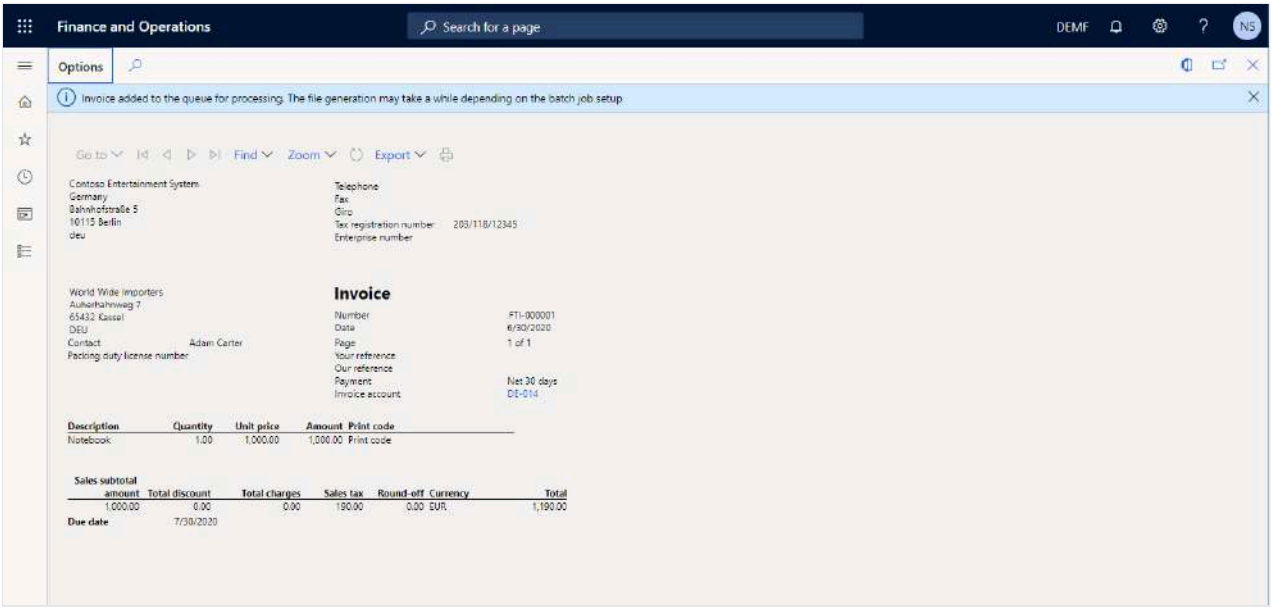
1. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.
2. On **Free text invoice**, on the Action Pane, select **Post**.
3. In the **Post free text invoice** dialog box, select **OK**.



Send a posted invoice

1. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.

2. On **Free text invoice**, on the Action Pane, in the **Document** group, select **Send** > **Original**.



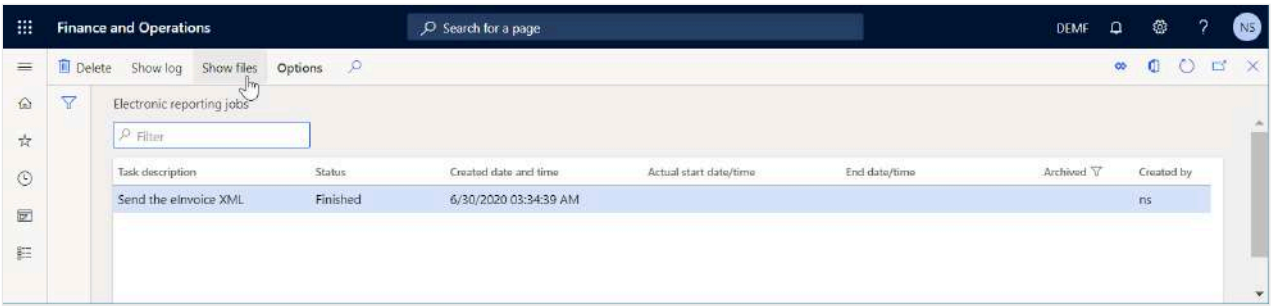
3. Close **Free text invoice**.

Analyze a generated e-invoice

1. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting jobs**.

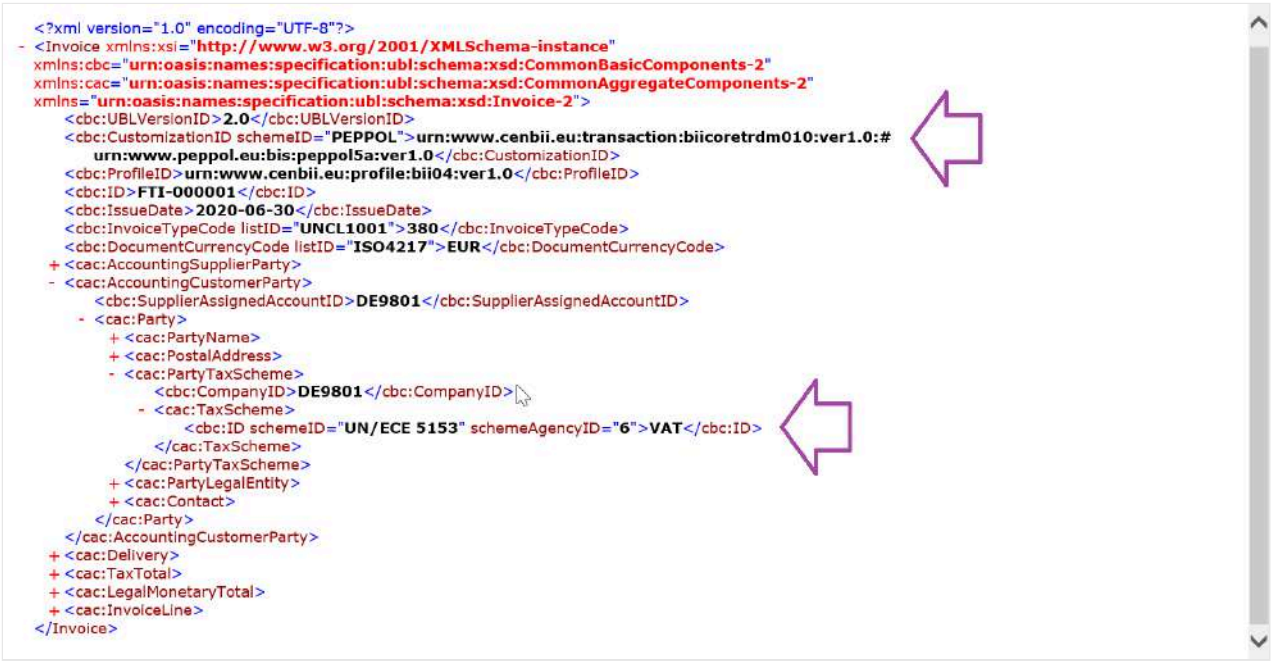
2. On **Electronic reporting jobs**, select the initial record that has the task description **Send the eInvoice XML**.

3. Select **Show files** to access the list of generated files.



4. Select **Open** to download the e-invoice XML file.

5. Analyze the e-invoice XML file. The customer tax schema is currently represented by the **schemeID** and **schemeAgencyID** XML attributes. The **cbc:CustomizationID** XML element currently contains the following text: `urn:www.cenbii.eu:transaction:biicoretrdm010:ver1.0:#` `urn:www.peppol.eu:bis:peppol5a:ver1.0`.



Add a custom database field

Use the Custom field feature to customize the current Finance instance:

- Customize the database structure by adding a new custom database field that stores a federal tax identification code for every customer.

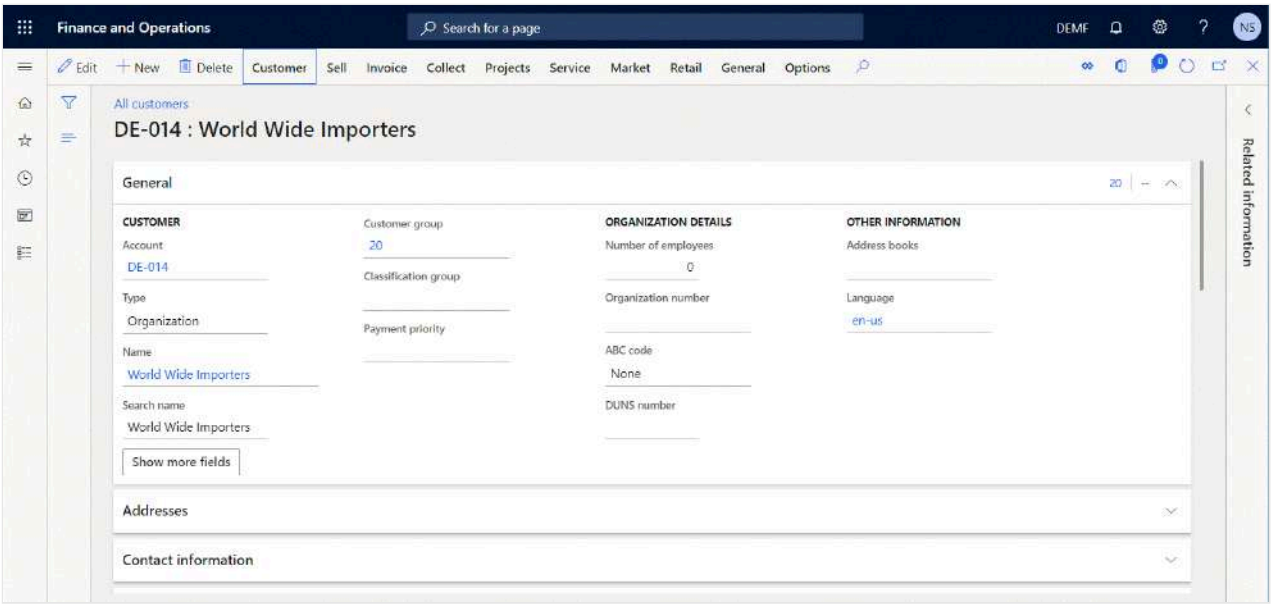
- Customize the **Customer** page by adding a new data entry field that you can use to enter a tax code value in the new custom database field.

Follow these steps to do the customization.

1. Go to **Accounts receivables** > **Customers** > **All customers**.
2. On the **All customers** page, select the **DE-014** customer account link.
3. On the **General** FastTab, right-click any blank area under the **Language** field, and then select **Personalize: UpperGroup**.

   The contents of the **General** FastTab are highlighted, and a **Personalize** menu appears.
4. On the **Personalize** menu, select **Add a field**.
5. In the **Add columns** dialog box, select **Create new field**.
6. In the **Create new field** dialog box, in the **Table name** field, select **Customers**.
7. In the **Name prefix** field, enter **FederalTaxID**.

   > ⓘ **Note**
   >
   > The whole field name is automatically defined as **FederalTaxID_Custom**.
8. In the **Label** field, enter **Federal Tax ID**.
9. In the **Type** field, select **Text**.
10. In the **Length** field, enter **20**.
11. Select **Save**.
12. In the message box that appears, select **Yes** to confirm that you want to create a new **FederalTaxID** field entry for the **Customers** table.
13. Select **Insert** to add the **FederalTaxID_Custom** field to the current page.



14. Close the **All customers** page.

Refresh the ER metadata

To make the custom field you added visible in the ER model mapping designer, refresh the ER metadata.

1. Go to **Organization administration** > **Electronic reporting** > **Rebuild table references**.
2. In **Update data model**, select **OK**.

Design the custom ER configurations

Use the Microsoft-provided ER configurations as a starting point to design your custom ER configurations. This way, you can generate e-invoices that contain the new tax code.

Customize the data model configuration

As a user in the Electronic Reporting Functional Consultant role, you can design your custom ER data model.

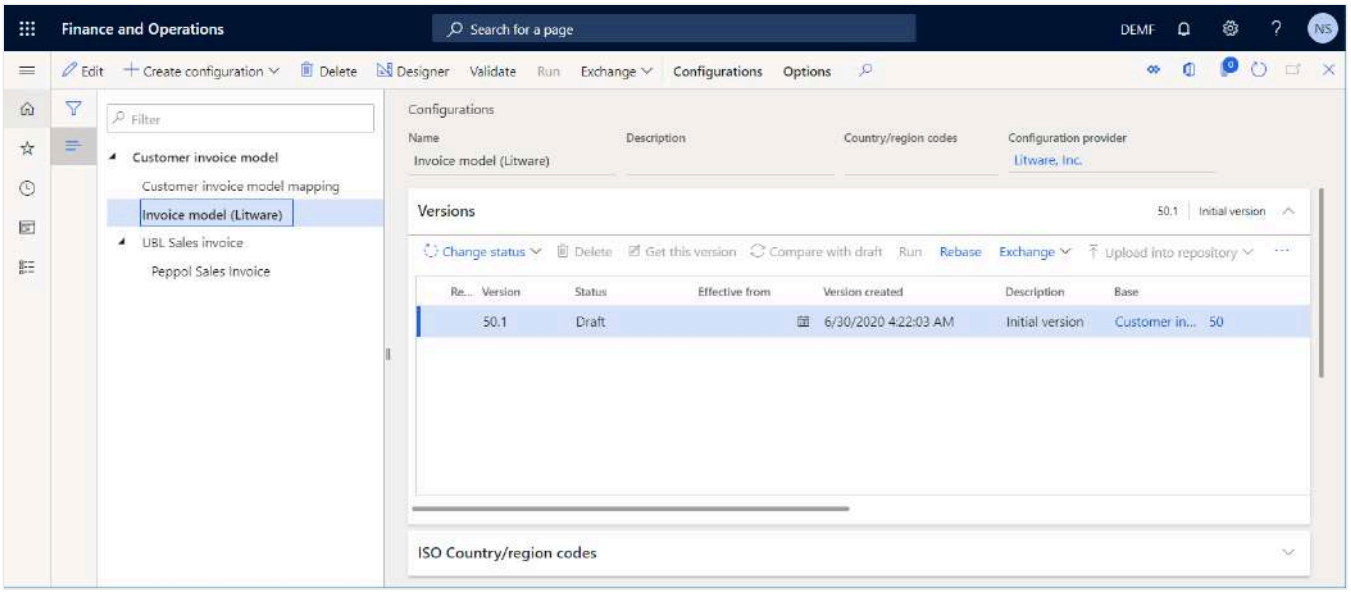
Add a custom data model configuration

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, select **Customer invoice model**.
3. On the Action Pane, select **Create configuration**.
4. In the drop-down dialog box, in the **New** field, select **Derive from Name: Customer invoice model, Microsoft** to indicate that your new custom ER data model configuration

should be based on the ER data model configuration.

5. In the **Name** field, enter **Invoice model (Litware)**.
6. Select **Create configuration** to add the new ER configuration.

You can now use the ER data model designer to edit version 50.1 of the **Invoice model (Litware)** ER configuration in **Draft** status.



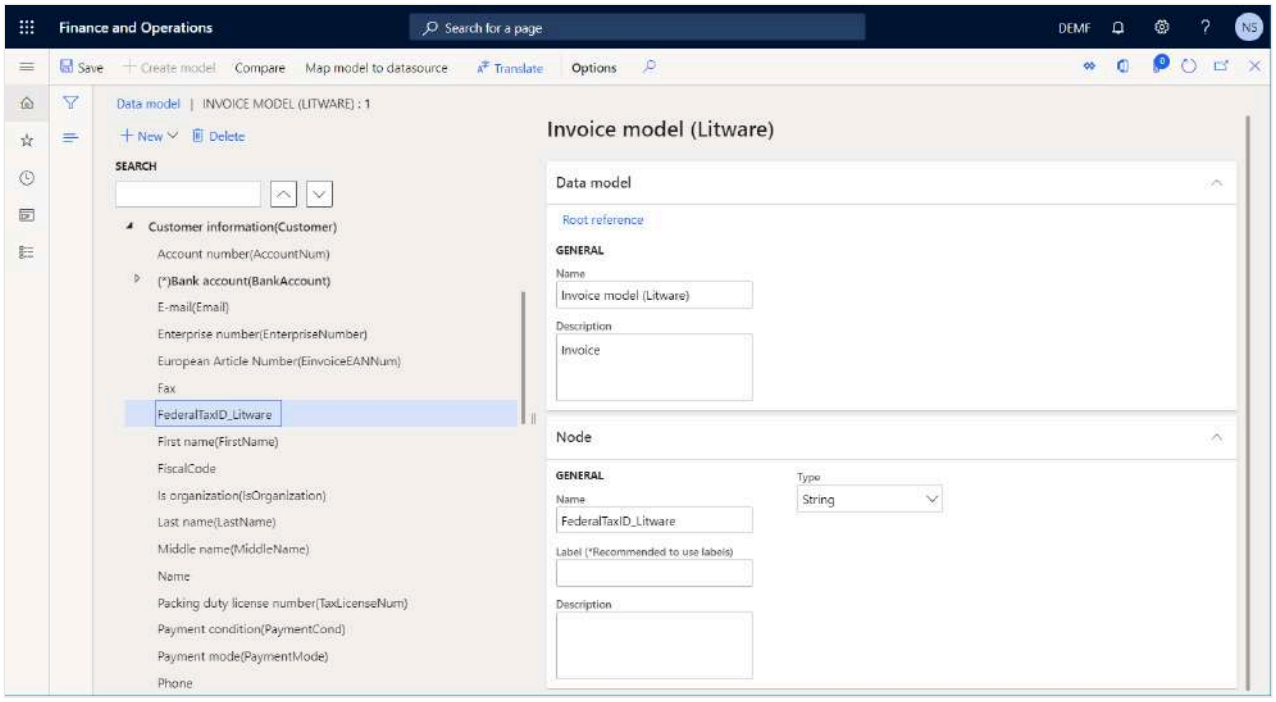
Configure a custom data model

Modify your custom data model by adding a new field to provide the value of a federal tax identification code. This code is part of the customer data for every ER format that uses this data model as a data source.

1. On **Configurations**, in the configuration tree in the left pane, select **Invoice model (Litware)**.
2. On the **Versions** FastTab, select version **50.1** of the selected ER data model configuration in **Draft** status.
3. On the Action Pane, select **Designer** for the selected configuration version.
4. On the **Data model designer** page, in the data model tree, select **Customer information (Customer)**.
5. Select **New**.
6. In the drop-down dialog box, in the **New node as a** field, accept the default value, **Child of an active node**.
7. In the **Name** field, enter **FederalTaxID_Litware**.

8. In the **Item type** field, accept the default value, **String**.

9. Select **Add**, and then select **Save**.



> **Note**
>
> The **Label** and **Description** fields describe the purpose of the new field. You can fill in these fields in multiple languages. For more information, see Design multilingual reports in Electronic reporting.

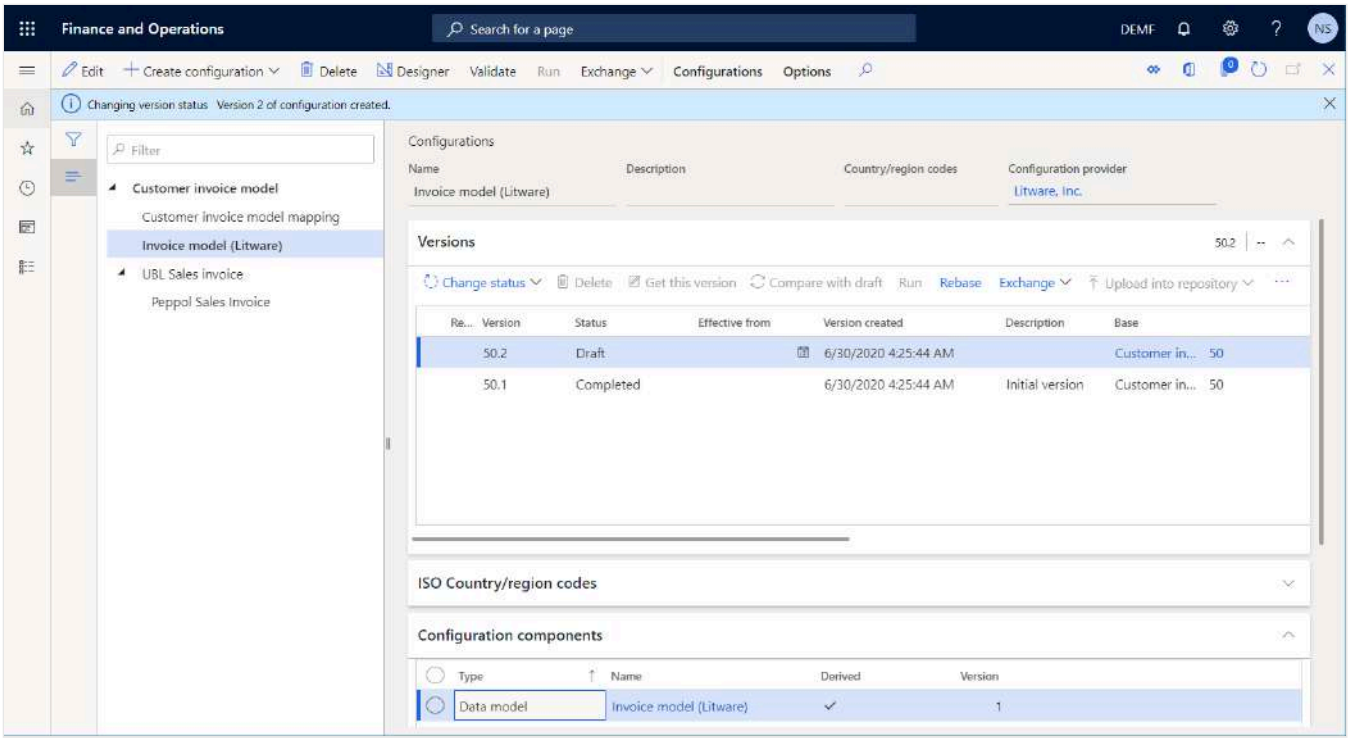
10. Close the **Data model designer** page.

Complete a custom data model configuration

Complete your work with version 50.1 of your custom ER data model configuration to make it available so that other custom ER configurations can be added.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Invoice model**, and select **Invoice model (Litware)**.
3. On the **Versions** FastTab, select **Change status** > **Complete**, and then select **OK**.

The status of version 50.1 changes from **Draft** to **Completed**, and the version becomes read-only. A new editable version, 50.2, is added and has a status of **Draft**. You can use this version to make further changes in your custom ER data model configuration.



Customize the model mapping configuration

As a user in the Electronic Reporting Developer role, you can design your custom ER model mapping.

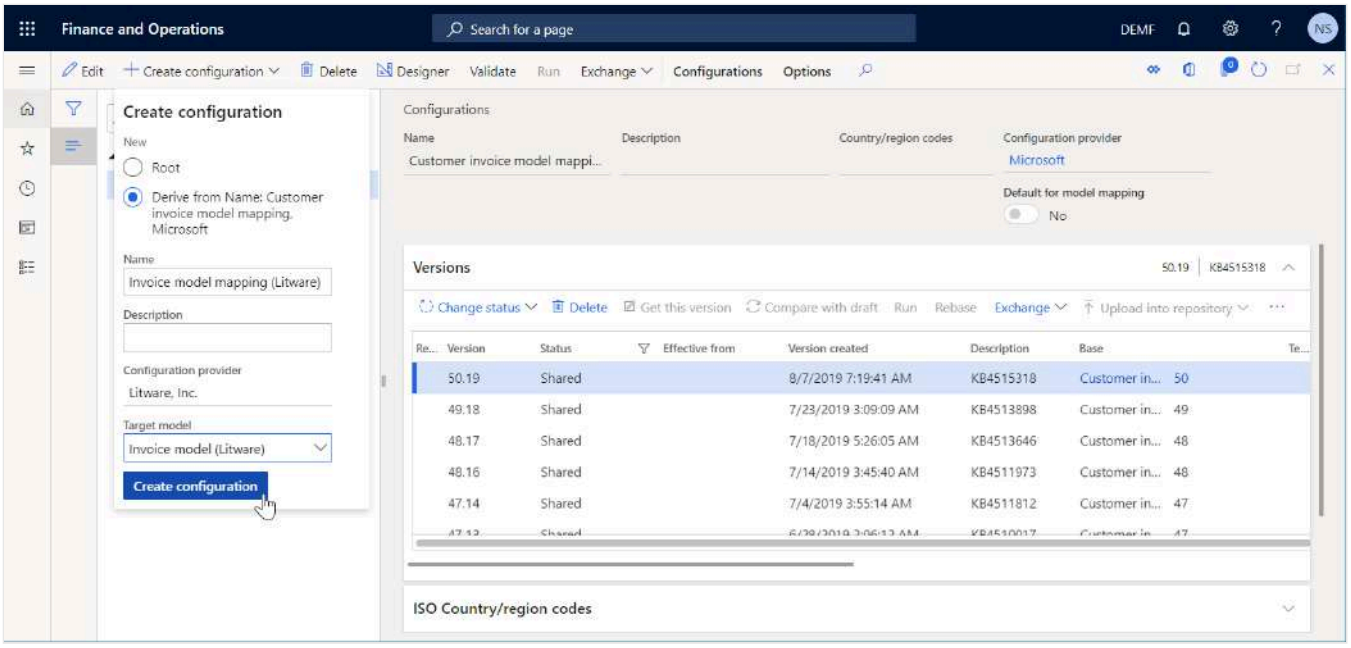
Add a custom model mapping configuration

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Customer invoice model**, and select **Customer invoice model mapping**.
3. On the Action Pane, select **Create configuration**.
4. In the drop-down dialog box, in the **New** field, select **Derive from Name: Customer invoice model mapping, Microsoft** to indicate that your new custom ER model mapping configuration should be based on the ER model mapping configuration.
5. In the **Name** field, enter **Invoice model mapping (Litware)**.
6. In the **Target model** field, select **Invoice model (Litware)**.

> **Important**

> This step is very important. If you omit it, you can't use your custom data model in the configured model mapping.

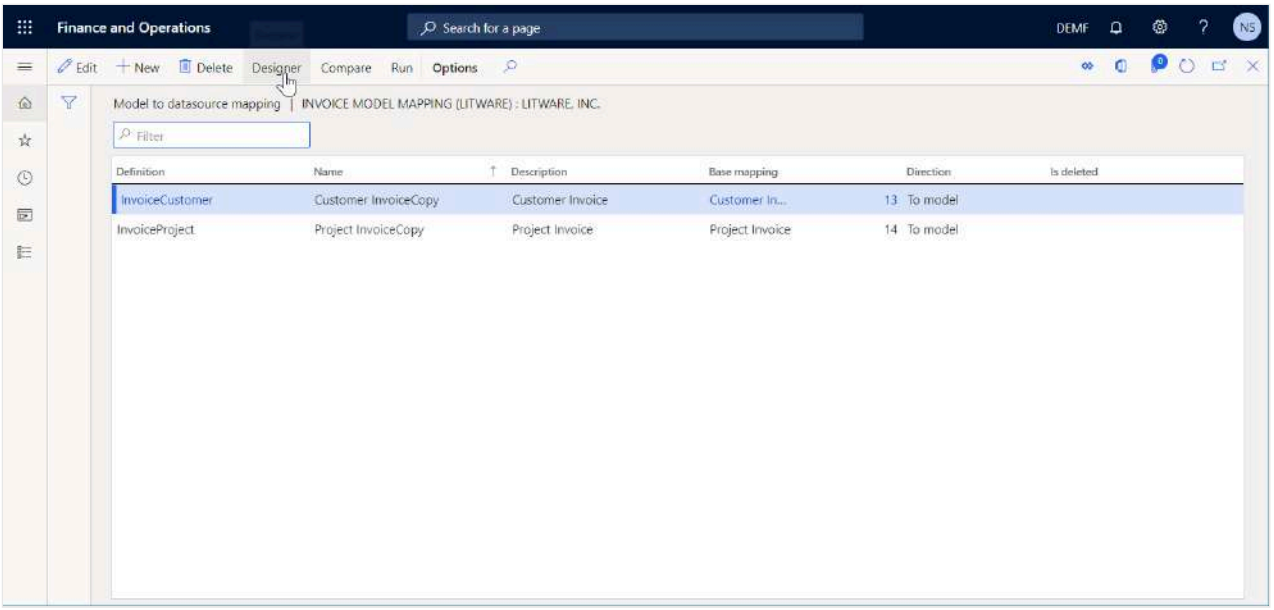
7. Select **Create configuration** to add the new ER configuration.



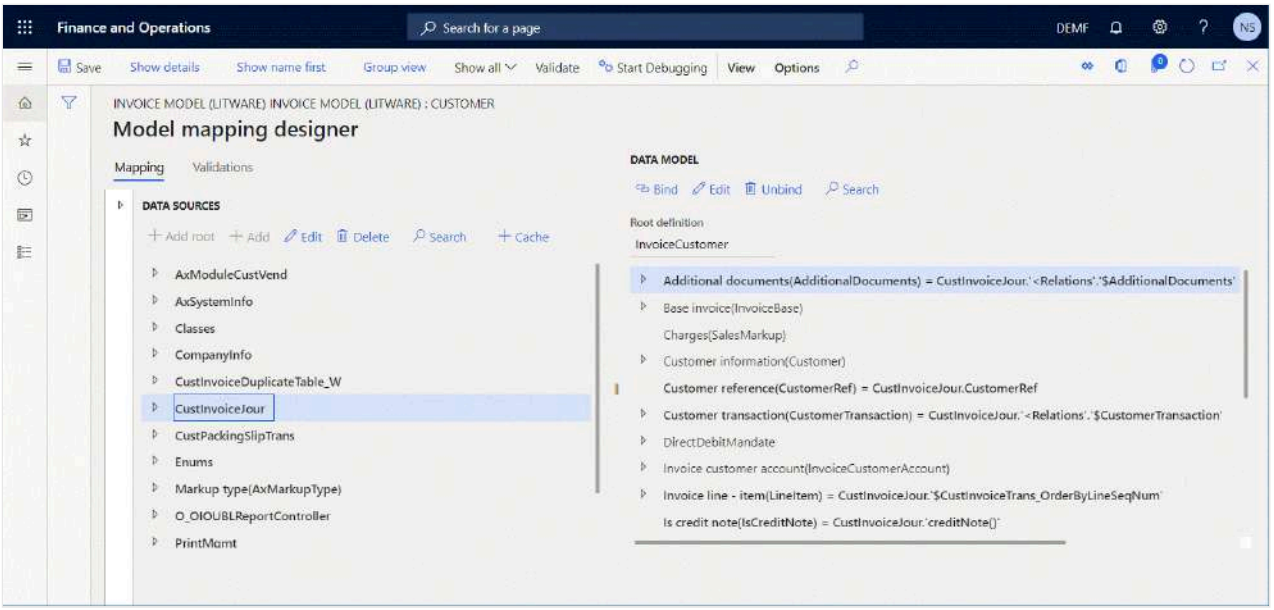
Configure a custom model mapping

You must modify your custom model mapping and specify how the custom **FederalTaxID_Litware** field of the custom data model should be filled in with application data at runtime.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Customer invoice model** > **Customer invoice model mapping**, and select **Invoice model mapping (Litware)**.
3. On the Action Pane, select **Designer**.
4. On the **Model to datasource mapping** page, select the **Customer invoice** mapping.



5. Select **Designer**.
6. On the **Model mapping designer** page, in the **Data sources** pane, expand the **CustInvoiceJour** data source that represents the **CustInvoiceJour** application table.
7. Under **CustInvoiceJour**, expand **Relations** to review the list of relations of the many-to-one (N:1) type for the **CustInvoiceJour** table.
8. Under **CustInvoiceJour** > **Relations**, expand **Customers (CustTable)** to access the fields and relations of the **Customers (CustTable)** table.
9. Select the **FederalTaxID_Custom** data source field that you implemented earlier.
10. In the **Data model** pane, expand **Customer information (Customer)**, and select the **FederalTaxID_Litware** data model field.
11. Select **Bind**.



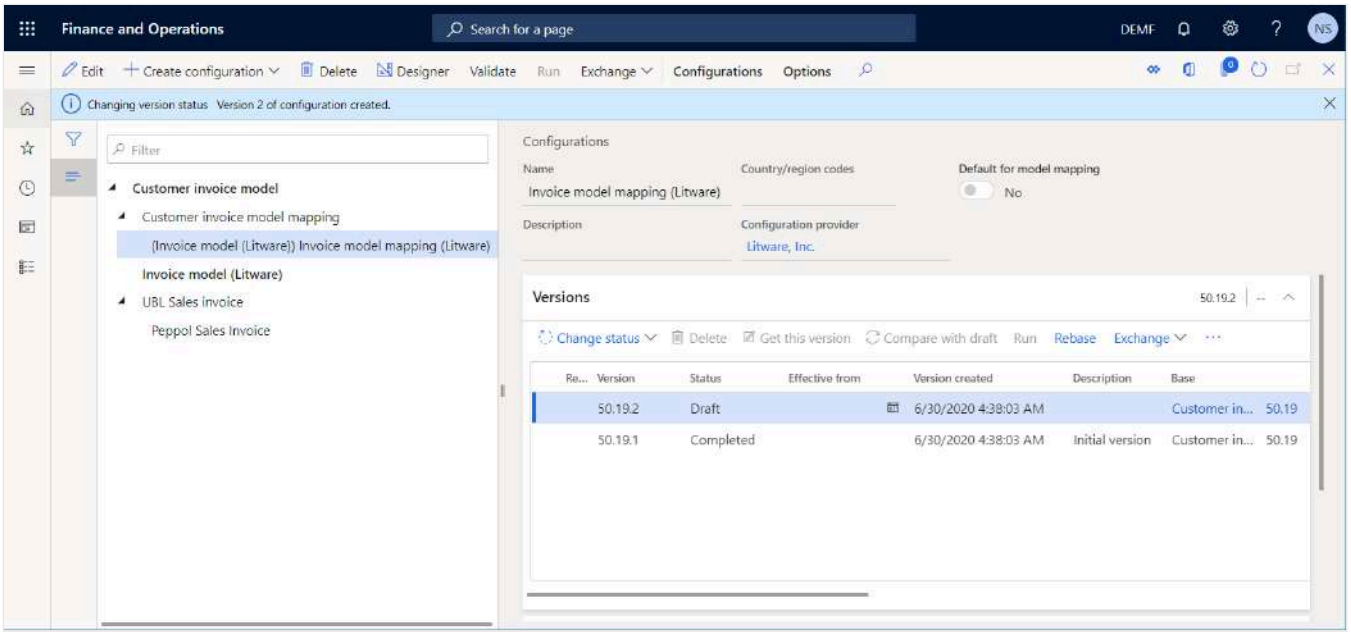
12. Select **Save**.
13. Close the **Model mapping designer** page.
14. Close the **Model to datasource mapping** page.

Complete a custom model mapping configuration

You must complete your work with version 50.19.1 of your custom ER model mapping configuration to make it available for use.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Customer invoice model** > **Customer invoice model mapping**, and select **Invoice model mapping (Litware)**.
3. On the **Versions** FastTab, select **Change status** > **Complete**, and then select **OK**.

The status of version 50.19.1 changes from **Draft** to **Completed**, and the version becomes read-only. A new editable version, 50.19.2, is added and has a status of **Draft**. You can use this version to make further changes in your custom ER model mapping configuration.



> **Note**
>
> The supported configuration lifecycle doesn't cover the lifecycle of database changes. If you export version 50.19.1 of the **Invoice model mapping (Litware)** configuration from the current Finance instance and try to import it into another instance that doesn't contain the custom **FederalTaxID_Custom** field in the **CustTable** table, an exception occurs. The exception states that the imported ER configuration isn't compatible with the metadata of the target Finance instance.

Customize the format configuration

As a user in the Electronic Reporting Functional Consultant role, you can design your custom ER format.

Add a custom format configuration

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Customer invoice model** > **UBL Sales invoice**, and select **Peppol Sales Invoice**.
3. On the Action Pane, select **Create configuration**.
4. In the drop-down dialog box, in the **New** field, select **Derive from Name: Peppol Sales Invoice, Microsoft** to indicate that your custom ER format configuration should be based on the ER format configuration.

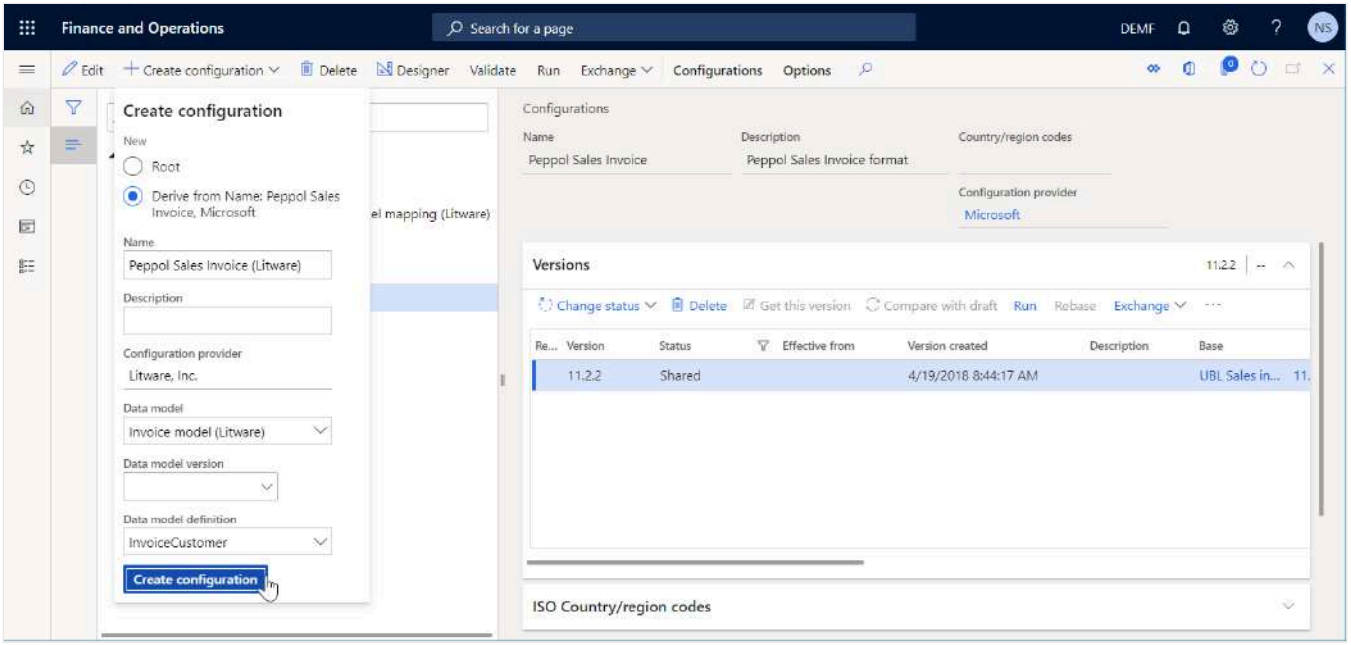
5. In the **Name** field, enter **Peppol Sales Invoice (Litware)**.

6. In the **Data model** field, select **Invoice model (Litware)** to use your custom data model and model mapping components.

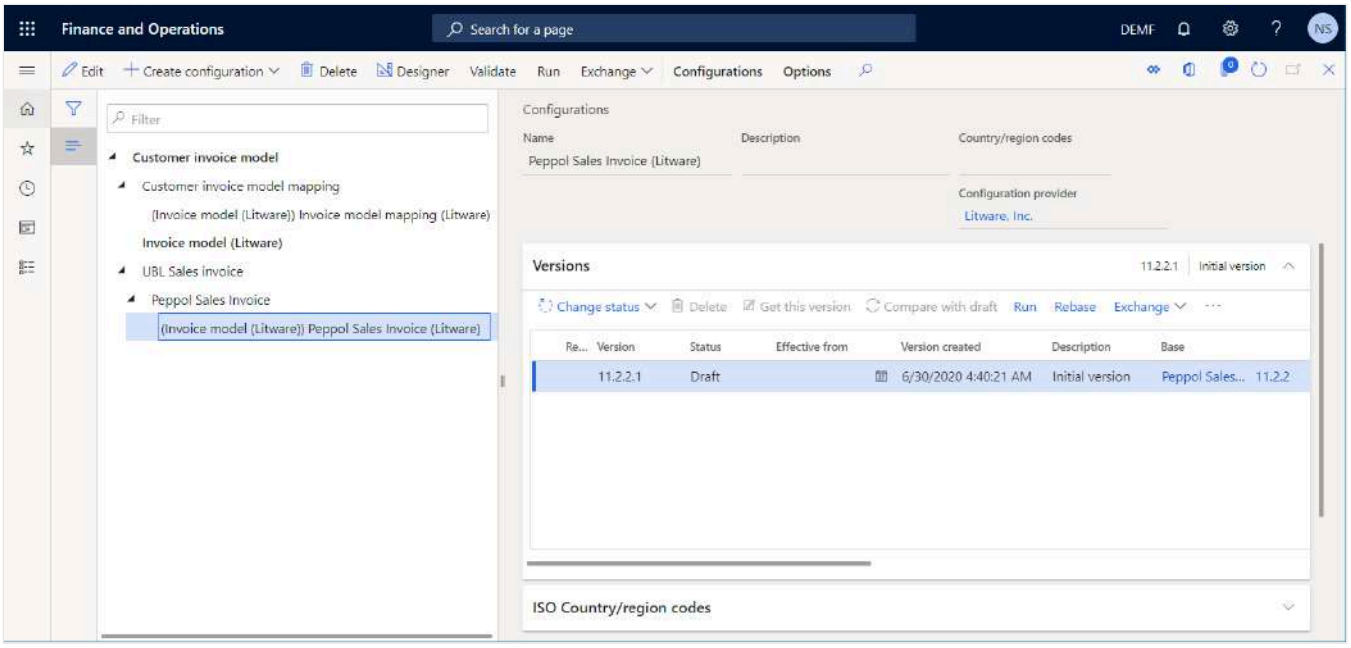
> **Note**
>
> This step is very important. If you omit it, you can't use your custom data model in the configured format.

7. In the **Data model** field, select the **InvoiceCustomer** root definition.

8. Select **Create configuration** to add the new ER configuration.



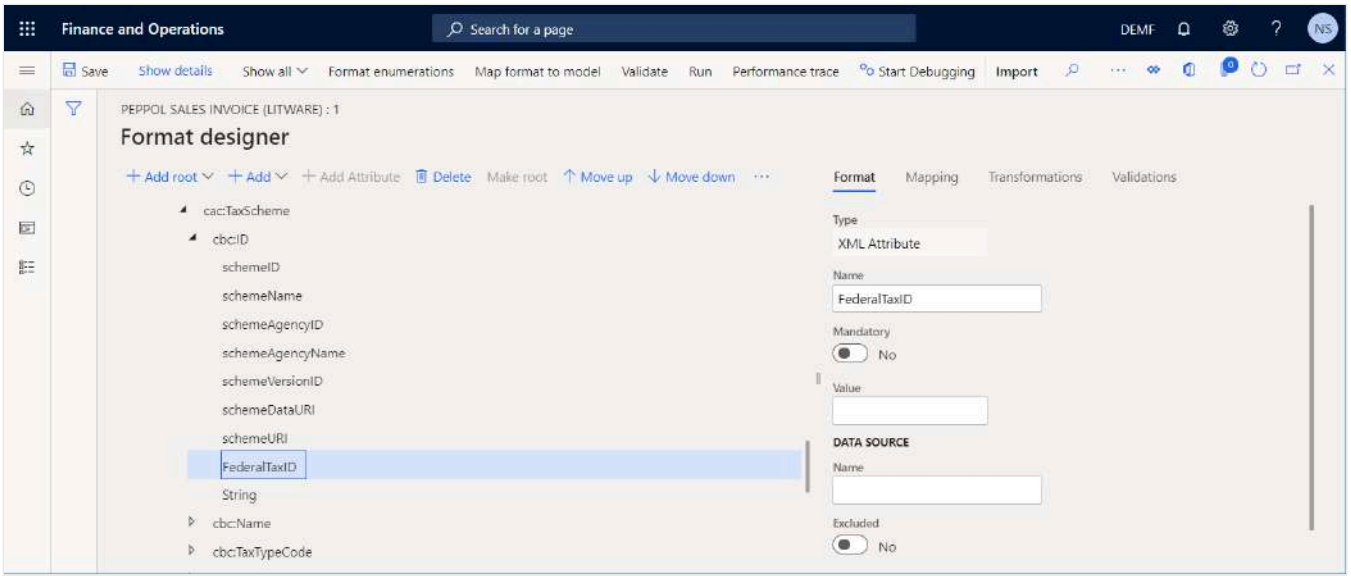
You can now use the ER Operations designer to edit version 11.2.2.1 of the **Peppol Sales Invoice (Litware)** ER configuration in **Draft** status.



Configure a custom format

Modify your custom format by adding a new format element to fill in the value of an invoiced customer's federal tax identification code.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Customer invoice model** > **UBL Sales invoice** > **Peppol Sales Invoice**, and select **Peppol Sales Invoice (Litware)**.
3. On the Action Pane, select **Designer**.
4. In the format tree, expand **XMLHeader** > **Invoice** > **cac:AccountingCustomerParty** > **cac:Party** > **cac:PartyTaxScheme** > **cac:TaxScheme**, and select **cbc:ID**.
5. Select **Add**, and then select **XML** > **Attribute**.
6. In the **Component property** dialog box, in the **Name** field, enter **FederalTaxID**.
7. Select **OK** to add a new format element to create a new **FederalTaxID** XML attribute in a generated XML file.
8. In the format tree, under **XMLHeader** > **Invoice** > **cac:AccountingCustomerParty** > **cac:Party** > **cac:PartyTaxScheme** > **cac:TaxScheme** > **cbc:ID**, select **FederalTaxID**.
9. Select **Move up**.

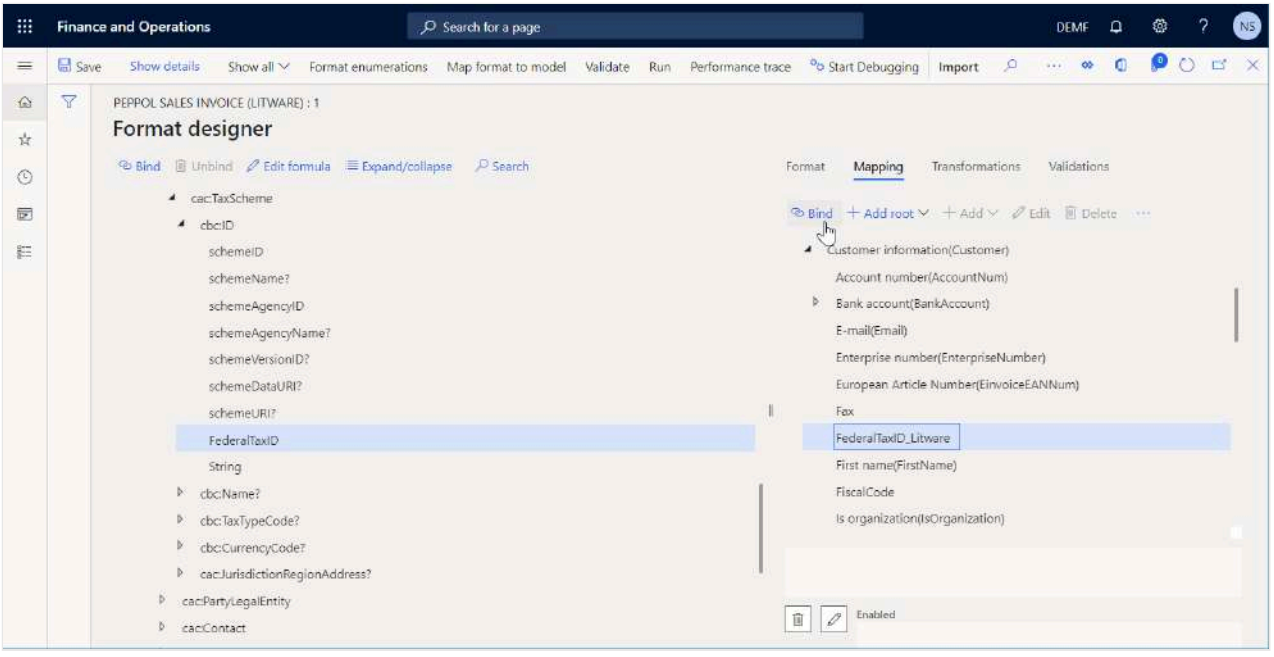


Configure a custom format mapping

1. On the **Format designer** page, on the **Mapping** tab, expand the **Invoice** data source of the **Model** type.

2. Under **Invoice**, expand **Customer information (Customer)**, and select **FederalTaxID_Litware**.

3. Select **Bind**.



4. Select the **Invoice** data source of the **Model** type, and then select **Edit**.

5. In the **Version** field, select version **1** of your custom data model, and then select **OK**.

6. Select **Save**.

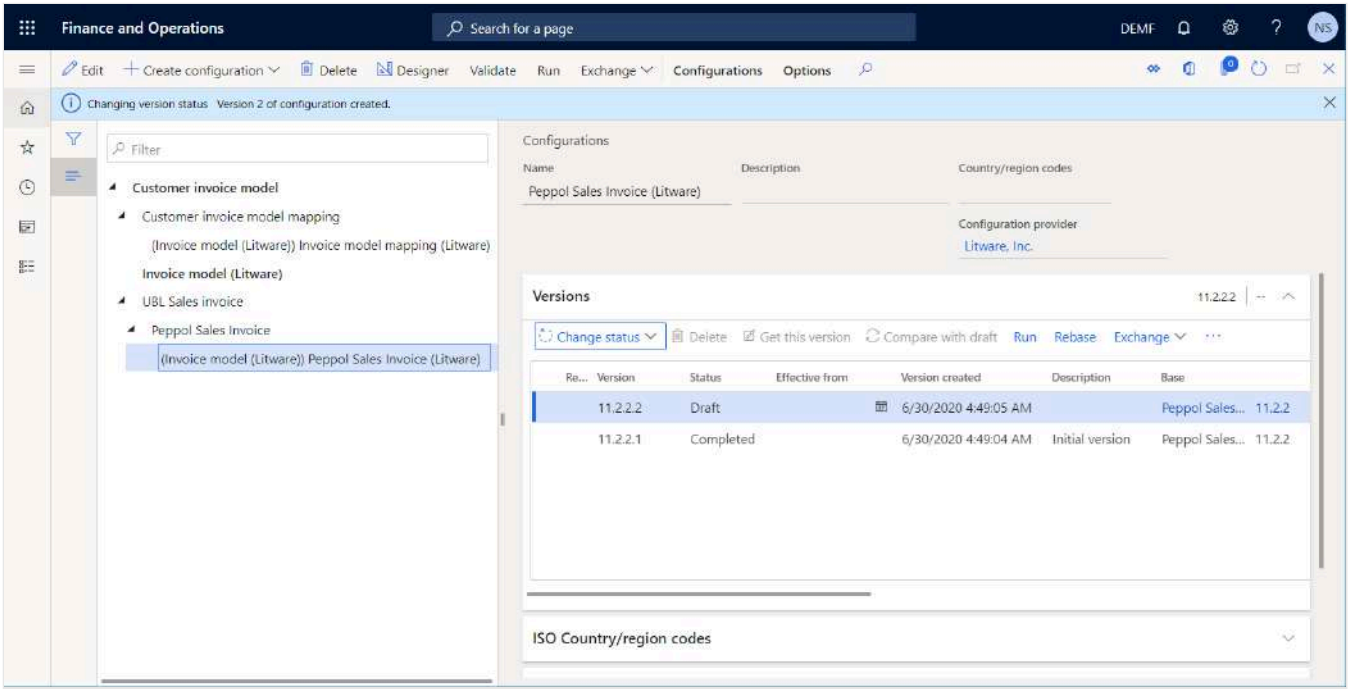
7. Close the **Format designer** page.

Complete a custom format configuration

Complete your work with version 11.2.2.1 of your custom ER format configuration to make it available for use.

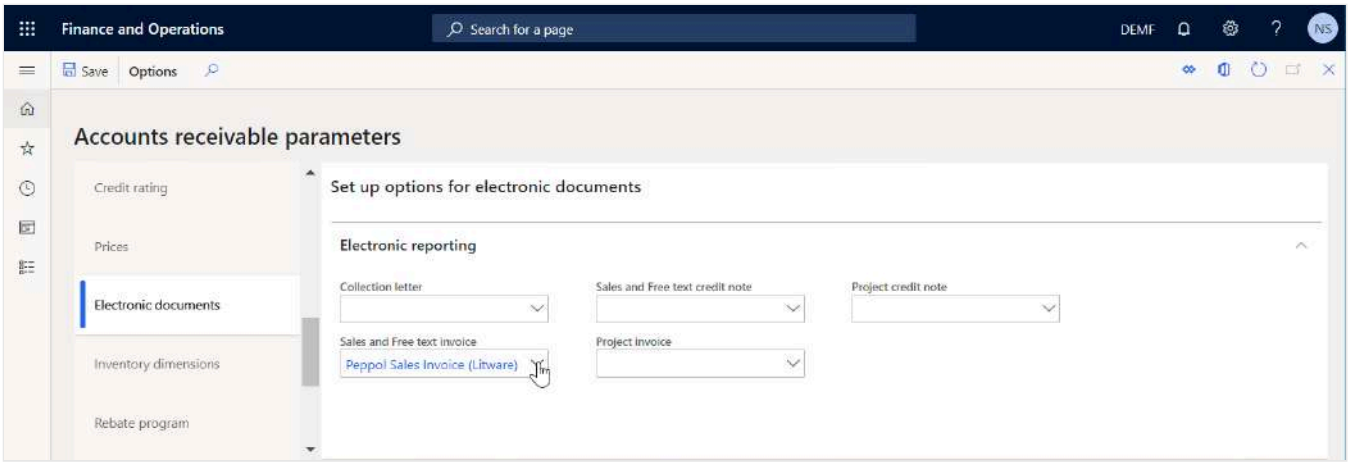
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Customer invoice model** > **UBL Sales invoice** > **Peppol Sales Invoice**, and select **Peppol Sales Invoice (Litware)**.
3. On the **Versions** FastTab, select **Change status** > **Complete**, and then select **OK**.

The status of version 11.2.2.1 changes from **Draft** to **Completed**, and the version becomes read-only. The system adds a new editable version, 11.2.2.2, with a status of **Draft**. Use this version to make further changes in your custom ER format configuration.



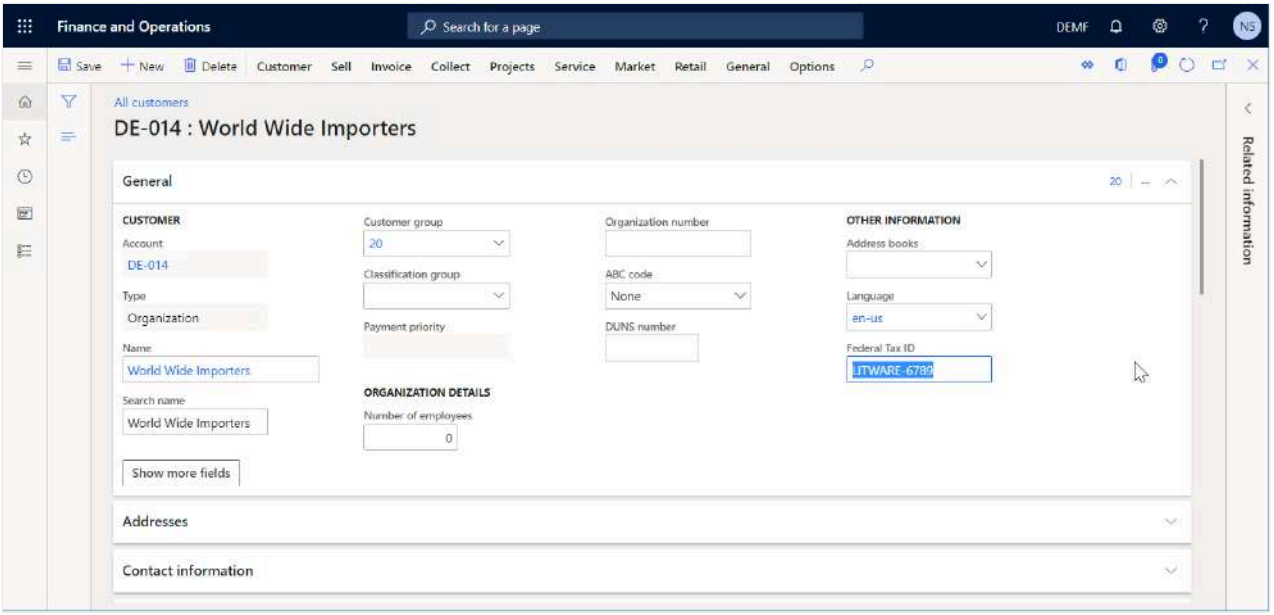
Configure the Accounts receivable parameters to start using custom ER configurations

1. Go to **Accounts receivable** > **Setup** > **Accounts receivable parameters**.
2. On the **Electronic documents** tab, in the **Electronic reporting** section, select **Peppol Sales Invoice (Litware)** in the **Sales and Free text invoice** field.
3. Select **Save**.



Update a customer record by adding a federal tax identification code

1. Go to **Accounts receivable** > **Customers** > **All customers**.
2. On the **All customers** page, select the **DE-014** customer account link.
3. On the **General** section, enter **LITWARE-6789** in the **Federal Tax ID** field.
4. Select **Save**.



5. Close the **All customers** page.

Process a customer invoice by using custom ER configurations

Select and send a posted invoice

1. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.
2. On **Free text invoice**, select the invoice that you previously added and posted.
3. On the Action Pane, in the **Document** group, select **Send** > **Original**.
4. Close **Free text invoice**.

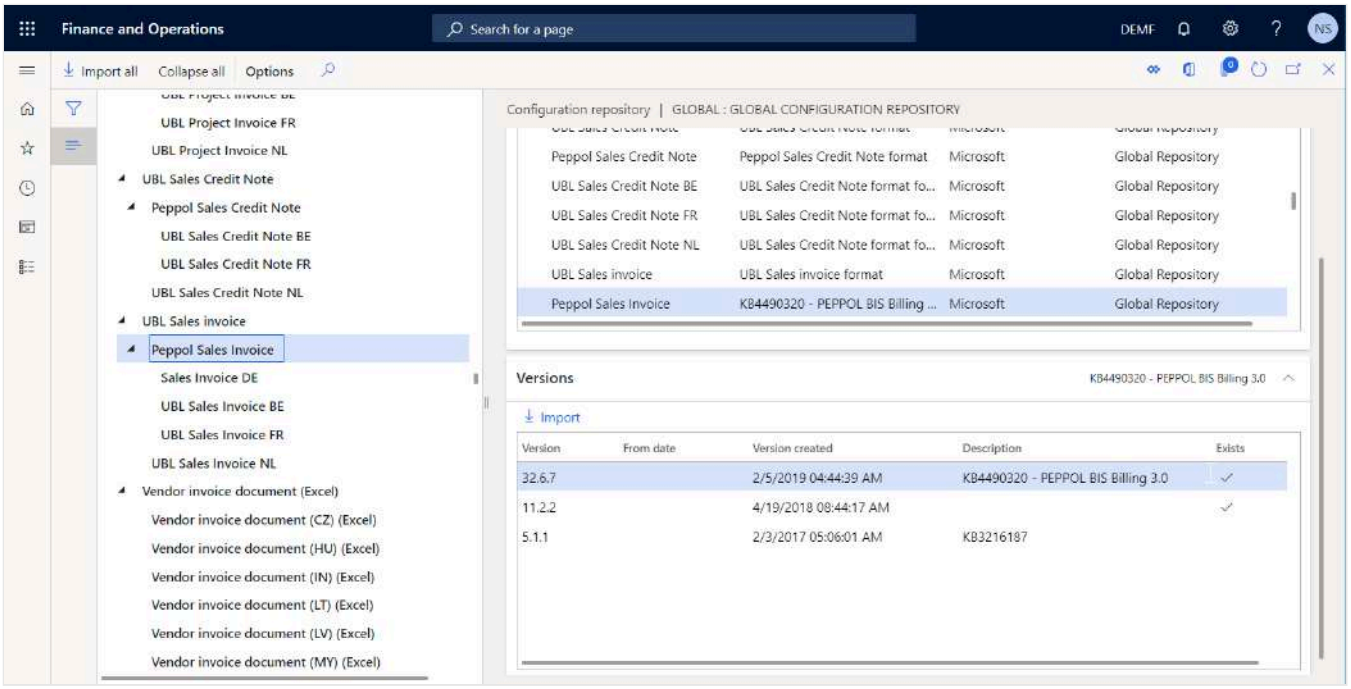
Analyze a generated e-invoice

1. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting jobs**.
2. On **Electronic reporting jobs**, select the latest record that has the task description **Send the eInvoice XML**.
3. Select **Show files** to access the list of generated files.
4. Select **Open** to download the e-invoice XML file.
5. Analyze the e-invoice XML file. Notice that, in accordance with your customization, the customer tax schema includes the custom **FederalTaxID** XML attribute in addition to the **schemeID** and **schemeAgencyID** XML attributes. The value of this new XML attribute is specified by the **LITWARE-6789** federal tax ID that you entered for an invoiced customer.

Import the latest versions of standard ER configurations

To keep the set of standard ER configurations in your Finance instance up to date, import new versions whenever they become available in the ER repository that you configured for the instance.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configuration providers** section, select the **Microsoft** tile, and then select **Repositories** to view the list of repositories for the Microsoft provider.
3. On **Configuration repositories**, select the repository of the **Global** type, and then select **Open**. If you're prompted for authorization to connect to Regulatory Configuration Service, follow the authorization instructions.
4. On **Configuration repository**, in the configuration tree in the left pane, select the **Peppol Sales Invoice** format configuration.
5. On the **Versions** FastTab, select version **32.6.7** of the selected ER format configuration that supports customer electronic invoices in PEPPOL BIS 3 format. For more information, see KB4490320.
6. Select **Import** to download the selected version from the Global repository to the current Finance instance.



For information about how to automate this process, see Import updated versions of ER configurations.

Review the imported ER configurations

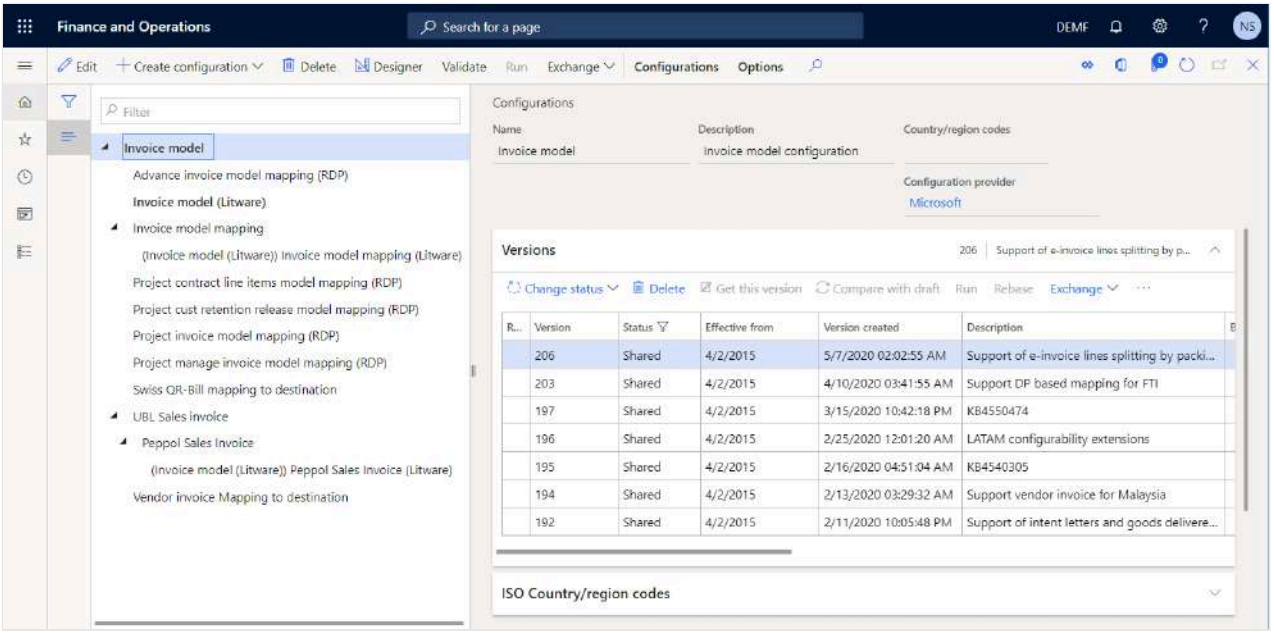
1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configurations** section, select the **Reporting configurations** tile.
3. Expand the **Configuration components** FastTab.

4. In the configuration tree in the left pane, expand **Invoice model**. The name of **Customer invoice model** changed to **Invoice model** in one of the imported ER data model configurations.
5. In the configuration tree in the left pane, expand **Invoice model mapping**. The name of **Customer invoice model mapping** changed to **Invoice model mapping** in one of the imported ER model mapping configurations.
6. Expand **UBL Sales invoice** > **Peppol Sales Invoice**.

In addition to the selected **Peppol Sales Invoice** ER format, the latest versions of other required ER configurations are imported. Because new versions of ER configurations are constantly published to the Global repository and Lifecycle Services to keep the corresponding ER solutions compliant with new requirements, the latest versions of the required data model configuration and its model mapping configurations are imported.

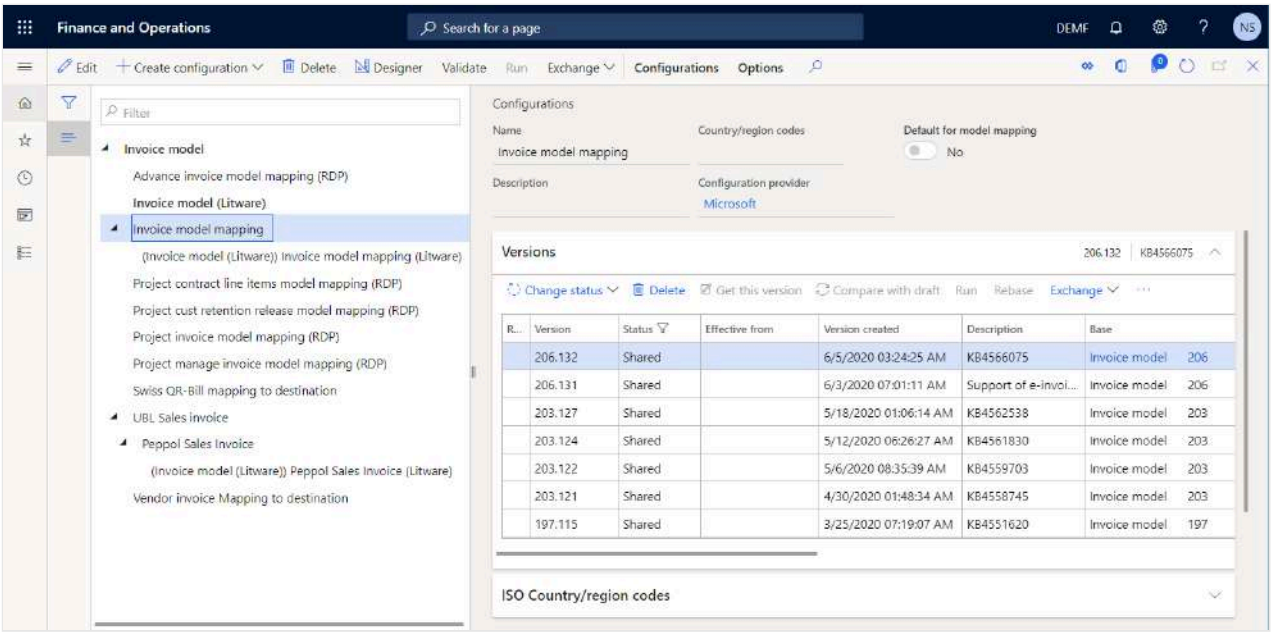
Make sure that the following ER configurations are eventually available in the configuration tree:

- **Invoice model** ER data model configuration:
  - Version 206 (or later) contains version 24 (or later) of the data model ER component that represents the data structure of the invoicing business domain. This ER configuration is imported as an ancestor of the latest available **Invoice model mapping** ER model mapping configuration.



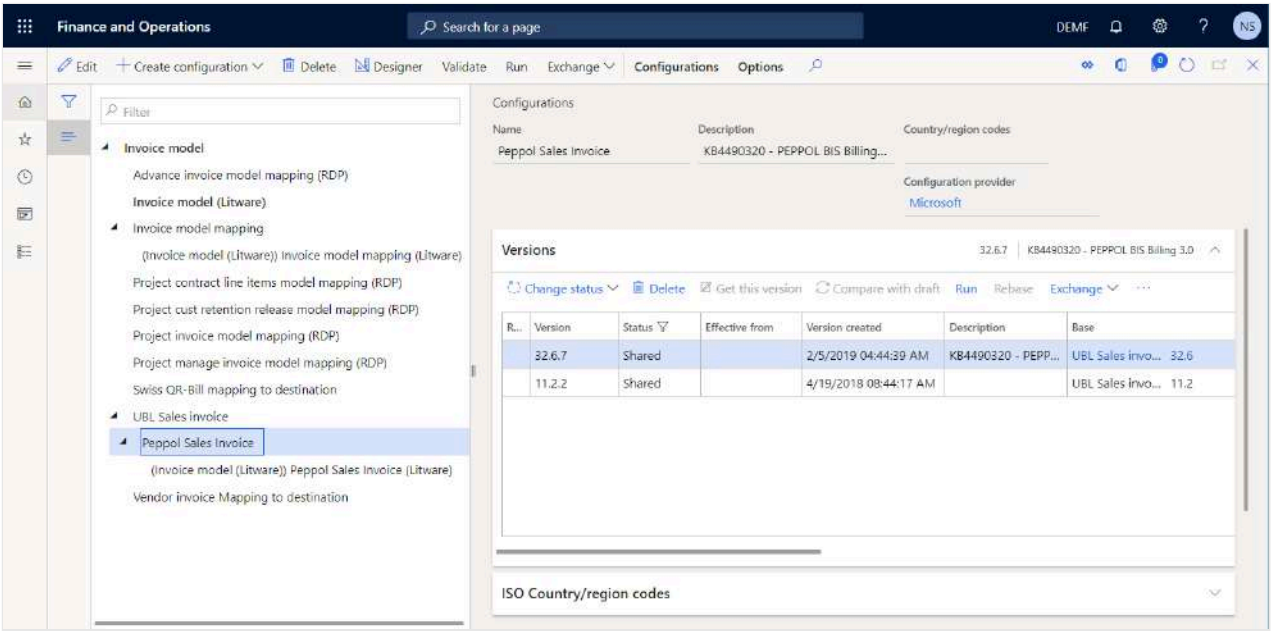
- **Invoice model mapping** ER model mapping configuration:
  - Version 206.132 (or later) is imported as the latest implementation of version 206 of the **Invoice model** ER data model configuration. It contains several model mapping ER

components that describe how the data model is filled in with application data at runtime.



- **UBL Sales invoice** ER format configuration:
  - Version 32.6 contains the format and format mapping ER components. The format component specifies the report layout. The format mapping component contains the model data source and specifies how this data source is used to fill in the report layout at runtime. This ER format is configured to generate e-invoices in UBL format. It's imported as a parent of the **Peppol Sales Invoice** ER format that you selected for import.

- **Peppol Sales Invoice** ER format configuration:
  - Version 32.6.7 contains the format and format mapping ER components that are configured to generate e-invoices in PEPPOL format.



Adopt the changes to the new standard ER configurations in your custom ER configurations

Adopt your custom ER data model

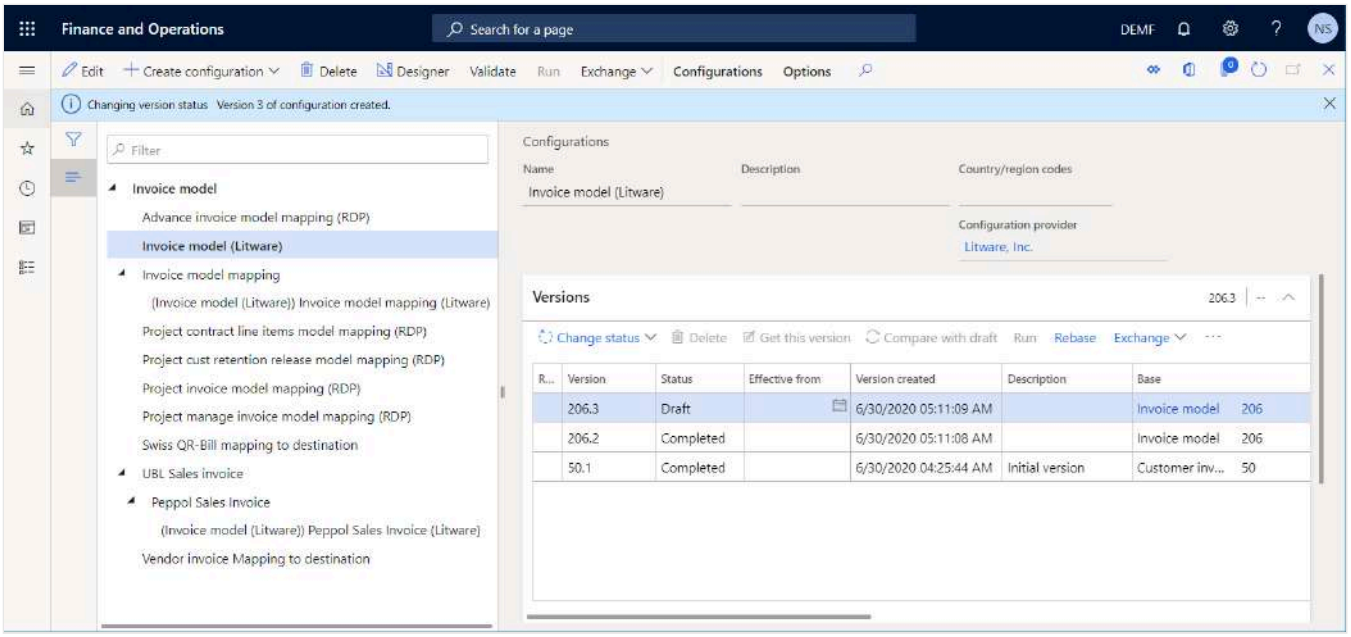
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Invoice model**, and select **Invoice model (Litware)**.
3. On the **Versions** FastTab, for draft version **50.2** of the selected data model configuration, select **Rebase**.
4. In the **Target version** field, confirm the selection of version **206** of the base ER data model configuration, and then select **OK**.

   The system renumbers the draft version of your custom ER data model configuration from **50.2** to **206.2** to indicate that it now contains your customization that was merged with the changes in the latest version (206) of the base ER data model configuration.

   > ⓘ **Note**
   >
   > The rebase action is reversible. To cancel this rebase, select version **50.1** of the **Invoice model (Litware)** model on the **Versions** FastTab, and then select **Get this version**. Version 206.2 is renumbered back to **50.2**, and the content of draft version 50.2 matches the content of version 50.1.

5. On the **Versions** FastTab, select **Change status** > **Complete**, and then select **OK**.

The status of version 206.2 changes from **Draft** to **Completed**, and the version becomes read-only. A new editable version, 206.3, is added and has a status of **Draft**. You can use this version to make further changes in your custom ER data model configuration.



Adopt your custom ER model mapping

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.

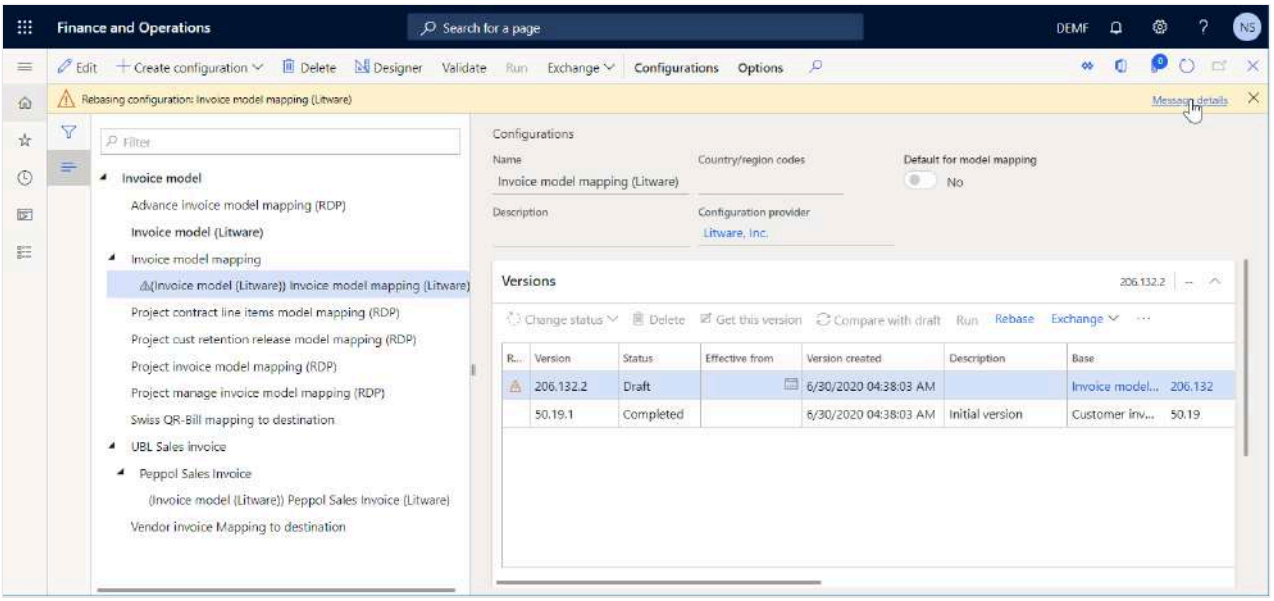
2. On **Configurations**, in the configuration tree in the left pane, expand **Invoice model** > **Invoice model mapping**, and select **Invoice model mapping (Litware)**.

3. On the **Versions** FastTab, for draft version **50.19.2** of the selected model mapping configuration, select **Rebase**.

4. In the **Target version** field, confirm the selection of version **206.132** of the base ER model mapping configuration, and then select **OK**.

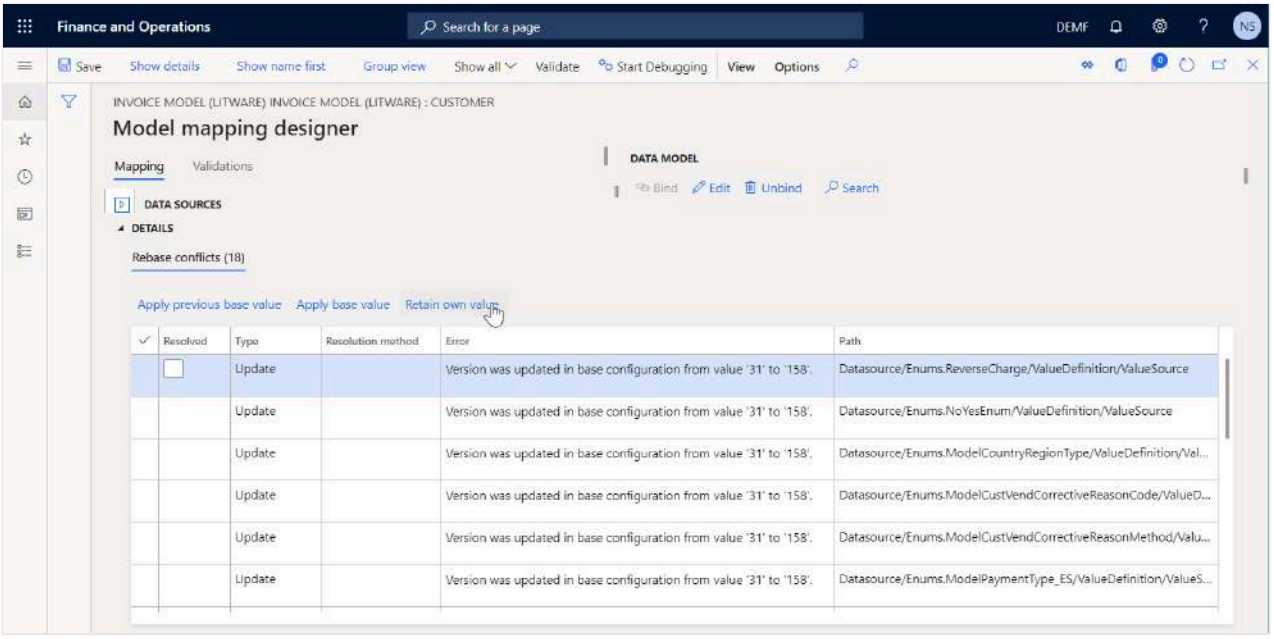
   The system renumbers the draft version of your custom ER model mapping configuration from **50.19.2** to **206.132.2** to indicate that it now contains your customization that was merged with the changes in the latest version (206.132) of the base ER model mapping configuration.

   The system discovers some rebase conflicts. You must now manually resolve those conflicts.



5. On the Action Pane, select **Designer**, and then, in the list of mappings, select **Customer Invoice**.

6. For each rebase conflict, select **Retain own value**, because you must keep the version number of your custom data model for every component that the system mentions.



7. Select **Save**, and then close the **Model mapping designer** page.

8. In the list of mappings, select **Project Invoice**.

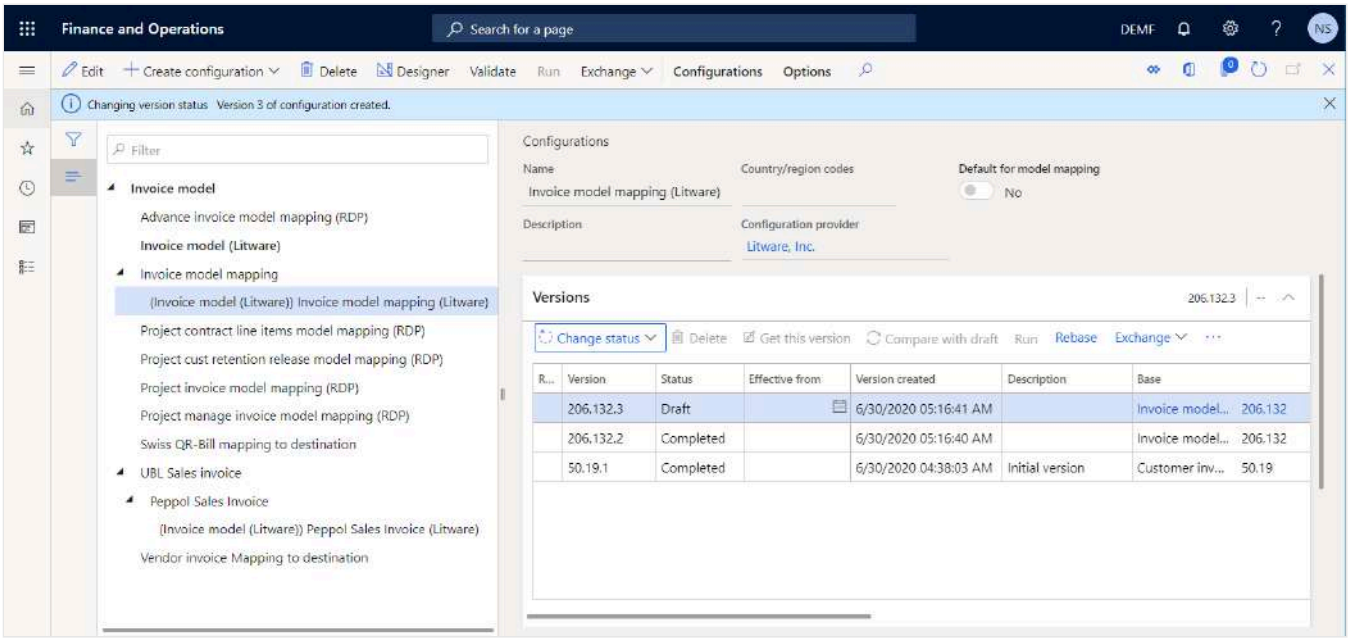
9. For each rebase conflict, select **Retain own value**, because you must keep the version number of your custom data model for every component that the system mentions.

10. Select **Save**, and then close the **Model mappings** page.

> **Note**
>
> The rebase action is reversible. To cancel this rebase, select version **50.19.1** of the **Invoice model mapping (Litware)** model mapping on the **Versions** FastTab, and then select **Get this version**. The system renumbers version 206.132.2 back to **50.19.2**, and the content of draft version 50.19.2 matches the content of version 50.19.1.

11. On the **Versions** FastTab, select **Change status** > **Complete**, and then select **OK**.

The system changes the status of version 206.132.2 from **Draft** to **Completed**, and makes the version read-only. The system adds a new editable version, 206.132.3, and sets its status to **Draft**. You can use this version to make further changes in your custom ER model mapping configuration.



Adopt your custom ER format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree in the left pane, expand **Invoice model** > **UBL Sales invoice** > **Peppol Sales Invoice**, and select **Peppol Sales Invoice (Litware)**.
3. On the **Versions** FastTab, for draft version **11.2.2.2** of the selected format configuration, select **Rebase**.
4. In the **Target** version field, confirm the selection of version **32.6.7** of the base ER format configuration, and then select **OK**.

The system renumbers the draft version of your custom ER format configuration from **11.2.2.2** to **32.6.7.2** to indicate that it now contains your customization that was merged with the changes in the latest version (32.6.7) of the base ER format configuration.

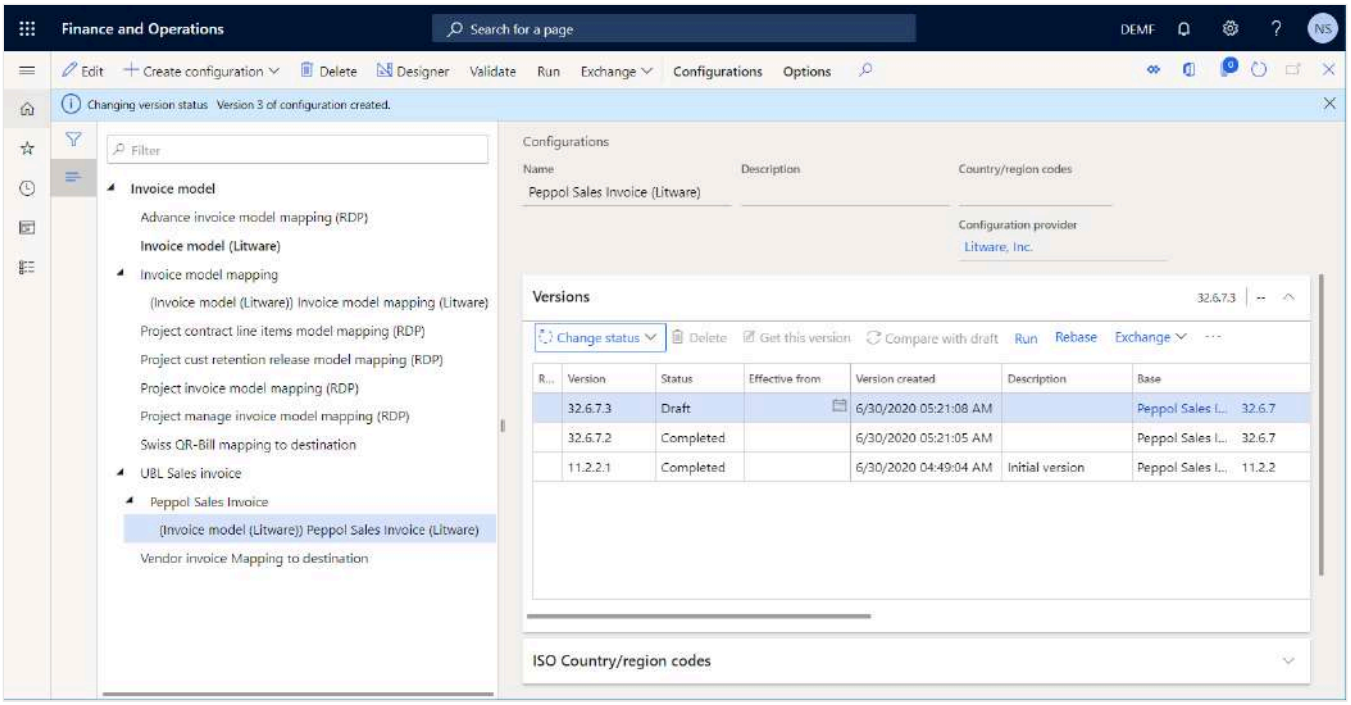
The system discovers some rebase conflicts. You must now manually resolve those conflicts.

5. On the Action Pane, select **Designer**.
6. For each rebase conflict, select **Retain own value**, because you must keep the version number of your custom data model for every component that the system mentions.
7. Select **Save**.
8. On the **Mapping** tab, select the **Invoice** data source of the **Model** type, and then select **Edit**.
9. In the **Version** field, select version **2** of your custom data model, and then select **OK**.
10. Select **Save**.

> ⓘ **Note**
>
> The rebase action is reversible. To cancel this rebase, select version **11.2.2.1** of the **Peppol Sales Invoice (Litware)** format on the **Versions** FastTab, and then select **Get this version**. Version 32.6.7.2 is renumbered back to **11.2.2.2**, and the content of draft version 11.2.2.2 matches the content of version 11.2.2.1.

11. Close the **Format designer** page.
12. On the **Versions** FastTab, select **Change status** > **Complete**, and then select **OK**.

The status of version 32.6.7.2 changes from **Draft** to **Completed**, and the version becomes read-only. A new editable version, 32.6.7.3, is added and has a status of **Draft**. You can use this version to make further changes in your custom ER format configuration.



Process a customer invoice by using new versions of the custom ER configurations

Select and send a posted invoice

1. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.
2. On **Free text invoice**, select the invoice that you previously added and posted.
3. On the Action Pane, in the **Document** group, select **Send** > **Original**.

> **Note**
>
> Because you now have two versions of the **Peppol Sales Invoice (Litware)** ER format configuration, and neither version has an effective date value, the latest version is used to generate an e-invoice.

4. Close **Free text invoice**.

Analyze a generated e-invoice

1. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting jobs**.
2. On **Electronic reporting jobs**, select the most recent record that has the task description **Send the eInvoice XML**.

3. Select **Show files** to access the list of generated files.

4. Select **Open** to download the e-invoice XML file.

5. Analyze the e-invoice XML file. Notice that, in accordance with your customization, the customer tax schema still contains the custom **FederalTaxID** XML attribute in addition to the **schemeID** and **schemeAgencyID** XML attributes. Additionally, because the changes in the new version of the base **UBL Sales invoice** format were merged with your customization, the text of the **cbc:CustomizationID** XML element changed from `urn:www.cenbii.eu:transaction:biicoretrdm010:ver1.0:#` `urn:www.peppol.eu:bis:peppol5a:ver1.0` to `urn:cen.eu:en16931:2017#compliant#urn:fdc:peppol.eu:2017:poacc:billing:3.0`.

Use JOIN data sources to get data from multiple application tables in Electronic reporting (ER) model mappings

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

While configuring Electronic reporting (ER) model mappings or formats, you can add required data sources of the **Join** type. At design time, you configure a **Join** data source as a set of several data sources, each of which returns a list of records. For every data source except the first one, you need to define the necessary conditions to join records of the current and previous data sources. At runtime, a configured data source of **Join** type returns a single joined list of records containing fields from the records of nested data sources.

The following types of joins are currently supported:

- Outer (left) join:
  - Join all records of the first (left-most) data source and then any matching records of the second (right-most) data source according to the configured conditions.
- Inner (right) join:
  - Join only records of the first (left-most) data source and only records of the second (right-most) data source that match each other according to the configured conditions.

In the configured **Join** data source, when all data sources are the **Table records** type, execution of the Join data source can be performed at the database level using a single SQL statement. This statement reduces the number of database calls, which improves model-mapping performance. Otherwise, execution of **Join data** source is performed in memory.

> **Note**

Using the **VALUEIN** function in ER expressions that specify conditions for joining records in data sources of Join type isn't supported yet. For more information about this function, see Formula designer in Electronic reporting.

To learn more about this feature, complete the example in this article.

Example: Use JOIN data sources in ER model mappings

The following steps explain how the system administrator or Electronic reporting developer can configure an Electronic reporting (ER) model mapping to get data from multiple application tables at once by using data sources of the **Join** type to improve data access performance. You can perform these steps for any company of Dynamics 365 Finance or Regulatory Configuration Services (RCS).

Prerequisites

To complete the examples in this article, you must have access to one of the following roles, depending on the service you use to complete these steps:

Access to Finance for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

Access to RCS for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

You must also complete the steps in the Create a configuration provider and mark it as active procedure.

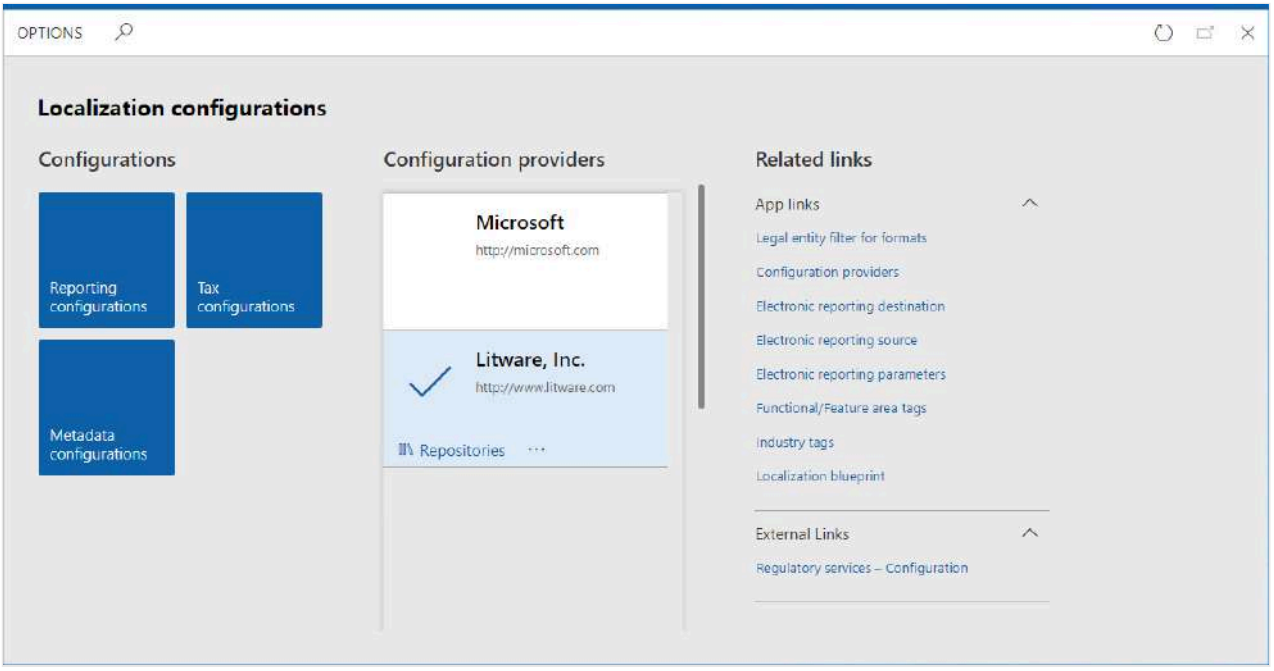
In advance, download and save the following sample ER configuration files:

Expand table

Content description	File name
Sample **ER data model** configuration file, which is used as the data source for the examples.	Model to learn JOIN data sources.version.1.1.xml
Sample **ER model mapping** configuration file, which implements the ER data model for the examples.	Mapping to learn JOIN data sources.version.1.1.xml
Sample **ER format** configuration file. This file describes the data to populate the ER format component for the examples.	Format to learn JOIN data sources.version.1.1.xml

Activate a configurations provider

1. Access either Finance or RCS in the first session of your web browser.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. On the **Localization configurations** page, in the **Configuration providers** section, make sure that the configuration provider for the Litware, Inc. sample company is listed, and that it's marked as **Active**. If you don't see this configuration provider, follow the steps in Create a configuration provider and mark it as active procedure.



Import sample ER configuration files

1. Select **Reporting configurations**.
2. Import the ER data model configuration file.
   a. Select **Exchange**.
   b. Select **Load from XML file**.

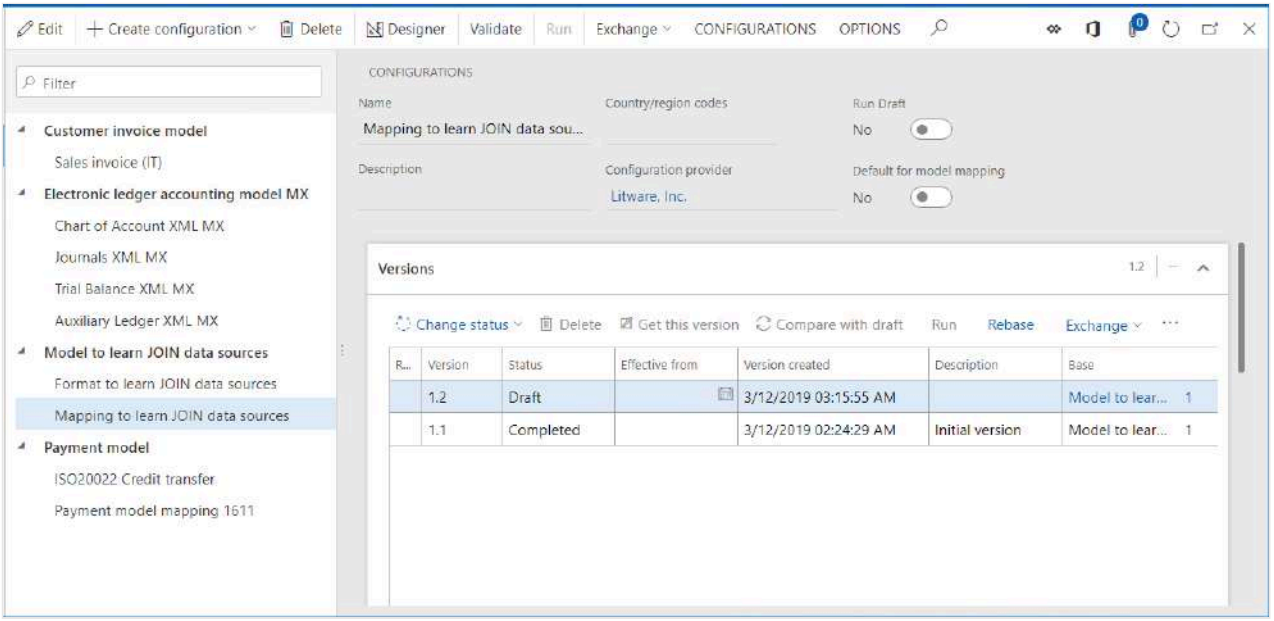
c. Select **Browse** to find the **Model to learn JOIN data sources.version.1.1.xml** file.
d. Select **OK**.

3. Import the ER model-mapping configuration file.
   a. Select **Exchange**.
   b. Select **Load from XML file**.
   c. Select **Browse** to find the **Mapping to learn JOIN data sources.version.1.1.xml** file.
   d. Select **OK**.

4. Import the ER format configuration file.
   a. Select **Exchange**.
   b. Select **Load from XML file**.
   c. Select **Browse** to find the **Format to learn JOIN data sources.version.1.1.xml** file.
   d. Select **OK**.

5. In the configurations tree, expand the **Model to learn JOIN data sources** item as well as other model items (when available).

6. Observe the list of ER configurations in the tree as well as version details on the **Versions** FastTab – they are the source of data for your sample report.

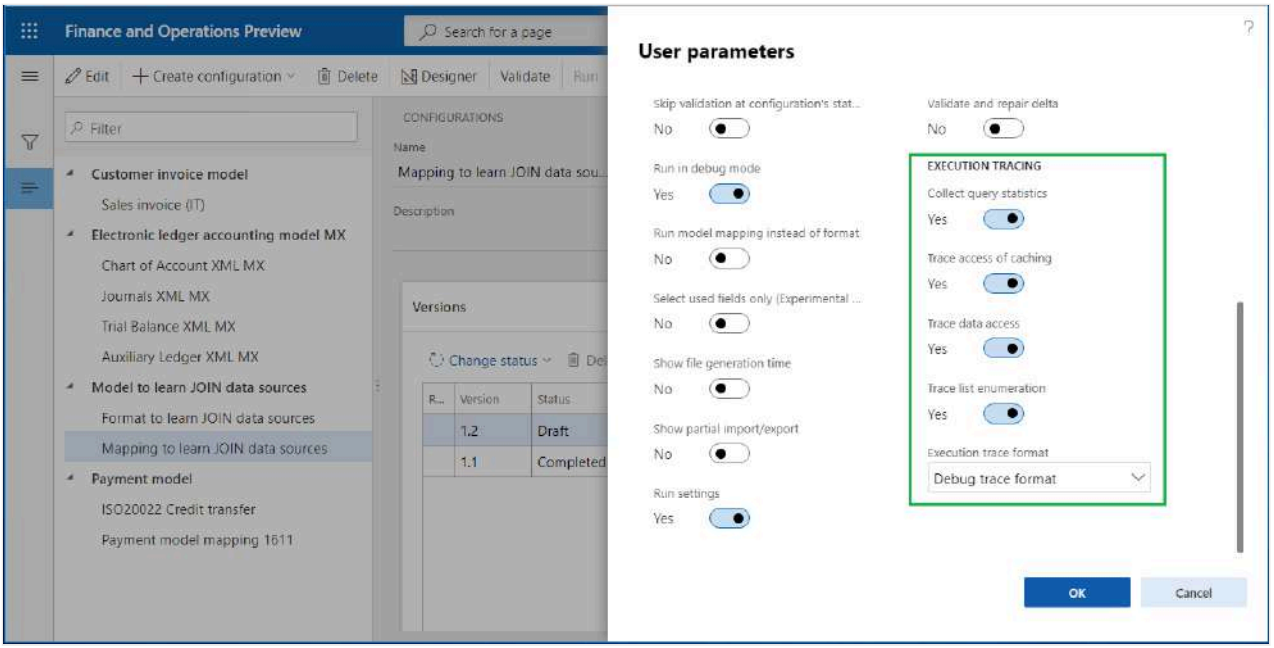


Turn on execution trace options

1. Select **CONFIGURATIONS**.

2. Select **User parameters**.

3. Set execution trace parameters as shown in the following screenshot.



When you turn on these parameters, the system generates an execution trace for every execution of the imported ER format file. By using the details in the generated execution trace, you can analyze the execution of ER format and ER model-mapping components. For more information about the ER execution trace feature, see Trace execution of ER format to troubleshoot performance issues.

Review ER model mapping (part 1)

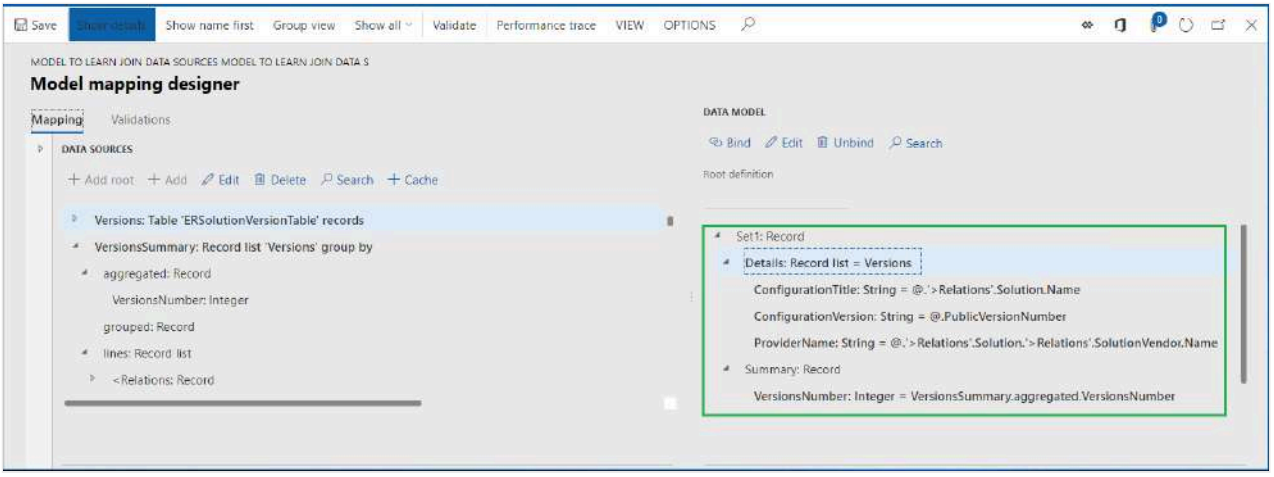
Review the settings of the ER model-mapping component. The component is configured to access information about versions of ER configurations, details of configurations, and configuration providers without using data sources of the **Join** type.

1. Select **Mapping to learn JOIN data sources** configuration.
2. Select **Designer** to open the list of mappings.
3. Select **Designer** to review the mapping details.
4. Select **Show details**.
5. In the configurations tree, expand the **Set1** and **Set1.Details** data model items:
   a. Binding **Details: Record list = Versions** indicates that the **Set1.Details** item is bound to the **Versions** data source returning records of the **ERSolutionVersionTable** table. Each record of this table represents a single version of an ER configuration. The content of this table is presented in the **Versions** FastTab on the **Configurations** page.
   b. Binding **ConfigurationVersion: String = @.PublicVersionNumber** means that the value of the public version of each ER configuration's version comes from the

PublicVersionNumber field of the **ERSolutionVersionTable** table and goes to the **ConfigurationVersion** item.

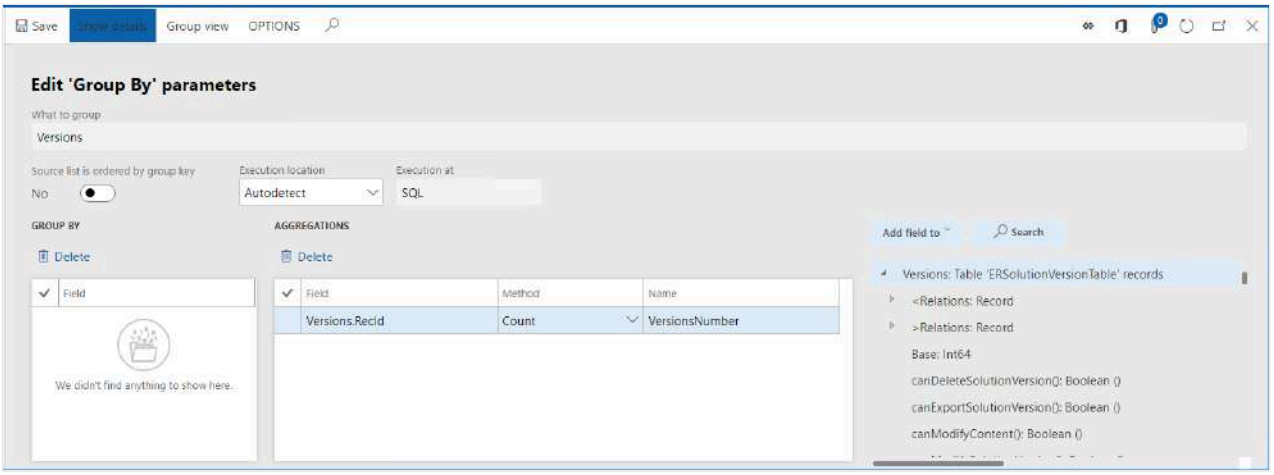
c. Binding **ConfigurationTitle: String = @.'>Relations'.Solution.Name** indicates that the name of an ER configuration comes from the **Name** field of the **ERSolutionTable** table, accessed by using the many-to-one relation ('>**Relations**') between the **ERSolutionVersionTable** and **ERSolutionTable** tables. Names of ER configurations of the current application instance are presented in the configurations tree on the **Configurations** page.

d. Binding **@.'>Relations'.Solution.'>Relations'.SolutionVendor.Name** means that the name of the configuration provider that owns the current configuration comes from the **Name** field of the **ERVendorTable** table, accessed by using the many-to-one relation between **ERSolutionTable** and **ERVendorTable** tables. Names of ER configuration providers are presented in the configurations tree on the **Configurations** page on the page header for each configuration. The entire list of ER configuration providers can be found on the **Organization administration** > **Electronic reporting** > **Configuration provider** table page.



6. In the configurations tree, expand the **Set1.Summary** data model item:

a. Binding **VersionsNumber: Integer = VersionsSummary.aggregated.VersionsNumber** indicates that the **Set1.Summary.VersionsNumber** item is bound to the **VersionsNumber** aggregation field of the **VersionsSummary** data source of the **GroupBy** type that you configured to return the number of records of the **ERSolutionVersionTable** table via the **Versions** data source.

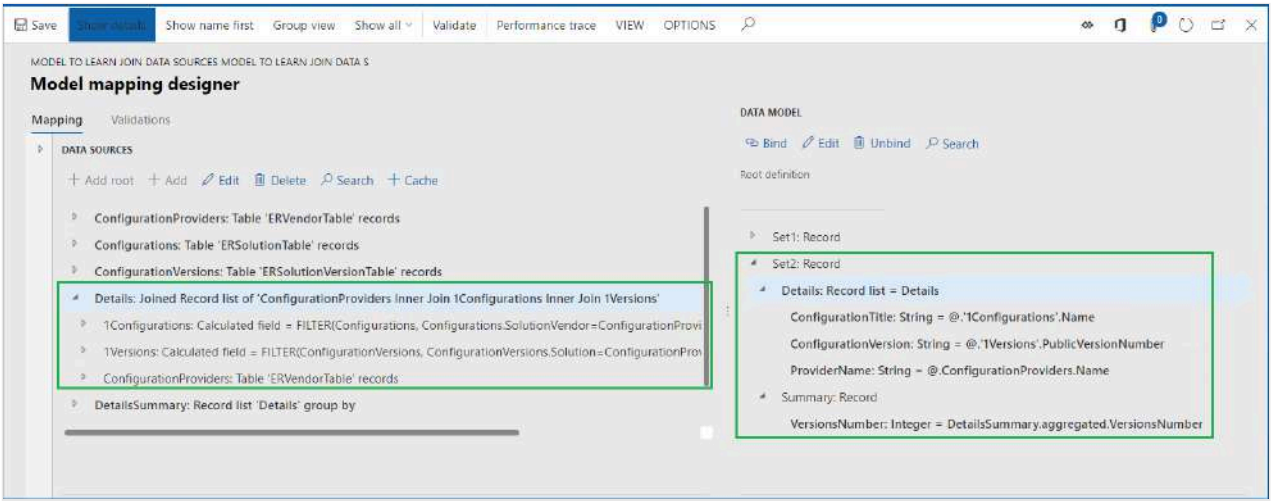


7. Close the page.

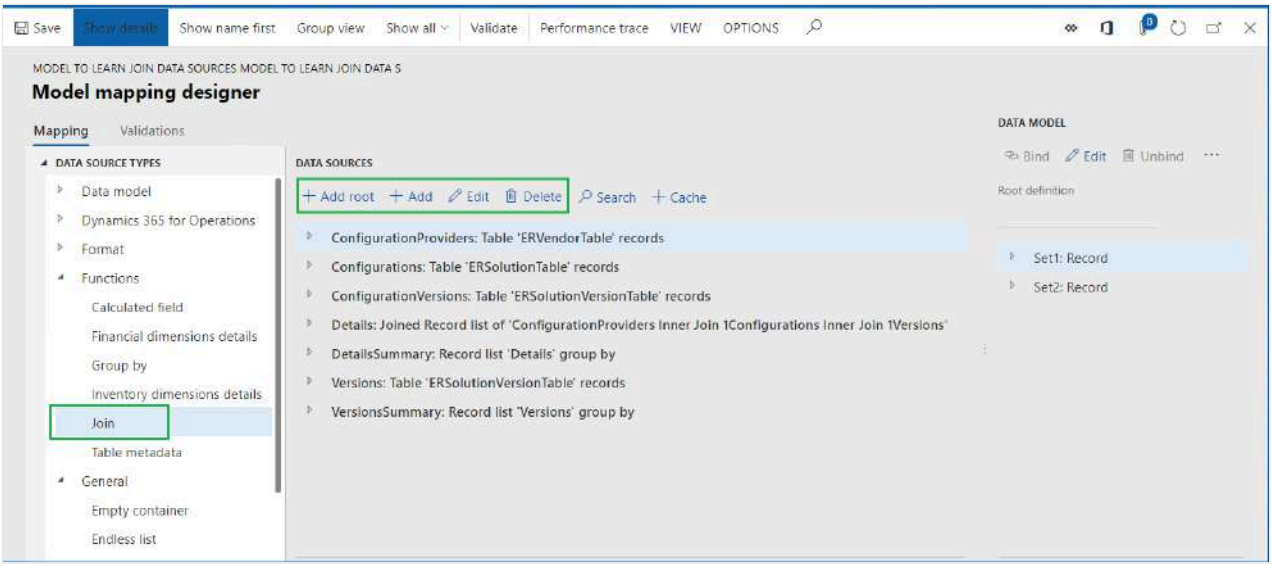
Review ER model mapping (part 2)

Review the settings of the ER model-mapping component. The component is configured to access information about versions of ER configurations, details of configurations, and configuration providers by using a data source of the **Join** type.

1. In the configurations tree, expand the **Set2** and **Set2.Details** data model items. The binding **Details: Record list = Details** indicates that the **Set2.Details** item is bound to the **Details** data source configured as the data source of the **Join** type.



Add the **Join** data source by selecting the **Functions\Join** data source:

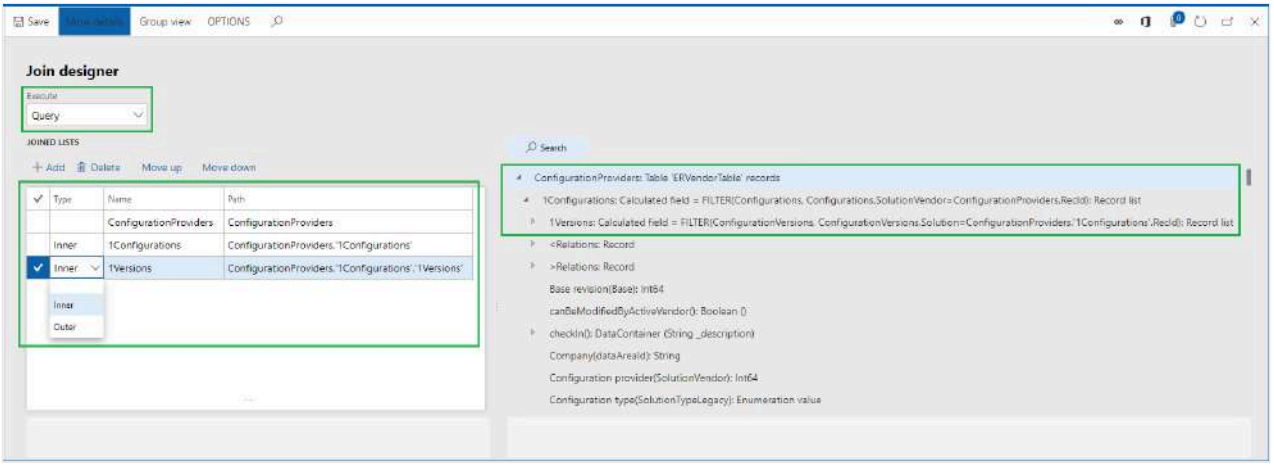


2. Select **Details** data source.

3. Select **Edit** in the **Data sources** pane.

4. Select **Edit join**.

5. Select **Show details**.



Use this page to design the required data source of the **Join type**. At runtime, this data source creates a single joined list of records from the data sources in the **Joined list** grid. The join of records starts from the **ConfigurationProviders** data source that is in the grid as the first one (the **Type** column is blank for it). Records of every other data source are joined consequently to records of the parent data source based on its order in this grid. You must configure every joining data source as a data source nested under a target data source (`1Versions` data source is nested under `1Configurations` one; `1Configurations` data source is nested under **ConfigurationProviders** one). Each configured data source must contain the conditions for the join. In the data source for this particular **Join**, the following joins are defined:

- Each record of the **ConfigurationProviders** data source (referred to the **ERVendorTable** table) is joined with only records of the **1Configurations** one (referred to in the **ERSolutionTable** table) that have the same value in the **SolutionVendor** and **RecId** fields. The **Inner join** type is used for this join as well as the following conditions for matching records:

FILTER (Configurations, Configurations.SolutionVendor = ConfigurationProviders.RecId)

- Each record of the **1Configurations** data source (referred to the **ERSolutionTable** table) is joined with the only records of the **1Versions** one (referred to the **ERSolutionVersionTable** table) that have the same value in the **Solution** and **RecId** fields. **Inner join** type is used for this join as well as the following conditions for matching records:

FILTER (ConfigurationVersions, ConfigurationVersions.Solution = ConfigurationProviders.'1Configurations'.RecId)

- The **Execute** option is configured as **Query** meaning that this join data source is executed at runtime on database level as a direct SQL call.

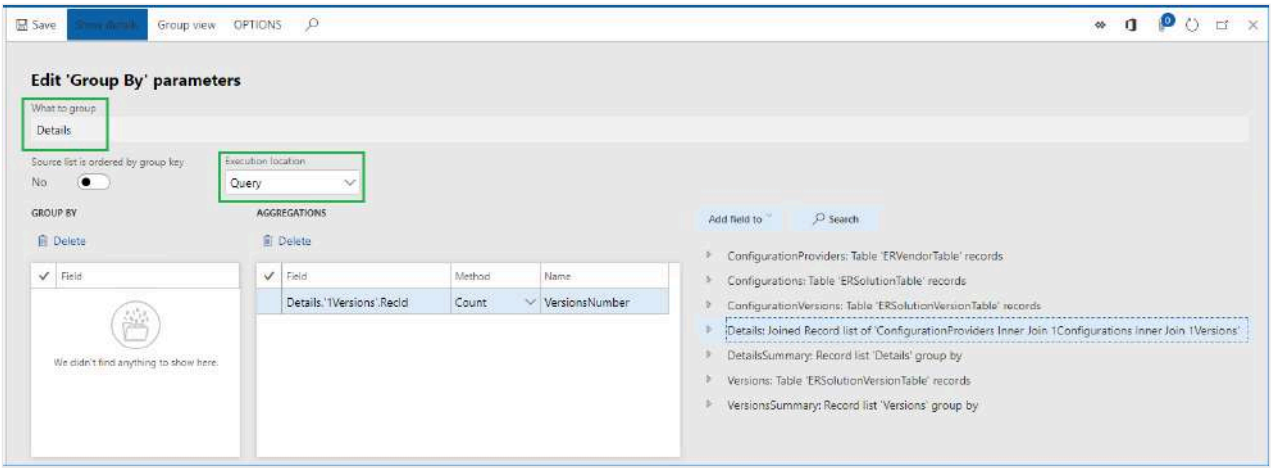
To join records of data sources that represent application tables, specify join conditions by using pairs of fields other than ones that describe existing in AOT relations between these tables. You can configure this type of join to execute at the database level as well.

6. Close the page.

7. Select **Cancel**.

8. In the configurations tree, expand the **Set2.Summary** data model item:

- Binding **VersionsNumber: Integer = DetailsSummary.aggregated.VersionsNumber** indicates that the **Set2.Summary.VersionsNumber** item is bound to the **VersionsNumber** aggregation field of the **DetailsSummary** data source of the **GroupBy** type that you configured to return the number of joined records of the **Details** data source of the **Join** type.
- The **Execution** location option is configured as **Query** meaning that this **GroupBy** data source runs at runtime as a direct SQL call at the database level. This behavior is possible because the base data source **Details** of the **Join** type is configured as executed at the database level.

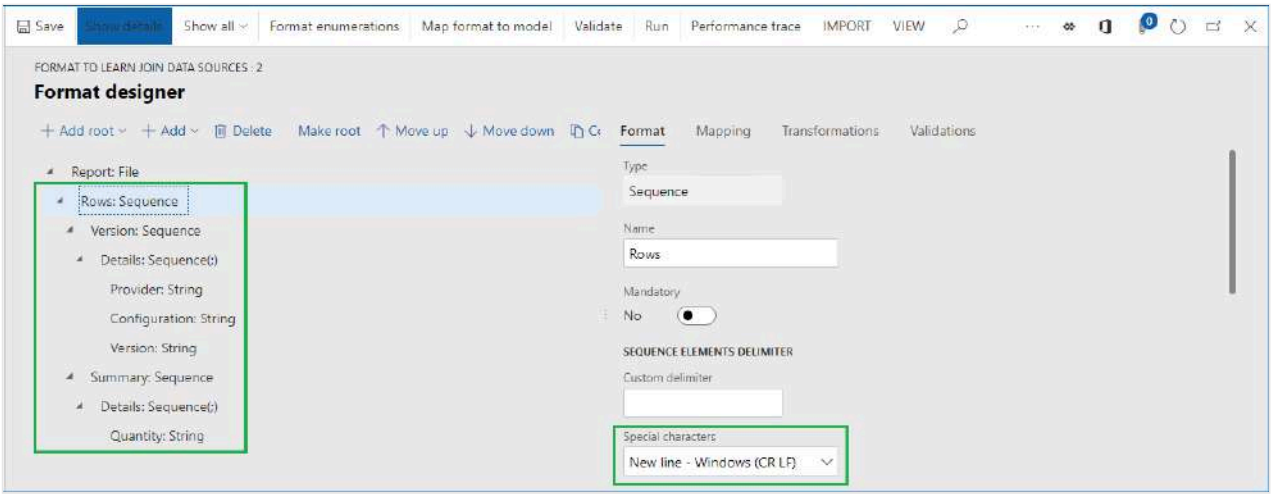


9. Close the page.
10. Select **Cancel**.

Execute ER format

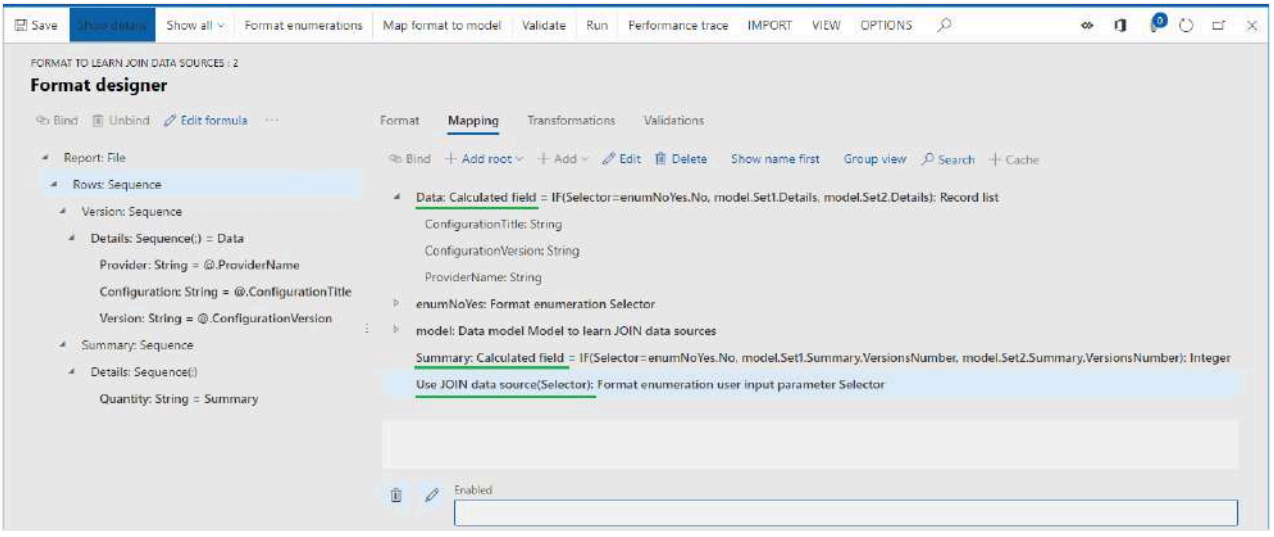
1. Access Finance or RCS in the second session of your web browser by using the same credentials and company as in the first session.
2. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
3. Expand **Model to learn JOIN data sources** configuration.
4. Select **Format to learn JOIN data sources** configuration.
5. Select **Designer**.
6. Select **Show details**.
7. Select **Mapping**.
8. Select **Expand/Collapse**.

   This format populates a generated text file with a new line for every version of an ER configuration (**Version** sequence). Each generated line contains the name of a configuration provider that owns the current configuration, the configuration name, and the configuration version separated by semicolon mark. The final line of generated file contains the number of discovered versions of ER configurations (**Summary** sequence).

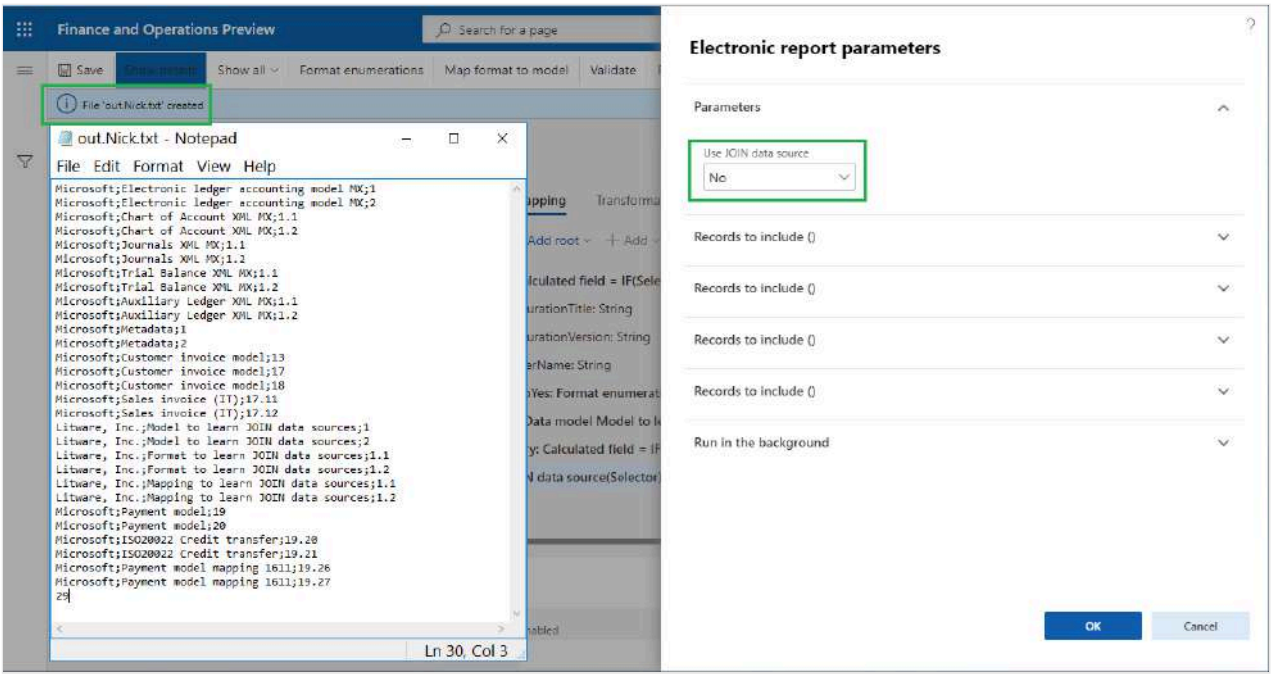


The **Data** and **Summary** data sources populate configuration version details to the generated file:

- The **Set1** data model provides information when you choose **No** for the **Selector** data source at runtime on the user dialog page when running ER format.
- The **Set2** data model provides information when you choose **Yes** for the **Selector** data source at runtime on the user dialog page.



9. Select **Run**.
10. On the dialog page, select **No** in the **Use JOIN data source** field.
11. Select **OK**.
12. Review generated file.

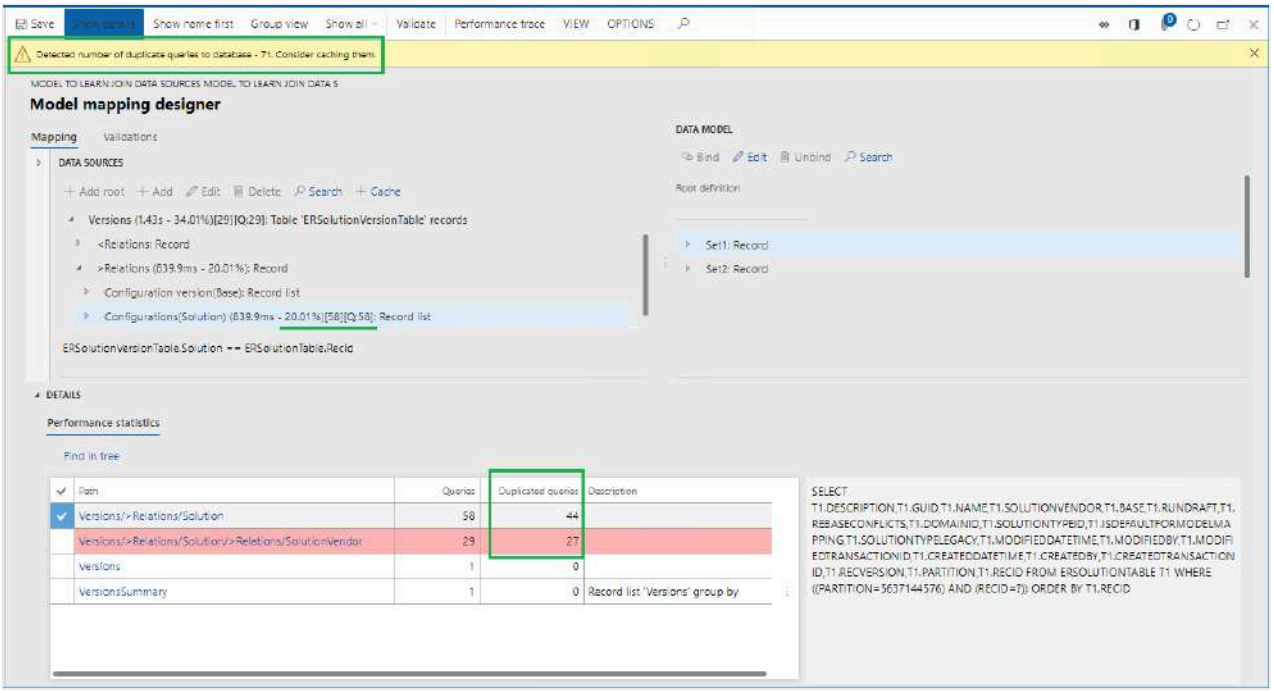


Analyze ER format execution trace

1. In the first session of Finance or RCS, select **Designer**.
2. Select **Performance trace**.
3. In the **Performance trace** grid, select the top-most record of the latest execution trace of an ER format that used the current model mapping component.
4. Select **OK**.

   Execution statistics inform you about duplicated calls to application tables:

   - The process calls **ERSolutionTable** as many times as you have configuration version records in the **ERSolutionVersionTable** table, while the number of such calls could be reduced for performance improvement.
   - The process calls **ERVendorTable** twice for every configuration version record that the process discovers in the **ERSolutionVersionTable** table, while the number of such calls could be reduced.



5. Close the page.

Execute ER format

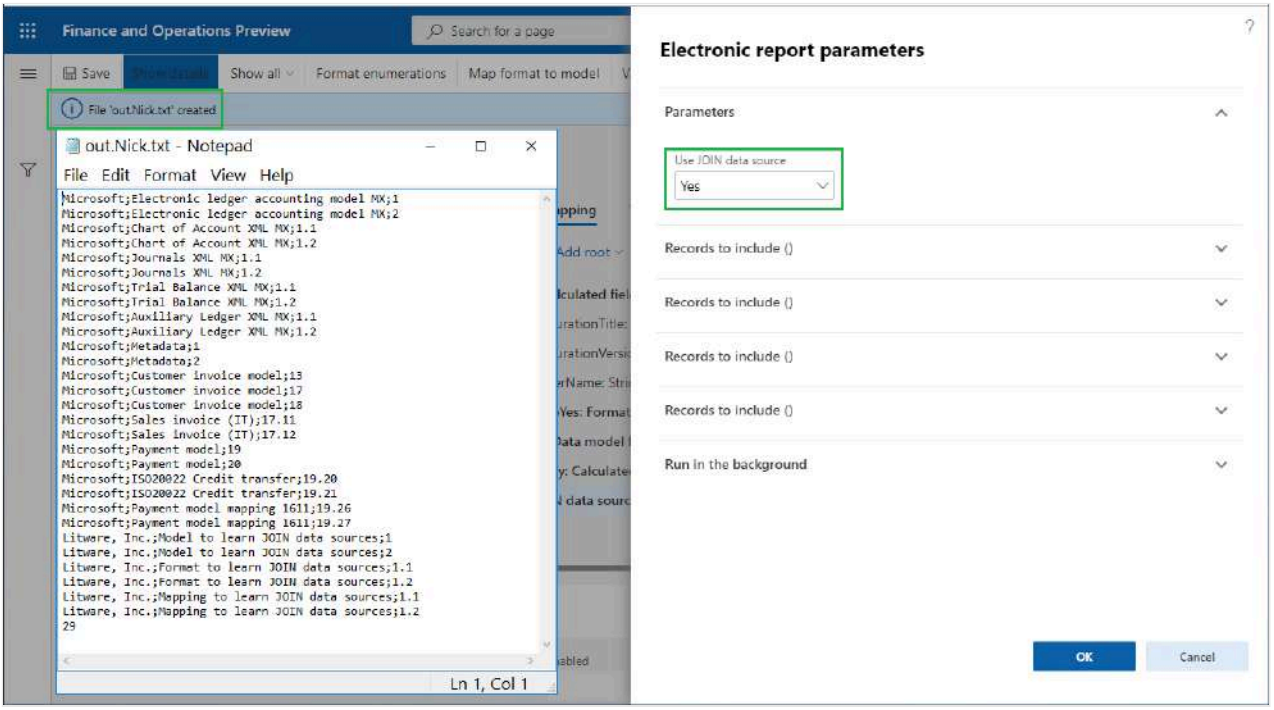
1. Switch to your web browser tab with the second session of Finance or RCS.

2. Select **Run**.

3. On the dialog page, select **Yes** in the **Use JOIN data source** field.

4. Select **OK**.

5. Review generated file.



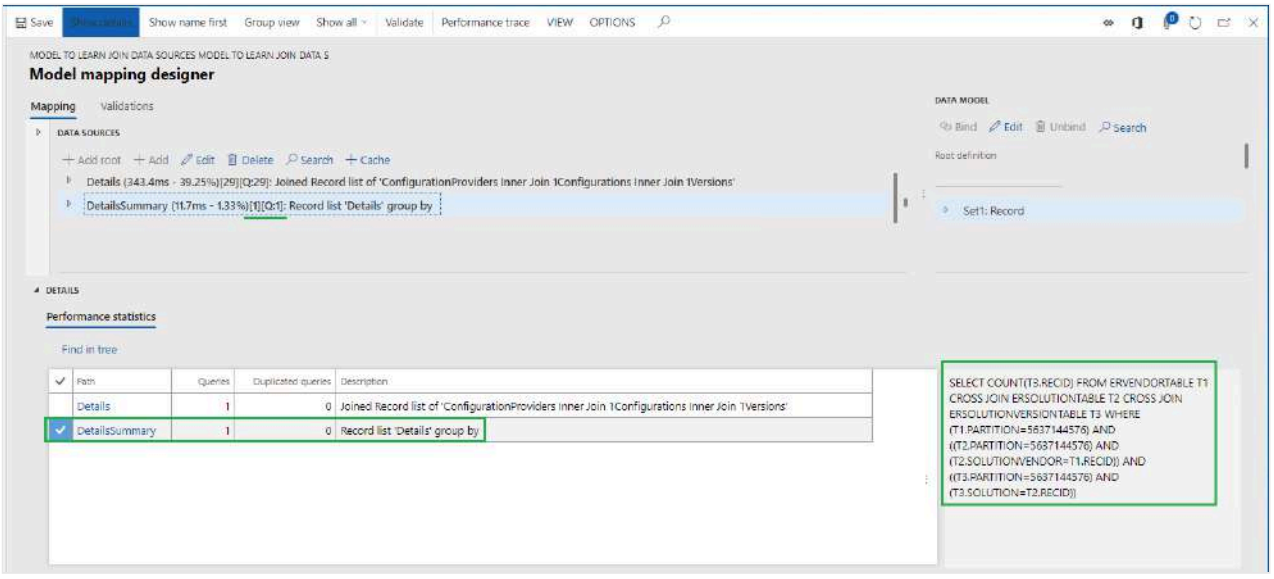
Analyze ER format execution trace

1. In the first session of Finance or RCS, select **Designer**.
2. Select **Performance trace**.
3. In the **Performance trace** grid, select the top-most record representing the latest execution trace of an ER format that used the current model mapping component.
4. Select **OK**.

   The statistics inform you about the following information:

   - The application database is called once to get records from **ERVendorTable**, **ERSolutionTable**, and **ERSolutionVersionTable** tables to access required fields.

   - The application database is called once to calculate the number of configuration versions by using joins that are configured in the **Details** data source.



Limitations

As you can see from the example in this article, you can build the **JOIN** data source from several data sources that describe the individual datasets of the records that you eventually join. Use the built-in ER FILTER function to configure those data sources. When you configure the data source so that it calls beyond the **JOIN** data source, you can use company ranges as part of the condition for data selection. The initial implementation of the **JOIN** data source doesn't support data sources of this type. For example, if you call a FILTER-based data source within the scope of execution of a **JOIN** data source and the called data source contains company ranges as part of the condition for data selection, an exception occurs.

In Microsoft Dynamics 365 Finance version 10.0.12 (August 2020), you can use company ranges as part of the condition for data selection in FILTER-based data sources that you call within the scope of execution of a **JOIN** data source. Because of the limitations of the application query builder, the company ranges are supported only for the first data source of a **JOIN** data source.

Example

For example, you must make a single call to the application database to get the list of foreign trade transactions of multiple companies and the details of the inventory item that is referred to in those transactions.

In this case, you configure the following artifacts in your ER model mapping:

- **Intrastat** root data source that represents the **Intrastat** table.
- **Items** root data source that represents the **InventTable** table.
- **Companies** root data source that returns the list of companies (**DEMF** and **GBSI** in this example) where transactions must be accessed. The company code is available from the

Companies.Code field.

- **X1** root data source that has the expression `FILTER (Intrastat, VALUEIN(Intrastat.dataAreaId, Companies, Companies.Code))`. As part of the condition for data selection, this expression contains the definition of company ranges `VALUEIN(Intrastat.dataAreaId, Companies, Companies.Code)`.
- **X2** data source as a nested item of the **X1** data source. It includes the expression `FILTER (Items, Items.ItemId = X1.ItemId)`.

Finally, you can configure a **JOIN** data source where **X1** is the first data source and **X2** is the second data source. You can specify **Query** as the **Execute** option to force ER to run this data source on the database level as a direct SQL call.

When you run the configured data source while the ER execution is traced, the following statement is shown in the ER model mapping designer as part of the ER performance trace.

```
SELECT ... FROM INTRASTAT T1 CROSS JOIN INVENTTABLE T2 WHERE ((T1.PARTITION=?) AND (T1.DATAAREAID IN (N'DEMF',N'GBSI') )) AND ((T2.PARTITION=?) AND (T2.ITEMID=T1.ITEMID AND (T2.DATAAREAID = T1.DATAAREAID) AND (T2.PARTITION = T1.PARTITION))) ORDER BY T1.DISPATCHID,T1.SEQNUM
```

> **Note**
>
> An error occurs if you run a **JOIN** data source that you configured so that it contains data selection conditions that have company ranges for additional data sources of the executed **JOIN** data source.

Generate reports by adding content as raw XML

> ⓘ Note
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use the new **RAW XML** format element to design Electronic reporting (ER) formats that generate outgoing documents in XML format. In some cases, you might prefer to add raw XML data to these reports for one or more of the following reasons:

- It's more convenient to use raw XML for the original design and ongoing maintenance of a report because the XML structure can be automatically generated by executing a runtime expression. Therefore, you don't need to determine multiple bindings for multiple format elements at design time. This approach is possible when the data sources you use contain information that can be used to make XML elements while the report is generated.
- No other method can fill the report with XML content that the system previously received and stored. For example, the XML response that is generated might have to contain the content of an XML request that was sent earlier.
- No other method can insert characters into the generated document based on their numeric codes. For some languages and characters, codes of this type don't exist. Examples include the Greek letter rho (ρ) and HTML entity codes such as é for an *e* that has an acute accent (é).

> ⓘ Note
>
> The framework doesn't validate whether the XML content that you add to the generated document by using the **RAW XML** format element is correct.

To learn more about this feature, watch the **ER Use raw XML data to generate XML reports (Part 1: Design data model)** and **ER Use raw XML data to generate XML reports (Part 2:**

Design and run report) task guides. These task guides are part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process, and you can download them from the Microsoft Download Center. The task guides walk you through the process of configuring an ER format to insert raw XML data into generated files.

Support parameterized calls of ER data sources of the Calculated field type

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how you can design an Electronic reporting (ER) data source by using the **Calculated field** type. This data source can contain an ER expression that, when executed, can be controlled by the values of the parameter arguments configured in a binding that calls this data source. By configuring parameterized calls of such a data source, you can reuse a single data source in many bindings. This approach reduces the total number of data sources that you must configure in ER model mappings or ER formats. It also simplifies the configured ER component, which reduces maintenance costs and the cost of use by other consumers.

Prerequisites

To complete the examples in this article, you must have the following access:

- Access to one of these roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator
- Access to Regulatory Configuration Services (RCS) that are provisioned for the same tenant as finance and operations for one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator

You must also download and locally store the following files.

Expand table

Content	File name
Sample ER data model configuration	Model to learn parameterized calls.version.1.xml
Sample ER metadata configuration	Metadata to learn parameterized calls.version.1.xml
Sample ER model mapping configuration	Mapping to learn parameterized calls.version.1.1.xml
Sample ER format configuration	Format to learn parameterized calls.version.1.1.xml

Sign in to your RCS instance

In this example, you create a configuration for the sample company, Litware, Inc. First, in RCS, complete the steps in the Create configuration providers and mark them as active procedure:

1. On the default dashboard, select **Electronic reporting**.
2. Select **Reporting configurations**.
3. Import the downloaded configurations to RCS in the following sequence: data model, metadata, model mapping, format. Complete the following steps for each ER configuration:
   a. Select **Exchange**.
   b. Select **Load from XML file**.
   c. Select **Browse**, and then select the required ER configuration in XML format.
   d. Select **OK**.

Review the provided ER solution

Review model mapping

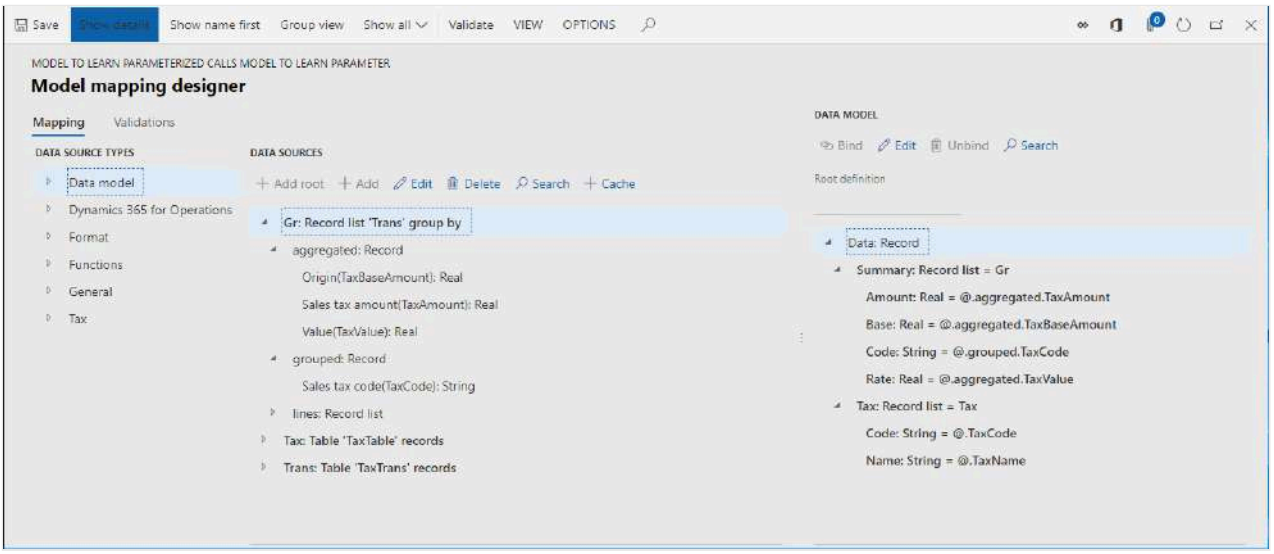
1. In the configuration tree, expand the content of the **Model to learn parameterized calls** item.
2. Select **Mapping to learn parameterized calls**.
3. Select **Designer**.
4. Select **Designer**.

   This ER model mapping is designed to do the following tasks:

   - Fetch the list of tax codes (**Tax** data source) residing in the **TaxTable** table.

- Fetch the list of tax transactions (**Trans** data source) residing in the **TaxTrans** table.
  - Group the list of fetched transactions (**Gr** data source) by tax code.
    - Calculate the following aggregated values per tax code, for grouped transactions:
    - Sum of tax base values.
    - Sum of tax values.
    - Minimum value of applied tax rate.

The model mapping in this configuration implements the base data model for any of the ER formats created for this model and executed in finance and operations. As a result, the content of the **Tax** and **Gr** data sources is exposed for ER formats such as abstract data sources.

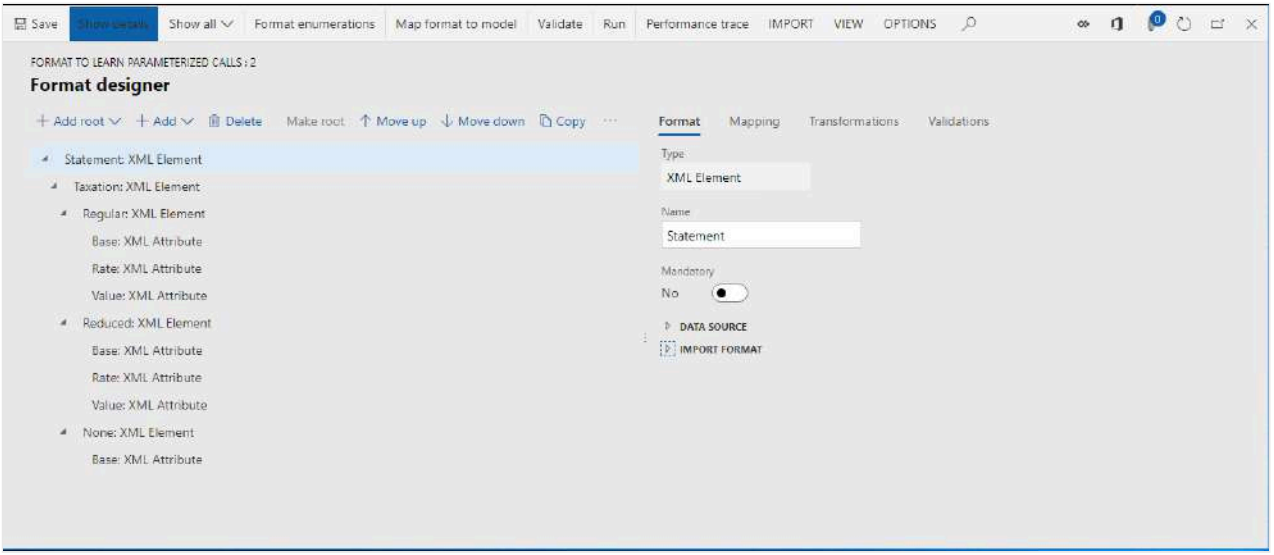


5. Close the **Model mapping designer** page.
6. Close the **Model mapping** page.

Review format

1. In the configuration tree, expand the content of the **Model to learn parameterized calls** item.
2. Select **Format to learn parameterized calls**.
3. Select **Designer**. This ER format is designed to do the following:
   - Generate a tax statement in XML format.

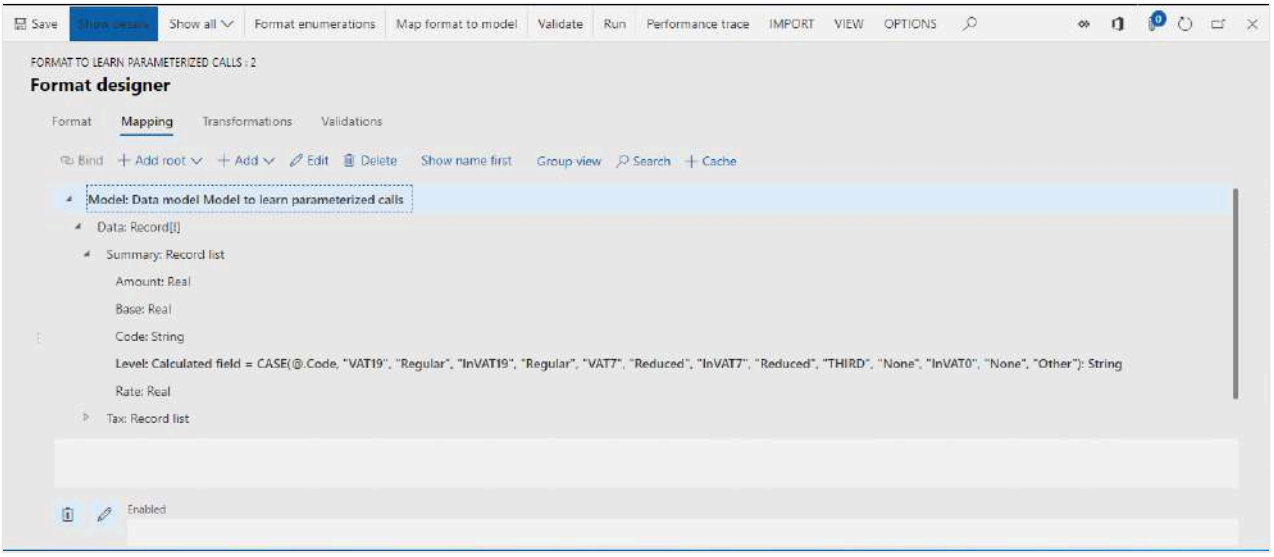
- Present the following levels of taxation in the tax statement: regular, reduced, and none.
- Present multiple details at each taxation level, having a different number of details in each level.



4. Select **Mapping**.

5. Expand the **Model**, **Data,** and **Summary** items.

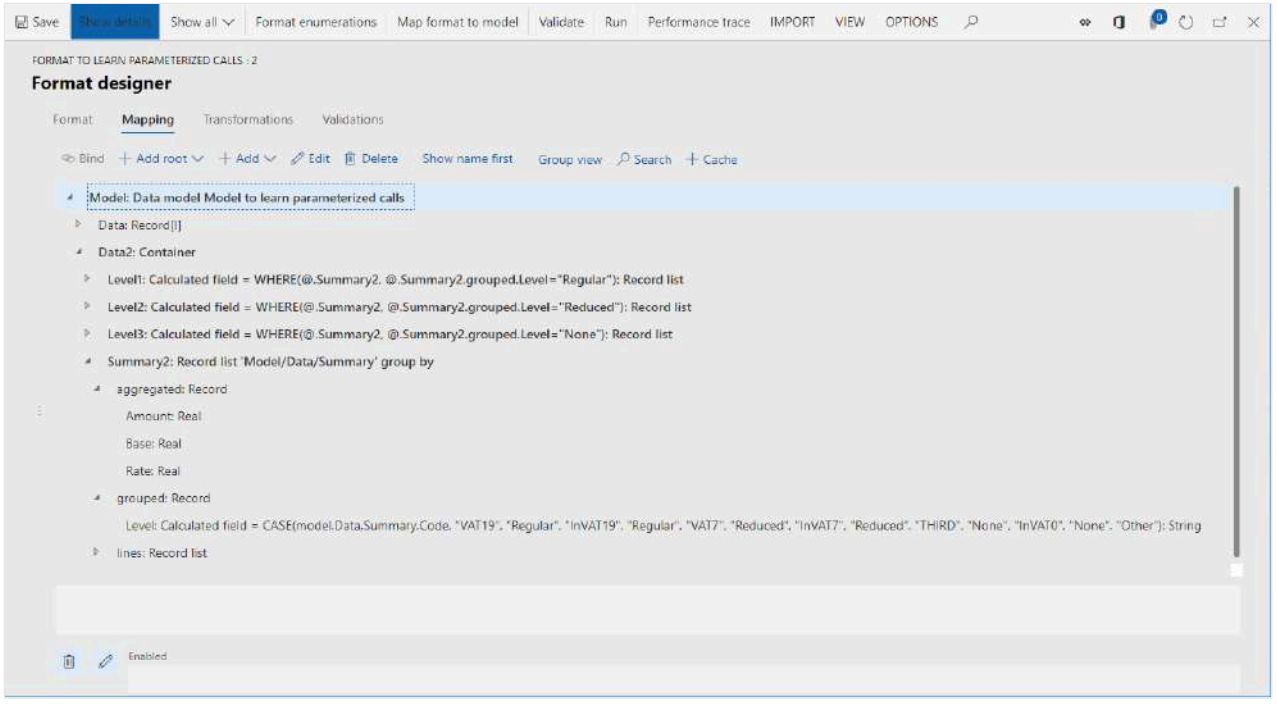
   The calculated field **Model.Data.Summary.Level** contains the expression that returns the code of the taxation level (**Regular**, **Reduced**, **None**, or **Other**) as a text value for any tax code that can be retrieved from the **Model.Data.Summary** data source at run time.



6. Expand the **Model.Data2** item.

7. Expand the **Model.Data2.Summary2** item.

The **Model.Data2.Summary2** data source is configured to group the **Model.Data.Summary** data source transaction details by taxation level (returned by the **Model.Data.Summary.Level** calculated field) and compute the aggregations.



8. Review the calculated fields **Model.Data2.Level1**, **Model.Data2.Level2**, and **Model.Data2.Level3**. Use these calculated fields to filter the **Model.Data2.Summary2** records list and return only records that represent a particular taxation level.

9. Close the **Format designer** page.

Create a derived format

You can improve the provided format by adding one calculated field to filter the required taxation level instead of using the existing three fields: **Model.Data2.Level1**, **Model.Data2.Level2**, and **Model.Data2.Level3**. The required taxation level can be specified in the location where this new calculated field is called.

1. In the configuration tree, expand the content of the **Model to learn parameterized calls** item.
2. Select **Format to learn parameterized calls**.
3. Select **Create configuration**.
4. Select **Derive from Name: Format to learn parameterized calls, Microsoft**.
5. In the **Name** field, enter **Format to learn parameterized calls (custom)**.
6. Select **Create configuration**.

Configure a parameterized calculated field that returns a list of records

Start adding a new calculated field

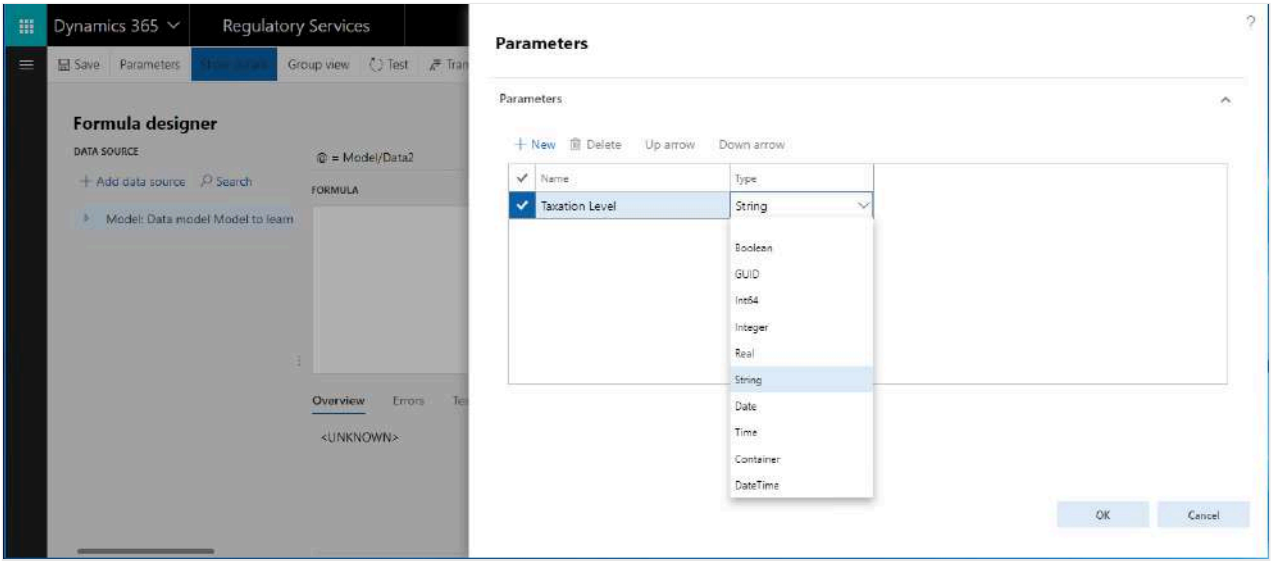
1. Select **Designer**.
2. Select **Expand/collapse** to expand all format items.
3. Select **Mapping**.
4. Expand the **Model** item.
5. Select the **Model.Data2** item.
6. Select **Add**.
7. Select **Functions\Calculated field**.
8. In the **Name** field, enter **Levels**.
9. Select **Edit formula**.

Define a parameter for adding a calculated field

1. Select **Parameters**.
2. Select **New**.
3. In the **Name** field, enter **Taxation Level**.
4. In the **Type** field, select **String**.

   You can only use primitive data types to specify the type of the parameter's argument. Therefore, you can't use **Record list**, **Record**, or **Enum** types for this purpose.

   You can specify up to eight parameters for a single calculated field.

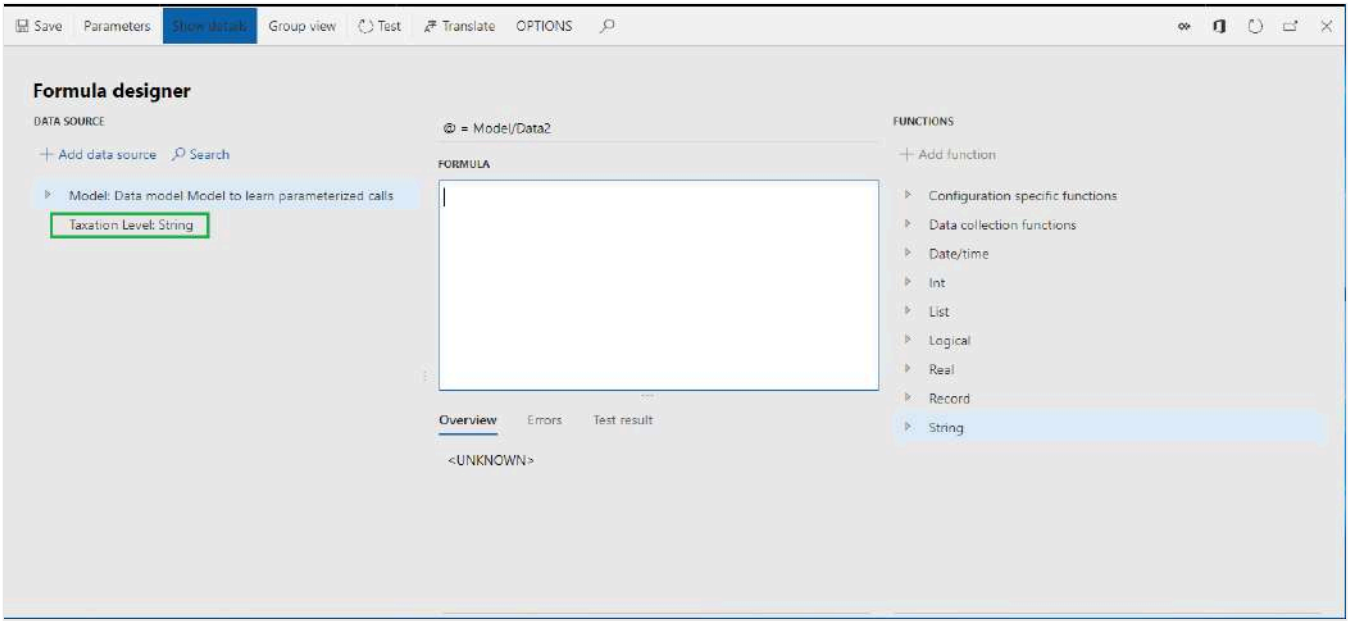


5. Select **OK**.

By adding this parameter, you specify the condition that must be in place to call this calculated field. When you call this calculated field, you need to specify the argument of the **Taxation Level** parameter as a value with **String** format.

Make sure that you define parameters only for those calculated fields that reside in a container (either **Record list**, **Record**, or **Container**).

The configured parameter is available in the list of data sources for this calculated field. You can add the parameter to the configured expression by selecting **Add data source**.



Define an expression for adding a calculated field

1. In the **Formula** field, enter:

   ```
   WHERE(\@.Summary2, \@.Summary2.grouped.Level =
   ```

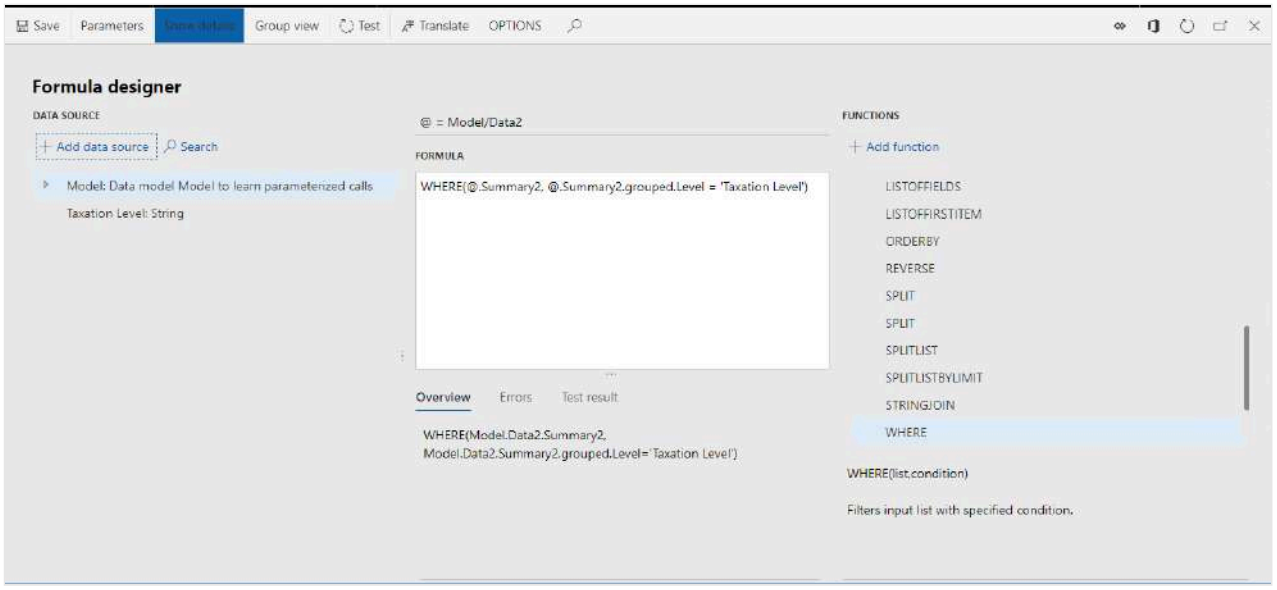
2. Select the **Taxation Level** parameter in the list of data sources.

3. Select **Add data source**.

4. In the **Formula** field, finalize the expression as:

   ```
   WHERE(\@.Summary2, \@.Summary2.grouped.Level = 'Taxation Level')
   ```

5. Select **Save**.

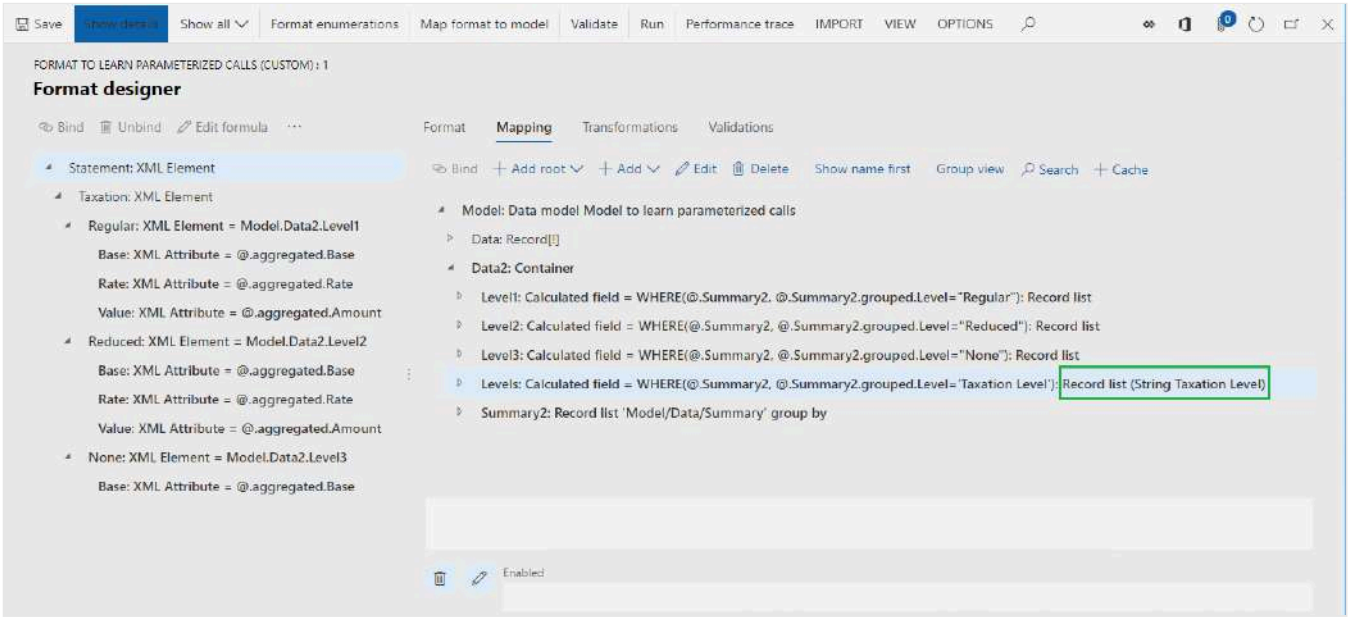


6. Close the **Formula designer** page.

Finish adding a new calculated field

- Select **OK**.

On the **Format designer** page, the configured parameterized calculated field **Levels** requires a **String** argument.



Use the configured calculated field for binding format elements

1. Select **Model.Data2.Levels** to select the configured calculated field.

2. Select the **Statement.Taxation.Regular** format element.

3. Select **Bind**.
4. Select **Yes** to confirm the replacement of the currently used data source, **Level1**, by the new data source, **Levels**, in all nested format elements of the selected format element.

   Applied binding is a call of the parameterized calculated field. By default, the name of the bound format element is used as an argument for the parameterized calculated field under the following conditions:

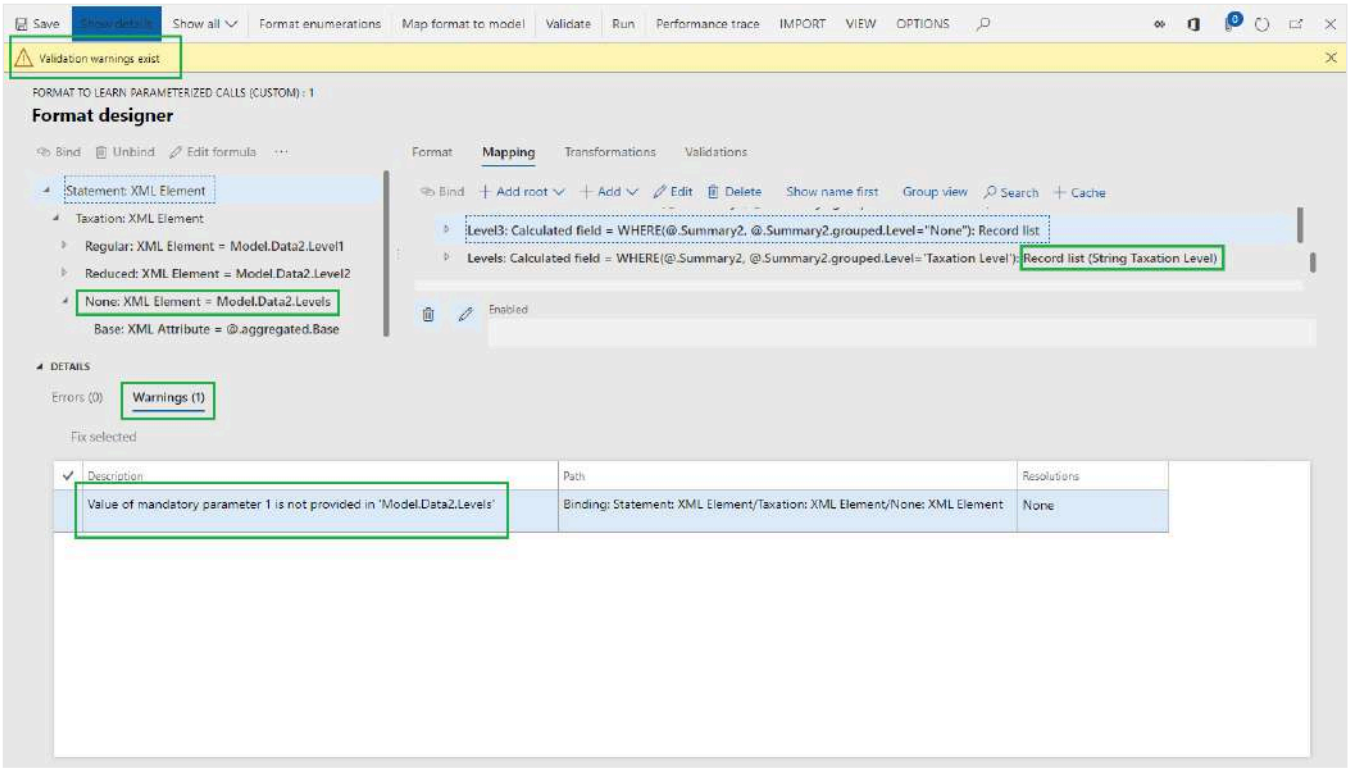
   - The calculated field is configured to use a single parameter.
   - The data type of this parameter is defined as **String**.

   When the name of the bound format element is blank, the data source name of this element is used in applied binding.
5. Select the **Statement.Taxation.Reduced** format element.
6. Select **Bind**.
7. Select **Yes** to confirm the replacement of the currently used data source, **Level2**, by the new data source, **Levels**, in all nested format elements under the selected format element.
8. Select the **Statement.Taxation.None** format element.
9. Select **Bind**.
10. Select **Yes** to confirm the replacement of the currently used data source, **Level3**, by the new data source, **Levels**, in all nested format elements under the selected format element.

    When you specify the argument of the parameterized calculated field for the XML element representing taxation level (for example, **Model.Data2.Levels("Reduced")** as a text value), you don't need to specify the argument for nested XML attributes—their bindings automatically inherit the value of the argument defined on the parent level (**Model.Data2.Levels.aggregated.Base**, not **Model.Data2.Levels("Reduced").aggregated.Base**).

Recurrent calls of any parameterized calculated field aren't supported.

You can select **Edit formula** and change the applied-by-default argument of the parameterized calculated field in the selected binding. If this argument is missing, it can cause errors at run time. Users are informed about such a situation when the current format is validated.



Configure a parameterized calculated field to return a record

When a parameterized calculated field returns a record, you need to support binding of individual fields of this record to format elements. In such cases, there's no parent binding that contains the value of an argument to call a parameterized calculated field — this value must be defined in the binding of a single record's field.

Start adding a new calculated field

5. Select the **Model.Data2** item.
6. Select **Add**.
7. Select **Functions\Calculated field**.
8. In the **Name** field, enter **LevelRecord**.
9. Select **Edit formula**.

Define a parameter for adding a calculated field

1. Select **Parameters**.
2. Select **New**.
3. In the **Name** field, enter **Taxation Level**.
4. In the **Type** field, select **String**.
5. Select **OK**.

Define an expression for adding a calculated field

1. In the **Formula** field, enter the following formula:

   `FIRSTORNULL(@.Levels(`

2. Select the **Taxation Level** parameter.

3. Select **Add data source**.

4. In the **Formula** field, append `'Taxation Level'))` to the formula you entered in Step 1 to finalize the expression:

   `FIRSTORNULL(@.Levels('Taxation Level'))`

5. Select **Save**.

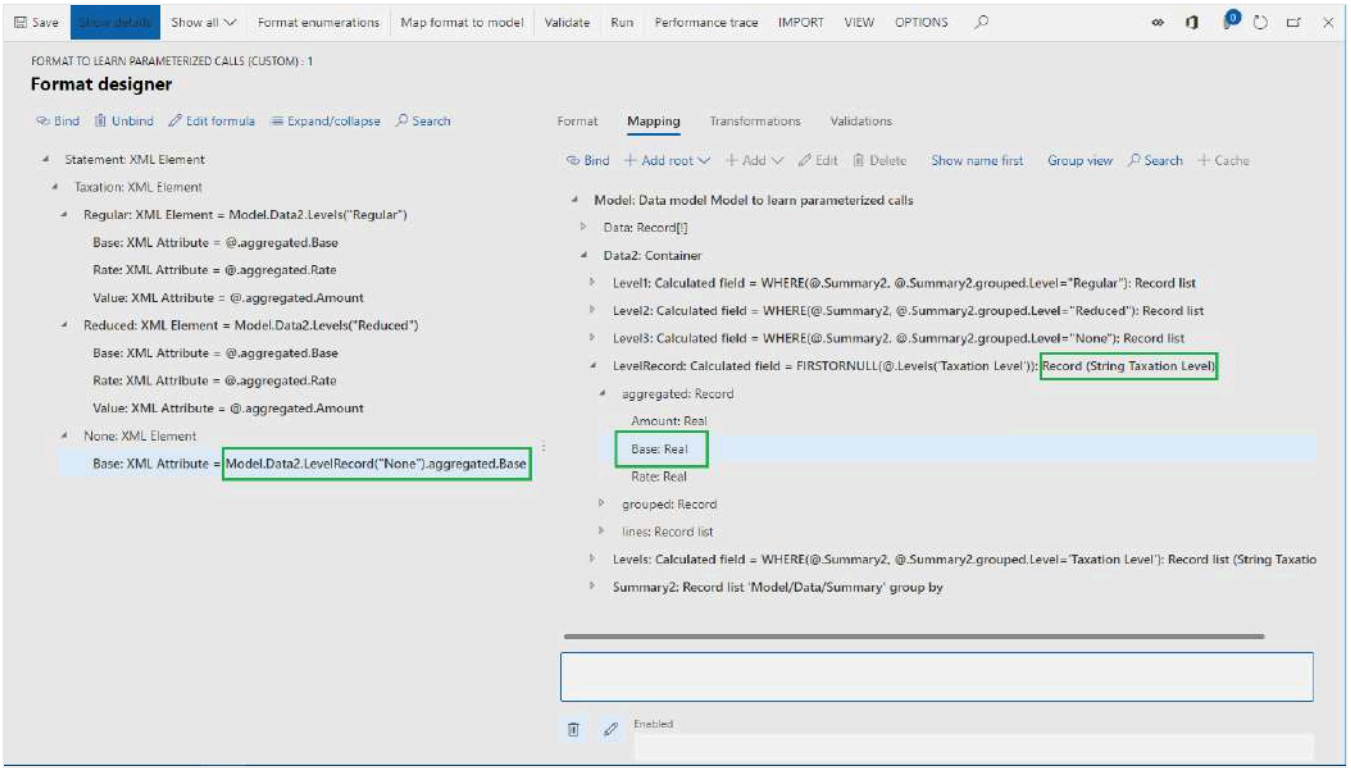
6. Close **Formula designer**.

Finish adding a new calculated field

1. Select **OK**.

Use the configured calculated field to bind format elements

1. Expand **Model.Data2.LevelRecord** to select the configured calculated field.
2. Expand the **Model.Data2.LevelRecord.aggregated** container of the configured calculated field.
3. Select the **Model.Data2.LevelRecord.aggregated.Base** field.
4. Select the **Statement.Taxation.None** format element.
5. Select **Unbind**.
6. Select the **Statement.Taxation.None.Base** format element.
7. Select **Bind**.
8. Select **Edit formula**.
9. Change the expression to **Model.Data2.LevelRecord("None").aggregated.Base**.



Remove calculated fields that are not used

1. Select **Model.Data2.Level1**.
2. Select **Delete**.
3. Select **Model.Data2.Level2**.
4. Select **Delete**.
5. Select **Model.Data2.Level3**.
6. Select **Delete**.
7. Select **Save**.

> **Note**
>
> You reused the same calculated field **Model.Data2.Levels** several times in format bindings. It's much easier to use and maintain a single calculated field instead of doing this for multiple similar fields.

1. Close the **Format designer** page.

Complete adjusted version of a derived format

1. In the **Versions** tab, select **Change status**.
2. Select **Complete**.

Export completed version of a derived format

1. Select **Format to learn parameterized calls (custom)** format in the configurations tree.
2. In the **Versions** tab, select the completed version 1.1.1.
3. Select **Exchange**.
4. Select **Export as XML file**.
5. Store the downloaded configuration locally, in XML format.

Test ER formats

To make sure that configured parameterized calculated fields work properly, run the initial and improved ER formats.

Import ER configurations

You can import reviewed configurations from RCS by using the ER repository of the **RCS** type. If you already went through the steps in the article, Import Electronic reporting (ER) configurations from Regulatory Configuration Services (RCS), use the configured ER repository to import configurations discussed earlier in this article to your environment. Otherwise, follow these steps:

1. Select the **DEMF** company and on the default dashboard, select **Electronic reporting**.

2. Select **Reporting configurations**.

3. Import the configurations from Microsoft Download Center in the following sequence: data model, model mapping, format. Complete the following steps for each ER configuration:
   a. Select **Exchange**.
   b. Select **Load from XML file**.
   c. Select **Browse** to select the required ER configuration in XML format.
   d. Select **OK**.

4. Import the exported from RCS completed version 1.1.1 of the **Format to learn parameterized calls (custom)** format:
   a. Select **Exchange**.
   b. Select **Load from XML file**.
   c. Select **Browse** to select the locally stored **Format to learn parameterized calls (custom)** file in XML format.
   d. Select **OK**.

Run ER formats

1. In the configuration tree, expand the content of the **Model to learn parameterized calls** item.
2. Select **Format to learn parameterized calls**.
3. Select **Run** on the top-most ribbon.
4. Save the locally generated output.
5. Select the **Format to learn parameterized calls (custom)** item.
6. Select **Run** on the top-most ribbon.
7. Save the generated output locally.
8. Compare the contents of the generated outputs.

Improve the performance of ER solutions by adding parameterized CALCULATED FIELD data sources

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how you can take performance traces of Electronic reporting (ER) formats that are run, and then use the information from those traces to help improve performance by configuring a parameterized **Calculated field** data source.

As part of the process of designing ER configurations to generate business documents, you define the method to retrieve data from the application and enter it in the generated output. By designing a parameterized ER data source of the **Calculated field** type, you can reduce the number of database calls and significantly reduce the time and cost that are involved in collecting the details of ER format execution.

Prerequisites

- To complete the examples in this article, you must have access to one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator
- The company must be set to **DEMF**.
- Follow the steps in Appendix 1 of this article to download the components of the sample Microsoft ER solution that you need to complete the examples in this article.
- Follow the steps in Appendix 2 of this article to configure the minimal set of ER parameters that you need to use the ER framework to help improve the performance of

the sample Microsoft ER solution.

Import the sample ER solution

Imagine that you must design an ER solution to generate a new report that shows vendor transactions. Currently, you can find the transactions for a selected vendor on the **Vendor transactions** page (go to **Account payable** > **Vendors** > **All vendors**, select a vendor, and then, on the Action Pane, on the **Vendor** tab, in the **Transactions** group, select **Transactions**). However, you want to have all vendor transactions together in one electronic document in XML format. This solution consists of several ER configurations that contain the required data model, model mapping, and format components.

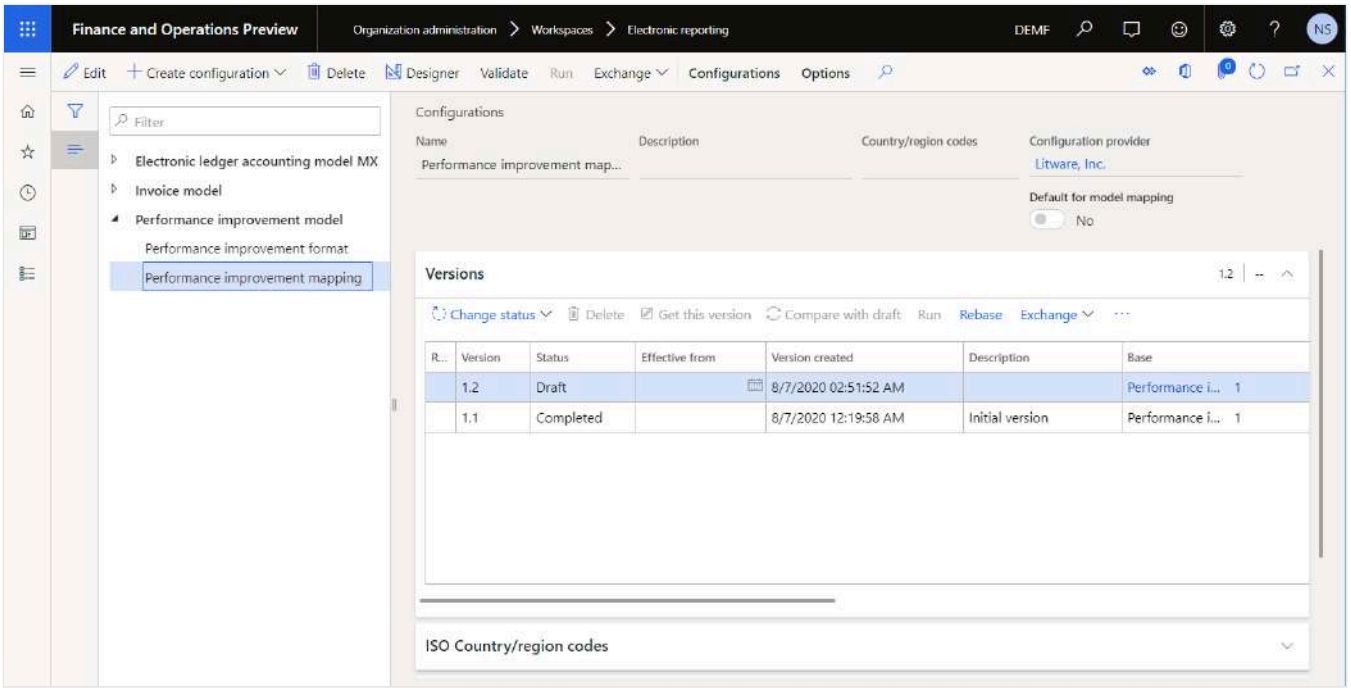
The first step is to import the sample ER solution to generate a vendor transactions report.

1. Sign in to the instance of Microsoft Dynamics 365 Finance that is provisioned for your company.

2. In this article, you create and modify configurations for the **Litware, Inc.** sample company. Make sure that this configuration provider is added to your Finance instance and is marked as active. For more information, see Create configuration providers and mark them as active.

3. In the **Electronic reporting** workspace, select the **Reporting configurations** tile.

4. On the **Configurations** page, import the ER configurations that you downloaded as a prerequisite into Finance, in the following order: data model, model mapping, format. For each configuration, follow these steps:
   a. On the Action Pane, select **Exchange** > **Load from XML file**.
   b. Select **Browse**, and select the appropriate file for the ER configuration in XML format.
   c. Select **OK**.



Review the sample ER solution

Review the model mapping

1. On **Configurations**, in the configuration tree, expand **Performance improvement model**, and select **Performance improvement mapping**.

2. On the Action Pane, select **Designer**.

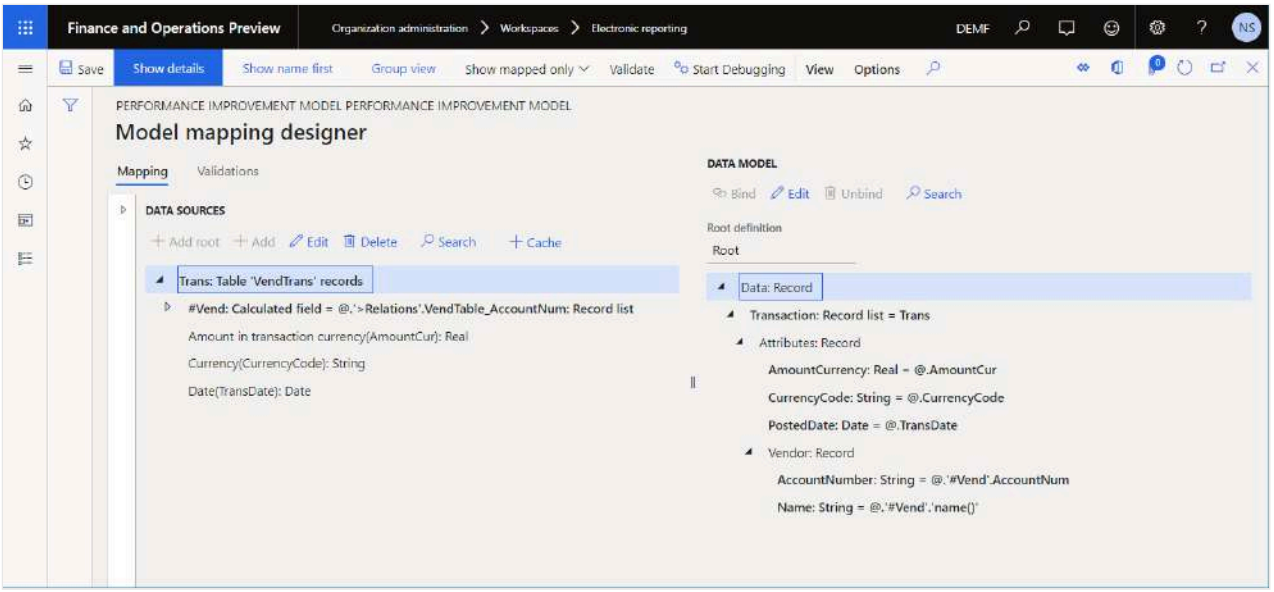
3. On **Model to datasource mapping**, on the Action Pane, select **Designer**.

   This ER model mapping is designed to perform the following actions:

   - Fetch the list of vendor transactions that are stored in the VendTrans table (**Trans** data source).
     - For every transaction, fetch, from the VendTable table, the record of a vendor that the transaction is posted for (**#Vend** data source).

   > ⓘ **Note**
   >
   > The **#Vend** data source is configured to fetch the corresponding vendor record by using the existing many-to-one relation **@.'>Relations'.VendTable_AccountNum**.

   The model mapping in this configuration implements the base data model for any ER formats that are created for this model and run in Finance. Therefore, the content of the **Trans** data source is exposed for ER formats such as abstract **model** data sources.



4. Close **Model mapping designer**.

5. Close **Model to datasource mapping**.

Review format

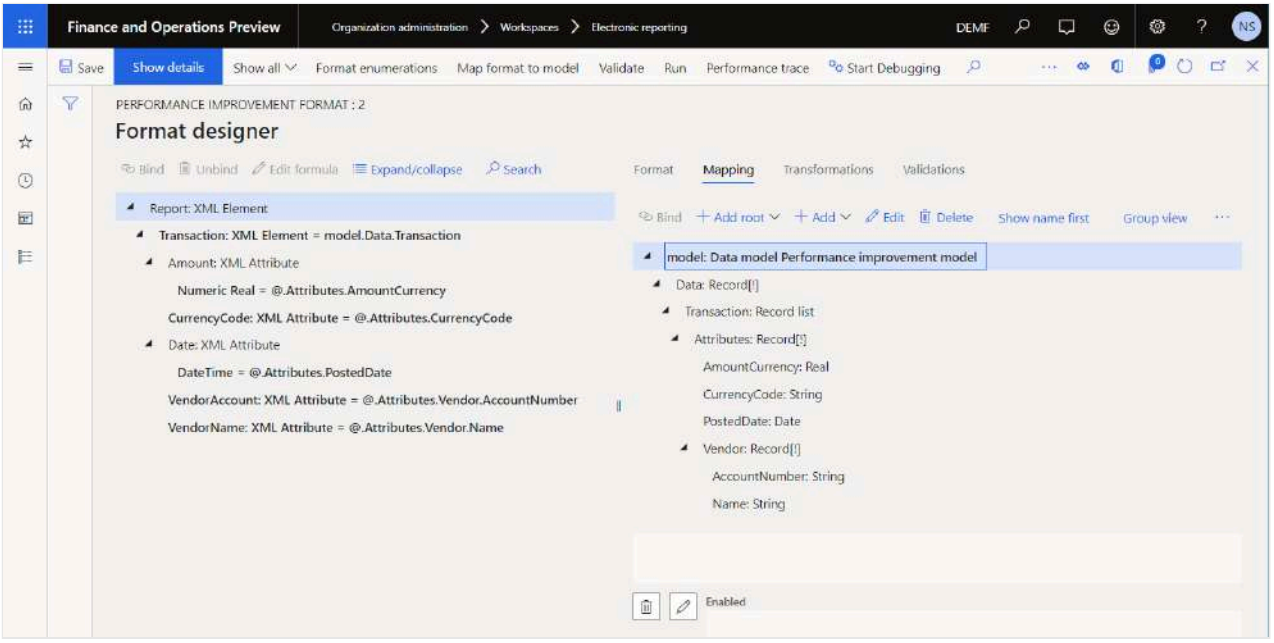
1. On **Configurations**, in the configuration tree, expand **Performance improvement model**, and select **Performance improvement format**.

2. On the Action Pane, select **Designer**.

3. On **Format designer**, on the **Mapping** tab, select **Expand/Collapse**.

4. Expand the **Model**, **Data**, and **Transaction** items.

   This ER format generates a vendor transactions report in XML format.



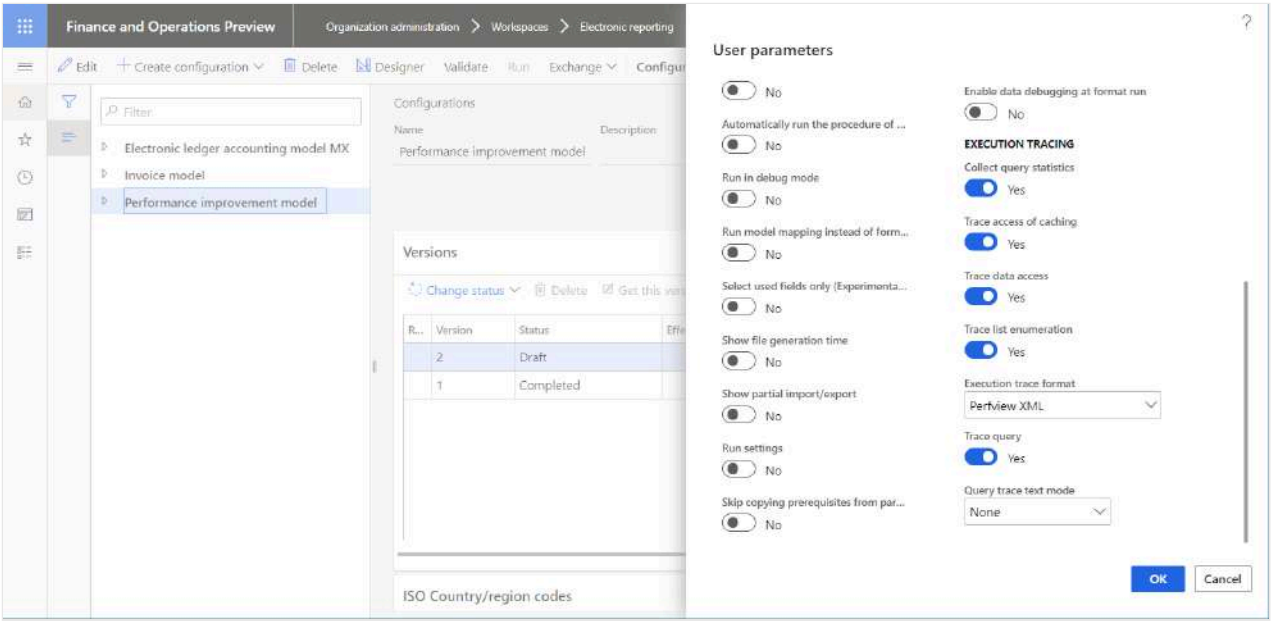
5. Close **Format designer**.

Run the sample ER solution to trace execution

Imagine that you finish designing the first version of the ER solution. You want to test the solution in your Finance instance and analyze the execution performance.

Turn on the ER performance trace

1. Select the **DEMF** company.
2. Follow the steps in Turn on the ER performance trace to generate a performance trace while an ER format runs.



Run the ER format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, select **Performance improvement format**.
3. On the Action Pane, select **Run**.

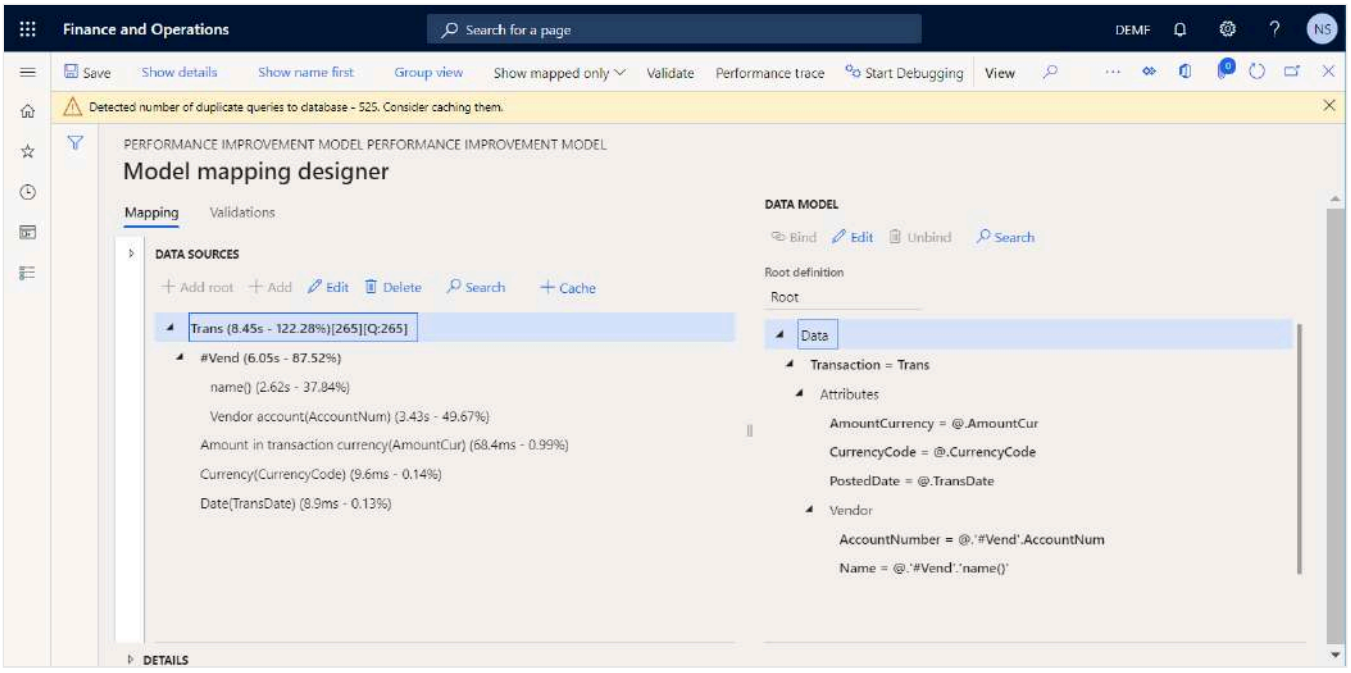
Use the performance trace to analyze model mapping performance

1. On **Configurations**, in the configuration tree, select **Performance improvement mapping**.
2. On the Action Pane, select **Designer**.
3. On **Model mappings**, on the Action pane, select **Designer**.
4. On the **Model mapping designer** page, on the Action Pane, select **Performance trace**.

5. Select the most recently generated trace, and then select **OK**.

New information is now available for some data source items of the current model mapping:

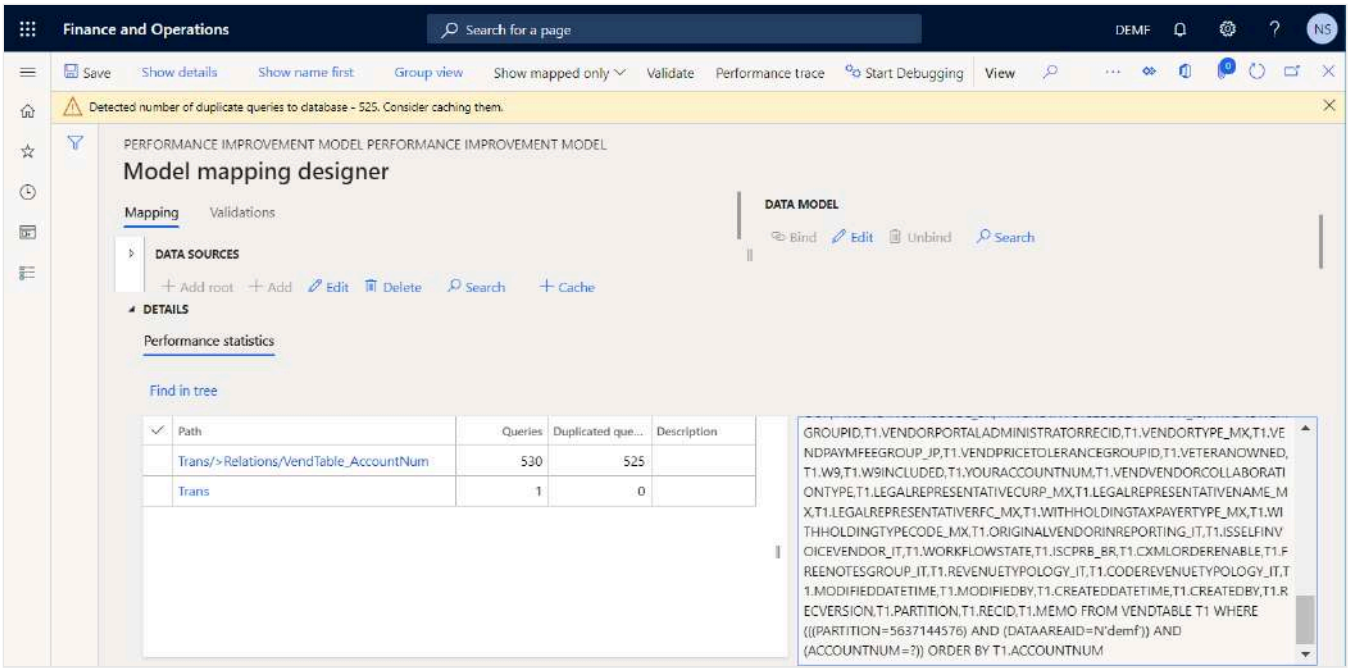
- The actual time spent getting data by using the data source
- The same time expressed as a percentage of the total time spent running the whole model mapping



The **Performance statistics** grid shows that the **Trans** data source calls the VendTrans table one time. The value **[265][Q:265]** of the **Trans** data source indicates that 265 vendor transactions are fetched from the application table and returned to the data model.

The **Performance statistics** grid also shows that the current model mapping duplicates database requests while the **#Vend** data source runs. This duplication occurs for the following reasons:

- The vendor table is called two times for each of the 265 iterated vendor transactions, for a total of 530 calls:
  - One call is made to enter the vendor account number.
  - One call is made to enter the vendor name.
- The vendor table is called for each iterated vendor transaction, even though the fetched transactions are posted for only five vendors. Of the 530 calls, 525 are duplicates. The following illustration shows the message that you receive about duplicate calls (database requests).



Of the total model mapping execution time (approximately eight seconds), more than 80 percent (approximately six seconds) is spent retrieving values from the VendTable application table. That percentage is too large for two attributes of five vendors, compared with the volume of information from the VendTrans application table.

To reduce the number of calls that get the vendor details for every transaction and to improve the performance of the model mapping, you can use caching for the **#Vend** data source.

> **Note**
>
> At runtime, the **Trans\#Vend** data source is cached in the scope of the current transaction of the **Trans** data source.

By caching the **#Vend** data source, you reduce the number of duplicated calls from 525 to 260, but you don't completely eliminate the duplication. To completely eliminate duplication, you can configure a new parameterized data source of the **Calculated field** type.

Improve the model mapping based on information from the execution trace

Change the logic of the model mapping

Follow these steps to use caching and a data source of the **Calculated field** type, to help prevent duplicate calls to the database.

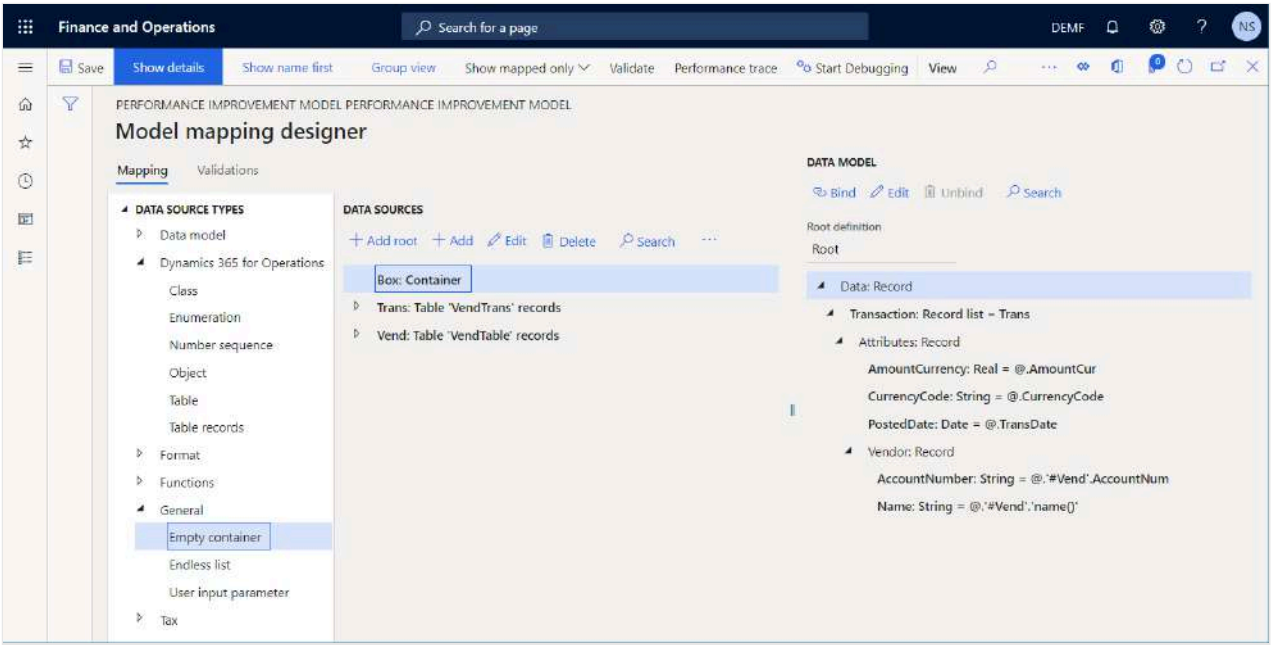
1. On **Configurations**, in the configuration tree, select **Performance improvement mapping**.

2. On the Action Pane, select **Designer**.

3. On **Model mappings**, on the Action pane, select **Designer**.

4. On **Model mapping designer**, add a data source of the **Table records** type to access records in the VendTable application table:
   a. In the **Data source types** pane, expand **Dynamics 365 for Operations**, and select **Table records**.
   b. Select **Add root**.
   c. In the dialog box, enter **Vend** in the **Name** field.
   d. Enter **VendTable** in the **Table** field.
   e. Select **OK**.

5. You can parameterize calls to data sources of the **Calculated field** type only if those data sources reside in a container. Therefore, add a data source of the **Empty container** type to hold a new parameterized data source of the **Calculated field** type:
   a. In the **Data source types** pane, expand **General**, and select **Empty container**.
   b. Select **Add root**.
   c. In the dialog box, enter **Box** in the **Name** field.
   d. Select **OK**.



6. Add a parameterized data source of the **Calculated field** type:
   a. In the **Data sources** pane, select **Box**.
   b. In the **Data source types** pane, expand **Functions**, and select **Calculated field**.
   c. Select **Add**.

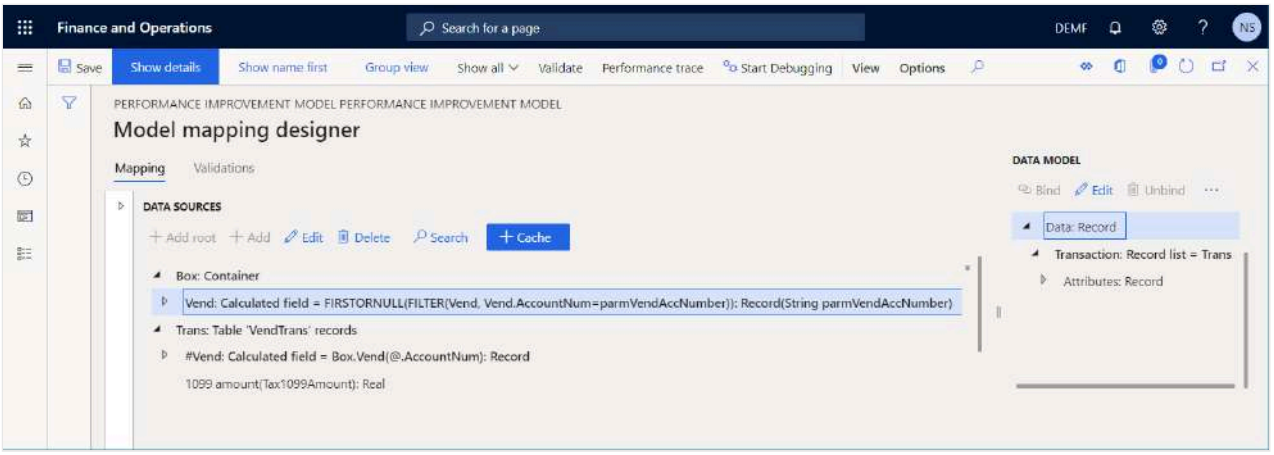
d. In the dialog box, enter **Vend** in the **Name** field.
e. Select **Edit formula**.
f. On **Formula designer**, select **Parameters** to specify the parameters that must be provided when this data source is called.
g. In **Parameters**, select **New**.
h. Enter **parmVendAccNumber** in the **Name** field.
i. Select **String** in the **Type** field.
j. Select **OK**.
k. In the **Formula** field, enter `FIRSTORNULL(FILTER(Vend, Vend.AccountNum=parmVendAccNumber))`.
l. Select **Save**, and close **Formula designer**.
m. Select **OK** to add the new data source.

7. Mark the added data source as cached during the execution:
   a. In the **Data sources** pane, select **Box\Vend**.
   b. Select **Cache**.

> ⓘ **Note**
>
> The **Box\Vend** data source is cached in the scope of all vendor transactions of the **Trans** data source at runtime.

8. Update the nested **Trans\#Vend** data source so that it uses the **Box\Vend** data source:
   a. In the **Data sources** pane, expand **Trans**.
   b. Select the **Trans\#Vend** data source, and then select **Edit** > **Edit formula**.
   c. On **Formula designer**, enter `Box.Vend(@.AccountNum)` in the **Formula** field.
   d. Select **Save**, and then close **Formula designer**.
   e. Select **OK** to complete your changes to the selected data source.

9. Select **Save**.



10. Close **Model mapping designer**.

11. Close the **Model mappings** page.

Complete the modified version of the ER model mapping

1. On **Configurations**, on the **Versions** FastTab, select version **1.2** of the **Performance improvement mapping** configuration.
2. Select **Change status** > **Complete**, and then select **OK**.

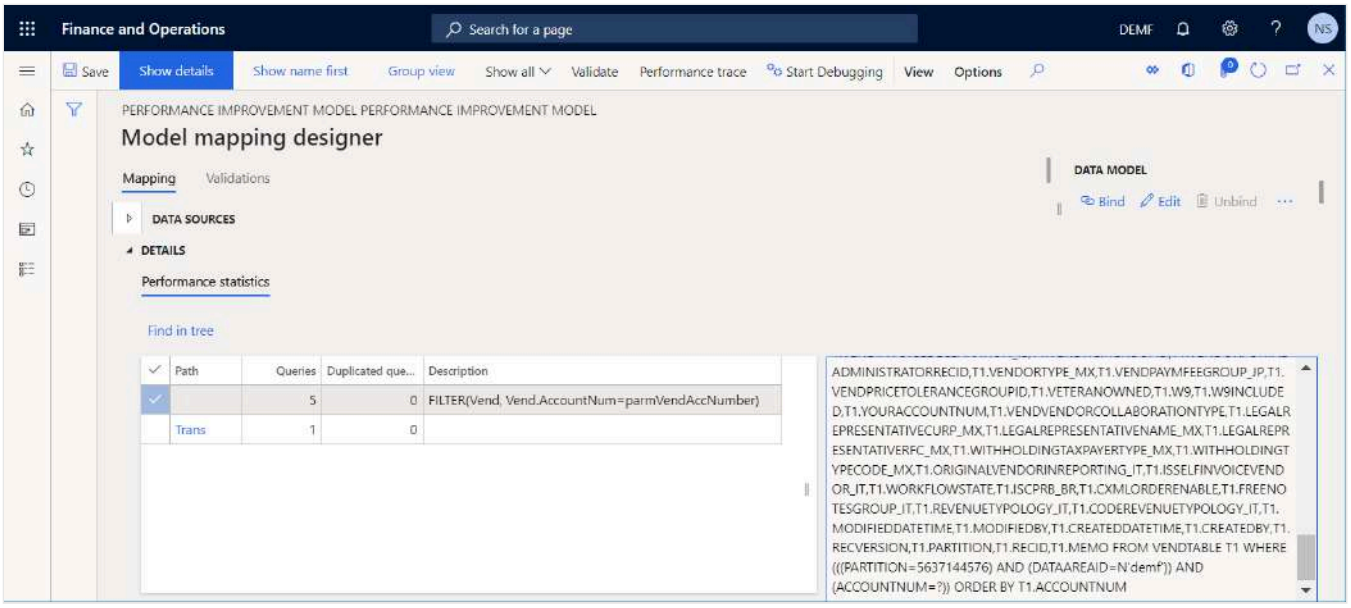
Run the modified ER solution to trace execution

Repeat the steps in the Run the ER format section earlier in this article to generate a new performance trace.

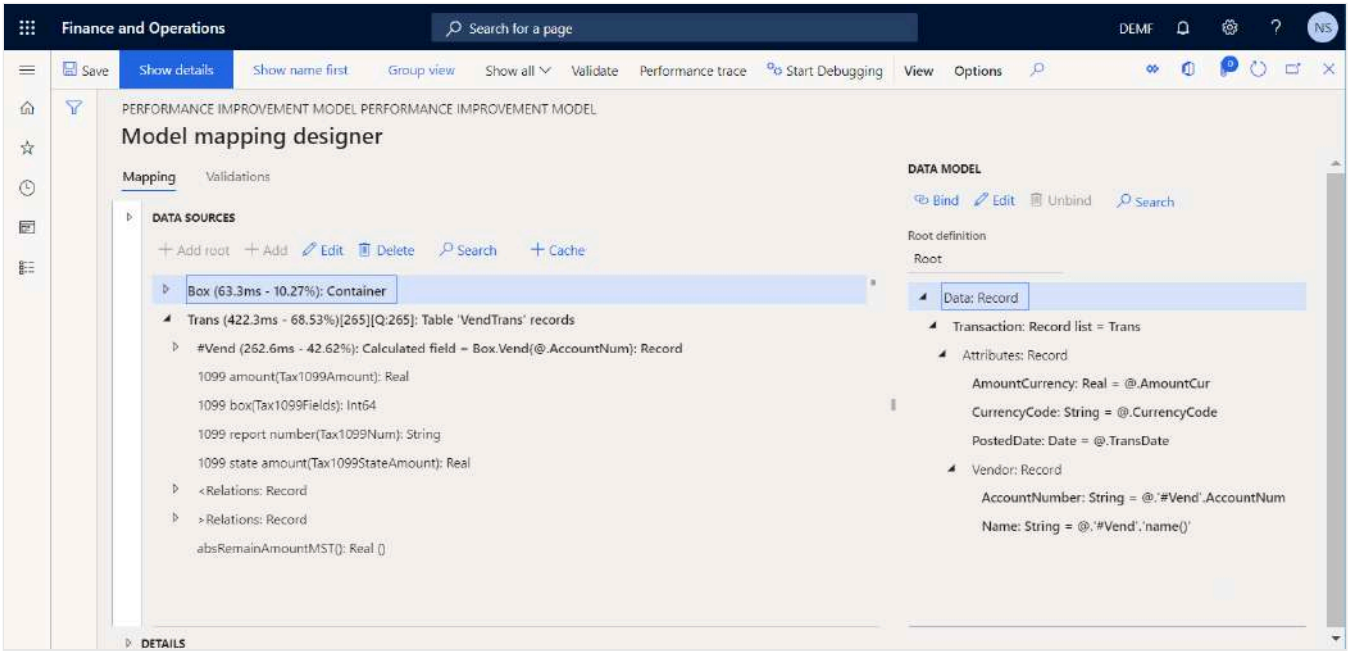
Use the performance trace to analyze adjustments to the model mapping

1. On **Configurations**, in the configuration tree, select **Performance improvement mapping**.
2. On the Action Pane, select **Designer**.
3. On **Model mappings**, on the Action Pane, select **Designer**.
4. On **Model mapping designer**, on the Action Pane, select **Performance trace**.
5. Select the most recent trace that was generated, and then select **OK**.

Notice that the adjustments you made to the model mapping eliminated duplicate queries to the database. The number of calls to database tables and data sources for this model mapping is also reduced.



The total execution time is reduced by about 20 times (from about 8 seconds to about 400 milliseconds). Therefore, the performance of the whole ER solution is improved.



Appendix 1: Download the components of the sample Microsoft ER solution

Download the following files and store them locally.

Expand table

File	Content
Performance improvement model.version.1	Sample ER data model configuration
Performance improvement mapping.version.1.1	Sample ER model mapping configuration

File	Content
Performance improvement format.version.1.1	Sample ER format configuration

Appendix 2: Configure the ER framework

Before you can start to use the ER framework to improve the performance of the sample Microsoft ER solution, you must configure the minimal set of ER parameters.

Configure ER parameters

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization configurations** page, in the **Related links** section, select **Electronic reporting parameters**.
3. On the **Electronic reporting parameters** page, on the **General** tab, set the **Enable design mode** option to **Yes**.
4. On the **Attachments** tab, set the following parameters:
    - In the **Configurations** field, select the **File** type for the **DEMF** company.
    - In the **Job archive**, **Temporary**, **Baseline**, and **Others** fields, select the **File** type.

For more information about ER parameters, see Configure the ER framework.

Activate an ER configuration provider

Every ER configuration that you add is marked as owned by an ER configuration provider. Use the ER configuration provider activated in the **Electronic reporting** workspace for this purpose. Therefore, you must activate an ER configuration provider in the **Electronic reporting** workspace before you start to add or edit ER configurations.

> **Note**
>
> Only the owner of an ER configuration can edit the configuration. Therefore, before editing an ER configuration, you must activate the appropriate ER configuration provider in the **Electronic reporting** workspace.

Review the list of ER configuration providers

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Related links** section, select **Configuration providers**.
3. On **Configuration provider table**, each provider record has a unique name and URL. Review the contents of this page. If a record for **Litware, Inc.** already exists, skip the next procedure, Add a new ER configuration provider.

Add a new ER configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Related links** section, select **Configuration providers**.
3. On **Configuration providers**, select **New**.
4. In the **Name** field, enter **Litware, Inc.**.
5. In the **Internet address** field, enter `https://www.litware.com`.
6. Select **Save**.

Activate an ER configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configuration providers** section, select the **Litware, Inc.** tile, and then select **Set active**.

For more information about ER configuration providers, see Create configuration providers and mark them as active.

Cross-company data sources in Electronic reporting (ER)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can design Electronic reporting (ER) formats to generate outgoing documents in various formats. When you generate a document, an ER format calls data sources that you configured in a corresponding ER model mapping. To configure access to application tables for record retrieval, use ER data sources of the **Table records** type. When the accessing table is a shared table (that is, a table where data is saved without a company identifier), this data source returns all records. When the accessing table is a company-dependent table (that is, a table where data is saved per company), this data source returns only the records saved for the current company (that is, the company context that the ER format is running under).

You can now mark every data source of the **Table records** type in a model mapping as a cross-company data source. Therefore, you can use data sources of the **Table records** type to access cross-company data in application tables.

If you mark a data source as cross-company, the following behavior occurs:

- For a data source that refers to any shared table except CompanyInfo, the data source returns all records that exist in the referenced table.
- For a data source that refers to the CompanyInfo table, even though CompanyInfo is a shared table, the data source returns the records that contain the identifier of a company from the defined scope.
- For any company-dependent table, the data source returns the records of the referenced table that contain the identifier of a company from the defined scope.

In the system query dialog box, when the **Ask for query** option is turned on for any data source marked as cross-company, you can manually select one or more companies to include on the **Company range** tab.

> **ⓘ Important**
>
> Like other filters, the company filter is persisted as a last-used value for queries when you run an ER format. The filter isn't automatically changed if you change the cross-company value for a data source. To use a different cross-company value for another data source, delete the corresponding user-specific selection.

For every data source that is marked as cross-company, you can select the records that you want by using the **FILTER** and **WHERE** functions in ER expressions. The **dataAreaID** field can also be used as a company identifier. Currently, the **dataAreaID** field is limited to the following types of conditions when the **FILTER** function is used:

- Only conditions that have a single **dataAreaID** field comparison are supported.
- Only comparisons that have expressions that don't depend on records list items are allowed.

Therefore, the following expression is valid.

ER

```
FILTER (MyTable, MyTable.dataAreaID = $StringUserInputParameter)
While shown below expressions will not pass the validation:
FILTER (MyTable, MyTable.dataAreaID = MyTable2RecordsList.MyField)
FILTER (MyTable,
    OR(
        MyTable.dataAreaID = $StringUserInputParameter1,
        MyTable.dataAreaID = $StringUserInputParameter2
    )
)
```

By default, the scope includes all companies of the current application. However, you can restrict it. To restrict the scope of cross-company data access for a single ER format, assign a specific organization hierarchy to the format. When you define a hierarchy for an ER format, only records for legal entities that are presented in the assigned hierarchy are returned, even though the format calls cross-company data sources. When a reference to a hierarchy that no longer exists is defined for an ER format, the default scope is applied, and the format calls cross-company data sources. In this situation, records for all application companies are returned.

When you turn on the **Use draft** option for the assigned to a single ER format organization hierarchy, the legal entities from the draft version of this hierarchy are used to identify the

scope for cross-company data sources. If the draft version doesn't exist, the legal entities from the last published version of this organization hierarchy are used.

When you turn off the **Use draft** option for the assigned to a single ER format organization hierarchy, the legal entities from the last published version of this organization hierarchy are used to identify the scope for cross-company data sources. Date effectiveness of organization hierarchies isn't supported yet in the ER framework.

Assign the hierarchy to a format in a specific page that you can access from the ER workspace or by using the **Organization administration** > **Electronic reporting** > **Legal entity filter for formats** menu item. To access the page, grant the **Maintain legal entity filters for format** privilege (ERMaintainFormatMappingLegalEntityFilters) to a user. The scope restriction of hierarchy-based legal entities for the format is applied in addition to the restriction that the user can manually specify in the system query dialog box. The intersection of these restrictions is used when the format is run.

To learn more about this feature, play the task guide, **ER Access records of company dependent tables in cross-company mode**, which is part of the 7.5.4.3 Acquire/Develop IT service/solution components (10677) business process, and can be downloaded from the Microsoft Download Center. This task guide walks you through the process of configuring an ER model mapping and ER format to access application tables in cross-company mode.

Download the following files to complete the task guide:

- ER model configuration - CrossCompanyDataAccessModel.xml
- ER format configuration - CrossCompanyDataAccessFormat.xml

ER Use financial dimensions as a data source (Part 1 - Design data model)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a system administrator or electronic reporting developer can configure an Electronic reporting (ER) model to use financial dimensions as a data source for ER reports. You can perform these steps in any company.

To complete these steps, you must first complete the steps in the procedure, "Create a configuration provider and mark it as active".

Create a new data model

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
    - Make sure that the **Litware, Inc.** provider is available and marked as active.
2. Select **Reporting configurations**.
3. Select **Create configuration** to open the form.
4. In the **Name** field, type *Financial dimensions sample model*.
5. Select **Create configuration**.
6. Select **Designer**.
7. Select **New** to open the form.
8. In the **Name** field, type *Entry*.
9. Select **Add**.
10. Select **New** to open the form.
11. In the **Name** field, type *Company*.
12. Select **Add**.
    - Add a new record list to your model. This list exposes the settings of selected financial dimensions for any ER reports that use this model as a data source. Each

financial dimension appears in this list as a record with fields that represent the dimension's settings.

13. Select **New** to open the form.
14. In the **Name** field, type *Dimensions setting*.
15. In the **Item type** field, select **Record list**.
16. Select **Add**.
17. Select **New** to open the form.
18. In the **Name** field, type *Code*.
19. In the **Item type** field, select **String**.
20. Select **Add**.
21. Select **New** to open the form.
22. In the **Name** field, type *Name*.
23. Select **Add**.
24. In the tree, select **Entry**.
25. Select **New** to open the form.
26. In the **Name** field, type *Journal*.
27. In the **Item type** field, select **Record list**.
28. Select **Add**.
29. Select **New** to open the form.
30. In the **Name** field, type *Batch*.
31. In the **Item type** field, select **String**.
32. Select **Add**.
33. Select **New** to open the form.
34. In the **Name** field, type *Transaction*.
35. In the **Item type** field, select **Record list**.
36. Select **Add**.
37. Select **New** to open the form.
38. In the **Name** field, type *Date*.
39. In the **Item type** field, select **Date**.
40. Select **Add**.
41. Select **New** to open the form.
42. In the **Name** field, type *Debit*.
43. In the **Item type** field, select **Real**.
44. Select **Add**.
45. Select **New** to open the form.
46. In the **Name** field, type *Credit*.
47. Select **Add**.

48. Select **New** to open the form.
49. In the **Name** field, type *Currency*.
50. In the **Item type** field, select **String**.
51. Select **Add**.
52. Select **New** to open the form.
53. In the **Name** field, type *Voucher*.
54. Select **Add**.
55. Select **New** to open the form.
56. In the **Name** field, type *Dimensions data*.
57. In the **Item type** field, select **Record list**.
58. Select **Add**.

    - You add a new record list to your model. This list exposes the values of selected financial dimensions for any ER reports that use this model as a data source. Each financial dimension appears in this list as a record with fields that represent the dimension's values. The dimension name also appears in this record as a field that you can use for selection purposes.

59. Select **New** to open the form.
60. In the **Name** field, type *Code*.
61. In the **Item type** field, select **String**.
62. Select **Add**.
63. Select **New** to open the form.
64. In the **Name** field, type **Description**.
65. Select **Add**.
66. Select **New** to open the form.
67. In the **Name** field, type *Name*.
68. Select **Add**.
69. Select **Save**.
70. Close the page.

ER Use financial dimensions as a data source (Part 2 - Model mapping)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) model to use financial dimensions as a data source for ER reports. You can perform these steps in any company.

To complete these steps, you must first complete the steps in the "ER Use financial dimensions as a data source (Part 1: Design data model" procedure.

Add required data sources to model mapping

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, select **Financial dimensions sample model**.
3. Select **Designer**.
4. Select **Map model to datasource**.
5. Select **New**.
6. In the **Definition** field, select **Entry**.
7. In the **Name** field, type **Dimensions data mapping**.
8. In the **Description** field, type **Dimensions data mapping**.
9. Select **Save**.
10. Select **Designer**.
11. In the tree, select **Dynamics 365 for Operations\Table**.

12. Select **Add root**.

13. In the **Name** field, type **Company**.

14. In the **Table** field, type **CompanyInfo**.

15. Select **OK**.

16. In the tree, select **Functions\Financial dimensions details**.

17. Select **Add root**.

    - This data source specifies how the scope of financial dimensions is defined for any report that uses this model as a data source.

18. In the **Name** field, type a value.

19. Select **Yes** in the **Ask for dimensions** field.

    - Select **Yes** to allow the user to select dimensions at run-time on the User dialog form. If set to **No**, all financial dimensions of the current instance are used by default.

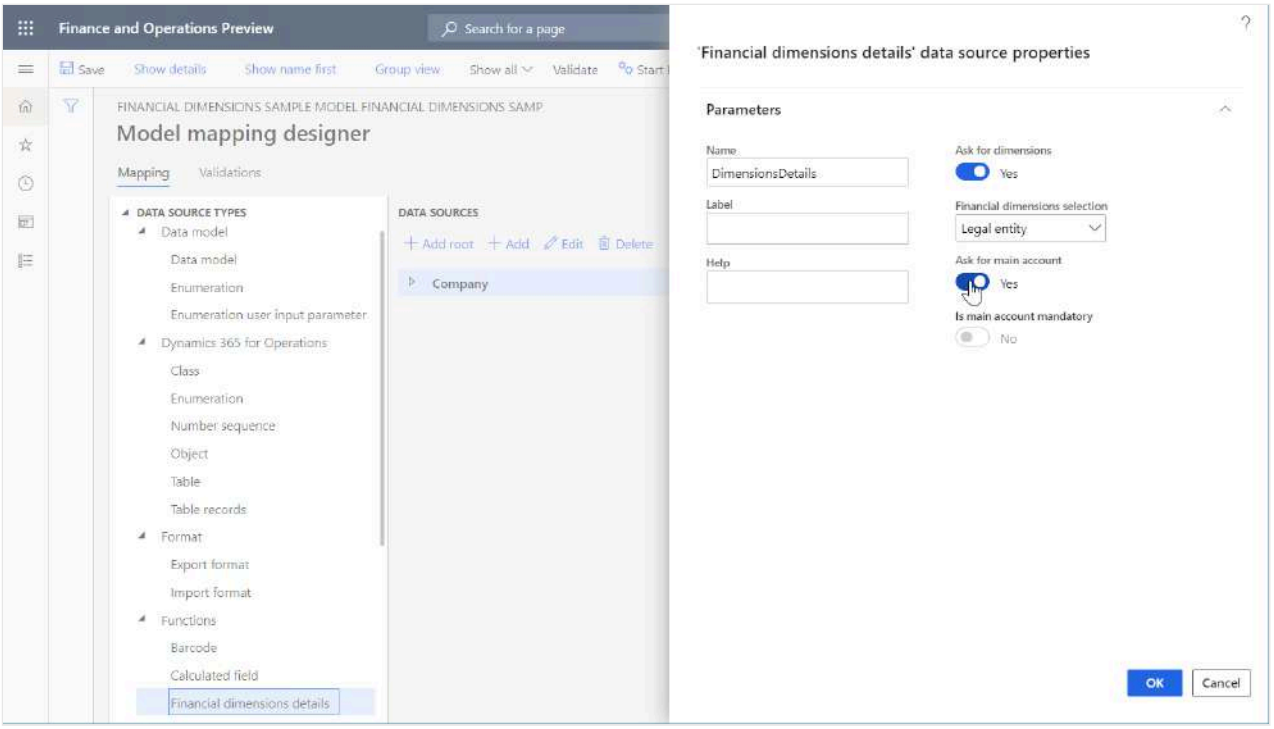
20. In the **Financial dimensions selection** field, select **Legal entity**.

    - Select **All** to allow the user to select desired dimensions for the current instance in the **Lookup** field. Select **Legal entity** to allow the user to select dimensions for the company in the **Lookup** field. Select **Dimension** to allow the user to select dimensions using a single dimension set.

21. Select **Yes** in the **Ask for main account** field.

    - Set **Ask for main account** to **Yes** to allow users to select the main account as part of the list of dimensions. If set to **No**, the main account isn't included in the list of dimensions and the **Is main account mandatory** option is enabled. If **Is main account mandatory** is set to **Yes**, include the main account in the list of dimensions regardless of the user's selection.

22. Select **OK**.



23. In the tree, select **Dynamics 365 for Operations\Table records**.

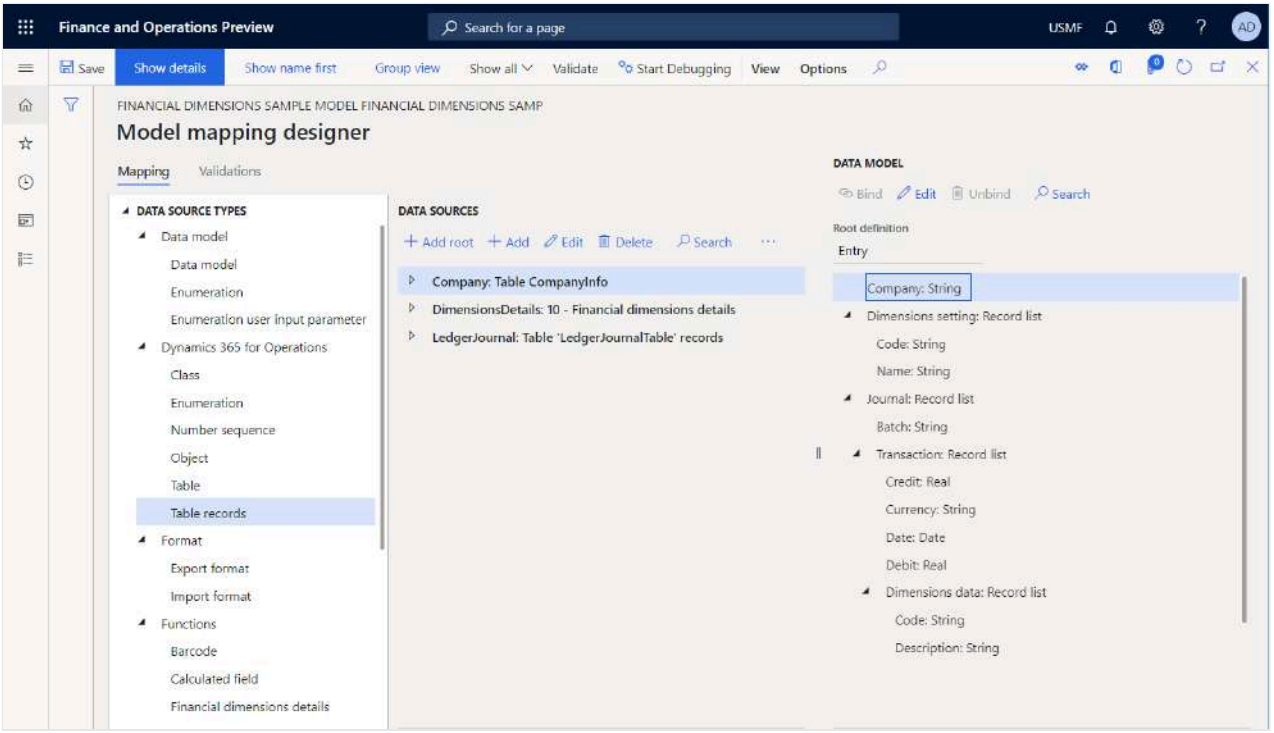
24. Select **Add root**.

25. In the **Name** field, type **LedgerJournal**.

26. Select **Yes** in the **Ask for query** field.

27. In the **Table** field, type **LedgerJournalTable**.

28. Select **OK**.



Map data model elements to added data sources

1. In the tree, expand **Journal**.
2. In the tree, expand **Journal\Transaction**.
3. In the tree, expand **Journal\Transaction\Dimensions data**.
4. In the tree, expand **Dimensions setting**.
5. In the tree, expand **LedgerJournal**.
6. In the tree, expand **LedgerJournal<Relations**.
7. In the tree, expand **LedgerJournal<Relations\LedgerJournalTrans**.
8. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Voucher**.
9. In the tree, select **Journal\Transaction\Voucher**.
10. Select **Bind**.
11. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)**.
    - For any reference to financial dimensions that you set to, for example, `LedgerDimension`, a corresponding data source item is available (`LedgerDimension.Dimension`). This data source item offers the financial dimensions of that dimensions set as the record's list.
12. In the tree, expand **LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)**.
13. In the tree, expand **LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions**.
14. In the tree, expand **LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Value**.

15. In the tree, expand **LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Definition**.

16. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Definition\Name**.

17. In the tree, select **Journal\Transaction\Dimensions data\Name**.

18. Select **Bind**.

19. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Value\Description**.

20. In the tree, select **Journal\Transaction\Dimensions data\Description**.

21. Select **Bind**.

22. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions\Value\Code**.

23. In the tree, select **Journal\Transaction\Dimensions data\Code**.

24. Select **Bind**.

25. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Account.Dimension(LedgerDimension.Dimension)\Main account and dimensions**.

26. In the tree, select **Journal\Transaction\Dimensions data**.

27. Select **Bind**.

28. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Debit(AmountCurDebit)**.

29. In the tree, select **Journal\Transaction\Debit**.

30. Select **Bind**.

31. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Date(TransDate)**.

32. In the tree, select **Journal\Transaction\Date**.

33. Select **Bind**.

34. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Currency(CurrencyCode)**.

35. In the tree, select **Journal\Transaction\Currency**.

36. Select **Bind**.

37. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans\Credit(AmountCurCredit)**.

38. In the tree, select **Journal\Transaction\Credit**.

39. Select **Bind**.

40. In the tree, select **LedgerJournal<Relations\LedgerJournalTrans**.

41. In the tree, select **Journal\Transaction**.

42. Select **Bind**.

43. In the tree, select **LedgerJournal\Journal batch number(JournalNum)**.

44. In the tree, select **Journal\Batch**.

45. Select **Bind**.

46. In the tree, select **LedgerJournal**.

47. In the tree, select **Journal**.

48. Select **Bind**.

49. In the tree, expand **Dimensions**.

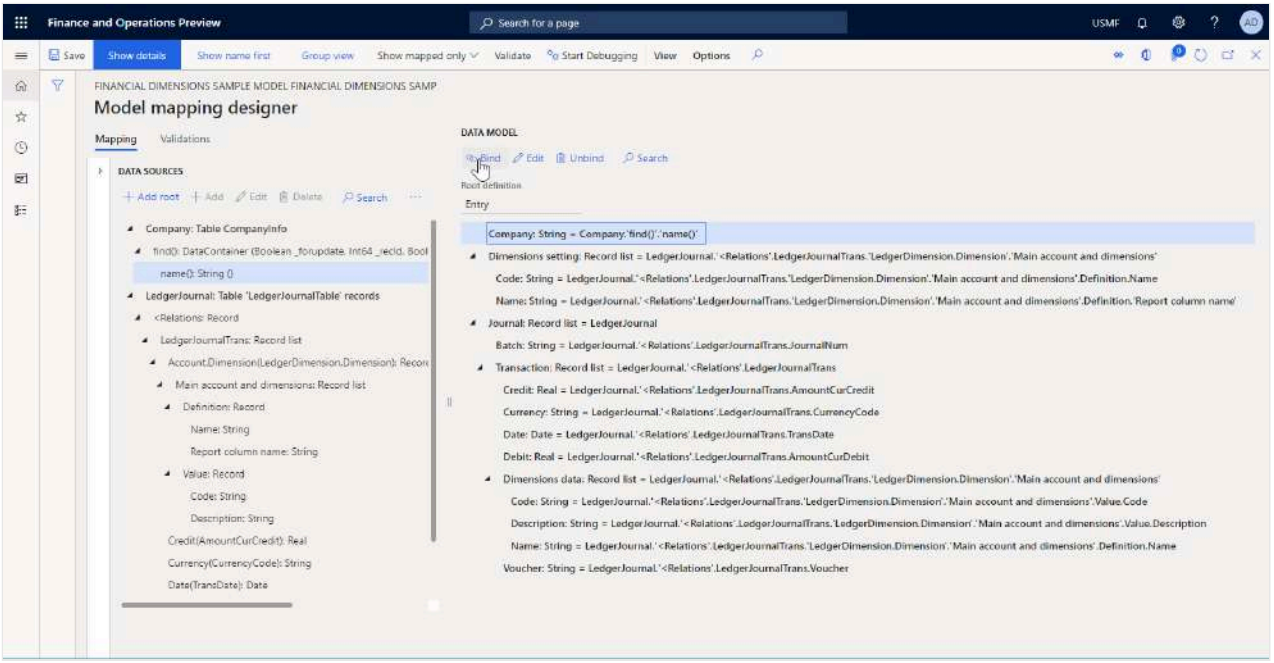
50. In the tree, expand **Dimensions\Main account and dimensions**.

51. In the tree, expand **Dimensions\Main account and dimensions\Definition**.

52. In the tree, select **Dimensions\Main account and dimensions\Definition\Name**.

53. In the tree, select **Dimensions setting\Code**.

54. Select **Bind**.
55. In the tree, select **Dimensions\Main account and dimensions\Definition\Report column name**.
56. In the tree, select **Dimensions setting\Name**.
57. Select **Bind**.
58. In the tree, select **Dimensions\Main account and dimensions**.
59. In the tree, select **Dimensions setting**.
60. Select **Bind**.
61. In the tree, select **Company**.
62. Click **Edit**.
63. In the **expressionAsStringText** field, enter `Company.'find()'.'name()'`.
    - `Company.'find()'.'name()'`
64. Select **Save**.



65. Close the page.
66. Select **Save**.
67. Close the page.

Complete this draft model's version

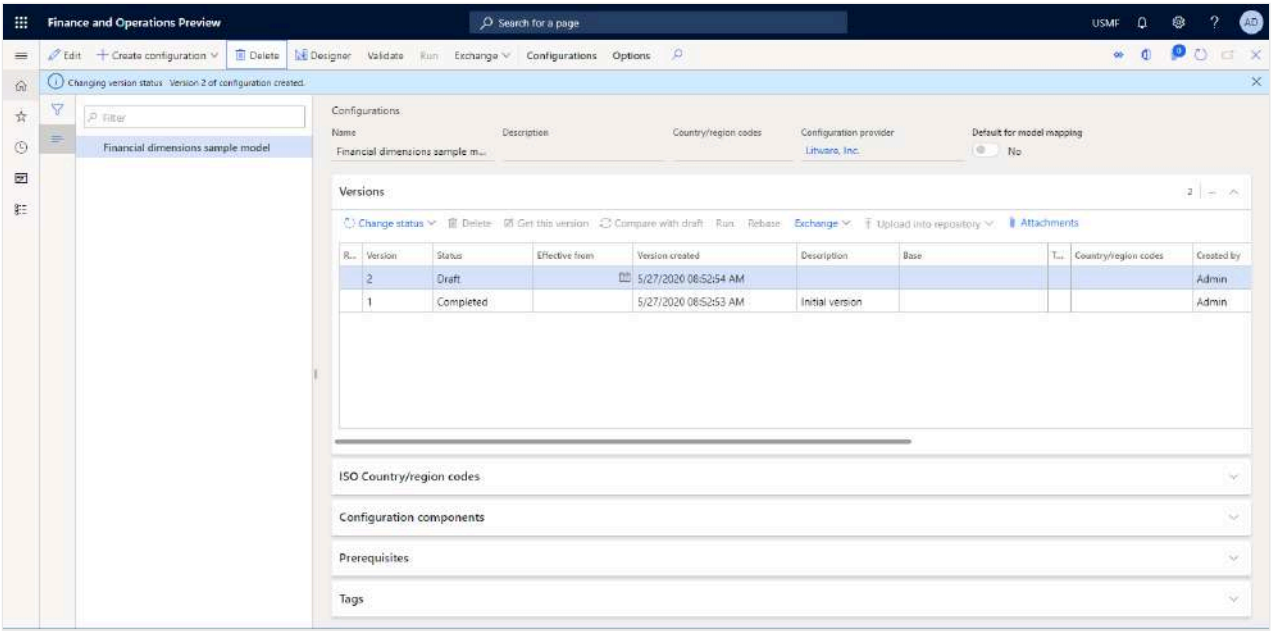
1. Close the page.

2. Close the page.

3. Select **Change status**.

4. Select **Complete**.

5. Select **OK**.



Last updated on 04/13/2026

ER Use financial dimensions as a data source (Part 3 - Design the report)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) model to use financial dimensions as a data source for ER reports. You can perform these steps in any company.

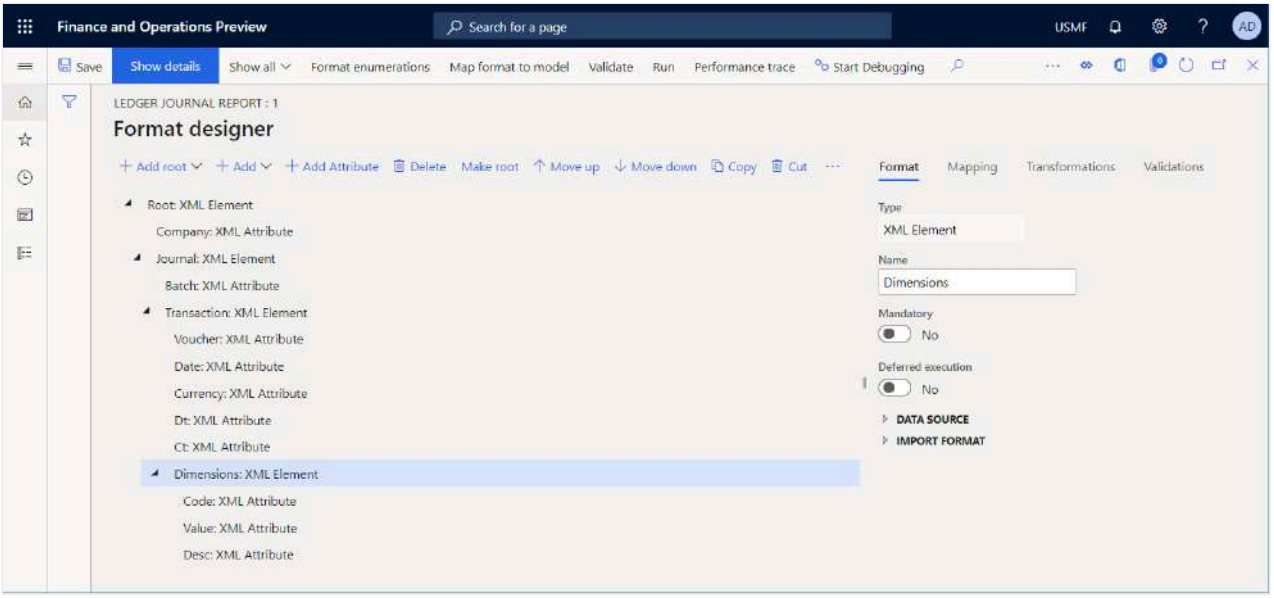
To complete these steps, you must first complete the steps in the "ER Use financial dimensions as a data source (Part 2: Model mapping)" procedure.

Design a report to present financial dimensions

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, select **Financial dimensions sample model**.
3. Select **Create configuration** to open the form.
4. In **New**, enter *Format based on data model Financial dimensions sample model*.
    - Use the model that you created in advance as the data source for your new report.
5. In **Name**, type *Ledger journal report*.
6. In **Data model definition**, select *Entry*.
7. Select **Create configuration**.
8. Select **Designer**.
9. Select **Add root** to open the form.
10. In the tree, select **XML\Element**.
11. In **Name**, type *Root*.
12. Select **OK**.
13. Select **Add** to open the form.
14. In the tree, select **XML\Attribute**.

15. In **Name**, type *Company*.
16. Select **OK**.
17. Select **Add** to open the form.
18. In the tree, select **XML\Element**.
19. In **Name**, type *Journal*.
20. Select **OK**.
21. In the tree, select **Root: XML Element\Journal: XML Element**.
22. Select **Add** to open the form.
23. In the tree, select **XML\Attribute**.
24. In **Name**, type *Batch*.
25. Select **OK**.
26. Select **Add** to open the form.
27. In the tree, select **XML\Element**.
28. In **Name**, type *Transaction*.
29. Select **OK**.
30. In the tree, select **Root: XML Element\Journal: XML Element\Transaction: XML Element**.
31. Select **Add** to open the form.
32. In the tree, select **XML\Attribute**.
33. In **Name**, type *Voucher*.
34. Select **OK**.
35. Select **Add Attribute**.
36. In **Name**, type *Date*.
37. Select **OK**.
38. Select **Add Attribute**.
39. In **Name**, type *Currency*.
40. Select **OK**.
41. Select **Add Attribute**.
42. In **Name**, type *Dt*.
43. Select **OK**.
44. Select **Add Attribute**.
45. In **Name**, type *Ct*.
46. Select **OK**.
47. Select **Add** to open the form.
48. In the tree, select **XML\Element**.
49. In **Name**, type *Dimensions*.
50. Select **OK**.

51. In the tree, select **Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element**.
52. Select **Add** to open the form.
53. In the tree, select **XML\Attribute**.
54. In **Name**, type *Code*.
55. Select **OK**.
56. Select **Add Attribute**.
57. In **Name**, type *Value*.
58. Select **OK**.
59. Select **Add Attribute**.
60. In the **Name** field, enter `Desc`.
61. Select **OK**.



Map report elements to data sources

1. Select the **Mapping** tab.
2. In the tree view, expand `model: Data model Financial dimensions sample model`.
3. In the tree view, expand `model: Data model Financial dimensions sample model\Journal: Record list`.
4. In the tree view, expand `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list`.
5. In the tree view, expand `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list`.
6. In the tree view, select `Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element\Desc: XML Attribute`.

7. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list\Description: String`.
8. Select **Bind**.
9. In the tree view, select `Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element\Value: XML Attribute`.
10. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list\Code: String`.
11. Select **Bind**.
12. In the tree view, select `Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element\Code: XML Attribute`.
13. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list\Name: String`.
14. Select **Bind**.
15. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Dimensions data: Record list`.
16. In the tree, select **Root: XML Element\Journal: XML Element\Transaction: XML Element\Dimensions: XML Element**.
17. Select **Bind**.
18. In the tree view, select `Root: XML Element\Journal: XML Element\Transaction: XML Element\Ct: XML Attribute`.
19. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Credit: Real`.
20. Select **Bind**.
21. In the tree view, select `Root: XML Element\Journal: XML Element\Transaction: XML Element\Dt: XML Attribute`.
22. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Debit: Real`.
23. Select **Bind**.
24. In the tree view, select `Root: XML Element\Journal: XML Element\Transaction: XML Element\Currency: XML Attribute`.
25. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Currency: String`.
26. Select **Bind**.
27. In the tree view, select `Root: XML Element\Journal: XML Element\Transaction: XML Element\Date: XML Attribute`.

28. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Date: Date`.
29. Select **Bind**.
30. In the tree view, select `Root: XML Element\Journal: XML Element\Transaction: XML Element\Voucher: XML Attribute`.
31. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list\Voucher: String`.
32. Select **Bind**.
33. In the tree, select **Root: XML Element\Journal: XML Element\Transaction: XML Element**.
34. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Transaction: Record list`.
35. Select **Bind**.
36. In the tree view, select `Root: XML Element\Journal: XML Element\Batch: XML Attribute`.
37. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list\Batch: String`.
38. Select **Bind**.
39. In the tree, select **Root: XML Element\Journal: XML Element**.
40. In the tree view, select `model: Data model Financial dimensions sample model\Journal: Record list`.
41. Select **Bind**.
42. In the tree view, select `Root: XML Element\Company: XML Attribute`.
43. In the tree view, select `model: Data model Financial dimensions sample model\Company: String`.
44. Select **Bind**.
45. Select **Save**.

46. Close the page.

ER Use financial dimensions as a data source (Part 4 - Run the report)

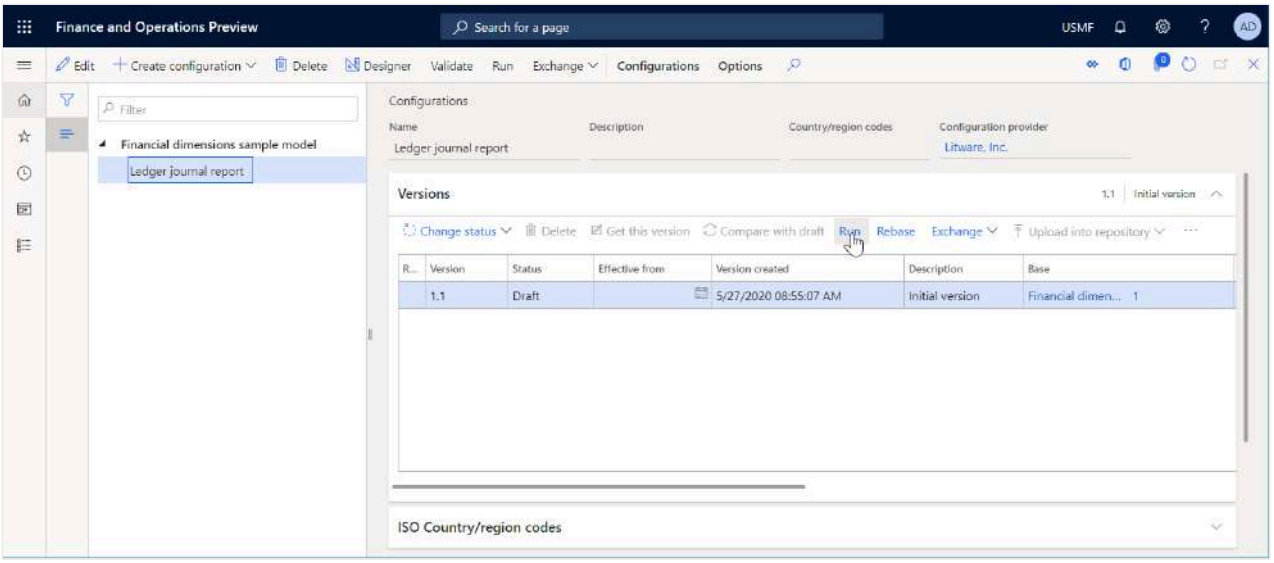
> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) model to use financial dimensions as a data source for ER reports. You can perform these steps in the DEMF company.

To complete these steps, you must first complete the steps in the "ER Use financial dimensions as a data source (Part 3: Design the report)" procedure. You must also configure default document types on the Electronic reporting parameters page. When you download and import any ER configuration, you also set default document types.

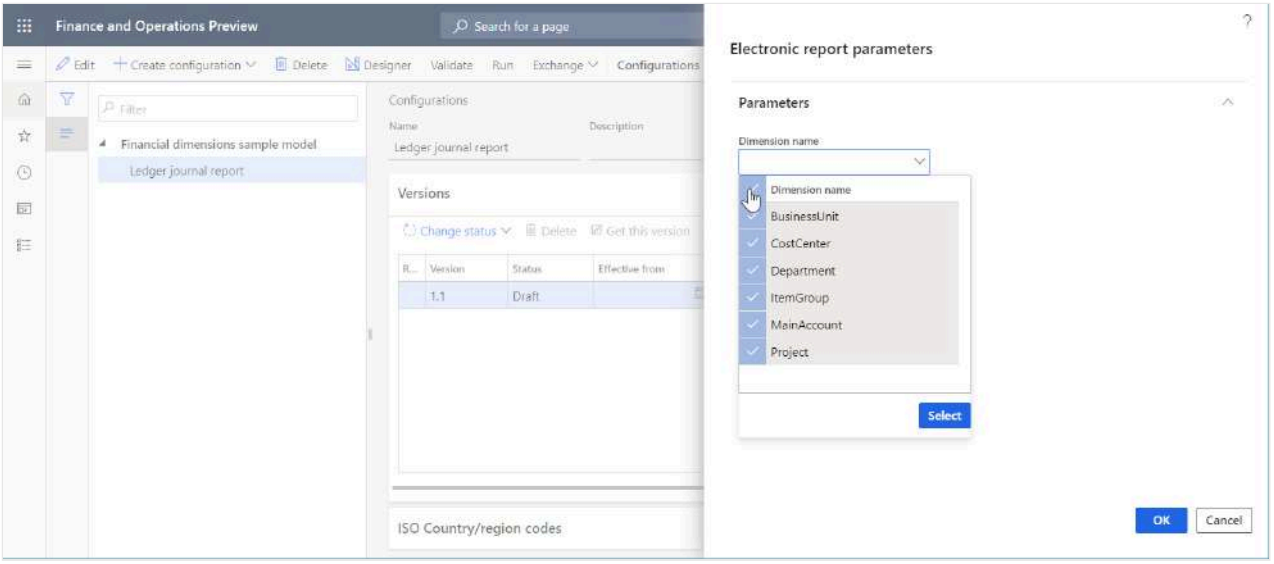
Run report

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Financial dimensions sample model**.
3. In the tree, select **Financial dimensions sample model\Ledger journal report**.
4. Select **Run**.



5. In the **Dimension name** field, enter or select a value.

    - To select all dimensions in the current company, enter the following information: BusinessUnit;CostCenter;Department;ItemGroup;MainAccount;Project



6. Expand the **Records to include** section.

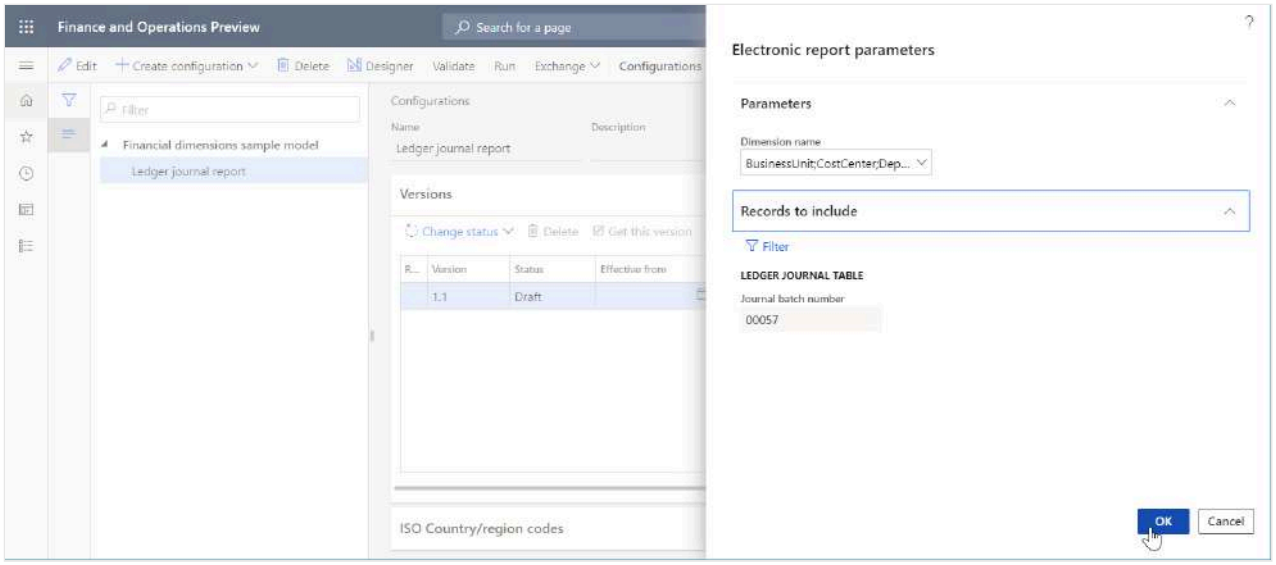
7. Select **Filter**.

8. Select the row for the **Ledger journal** table and the **Journal batch number** field.

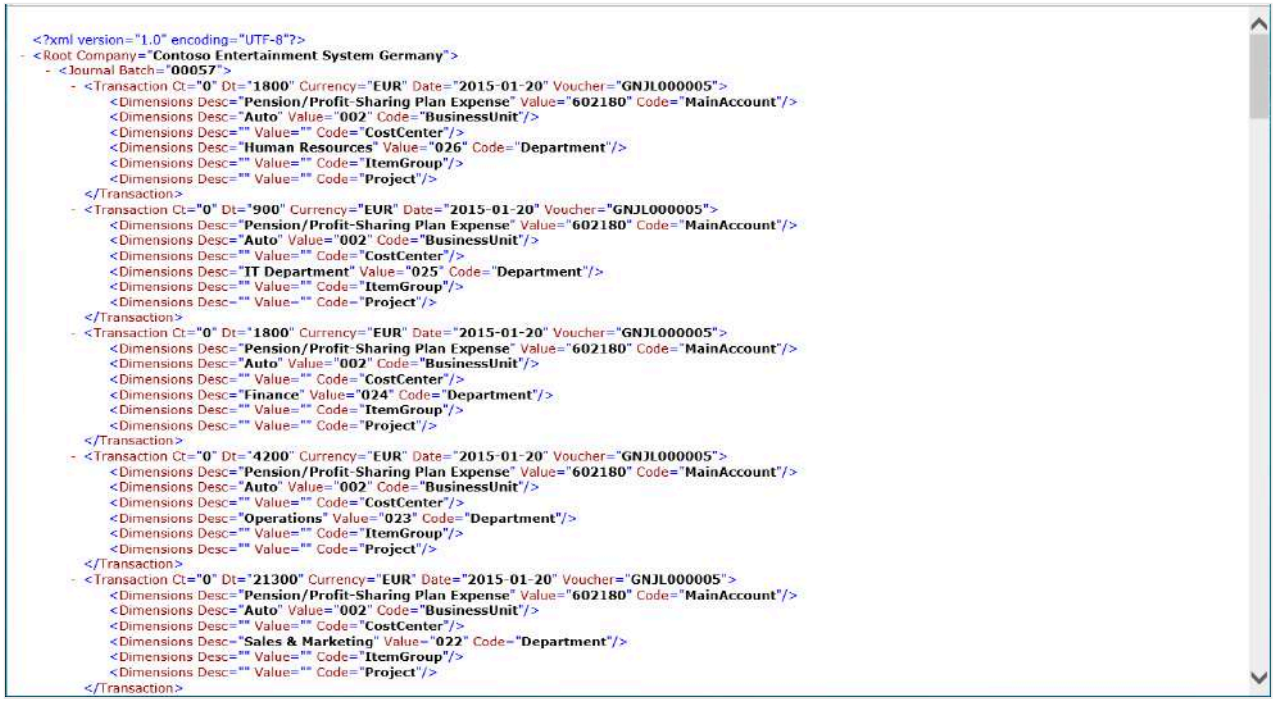
9. In the **Criteria** field, type `00057`.

10. Select **OK**.

11. Select **OK**.



- Review the generated output. For each transaction of the selected batch, the financial dimensions from the corresponding dimensions set are presented. Run this report and select different dimensions to see that the report isn't dependent on the number of selected dimensions or the number of dimensions configured for this instance.



```
<?xml version="1.0" encoding="UTF-8"?>
- <Root Company="Contoso Entertainment System Germany">
  - <Journal Batch="00057">
    - <Transaction Ct="0" Dt="1800" Currency="EUR" Date="2015-01-20" Voucher="GNJL000005">
        <Dimensions Desc="Pension/Profit-Sharing Plan Expense" Value="602180" Code="MainAccount"/>

        <Dimensions Desc="" Value="" Code="CostCenter"/>
        <Dimensions Desc="Sales & Marketing" Value="022" Code="Department"/>
        <Dimensions Desc="" Value="" Code="ItemGroup"/>
        <Dimensions Desc="" Value="" Code="Project"/>
      </Transaction>
```

Last updated on 04/13/2026

Group records and aggregate calculations by using GROUPBY data sources

When you configure Electronic reporting (ER) model mappings or formats, you can add required data sources of the **GroupBy** type.

At design time, you configure a **GroupBy** data source to identify the following elements:

- A base data source that contains records grouped at runtime.
- Grouping fields of the base data source that are used for record grouping at runtime.
- Aggregate functions that specify the aggregate calculations that are done for each discovered group at runtime.

At runtime, a configured **GroupBy** data source groups records that have the same values in the grouping fields, and then returns a list of records. Each record represents a single group. For each group, the data source exposes the field values that the initial records were grouped by, the values of the calculated aggregate functions, and the list of records of the base data source that belongs to the group.

Aggregate functions

At runtime, the system performs every aggregate calculation for each group of records. This calculation uses the value of a single field or an expression in the records of a data source that you selected for grouping in the editable data source of the **GroupBy** type. The following aggregate functions are currently supported:

- **Avg** – This function returns the average of the values in a group. You can use it only with numeric fields.
- **Count** – This function returns the number of items that it found in a group.
- **Min** – This function returns the minimum value among the values in a group.
- **Max** – This function returns the maximum value among the values in a group.
- **Sum** – This function returns the sum of all the values in a group. You can use it only with numeric fields.
- **Any** - This function returns any value in a group. You can use it for any type of fields, including Enum. This function is available as of 10.0.46 version of Finance.

Execution location

When you edit a **GroupBy** data source and specify the base data source that contains the records to group, the system automatically detects the most efficient location for executing that **GroupBy** data source. If the base data source is queryable (that is, if it can run at the database level), the application database is also the execution location of the editable **GroupBy** data source. Otherwise, the application server memory is the execution location.

You can manually change the automatically detected execution location by selecting the location that is applicable to the configured data source. If the execution location that is selected isn't applicable, a validation error is thrown at design time.

> **Tip**
>
> Use the database location to group data sources that expose a large number of records.

Memory consumption

By default, if you run a **GroupBy** data source in memory, the application server memory stores records of the base data source that belong to each discovered group as records of a single group. To help reduce memory consumption, you can suppress record storage for **GroupBy** data sources if they're configured to compute only aggregated functions and their group's records aren't used at runtime. To reduce memory consumption in this way, enable the **Reduce memory usage in ER when records grouping is only used to compute aggregations** feature in the **Feature management** workspace.

Alternatives

You can calculate similar aggregations by using different types of data sources or ER built-in functions.

To learn more about this feature, complete the example that follows.

Example: Use a GROUPBY data source for aggregate calculations and record grouping

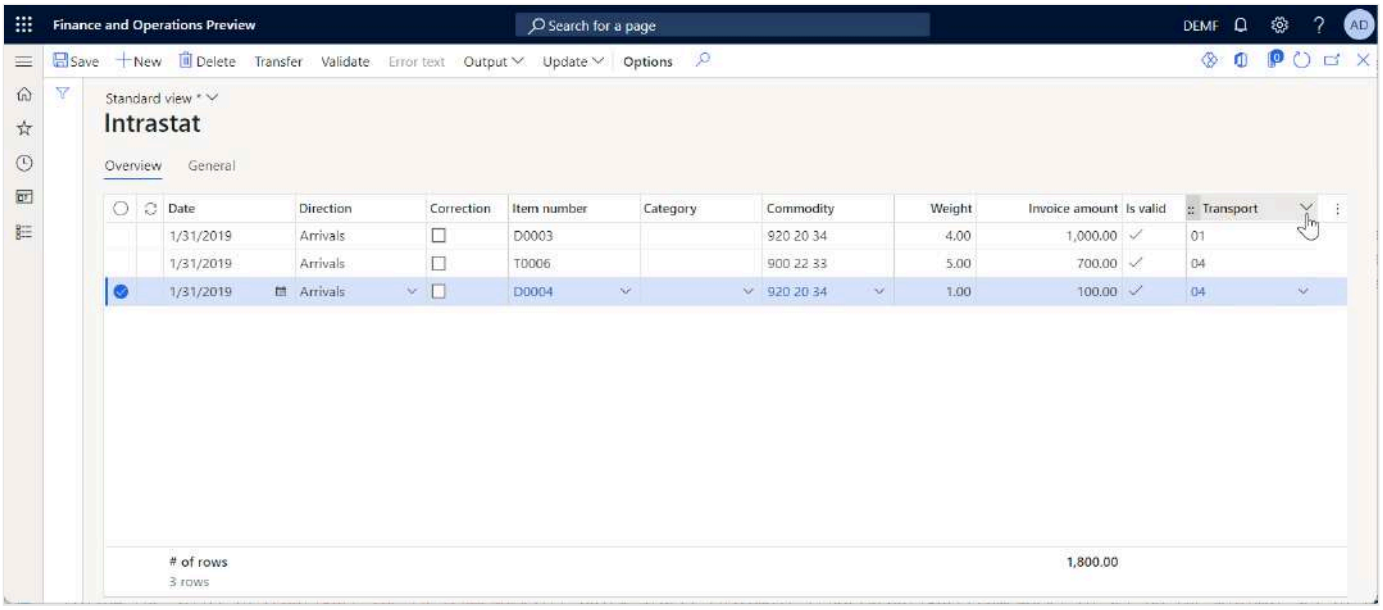
This example shows how a user in the System administrator or Electronic reporting functional consultant role can configure an ER model mapping that has a **GROUPBY** data source that calculates aggregate functions and groups records. This model mapping prints the control report

when the Intrastat declaration is generated. That report lets you review reported Intrastat transactions.

You can complete the procedures in this example in the **DEMF** company in Microsoft Dynamics 365 Finance.

Prepare sample data

Make sure that you have Intrastat transactions for reporting on the **Intrastat** page. You must have transactions for different transport codes, because you group transactions by the **Transport** field in this example.



Configure the ER framework

Follow the steps in Configure the ER framework to set up the minimal set of ER parameters. You must complete this setup before you start to use the ER framework to design an ER model mapping.

Import the standard ER format configuration

Follow the steps in Import the standard ER format configuration to add the standard ER configurations to your current instance of Dynamics 365 Finance. Import version 1 of the **Intrastat model** configuration from the repository.

Create a custom data model configuration

Follow the steps in Add a custom data model configuration to manually add a new **Intrastat model (Litware)** ER data model configuration that you derive from the imported **Intrastat model**

configuration.

Configure a custom data model component

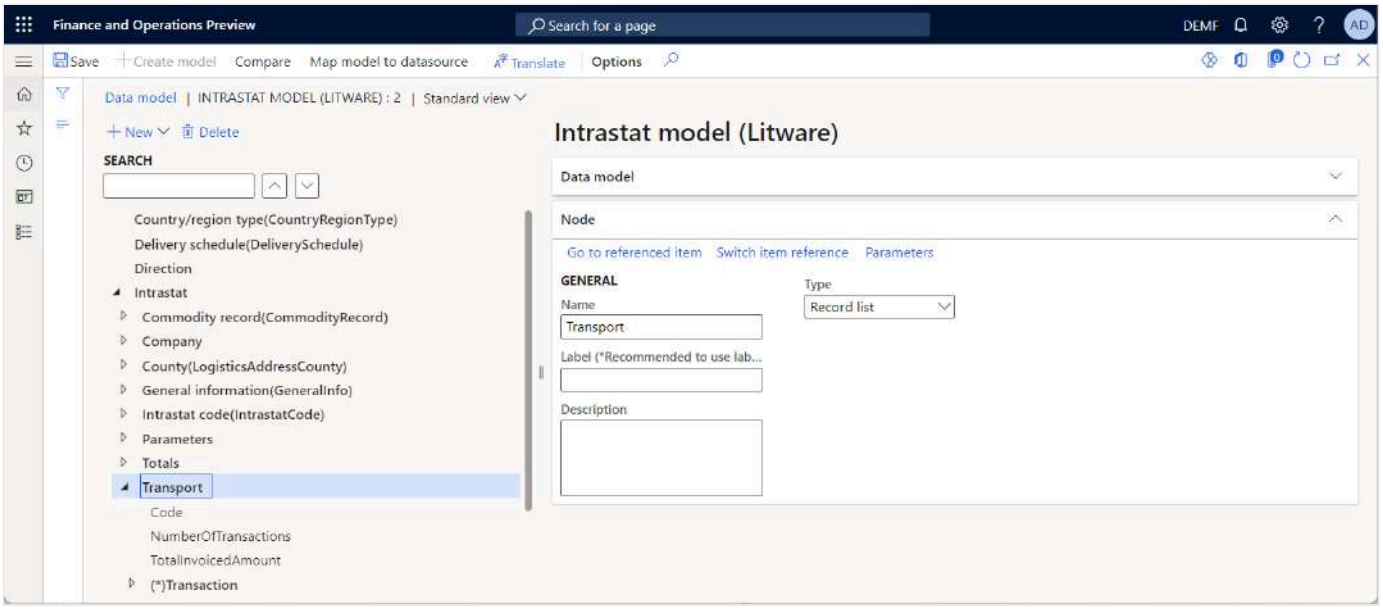
Follow these steps to make the required changes to the derived **Intrastat model (Litware)** data model, so that you can use it to expose transport codes that have the required details.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, select **Intrastat model (Litware)**.
3. Select **Designer**.
4. On **Data model designer**, in the model tree, select **Intrastat**.
5. Select **New** to add a new nested node for the selected **Intrastat** node. In the drop-down dialog box for adding a data model node, follow these steps:
   a. In the **Name** field, enter **Transport**.
   b. In the **Item type** field, select **Record list**.
   c. Select **Add** to add the new node.
6. Select **New** to add a new nested node for the **Transport** node that you just added. In the drop-down dialog box for adding a data model node, follow these steps:
   a. In the **Name** field, enter **Code**.
   b. In the **Item type** field, select **String**.
   c. Select **Add** to add the new node.
7. Select **New** to add another new nested node for the **Transport** node. In the drop-down dialog box for adding a data model node, follow these steps:
   a. In the **Name** field, enter **TotalInvoicedAmount**.
   b. In the **Item type** field, select **Real**.
   c. Select **Add** to add the new node.
8. Select **New** to add another new nested node for the **Transport** node. In the drop-down dialog box for adding a data model node, follow these steps:
   a. In the **Name** field, enter **NumberOfTransactions**.
   b. In the **Item type** field, select **Integer**.
   c. Select **Add** to add the new node.
9. Select **New** to add another new nested node for the **Transport** node. In the drop-down dialog box for adding a data model node, follow these steps:

a. In the **Name** field, enter **Transaction**.
b. In the **Item type** field, select **Record list**.
c. Select **Add** to add the new node.

10. For the **Transaction** node that you just added, on the **Node** FastTab, select **Switch item reference**.

11. In the **Switch item reference** dialog box, in the data model tree, select **CommodityRecord**. Then select **OK**.



Complete the design of a custom data model

Follow the steps in Complete the design of the data model to complete the design of the derived **Intrastat model (Litware)** data model.

Create a new model mapping configuration

Follow the steps in Create a new model mapping configuration to manually add a new **Intrastat sample mapping** ER model mapping configuration for the derived **Intrastat model (Litware)** configuration.

Add a new model mapping component

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, expand the **Intrastat model** configuration.
3. Select the **Intrastat sample mapping** configuration.
4. Select **Designer** to open the list of mappings.
5. Select **Delete** to remove the existing mapping component.

6. Select **New** to add a new mapping component.
7. In the **Definition** field, select **Intrastat**.
8. In the **Name** field, enter **Intrastat mapping**.
9. Select **Designer** to configure the new mapping.

Design the added model mapping component

Add a data source to access an application table

Configure a data source to access the application tables that contain the details of Intrastat transactions.

1. On the **Model mapping designer** page, in the **Data source types** pane, select **Dynamics 365 for Operations\Table records**.
2. In the **Data sources** pane, select **Add root** to add a new data source that accesses the **Intrastat** table. Each record in the **Intrastat** table represents a single Intrastat transaction.
3. In the **Data source properties** dialog box, in the **Name** field, enter **Transaction**.
4. In the **Table** field, enter **Intrastat**.
5. Select **OK** to add the new data source.

Add a data source to group Intrastat transactions

Configure a **GroupBy** data source to group Intrastat transactions and compute aggregate functions.

1. On the **Model mapping designer** page, in the **Data source types** pane, select **Functions\Group by**.
2. In the **Data sources** pane, select **Add root** to add a new data source that groups Intrastat transactions and computes aggregate functions.
3. In the **Data source properties** dialog box, in the **Name** field, enter **TransportRecord**.
4. Select **Edit group by** to configure grouping conditions.
5. On the **Edit 'Group By' parameters** page, in the data sources list in the right pane, select the **Transaction** data source, and expand it.
6. Select **Add field to** > **What to group** to indicate that the **Transaction** data source is selected as the base data source for the configured **GroupBy** data source. The records of the

Transaction data source are grouped, and the field values of this data source are used for calculations in aggregate functions.

7. Select the **Transaction\Transport** field, and then select **Add field to** > **Grouped field** to indicate that the **Transport** field of the base data source is selected as the grouping criterion for the configured **GroupBy** data source. In other words, the records of the **Transaction** data source are grouped based on the value of the **Transport** field. Every record of the configured **GroupBy** data source represents a single transport code found in records of the base data source.

8. Select the **Transaction\AmountMST** field, and then follow these steps:
   a. Select **Add field to** > **Aggregate fields** to indicate that an aggregate function is calculated for this field.
   b. In the **Aggregations** pane, in the record that you added for the selected **Transaction\AmountMST** field, in the **Method** field, select the **Sum** function.
   c. In the **Name** optional field, enter **TotalInvoicedAmount**.

   These settings specify that, for every transport group, the total amount of the **Transaction\AmountMST** field is calculated.

9. Select the **Transaction\RecId** field, and then follow these steps:
   a. Select **Add field to** > **Aggregate fields** to indicate that an aggregate function is calculated for this field.
   b. In the **Aggregations** pane, in the record that you added for the selected **Transaction\RecId** field, in the **Method** field, select the **Count** function.
   c. In the **Name** optional field, enter **NumberOfTransactions**.

   These settings specify that, for every transport group, the number of transactions in the group is calculated.

10. Select **Save**.

11. Review the execution parameters of the editable data source. Notice that **Autodetect** is automatically selected in the **Execution location** field, and the **Execution at** field contains the value **SQL**. These settings specify that the selected **Transaction** base data source is currently queryable, and you can run the editable **GroupBy** data source at database level.

12. Open the lookup for the **Execution location** field to review the list of available values. Notice that you can select **Query** or **In memory** to force this **GroupBy** data source to run on the database level or in the application server memory.

13. Select **Save**, and close the **Edit 'Group By' parameters** page.

14. Select **OK** to complete the settings of the **GroupBy** data source.

Bind the GroupBy data source to data model fields

Bind the configured data source to the fields of the data model to specify how the data model is filled in with application data at runtime.

1. On the **Model mapping designer** page, in the **Data model** pane, expand the **Transport** node.

2. In the **Data sources** pane, expand the **TransportRecord** data source.

3. Add a binding to expose the list of discovered transport groups:
   a. In the **Data model** pane, select the **Transport** item.
   b. In the **Data sources** pane, select the **TransportRecord** data source.
   c. Select **Bind**.

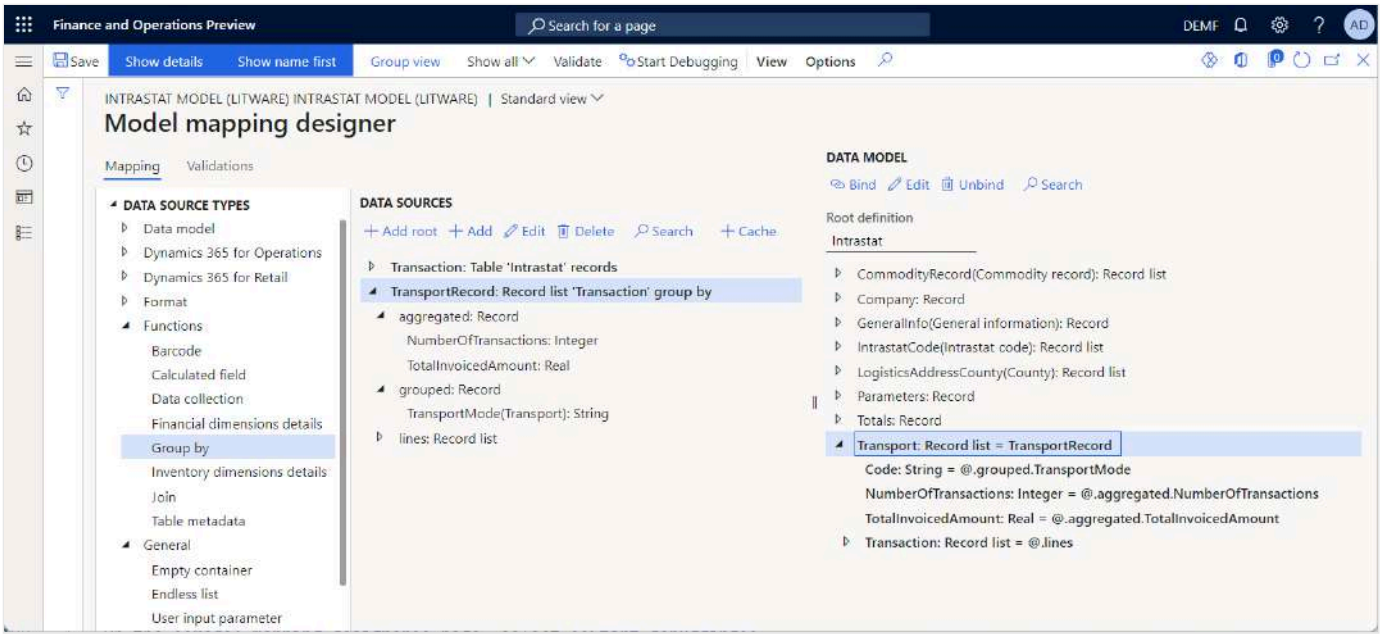
4. Add a binding to expose the transport code of each discovered transport group:
   a. Select the **Transport.Code** data model item.
   b. Select the **TransportRecord.grouped.TransportMode** grouped field.
   c. Select **Bind**.

5. Add a binding to expose the values of calculated aggregate functions for each discovered transport group:
   a. Select the **Transport.NumberOfTransactions** data model item.
   b. Select the **TransportRecord.aggregated.NumberOfTransactions** aggregated field.
   c. Select **Bind**.
   d. Select the **Transport.TotalInvoicedAmount** data model item.
   e. Select the **TransportRecord.aggregated.TotalInvoicedAmount** aggregated field.
   f. Select **Bind**.

6. Add a binding to expose transaction records that belong to each discovered transport group:
   a. Select the **Transport.Transaction** data model item.
   b. Select the **TransportRecord.lines** field.
   c. Select **Bind**.

   You can continue to configure bindings for the nested items of the **Transport.Transaction** data model item and the **TransportRecord.lines** data source field to expose, at runtime,

details of the Intrastat transactions that belong to each discovered transport group.



Debug the added model mapping component

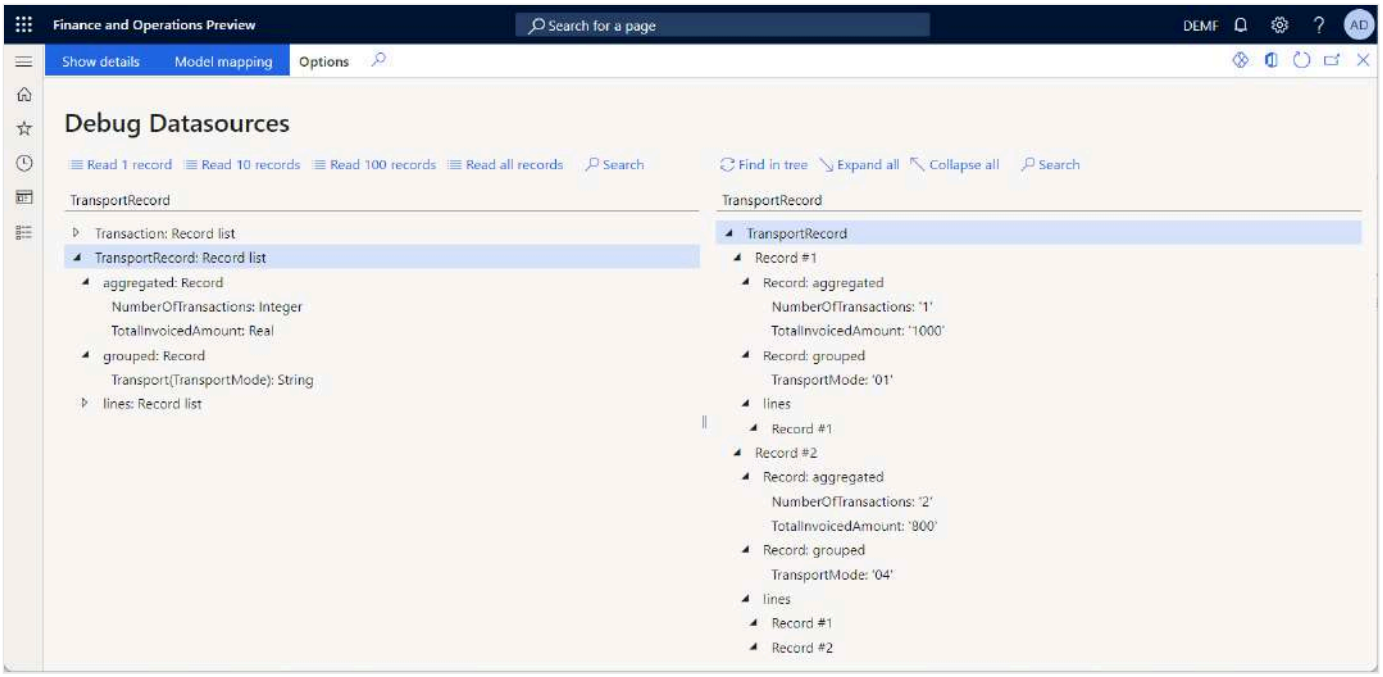
Use the ER data source debugger to test the configured model mapping.

1. On the **Model mapping designer** page, select **Start debugging**.
2. On the **Debug datasources** page, in the left pane, select the **TransportRecord** data source, and then select **Read all records**.
3. Expand the **TransportRecord** data source, and then follow these steps:
   a. Select the **TransportRecord.grouped.TransportMode** data source.
   b. Select **Get value**.
   c. Select the **TransportRecord.grouped.NumberOfTransactions** data source.
   d. Select **Get value**.
   e. Select the **TransportRecord.grouped.TotalInvoicedAmount** data source.
   f. Select **Get value**.
4. In the right pane, select **Expand all**.

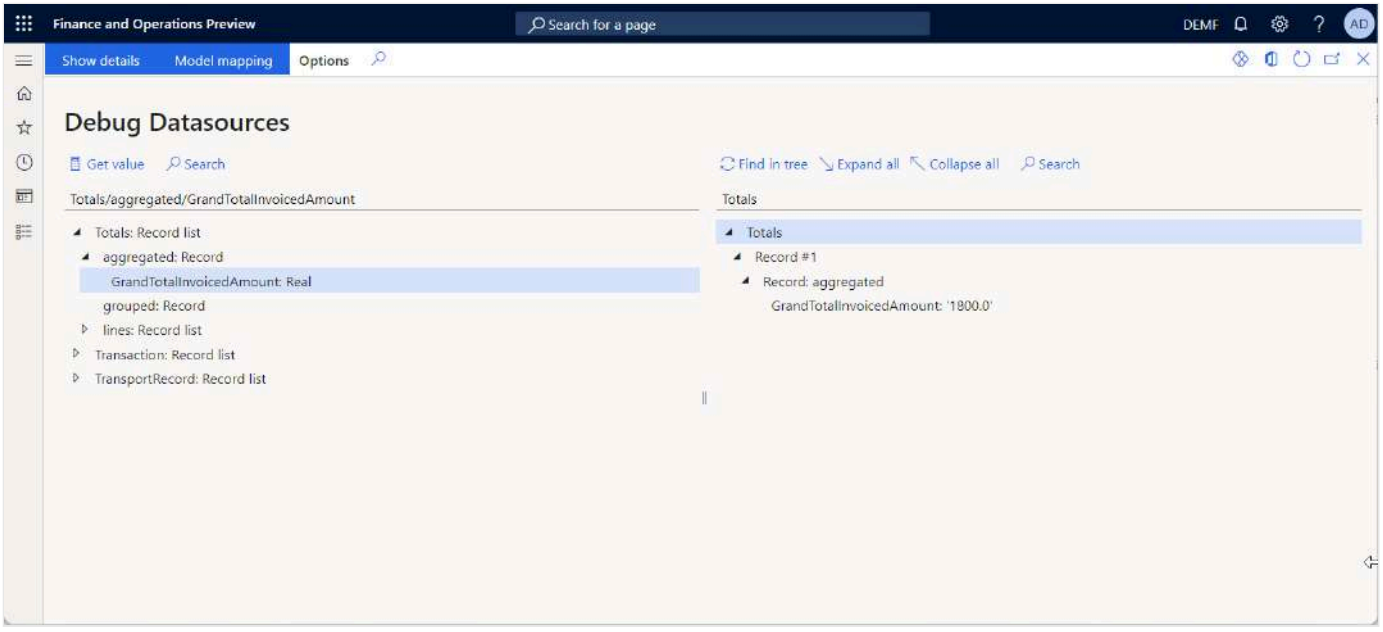
The **TransportRecord** data source exposes two records and presents two transport codes. For each transport code, the number of transactions and the total invoiced amount are calculated.

> **Note**
>
> The "lazy reading" approach is used when a **GroupBy** data source is called to optimize database calls. Therefore, some of the field values in a **GroupBy** data source are calculated in

the ER data source debugger only when they're bound to data model fields.



The following illustration shows the results of the **Totals** data source debugging.



Best practices for working with GroupBy data sources

Calling table extension methods in a GroupBy data source

When you design expressions for an in-memory **GroupBy** data source in an ER model mapping, avoid calling application (X++) table extension methods that require parameters on grouped table records. In the current implementation, the runtime might not resolve these method calls when applied to grouped records. As a result, the expression can return an error or an empty value. This behavior occurs only when all the following conditions are met:

- The table extension method declares one or more parameters, in addition to the table variable (`this`) that it extends.
- You call the method as an instance method on the table record (for example, `record.myExtensionMethod(parameter)`).
- The in-memory **GroupBy** data source wraps the table record.
- You define both the **GroupBy** data source and the underlying table records data source at the model mapping level.

> ⓘ **Note**
>
> This limitation doesn't affect:
>
> - Table extension methods that don't require parameters.
> - Methods called on table records that aren't wrapped by a **GroupBy** data source.

Recommendation

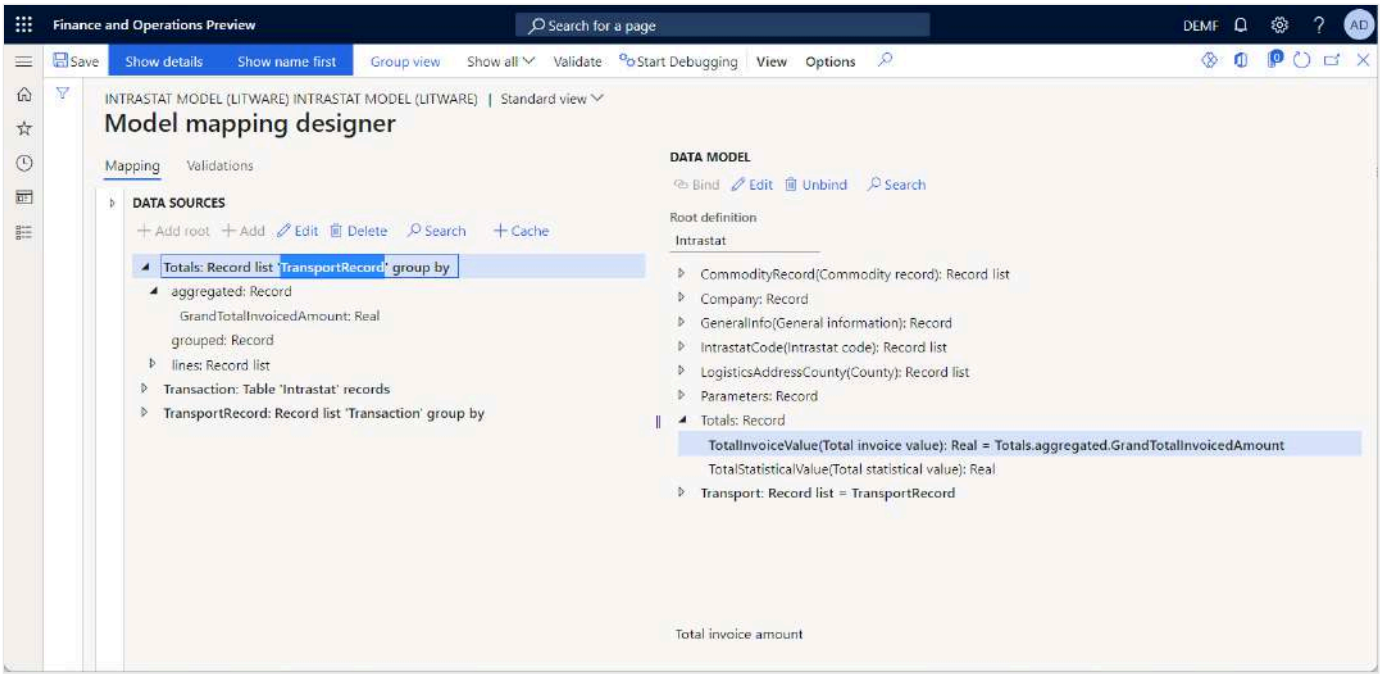
To achieve the expected behavior, consider one of the following approaches:

- Refactor the logic into a parameterless method when possible.
- Evaluate the method on the base data source (before applying **GroupBy**) and expose the result as a calculated field.
- Move the required calculation logic into ER expressions or computed fields that don't depend on parameterized method calls.

Frequently asked questions

Is there a way to calculate grand totals when the group totals are calculated?

Yes. To calculate grand totals, configure another **GroupBy** data source where the previously configured **GroupBy** data source is the base data source. The following illustration shows the **Totals** data source of the **GroupBy** type that calculates the aggregate **SUM** function, based on the **SUM** aggregation of the **TransportRecord** data source of the **GroupBy** type.



The following illustration shows the results of the **Totals** data source debugging.

ER Configure format to do counting and summing (Part 1 - Create format)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to do counting and summing based on data of the already generated text output. You can perform these steps in any company.

To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Get access to the list of configurations provided by Microsoft

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
    - Make sure that the **Litware, Inc.** provider is available and marked as active.
2. Select the **Litware, Inc.** provider.
3. Click **Repositories**.
    - If a repository of the **Operations resources** type already exists, skip the remaining steps of the current sub-task.
4. Click **Add** to open the drop dialog.
5. In the **Configuration repository type** field, enter **Operations resources**.
6. Click **Create repository**.
7. Click **OK**.

Get the Intrastat configurations provided by Microsoft

1. Select **Open**.
2. In the tree, select **Intrastat model\Intrastat (DE)**.
3. Select **Import**.
    - Select **Import** for version 1.1 of the selected configuration.
4. Select **Yes**.
5. Close the page.
6. Close the page.
7. Select **Reporting configurations**.
8. In the tree, expand **Intrastat model**.
9. In the tree, select **Intrastat model\Intrastat (DE)**.

ER Configure format to do counting and summing (Part 2 - Configure computations)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to do counting and summing based on data of the already generated text output. You can perform these steps in any company.

To complete these steps, you must first complete the steps in the "ER Configure format to do counting and summing (Part 1: Create format)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Create a format configuration to add counting and summing details

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. In the tree, expand **Intrastat model**.
4. In the tree, select **Intrastat model\Intrastat (DE)**.
    - To customize the format that Microsoft provides, add lines with summary details at the end of the Intrastat report. Derive your own instance of the Intrastat configuration from the Microsoft instance to make modifications.
5. Select **Create configuration** to open the dialog.
6. In the **New** field, enter `Intrastat (DE), Microsoft`.
7. In the **Name** field, type `Intrastat (DE) with counting & summing`.

8. Select **Create configuration**.

Configure this report to count and sum based on output details

1. Select **Designer**.
2. Select **Yes** in the **Collect output details** field.

    - This flag activates at run-time the process of collecting output details for generating the Intrastat file.
    - You need to count for different Intrastat directions, so add a dedicated model enumeration to the data sources' list of this format configuration.

3. Select the **Mapping** tab.
4. Select **Add root** to open the drop dialog.
5. In the tree, select `Data model\Enumeration`.
6. In the **Name** field, type `Direction`.
7. In the **Model enumeration** field, enter or select a value.

    - Select the value `Direction`.

8. Select **OK**.
9. Select **Add root** to open the drop dialog.
10. In the tree, select `Functions\Calculated field`.
11. In the **Name** field, type `$BlockName`.
12. Select **Edit formula**.
13. In the **Formula** field, enter `"block"`.
14. Select **Save**.
15. Close the page.
16. Select **OK**.
17. Select **Add root** to open the drop dialog.
18. In the tree, select `Functions\Calculated field`.
19. In the **Name** field, type `$RecName`.
20. Select **Edit formula**.
21. In the **Formula** field, enter `"record"`.
22. Select **Save**.
23. Close the page.
24. Select **OK**.
25. Select **Add root** to open the drop dialog.

26. In the tree, select `Functions\Calculated field`.
27. In the **Name** field, type `$InvName`.
28. Select **Edit formula**.
29. In the **Formula** field, enter `"InvoicedAmountEUR"`.
30. Select **Save**.
31. Close the page.
32. Select **OK**.
33. In the tree, select `Intrastat\Data`.
34. Select **Edit** for the **Collected data key name** field.
35. Select **Add data source**.

    - Use `$BlockName`.

36. Select **Save**.
37. Close the page.
38. Select **Edit** for the **Collected data key value** field.
39. In the **Formula** field, enter `IF(Intrastat.CommodityRecord.Direction=Direction.Import, "Import", "Export")`.

    - Use `IF(Intrastat.CommodityRecord.Direction=Direction.Import, "Import", "Export")`.

40. Select **Save**.
41. Close the page.

    - Count the lines of this sequence. The results are used with the name `block` separately for different directions. Value `Import` is used for any arrivals Intrastat transactions. The value `Export` is used for any Intrastat dispatches transactions. Consider this to be a virtual Excel spreadsheet. For each transaction a row where the first column `block` is filled with the values `Import` and `Export` accordingly.

42. In the tree, expand `Intrastat\Data: Sequence`.
43. In the tree, select `Intrastat\Data: Sequence\Arrivals?`.
44. Select **Edit** for the **Collected data key name** field.

    - Count the lines of this sequence. The results are stored using the name `record`.

45. In the tree, select `$RecName`.
46. Select **Add data source**.
47. Select **Save**.

48. Close the page.
49. Select **Edit** for the **Collected data key value** field.
50. In the **Formula** field, enter `Intrastat.CommodityRecord.CommodityCode`.
51. Select **Save**.
52. Close the page.

    - Count the lines in this sequence. Use the results with the name "record" for different commodity codes. Consider this count as a virtual Excel spreadsheet. For each transaction, create a row where the first column "block" contains the values "Import" and "Export" accordingly, and the second column "record" contains the commodity code value.

53. In the tree, select `Intrastat\Data: Sequence\Dispatches?`.
54. Select **Edit** for the **Collected data key name** field.
55. In the tree, select `$RecName`.
56. Select **Add data source**.
57. Select **Save**.
58. Close the page.
59. Select **Edit** for the **Collected data key value** field.
60. In the **Formula** field, enter `Intrastat.CommodityRecord.CommodityCode`.
61. Select **Save**.
62. Close the page.
63. In the tree, expand `Intrastat\Data: Sequence\Dispatches: Sequence?`.
64. In the tree, expand `Intrastat\Data: Sequence\Dispatches: Sequence?\Record = Intrastat.CommodityRecord`.
65. Select the **Format** tab.
66. In the tree, select `Intrastat\Data\Dispatches\Record\Invoice amount EUR`.
67. Select the **Mapping** tab.
68. Select **Edit** for the **Collected data key name** field.
69. In the tree, select `$InvName`.
70. Select **Add data source**.
71. Select **Save**.
72. Close the page.

    - Summarize the invoiced amount values for lines in this sequence. Use the results with the name "InvoicedAmountEUR" for different Intrastat directions and commodity codes. Consider this summary as a virtual creation in an Excel spreadsheet. For each transaction, create a row where the first column "block"

contains the values "Import" and "Export" accordingly. The second column "record" contains the commodity code value, and the third column "InvoicedAmountEUR" contains the invoice amount value.

73. In the tree, expand `Intrastat\Data\Arrivals?`.
74. In the tree, expand `Intrastat\Data\Arrivals?\Record = Intrastat.CommodityRecord`.
75. Select the **Format** tab.
76. In the tree, select `Intrastat\Data\Arrivals\Record\Invoice amount EUR`.
77. Select the **Mapping** tab.
78. Select **Edit** for the **Collected data key name** field.
79. In the tree, select `$InvName`.
80. Select **Add data source**.
81. Select **Save**.
82. Close the page.
83. Select **Save**.
84. Close the page.

ER Configure format to do counting and summing (Part 3 - Use computations to make the output)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to do counting and summing based on data of the already generated text output. You can perform these steps in any company.

To complete these steps, you must first complete the steps in the "ER Configure format to do counting and summing (Part 2: Configure computations)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Configure this report to use counting and summing info

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. In the tree, expand **Intrastat model**.
4. In the tree, expand **Intrastat model\Intrastat (DE)**.
5. In the tree, select **Intrastat model\Intrastat (DE)\Intrastat (DE) with counting & summing**.
6. Select **Designer**.
7. Select the **Mapping** tab.
8. Select **Add root** to open the drop dialog.

    - Add a new data source to get the list of memorized blocks.

9. In the tree, select **Functions\Calculated field**.
10. In the **Name** field, type `$BlocksList`.

    - `$BlocksList`

11. Select **Edit formula**.
12. In the tree, select **Data collection functions\COLLECTEDLIST**.
13. Select **Add function**.
14. Select **Add data source**.
15. In the **Formula** field, enter `COLLECTEDLIST('$BlockName', '`.

    - `COLLECTEDLIST('$BlockName',`

16. In the **Formula** field, enter `COLLECTEDLIST('$BlockName', "*")`.

    - `COLLECTEDLIST('$BlockName', "*")`

17. Select **Save**.

    - The pattern `*` means that all blocks are included in the list for this record.

18. Close the page.
19. Click OK.
20. Select the **Format** tab.
21. In the tree, select 'Intrastat\Data'.
22. Click Add to open the drop dialog.
23. In the tree, select 'Text\Sequence'.
24. In the Name field, type 'Totals by blocks'.

    - Totals by blocks

25. In the Special characters field, select 'New line - Windows (CR LF)'.
26. Click OK.
27. In the tree, select 'Intrastat\Data\Totals by blocks'.
28. Click Add to open the drop dialog.
29. In the tree, select 'Text\String'.
30. In the Name field, type 'Block code'.

    - Block code

31. Click OK.
32. Click Add String.

33. In the Name field, type 'Lines counting'.

    - Lines counting

34. Click OK.
35. Click Add String.
36. In the Name field, type 'Total amount'.

    - Total amount

37. Click OK.
38. Select the **Mapping** tab.
39. In the tree, select '$BlocksList'.
40. Click Bind.

    - Create a summary line for each memorized block.

41. Select the **Format** tab.
42. In the tree, select 'Intrastat\Data\Totals by blocks\Block code'.
43. Select the **Mapping** tab.
44. Select **Edit formula**.
45. In the Formula field, enter '"Block id: " & '.

    - "Block id: " &

46. In the tree, expand `$BlocksList`.
47. In the tree, select `$BlocksList\Value`.
48. Select **Add data source**.
49. Select **Save**.
50. Close the page.
51. Select the **Format** tab.
52. In the tree, select `Intrastat\Data\Totals by blocks\Lines counting`.
53. Select the **Mapping** tab.
54. Select **Edit formula**.

    - Create output for the number of lines for each block presented in this report.

55. In the **Formula** field, enter `"Number of lines in this block: " &` .

    - `"Number of lines in this block: " &`

56. In the **Formula** field, enter `"Number of lines in this block: " & TEXT(` .

- `"Number of lines in this block: " & TEXT(`

57. In the tree, select `Data collection functions\COUNTIFS`.
58. Select **Add function**.
59. Select **Add data source**.
60. In the **Formula** field, enter `"Number of lines in this block: " & TEXT(COUNTIFS('$BlockName', `.

    - `"Number of lines in this block: " & TEXT(COUNTIFS('$BlockName',`

61. In the tree, expand `$BlocksList`.
62. In the tree, select `$BlocksList\Value`.
63. Select **Add data source**.
64. In the **Formula** field, enter `"Number of lines in this block: " & TEXT(COUNTIFS('$BlockName', '$BlocksList'.Value, `.

    - `"Number of lines in this block: " & TEXT(COUNTIFS('$BlockName', '$BlocksList'.Value,`

65. In the tree, select `$RecName`.
66. Select **Add data source**.
67. In the **Formula** field, enter `"Number of lines in this block: " & TEXT(COUNTIFS('$BlockName', '$BlocksList'.Value, '$RecName', "*"))`.

    - `"Number of lines in this block: " & TEXT(COUNTIFS('$BlockName', '$BlocksList'.Value, '$RecName', "*"))`

68. Select **Save**.
69. Close the page.
70. Select the **Format** tab.
71. In the tree, select `Intrastat\Data\Totals by blocks\Total amount`.
72. Select the **Mapping** tab.
73. Select **Edit formula**.

    - Create output that is the total of the invoiced amount for each block presented in this report.

74. In the **Formula** field, enter `"Sum of invoiced amount: " & TEXT(SUMIFS('$InvName', '$BlockName', '$BlocksList'.Value, '$RecName', "*"))`.

    - `"Sum of invoiced amount: " & TEXT(SUMIFS('$InvName', '$BlockName', '$BlocksList'.Value, '$RecName', "*"))`

75. Select **Save**.
76. Close the page.
77. Select **Save**.
78. Close the page.

ER Configure format to do counting and summing (Part 4 - Run format)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to do counting and summing based on data from the already generated text output. You can perform these steps in the DEMF company.

To complete these steps, you must first complete the steps in the "ER Configure format to do counting and summing (Part 3: Use computations to make the output)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Test this configuration for generation of the Intrastat reports

1. Go to Organization administration > Workspaces > Electronic reporting.
2. Click Reporting configurations.
3. In the tree, expand **Intrastat model**.
4. In the tree, expand **Intrastat model\Intrastat (DE)**.
5. In the tree, select **Intrastat model\Intrastat (DE)\Intrastat (DE) with counting & summing**.
6. On the Action Pane, select **Configurations**.
7. Select **User parameters**.
8. Select Yes in the Run settings field.
9. Select **OK**.
10. Click Edit.
11. Select Yes in the Run Draft field.

12. Click Save.
13. Go to Tax > Setup > Foreign trade > Foreign trade parameters.
14. Expand the Electronic reporting section.
15. Select the "Intrastat (DE) with counting & summing" configuration.
16. Select the "Intrastat (DE) with counting & summing" configuration.
17. Click Save.
18. Close the page.
19. Go to **Tax** > **Declarations** > **Foreign trade** > **Intrastat**.
20. Select **Output**.
21. Select **Report**.

    - Run the Intrastat report generation process.

22. In the From date field, set the date to '2000-01-01'.

    - Define start and end dates for the reporting period that include the existing on the form transactions.

23. In the To date field, set the date to '2022-12-31'.

    - Define start and end dates for the reporting period that include the existing on the form transactions.

24. In the Direction field, select 'Arrivals'.
25. Select Yes in the Generate file field.
26. Select **OK**.

    - Review the created output with the summary lines in the end.

27. Click New.
28. In the list, mark the selected row.
29. In the Direction field, select 'Dispatches'.
30. In the Item number field, enter or select a value.
31. In the Commodity field, enter or select a value.
32. Set Weight to '10'.
33. Set Invoice amount to '10000'.
34. Set Statistical amount to '10000'.
35. Select **Output**.
36. Select **Report**.
37. In the Direction field, select 'Dispatches'.

38. Select **OK**.

    - Review the created output with the summary lines in the end. Note that it has been changed in comparison to the first run.

Run this configuration in debug mode to review the collected counting and summing data

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Intrastat model**.
3. In the tree, expand **Intrastat model\Intrastat (DE)**.
4. In the tree, select **Intrastat model\Intrastat (DE)\Intrastat (DE) with counting & summing**.
5. On the Action Pane, select **Configurations**.
6. Select **User parameters**.
7. Select **Yes** in the **Run in debug mode** field.
8. Select **OK**.
9. Close the page.
10. Go to **Tax** > **Declarations** > **Foreign trade** > **Intrastat**.
11. Select **Output**.
12. Select **Report**.
13. Select **OK**.
14. Close the page.
15. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
16. In the tree, expand **Intrastat model**.
17. In the tree, expand **Intrastat model\Intrastat (DE)**.
18. In the tree, select **Intrastat model\Intrastat (DE)\Intrastat (DE) with counting & summing**.
19. Select **Debug logs**.

    - A debug log record is created for the execution process of the selected configuration.

20. Select **Attach**.
21. Select **Open**.

    - Review the created XML file that contains counting and summing details that the system collects during the execution of the selected configuration.

ER use Document Management files in format outputs (Part 1 - Prepare data model)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. You can perform these steps in any company.

To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Get access to the list of configurations provided by Microsoft

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

   Make sure that the **Litware, Inc.** provider is available and marked as active.

2. Select the **Litware, Inc.** provider.

3. Select **Repositories**.

   If a repository of the **Operations resources** type already exists, skip the remaining steps of the current sub-task.

4. Select **Add** to open the drop dialog.

5. In the **Configuration repository type** field, enter **Operations resources**.

6. Select **Create repository**.
7. Select **OK**.

Get the customer invoice model configurations provided by Microsoft

1. Select **Show filters**.
2. Apply the following filters: Enter a filter value of **Operations resources** on the **Name** field by using the **begins with** filter operator. Enter a filter value of "" on the **Description** field by using the **begins with** filter operator.
3. Select **Show filters**.
4. Select **Open**.
5. In the tree, select **Customer invoice model**.

   Select the model configuration **Customer invoice model** to import it.
6. Select **Import**.

   Select **Import** for version 1 of the selected configuration.
7. Select **Yes**.
8. Close the page.
9. Close the page.
10. Select **Reporting configurations**.
11. In the tree, select **Customer invoice model**.

Create the derived model to support access to the Document Management files

Create your own configuration of the Customer invoice model by deriving it from the configuration provided by Microsoft. Use this configuration to implement access to the Document Management files and make them available for electronic documents that you create based on this model.

1. Select **Create configuration** to open the drop dialog.
2. In the **New** field, enter `Derive from Name: Customer invoice model, Microsoft`.
3. In the **Name** field, type `Customer invoice model (custom)`.
4. Select **Create configuration**.

Last updated on 04/13/2026

ER Use Document Management files in format outputs (Part 2 - Extend data model)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the System Administrator or Electronic Reporting Developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. You can perform these steps in any company.

To complete these steps, you must first complete the steps in the "ER Use Document Management files in format outputs (Part 1: Prepare data model)" task guide.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Extend data model to present the Document Management files in it

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. In the tree, expand **Customer invoice model**.
4. In the tree, select **Customer invoice model\Customer invoice model (custom)**.
5. Select **Designer**.
6. In the tree, select **Customer invoice(InvoiceCustomer)**.
    - Extend this data model to expose any files that you attached to a sales order that is related to an electronically processing invoice.
7. Select **New** to open the drop dialog.
8. In the **Name** field, type **Invoice attachments**.

- Invoice attachments

9. In the **Item type** field, select **Record list**.
10. Select **Add**.
11. Select **New** to open the drop dialog.
12. In the **Name** field, type **File content**.

    - File content

13. In the **Item type** field, select **Container**.
14. Select **Add**.
15. Select **New** to open the drop dialog.
16. In the **Name** field, type **File name**.

    - File name

17. In the **Item type** field, select **String**.
18. Select **Add**.

Map new data model elements to data sources

1. Select **Map model to datasource**.
2. Use the Quick Filter to filter on the Definition field with a value of `InvoiceCustomer`.

    - InvoiceCustomer
    - Map new model elements to appropriate data sources.

3. Select **Designer**.
4. In the tree, select **Invoice attachments**.
5. In the tree, expand **Invoice attachments**.
6. In the tree, select **Invoice attachments\File name**.
7. Select **Edit**.
8. In the Formula field, enter `CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'.'originalFileName()'`.

    - `CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'.'originalFileName()'`

9. Select **Save**.
10. Close the page.
11. In the tree, select **Invoice attachments\File content**.

12. Select **Edit**.
13. In the Formula field, enter `CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'.'getFileContentAsContainer()'`.

    - `CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'.'getFileContentAsContainer()'`

14. Select **Save**.
15. Close the page.
16. In the tree, select **Invoice attachments**.
17. Select **Edit**.
18. In the Formula field, enter `CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'`.

    - `CustInvoiceJour.'>Relations'.SalesTable.'<Relations'.'<Documents'`

19. Select **Save**.
20. Close the page.
21. Select **Save**.
22. Close the page.
23. Close the page.
24. Close the page.
25. Select **Change status**.
26. Select **Complete**.
27. Select **OK**.

Last updated on 04/13/2026

ER use Document Management files in format outputs (Part 3 - Create format)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. You can perform these steps in any company.

To complete these steps, you must first complete the steps in the "ER Use Document Management files in format outputs (Part 2: Extend data model" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Create a format to process invoices

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. In the tree, expand **Customer invoice model**.
4. In the tree, select **Customer invoice model\Customer invoice model (custom)**.

    - You create a format to generate electronic messages with information about any files that you attach to a sales order that relates to an electronically processing invoice.

5. Select **Create configuration** to open the drop dialog.
6. In the **New** field, enter *Format based on data model Customer invoice model (custom)*.
7. In the **Name** field, type *Electronic invoice sample message*.

    - Electronic invoice sample message

8. In the **Data model definition** field, enter or select a value.

- InvoiceCustomer

9. Select **Create configuration**.

Design a format to populate attachments into generating a message in MIME format

1. Click **Designer**.
2. Click **Add root** to open the drop dialog.
3. In the tree, select **XML\Element**.
4. In the **Name** field, type **Invoice**.

    - Invoice

5. Click **OK**.
6. Click **Add** to open the drop dialog.
7. In the tree, select **XML\Attribute**.
8. In the **Name** field, type **SalesOrder**.

    - SalesOrder

9. Click **OK**.
10. Click **Add Attribute**.
11. In the **Name** field, type **InvoiceNumber**.

    - InvoiceNumber

12. Click **OK**.
13. Click **Add Attribute**.
14. In the **Name** field, type **InvoiceAmount**.

    - InvoiceAmount

15. Click **OK**.
16. Click **Add** to open the drop dialog.
17. In the tree, select **XML\Element**.
18. In the **Name** field, type **EnclosedDocs**.

    - EnclosedDocs

19. Click **OK**.
20. In the tree, select **Invoice\EnclosedDocs**.

21. Click **Add Element**.
22. In the **Name** field, type **Document**.

    - Document

23. Click **OK**.
24. In the tree, select **Invoice\EnclosedDocs\Document**.
25. Click **Add** to open the drop dialog.
26. In the tree, select **XML\Attribute**.
27. In the **Name** field, type **FileName**.

    - FileName

28. Click **OK**.
29. Click **Add** to open the drop dialog.
30. In the tree, select **XML\Element**.
31. In the **Name** field, type **FileContent**.

    - FileContent

32. Click **OK**.
33. In the tree, select **Invoice\EnclosedDocs\Document\FileContent**.
34. Click **Add** to open the drop dialog.
35. In the tree, select **Text\Base64**.
36. Click **OK**.

Map format elements to data model as data source

1. In the tree, select `Invoice\SalesOrder`.
2. Select the **Mapping** tab.
3. In the tree, expand `model`.
4. In the tree, select `model\Sales order number(SalesId)`.
5. Select **Bind**.
6. In the tree, select `Invoice\InvoiceNumber`.
7. In the tree, expand `model\Base invoice(InvoiceBase)`.
8. In the tree, select `model\Base invoice(InvoiceBase)\Invoice number(Id)`.
9. Select **Bind**.
10. In the tree, select `Invoice\InvoiceAmount`.
11. In the tree, select `model\Base invoice(InvoiceBase)\Invoice amount(Amount)`.
12. Select **Bind**.

13. In the tree, expand `model\Invoice attachments`.
14. In the tree, select `model\Invoice attachments\File content`.
15. In the tree, select `Invoice\EnclosedDocs\Document\FileContent\Base64`.
16. Select **Bind**.
17. In the tree, select `model\Invoice attachments\File name`.
18. In the tree, select `Invoice\EnclosedDocs\Document\FileName`.
19. Select **Bind**.
20. In the tree, select `model\Invoice attachments`.
21. In the tree, select **Invoice\EnclosedDocs\Document**.
22. Select **Bind**.
23. Select **Save**.
24. Close the page.

ER Use Document Management files in format outputs (Part 4 - Run format)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. You can perform these steps in the DEMF company.

To complete these steps, you must first complete the steps in the "ER Use Document Management files in format outputs (Part 3: Create format)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Add necessary attachments for sales order of a single invoice

1. Go to **Accounts receivable** > **Invoices** > **Open customer invoices**.
2. Use the Quick Filter to find records. For example, filter on the **Invoice** field with a value of `CIV-000148`.
    - CIV-000148
3. Select the invoice link.
    - CIV-000148
4. Select the link in the **Sales order** field.
    - 000148
5. In the **Lines or header** field, select the option of **Header**.

- Select **Header** to indicate that this sales order is the target for adding attachments.

6. Select **Attach**.

    - Add a few files as attachments for this sales order. Use the files of the document types that are supported by the Document Management system, such as DOCX, PDF, XML, JPG, and more. Browse and select files to attach and further process with the related invoice in the ER electronic message.

7. Select **New**.
8. Select **File**.
9. Select **New**.
10. Select **File**.
11. Close the page.
12. Close the page.
13. Close the page.
14. Close the page.

Run the designed report for the selected invoice

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Customer invoice model**.
3. In the tree, expand **Customer invoice model\Customer invoice model (custom)**.
4. In the tree, select **Customer invoice model\Customer invoice model (custom)\Electronic invoice sample message**.
5. Select **Run**.
6. Expand the **Records to include** section.
7. Select **Filter**.
8. Select the row of the **Customer invoice journal** and the **Sales order** field.
9. In the **Criteria** field, type `000148`.

    - In the criteria **Sales order** field, type the order number `000148`.

10. Select **OK**.
11. Select **OK**.

    - Review the generated output. For each attachment, the report creates a single XML node. The attachment's content is added to the XML output in MIME (base64) text format.

ER Use Document Management files in format outputs (Part 5 - Modify and run format)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the system administrator or electronic reporting developer role can configure an Electronic reporting (ER) format to use Document Management files (attachments) in ER output. You can perform these steps in the DEMF company.

To complete these steps, you must first complete the steps in the "ER Use Document Management files in format outputs (Part 4: Run format)" procedure.

This procedure is for a feature that was added in Dynamics 365 for Operations version 1611.

Modify the format to populate attachments into generating messages in binary format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Customer invoice model**.
3. In the tree, expand **Customer invoice model\Customer invoice model (custom)**.
4. In the tree, select **Customer invoice model\Customer invoice model (custom)\Electronic invoice sample message**.
5. Select **Designer**.

    - You populate the invoice message in the generating output as an XML file using UNICODE encoding.

6. Select **Add root** to open the drop dialog.
7. In the tree, select **Common\File**.

8. In the **Name** field, type **Xml message**.
    - Xml message
9. In the **Encoding** field, type **UTF-8**.
    - UTF-8
10. Select **OK**.
    - Configure the generating output as a zipped file.
11. Select **Add root** to open the drop dialog.
12. In the tree, select **Common\Folder**.
13. In the **Name** field, type **Zip output**.
    - Zip output
14. Select **OK**.
15. In the tree, select **Zip output**.
    - Add attachments to the generating zipped file as files with original names and extensions.
16. Select **Add** to open the drop dialog.
17. In the tree, select **Common\File**.
18. In the **Name** field, type **Attached file**.
    - Attached file
19. Select **OK**.
20. In the tree, select **Zip output\Attached file**.
21. Select **Add** to open the drop dialog.
22. In the tree, select **Text\Base64**.
23. Select **OK**.

Map new format elements to data model

1. Select the **Mapping** tab.
2. In the tree, expand `model`.
3. In the tree, expand `model\Invoice attachments`.
4. In the tree, select `Zip output\Attached file\Base64`.

5. In the tree, select `model\Invoice attachments\File content`.
6. Select **Bind**.
7. In the tree, select **Zip output\Attached file**.
8. Select **Edit filename**.
9. In the tree, expand `model`.
10. In the tree, expand `model\Invoice attachments`.
11. In the tree, select `model\Invoice attachments\File name`.
12. Select **Add data source**.
13. Select **Save**.
14. Close the page.
15. In the tree, select `model\Invoice attachments`.
16. Select **Bind**.
17. Select **Save**.
18. Close the page.

Run the designed report for the selected invoice

1. Select **Run**.
2. Expand the **Records to include ()** section.
3. Select **Filter**.
4. Select the row of the **Customer invoice journal** and the **Sales order** field.
5. In the **Criteria** field, enter the order number `000148`.

    - 000148

6. Select **OK**.
7. Select **OK**.

    - Review the generated output. In addition to the invoice message in XML format, the process creates a single file for each attachment. The attachment files are populated with the zipped output in binary format.

Last updated on 04/13/2026

Use Barcode data sources to generate bar code images

10/02/2025

You can use the Electronic reporting (ER) framework to design ER format components that you can run to generate electronic and printable outbound documents that you require. To generate an outbound document in Microsoft Office format, you must specify the layout of the report by using either a Microsoft Excel document or a Microsoft Word document as a report template. The ER Operations designer lets you attach an Excel or Word document as a template for an ER format. The following named elements in the attached template are associated with the elements of the configured format component:

- Content controls in Word
- Named sheets, ranges, cells, shapes, and images in Excel

These named elements are used as placeholders for data that is entered in a generated document when an ER format is run. ER format elements are bound to data sources. These data sources specify the data that will be entered in the generated documents at runtime. For more information, see Embed images and shapes in documents that you generate by using ER.

ER now supports the **Barcode** data source type. Therefore, you can now generate an image that represents the bar code for specified text. When you configure an ER format, you can specify data sources of the **Barcode** type to generate bar code images. You can then add those images to generated business documents, such as orders, invoices, packing slips, and receipts. You can also add them to various kind of labels, such as product and shelf labels, and packaging and shipping labels.

The following placeholders can be used in report templates to enter bar code images:

- Picture content control for Word
- Picture object in Excel

By using a data source of the **Barcode** type, you can generate bar codes in the following formats:

- One-dimensional bar codes:
  - Codabar
  - Code 39
  - Code 93
  - Code 128
  - EAN-8
  - EAN-13

    - ITF-14
    - Intelligent Mail
    - MSI
    - Plessey
    - PDF417
    - UPC-A
    - UPC-E

- Two-dimensional bar codes:
    - Aztec
    - Data Matrix
    - QR Code

When you configure a **Barcode** data source, you can define specific rendering parameters that are used to generate an image:

- **Width** – Specify the bar code's width in pixels. A value of **0** (zero) indicates that the default width is used. The meaning can vary for different formats.
- **Height** – Specify the bar code's height in pixels. A value of **0** (zero) indicates that the default height is used. The meaning can vary for different formats.
- **Margin** – Specify the size of the bar code's margin in pixels. The margin is the area on each side of a bar code that must be kept clear (quiet zone). A value of **0** (zero) indicates that the default margin is used. The meaning can vary for different formats.
- **Output content** – Set the value to **Yes** to generate a bar code image that contains the encoded information as text. The default value is **No**.
- **Encoding** – Specify the type of characters that are encoded in the generated bar code image. By default, the **UTF-8** encoding is used.

> ⓘ **Important**
>
> When you add a new **Barcode** data source, you must place it under another item (container) as a nested element.
>
> When you bind a **Barcode** data source to a cell element in a format, and the cell element represents either a Word content control or an Excel picture, the data source is presented in that binding as a function that has a single parameter of the **String** type. You must use this parameter to specify the text that should be transformed into a bar code image and read when a generated bar code is scanned.

For more information about this feature, complete the examples in this article.

Example: Generate a payment check that contains a bar code that encodes the payable amount

This example shows how a user in the **System administrator** or **Electronic reporting functional consultant** role can configure an ER format that contains a template that is used to generate an outbound document in Excel format that contains a bar code. Here is an overview of the steps that are involved.

1. Complete the prerequisites.
2. Activate a configuration provider.
3. Import the provided ER solution.
4. Generate a payment check.
5. Review the generated payment check.
6. Modify the format of the provided ER solution.
    a. Apply a new check template.
    b. Add a new Barcode data source.
    c. Bind a new format element.
    d. Make the modified version available for test runs.
        i. Complete the modified format version.
        ii. Make the draft version available for use.
7. Generate a payment check.
8. Convert the generated check to a PDF.

In this example, you will use the provided ER solution that has been configured to generate payment checks. This solution generates payment checks where the payable amount is written both as a number and as text. You will modify this ER solution so that the check also includes a generated bar code where the payable amount is encoded and can be read by using a bar code scanner.

The steps can be completed in the **USMF** company in Microsoft Dynamics 365 Finance.

Complete the prerequisites

To complete this example, you must have access to the USMF company in Finance for one of the following roles:

- Electronic reporting functional consultant
- System administrator

If you haven't yet completed the example in the Embed images and shapes in documents that you generate by using ER article, download the following configurations of the sample ER solution.

Expand table

Content description	File name
ER data model configuration	Model for cheques.xml
ER format configuration	Cheques printing format.xml

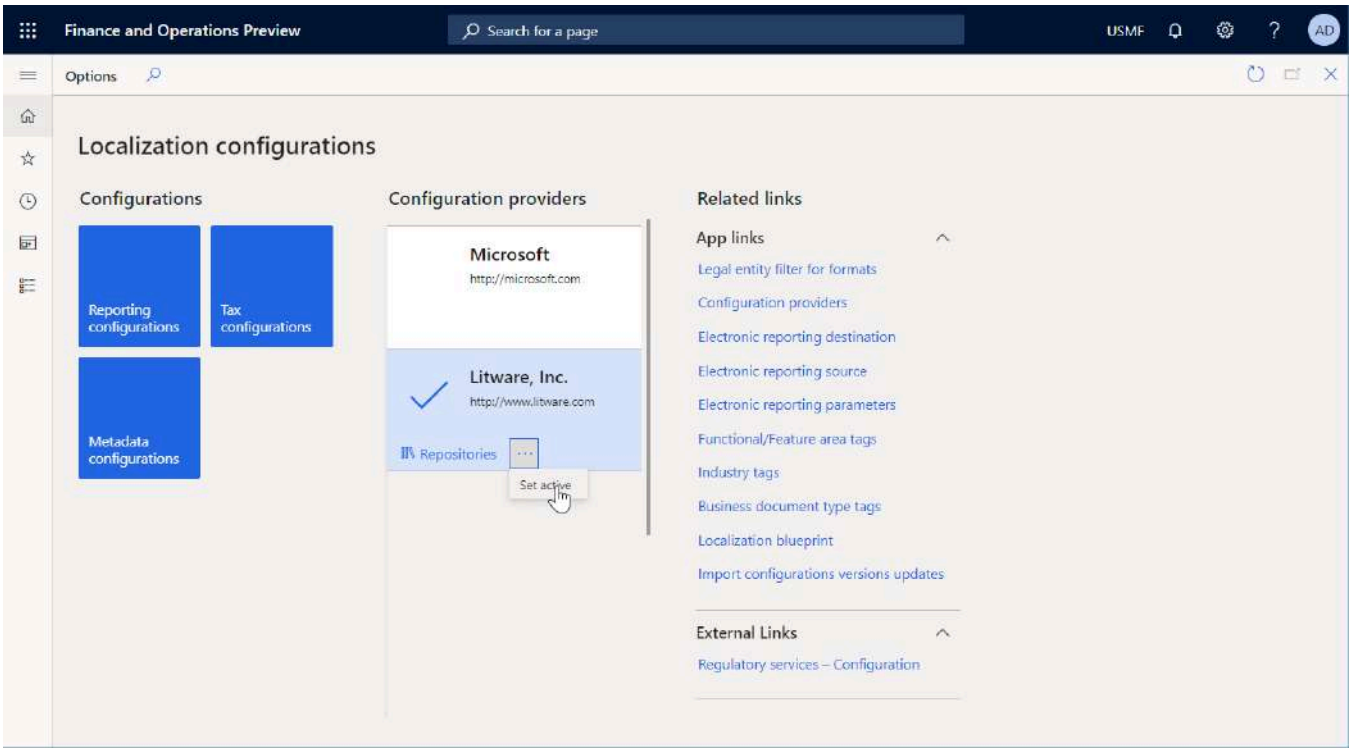
Additionally, download the following Excel file that contains the modified template for the provided ER solution.

Expand table

Content description	File name
Report template	Check template Excel.xlsx

Activate a configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization configurations** page, in the **Configuration providers** section, make sure that the configuration provider for the **Litware, Inc.** sample company is listed, and that it's marked as active. If it isn't listed, or if it isn't marked as active, follow the steps in the Create a configuration provider and mark it as active article.



Import the provided ER solution

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization configurations** page, in the **Configurations** section, select the **Reporting configurations** tile.
3. On the **Configurations** page, if the **Model for cheques** configuration isn't available in the configuration tree, follow these steps to import the ER data model configuration:
   a. On the Action Pane, select **Exchange** > **Load from XML file**.
   b. In the dialog box, select **Browse**, find and select the **Model for cheques.xml** file, and then select **OK**.
4. If the **Cheques printing format** configuration isn't available in the configuration tree, follow these steps to import the ER format configuration:
   a. On the Action Pane, select **Exchange** > **Load from XML file**.
   b. In the dialog box, select **Browse**, find and select the **Cheques printing format.xml** file, and then select **OK**.
5. In the configuration tree, expand **Model for cheques**.
6. Review the list of imported ER configurations in the configuration tree.

Generate a payment check

1. Go to **Cash and bank management** > **Bank accounts** > **Bank accounts**.

2. On the **Bank accounts** page, select the **USMF OPER** account.

3. On the bank account details page, on the Action Pane, on the **Set up** tab, in the **Layout** group, select **Check**.

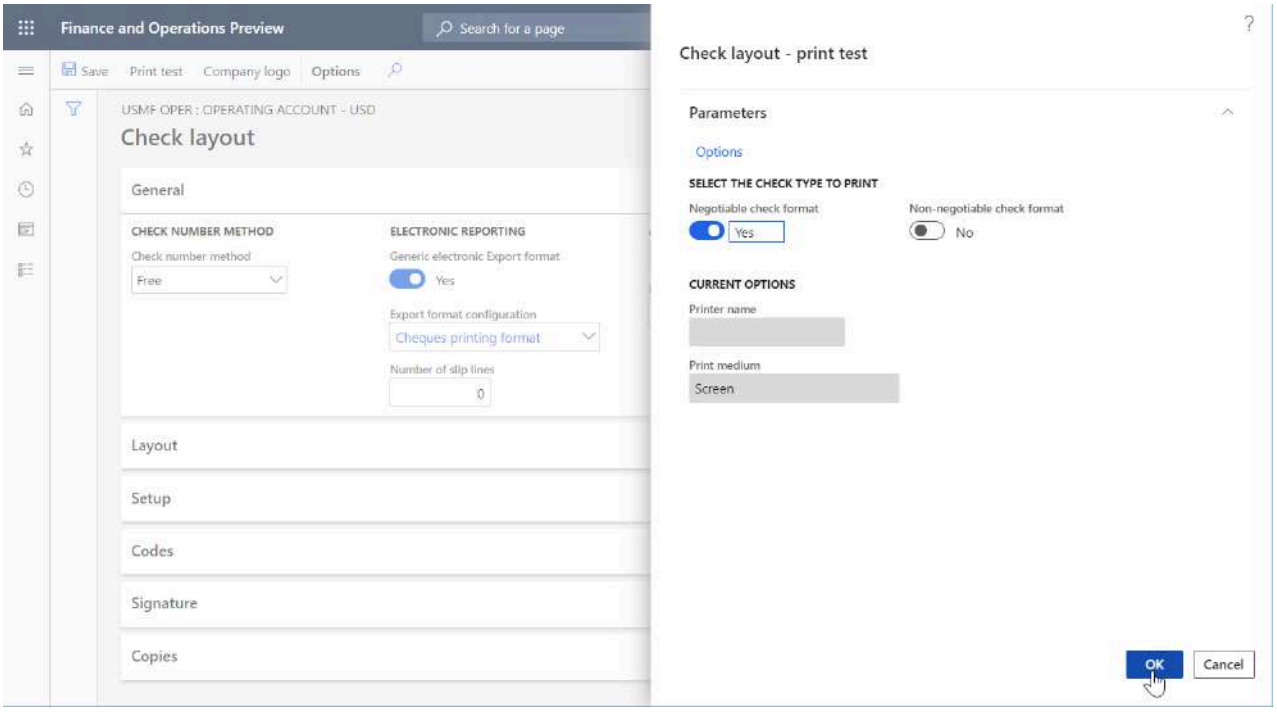
4. On the **Check layout** page, select **Edit**.

5. On the **General** FastTab, set the **Generic electronic Export format** option to **Yes**.

6. In the **Export format configuration** field, select the **Cheques printing format** ER format that you imported earlier.

7. On the Action Pane, select **Print test**.

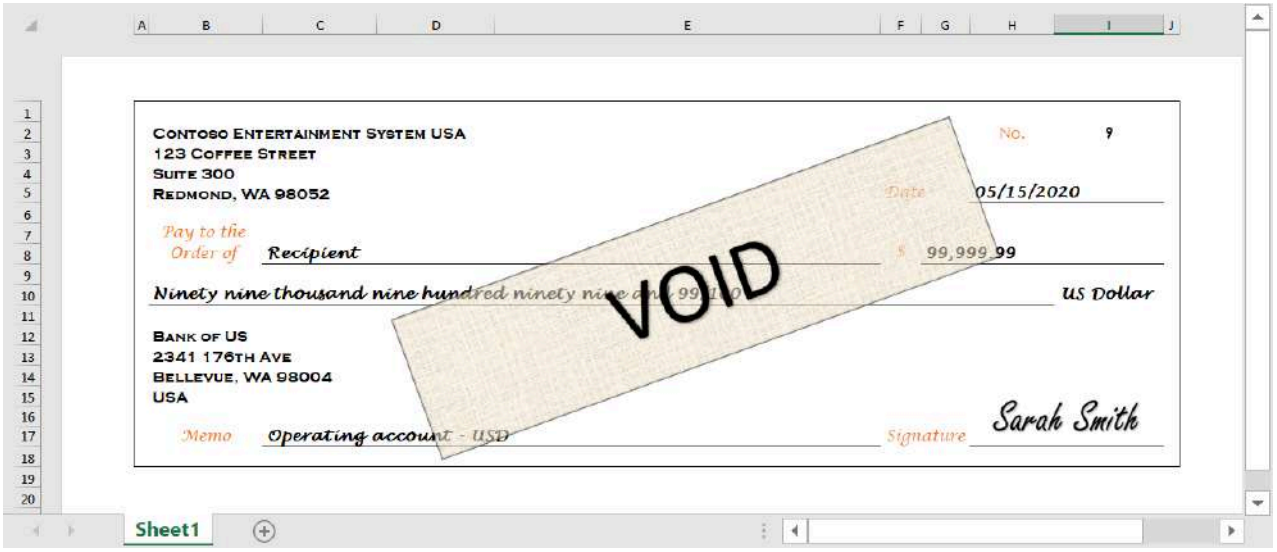
8. In the dialog box, set the **Negotiable check format** option to **Yes**, and then select **OK**.



Review the generated payment check

- Open the generated check in Excel.

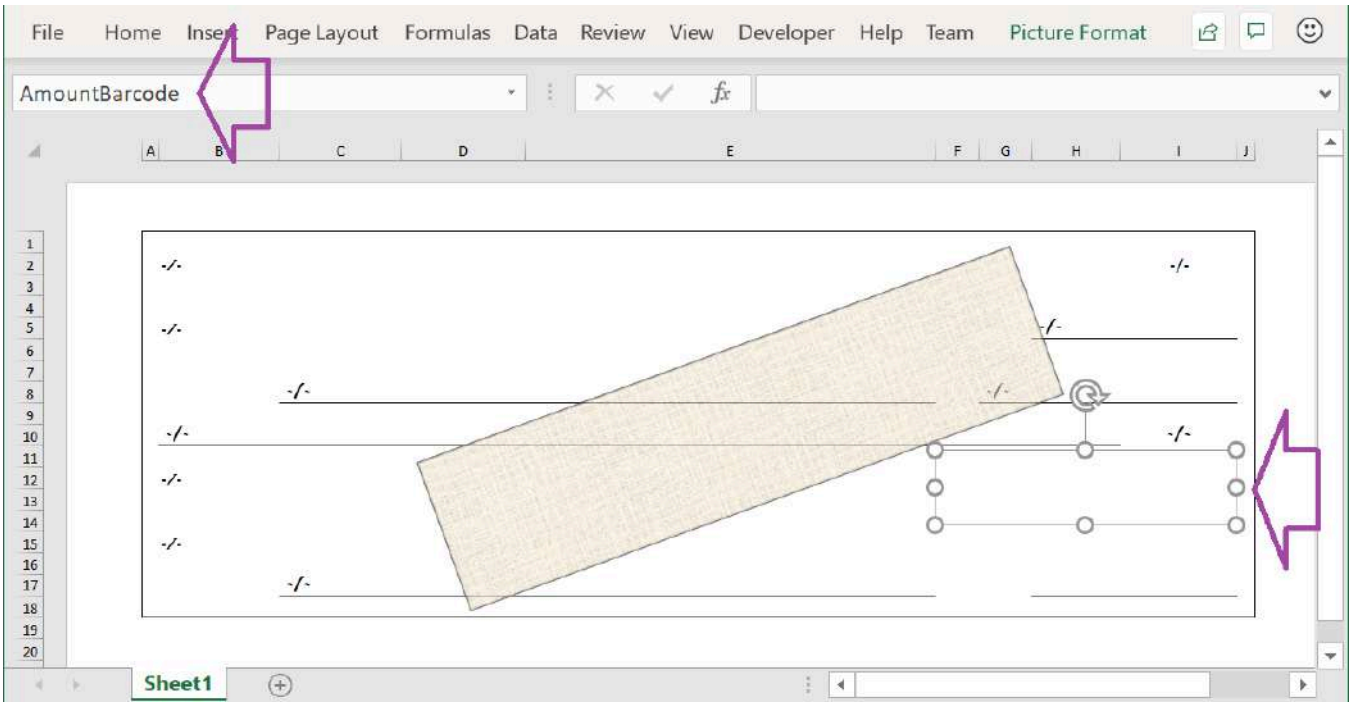
2. Review the generated check.



Modify the format of the provided ER solution

Apply a new check template

You can use the Excel desktop application to open the **Cheque template Excel.xlsx** file that you imported earlier. Notice that this template differs from the template that you used to generate a payment check in the provided ER solution. In addition, it includes an **AmountBarcode** element for the bar code image.



You must now modify the ER solution and then reapply the modified template.

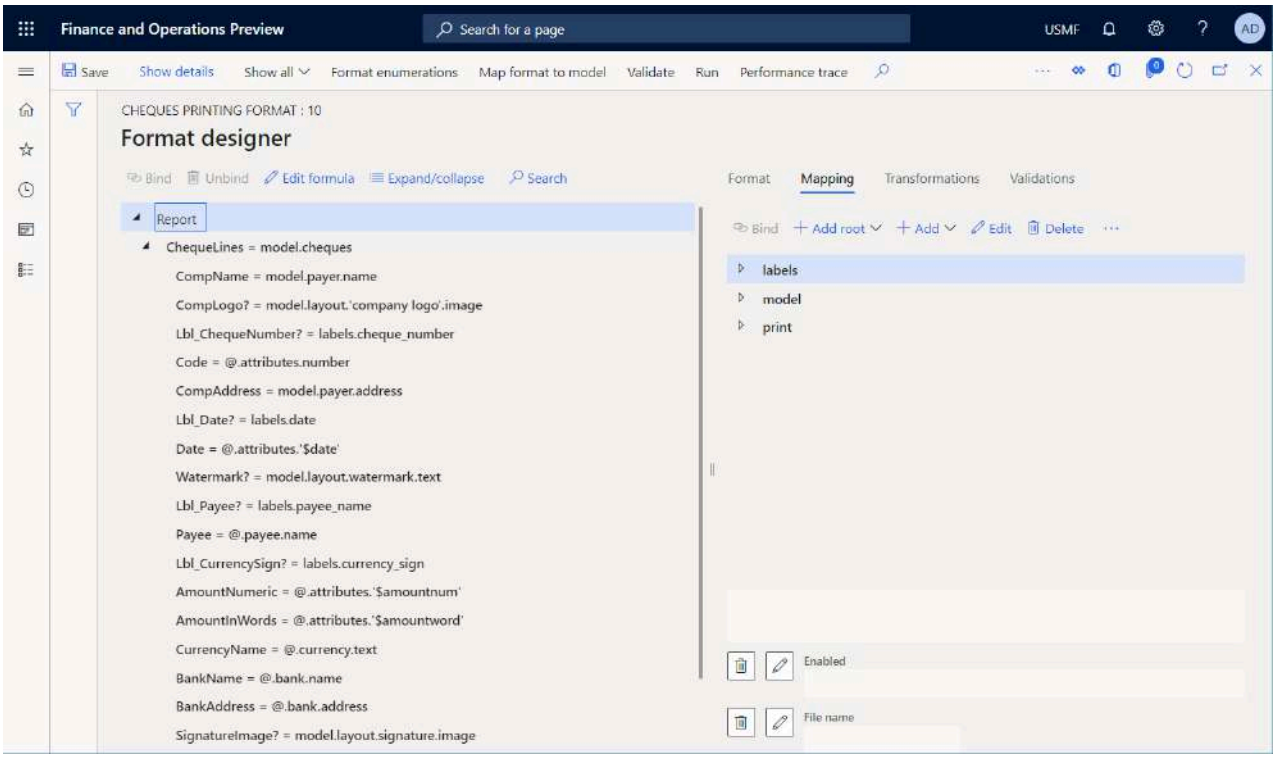
1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization configurations** page, in the **Configurations** section, select **Reporting configurations**.

3. On the **Configurations** page, in the configuration tree, expand **Model for cheques**, and select **Cheques printing format**.

4. On the Action Pane, select **Designer**.

5. In the ER Operations designer, select the **Mapping** tab on the right side of the page, and then, in the format tree pane on the left, select **Expand/collapse**.

6. Notice that all cell format elements are bound to the appropriate data sources.



7. Select the **Format** tab on the right side of the page.

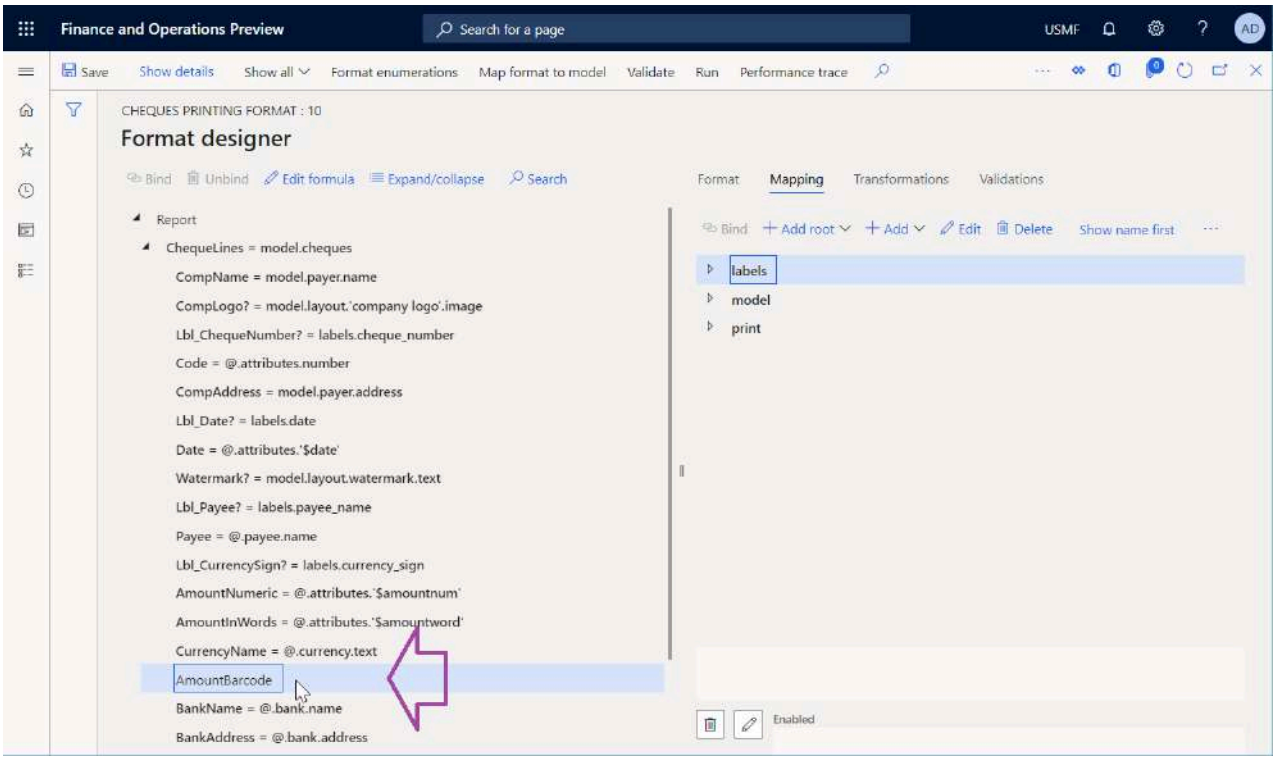
8. On the Action Pane, select the ellipsis (**...**), and then select **Import**.

9. In the **Import** group, select **Update from Excel**, and then select **Update template**.

10. In the dialog box, browse to the **Cheque template Excel.xlsx** file that is saved on your computer, select it, and then select **OK** to confirm that the selected template should be applied.

11. Select the **Mapping** tab on the right side of the page, and then, in the format tree pane on the left, select **Expand/collapse**.

12. Notice that the **AmountBarcode** cell element has been added to the format. This element is associated with the **AmountBarcode** element that has been added to the modified Excel template as a placeholder for a bar code image.

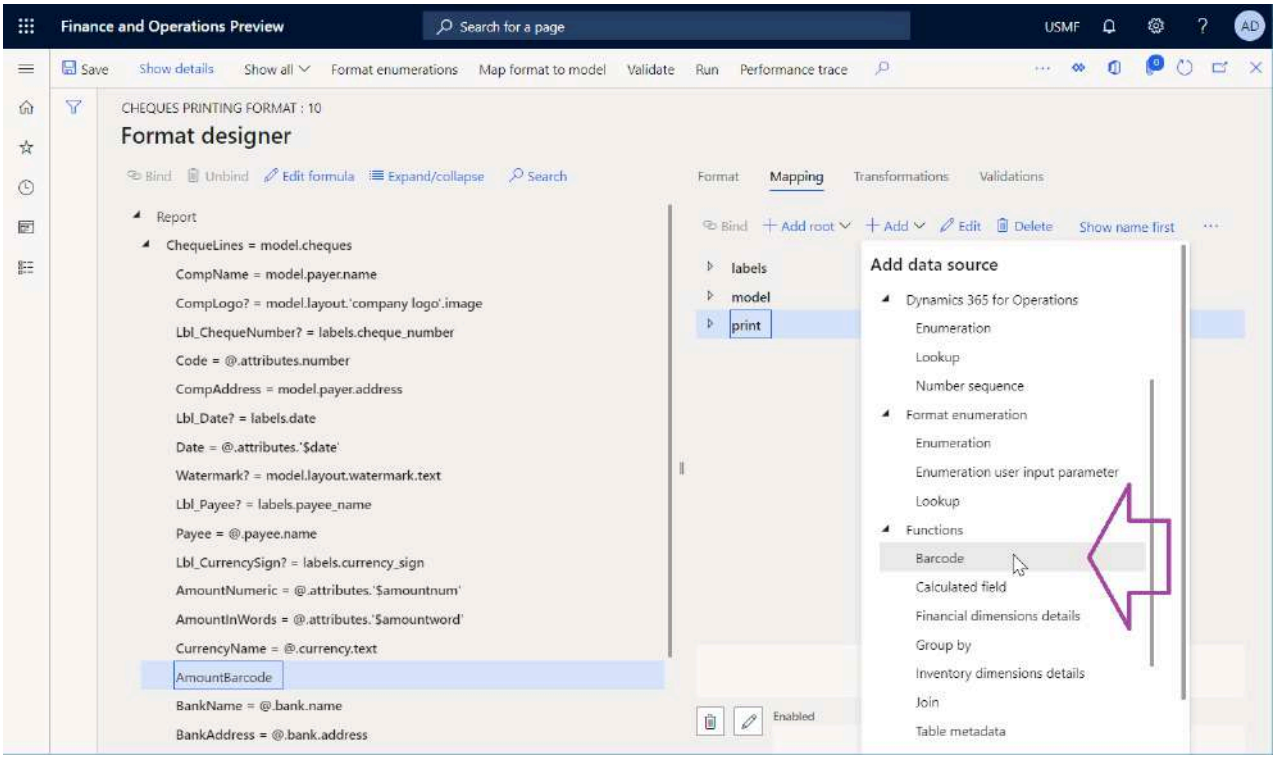


Add a new Barcode data source

Next, you must add a new data source of the **Barcode** type.

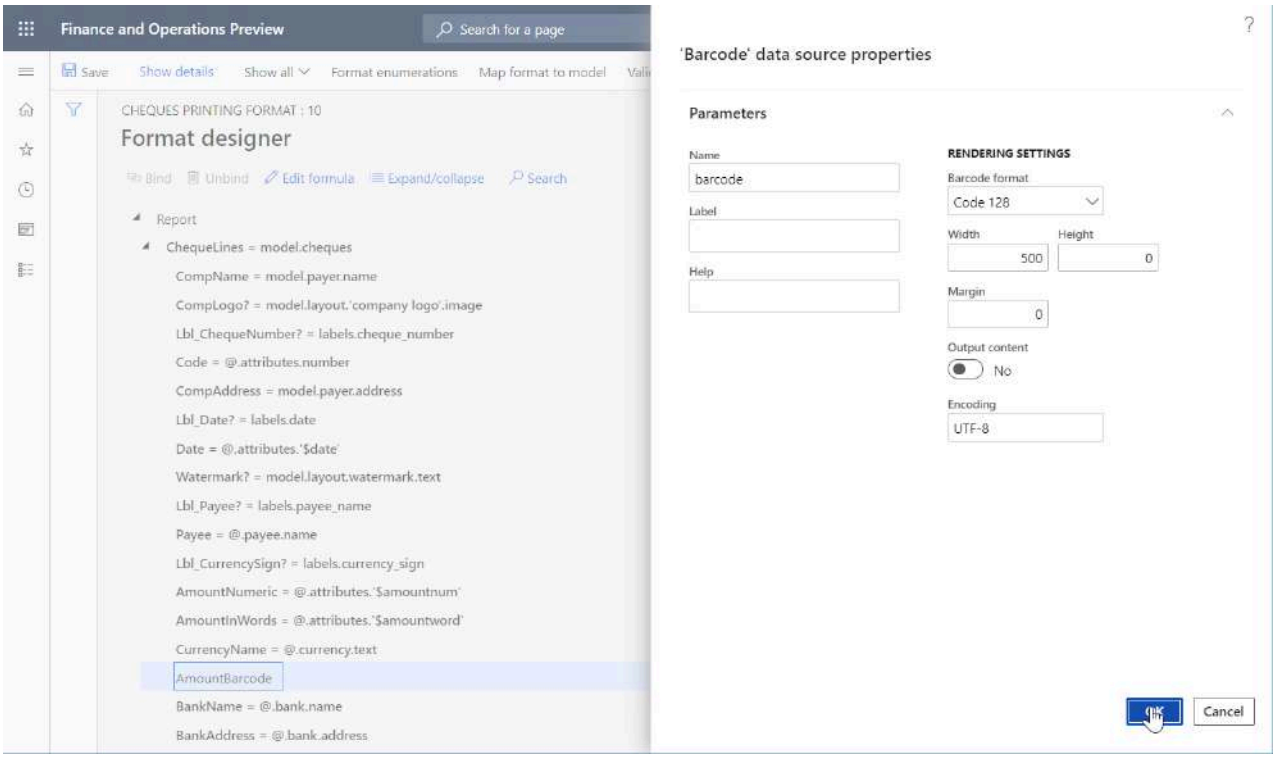
1. In the ER Operations designer, on the **Mapping** tab on the right side of the page, select the **print** data source.

2. Select **Add**, and then, in the **Functions** group, select the **Barcode** data source type.



3. In the dialog box, in the **Name** field, enter **barcode**.

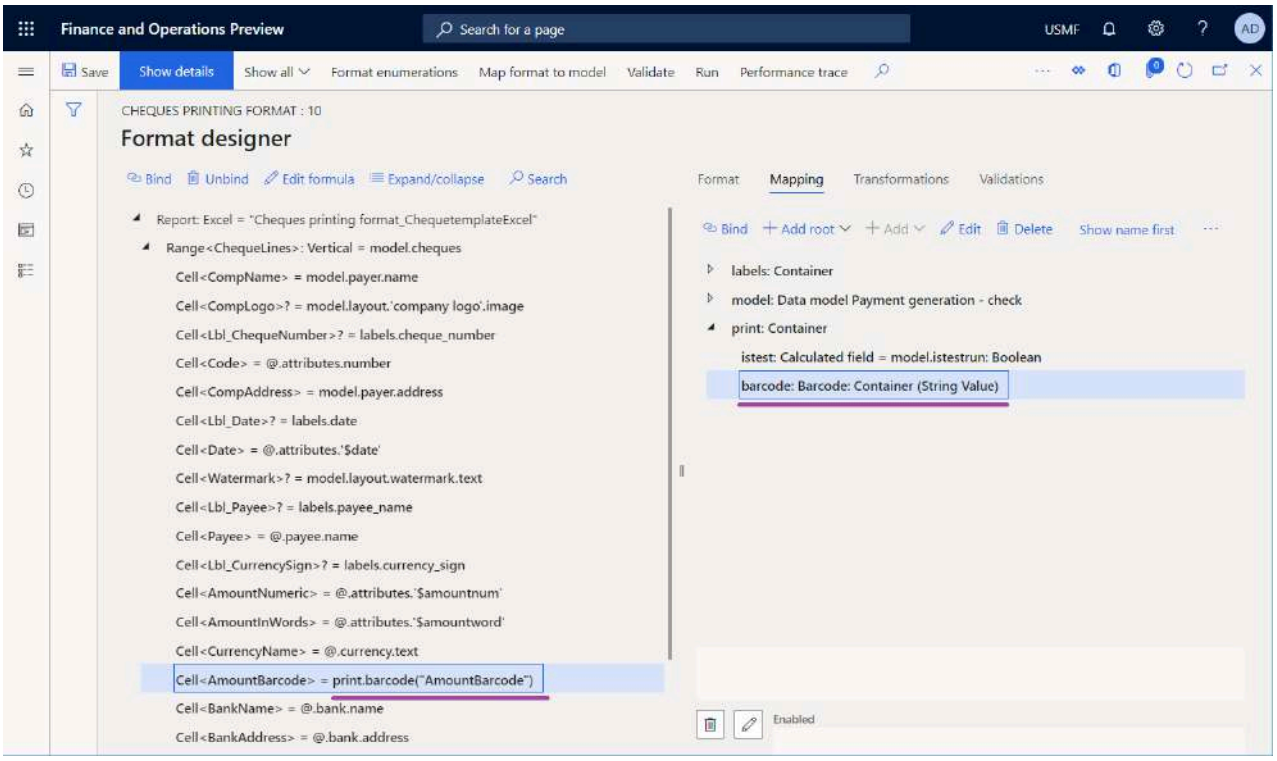
4. In the **Barcode format**, select **Code 128**.
5. In the **Width** field, enter **500**.
6. Select **OK**.



Bind a new format element

Next, you must bind the new format element to the data source that you just added.

1. In the ER Operations designer, on the **Mapping** tab on the right side of the page, select the **print\barcode** data source.
2. In the format tree pane on the left, select the **AmountBarcode** cell element, and then select **Bind**.
3. On the Action Pane, select **Show details**.
4. Notice that, because the **Barcode** data source is represented in the binding as a function that contains a single parameter, the name of the bound format element has been automatically taken as the argument of that parameter.



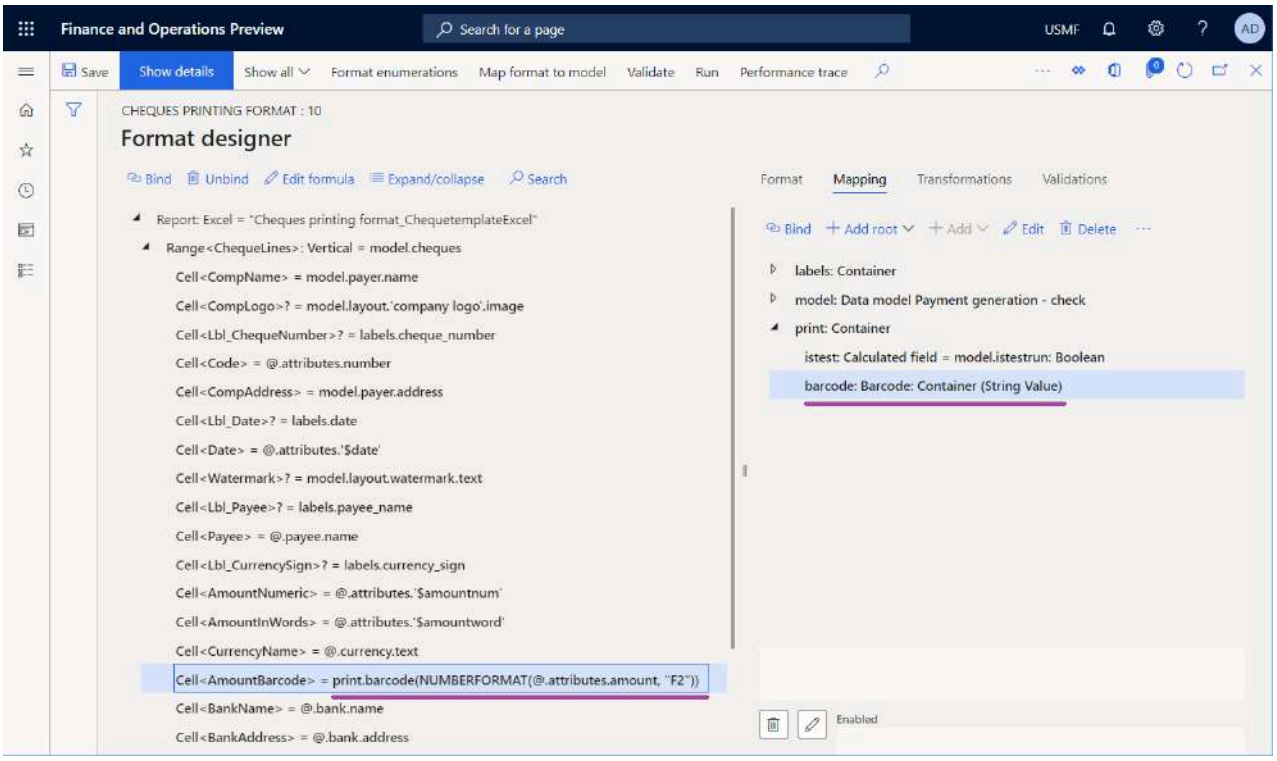
5. Select **Edit formula** to adjust the binding.

   You don't want the name of the cell element to be returned. Therefore, you must configure an expression that returns text that contains the payable amount of the current check. Because the parent **ChequeLines** range is bound to the **model.cheques** data source, the payable amount of the current check is available in the **model.cheques.attributes.amount** field of the **Real** data type.

6. In the **Formula** field, enter **print.barcode(NUMBERFORMAT(@.attributes.amount, "F2"))**.

7. Select **Save**, and then close the ER Formula designer.

8. Notice that the binding has been adjusted.



9. Select **Save**, and then close the ER Operations designer.

Make the modified version available for test runs

By default, the only versions that have a status of **Completed** and **Shared** are used when you run an ER format.

If you've finalized your changes, you can complete your work with the current draft version and make your changes available for use. For instructions, see the Complete the modified format version section that follows.

If you want to continue to work with the current draft version, but you have to use it to generate checks, you must explicitly specify that you want to use the draft version of the format for execution. For instructions, see the Make the draft version available for use section.

Complete the modified format version

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization configurations** page, in the **Configurations** section, select **Reporting configurations**.
3. On the **Configurations** page, in the configuration tree, expand **Model for cheques**, and select **Cheques printing format**.
4. On the **Versions** FastTab, select the record that has a status of **Draft**.
5. Select **Change status**, and then select **Complete**.
6. In the dialog box, select **OK**.

The status of the current version is changed from **Draft** to **Completed**, and a new version that has a status of **Draft** is created. You can use this new draft version to apply additional changes.

Make the draft version available for use

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization configurations** page, in the **Configurations** section, select **Reporting configurations**.
3. On the **Configurations** page, on the Action Pane, in the **Configurations** tab, in the **Advance settings** group, select **User parameters**.
4. In the dialog box, set the **Run setting** options to **Yes**, and then select **OK**.
5. In the configuration tree, expand **Model for cheques**, and select **Cheques printing format**.
6. Set the **Run draft** option to **Yes**.
7. Select **Save**.

The draft version of the selected format is marked as available for use when the selected format is run.

Generate a payment check

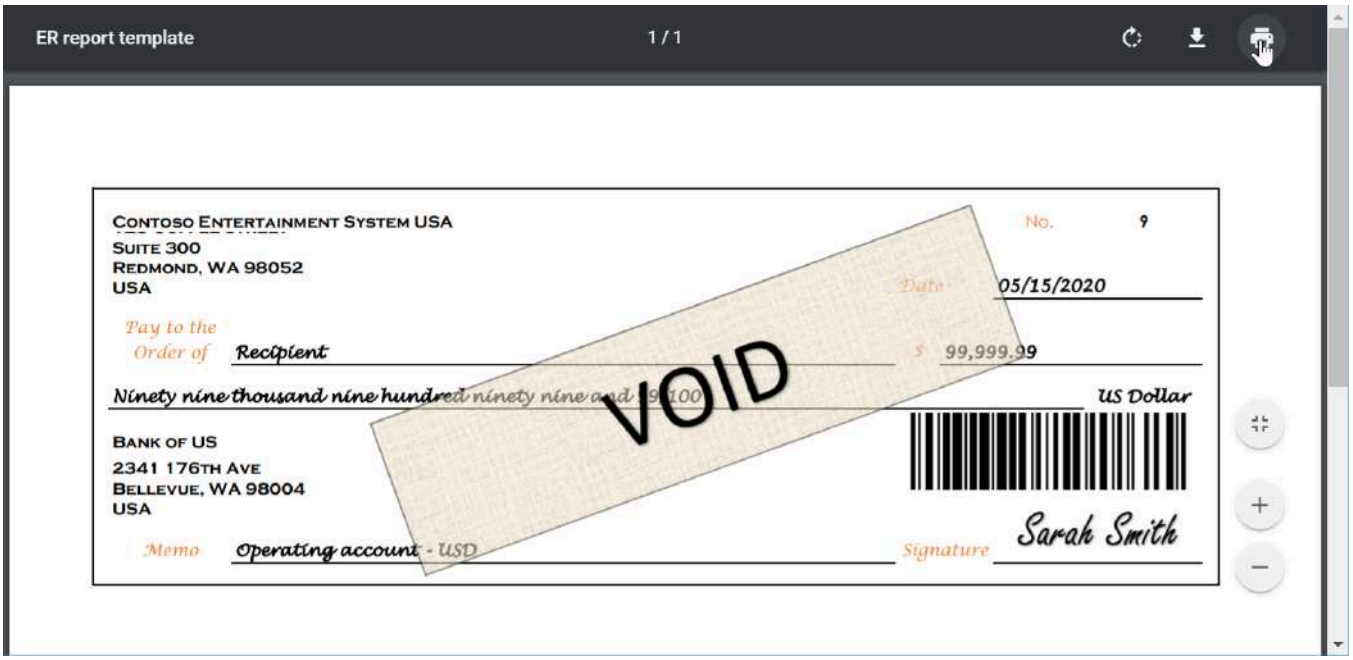
1. Go to **Cash and bank management** > **Bank accounts** > **Bank accounts**.
2. On the **Bank accounts** page, select the **USMF OPER** account.
3. On the bank account details page, on the Action Pane, on the **Set up** tab, in the **Layout** group, select **Check**.
4. On the **Check layout** page, on the Action Pane, select **Print test**.
5. In the dialog box, set the **Negotiable check format** option to **Yes**.
6. Select **OK**.
7. Review the generated check. Notice that a bar code has been generated to encode the payable amount of the check.

> **Important**
>
> An exception is thrown if the argument of a **Barcode** data source doesn't comply with the appropriate requirements that are specific to the bar code format. For example, when the **Barcode** data source is called to generate an EAN-8 bar code for the provided text, an exception is thrown if the length of the text exceeds seven characters.

Convert the generated check to a PDF

As described in the Generate printable FTI forms article, you can use a special font to produce bar codes in a generated document. In this case, additional transformations of the generated document might depend on the availability of that font in the transformation environment. For example, if you try to convert a document to PDF format or preview it in an environment where the font is missing, bar codes won't be rendered correctly.

However, when you use the **Barcode** data source to produce bar codes, the rendering of those bar codes doesn't depend on any font. Therefore, you can easily convert documents that contain the bar codes to PDF format. The following illustration shows the preview of a generated payment check that has been converted to a PDF, based on the setting of the configured ER destination.



Limitations

> **Note**
>
> Some types of bar codes that are generated have a fixed aspect ratio. This behavior makes sense if you've turned on the **Enable usage of EPPlus library in Electronic reporting framework** feature to work with Excel documents in ER. In that case, an image is entered into a placeholder that has a locked aspect ratio. Therefore, when the dimensions of a placeholder in a template correspond to the ratio of an image that is entered, a real picture in a generated document might be resized to maintain the required aspect ratio. To prevent picture resizing, use a placeholder that has an expected aspect ratio.

- NUMBERFORMAT function

Configure Lookup data sources to use ER application-specific parameters

The Electronic reporting (ER) application-specific parameters feature lets you configure data filtering in an ER format so that it's based on a set of abstract rules. You can configure this set of rules to use the data source of the **Lookup** type that is available in an ER format. Use the user interface (UI) that is automatically generated based on the settings of the **Lookup** data source of the corresponding ER format and the current legal entity data to specify real rules beyond the ER components designers. Eventually, the ER format's **Lookup** data source accesses the specified rules when this ER format is executed.

> **Note**
>
> Use the configured data sources of the editable ER format to specify what application data is used to configure real rules.

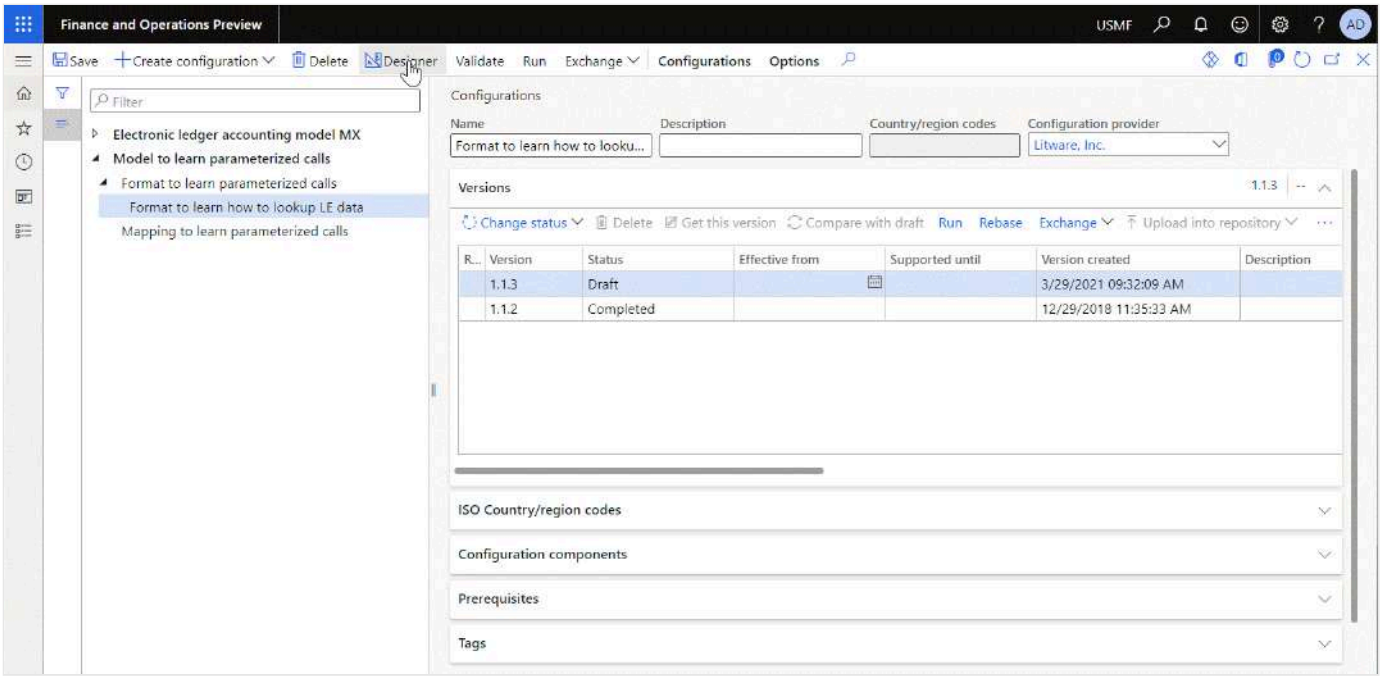
Use the ER Operations designer to bring a data source of the **Lookup** type into your ER format. You must configure the data source to describe how your abstract rules look, including the following elements:

- The parameter set of a certain data type whose value specifies a single rule.
- The value type of a certain data type that a single rule returns when this rule is considered the most appropriate among others.

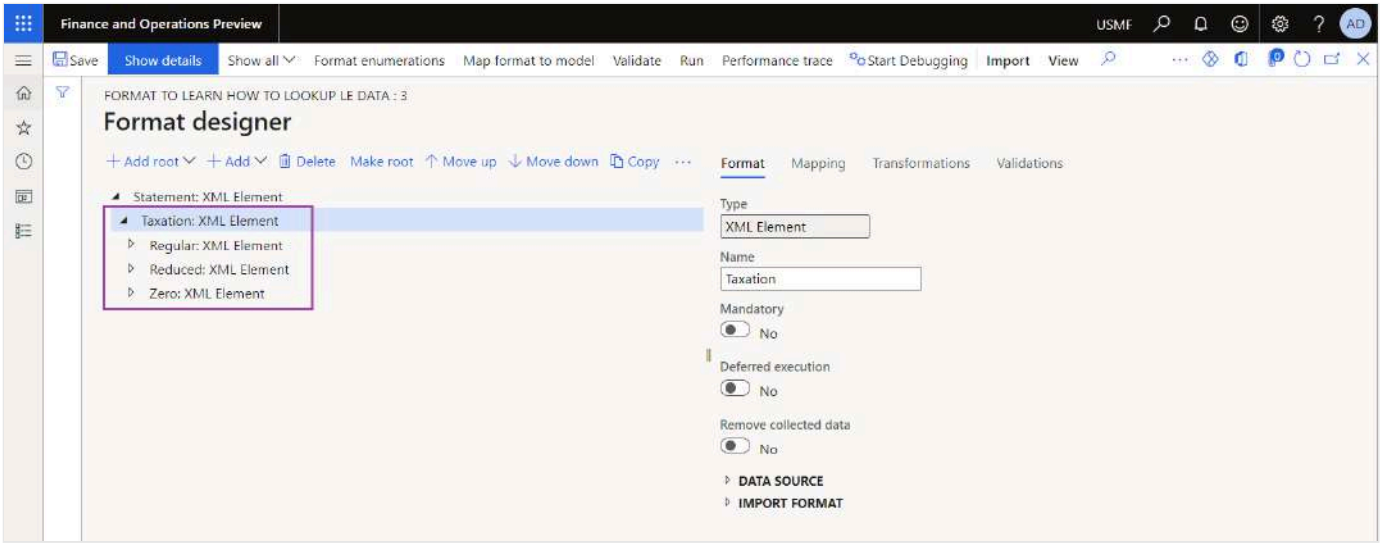
Depending on the type of value that any configured rule returns, you can configure the following types of **Lookup** data sources:

- Use the **Data model\Lookup** type when you must return a model enumeration value.
- Use the **Dynamics 365 Operations\Lookup** type when you must return an application enumeration value or an application extended data type value.
- Use the **Format enumeration\Lookup** type when you must return a format enumeration value.

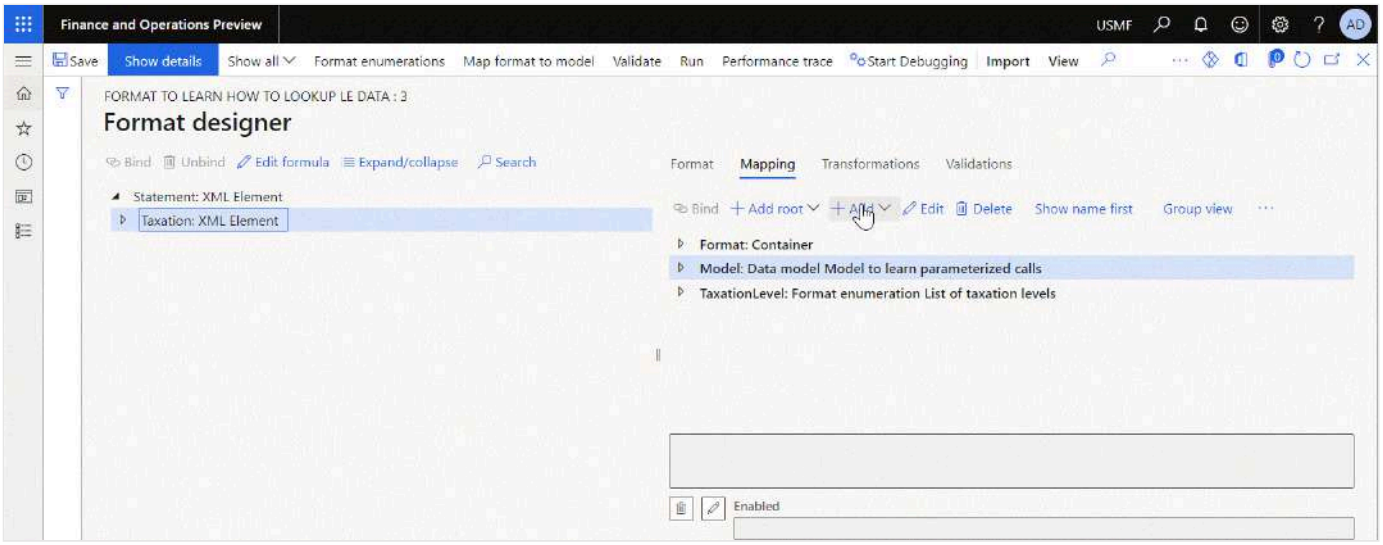
The following illustration shows how you can configure a format enumeration in the sample ER format.



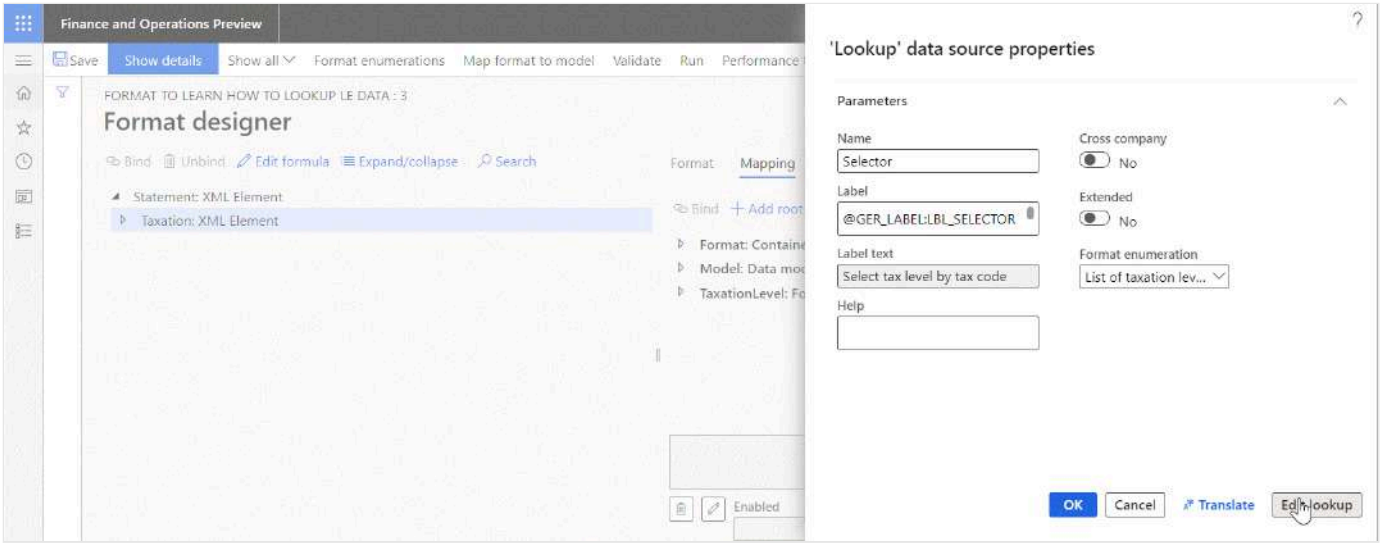
The following illustration shows the format components that you configured to report different types of taxes in different sections of a generated report.



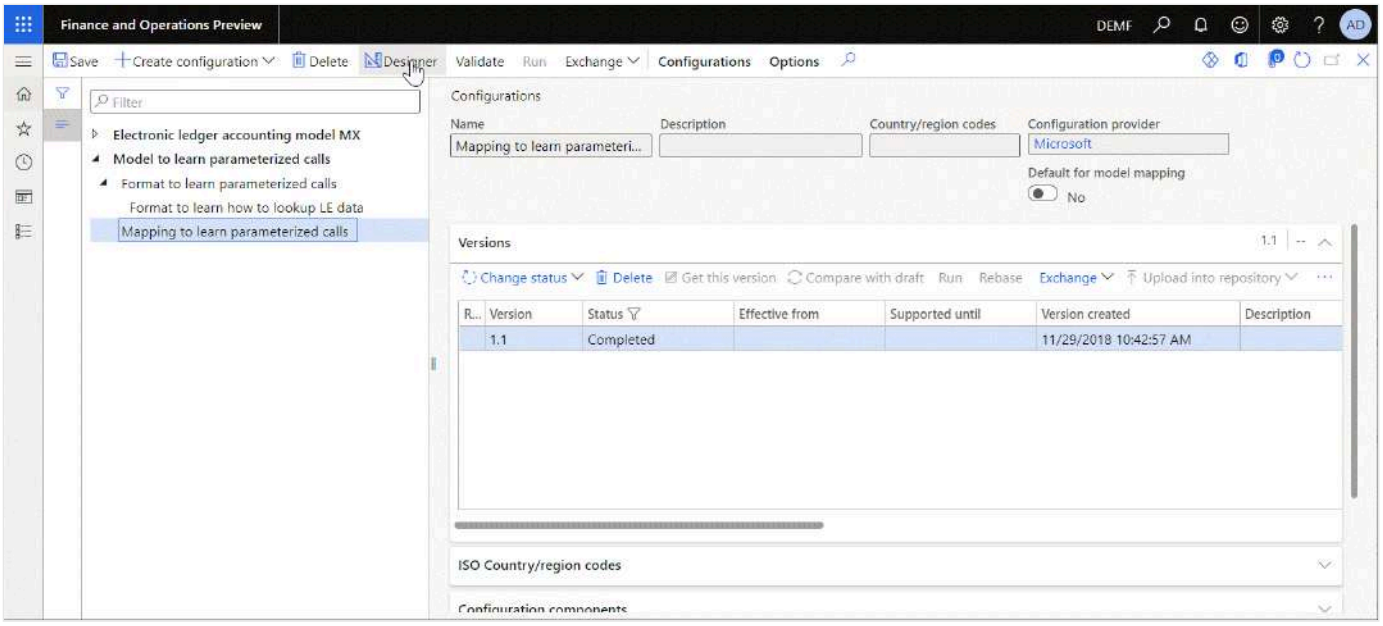
The following illustration shows how the ER Operations designer allows you to add a data source of the **Format enumeration\Lookup** type. The added data source is configured as returning a value of the `List of taxation levels` format enumeration.



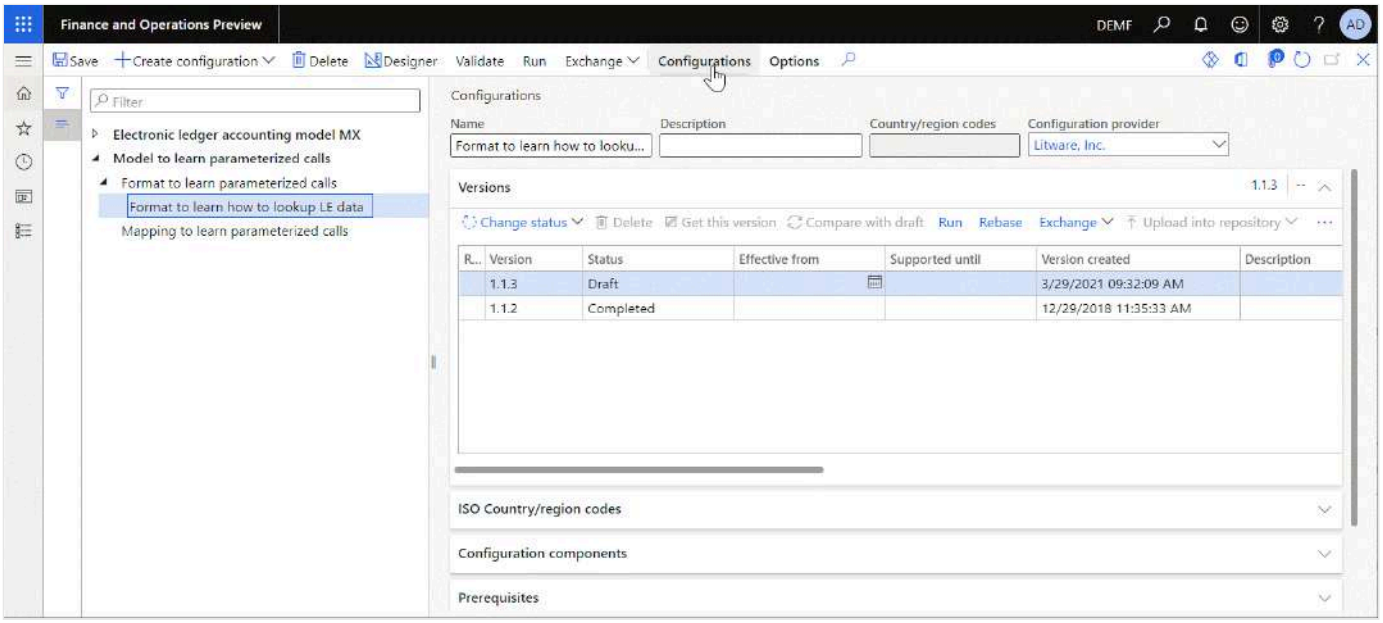
The following illustration shows how you configure the added data source to use the **Code** field of the **Model.Data.Tax** record list of the **Model** data source as a parameter that you must specify for every configured rule.



You configure the added `Model.Data.Tax` data source to specify a tax code for every configured rule by accessing records of the **TaxTable** application table.

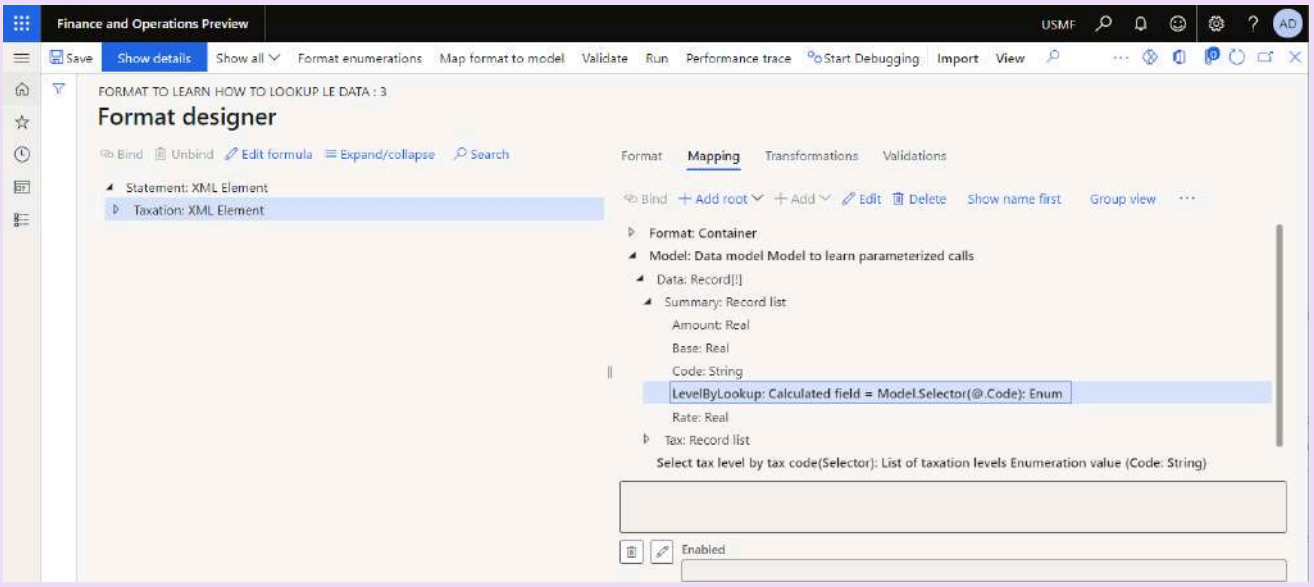


Set up the lookup rules for the selected ER format by using the UI that automatically aligns with the structure of the configured data source. Currently, this UI requires that for each rule, you specify the returned value as the `List of taxation levels` format enumeration value as well as the tax code as a parameter.

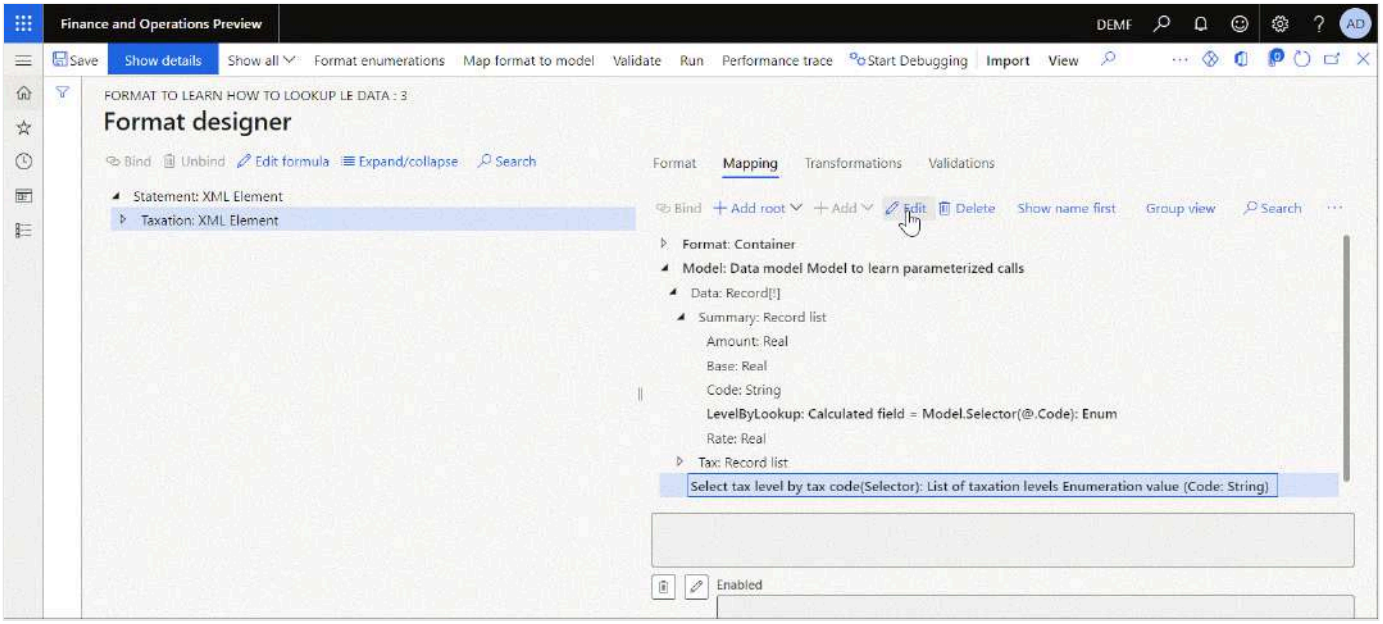


The following illustration shows how you can configure the `Model.Data.Summary.LevelByLookup` data source of the **Calculated field** type to call the configured **Lookup** data source by providing the required parameters. To process this call at runtime, ER goes through the list of configured rules in the defined sequence to locate the first rule that satisfies the provided conditions. In this example, it's the rule that contains the tax code that matches the provided one. As the result, ER finds the most appropriate rule and returns the enumeration value that you configured for the found rule.

> **Note**
>
> An exception is thrown when no applicable rule is found. To prevent these exceptions, configure additional rules at the end of the rules list to handle cases when a non-configured value or no value is provided. Use the ***Not blank*** and ***Blank*** options accordingly.

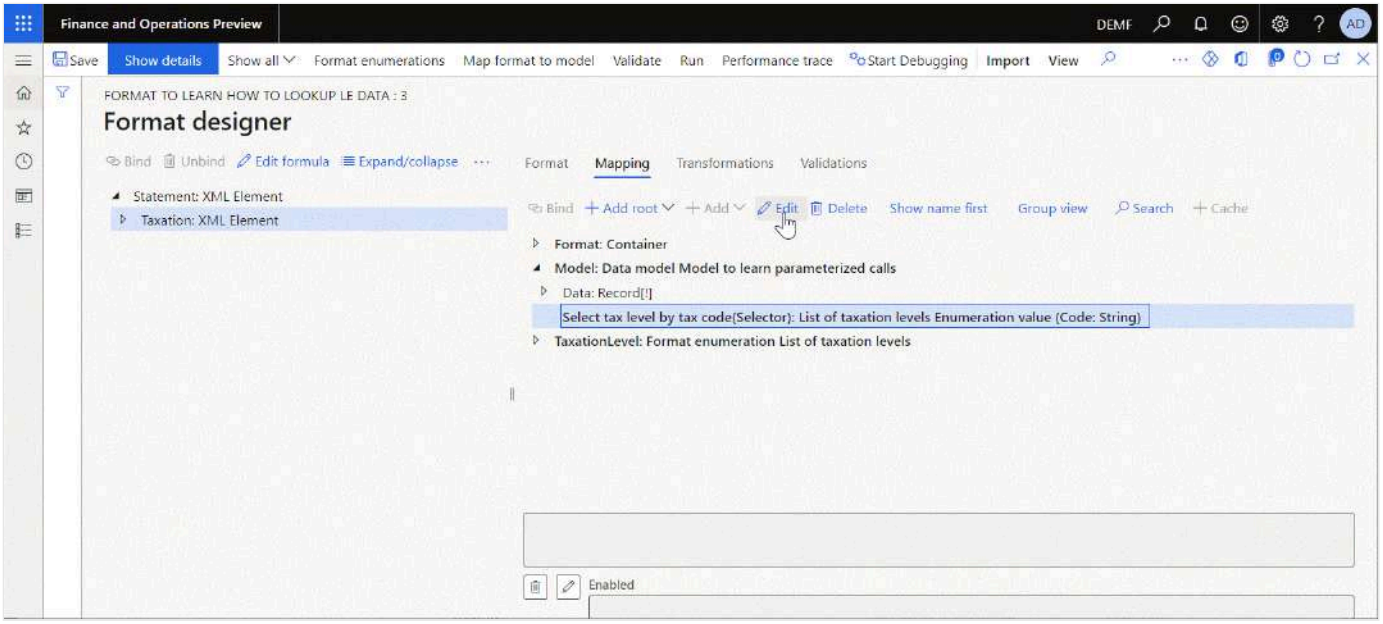


When you set the **Cross-company** option to **Yes** for the editable lookup data source, you add a new required **Company** parameter to the set of parameters for this data source. You must specify the value of the **Company** parameter at runtime when the lookup data source is called. When you specify the company code at runtime, the rules configured for this company are used to find the most appropriate rule, and the corresponding value is returned. The following illustration shows how you can do this and how the set of parameters of the editable data source is changed.



> **Note**
>
> Select every company separately to configure the set of rules for this lookup data source of the editable ER format. An exception is thrown at runtime when the cross-company lookup is called with the code of the company for which the lookup setting wasn't completed.
>
> Make sure that you grant permissions for a user who runs the ER format with the cross-company **Lookup** data source to access the data of every company that is in scope of this data source. Otherwise, an exception is thrown at runtime.

Starting in version 10.0.19, the **Lookup** data sources include extended capabilities. When you set the **Extended** option to **Yes** for the editable lookup data source, the configured lookup data source transforms into a structured data source that offers extra capabilities to analyze the configured set of rules. The following illustration shows this transformation.



- The **Lookup** subitem works as a function that finds the most appropriate rule from the set of configurable rules based on the provided set of parameters.
- The **IsLookupResultSet** subitem works as a function that accepts the provided value of the base enumeration data source and returns the *Boolean* value of **True** when the set of rules contains at least one rule for which the provided enumeration value is configured as a returned value. This function returns the *Boolean* value of **False** when there are no rules configured to return the provided enumeration value.
- The **Setting** subitem works as a function that returns the set of configured rules as records of a record list. The returned values and the set of parameters of the configured rules are

presented in every returned record as fields of the relevant data types:

- The returned value appears as the **Lookup result** field.
- The configured parameters appear as fields with names of parameters (**Code** field in this example).

For more information about how to configure the **Lookup** data source, see Configure ER formats to use parameters that are specified per legal entity. To learn how to set the Lookup rules, see Set up the parameters of an ER format per legal entity.

Use DATA COLLECTION data sources in Electronic reporting formats

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use the Operations designer of the Electronic reporting (ER) framework to configure the format component of an ER solution that generates outbound documents in different formats. The hierarchical structure of the configured format component consists of various types of format elements. These format elements fill generated documents with the required information at runtime. By default, when you run an ER format, the format elements run in the same order as they appear in the format hierarchy: one by one, from top to bottom.

When ER runs a format element that contains a binding, the formula of that binding is run. The format element adds the value to a generated document. For example, the binding can pass the value of a data model field to a format element. You can configure a DATA COLLECTION data source to collect values of data model fields at runtime, sum values, and fill a generated document with the collected values. To use this approach, change the initial binding so that the configured DATA COLLECTION data source passes the value of a data model field to a format element. By passing values through the DATA COLLECTION data source, you can collect required details for further use.

When you configure a DATA COLLECTION data source, specify a value type that will be managed in the data source. The following data types are currently supported for collecting values:

- Boolean
- Date
- DateTime
- GUID
- Int64
- Integer

- Real
- String
- Time

Use the `Collect(Value)` method of a DATA COLLECTION data source to pass a value to a data source for collection. In this method, the `Value` argument is either a constant or the valid path of a data source field of the relevant data type.

Use the `Result` property of a DATA COLLECTION data source to access the list of collected values. This property returns a record list. The records of the record list contain the `Value` field that you can use to access collected values.

By default, a DATA COLLECTION data source collects only unique values.

To collect all values, set the **Collect all values** field of the configured DATA COLLECTION data source to **Yes**. When the **Collect all values** field is set to **Yes**, the `Sum(Flag)` parameterized property becomes available. You can use this property to get the total amount of all currently collected values. In this property, the `Flag` argument is a Boolean value that is used to indicate whether the total value must be reset.

- When the value **False** is provided, summing continues from the previously collected amount.
- When the value **True** is provided, a new summing starts.

The following data types are currently supported for summing:

- Int64
- Integer
- Real

To learn more about this feature, complete the example that follows.

Example: Configure an ER format to do counting and summing by using a DATA COLLECTION data source

This example shows how a user in the System administrator or Electronic reporting functional consultant role can configure an ER format that has a DATA COLLECTION data source that calculates running totals and collects summed values.

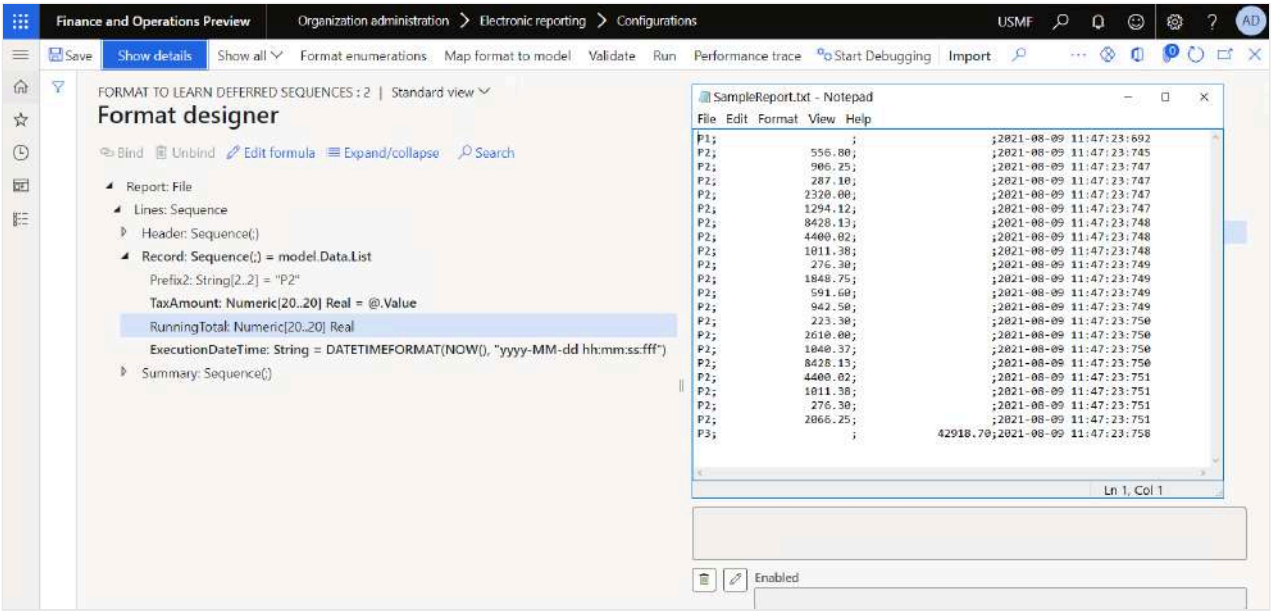
You can complete the procedures in this example in the USMF company in Microsoft Dynamics 365 Finance.

Upload and use the provided ER solution

1. Import the sample ER configurations.
2. Activate a configuration provider.
3. Review the imported model mapping.
4. Review the imported format.
5. Run the imported format.

Run the format of the provided ER solution

1. On the **Format designer** page, select **Run**.
2. In the **Electronic report parameters** dialog box, select **OK**.
3. Download and review the file that the web browser offers.



Modify the format of the ER solution to calculate the running tax total

If the volume of transactions is much larger than the volume in the current example, the time that summing requires might increase and cause performance issues. By changing the settings of the format, you can help prevent these performance issues. Because you access tax values to include them in the generated report, you can reuse that information to sum tax values.

1. On the **Format designer** page, on the **Mapping** tab, select **Add root**.
2. In the **Add data source** dialog box, select **Functions** > **Data collection**.

3. In the **'Data collection' data source properties** dialog box, follow these steps:
   a. In the **Name** field, enter **CollectedTaxValues**.
   b. In the **Item type** field, select **Real**.
   c. In the **Collect all values** field, select **Yes**.
   d. Select **OK**.

4. Select the **Report\Lines\Record\TaxAmount** numeric format element.

> ⓘ **Note**
>
> Currently, the `@.Value` binding is configured for this element. Therefore, a generated document is filled with tax values from the `model.Data.List.Value` field.

5. Select **Edit formula**.

6. On **Formula designer**, follow these steps:
   a. In the **Formula** field, replace `@.Value` with `CollectedTaxValues.Collect(@.Value)`.
   b. Save your changes, and close the page.

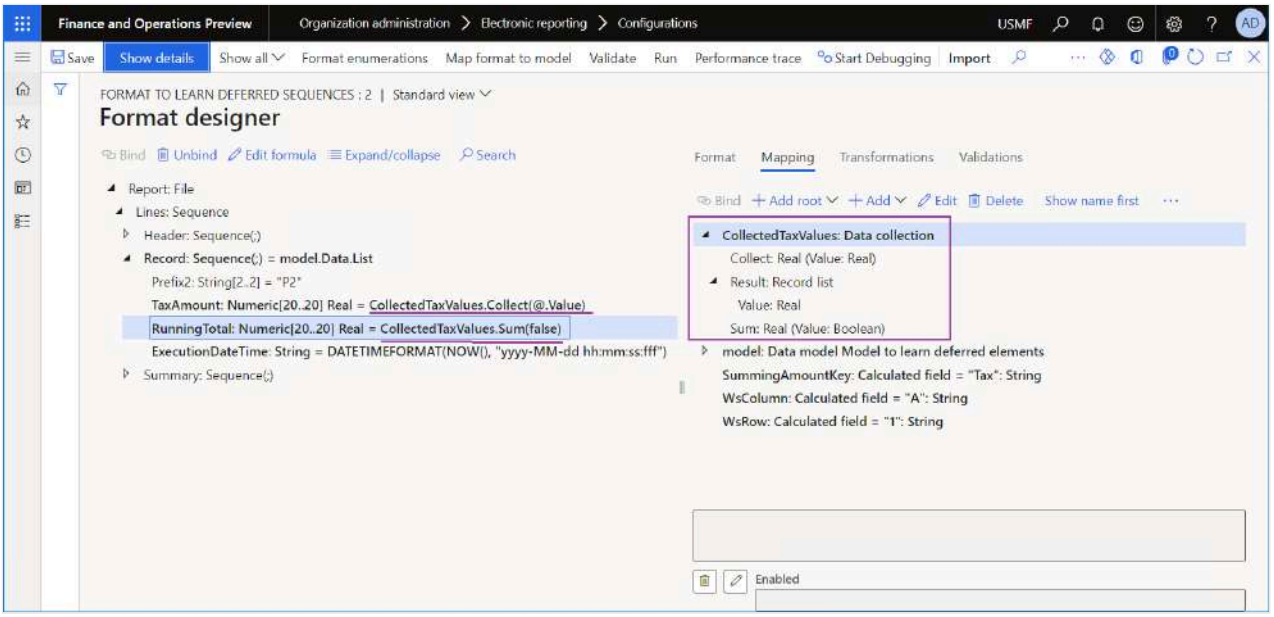
> ⓘ **Note**
>
> The new binding passes the same tax values to a generated document. However, those values are also collected in the **CollectedTaxValues** data source.

7. Select the **Report\Lines\Record\RunningTotal** numeric format element.

8. Select **Edit formula**.

9. On **Formula designer**, follow these steps:
   a. In the **Formula** field, enter `CollectedTaxValues.Sum(false)`.
   b. Save your changes, and close the page.

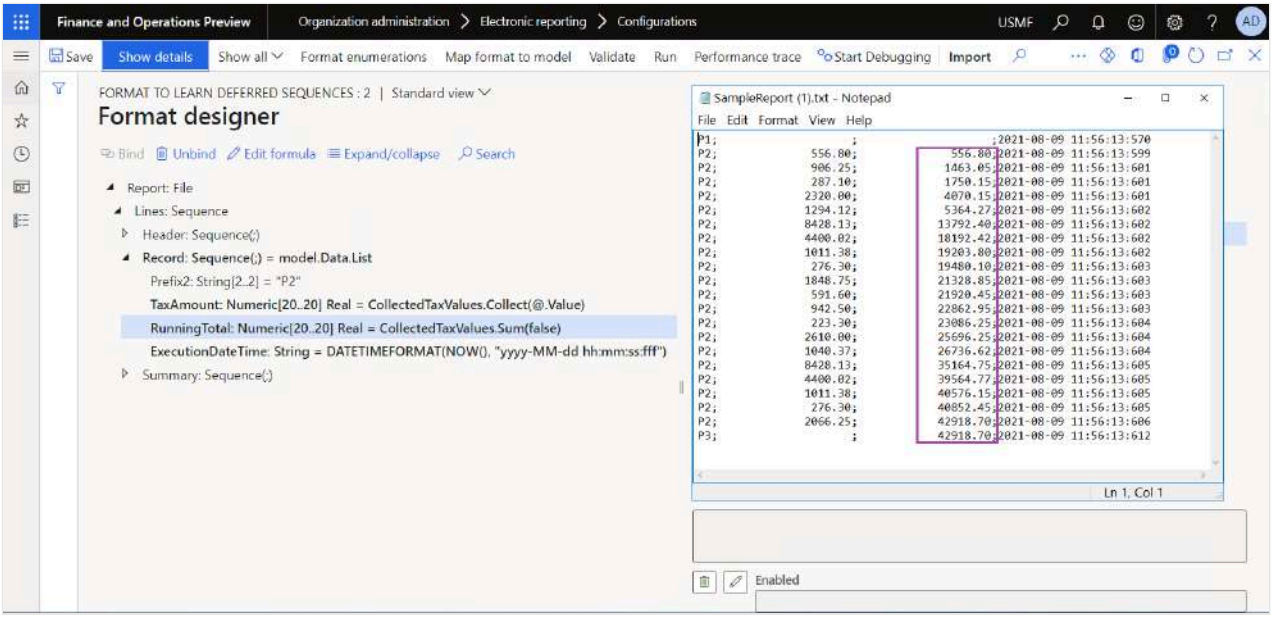
> ⓘ **Note**
>
> The new binding passes, to a generated document, the total amount of tax values that are already entered.



10. Select **Save**, and then select **Run**.

11. In the **Electronic report parameters** dialog box, select **OK**.

12. Download and review the file that the web browser offers.



Modify the format to evaluate the list of collected tax values

1. On **Format designer**, on the **Format** tab, select the **Report\Lines\Record\RunningTotal** numeric format element, and then follow these steps:
   a. In the **Numeric type** field, change the value from **Real** to **Integer**.
   b. In the **Numeric format** field, change the value from **F2** to **F0**.

2. On the **Mapping** tab, select **Edit formula**.

3. On **Formula designer**, follow these steps:

a. In the **Formula** field, enter `COUNT(CollectedTaxValues.Result)`.

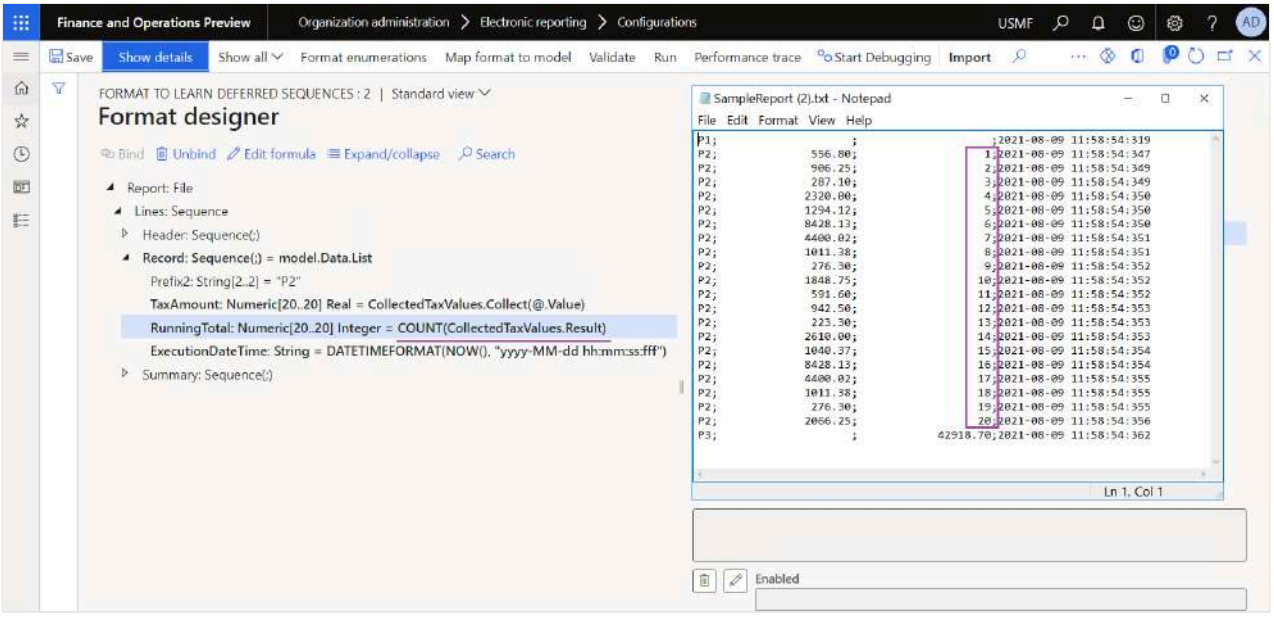
b. Save your changes, and close the page.

> **Note**
>
> The new binding passes the number of records in the list where the tax values are collected to a generated document.

4. Select **Save**, and then select **Run**.

5. In the **Electronic report parameters** dialog box, select **OK**.

6. Download and review the file that the web browser offers.



Frequently asked questions

If I need to calculate running totals and collect data, what's the difference between using a DATA COLLECTION data source and using the built-in DATA COLLECTION functions?

You can use both a DATA COLLECTION data source and the built-in DATA COLLECTION functions for data collection, summing, and counting, based on information that is passed to a generated outbound document. However, consider the following points when deciding which technique to use.

Expand table

Data source	Built-in functions
Only values are collected.	Named values are collected. Therefore, totals can be computed for separate groups of values. Additionally, groups can be extracted as a list. Text values can also be collected.
Unique values are automatically collected.	Additional settings are required to extract a list of unique values from the collected values.
Performance depends on the volume of collected values.	In practice, performance doesn't depend on the volume of collected values.
This technique works for all types of outbound documents.	This technique works only for text and XML documents.

Additional resources

- Configure format to do counting and summing
- Defer the execution of sequence elements in ER formats

Use USER INPUT PARAMETER data sources to specify parameters for a report

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you design Electronic reporting (ER) model mapping and ER format components, use data sources of the *USER INPUT PARAMETER* type to get the values you need. You can specify these values in data entry fields in the dialog box at runtime, before execution of an ER format begins. This article describes the *USER INPUT PARAMETER* data sources that are currently supported.

Mandatory properties

Specify the following properties for data sources of every *USER INPUT PARAMETER* type:

- In the **Name** field, enter the internal name of the data source. Use this name in other expressions and bindings of the configured model mapping or format component.

Optional properties

Optionally, specify the following properties for data sources of a *USER INPUT PARAMETER* type:

- In the **Label** field, enter the label for the related data entry field in the dialog box at runtime. To add different label text for different language codes, activate the **Label** field and then select **Translate**.
- In the **Help** field, enter the help text that appears at design time at the bottom of the **Format designer** page or the **Model mapping designer** page when you select an editable data source of a *USER INPUT PARAMETER* type. This text might provide extra details about the data source to help users when they configure the editable format or model mapping component. To add different help text for different language codes, select **Translate**.

> **Note**
>
> The **Translate** button that you use to add language specific labels and text becomes available only after you add the data source, save your changes, and then reopen the data source for editing.

- In the **Read only** field, configure an expression that returns a *Boolean* value.
  - If the configured expression returns **True** at runtime, the related data entry field appears dimmed in the dialog box, and you can't change its value.
  - If the configured expression returns **False** at runtime, or if you don't configure an expression, the related data entry field is available in the dialog box, and you can change its value.

- In the **Default value** field, configure an expression that returns the value of the referenced parameter type. This value fills in a default value for the related data entry field in the dialog box at runtime.

  When you run an ER format, the value that you enter in the related data entry field in the dialog box at runtime is saved in memory as the previously used value. The system saves previously used values individually for each field, running ER format, current user, and current organization (company).

  - Set the **Always reset to default value** option to **Yes** if the value that the **Default value** expression returns should always be used as the default value, regardless of the previously used value.

  - Set the **Always reset to default value** option to **No** if the value that the **Default value** expression returns should be used as the default value only when the previously used value is missing.

    > **Note**
    >
    > If you set the **Always reset to default value** option to **Yes**, you must configure an expression in the **Default value** field.

- If you set the **Allow multiple selection** option to **Yes**, you can select multiple values for the configured parameter at runtime. If you set it to **No**, you can select only a single value.

> **Note**
>
> This option isn't applicable to all *USER INPUT PARAMETER* types. At design time, an exception is thrown to inform the user that the configured user input parameter doesn't support multiple selection, and that only a single value can be selected or entered.
>
> If you set the **Allow multiple selection** option to **Yes**, and you specify an expression in the **Default value** field, that expression can set only a single default value.

- Select the **Edit visibility** option to specify whether the configured parameter should be shown in the dialog box at runtime.

  > **Note**
  >
  > The default visibility of data sources of a *USER INPUT PARAMETER* type depends on the ER component that holds them.
  > - If you configure a data source in the format component, it's visible by default.
  > - If you configure a data source in the model mapping component, it's visible only if the value of the data source affects the outcome when an ER component is run. For example, you added a data source but didn't use it in expressions and bindings of the current model mapping component. In this case, by default, the relevant data entry field isn't shown in the dialog box at runtime.

  On the **Formula designer** page, in the **Formula** field, configure an expression that returns a *Boolean* value.
  - If the configured expression returns **True** at runtime, or if you don't configure an expression, the related data entry field is visible in the dialog box at runtime.
  - If the configured expression returns **False**, the related data entry field is hidden in the dialog box at runtime. When other expressions call it at runtime, it returns the default value, the previously used value, or the default for the current data type value, depending on other settings.

Type-specific properties

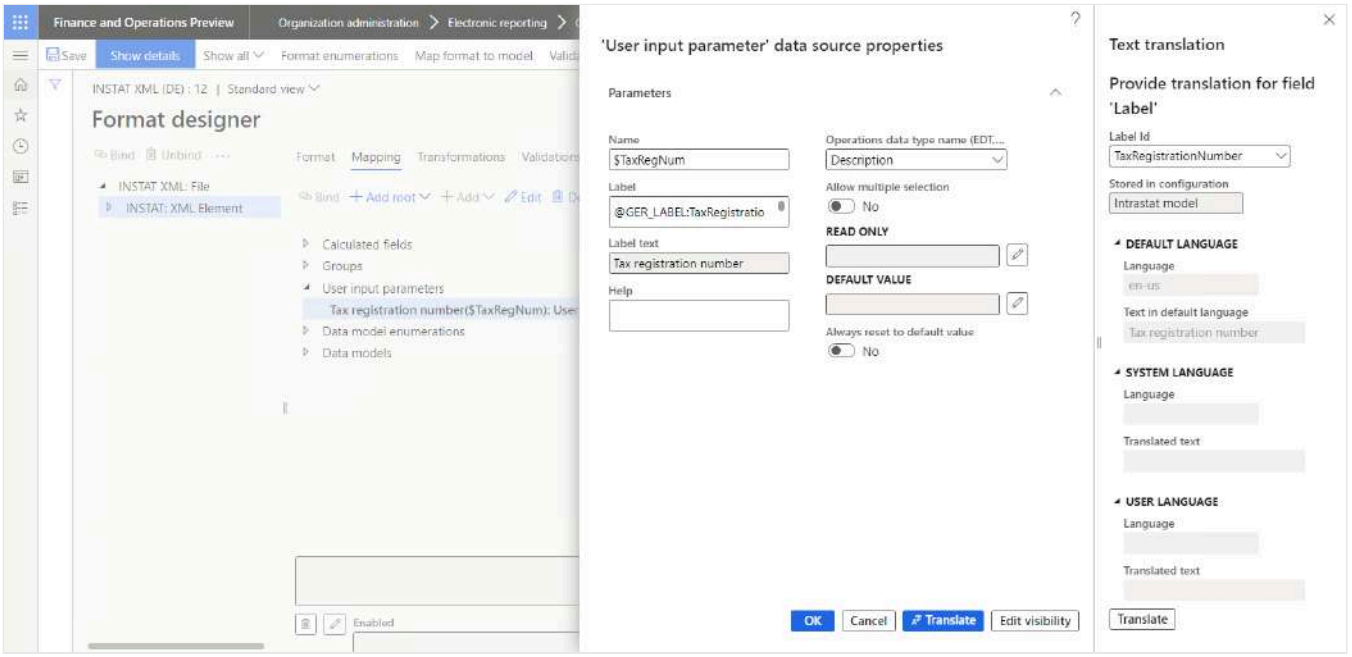
Application-dependent user input parameter

Use a data source of the **General** > **User input parameter** type to get the required value or values of a data type that you specify for the current instance of the Microsoft Dynamics 365 Finance application. When you add a data source of this type to an ER component, specify the following properties:

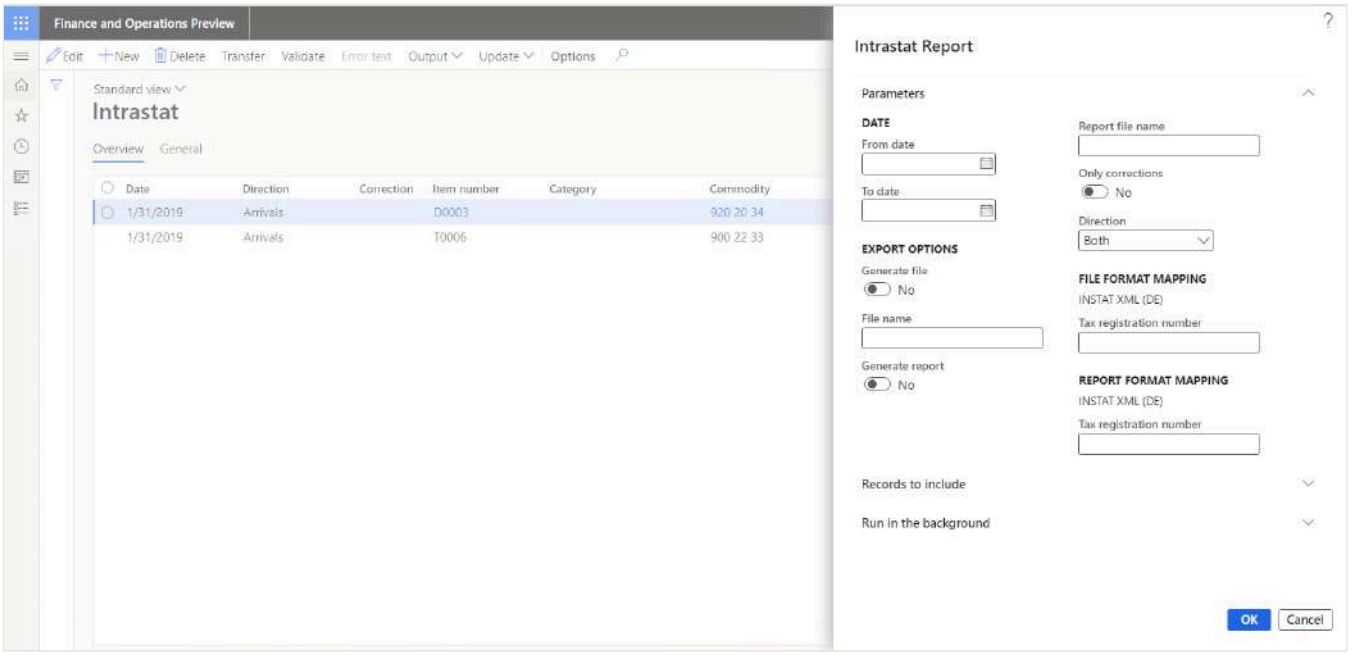
- In the **Operations data type name (EDT, enum)** field, select an application extended data type (EDT) or an application enumeration.

> **Note**
>
> Review the expressions that are configured in the **Read only** and **Default value** fields when you change the **Operations data type name (EDT, enum)** reference in an editable data source of this *USER INPUT PARAMETER* type.

The following illustration shows properties of the `$TaxRegNum` data source that you configure in the **Instat XML (DE)** ER format configuration. This data source uses the *Description* EDT to offer the **Tax registration number** data entry field in the dialog box at runtime.



The following illustration shows the dialog box that appears at runtime when you run the **Instat XML (DE)** ER format configuration to generate the Intrastat declaration. The configured **Tax registration number** field is available for data entry.



Data model enumeration user input parameter

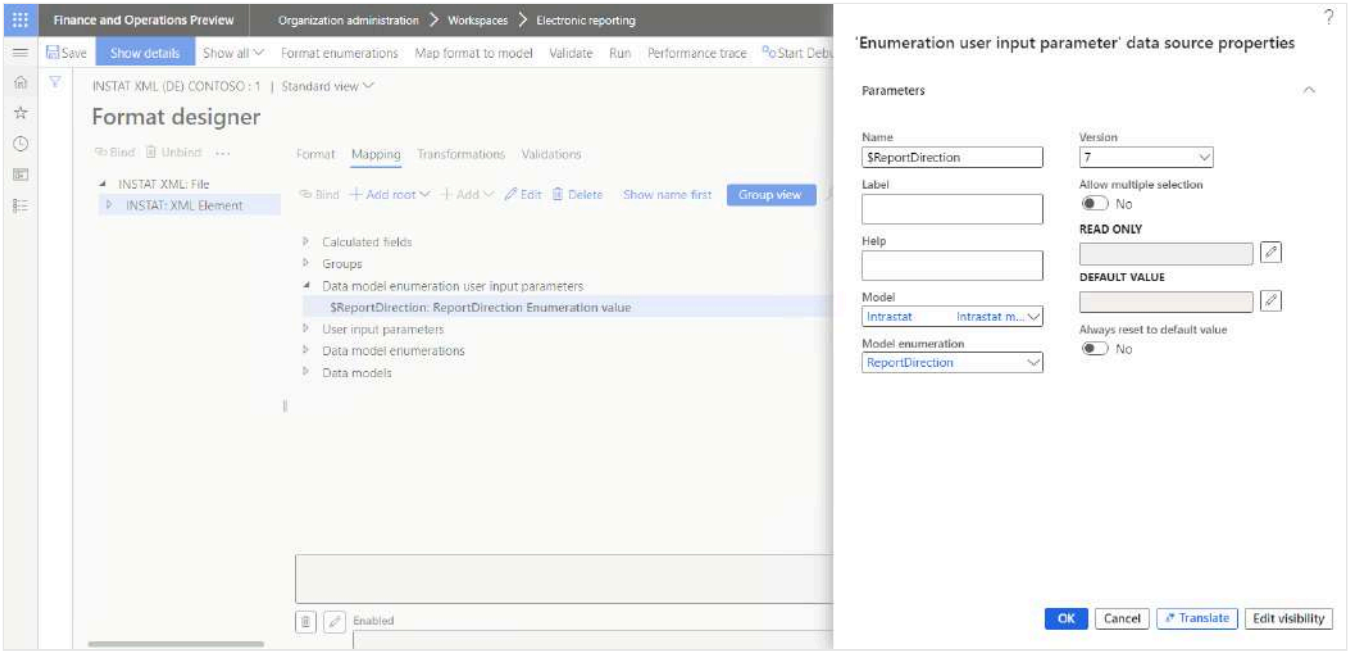
Use a data source of the **Data model** > **Enumeration user input parameter** type to get the required value or values for a single data model enumeration. When you add a data source of this type to an ER component, specify the following properties:

- In the **Model** field, specify a reference to the base data model.
- In the **Model enumeration** field, specify a reference to an enumeration of the referenced data model.
- In the **Version** field, select the revision number of the ER data model component that contains the referenced model enumeration.

> **Tip**
>
> At design time, you can leave the **Version** field blank to access the list of enumerations for the referenced data model component that resides in the draft version of the corresponding ER data model configuration. By using this approach, you can simultaneously edit the draft version of your model mapping or format component and the draft version of the base data model component.
>
> However, you can leave the **Version** field blank only in the draft version of a model mapping or format component. When you change the status of an ER model mapping or format configuration from **Draft** to **Completed**, the highest model revision number that's available in the current Finance instance automatically fills in this field. If you introduce a new enumeration or a new enumeration value in the

draft version of your base data model and refer to it in the editable model mapping or format component, complete that draft version of the base data model configuration before the draft version of your ER model mapping or format configuration is completed. Otherwise, a "Path not found" exception is thrown when you change the status of the model mapping or format configuration from **Draft** to **Completed**. The message informs you that the referenced enumeration or enumeration value is missing in the base data model.

The following illustration shows properties of the `$ReportDirection` data source that you configured in the **Instat XML (DE) Contoso** ER format configuration. The **Instat XML (DE) Contoso** configuration is derived from the **Instat XML (DE)** configuration. This data source is configured to use the *ReportDirection* model enumeration to offer the appropriate lookup field in the dialog box at runtime.



Format enumeration user input parameter

Use a data source of the **Format enumeration** > **Enumeration user input parameter** type to get the required value or values for a single format enumeration. When you add a data source of this type to an ER component, specify the following property:

- In the **Format enumeration** field, specify an enumeration of the editable format.

> **Note**

You can configure data sources of this type only in the scope of the editable format component.

Debug data sources of an executed ER format to analyze data flow and transformation

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you configure an Electronic reporting (ER) solution to generate outbound documents, you define the methods that get data out of the application and enter it in the generated output. To make the life cycle support of the ER solution more efficient, your solution should consist of an ER data model and its mapping components, and also an ER format and its mapping components. The model mapping is application-specific, whereas other components remain application-agnostic. Therefore, several ER components might affect the process of entering data in the generated output.

Sometimes, the data in the generated output looks different from the same data in the application database. In these cases, you want to determine which ER component is responsible for the data transformation. The ER data source debugger feature significantly reduces the time and cost that are involved in this investigation. You can interrupt the execution of an ER format and open the data source debugger interface. There, you can browse the available data sources and select an individual data source for execution. This manual execution simulates the execution of the data source during the real run of an ER format. The result is presented on a page where you can analyze the data that is received.

To turn on the data source debugging feature, set the **Enable data debugging at format run** option to **Yes** in the ER user parameters. You can then start data source debugging while you run an ER format to generate outbound documents. You can also use the **Start debugging** option to initiate data source debugging for an ER format that is configured in the ER Operation designer.

This article provides guidelines for initiating data source debugging for executed ER formats. It explains how the information can help you understand the data flow and data transformations. The examples in this article use the business process for vendor payments processing.

Limitations

You can use the data source debugger to access the data of data sources that are used in ER formats that run to generate outbound documents. You can't use it to debug data sources of ER formats that are designed to parse inbound documents.

The following settings of ER formats aren't currently accessible for data source debugging:

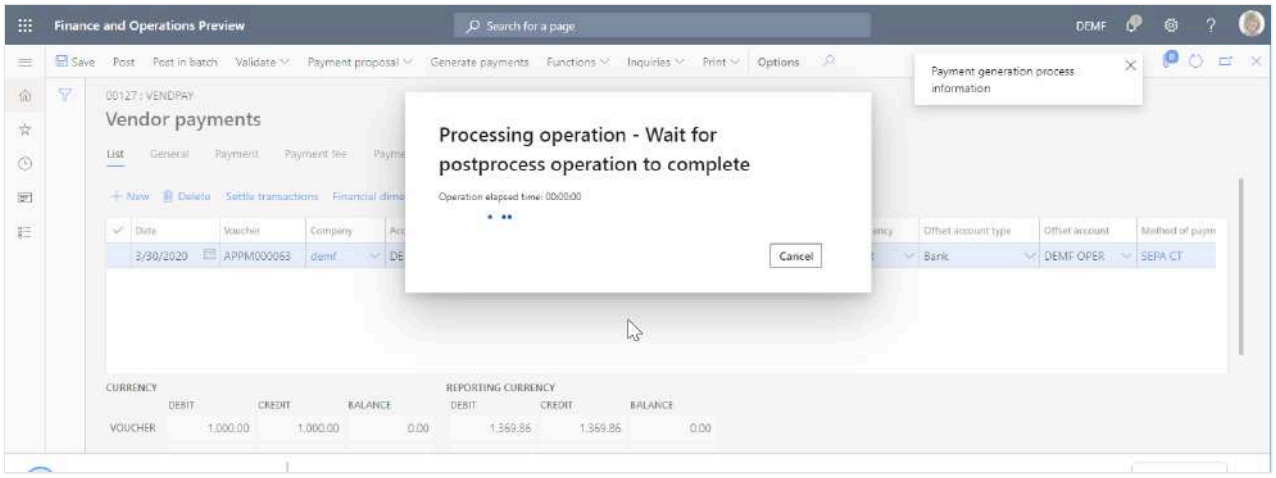
- Format transformations
- Format and mapping validation rules
- Enabling expressions
- Details of in-memory data collection

Prerequisites

- To complete the examples in this article, you must have access to one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator
- Set the company to **DEMF**.
- Follow the steps in Appendix 1 of this article to download the components of the Microsoft ER solution that are required to process vendor payments.
- Follow the steps in Appendix 2 of this article to prepare Accounts payable for vendor payment processing by using the ER solution that you download.

Process a vendor payment to get a payment file

1. Follow the steps in Appendix 3 of this article to process vendor payments.



2. Download and save the ZIP file to your local computer.

3. Extract the **ISO20022 Credit transfer.xml** payment file from the ZIP file.

4. Open the extracted payment file by using the XML file viewer.

   In the payment file, the International Bank Account Number (IBAN) code of the vendor bank account contains no spaces. Therefore, it differs from the value that was entered on the **Bank accounts** page.

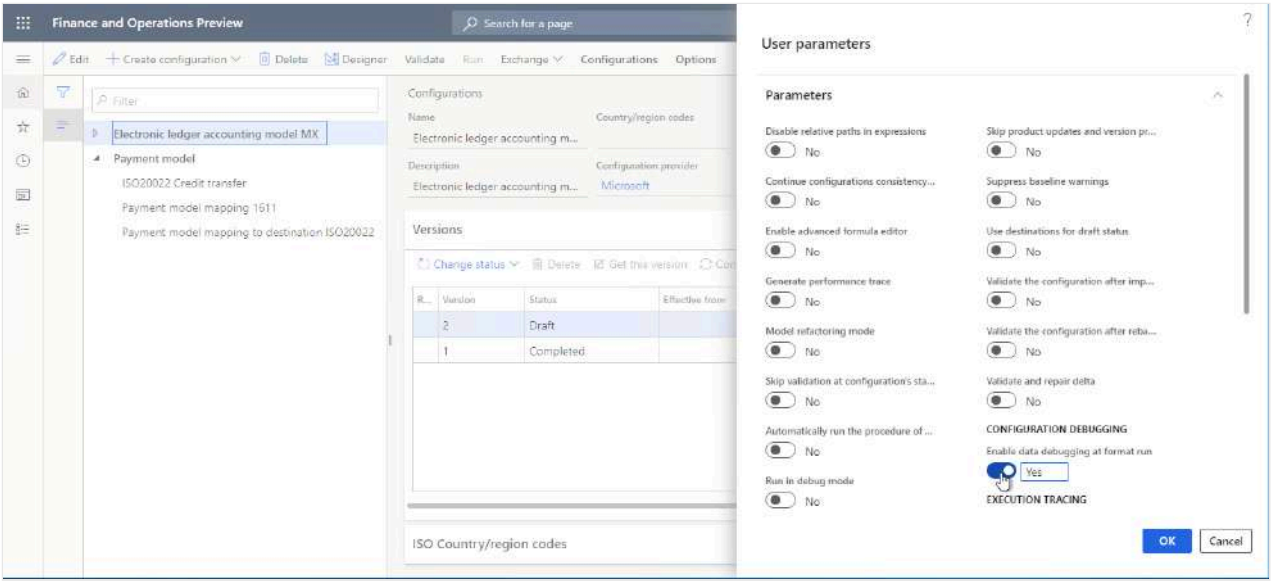
        </CdtTrfTxInf>
      </PmtInf>
  </CstmrCdtTrfInitn>
</Document>
```

Use the ER data source debugger to learn which component of the ER solution truncates spaces in the IBAN code.

Turn on data source debugging

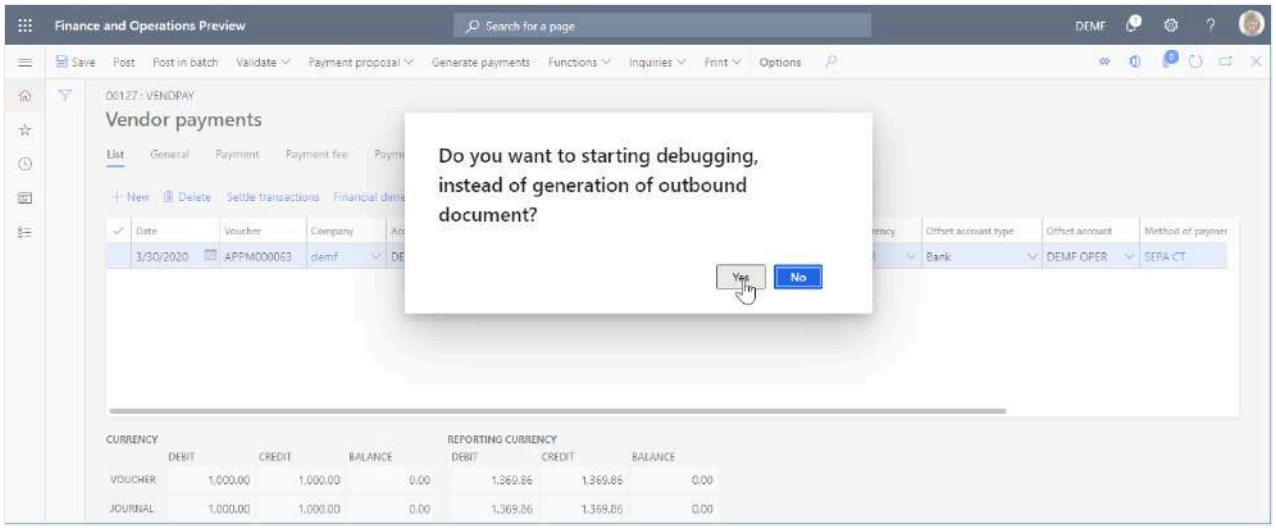
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. Set the **Enable data debugging at format run** option to **Yes**.

> **Note**
>
> This parameter is user-specific and company-specific.



Process a vendor payment for debugging

1. Follow the steps in Appendix 3 of this article to process vendor payments.
2. In the message box, select **Yes** to confirm that you want to interrupt vendor payment processing and instead start data source debugging on the **Debug Datasources** page.



Debug data sources that are used in payment processing

Debug the model mapping

1. On **Debug Datasources**, on the Action Pane, select **Model mapping** to start debugging from this ER component.

2. In the data source pane on the left, select the **$notSentTransactions** data source, and then select **Read all records**.

   To force the appropriate number of records to be read from the selected data source, select **Read 1 record**, **Read 10 records**, **Read 100 records**, or **Read all records**. By using this approach, you can simulate access to the data source from the running ER format.

3. In the data pane on the right, select **Expand all**.

   You see that the selected data source of the **Record list** type contains a single record.

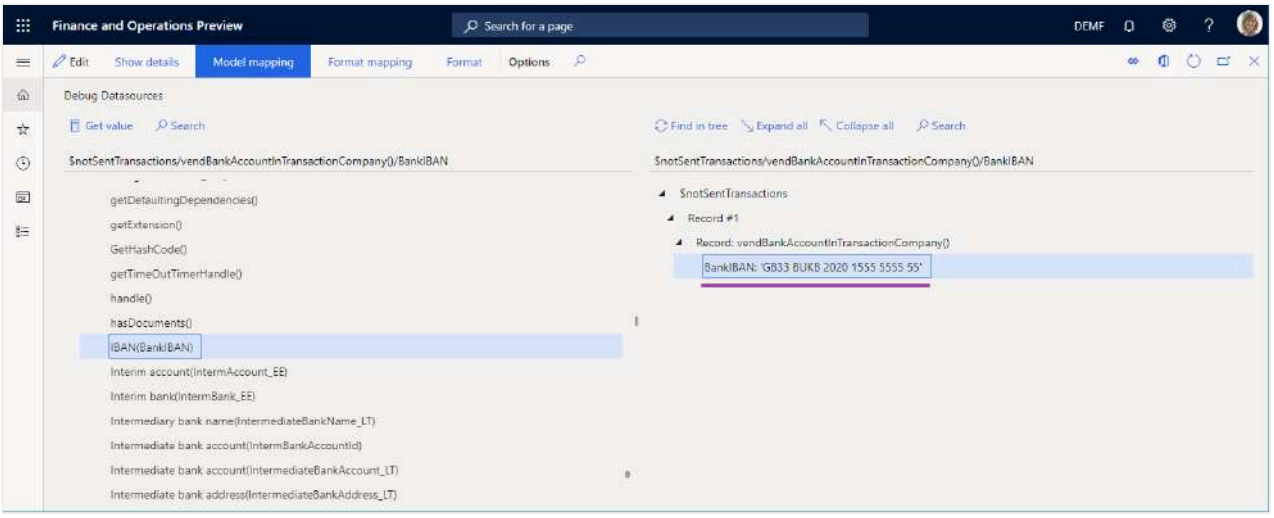
4. Expand the **$notSentTransactions** data source, and select the nested **vendBankAccountInTransactionCompany()** method.

5. Expand the **vendBankAccountInTransactionCompany()** method, and select the nested **IBAN** field.

6. Select **Get value**.

   Select **Get value** to force the value of a selected field of the selected data source to be read. By using this approach, you can simulate access to this field from the running ER format.

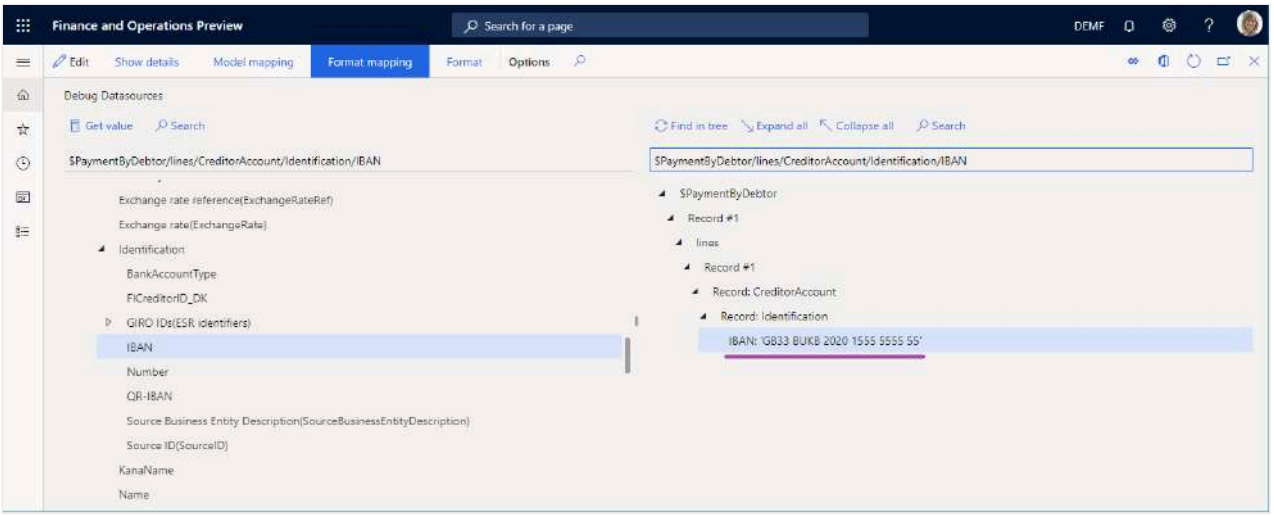
7. Select **Expand all**.



As you can see, the model mapping isn't responsible for the truncated spaces, because the IBAN code that it returns for the vendor bank account includes spaces. Therefore, you must continue data source debugging.

Debug the format mapping

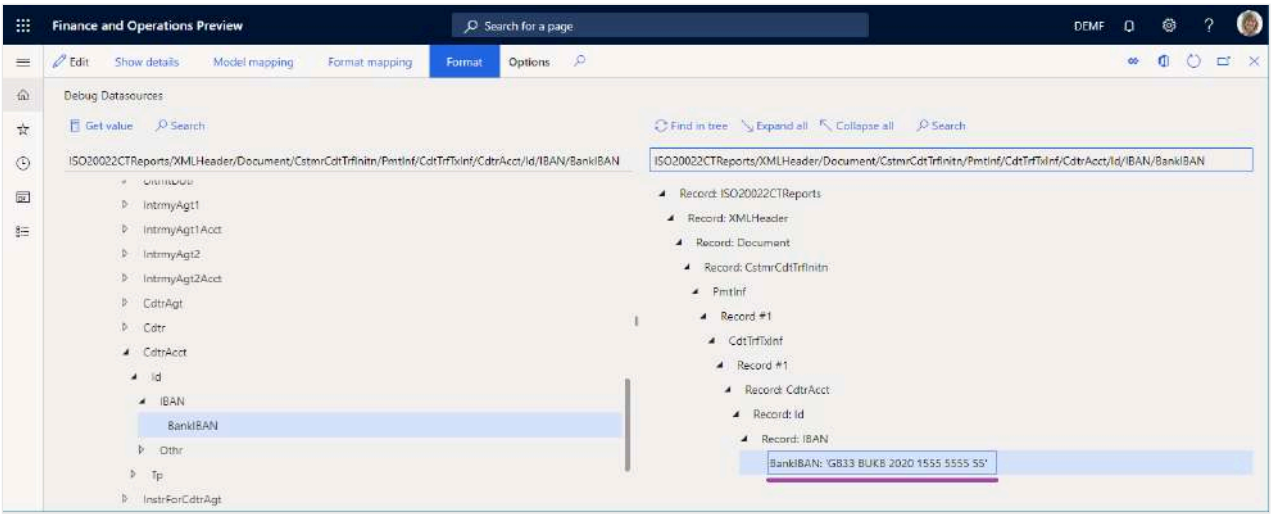
1. On **Debug Datasources**, on the action pane, select **Format mapping** to continue debugging from this ER component.
2. Select the **$PaymentByDebtor** data source, and then select **Read all records**.
3. Expand **$PaymentByDebtor**.
4. Expand **$PaymentByDebtor.Lines**, and then select **Read all records**.
5. Expand **$PaymentByDebtor.Lines.CreditorAccount**.
6. Expand **$PaymentByDebtor.Lines.CreditorAccount.Identification**, and then select **$PaymentByDebtor.Lines.CreditorAccount.Identification.IBAN**.
7. Select **Get value**.
8. Select **Expand all**.



As you can see, the data sources of the format mapping aren't responsible for the truncated spaces, because the IBAN code that they return for the vendor bank account includes spaces. Therefore, you must continue data source debugging.

Debug the format

1. On **Debug Datasources**, on the action pane, select **Format** to continue debugging from this ER component.
2. Expand the format elements to select **ISO20022CTReports** > **XMLHeader** > **Document** > **CstmrCdtTrfInitn** > **PmtInf**, and then select **Read all records**.
3. Expand the format elements to select **ISO20022CTReports** > **XMLHeader** > **Document** > **CstmrCdtTrfInitn** > **PmtInf** > **CdtTrfTxInf**, and then select **Read all records**.
4. Expand the format elements to select **ISO20022CTReports** > **XMLHeader** > **Document** > **CstmrCdtTrfInitn** > **PmtInf** > **CdtTrfTxInf** > **CdtrAcct** > **Id** > **IBAN** > **BankIBAN**, and then select **Get value**.
5. Select **Expand all**.

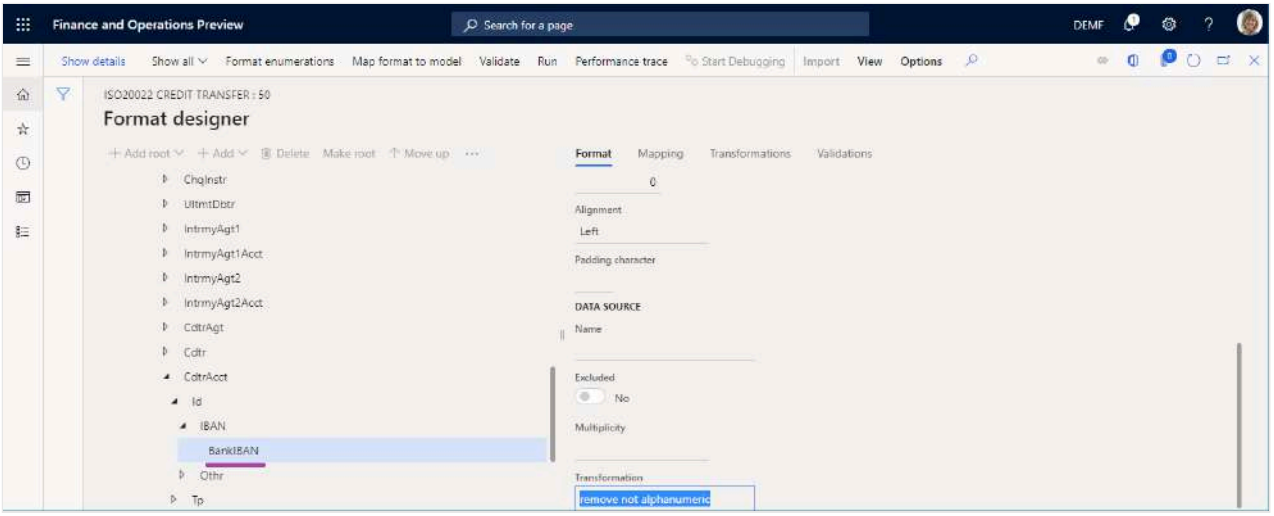


As you can see, the format binding isn't responsible for the truncated spaces because the IBAN code that it returns for the vendor bank account includes spaces. Therefore, the **BankIBAN** element is configured to use a format transformation that truncates spaces.

6. Close the data source debugger.

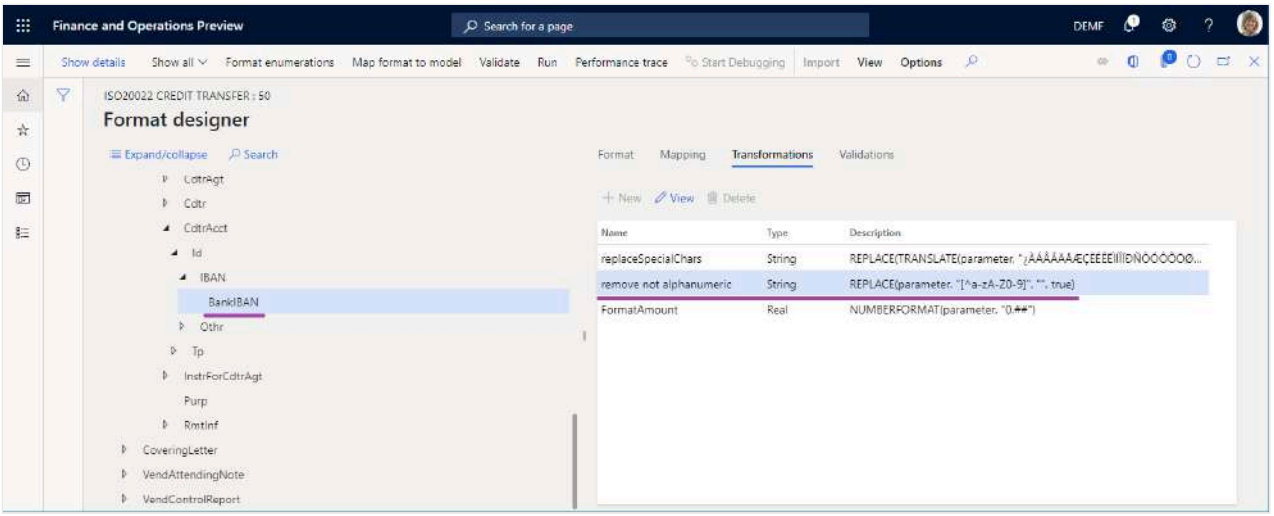
Review the format transformations

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, select **Payment model** > **ISO20022 Credit transfer**.
3. Select **Designer**, and then expand the elements to select **Document** > **CstmrCdtTrfInitn** > **PmtInf** > **CdtTrfTxInf** > **CdtrAcct** > **Id** > **IBAN** > **BankIBAN**.



As you can see, the **BankIBAN** element is configured to use the **remove not alphanumeric** transformation.

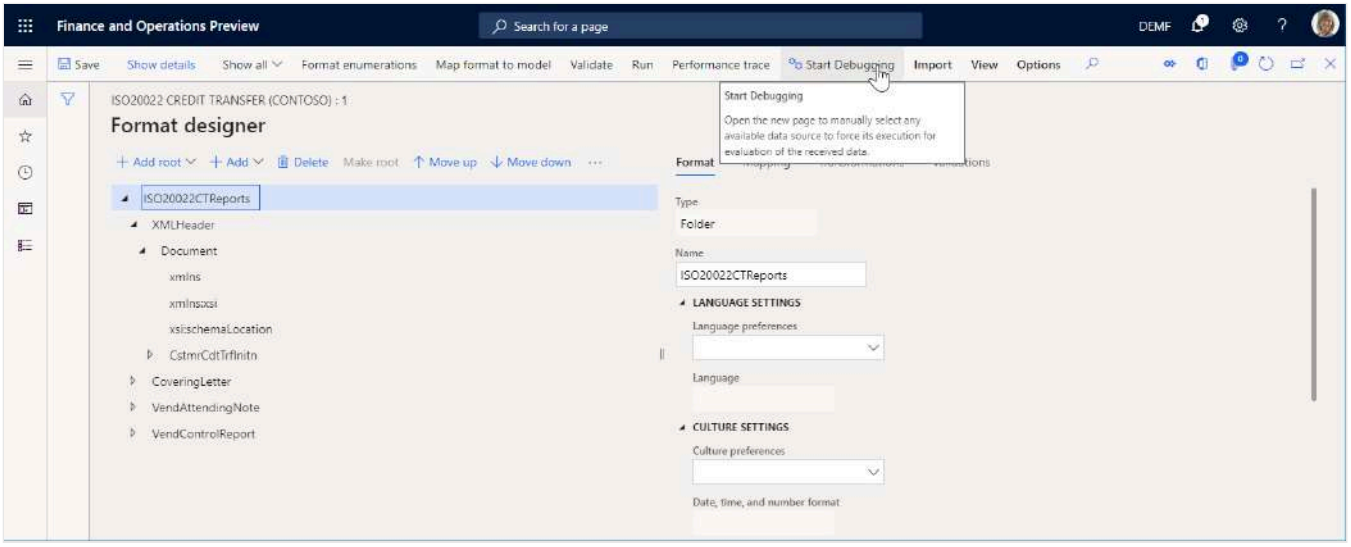
4. Select the **Transformations** tab.



As you can see, the **remove not alphanumeric** transformation uses an expression that truncates spaces from the provided text string.

Start to debug in the Operation designer

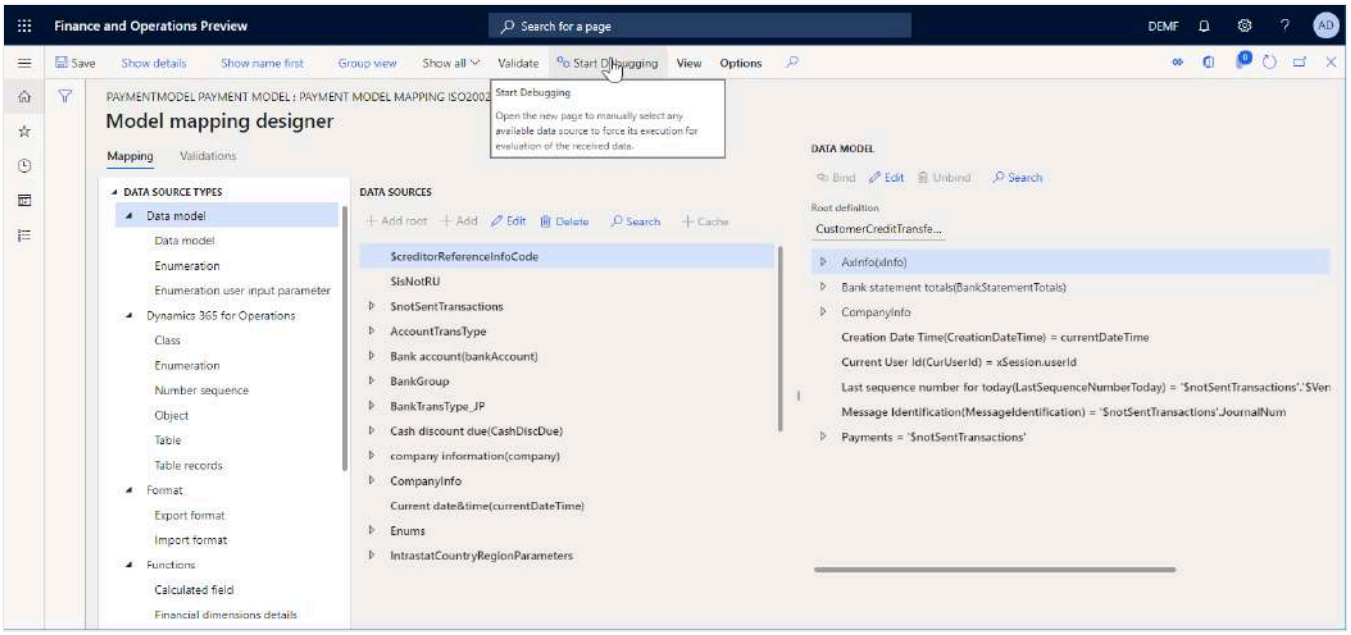
When you configure a draft version of the ER format that you can run directly from the Operation designer, you can access the data source debugger by selecting **Start Debugging** on the Action Pane.



You can debug the format mapping and format components of the ER format that you're editing.

Start debugging in the Model mapping designer

When you configure an ER model mapping that you can run from the **Model mapping** page, select **Start Debugging** on the Action Pane to access the data source debugger.

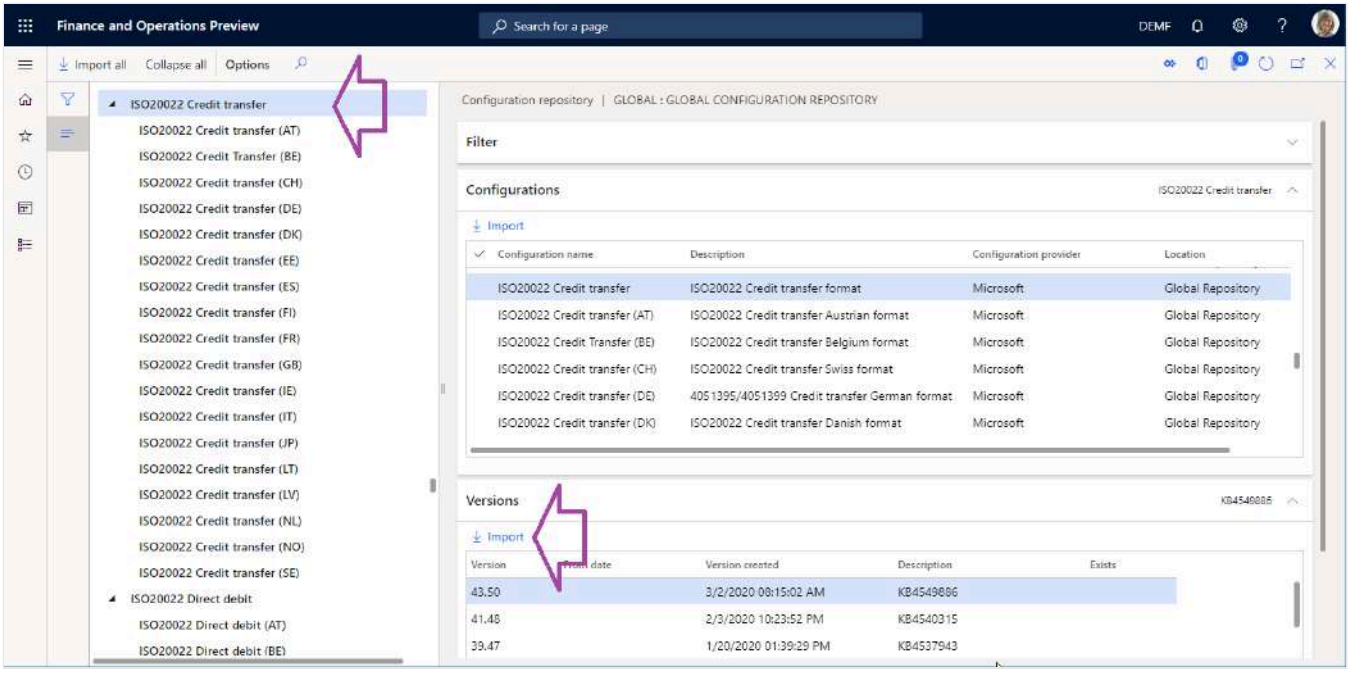


You can debug the model mapping component of the ER mapping that you're editing.

Appendix 1: Get an ER solution

Download an ER solution

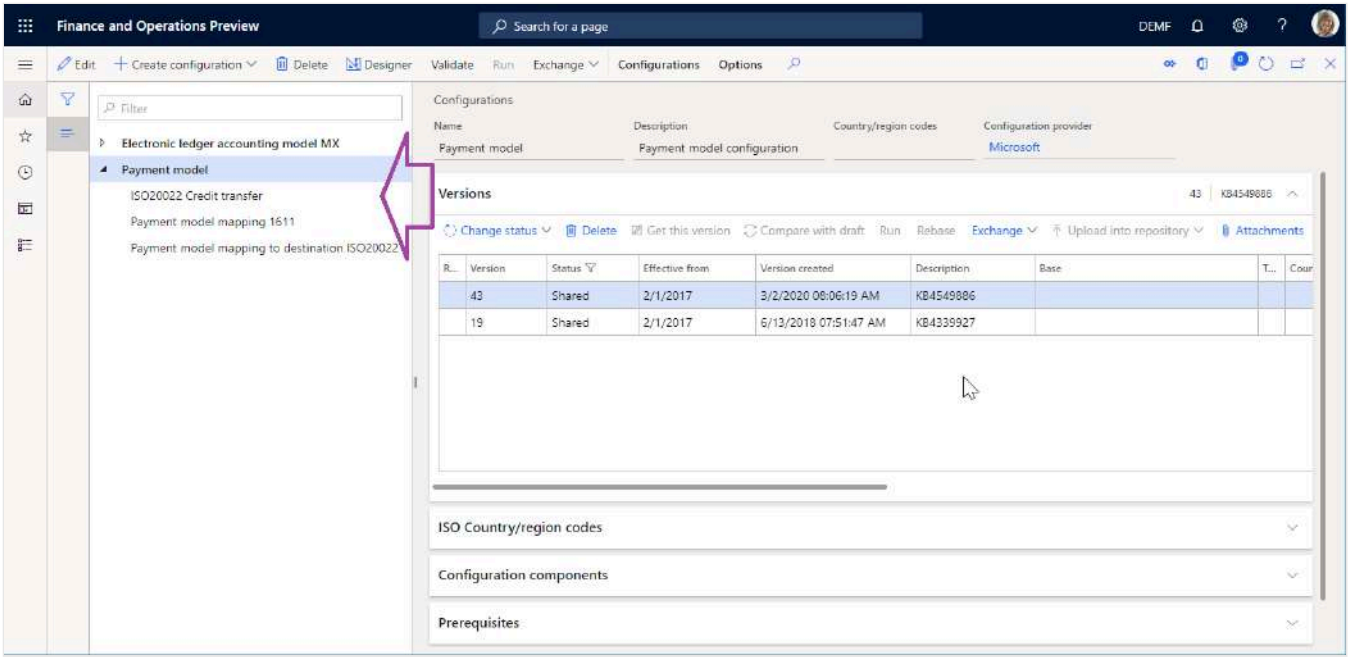
To use an ER solution to generate an electronic payment file for a processed vendor payment, download the **ISO20022 Credit transfer** ER payment format from the Shared asset library in Microsoft Dynamics Lifecycle Services (LCS) or from the Global repository.



In addition to the selected ER format, automatically import the following configurations into your Microsoft Dynamics 365 Finance instance as part of the **ISO20022 Credit transfer** ER solution:

- **Payment model** ER data model configuration
- **ISO20022 Credit transfer** ER format configuration
- **Payment model mapping 1611** ER model mapping configuration
- **Payment model mapping to destination ISO20022** ER model mapping configuration

You can find these configurations on the **Configurations** page of the ER framework (**Organization administration** > **Electronic reporting** > **Configurations**).



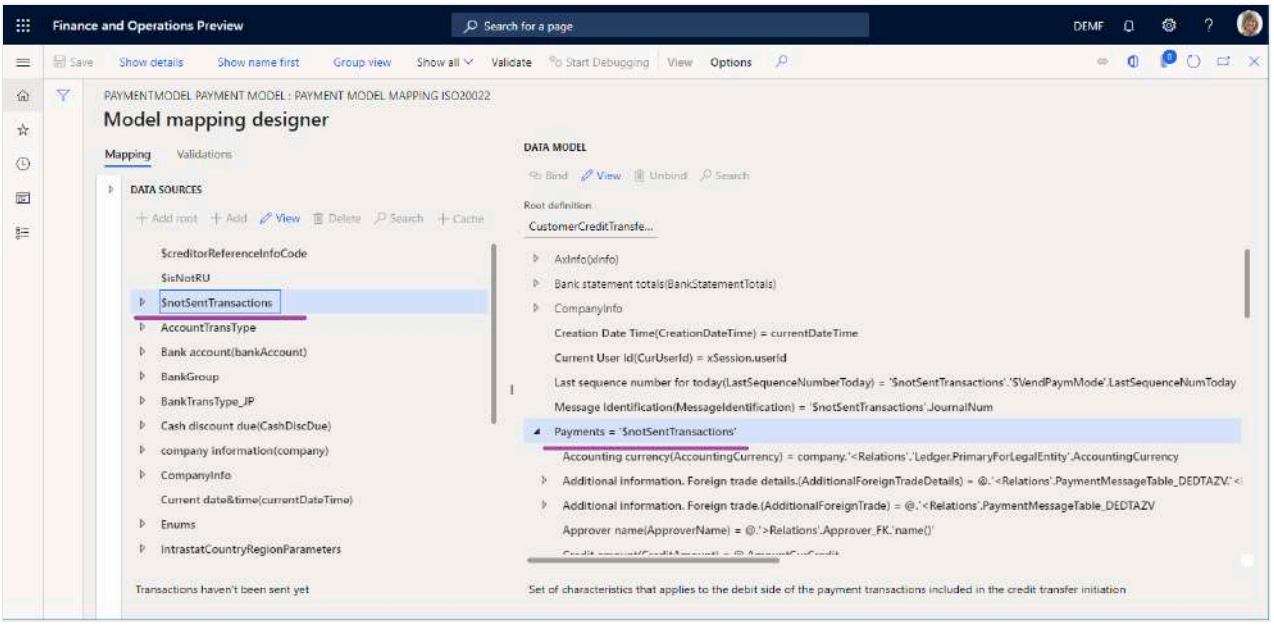
If any of the previously listed configurations are missing in the configuration tree, manually download them from the LCS Shared asset library in the same way that you downloaded the **ISO20022 Credit transfer** ER payment format.

Analyze the downloaded ER solution

Review the model mapping

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. Select **Payment model** > **Payment model mapping 1611**.
3. Select **Designer**.
4. Select the **Payment model mapping ISO20022 CT** mapping record.
5. Select **Designer**, and then review the model mapping that opens.

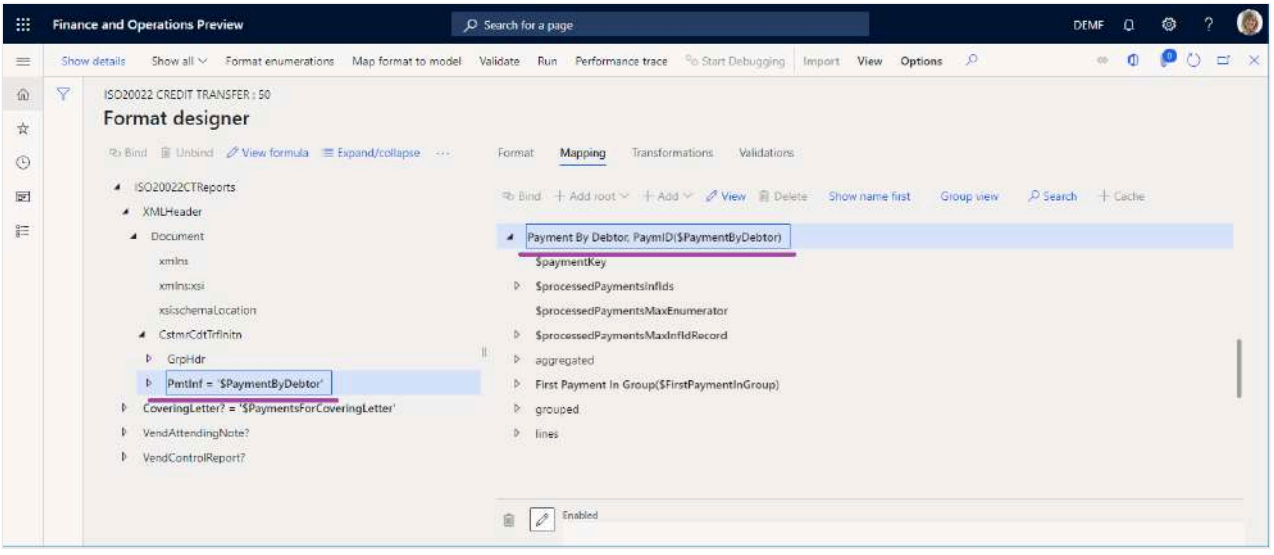
   Notice that the **Payments** field of the data model is bound to the **$notSentTransactions** data source that returns the list of vendor payment lines that are being processed.



Review the format mapping

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. Select **Payment model** > **ISO20022 Credit transfer**.
3. Select **Designer**.
4. On the **Mapping** tab, review the format mapping that opens.

   Notice that the **Document** > **CstmrCdtTrfInitn** > **PmtInf** element of the **ISO20022CTReports** > **XMLHeader** file is bound to the **$PaymentByDebtor** data source that is configured to group records of the data model's **Payments** field.



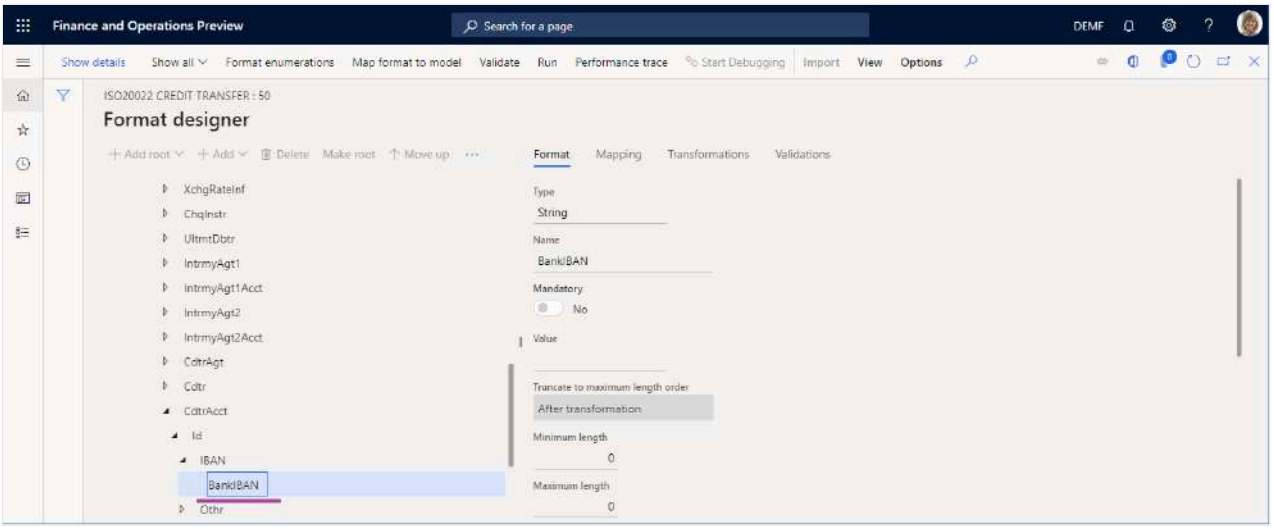
Review the format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.

2. Select **Payment model** > **ISO20022 Credit transfer**.

3. Select **Designer**, and then review the format that opens.

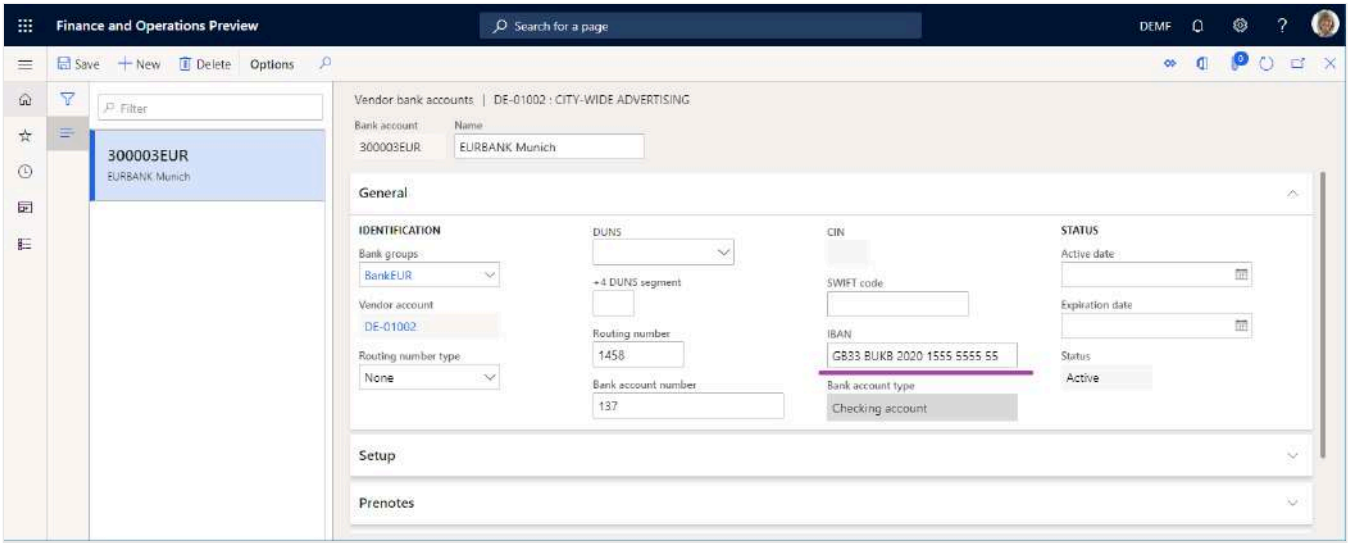
   Notice that the format element under **Document** > **CstmrCdtTrfInitn** > **PmtInf** > **CdtTrfTxInf** > **CdtrAcct** > **Id** > **IBAN** > **BankIBAN** is configured to enter the IBAN code of the vendor account in the payment file.



Appendix 2: Configure Accounts payable

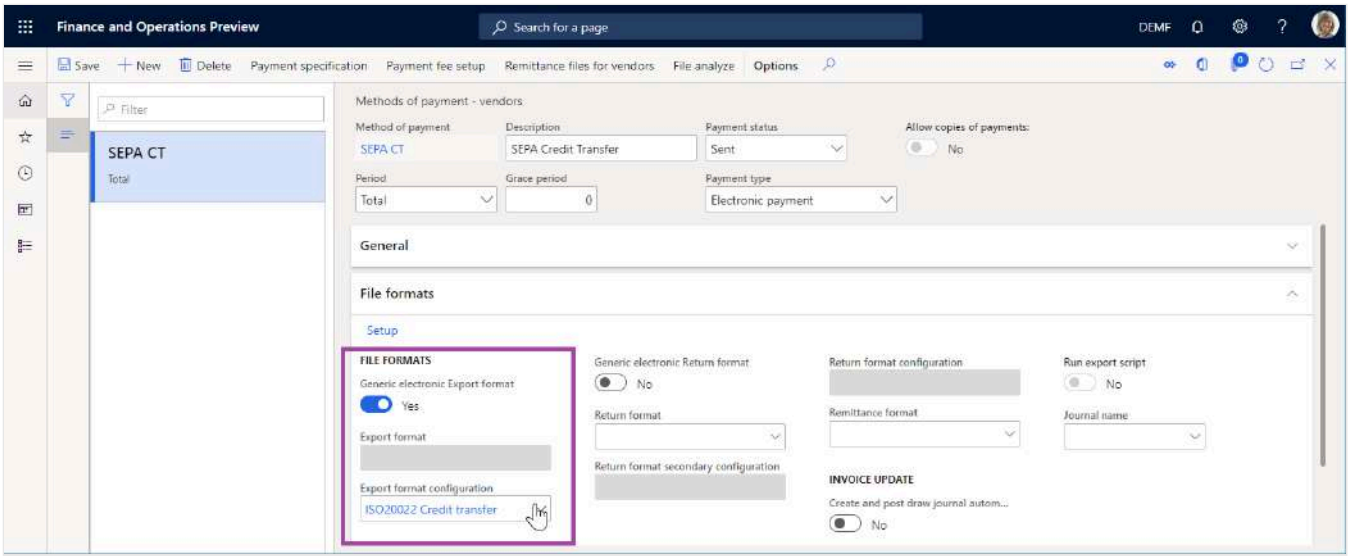
Modify a vendor property

1. Go to **Accounts payable** > **Vendors** > **All vendors**.
2. Select vendor **DE-01002**. On the Action Pane, on the **Vendor** tab, in the **Set up** group, select **Bank accounts**.
3. On the **Identification** FastTab, in the **IBAN** field, enter **GB33 BUKB 2020 1555 5555 55**.
4. Select **Save**.



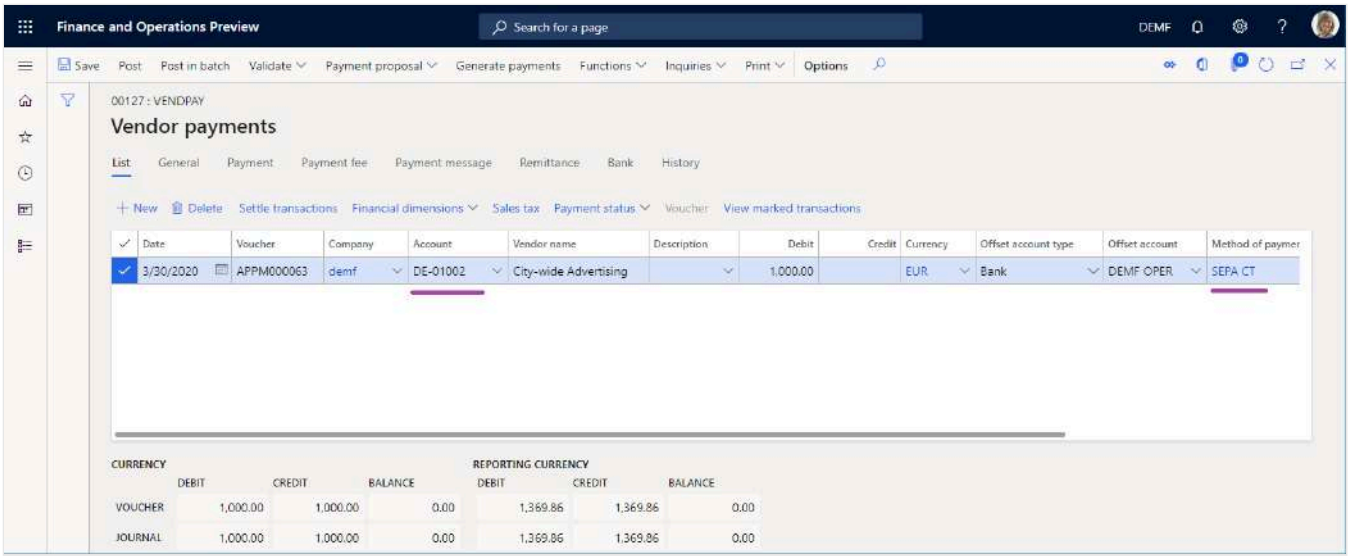
Set up a method of payment

1. Go to **Accounts payable** > **Payment setup** > **Methods of payment**.
2. Select the **SEPA CT** payment method.
3. On the **File formats** FastTab, in the **File formats** section, set the **Generic electronic Export format** option to **Yes**.
4. In the **Export format configuration** field, select the **ISO20022 Credit transfer** ER format.
5. Select **Save**.



Add a vendor payment

1. Go to **Accounts payable** > **Payments** > **Vendor payment journal**.
2. Add a new payment journal.
3. Select **Lines**, and add a new payment line.
4. In the **Account** field, select vendor **DE-01002**.
5. In the **Debit** field, enter a value.
6. In the **Method of payment** field, select **SEPA CT**.
7. Select **Save**.



Appendix 3: Process a vendor payment

1. Go to **Accounts payable** > **Payments** > **Vendor payment journal**.
2. On the **Vendor payment journal** page, select the payment journal that you previously created, and then select **Lines**.
3. Select the payment line, and then select **Payment status** > **None**.
4. Select **Generate payments**.
5. In the **Method of payment** field, select **SEPA CT**.
6. In the **Bank account** field, select **DEMF OPER**.
7. In the **Generate payments** dialog box, select **OK**.
8. In the **Electronic report parameters** dialog box, select **OK**.

Support parameterized calls of ER data models

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To generate business documents, configure an Electronic reporting (ER) solution that contains the following ER components:

- **Format** – This component specifies the structure of a business document.
- **Format mapping** – This component controls how a business document is filled in at runtime.
- **Model mapping** – This component specifies what data pulls from the application into a format mapping.
- **Data model** – This component passes information between individual components.

When you run an ER format, every format element runs, starting from the root format element. Whenever a format element that runs contains a binding to a data source, the data source runs to deliver the expected data and uses it to fill in the format element. When a data source of the *Model* type is called, the appropriate model mapping is called to pull data out of the application, based on the model mapping settings.

Previously, you couldn't parameterize these model mapping calls to make them dependent on the logic of the format that runs. Only the following data flow was supported.

Expand table

Format	***Binding***	Format mapping	***Data model***	Model mapping	***Binding***	Table
Format element	> request >	Data source	> request >	Data source	> request >	Record
	< value <		< value <		< value <	Field

However, in version 10.0.15 and later, you can configure data model fields that can be called only when the values of the configured parameters are provided. When such a field is configured and called from a format component, the required parameters must be provided in a format binding as arguments of the call. In these cases, the values of the arguments can be specified based on format-specific values. Therefore, you can use **dynamic runtime parametrization** for data model calls to support the following data flow.

Expand table

Format	***Binding***	Format mapping	***Data model***	Model mapping	***Binding***	Tal
Format element 1	> request 1 >	Data source 1	> field1 >	Data source 1	> request 1 >	Re
	< value 1 <		< value 1 <		< value 1 <	Fie
Format element 2	> request 2 >	**value2=Func(value1)**	**> field2(value2) >**	Data source 2	> request 2 >	**Tal**
	< value 3 <		< value 3 <		< value 3 <	Re
						Fie

The new functionality lets you parametrize the call to any data model field of the *Record* or *Record list* type. The following data types are supported for the parameters of a data model field:

- Boolean
- Container
- Date
- DateTime
- GUID
- Int64
- Integer
- Real
- String

You can specify every parameter of a data model field for which the argument can be provided as a single value of the defined data type and the *list* of such values.

> **Note**
>
> The default value for the parameter of a data model field isn't supported. If you add a parameter to a field in a data model, and the version of that data model is already released and published, you must rebase all corresponding model mappings and formats to the new version of this model, because this data model change isn't backward compatible.

You can configure parametrized data model fields to make model mapping calls format-specific. This approach can help you reduce the number of model mappings that must be configured for many formats of a single data model. You can also use this approach to improve the execution performance of your formats and reduce the time that is required to generate business documents. To learn more about this feature, complete the example in this article.

Example: Use parameterized calls of ER data models

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can design an ER solution that contains a data model, a model mapping, and a format ER component. These can be configured to call a model mapping by providing an argument for the call. The value of the call is calculated at runtime by using the formula of the running format.

You can complete these steps in the **DEMF** company. No code modifications are required.

In this example, you create the required ER configurations for the **Litware, Inc.** sample company. Make sure that the configuration provider for the **Litware, Inc.** (`http://www.litware.com`) sample company is listed for the ER framework, and that it's marked as **Active**. If this configuration provider isn't listed, or if it isn't marked as **Active**, follow the steps in Create a configuration provider and mark it as active.

Business scenario

You have an ER solution that includes a format that you can run to generate an electronic document for audit purposes. This format contains tax transactions that are related to sales orders and purchase orders, and that have the required details, such as the transaction date and tax value. As of the new fiscal year, the structure of this document has changed. You must now submit an extended document that includes additional details (names) of all parties (customers and vendors) whose transactions are presented on generated reports. Therefore, you must modify your ER solution so that it generates documents that comply with this new requirement.

Configure the ER framework

Follow the steps in Configure the ER framework to set up the minimal set of ER parameters. You must complete this setup before you start to use the ER framework to design a new ER solution.

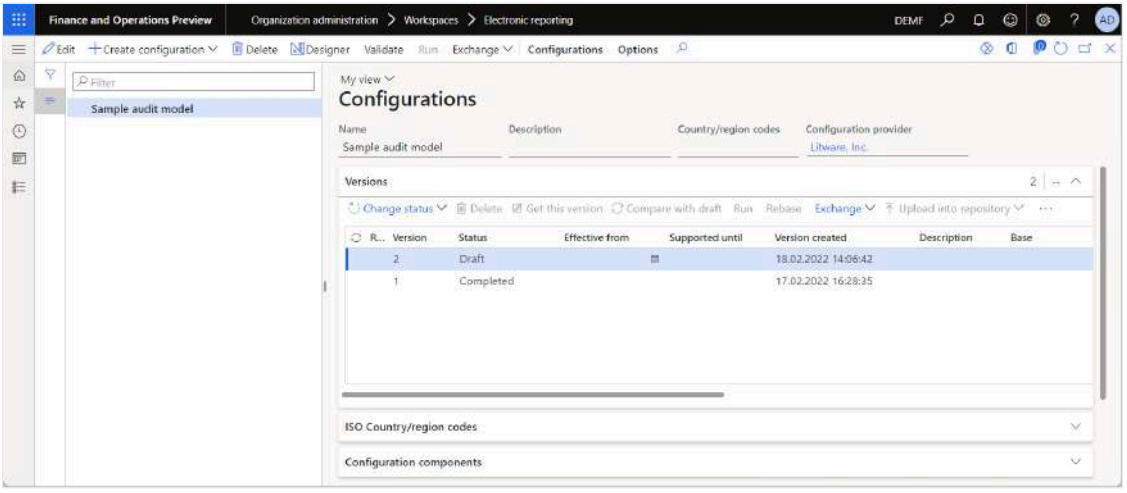
Design a domain-specific data model

Create a new ER configuration that contains the required data model component. Later, use this data model as a data source when you design an ER format to generate an audit report.

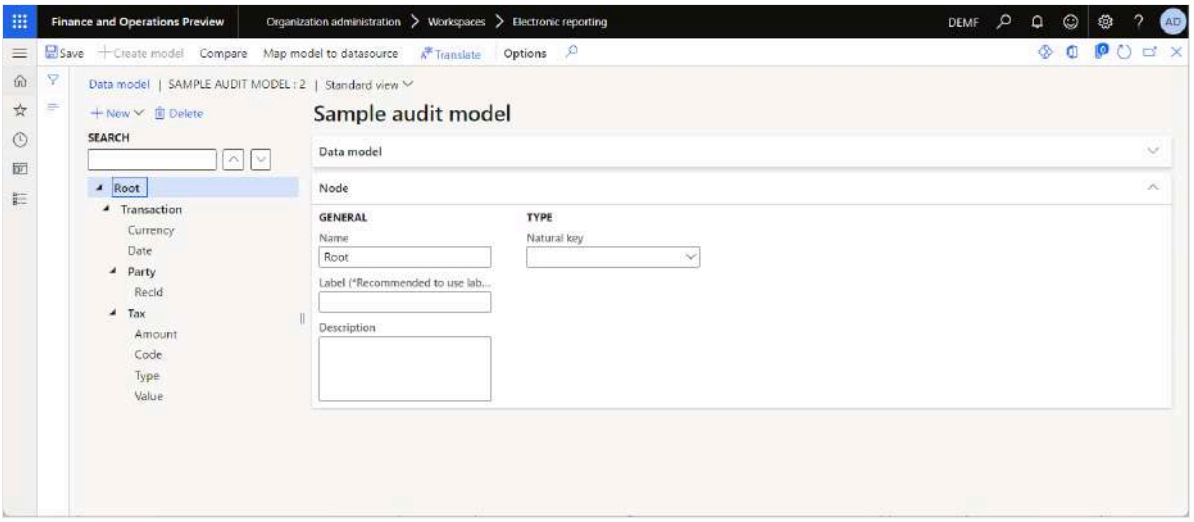
Follow these steps to import the required data model from an XML file that Microsoft provides.

1. Download the Sample audit model.version.1.xml file, and save it to your local computer.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. In the **Electronic reporting** workspace, select **Reporting configurations**.
4. On the **Configurations** page, on the Action Pane, select **Exchange** > **Load from XML file**.
5. Select **Browse**, and then find and select the **Sample audit model.version.1.xml** file.

6. Select **OK** to import the configuration.



The following illustration shows the editable version of the configured data model on the **Data model designer** page.



Currently, the model is designed to expose only tax transactions that have the required details.

Design a model mapping for the configured data model

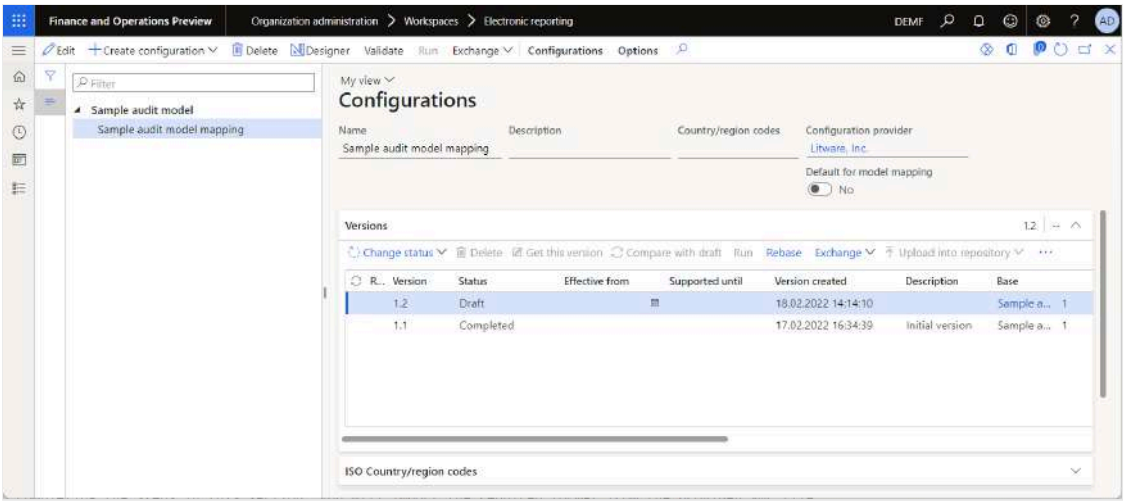
As a user in the Electronic Reporting Developer role, you must create a new ER configuration that contains a model mapping component for the Sample audit data model. This component implements the configured data model for Microsoft Dynamics 365 Finance and is specific to that app. You must configure the model mapping component to specify the application objects that fill the configured data model with application data at runtime. To complete this task, you must understand how the data structure of the tax business domain is implemented in Finance.

Follow these steps to import the required model mapping from an XML file that Microsoft provides.

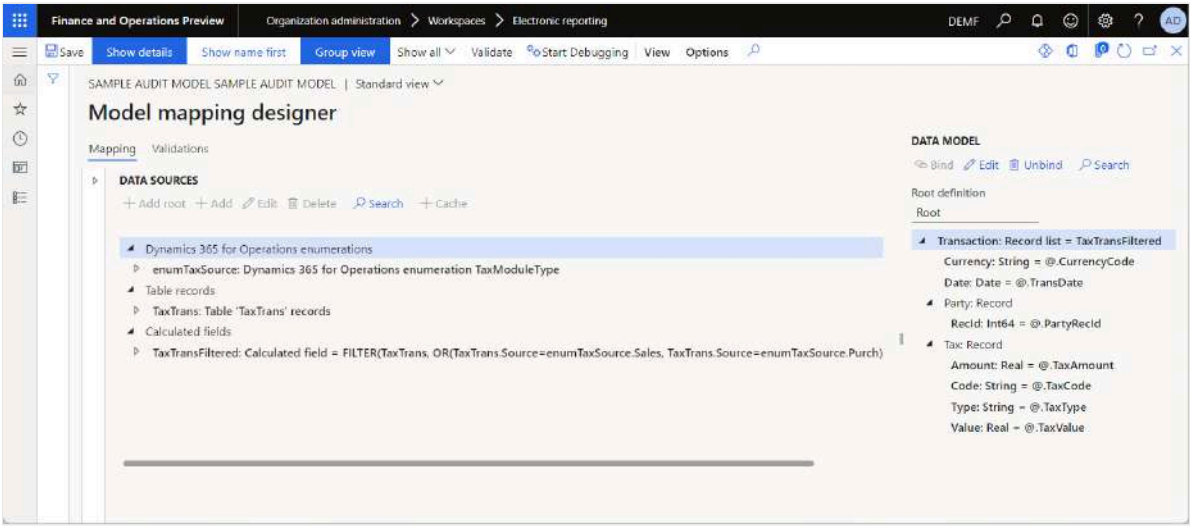
1. Download the Sample audit model mapping.version.1.1.xml file, and save it to your local computer.

2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

3. In the **Electronic reporting** workspace, select **Reporting configurations**.
4. On the **Configurations** page, on the Action Pane, select **Exchange** > **Load from XML file**.
5. Select **Browse**, and then find and select the **Sample audit model mapping.version.1.1.xml** file.
6. Select **OK** to import the configuration.



The following illustration shows the editable version of the configured model mapping on the **Model mapping designer** page.



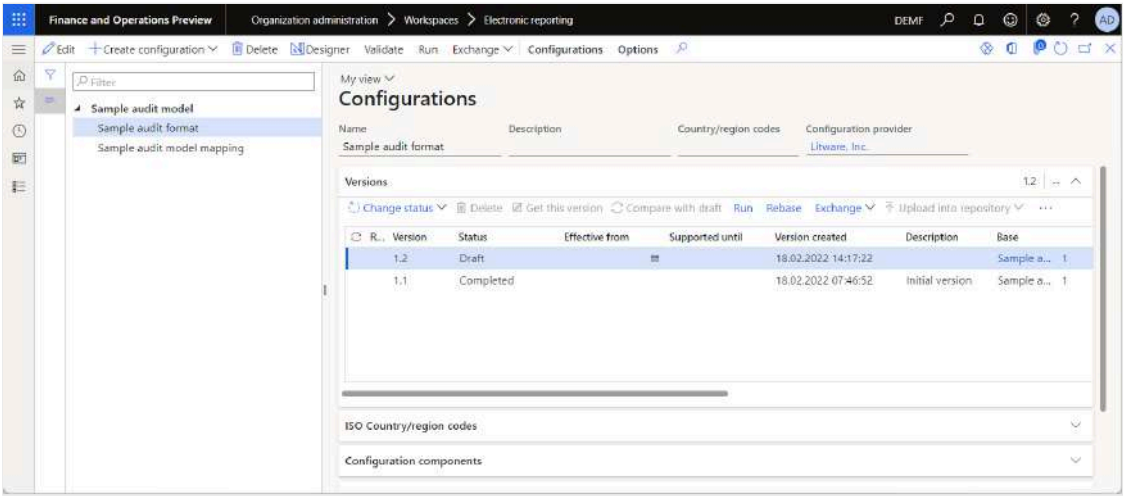
Currently, the model mapping exposes tax transactions that have the required details. It fetches this information from the `TaxTrans` application table by using the configured `TaxTrans` and `TaxTransFiltered` ER data sources.

Design a new format

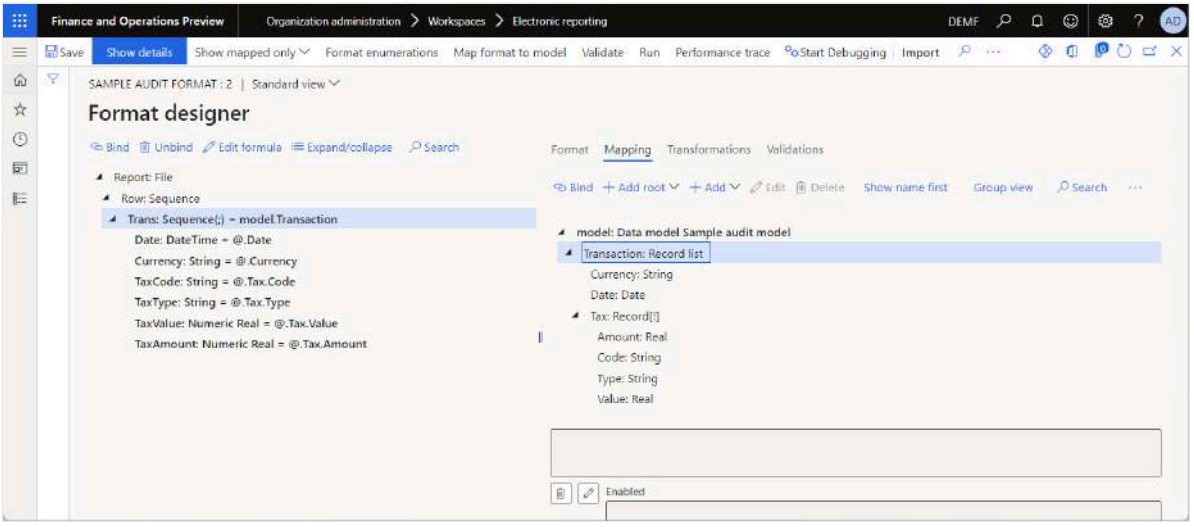
As a user in the Electronic Reporting Functional Consultant role, you must create a new ER configuration that contains a format component. You must configure the format component to fill in generated reports with tax transactions that have all the required details.

Follow these steps to import the required format from an XML file that Microsoft provides.

1. Download the Sample audit format.version.1.1.xml file, and save it to your local computer.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. In the **Electronic reporting** workspace, select **Reporting configurations**.
4. On the **Configurations** page, on the Action Pane, select **Exchange** > **Load from XML file**.
5. Select **Browse**, and then find and select the **Sample audit format.version.1.1.xml** file.
6. Select **OK** to import the configuration.



The following illustration shows the editable version of the configured format on the **Format designer** page.

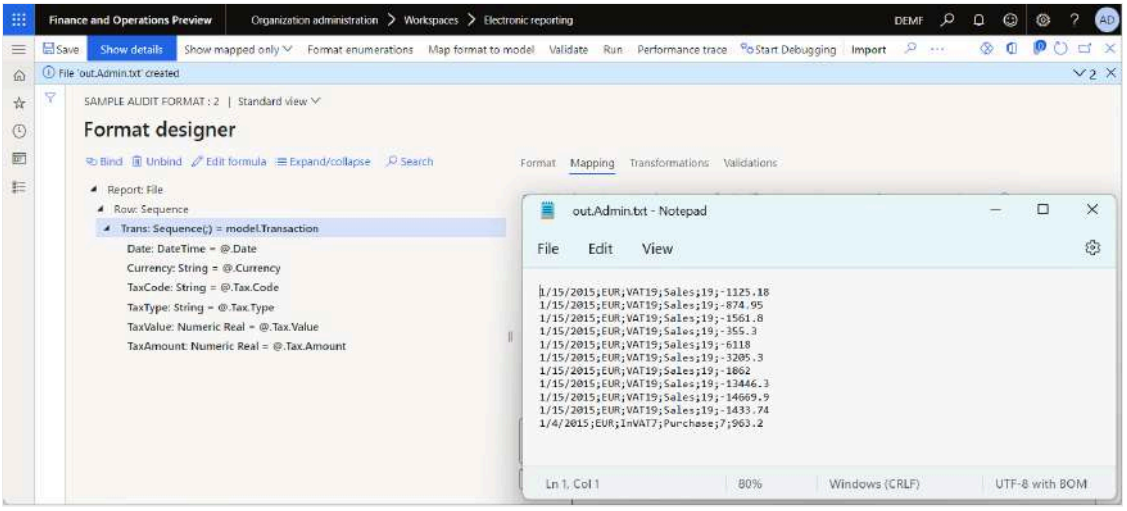


The ER format is configured to generate a report as a text file in comma-separated values (CSV) format.

Run the imported format

1. On **Configurations**, select the **Sample audit format** configuration. On the Action Pane, select **Run**.

2. In **Electronic report parameters**, on the **Records to include** tab, select **Filter**.
3. Specify the conditions to select the tax transactions for the **PIV-110000004** and **INV-10000001** vouchers.
4. Select **OK**.
5. Select **OK**.
6. Review the generated document that contains tax transactions for the selected vouchers.



Adjust the imported ER solution

According to the new requirement, the document that you must submit must contain the names of customers and vendors whose transactions are included. Therefore, you must modify the imported ER solution so that it generates a document that complies with this new requirement.

Decide how you want to implement the required modifications of the imported ER components.

The obvious approach is to implement the following modifications:

- In your data model, add the new `Transaction.Party.Name` data model field of the *String* type.
- In your model mapping, configure the binding for the new data model field by using available table relations to access the relevant record of the `DirPartyTable` application table and fetch the value of the `Name` field from it.

Although this approach works, it might cause performance issues in the SQL database, because `TaxTrans` is the transaction table and can therefore contain a large volume of records. In this case, the number of calls to `DirPartyTable` must equal the number of records in the `TaxTrans` table, which can cause performance issues.

Alternatively, you might implement the following modifications:

- In your data model, add the new `Party` root and the new `Party.Name` field.
- In your model mapping, add a new data source that joins all the records of tables that are used in table relations to access the relevant record of the `DirPartyTable` application table, starting from the `TaxTrans` table.

Although this approach works, it might cause some memory consumption issues. Even when a new JOIN data source runs as a single SQL request to the application database to prevent database performance problems, the result must be fetched to the memory of the application server. Because the number of records and the number of fields in those records are quite large, this approach might cause very heavy memory consumption. An out-of-memory runtime exception might even be thrown.

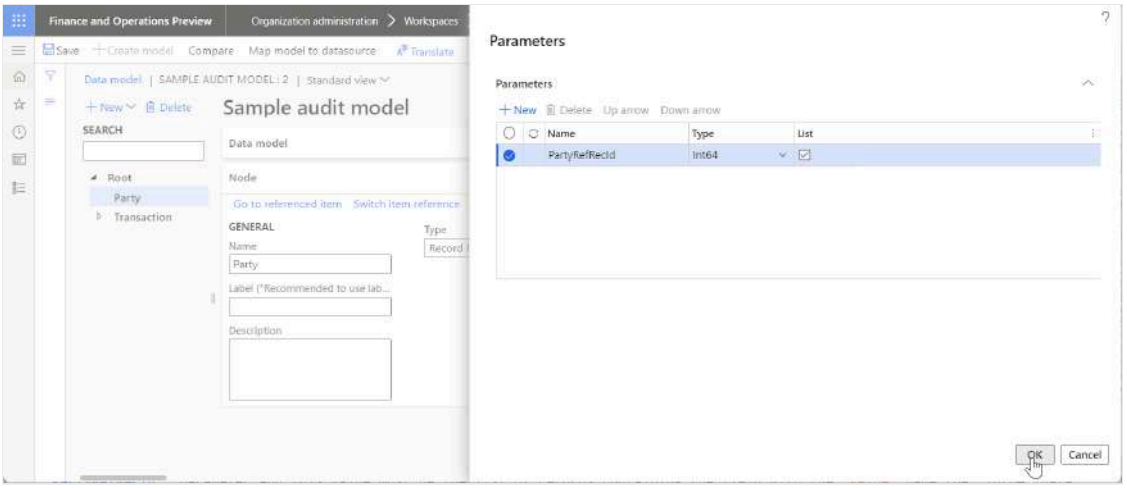
You can implement the modifications when a running format collects, in memory, the unique identification codes of customers and vendors for all tax transactions presented on a generated report. Because only unique codes are kept, the final set of codes isn't large enough to affect memory consumption. The set of codes is then passed to the model mapping as the argument of another call of the data source of the *Model* type. Based on that call, the model mapping runs a new ER data source that makes a single SQL request to the application database to fetch, from the `DirPartyTable` table, records only for those parties whose codes are presented in the provided set of codes.

Adjust the imported data model

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configurations tree in the left pane, select **Sample audit model**.
3. On the **Versions** FastTab, select version **2** that has a status of **Draft**.
4. Select the **Configuration components** FastTab.
5. Select **Designer** to open the data model for editing.
6. On **Data model**, make sure that the `Root` field is selected, and then select **New**.
7. In the drop-down dialog box, follow these steps:
   a. In the **New node as** field group, select the **Child of an active node** option.
   b. In the **Name** field, enter **Party**.
   c. In the **Item type** field, select **Record list**.
   d. Select **Add** to finish adding the new field.
8. Make sure that the `Root.Party` field is selected, and then, on the **Node** tab, select **Parameters**.
9. In the **Parameters** dialog box, follow these steps:
   a. On the **Parameters** tab, select **New**.
   b. In the **Name** field, enter **PartyRefRecId**.

c. In the **Type** field, select **Int64**.
d. Select the **List** checkbox.
e. Select **OK** to finish entering the parameters.

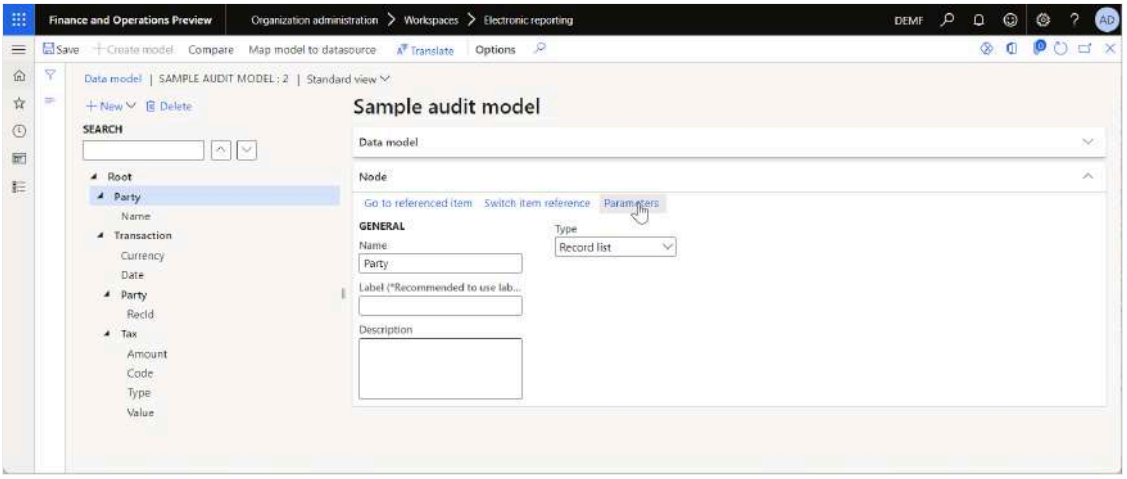
> **Note**
>
> You just configured the `Root.Party` data model field as a field that is called when a value is provided in the **PartyRefRecId** parameter. This value must be present in the list of records that contain a `Value` field of the *Int64* data type.



10. Make sure that the `Root.Party` field is still selected, and then select **New**.

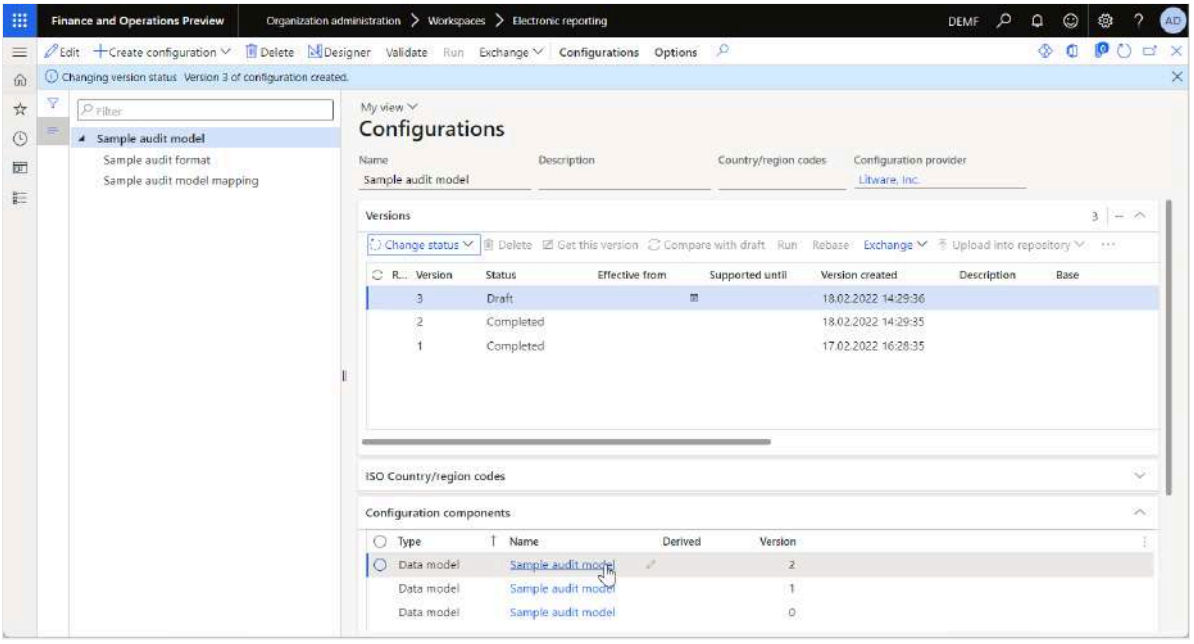
11. In the drop-down dialog box, follow these steps:
    a. In the **New node as** field group, select the **Child of an active node** option.
    b. In the **Name** field, enter **Name**.
    c. In the **Item type** field, select **String**.
    d. Select **Add** to finish adding the new field.

12. Select **Save**, and close the **Data model** page.



13. On the **Versions** FastTab, for version **2**, select **Change status** > **Complete**. Then select **OK**.

> **Note**
>
> Your data model changes are stored in the second revision of the **Sample audit model** data model component that is located in the second version of the **Sample audit model** ER configuration.



Adjust the imported model mapping

1. On **Configurations**, in the configurations tree in the left pane, expand **Sample audit model**.

2. Select **Sample audit model mapping**. On the **Versions** FastTab, select the second mapping version that is based on the first data model version (version **1.2**) and has a status of **Draft**.

3. Select **Rebase**.

4. In the **Target version** field, leave version **2** of the **Sample audit model** base model.

5. Select **OK** to rebase and align your model mapping with recent data model changes.

   The version number of your editable model mapping changes from **1.2** to **2.2** to indicate that the second model version is currently used as a base.

6. Select **Designer**.

7. On **Model to datasource mapping**, select **Designer** for the current model mapping.

8. Follow these steps to add a new data source to access the `DirPartyTable` application table:
   a. In the **Data source type** pane, select **Dynamics 365 for Operations** > **Table records**.

b. In the **Data sources** pane, select **Add root**.
c. In the **Name** field, enter **PartyTable**.
d. In the **Table** field, enter **DirPartyTable**.
e. Select **OK** to finish adding the new data source.

9. Follow these steps to add a new data source to request `DirPartyTable` records, based on the provided list of record identification codes:

a. In the **Data source type** pane, select **General** > **Empty container**.

b. In the **Data sources** pane, select **Add root**.

c. In the **Name** field, enter **Data**.

d. Select **OK** to finish adding the new data source.

e. In the **Data sources** pane, select the **Data** data source.

f. In the **Data source type** pane, select **Functions** > **Calculated field**.

g. In the **Data sources** pane, select **Add**.

h. In the **Name** field, enter **DirParty**.

i. Select **Edit formula**.

j. On **Formula designer**, select **Parameters**.

k. In the **Parameters** dialog box, follow these steps:
   i. On the **Parameters** tab, select **New**.
   ii. In the **Name** field, enter **DirPartyId**.
   iii. In the **Type** field, select **Int64**.
   iv. Select the **List** checkbox.
   v. Select **OK**.

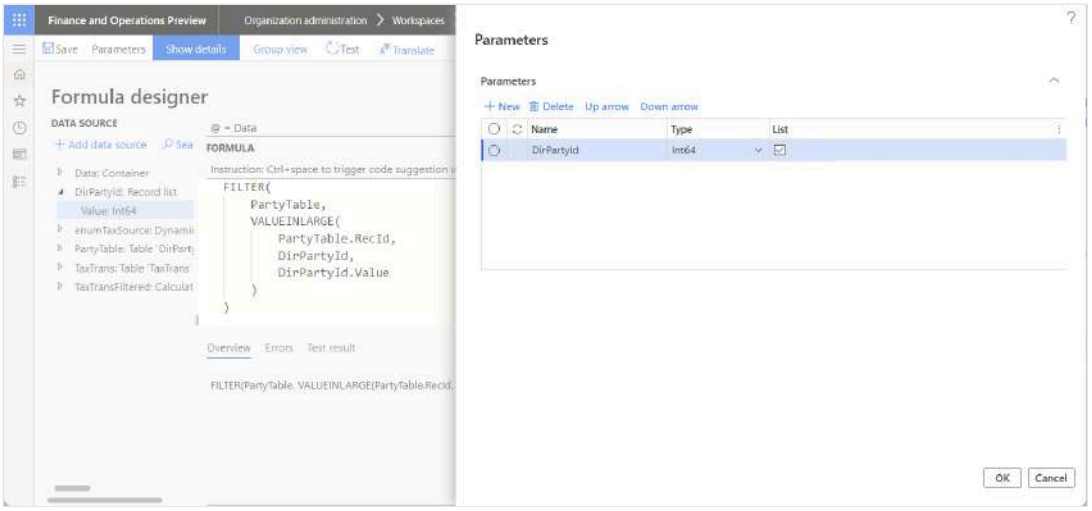
> ⓘ **Note**
>
> You just configured this calculated field so that it accepts, at runtime, the argument of a single parameter that is configured as a record list that has a single `Value` field of the *Int64* type.

l. In the **Formula** field, enter the following expression:

```
FILTER(PartyTable, VALUEINLARGE(PartyTable.RecId, DirPartyId, DirPartyId.Value))
```

> ⓘ **Note**

> You just configured the `DirParty` calculated field to fetch only `DirPartyTable` records where the record identification codes are included in the `DirPartyId` list that is provided as an argument when the `DirParty` field is called.



m. Select **Save**, and close **Formula designer**.

n. Select **Save**, and then select **OK** to finish adding the new data source.

10. Follow these steps to bind the new data source to the new data model field, so that the data model exposes party names:

    a. In the **Data model** pane, select the `Root.Party` data model field.

    b. In the **Data model** pane, select **Edit**.

    c. On **Formula designer**, in the **Formula** field, enter the expression `Data.DirParty(PartyRefRecId)`.

    d. Select **Save**, and close **Formula designer**.

    > ⓘ **Note**
    >
    > You just configured the binding to call the configured `Data.DirParty` data source and provide the list of record identification codes specified in the format when the `Root.Party` data model field is called.

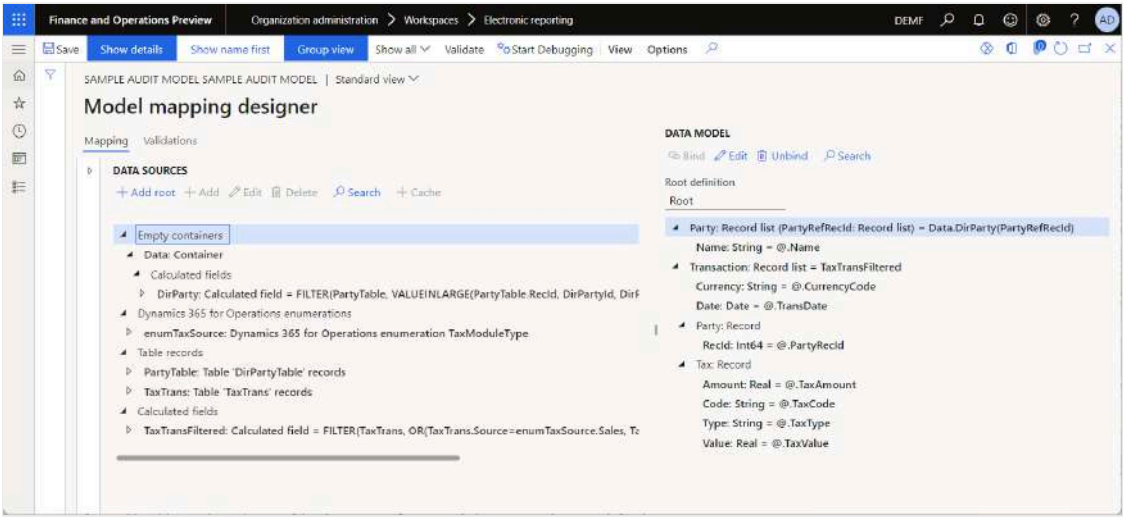
    e. In the **Data model** pane, select the `Root.Party.Name` data model field.

    f. In the **Data model** pane, select **Edit**.

    g. On the **Formula designer** page, in the **Data source** pane, expand **Data** > **DirParty**, and select **Name**.

    h. Select **Add data source**.

i. Select **Save**, and close **Formula designer**.



11. Select **Save**, and close the **Model mapping designer** page.
12. Close the **Model to datasource mapping** page.
13. On the **Versions** FastTab, for version **2.2**, select **Change status** > **Complete**. Then select **OK**.

Adjust the imported format

1. On **Configurations**, select **Sample audit format**.
2. On the **Versions** FastTab, select version **1.2** that has a status of **Draft**.
3. Select **Rebase**.
4. In the **Target version** field, leave version **2** of the **Sample audit model** base model.
5. Select **OK** to rebase and align your format with the recent data model changes.
6. Select **Designer**.
7. On the **Format designer** page, in the format structure tree in the left pane, select **Expand/Collapse**.
8. Follow these steps to add a new format element to collect record identification codes of parties whose transactions are presented on generated reports.
   a. In the format structure tree, select the **Report.Row.Trans** sequence element.
   b. Select **Add**.
   c. In **Add**, select **Data source** > **Item**.
   d. In **Component properties**, in the **Name** field, enter **Id**.
   e. In the **Data type** field, select **Int64**.
   f. Select **OK**.

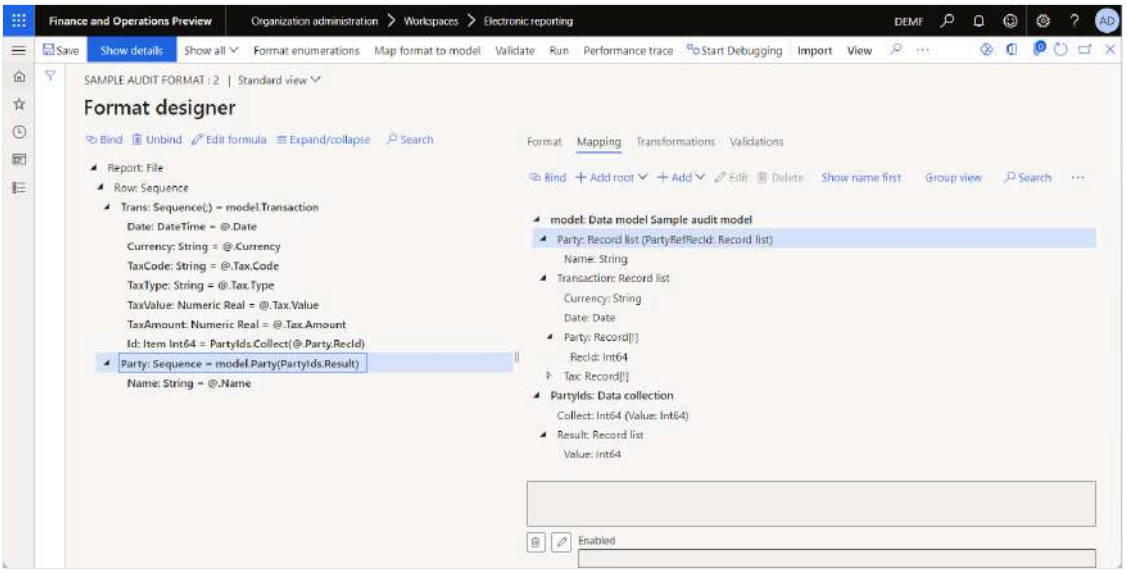
> ⓘ **Note**
>
> Use the **Data source** > **Item** element to perform internal calculations and data transformation only in the scope of the running format. Therefore, by adding this format element, you don't change the content of a generated document.

9. Follow these steps to add new format elements to enter party names on generated reports:
   a. Select the **Report.Row** sequence element.
   b. Select **Add**.
   c. In **Add**, select **Text** > **Sequence**.
   d. In **Component properties**, in the **Name** field, enter **Party**.
   e. Select **OK**.
   f. Select the **Report.Row.Party** sequence element.
   g. Select **Add**.
   h. In **Add**, select **Text** > **String**.
   i. In **Component properties**, in the **Name** field, enter **Name**.
   j. Select **OK**.

10. Follow these steps to add a new data source to collect record identification codes of parties whose transactions are presented on generated reports:
    a. On the **Mapping** tab, select **Add root**.
    b. In **Add data source**, select **Functions** > **Data collection**.
    c. In **'Data collection' data source properties**, in the **Name** field, enter **PartyIds**.
    d. In the **Item type** field, select **Int64**.
    e. Select **OK**.

11. Follow these steps to add a new binding to collect record identification codes of parties whose transactions are presented on generated reports:
    a. In the format structure tree, select the **Report.Row.Trans.Id** data item element.
    b. Select **Edit formula**.
    c. On the **Formula designer** page, enter the expression `PartyIds.Collect(model.Transaction.Party.RecId)`.
    d. Select **Save**, and close **Formula designer**.

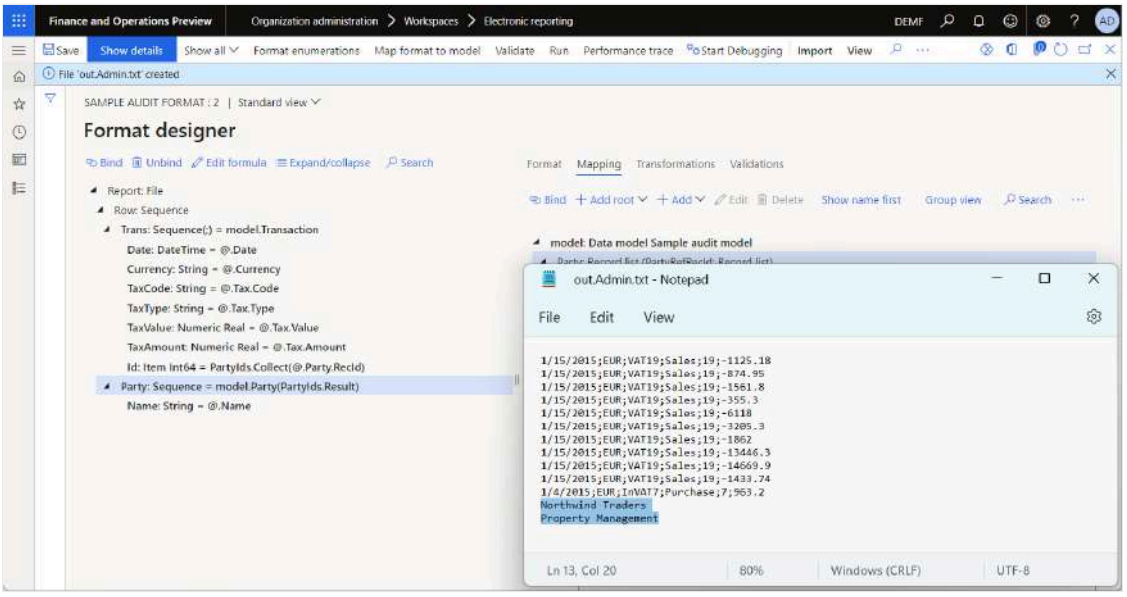
12. Follow these steps to add new bindings to enter party names on generated reports:
    a. In the format structure tree, select the **Report.Party** sequence element.
    b. Select **Edit formula**.
    c. On the **Formula designer** page, enter the expression `model.Party(PartyIds.Result)`.
    d. Select **Save**, and close **Formula designer**.
    e. In the format structure tree, select the **Report.Party.Name** sequence element.
    f. On the **Mapping** tab, select the `model.Party.Name` data model field.
    g. Select **Bind**.



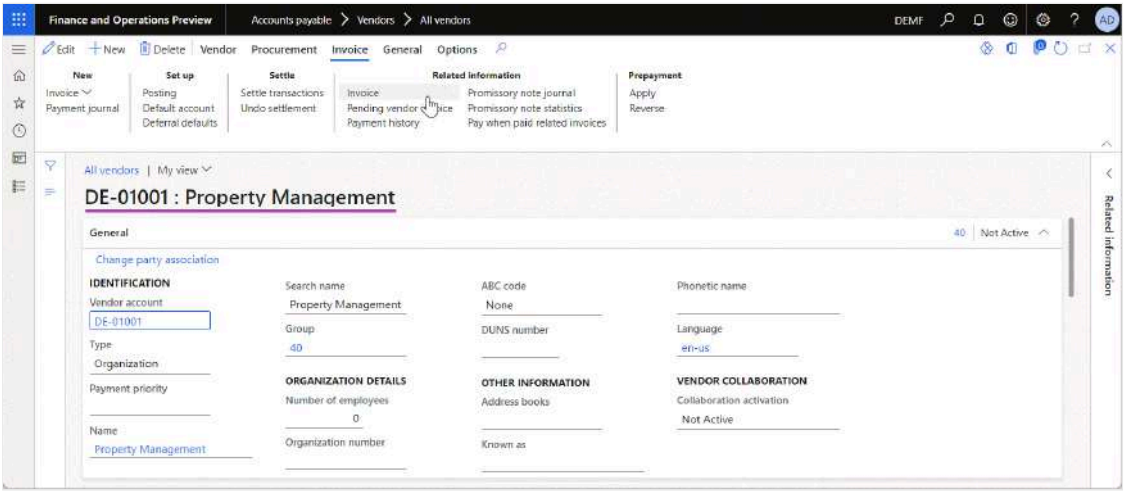
13. Select **Save**, and close the **Format designer** page.
14. Close the **Model to datasource mapping** page.
15. On the **Versions** FastTab, for version **2.2**, select **Change status** > **Complete**. Then select **OK**.

Run the adjusted format

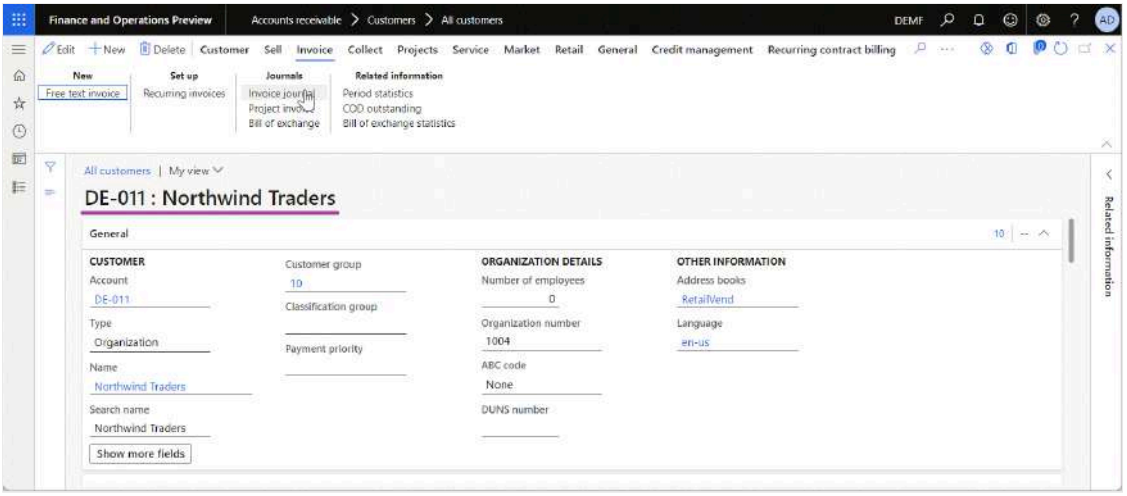
1. On **Configurations**, select **Sample audit format**. On the action pane, select **Run**.
2. In **Electronic report parameters**, on the **Records to include** tab, select **Filter**.
3. Specify the conditions to select tax transactions for the **PIV-110000004** and **INV-10000001** vouchers.
4. Select **OK**.
5. Select **OK**.
6. Review the generated document that contains tax transactions for the selected vouchers and the names of the corresponding customer and vendor.



7. Go to **Accounts payable** > **Vendors** > **All vendors**, and review the details of the selected **PIV-110000004** voucher, including the vendor name.



8. Go to **Accounts receivable** > **Customers** > **All customers**, and review the details of the selected **INV-10000001** voucher, including the customer name.



For more details about this execution of the ER solution, use the ER built-in performance trace parser.

Configure country/region context dependent ER model mappings

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can configure Electronic reporting (ER) model mappings so that they implement a generic ER data model but are specific to Dynamics 365 Finance. This article explains how to design multiple ER model mappings for an ER data model to control how corresponding ER formats use them when you run them from companies that have different country/region contexts.

Prerequisites

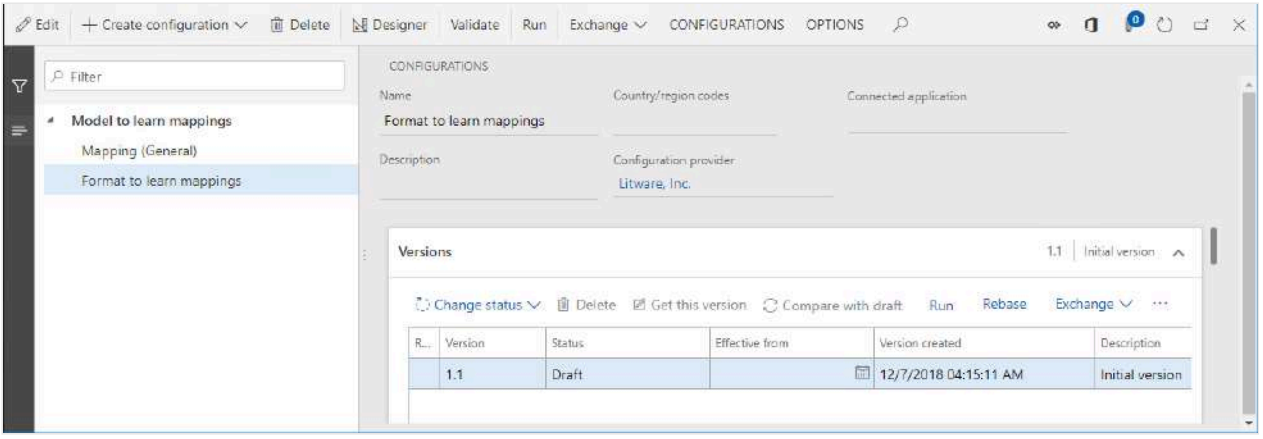
To complete the examples in this article, you must have the following access:

- Access to Finance for one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator
- Access to the instance of Regulatory Configuration Services (RCS) that is provisioned for the same tenant as Finance for one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator

Some steps in this article require execution of an ER format. In some cases, the country/region context of the company that you're currently signed in to affects execution of an ER format. You can run an ER format in the current RCS instance if the company that has the required country/region context is available in RCS. Otherwise, you must upload a completed version of the ER model mapping and ER format configurations that use the ER data model to your Finance instance, and then run the ER format in that Finance instance. For information about how to import configurations that reside in RCS into a Finance instance, see Import configurations from RCS.

Single model mapping case

Follow the steps in Appendix 1 of this article to design the required ER components. You now have the **Mapping (General)** model mapping configuration that contains the model mapping for the **Entry point 1** definition.



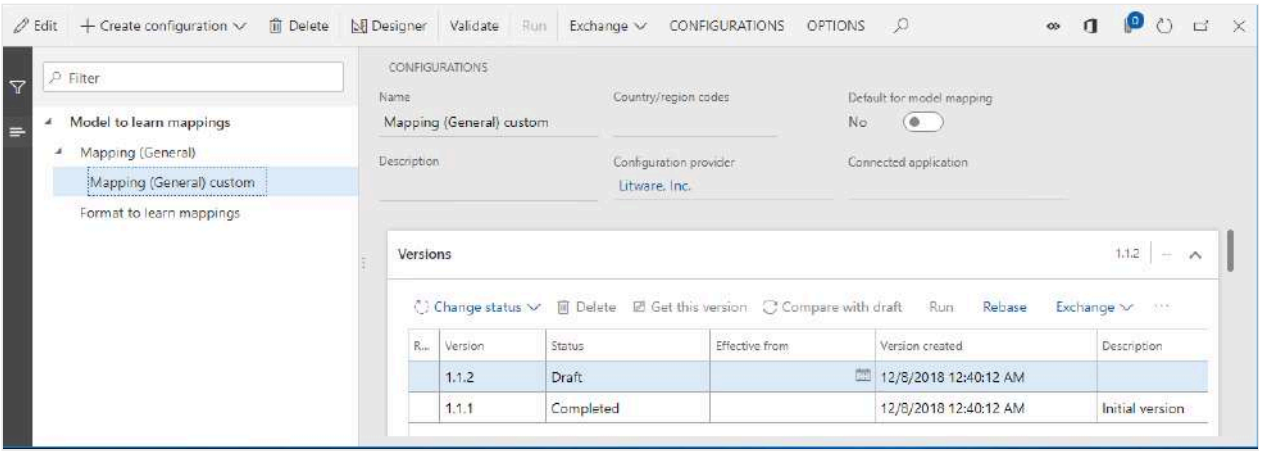
Run the configured format

1. On the **Configurations page**, on the **Versions** FastTab, select **Run**.
2. Select **OK**.

The web browser offers to download the text file that the executed ER format generated. Because you configured this format to use the **Entry point 1** definition, and only a single model mapping is currently available for the base model that contains a mapping for this definition, the executed ER format uses the **Mapping (General)** model mapping of the **Mapping (General)** configuration as a data source. Therefore, the downloaded file contains the **Generic functionality 1** text.

Multiple shared model mappings case

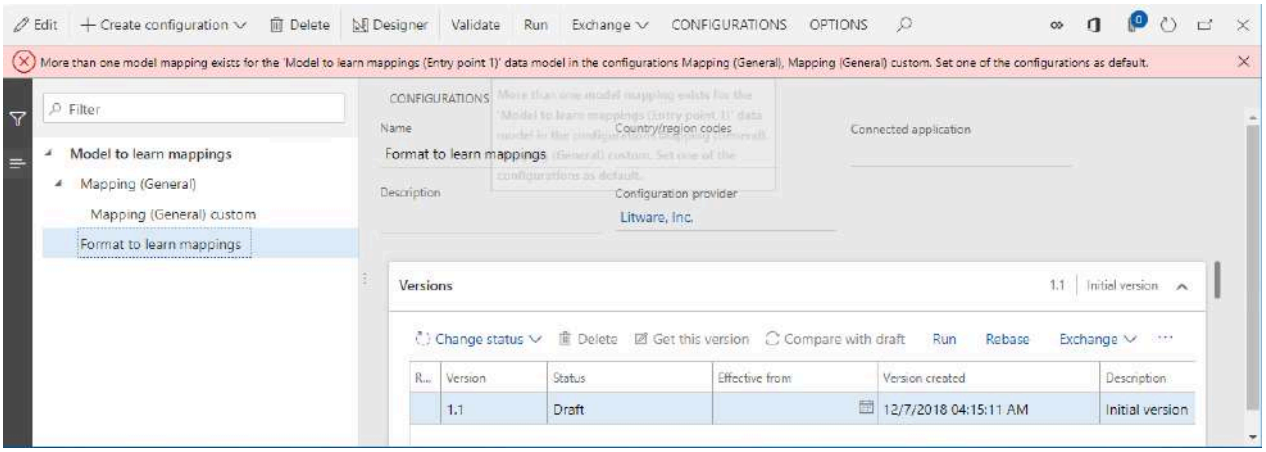
Follow the steps in Appendix 2 of this article to design the required ER components. You now have **Mapping (General)** and **Mapping (General) custom** model mapping configurations, each of which contains the model mapping for the **Entry point 1** definition.



Run the configured format

1. On **Configurations**, in the configurations tree, select **Format to learn mappings**.
2. On the **Versions** FastTab, select **Run**.
3. Select **OK**.

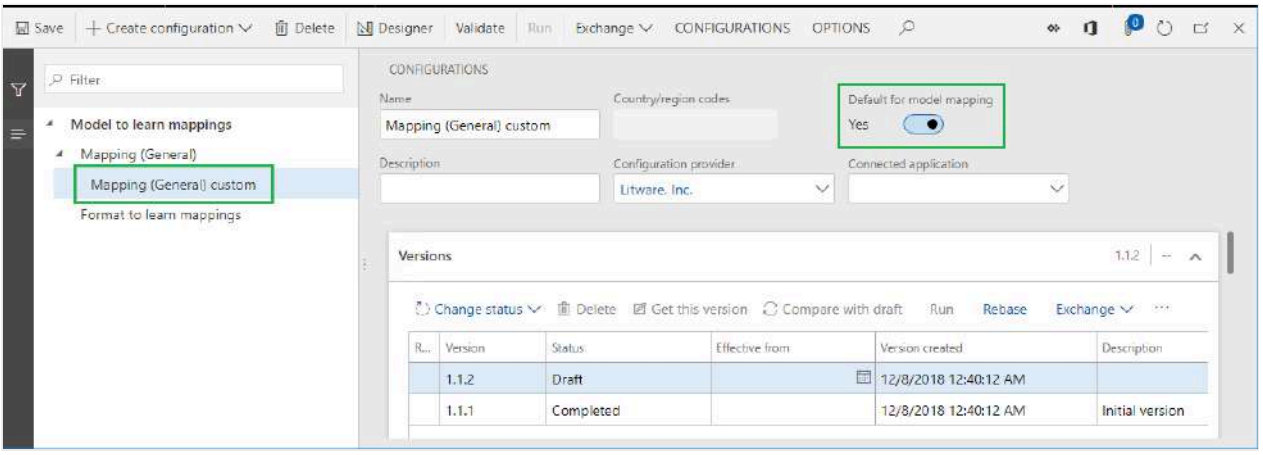
Execution of the selected ER format isn't successful. An error message informs you that more than one model mapping exists for the **Model to learn mappings** model and the **Entry point 1** definition in the **Mapping (General)** and **Mapping (General) custom** model mapping configurations. The message also recommends that you select one of those configurations as the default configuration.



Define a default mapping configuration

Follow these steps to define the **Mapping (General) custom** model mapping configuration as the default configuration, so that you can use its mappings as data sources for the **Format to learn mappings** ER format.

1. On **Configurations**, in the configurations tree, select **Mapping (General) custom**.
2. Select **Edit** to make the current page ready for editing.
3. Set the **Default for model mapping** option to **Yes**.
4. Select **Save**.



Run the configured format

1. On **Configurations**, in the configurations tree, select **Format to learn mappings**.
2. On the **Versions** FastTab, select **Run**.
3. Select **OK**.

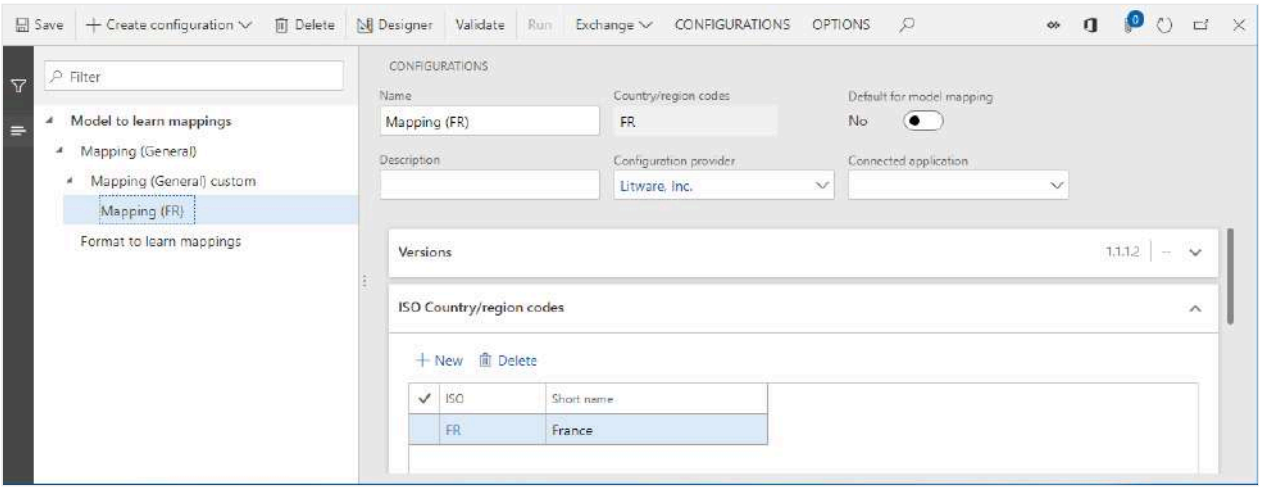
The execution of the selected ER format succeeds. The web browser offers to download the text file that the executed ER format generated. Because you configured this format to use the **Entry point 1** definition, and you selected the **Mapping (General) custom** model mapping configuration as the default configuration, the executed ER format uses the **Mapping (General) copy** model mapping of the **Mapping (General) custom** configuration as a data source. Therefore, the downloaded file contains the **Generic functionality 1 custom** text.

> **Note**
>
> If you change the company that you're currently signed in to and run this ER format again, you get the same content in the generated file, because the default ER model mapping configuration doesn't contain any company-dependent restrictions.

Multiple mixed model mappings case

Follow the steps in Appendix 3 of this article to design the required ER components. You now have **Mapping (General)**, **Mapping (General) custom**, and **Mapping (FR) model mapping** configurations that contain the model mapping for the **Entry point 1** definition.

Version 1 of the **Mapping (FR)** model mapping configuration is configured so that it applies only to ER formats of the **Model to learn mappings** model that run in Finance companies that have French country/region context.



Run the configured format

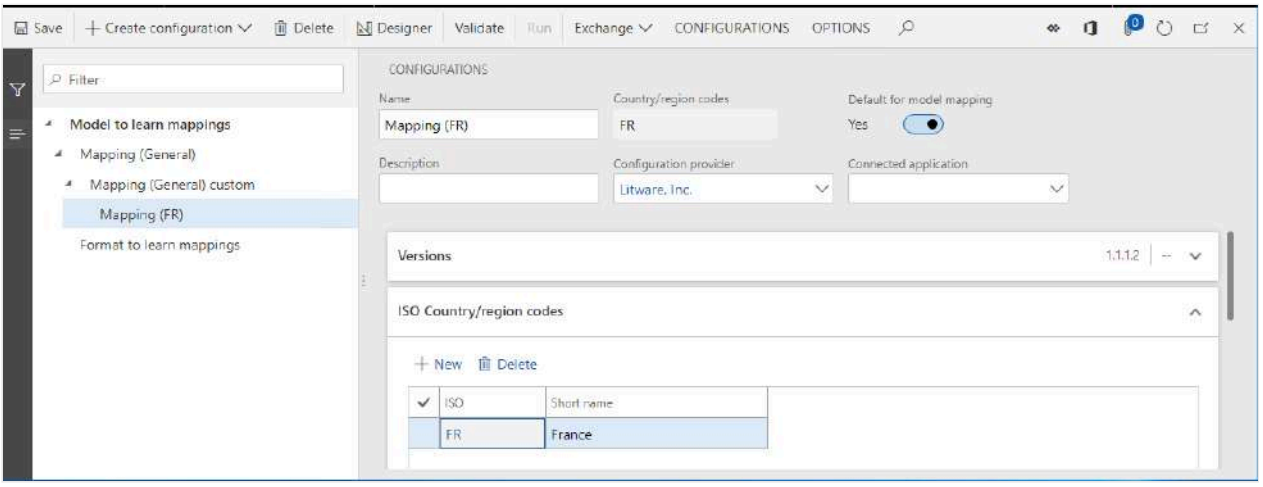
1. Change the company to **FRSI**.
2. On **Configurations**, in the configurations tree, select **Format to learn mappings**.
3. On the **Versions** FastTab, select **Run**.
4. Select **OK**.

The execution of the selected ER format succeeds. The web browser offers to download the text file that the executed ER format generated. Because this format uses the **Entry point 1** definition and the **Mapping (General) custom** model mapping configuration is selected as the default configuration, the executed ER format uses the **Mapping (General) copy** model mapping of the **Mapping (General) custom** configuration as a data source. Therefore, the downloaded file contains the **Generic functionality 1 custom** text.

Define the France-specific mapping configuration as the default configuration

Follow these steps to define the custom **Mapping (FR)** model mapping configuration as the default configuration. Because this mapping is specific to France, it's the default mapping between all model mapping configurations that have the **FR** country code specified in the **ISO country/region codes** field.

1. On **Configurations**, in the configurations tree, select **Mapping (FR)**.
2. Select **Edit** to make the current page ready for editing.
3. Set the **Default for model mapping** option to **Yes**.
4. Select **Save**.



Run the configured format

1. On **Configurations**, in the configurations tree, select **Format to learn mappings**.
2. On the **Versions** FastTab, select **Run**.
3. Select **OK**.

The execution of the selected ER format succeeds. The web browser offers to download the text file that the executed ER format generated. Because this format uses the **Entry point 1** definition and the **Mapping (FR)** model mapping configuration is selected as the default configuration, the executed ER format uses the **Mapping (FR)** model mapping of the **Mapping (FR)** configuration as a data source. Therefore, the downloaded file contains the **FR functionality 1** text.

> **Note**
>
> If you change the company that you're currently signed in to and run this ER format again, the output depends on the country/region context of the selected company.

Other model mapping cases

As you saw, the selection of a model mapping for the execution of an ER format works in the following way:

1. You specify the model mapping definition that an ER format uses (**Entry point 1** in the examples in this article).
2. You can potentially use all mapping configurations that contain a mapping that has the specified definition and satisfy any country/region context restrictions that you configure to run the ER format (**Mapping (General)**, **Mapping (General) custom**, and **Mapping (FR)** in the examples in this article).

3. Any default model mapping that has country/region context restrictions has the highest priority for selection (**Mapping (FR)** in the examples in this article).
4. Any default model mapping that doesn't have country/region context restrictions has the next higher priority for selection (**Mapping (General) custom** in the examples in this article).
5. Any model mapping that has country/region context restrictions has higher priority for selection than a model mapping that doesn't have country/region context restrictions.

The following table provides information about the results of model mapping selection for all possible cases for model mapping settings:

- Column 1 indicates whether the first model mapping that doesn't have country/region context restrictions (for example, the shared **Mapping (General)** mapping) is presented and, if it is, whether the **Default for model mapping** option is set to **Yes** for it.
- Column 2 indicates whether the second model mapping that doesn't have country/region context restrictions (for example, the shared **Mapping (General) custom** mapping) is presented and, if it is, whether the **Default for model mapping** option is set to **Yes** for it.
- Column 3 indicates whether the first model mapping that has country/region A context restrictions (for example, the France-specific **Mapping (FR)** mapping) is presented and, if it is, whether the **Default for model mapping** option is set to **Yes** for it.
- Column 4 indicates whether the second model mapping that has country/region A context restrictions is presented and, if it is, whether the **Default for model mapping** option is set to **Yes** for it.
- Column 5 presents the result of a model mapping selection for execution of an ER format under the control of a company that has country/region A context.
- Column 6 presents the result of a model mapping selection for execution of an ER format under the control of a company that has country/region B context.

In the table, a plus sign (+) indicates the presence of a model mapping configuration in the current instance of the Microsoft Azure service that is used to run an ER format (either Finance or RCS).

Expand table

Case	Model mapping 1 without country/region context (MM1)	Model mapping 2 without country/region context (MM2)	Model mapping 1 with country/region A context (MM1A)	Model mapping 2 with country/region A context (MM2A)	Run under control of a company that has country/region A context	Run under th control of a company tha has country/regi B context

Learn what mapping was used in the execution of an ER format

Configure ER user parameters

1. On **Configurations**, on the Action Pane, on the **CONFIGURATIONS** tab, select **User parameters**.

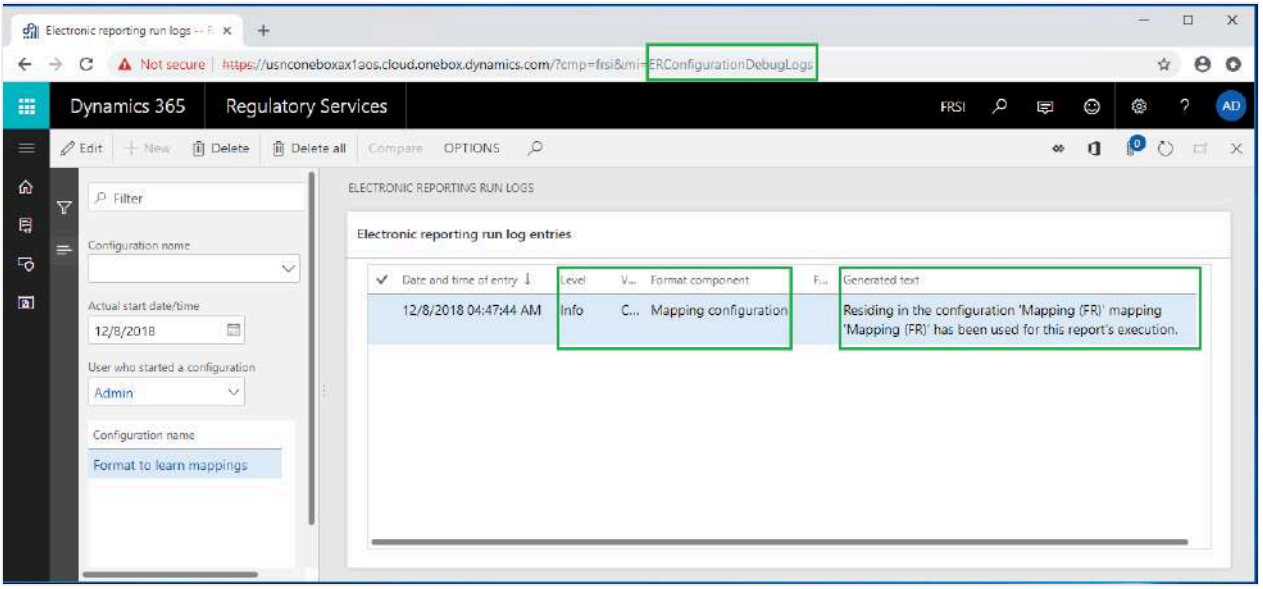
2. Set the **Run in debug mode** option to **Yes**.
3. Select **Ok**.

Run the configured format

1. On **Configurations**, in the configurations tree, select **Format to learn mappings**.
2. On the **Versions** FastTab, select **Run**.
3. Select **Ok**.

Review the ER debug log

1. In the navigation pane, go to **Modules** > **Organization administration** > **Electronic reporting** > **Configuration debug log**.
2. Select the **Reload this page** button.



A new record is added to the ER debug log for the executed ER format. Because the **Level** field of this record is set to **Info**, the record is informational. Because the **Format component** field is set to **Mapping configuration**, the record informs you about a model mapping that was used during execution of the **Format to learn mappings** ER format (selected in the **Configuration name** field). The content of the **Generated text** field informs you that the **Mapping (FR)** mapping component that resides in the **Mapping (FR)** configuration is used to run this report.

Appendix 1

Configure a sample data model

Sign in to your RCS instance.

In this example, you create a configuration for sample company, Litware, Inc. To complete these steps, you must first complete, in RCS, the steps in the Create a configuration provider and

mark it as active procedure.

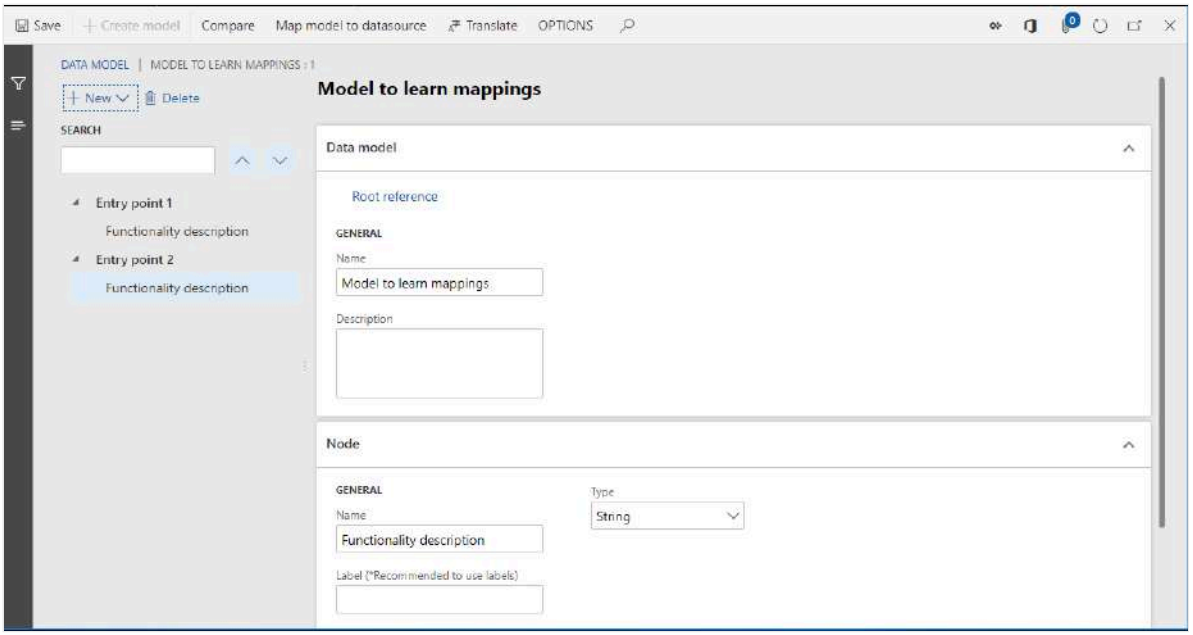
Create an ER data model configuration

1. On the default dashboard, select **Electronic reporting**.
2. Select the **Reporting configurations** tile.
3. On **Configurations**, select **Create configuration**.
4. In the drop-down dialog box, in the **Name** field, enter **Model to learn mappings**.
5. Select **Create configuration**.
6. Select the **Configuration components** FastTab.

Draft version 1 of this ER configuration is ready for editing. This version contains the data model component.

Design a sample data model

1. On the **Configurations page**, select **Designer**.
2. Select **New**.
3. In the drop-down dialog box, in the **Name** field, enter **Entry point 1**.
4. Select **Add**.
5. Select **New**.
6. In the drop-down dialog box, in the **Name** field, enter **Functionality description**.
7. Select **Add**.
8. Select **New**.
9. In the drop-down dialog box, in the **New node** field group, select **Model root**.
10. In the **Name** field, enter **Entry point 2**.
11. Select **Entry point 2**.
12. Select **Add**.
13. Select **New**.
14. In the drop-down dialog box, in the **Name** field, enter **Functionality description**.
15. Select **Add**.



16. Select **Save**.

17. Close the page.

Complete the modified version of the model configuration

1. On **Configurations**, on the **Versions** FastTab, select **Change status**.

   > Change the status of designed model configuration from **Draft** to **Completed**, so that you can use it to design the required model mappings and formats.

2. Select **Complete**.

3. Select **OK**.

The configuration that you created is saved as completed version 1.

Configure a sample model mapping

Create an ER model mapping configuration

1. On **Configurations**, select **Create configuration**.
2. In the drop-down dialog box, in the **New** field group, select **Model mapping based on data model Model to learn mappings**.
3. In the **Name** field, enter **Mapping (General)**.
4. In the **Data model definition** field, select **Entry point 1**.
5. Select **Create configuration**.

Draft version 1 of this ER configuration is ready for editing. This version contains the model mapping component.

Design a sample model mapping

1. On **Configurations**, select **Designer**.

   The model mapping of the **To model** direction type is automatically added to this component for the **Entry point 1** definition.

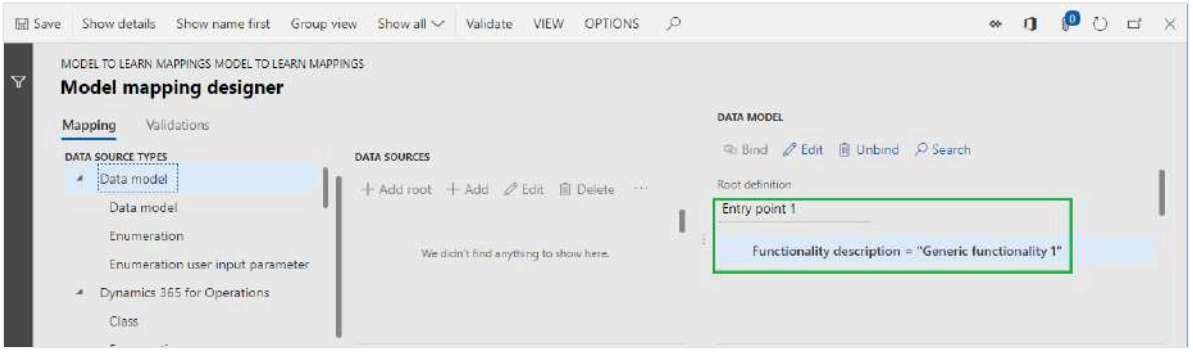
2. Select **Designer** to start editing the added model mapping.

3. In the **Data model** section, select **Edit**.

4. In the **Formula** field, enter **"Generic functionality 1"**.

5. Select **Save**.

6. Close the **Formula designer**.



7. Select **Save**.

8. Close the **Model mapping designer**.

9. Select **New**.

10. In the **Definition** field, select **Entry point 2**.

11. In the **Name** field, enter **Mapping (General) 2**.

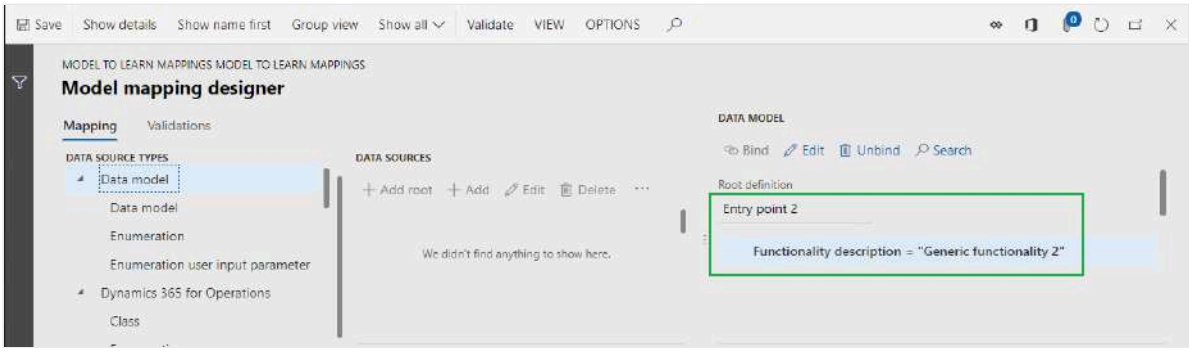
12. Select **Designer**.

13. In the **Data model** section, select **Edit**.

14. In the **Formula** field, enter **"Generic functionality 2"**.

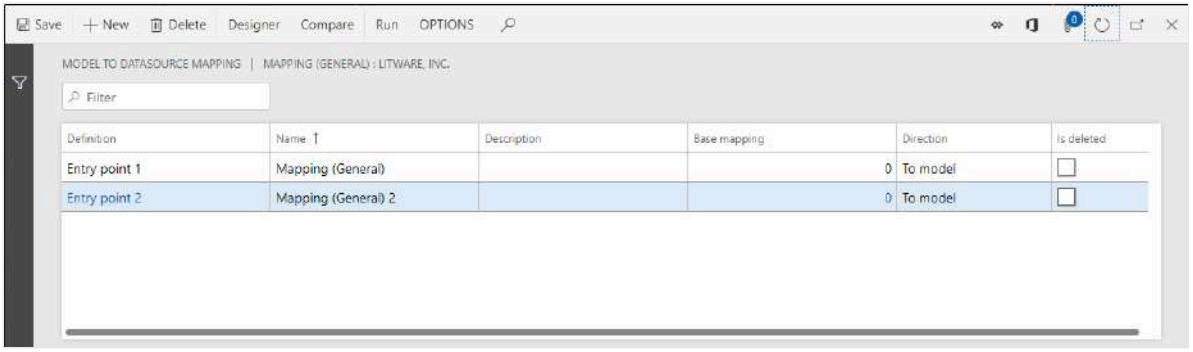
15. Select **Save**.

16. Close the **Formula designer**.



17. Select **Save**.

18. Close the **Model mapping designer**.



19. Close the **Model mappings**.

Complete the modified version of the model mapping configuration

1. On **Configurations**, on the **Versions** FastTab, select **Change status**.

   > Change the status of designed model mapping configuration from **Draft** to **Completed**, so that ER formats can use it.

2. Select **Complete**.

3. Select **OK**.

The configuration is saved as completed version 1.

Configure a sample format

Create an ER format configuration

1. On **Configurations**, in the configurations tree, select **Model to learn mappings**.
2. Select **Create configuration**.
3. In the drop-down dialog box, in the **New** field group, select **Format based on data model Model to learn mappings**.
4. In the **Name** field, enter **Format to learn mappings**.

5. In the **Data model definition** field, select **Entry point 1**.
6. Select **Create configuration**.

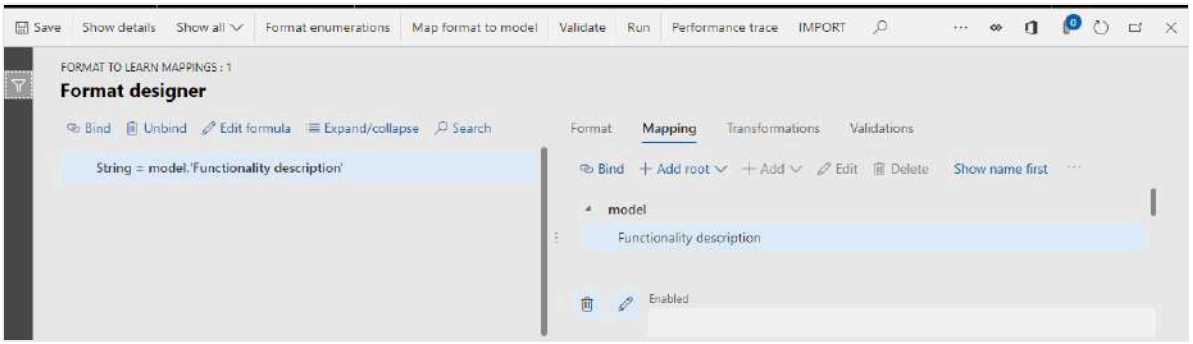
Draft version 1 of this ER configuration is ready for editing. This version contains the format component.

Design a sample format

1. On **Configurations**, select **Designer**.
2. Select **Add root**.
3. In the **Text** group, select the **String** item.
4. Select **OK**.

Bind format elements to a data source

1. On **Format designer**, on the **Mapping** tab, expand the model data source.
2. Select the **Functionality description** field.
3. Select **Bind**.



4. Select **Save**.
5. Close the page.

Appendix 2

Configure a sample model mapping for general customization

You might want to customize a model mapping that a configuration provider (partner) provided to you, and then use the customized version as a data source for your ER formats. In this case, you must create a custom ER model mapping configuration to make the required changes in existing model mappings. The procedures in this appendix use the **Mapping (General)** model mapping as an example.

Create an ER model mapping configuration

1. On the **Configurations** page, in the configurations tree, select **Mapping (General)**.
2. Select **Create configuration**.
3. In the drop-down dialog box, in the **New** field group, select **Derive from Name: Mapping (General), Litware, Inc.**.
4. In the **Name** field, enter **Mapping (General) custom**.
5. Select **Create configuration**.

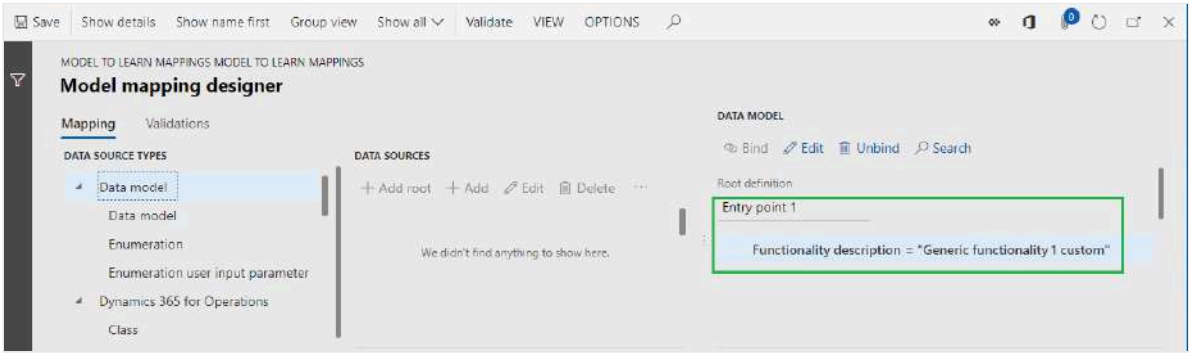
Draft version 1 of this ER configuration is ready for editing.

Design a sample model mapping

1. On **Configurations**, select **Designer**.

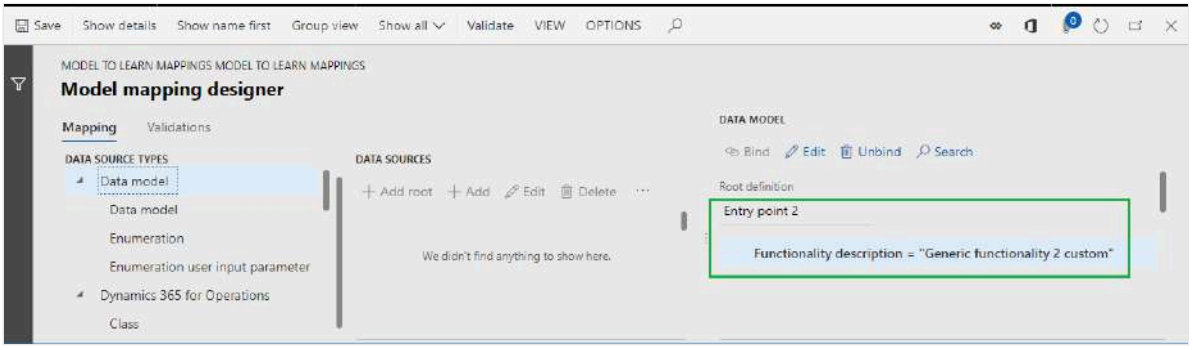
   > The model mappings of the base configuration are automatically copied to this configuration.

2. Select the **Mapping (General) Copy** mapping.
3. Select **Designer**.
4. In the **Data model** section, select **Edit**.
5. In the **Formula** field, enter **"Generic functionality 1 custom"**.
6. Select **Save**.
7. Close the page.

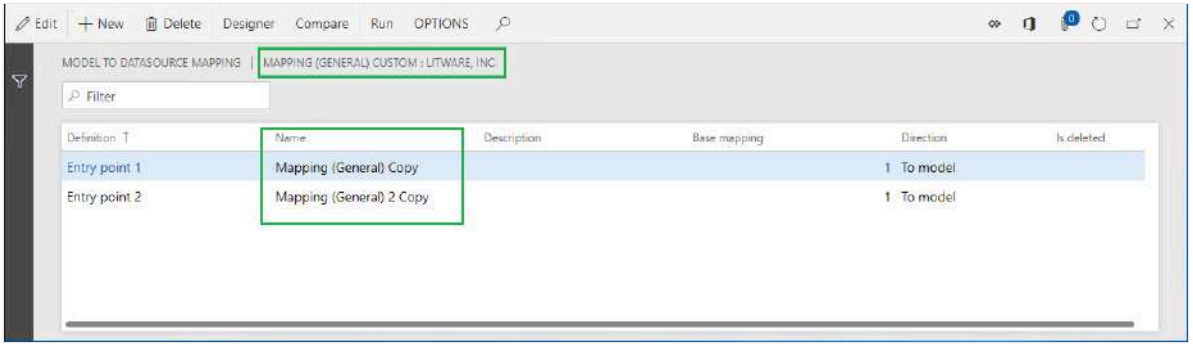


8. Select **Save**.
9. Close the page.
10. Select the **Mapping (General) 2 Copy** mapping.
11. Select **Designer**.

12. In the **Data model** section, select **Edit**.
13. In the **Formula** field, enter **"Generic functionality 2 custom"**.
14. Select **Save**.
15. Close the page.



16. Select **Save**.
17. Close the page.



18. Close the page.

Complete the modified version of the model mapping configuration

1. On **Configurations**, on the **Versions** FastTab, select **Change status**.

   > Change the status of designed model mapping configuration from **Draft** to **Completed**, so that ER formats can use it.

2. Select **Complete**.
3. Select **OK**.

The configuration is saved as completed version 1.

Appendix 3

Configure a sample model mapping for country/region-specific customization

For some ER formats, country/region-specific requirements exist for data preparation. In this case, manage a separate ER model mapping configuration to isolate the implementation of these country/region-specific requirements from the general implementation. The procedures in this appendix use the **Format to learn mappings** ER format and French-specific requirements as an example.

Create an ER model mapping configuration

First, create a new ER model mapping configuration to implement the country/region-specific requirements. Use your custom ER model mapping configuration as a base.

1. On **Configurations**, in the configurations tree, select **Mapping (General) custom**.
2. Select **Create configuration**.
3. In the drop-down dialog box, in the **New** field group, select **Derive from Name: Mapping (General) custom, Litware, Inc**.
4. In the **Name** field, enter **Mapping (FR)**.
5. Select **Create configuration**.

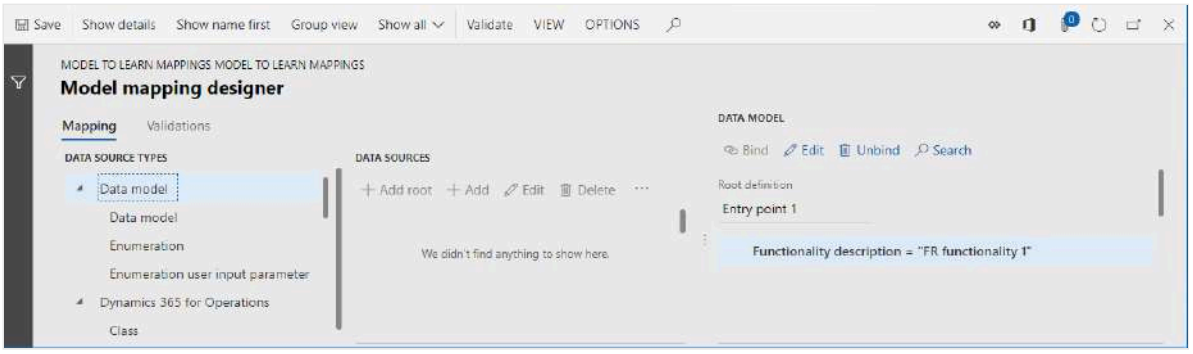
Draft version 1 of this ER configuration is ready for editing.

Design a sample model mapping

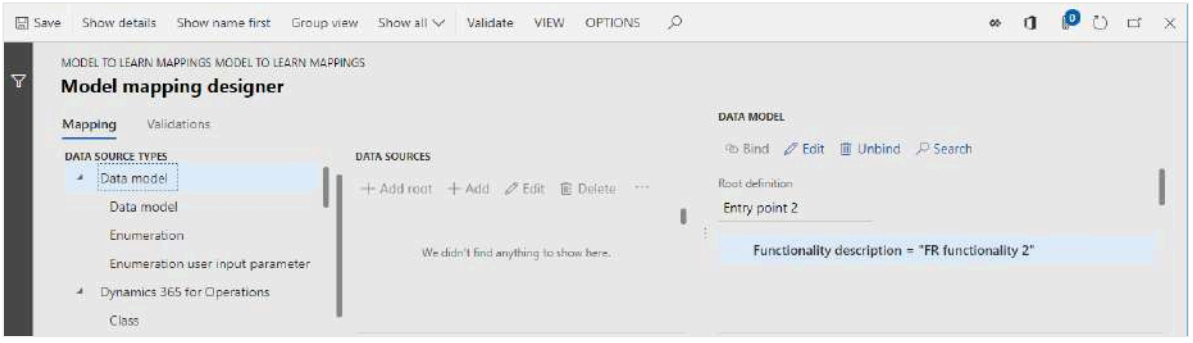
1. On **Configurations**, select **Designer**.

   > Model mappings of the base configuration are automatically copied to this configuration.

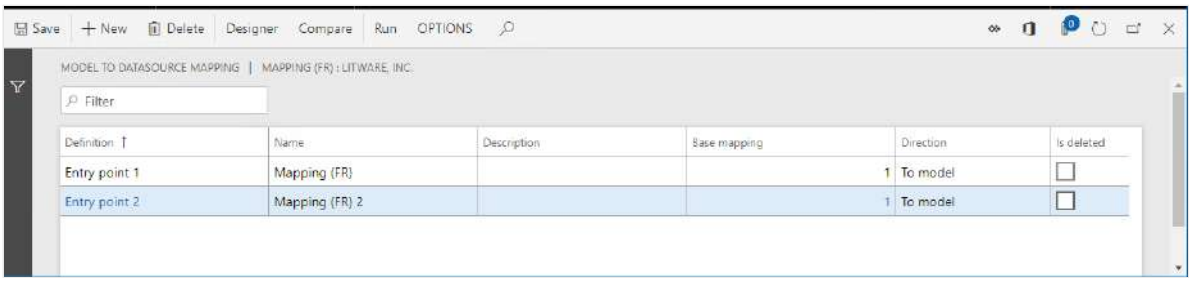
2. Select the **Mapping (General) Copy Copy** mapping.
3. Rename it **Mapping (FR)**.
4. Select **Designer**.
5. In the **Data model** section, select **Edit**.
6. In the **Formula** field, enter **"FR functionality 1"**.
7. Select **Save**.
8. Close the page.



9. Select **Save**.
10. Close the page.
11. Select the **Mapping (General) 2 Copy Copy** mapping.
12. Rename it **Mapping (FR) 2**.
13. Select **Designer**.
14. In the **Data model** section, select **Edit**.
15. In the **Formula** field, enter **"FR functionality 2"**.
16. Select **Save**.
17. Close the page.



18. Select **Save**.
19. Close the page.



20. Close the page.

Specify country/region context restrictions for use

1. On **Configurations**, on the **ISO Country/region codes** FastTab, select **New**.
2. In the **ISO** field, select **FR**.
3. Select **Save**.

You must sign in to a specific company in Finance to run an ER format. Therefore, this company controls both ER format execution and selection of the correct ER model mapping of the base ER data model. By adding the **FR** country code, you specify that this model mapping is available for selection by an ER format of the base data model only when that format runs under the control of a company that has French country/region context.

You can add multiple country/region codes for a single version of an ER model mapping configuration. In this way, model mappings that reside in that model mapping configuration can be used for an ER format that runs under the control of companies that have a different country/region context.

The list of country/region codes can vary between versions. Each version of an ER model mapping configuration specifies its own list.

Complete the modified version of the model mapping configuration

1. On **Configurations**, on the **Versions** FastTab, select **Change status**.

   > Change the status of designed model mapping configuration from **Draft** to **Completed**, so that ER formats can use it.

2. Select **Complete**.
3. Select **OK**.

The configuration is saved as completed version 1.

Electronic reporting (ER) overview

Manage ER model mapping in separate ER configurations

Apply country/region context

Frequently asked questions

I configured two shared ER model mapping configurations in RCS and marked one of them as the default model mapping configuration. I successfully ran an ER format that was created for the same base ER data model configuration, to test model mappings. I then imported the whole ER solution (ER data model, two ER model mapping configurations, and ER format configuration) into Finance. Why do I receive an error message when I try to run the same ER format in Finance?

The default model mapping setting is environment-specific. You configure it in RCS but it isn't exported to Finance. To successfully run this ER format, you must mark one of ER model mapping configurations as the default model mapping configuration in Finance too.

I configured one model mapping as a shared model mapping and completed the draft version of it. I then added a new model mapping configuration for same data model and configured it as French-specific. Why is the shared model mapping selected when I run an ER format, even though this ER format uses the correct root definition and execution is done under the control of the company that has French country/region context?

Make sure that you don't mark the shared model mapping configuration as the default model mapping configuration. Otherwise, it has higher priority during mapping selection. Also make sure that the French-specific model mapping configuration is considered when a mapping is selected during ER format execution. An ER model mapping configuration is available for selection only if at least one of the following conditions is met:

- At least one version of the ER model mapping configuration has either **Completed** or **Shared** status. In this case, the version that has the highest version number is used for ER format execution.
- The **Run draft** option for the ER model mapping configuration is turned on. In this case, the version that has **Draft** status is used for ER format execution.

> The **Run draft** option becomes available on the **Configurations** page for each ER model mapping configuration when the **Run setting** ER user parameter is turned on.

Manage ER model mapping in separate ER configurations

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user assigned to the System administrator or Electronic reporting developer role can manage Electronic reporting (ER) model mappings in separate ER configurations. In this task guide, you create required ER configurations for the sample company, Litware, Inc. To complete this task guide, you must first complete the steps in the Create configuration providers and mark them as active article.

Because ER configurations are shared among companies, you can complete this task guide using the company data set of your choice. The functionality for this task guide is available if you install one of the following hotfixes: https://fix.lcs.dynamics.com/Issue/Resolved?kb=4012872 for the Dynamics AX 7.0 version or https://fix.lcs.dynamics.com/Issue/Resolved?kb=4012871 for the Dynamics 365 for Operations version.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

    - Verify that the configuration provider for the sample company Litware, Inc. is available and marked as active. If you don't see this configuration provider, you must first complete the steps in the task guide, Create a configuration provider, and mark it as active.

Add a new ER model configuration

1. Select **Reporting configurations**.

    - Add a new model configuration. The name must be unique in the configurations tree.

2. Select **Create configuration** to open the form.
3. In the **Name** field, type *Sample data model*.

    - Sample data model

4. Select **Create configuration**.

5. Select **Designer**.
6. Select **New** to open the form.
7. In the **Name** field, type *Root*.

    - Root

8. Select **Add**.
9. Select **New** to open the form.
10. In the **Name** field, type *Company*.

    - Company

11. Select **Add**.
12. In the **Description** field, enter the text, *Description of the legal entity or company in which a user logged at run-time*.

    - Description of the legal entity or company in which a user logged at run-time.

13. Select **Root reference**.
14. Select **OK**.
15. Select **Save**.
16. Close the page.
17. Select **Change status**.
18. Select **Complete**.
19. Select **OK**.

Add a new ER model-mapping configuration

1. Select **Create configuration** to open the form.
2. In the **New** field, enter *Model Mapping based on data model Sample data model*.
3. In the **Name** field, type *Sample mapping*.

    - Sample mapping

4. Select **Create configuration**.
5. Expand the **Prerequisites** section.

    - The **Implementations prerequisites** group is added automatically. The group contains the prerequisite component that refers to the parent data model configuration and is marked as **Implementation**. This status means that the **Sample mapping** model-mapping configuration is considered the implementation of the data model, **Sample data model**. Therefore, this component forces ER to download the model-mapping configuration, **Sample mapping** from an ER repository when the model configuration, **Sample data model**, is downloaded.

6. Select **Designer**.

    - The created model-mapping configuration contains a new blank mapping with the same name as the created configuration. When a selected parent model configuration contains model mappings, they are copied to a new model-mapping configuration.

7. Select **Designer**.
8. In the tree, select *Dynamics 365 for Operations\Table*.
9. Select **Add root**.
10. In the **Name** field, type *Company*.

    - Company

11. In the **Table** field, type *CompanyInfo*.

    - CompanyInfo

12. Select **OK**.
13. In the tree, expand *Company*.
14. In the tree, expand *Company\find()*.
15. In the tree, select *Company\find()\Name*.
16. Select **Bind**.
17. Select **Save**.
18. Close the page.
19. Close the page.
20. On the Action Pane, select **Configurations**.
21. Select **User parameters**.
22. Select **Yes** in the **Run settings** field.
23. Select **OK**.
24. Select **Edit**.
25. Select **Yes** in the **Run Draft** field.

Add a new ER format configuration

1. In the tree, select **Sample data model**.
2. Select **Create configuration** to open the form.
3. In the **New** field, enter `Format based on data model Sample data model`.
4. In the **Name** field, type `Sample format`.

    - Sample format

5. Select **Create configuration**.

6. Select **Designer**.
7. Select **Add root** to open the **Drop** dialog.
8. In the tree, select `Text\String`.
9. Select **OK**.
10. Select the **Mapping** tab.
11. In the tree, expand `model`.
12. In the tree, select `model\Company`.
13. Select **Bind**.
14. Select **Save**.
15. Close the page.

    - Run the draft version of the created format for testing purposes.

16. Select **Run**.

    - On the **Versions** FastTab, select **Run**.

17. Select **OK**.

    - Review the output that contains the name of the company in which the user who is running this format configuration is logged into. The created model-mapping configuration is used by this format configuration because there's only one configuration available that contains required model mappings.

Add alternative ER model-mapping configuration

1. In the tree, select **Sample data model**.
2. Select **Create configuration** to open the form.
3. In the **New** field, enter *Model Mapping based on data model Sample data model*.
4. In the **Name** field, type *Sample mapping (alternative)*.

    - Sample mapping (alternative)

5. Select **Create configuration**.
6. Select **Designer**.
7. Select **Designer**.
8. In the tree, select *Dynamics 365 for Operations\Table*.
9. Select **Add root**.
10. In the **Name** field, type *Company*.

    - Company

11. In the **Table** field, type *CompanyInfo*.

- CompanyInfo

12. Select **OK**.
13. Select **Edit**.
14. In the tree, select **String\CONCATENATE**.
15. Select **Add function**.
16. In the tree, expand *Company*.
17. In the tree, expand *Company\find()*.
18. In the tree, select *Company\find()\Name*.
19. Select **Add data source**.
20. In the **Formula** field, type a value.

    - `CONCATENATE(Company.'find()'.Name, ";",`

21. In the tree, select **Company\find()\Company(DataArea)**.
22. Select **Add data source**.
23. In the **Formula** field, type a value.

    - `CONCATENATE(Company.'find()'.Name, ";", Company.'find()'.DataArea)`

24. Select **Save**.
25. Close the page.
26. Select **Save**.
27. Close the page.
28. Close the page.
29. Select **Yes** in the **Run Draft** field.

Use an existing ER model-mapping configuration

1. In the tree, select `Sample data model\Sample format`.
2. Select **Run**.

    - You can't run the selected draft version of the ER format configuration because more than one model-mapping configuration exists for the undefined data model that is selected as the data source of the running ER format.
    - Next, you need to define the alternative model-mapping configuration as the one from which model mappings are used as data sources for running ER format.

3. In the tree, select `Sample data model\Sample mapping (alternative)`.
4. Select **Yes** in the **Default for model-mapping** field.
5. In the tree, select `Sample data model\Sample format`.
6. Select **Run**.
7. Select **OK**.

- This format configuration uses the default model-mapping configuration to generate the electronic document. The created output contains the company code.

Manage several derived mappings for a single model root

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use an Electronic reporting (ER) data model component as the data source in every configured ER format component to generate outbound documents. To describe a single business domain, configure a data model component that has many root definitions.

Each root definition lets you represent data of that domain in the way that best suits specific reporting purposes. For every root definition, you can configure an ER model mapping component as the Microsoft Dynamics 365 Finance–specific implementation of your data model. In this way, you describe how your data model is filled in at runtime.

ER model mapping components can reside in ER data model configurations and ER model mapping configurations. A single ER configuration can contain many mapping components, each of which is configured for a single root definition. Alternatively, a single ER configuration can contain just one mapping component that is configured for a single root definition.

Many configuration providers might offer ER model mapping configurations for the same ER data model. Those model mapping configurations might contain mapping components for different root definitions. You might use a model mapping for one root definition that one provider offers and use a model mapping for another root definition that another provider offers.

The procedures in this article explain how to manage multiple ER model mapping configurations of an ER data model when they contain different model mapping components configured for the same root definition.

To complete the procedures in this article, you must be assigned to the System administrator or Electronic reporting developer role.

You can perform all the following procedures in the USMF company. No coding is required.

Configure the ER framework

As a user in the Electronic reporting developer role, configure the minimal set of ER parameters before you use the ER framework to generate business documents.

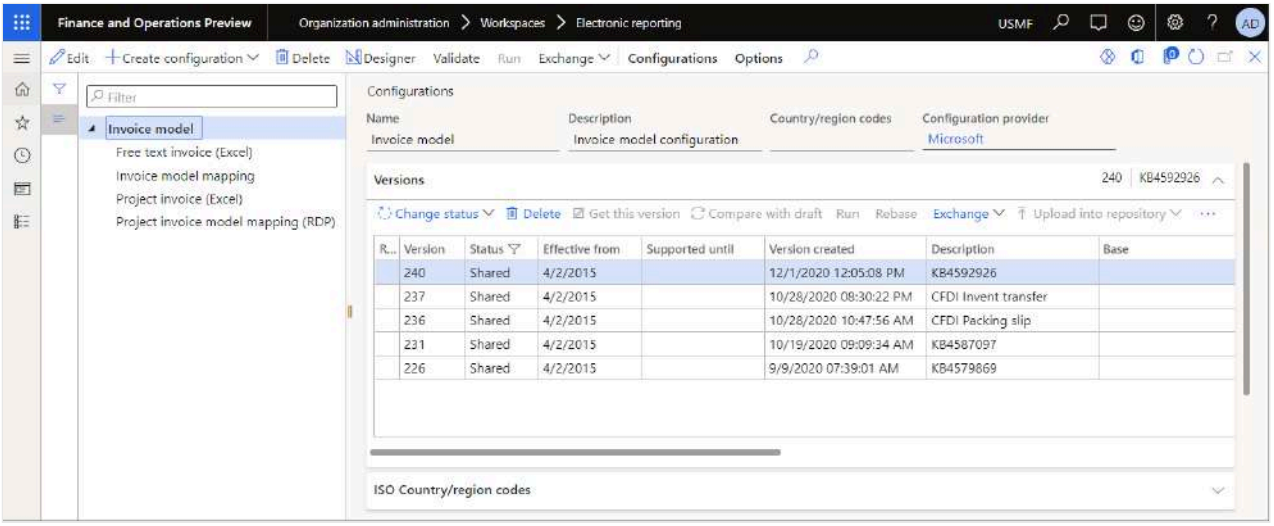
Import the standard ER format configurations

To add the standard ER configurations to your current instance of Finance, import them from the ER repository that you configured for that instance. Follow the steps in Download ER configurations from the Global repository of Configuration service to import the following ER format configurations:

- **Free text invoice (Excel)**, version 220.106
- **Project invoice (Excel)**, version 226.27

Review the imported ER configurations

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configurations** section, select the **Reporting configurations** tile.
3. On **Configurations**, in the configuration tree in the left pane, expand **Invoice model**.



4. Review the **Free text invoice (Excel)** format:

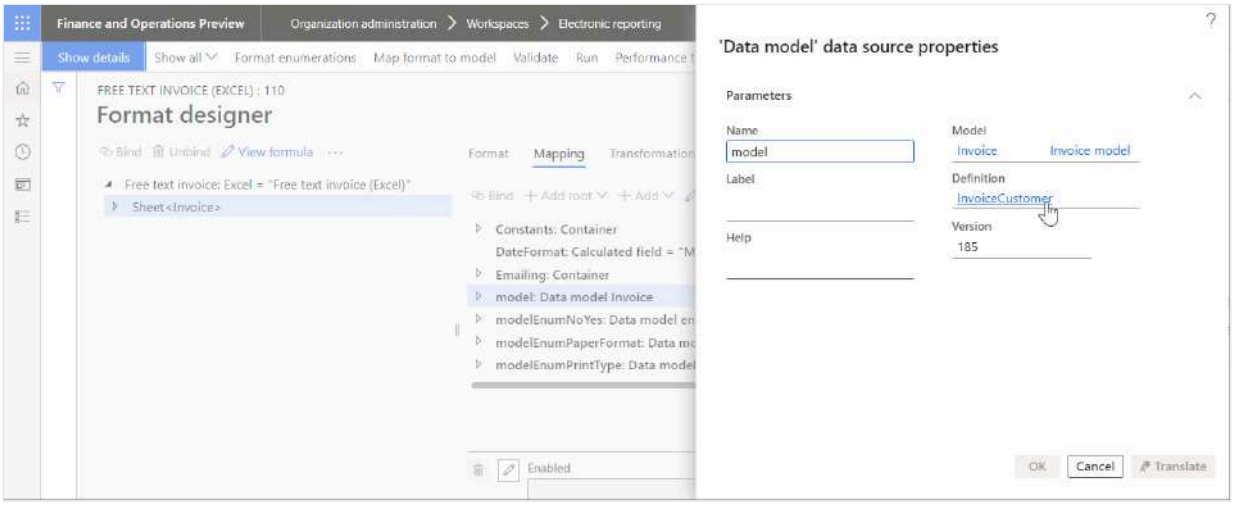
   a. In the configuration tree in the left pane, select **Free text invoice (Excel)**.

b. On the Action Pane, select **Designer**.

c. On **Format designer**, on the **Mapping** tab, in the data sources list, select **Model**.

d. Select **View**.

The current ER format is configured to use the **InvoiceCustomer** root definition of **Invoice model**. When you run this format and call the **Model** data source, the model mapping that you configured for the **InvoiceCustomer** root definition is used to access application data and fill in the data model.



e. Close **Format designer**.

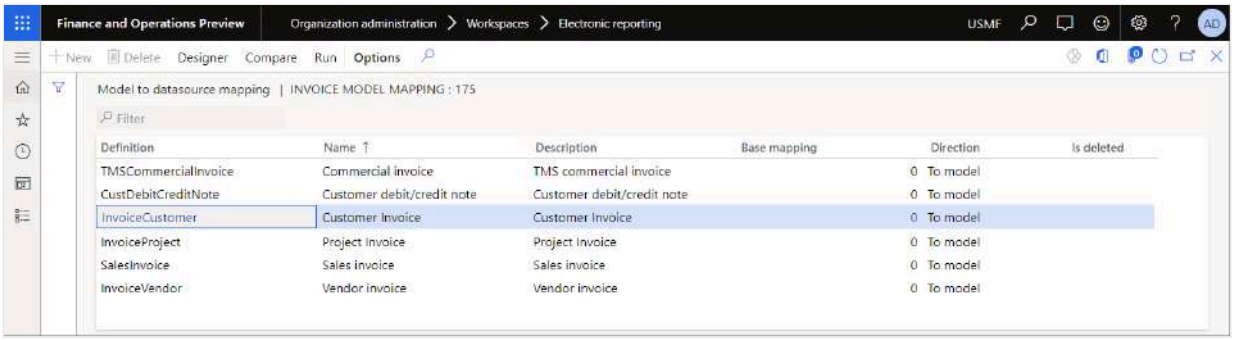
5. Review the content of the **Invoice model mapping** configuration:

a. In the configuration tree in the left pane, select **Invoice model mapping**.

b. On the Action Pane, select **Designer**.

c. On **Model to datasource mapping**, notice that the current ER model mapping configuration contains several model mapping components:

- The **Customer Invoice** model mapping is configured for the **InvoiceCustomer** root definition of **Invoice model**. Therefore, when you run the **Free text invoice (Excel)** ER format, you can choose the **Customer Invoice** model mapping of this ER configuration to access application data and fill in the data model.
- The **Project Invoice** model mapping is configured for the **InvoiceProject** root definition of **Invoice model**. Therefore, when you run the **Project invoice (Excel)** ER format, you can choose the **Project Invoice** model mapping of this ER configuration to access application data and fill in the data model.



d. Close **Model to datasource mapping**.

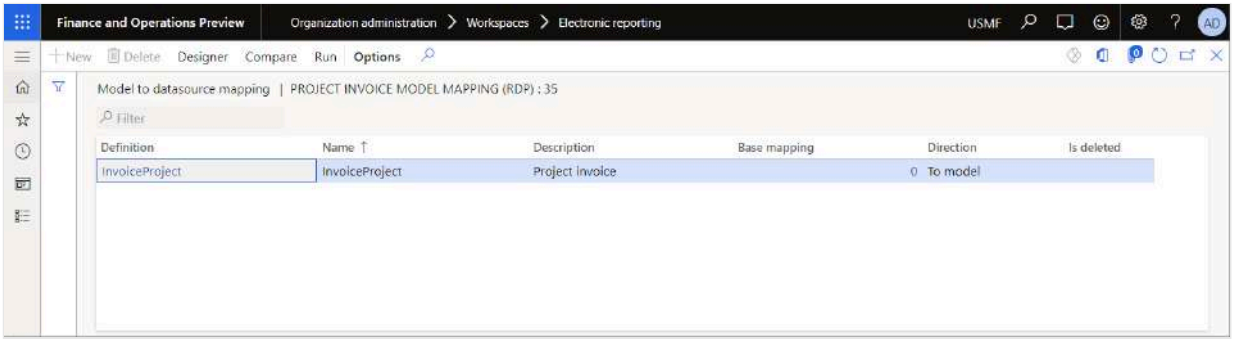
e. On the **Versions** FastTab, select **Delete** to delete all versions of this ER configuration that are later than version 240.175.

6. Review the content of the **Project invoice model mapping (RDP)** configuration:

a. In the configuration tree in the left pane, select **Project invoice model mapping (RDP)**.

b. On the Action Pane, select **Designer**.

c. On **Model to datasource mapping**, notice that the current ER model mapping configuration contains the **InvoiceProject** model mapping, and that this model mapping is configured for the **InvoiceProject** root definition of **Invoice model**. When you run the **Project invoice (Excel)** ER format, select the **InvoiceProject** model mapping of this ER configuration to access application data and fill in the data model.



d. Close **Model to datasource mapping**.

e. On the **Versions** FastTab, select **Delete** to delete all versions of this ER configuration that are later than version 226.35.

Customize the imported ER configurations

This section explains how to customize the model mappings that Microsoft provides. For example, you might need to customize the model mappings to implement your custom logic or add missing bindings.

Customize the Invoice model mapping configuration

1. On **Configurations**, in the configuration tree in the left pane, select **Invoice model mapping**.

2. On the action pane, select **Create configuration**.

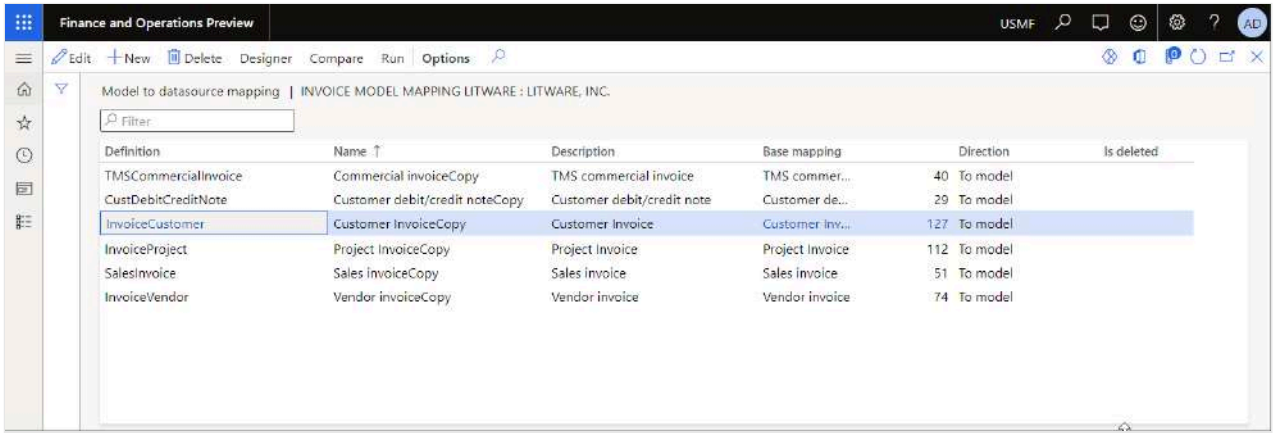
3. In **Create configuration**, select **Derive from Name: Invoice model mapping, Microsoft** in the **New** field.

4. Enter **Invoice model mapping Litware** in the **Name** field.

5. Select **Create configuration**.

6. Mark the draft version of the derived mapping as available for use at runtime:
   a. On the action pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
   b. In **User parameters**, set the **Run settings** option to **Yes**, and then select **OK**.
   c. Select **Edit** to make the page editable, as required.
   d. For the **Invoice model mapping Litware** configuration that you selected in the configuration tree, set the **Run Draft** option to **Yes**.

7. On the action pane, select **Designer** to review the model mappings of this configuration.

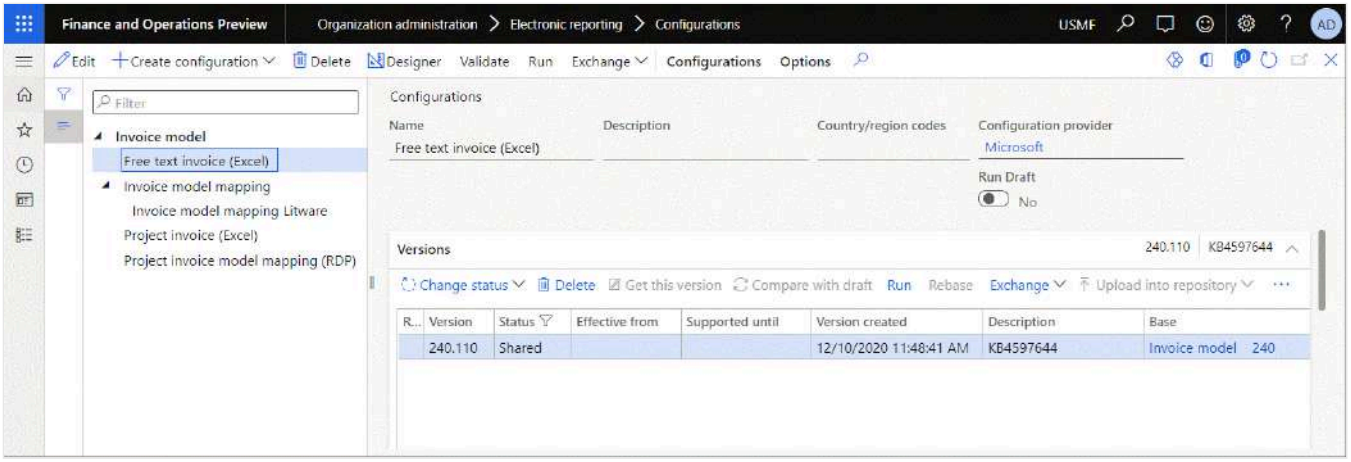


> **Tip**
>
> You can now open any of the ER model mapping components of this ER configuration in the designer to configure your custom logic. For more information, see Customize the model mapping configuration.

8. Close **Model to datasource mapping**.

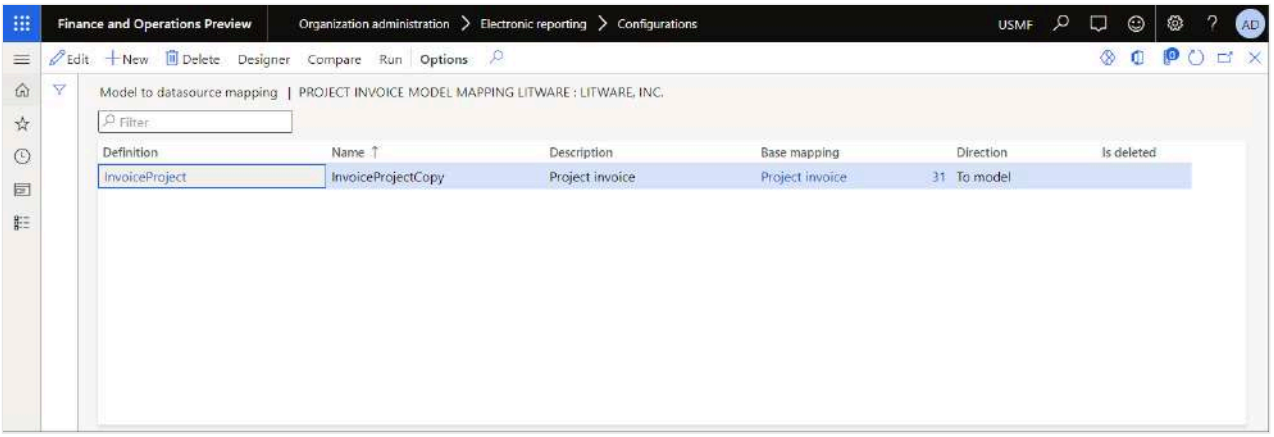
You now have **Invoice model mapping** and **Invoice model mapping Litware** configurations, each of which has a model mapping that is configured for the **InvoiceCustomer** root definition. Explicitly assign one of the model mappings as the default model mapping that any of the ER formats uses, such as the **Free text invoice (Excel)** format that contains a model data source that has the **InvoiceCustomer** root definition. Otherwise, when you run, edit, or validate one of the ER formats, the following exception is thrown to notify you that no default model mapping is explicitly assigned:

> More than one model mapping exists for the '<model name> (<root descriptor>)' data model in the configurations <configuration names separated by commas>. Set one of the configurations as default.



Customize the Project invoice model mapping (RDP) configuration

1. On **Configurations**, in the configuration tree in the left pane, select **Project invoice model mapping (RDP)**.
2. On the action pane, select **Create configuration**.
3. In **Create configuration**, in the **New** field, select **Derive from Name: Project invoice model mapping (RDP), Microsoft**.
4. In the **Name** field, enter **Project invoice model mapping Litware**.
5. Select **Create configuration**.
6. For the **Project invoice model mapping Litware** configuration that you selected in the configuration tree, set the **Run Draft** option to **Yes**.
7. On the action pane, select **Designer** to review the model mappings of this configuration.



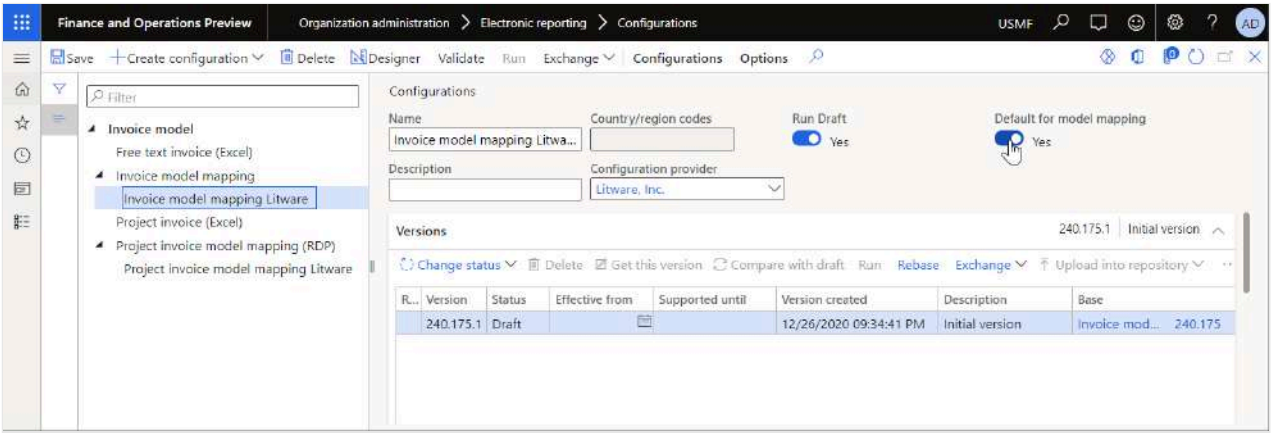
8. Close **Model to datasource mapping**.

You now have **Invoice model mapping**, **Project invoice model mapping (RDP)**, and **Project invoice model mapping Litware** configurations. Each of these configurations has a model mapping configured for the **InvoiceProject** root definition. You must explicitly assign one of the model mappings as the default model mapping that any of the ER formats uses. For example, use the **Project invoice (Excel)** format that contains a model data source that has the **InvoiceProject** root definition. Otherwise, when you run or edit one of the ER formats, an exception is thrown to notify you that no default model mapping is explicitly assigned.

Select the derived Invoice model mapping Litware configuration as the configuration that contains default model mappings

1. On **Configurations**, in the configuration tree in the left pane, select **Invoice model mapping Litware**.

2. Set the **Default for model mapping** option to **Yes**.



Because of this setting, the **Customer Invoice Copy** model mapping is used when you run the **Free text invoice (Excel)**, or when you edit or validate it. The **Customer invoice** model

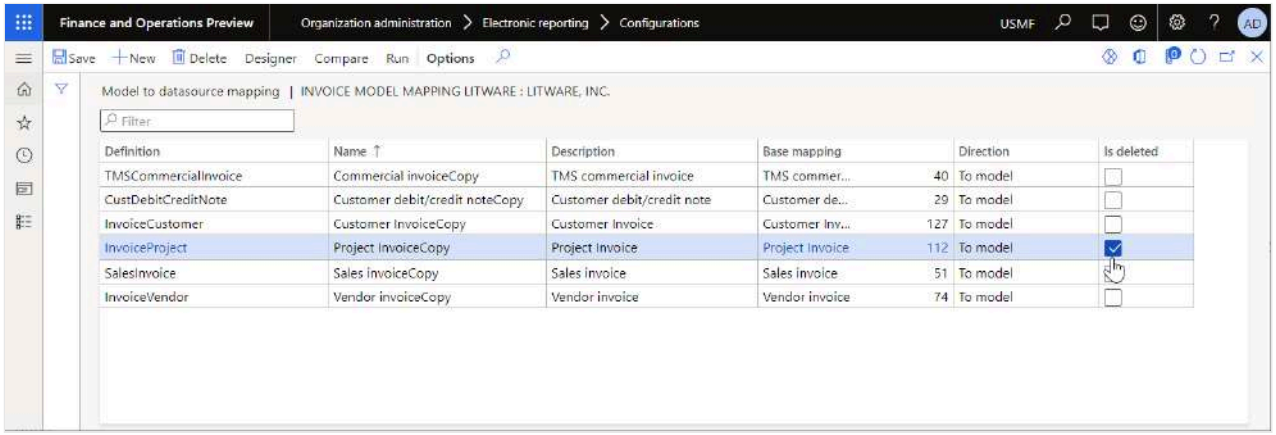
mapping from the **Invoice model mapping** configuration is ignored.

You can now open the **Free text invoice (Excel)** format for review in the format designer.

Select the derived Project invoice model mapping Litware configuration as the configuration that contains default model mappings

1. On **Configurations**, in the configuration tree in the left pane, select **Project invoice model mapping Litware**.
2. Set the **Default for model mapping** option to **Yes**.

   In this case, unlike the case that is described for the **Invoice model mapping Litware** configuration in the previous section, you can't start to use the **InvoiceProject Copy** model mapping from the **Project invoice model mapping Litware** configuration. Two configurations that contain a model mapping for the **InvoiceProject** root definition are currently marked as the default configuration. Therefore, they have equal priority for use. To resolve this issue, complete the remaining steps of this procedure.
3. In the configuration tree in the left pane, select **Invoice model mapping Litware**.
4. On the Action Pane, select **Designer**.
5. On the **Model to datasource mapping** page, select **Edit** to make the page editable, as required.
6. Select the **Project Invoice Copy** model mapping, and then select the **Is deleted** check box for it.



Because of this setting, the **Invoice model mapping Litware** configuration is treated as though it has no model mapping for the **InvoiceProject** root definition. The

InvoiceProject Copy model mapping is the default. The configuration, **Project invoice model mapping Litware**, which contains this model mapping, is marked as the default configuration. Because it is marked as default, it has a higher priority than the **InvoiceProject** model mapping from the **Project invoice model mapping (RDP)** configuration.

Other considerations

The **InvoiceProject Copy** model mapping of the **Project invoice model mapping Litware** configuration is designed to use the **ReportDataProvider** data source. The data source is part of the *Object* type that refers to the **PsaProjInvoiceDP** application class. This class is implemented as the data provider for the project invoice SQL Server Reporting Services (SSRS) report of the Print management framework. Select this data source as the ER integration point. The current ER implementation for Print management reports takes this setting into account. For more details, review the source code of the **ERPrintMgmtDataProviderReport** application class. At runtime, the assignment of the **ReportDataProvider** data source as the model mapping integration point forces Finance to treat this mapping component with a higher priority than the **InvoiceProject** mapping component from the **Project invoice model mapping (RDP)** configuration.

Select data model definitions when you create formats

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To complete the steps in this procedure, you must first complete the procedure, Create configuration providers and mark them as active.

This procedure shows how to select a model's root item as a data model definition for inserting an Electronic reporting (ER) format configuration that's designed to generate electronic documents. In this procedure, you add a new ER format configuration for the sample company Litware, Inc.

This procedure is intended for users who have the System administrator or Electronic reporting developer role assigned to them. You can complete the steps by using any dataset.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
    - Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure, Create configuration providers and mark them as active.
2. Select **Reporting configurations**.

Add a new ER data model configuration

1. Select **Create configuration** to open the **Drop** dialog.
    - Add a new ER model configuration containing a data model that is designed for use as a data source in generating ER reports.
2. In the **Name** field, enter `Payment model (fictitious)`.
    - Payment model (fictitious)
3. Select **Create configuration**.

4. Select **Designer**.

    - Open the ER designer to specify the structure of the data model for this configuration.
    - Design the data model for the payments business domain to support two payment methods – credit transfer and direct debit.

5. Select **New** to open the form.
6. In the **Name** field, enter `Payments – credit transfer`.

    - Payments – credit transfer

7. Select **Add**.
8. Select **New** to open the form.
9. In the **New node as a field**, enter `Model root`.
10. In the **Name** field, enter `Payments – direct debit`.

    - Payments – direct debit

11. Select **Add**.
12. Select **Save**.
13. Close the page.
14. Select **Change status**.

    - Complete the draft version of the model to make it available in new model mappings and formats.

15. Select **Complete**.
16. Select **OK**.

Start to enter a new ER format configuration

1. Select **Create configuration** to open the **Drop** dialog.
2. In the **New** field, enter *Format based on data model Payment model (fictitious)*.
3. In the **Data model definition** field, enter or select a value.

    - You can select any root item from the chosen data model as the data model definition. You can use any required root item from the data model to design your format. If a model mapping is missing for the selected root item, you can still continue.

4. Close the page.

Add a new ER model mapping configuration

1. Select **Create configuration** to open the **Drop** dialog.
2. In the **New** field, enter *Model Mapping based on data model Payment model (fictitious)*.
3. In the **Name** field, enter *Payment model mappings (fictitious)*.

    - Payment model mappings (fictitious)

4. In the **Data model definition** field, enter or select a value.
5. Select **Create configuration**.

Design ER model mappings

1. Select **Designer**.

    - Use the ER designer to specify the model mappings for the required root items.

2. Select **Designer**.

    - Simulate setting of selected model mapping for the selected model's root item.

3. In the tree, select `Dynamics 365 for Operations\Table records`.
4. Select **Add root**.
5. In the **Name** field, type `Ledger`.
6. In the **Table** field, type `LedgerJournalTrans`.

    - LedgerJournalTrans

7. Select **OK**.
8. Select **Save**.
9. Close the page.
10. Close the page.

Start to enter another new ER format configuration

1. In the tree, select `Payment model (fictitious)`.
2. Select **Create configuration** to open the **Drop** dialog.
3. In the **New** field, enter *Format based on data model Payment model (fictitious)*.
4. In the **Data model definition** field, enter or select a value.

    - Only one root item is available to map to the application data sources. When you add at least one model mapping, you can select only the model's root items that are

mapped to application data sources as a model definition while the ER format is added.

5. Close the page.

Configure ER formats to use parameters that are specified per legal entity

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Overview

In many of the Electronic reporting (ER) formats that you design, you must filter data by using a set of values that are specific to each legal entity of your instance (for example, a set of tax codes to filter tax transactions). Currently, when you configure this type of filtering in an ER format, you use values that depend on the legal entity (for example, tax codes) in expressions of the ER format to specify data filtering rules. Therefore, the ER format is legal entity–specific. To generate the required reports, you must create derived copies of the original ER format for each legal entity where you want to run the ER format. You must edit each derived ER format to add legal entity–specific values. You must rebase each derived ER format whenever the original (base) version is updated. You must export each derived ER format from a test environment and import it into a production environment when it must be deployed for production use. Maintenance of this type of configured ER solution is complex and time-consuming for several reasons:

- The more legal entities there are, the more ER format configurations you need to maintain.
- Maintenance of ER configurations requires that business users have ER knowledge.

By using the ER application-specific parameters feature, power users can configure data filtering in an ER format so that it's based on a set of abstract rules. They can configure this set of rules can to use the data sources available in an ER format. Business users can then specify real rules beyond the ER framework by using the user interface (UI) that is automatically generated based on the settings of the corresponding ER format and the current legal entity data that the ER format's dat asources can access. The set of rules specified for an ER format can be exported from the current legal entity of the Dynamics 365 Finance (Finance) instance. It can then be imported into another legal entity of either the same Finance instance or a different instance as a set of rules for the same ER format.

Prerequisites

To complete the examples in this article, you must have access to the instance of Regulatory Configuration Services (RCS) provisioned for the same tenant as Finance for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

You need to complete the steps in the Support parameterized calls of ER data sources of CALCULATED FIELD type article. If you completed those steps, you can skip the steps in the **Import ER configurations into RCS** section that follows.

Import ER configurations into RCS

Download and save the following ER configurations to your local device.

Expand table

Content description	File name
Sample **ER data model** configuration file	Model to learn parameterized calls.version.1.xml
Sample **ER metadata** configuration file	Metadata to learn parameterized calls.version.1.xml
Sample **ER model mapping** configuration file	Mapping to learn parameterized calls.version.1.1.xml
Sample **ER format** configuration	Format to learn parameterized calls.version.1.1.xml

Next, sign in to your RCS instance.

In this example, you create a configuration for the Litware, Inc sample company. Before you can complete this procedure, you must complete the steps in the Create a configuration provider and mark it as active article in RCS.

1. On the default dashboard, select **Electronic reporting**.
2. Select **Reporting configurations**.
3. Import the ER configurations that you downloaded earlier into RCS in the following order: data model, metadata, model mapping, and format. For each ER configuration, follow these steps:
   a. Select **Exchange**.
   b. Select **Load from XML file**.

c. Select **Browse** to select the file for the required ER configuration in XML format.
d. Select **OK**.

Review the ER solution provided.

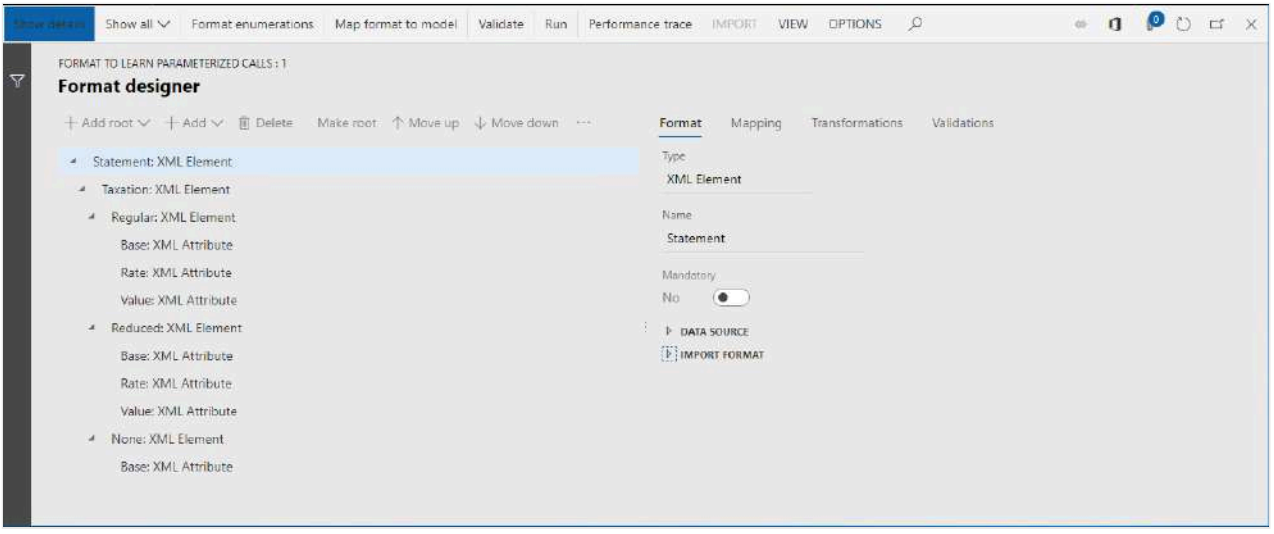
1. In the configuration tree, expand the contents of the **Model to learn parameterized calls** item.

2. Select the **Format to learn parameterized calls** item.

3. Select **Designer**.

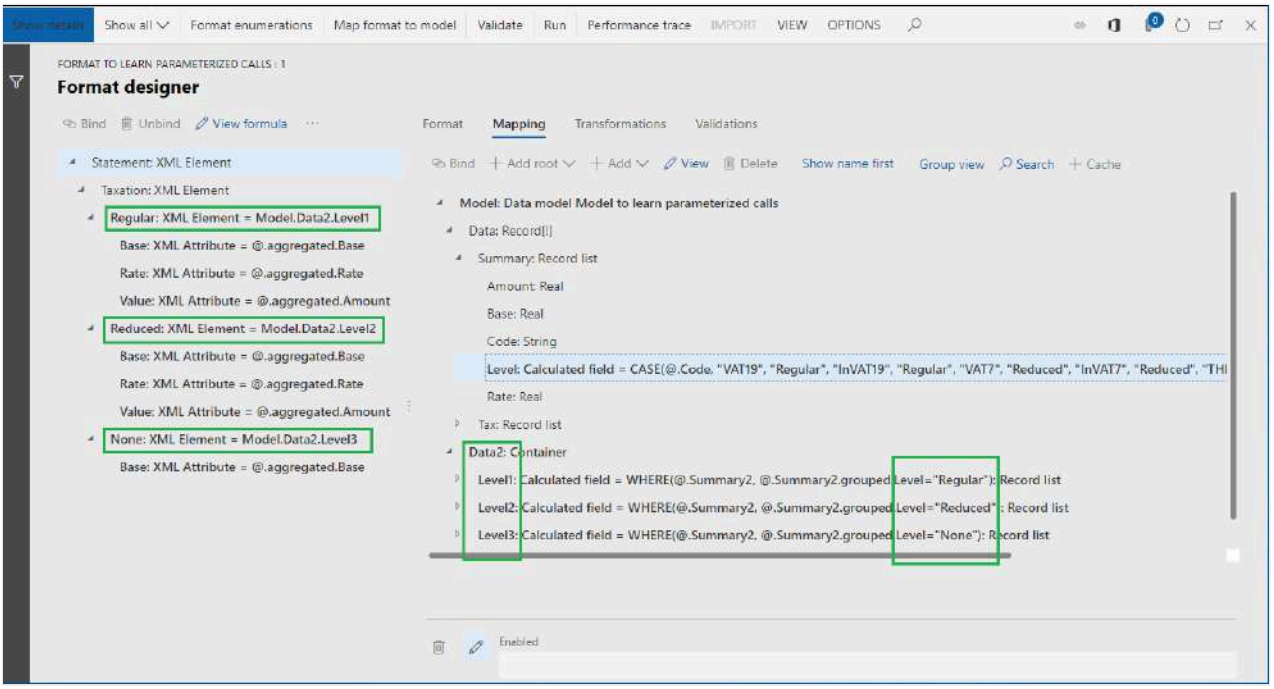
4. Select **Expand/Collapse**.

   The **Format to learn parameterized calls** ER format is designed to generate a tax statement in XML format that presents several levels of taxation (regular, reduced, and none). Each level has a different number of details.

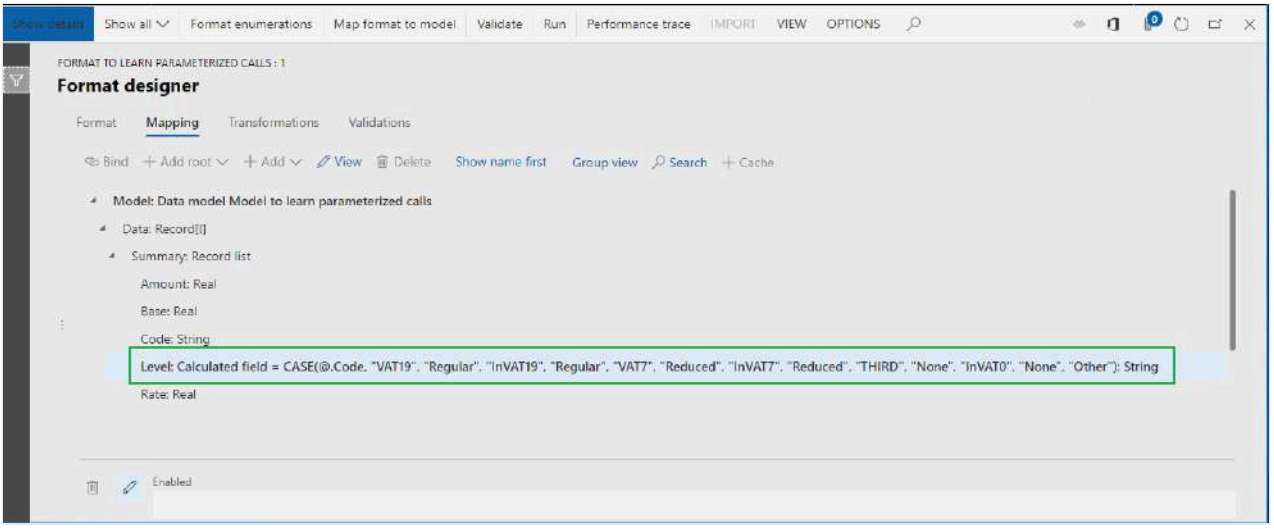


5. On the **Mapping** tab, expand the **Model**, **Data**, and **Summary** items.

   The **Model.Data.Summary** data source returns the list of tax transactions. These transactions are summarized by tax code. For this data source, the **Model.Data.Summary.Level** calculated field is configured to return the code for the taxation level of each summarized record. For any tax code retrieved from the **Model.Data.Summary** data source at runtime, the calculated field returns the taxation level code (**Regular**, **Reduced**, **None**, or **Other**) as a text value. The **Model.Data.Summary.Level** calculated field filters records of the **Model.Data.Summary** data source and enters the filtered data in each XML element that represents a taxation level by using the **Model.Data2.Level1**, **Model.Data2.Level2**, and **Model.Data2.Level3** fields.



The **Model.Data.Summary.Level** calculated field contains an ER expression. Tax codes (**VAT19**, **InVAT19**, **VAT7**, **InVAT7**, **THIRD**, and **InVAT0**) are hardcoded into this configuration. Therefore, this ER format depends on the legal entity where the tax codes were configured.



To support a different set of tax codes for each legal entity, you must follow these steps:

- Create a derived version of the ER format for each legal entity.
- Update the tax codes in the **Model.Data.Summary.Level** calculated field, based on the legal entity setting.

6. Close the **Format designer** page.

Create a derived format

Next, you will use the ER application-specific parameters feature to support a different set of tax codes for each legal entity in a single ER format.

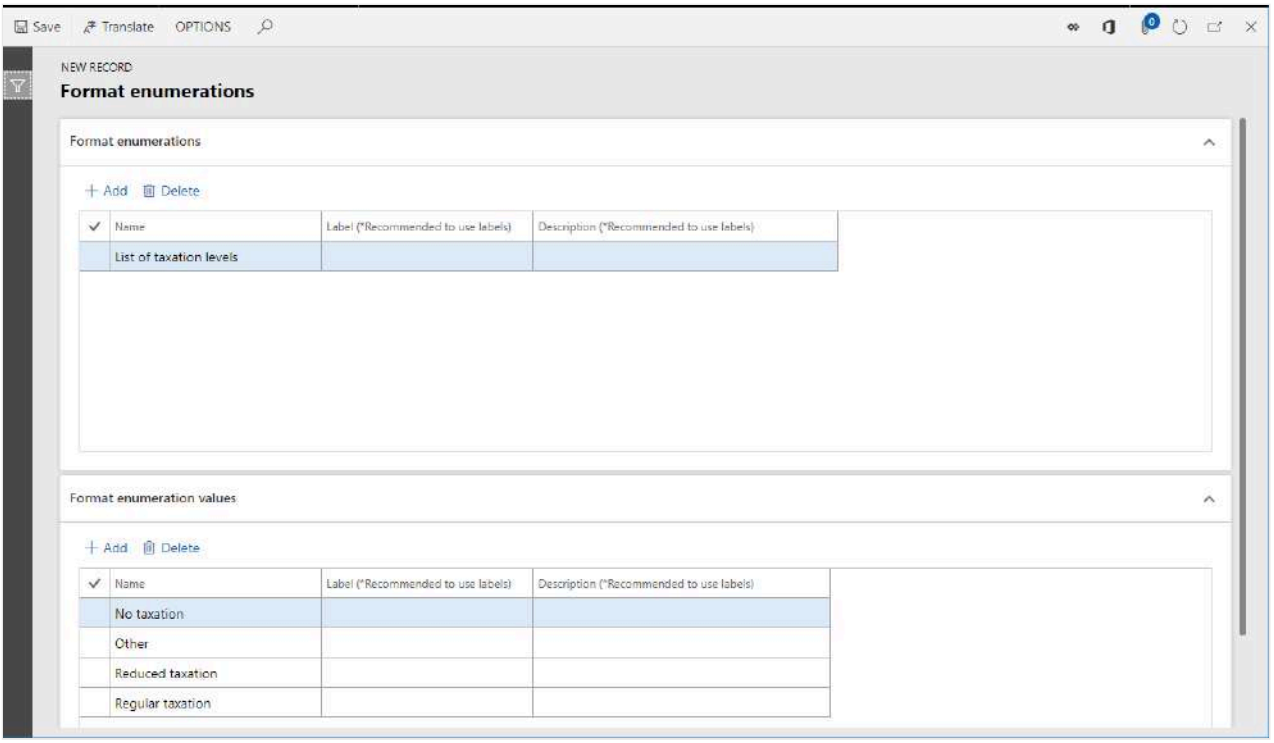
1. In the configuration tree, expand the contents of the **Model to learn parameterized calls** item.
2. Select the **Format to learn parameterized calls** item.
3. Select **Create configuration**.
4. Select the **Derive from Name: Format to learn parameterized calls, Microsoft** option.
5. In the **Name** field, enter **Format to learn how to lookup LE data**.
6. Select **Create configuration**.

Configure a derived format

Add a format enumeration

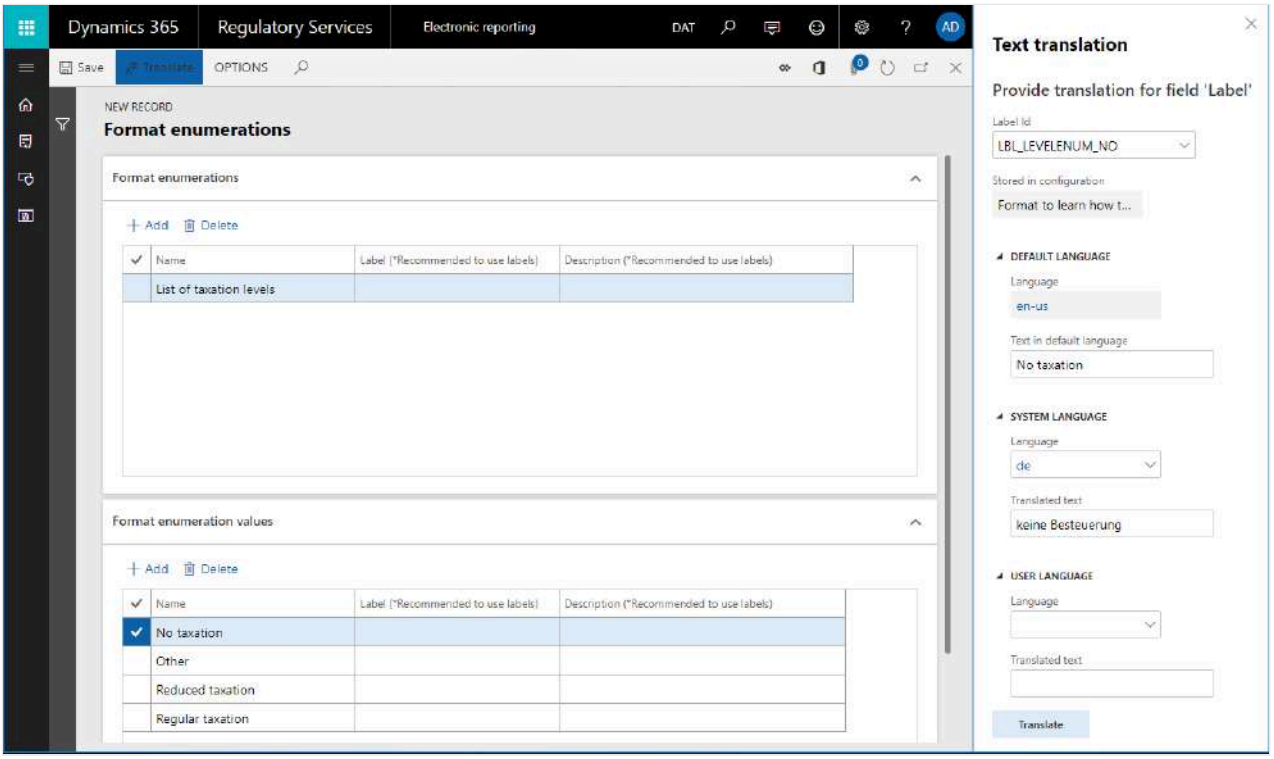
Next, add a new ER format enumeration. The values of this format enumeration are presented to business users so they can specify legal entity–dependent sets of tax codes for the various taxation levels that are used in the ER format.

1. Select **Designer**.
2. Select **Format enumerations**.
3. Select **Add**.
4. In the **Name** field, enter **List of taxation levels**.
5. Select **Save**.
6. On the **Format enumeration values** tab, select **Add**.
7. In the **Name** field, enter **Regular taxation**.
8. Select **Add** again.
9. In the **Name** field, enter **Reduced taxation**.
10. Select **Add** again.
11. In the **Name** field, enter **No taxation**.
12. Select **Add** again.
13. In the **Name** field, enter **Other**.



Because the business users might use different languages to specify legal entity–dependent sets of tax codes, we recommend that you translate the values of this enumeration into the languages that are configured as the preferred languages for those users in Finance.

14. Select the **No taxation** record.
15. Click in the **Label** field.
16. Select **Translate**.
17. In the **Text translation** pane, in the **Label ID** field, enter **LBL_LEVELENUM_NO**.
18. In the **Text in default language** field, enter **No taxation**.
19. Select **DE** in the **Language** field.
20. In the **Translated text** field, enter **keine Besteuerung**.
21. Select **Translate**.



22. Select **Save**.

23. Close the **Format enumerations** page.

Add a new lookup data source

Next, add a new data source to specify how business users can create legal entity–dependent rules to recognize the correct taxation level for each summarized transaction record.

1. On the **Mapping** tab, select **Add**.

2. Select **Format enumeration\Lookup**.

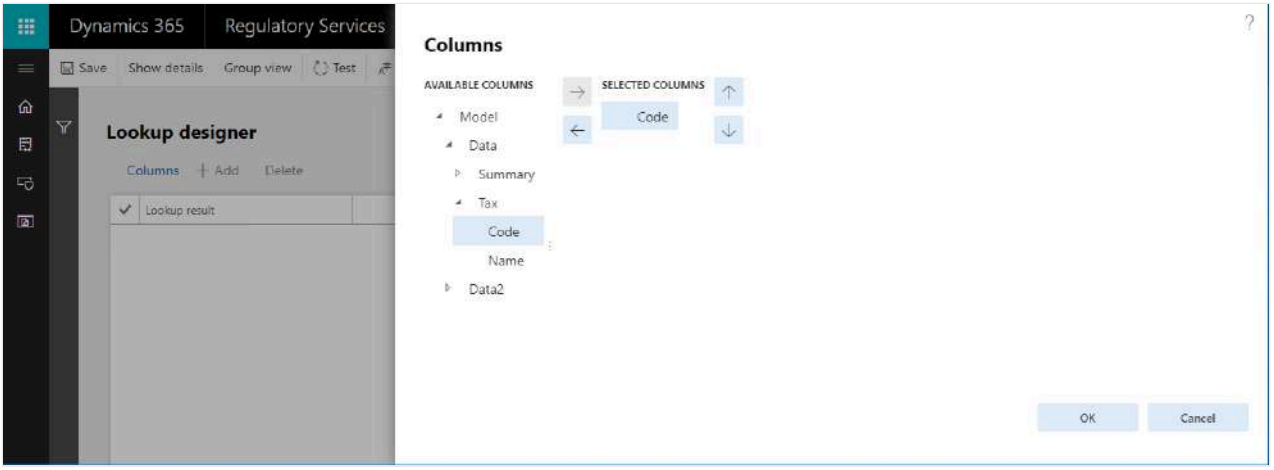
   You just identified that each rule business users specify for taxation level recognition returns a value of an ER format enumeration. Notice that the **Lookup** data source type can be accessed under the **Data model** and **Dynamics 365 for Operations** blocks in addition to the **Format enumeration** block. Therefore, you can use ER data model enumerations and application enumerations to specify the type of values returned for the data sources of that type. To learn more about the **Lookup** data sources, see Configure Lookup data sources to use the ER application-specific parameters feature.

3. In the **Name** field, enter **Selector**.

4. In the **Format enumeration** field, select **List of taxation levels**.

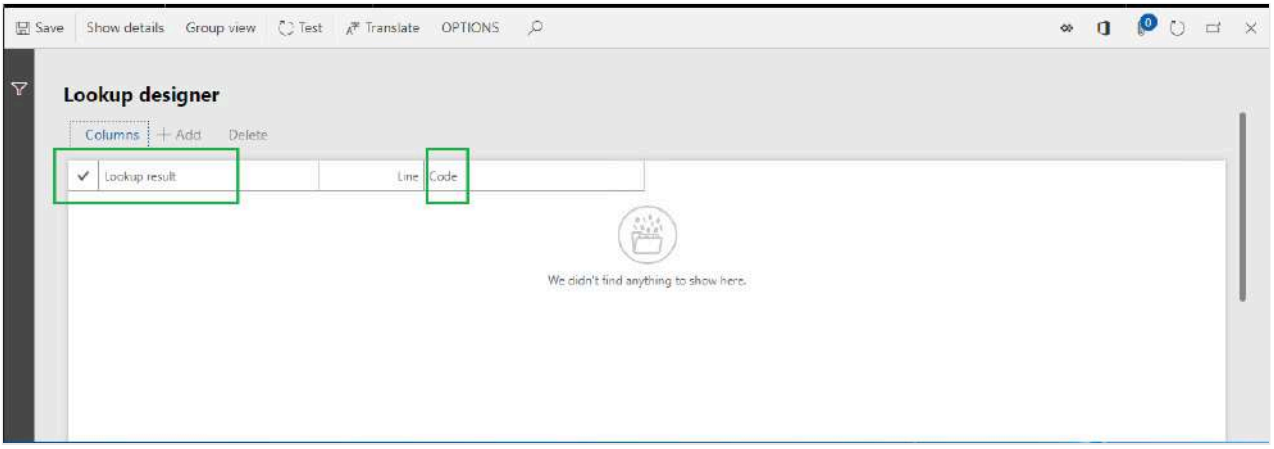
   You specified that for each rule in this data source, a business user must select one of the values of the **List of taxation levels** format enumeration as a returned value.

5. Select **Edit lookup**.
6. Select **Columns**.
7. Expand the **Model** item.
8. Expand the **Data** item.
9. Expand the **Tax** item.
10. Select the **Model.Data.Tax.Code** item.
11. Select the **Add** button (the right arrow).



You just specified that for each rule in this data source for taxation level recognition, a business user must select one of the tax codes as a condition. The **Model.Data.Tax** data source returns the list of tax codes that the business user can select. Because this data source contains the **Name** field, the name of the tax code appears for each tax code value in the lookup that is presented to the business user.

12. Select **OK**.



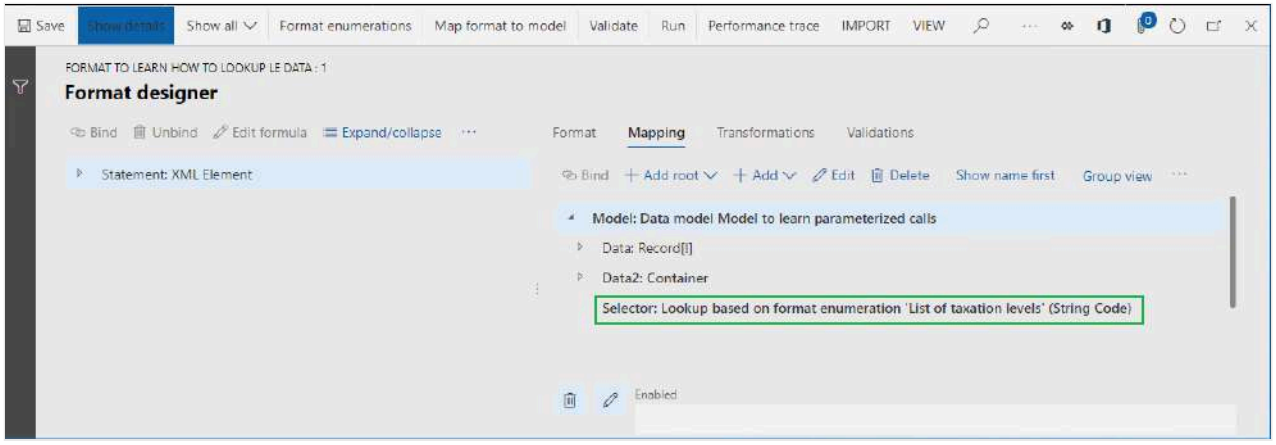
Business users can add multiple rules as records of this data source. Each record is numbered by a line code. Rules are evaluated in order of increasing line number.

Because you selected the **Tax code** field as a condition for rules in this lookup data source, and because **Tax code** is set up as a field of the **String** data type, each rule is evaluated at runtime by comparing the tax code that is passed to the data source with the tax code that is defined in this record of the data source.

When a rule that satisfies the configured condition is found, this data source returns the lookup value of the rule that is defined in the **Lookup result** field. If no rule is found, an exception is thrown to notify the user that the current data source can't return a correct value.

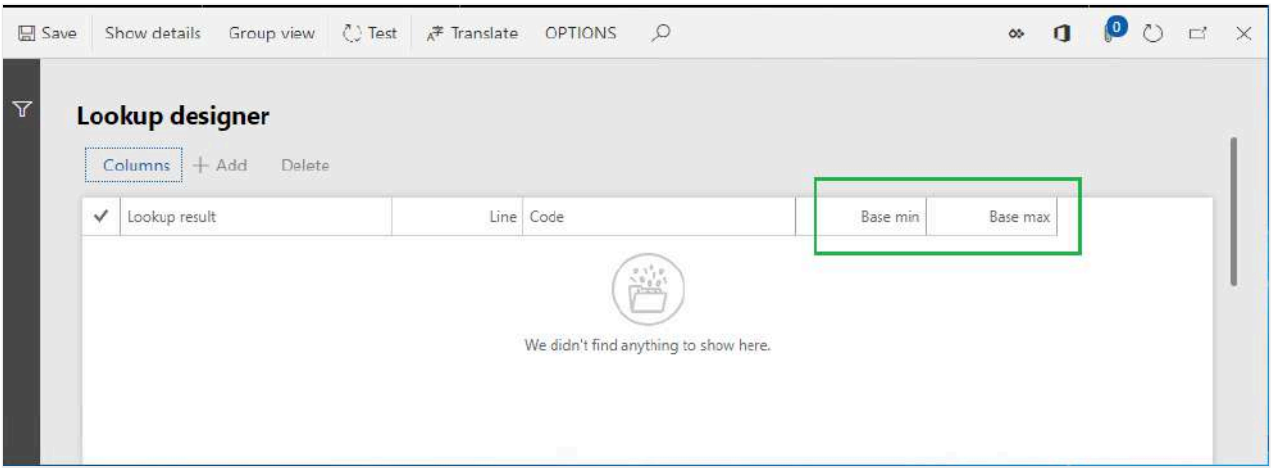
13. Select **Save**.
14. Close the **Lookup designer** page.
15. Select **OK**.

You added a new data source that returns the taxation level as the value of the **List of taxation levels** format enumeration for any tax code that is passed to the data source as the argument of the **Code** parameter of the **String** data type.



The evaluation of configured rules depends on the data type of the fields that you select to define conditions of those rules. When you select a field that is configured as a field of either the **Numeric** or **Date** data type, the criteria differ from the criteria described earlier for the **String** data type. For **Numeric** and **Date** fields, the rule must be specified as a range of values. The condition of the rule is considered satisfied when a value that is passed to the data source is in the configured range.

The following illustration shows an example of this type of setup. In addition to the **Model.Data.Tax.Code** field of the **String** data type, the **Model.Tax.Summary.Base** field of the **Real** data type is used to specify conditions for a lookup data source.



Because the **Model.Data.Tax.Code** and **Model.Tax.Summary.Base** fields are selected for this lookup data source, each rule of this data source is configured in the following way:

- In the list that is presented, select the value of the **List of taxation levels** format enumeration as a returned value.
- Enter the tax code as a condition of this rule. Only tax codes that the **Model.Data.Tax** data source provides are applicable.
- Enter minimum and maximum values of the tax base amount as conditions of this rule.

Here is how each rule of this data source will be evaluated at runtime:

- Does the code of the **String** data type that was passed to this data source equal the tax code of a rule?
- Does the value of the **Real** data type that was passed to this data source fall between specific minimum and maximum values?

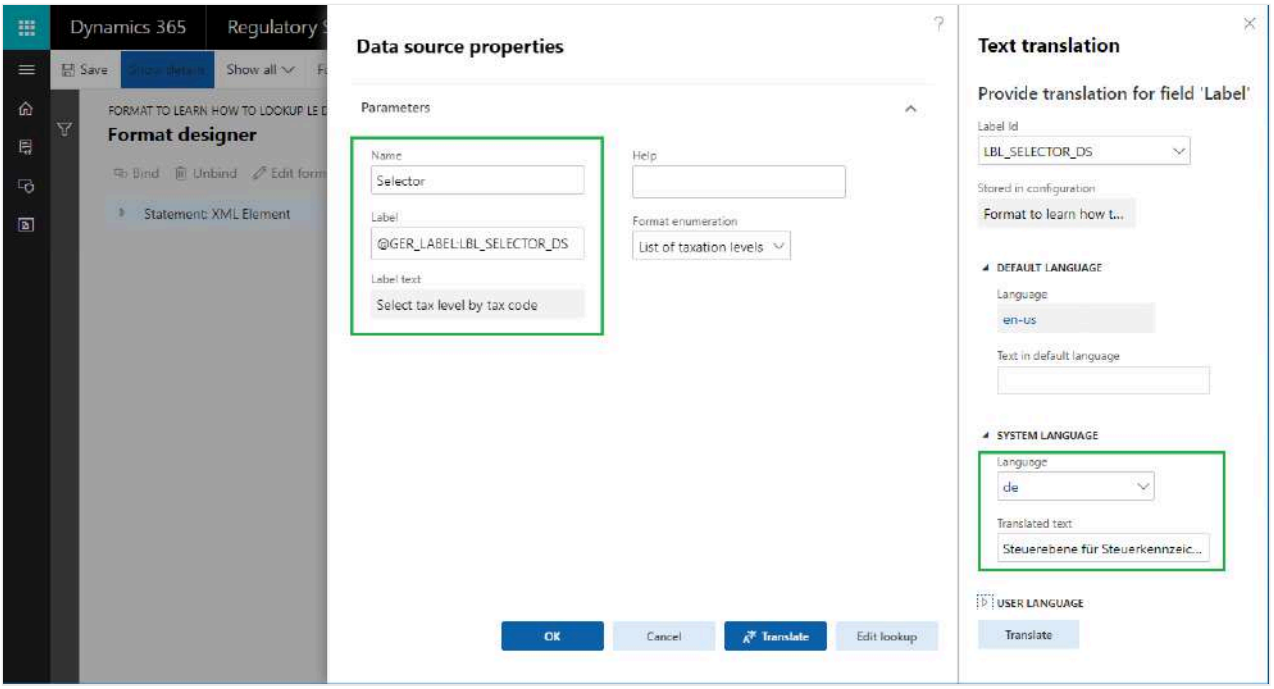
A rule is applicable when both conditions are satisfied.

Translate the label of the lookup data source that was added

Because business users might use different languages to specify legal entity–dependent sets of tax codes, translate the label of any lookup data source that you add. This way, it's presented in each user's preferred language on the corresponding page.

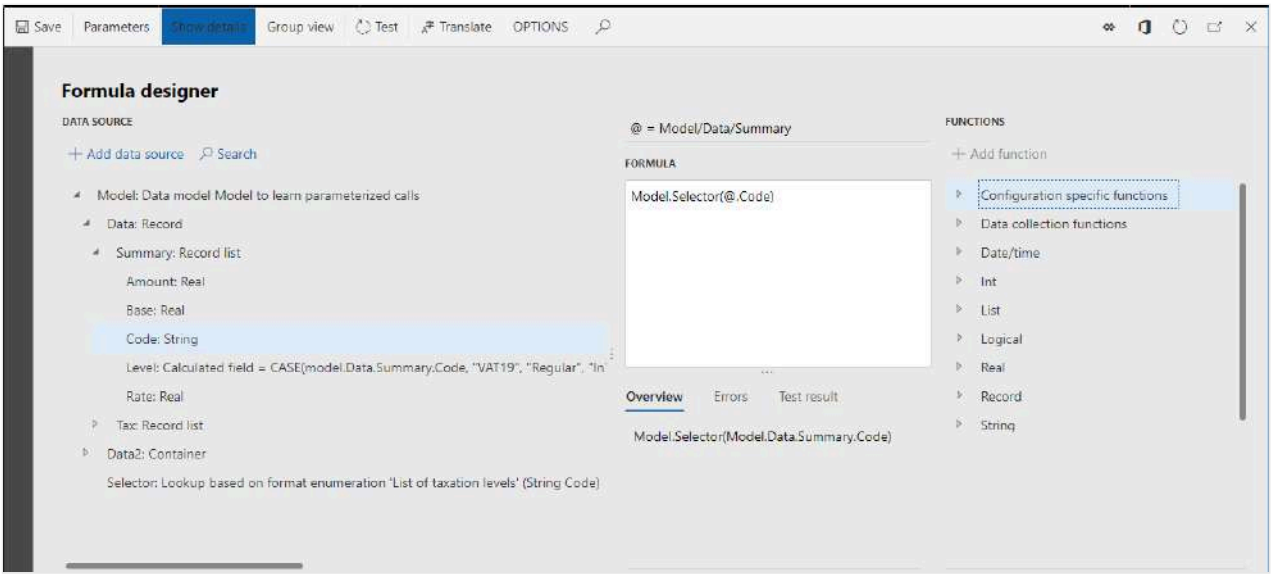
1. Select the **Model.Data.Selector** data source.
2. Select **Edit**.
3. Click in the **Label** field.
4. Select **Translate**.
5. In the **Text translation** pane, enter **LBL_SELECTOR_DS** in the **Label ID** field.

6. Enter **Select tax level by tax code** in the **Text in default language** field.
7. Select **DE** in the **Language** field.
8. Enter **Steuerebene für Steuerkennzeichen auswählen** in the **Translated text** field.
9. Select **Translate**.
10. Select **OK**.

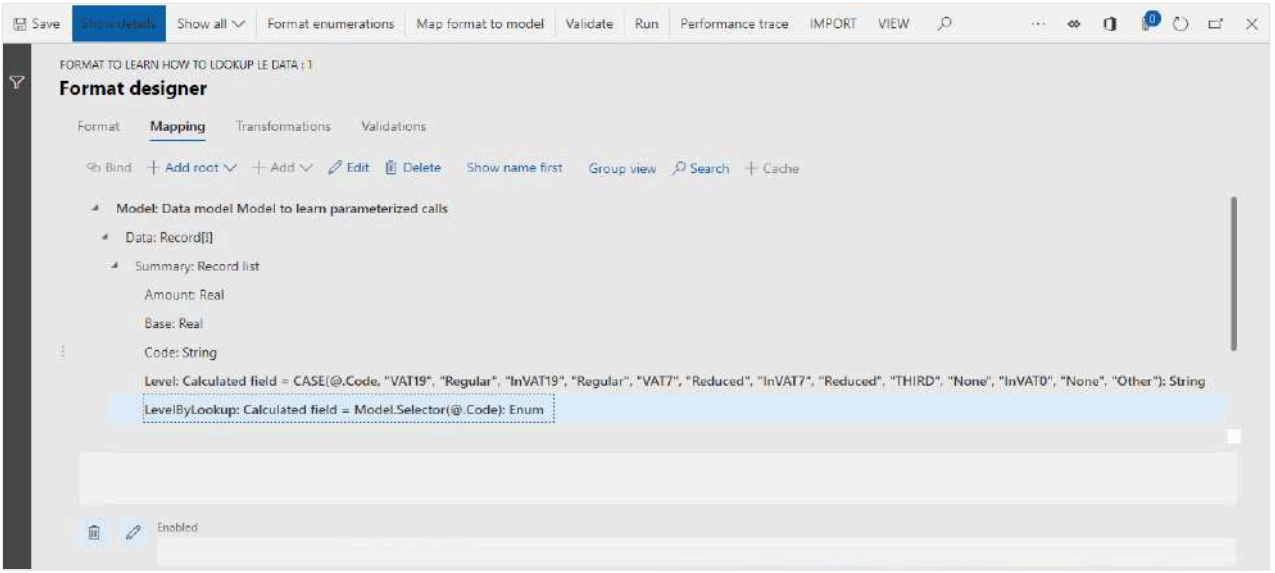


Add a new field to consume the configured lookup

1. Expand the **Model.Data** item.
2. Select the **Model.Data.Summary** item.
3. Select **Add**.
4. Select **Functions/Calculated field**.
5. In the **Name** field, enter **LevelByLookup**.
6. Select **Edit formula**.
7. In the **Formula field**, enter **Model.Selector(Model.Data.Summary.Code)**.
8. Select **Save**.



9. Close the **Formula editor** page.
10. Select **OK**.



The **LevelByLookup** calculated field that you added returns the taxation level as the value of the **List of taxation levels** format enumeration for each summarized tax transactions record. The tax code of the record is passed to the **Model.Selector** lookup data source, and the set of rules for this data source selects the correct taxation level.

Add a new format enumeration-based data source

Next, add a new data source that refers to the format enumeration that you added earlier. Values of this data source are used in an ER format expression later.

1. Select **Add root**.
2. Select **Format enumerations\Enumeration**.
3. In the **Name** field, enter **TaxationLevel**.
4. In the **Format enumeration** field, select **List of taxation levels**.

5. Select **Save**.

Modify an existing field to start using the lookup

Next, you modify the existing calculated field so that it uses the configured lookup data source to return the correct taxation level value, depending on the tax code.

1. Select the **Model.Data.Summary.Level** item.
2. Select **Edit**.
3. Select **Edit formula**.

   Notice that the current expression of the **Model.Data.Summary.Level** field includes the following hard-coded tax codes:

   ```
   CASE (@.Code, "VAT19", "Regular", "InVAT19", "Regular", "VAT7", "Reduced", "InVAT7", "Reduced", "THIRD", "None", "InVAT0", "None", "Other")
   ```

4. In the **Formula** field, enter `CASE(@.LevelByLookup, TaxationLevel.'Regular taxation', "Regular", TaxationLevel.'Reduced taxation', "Reduced", TaxationLevel.'No taxation', "None", "Other")`.

   
   The expression of the **Model.Data.Summary.Level** field now returns the taxation level, based on the tax code of the current record and the set of rules that a business user configures in the **Model.Data.Selector** lookup data source.

5. Select **Save**.
6. Close **Formula designer**.
7. Select **OK**.

8. Select **Save**.
9. Close **Format designer**.

Complete the draft version of a derived format

1. On the **Versions** FastTab, select **Change status**.
2. Select **Complete**.
3. Select **OK**.

Export completed version of modified format

1. In the configuration tree, select the **Format to learn how to look up LE data** item.
2. On the **Versions** FastTab, select the record that has a status of **Completed**.
3. Select **Exchange**.
4. Select **Export as XML file**.
5. Select **OK**.
6. The web browser downloads a **Format to learn how to look up LE data.xml** file. Store this file locally.

Repeat the preceding steps for parent items of the **Format to learn how to look up LE data** format, and store the following files locally:

- Format to learn parameterized calls.xml
- Mapping to learn parameterized calls.xml
- Model to learn parameterized calls.xml

To learn how to use the configured **Format to learn how to look up LE data** ER format to set up legal entity–dependent sets of tax codes to filter tax transactions by different taxation levels, complete the steps in the Set up the parameters of an ER format per legal entity article.

Last updated on 03/17/2026

Set up the parameters of an ER format per legal entity

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Prerequisites

To complete these steps, first complete the steps in Configure ER formats to use parameters that are specified per legal entity.

To complete the examples in this article, you must have access to Microsoft Dynamics 365 Finance for one of the following roles:

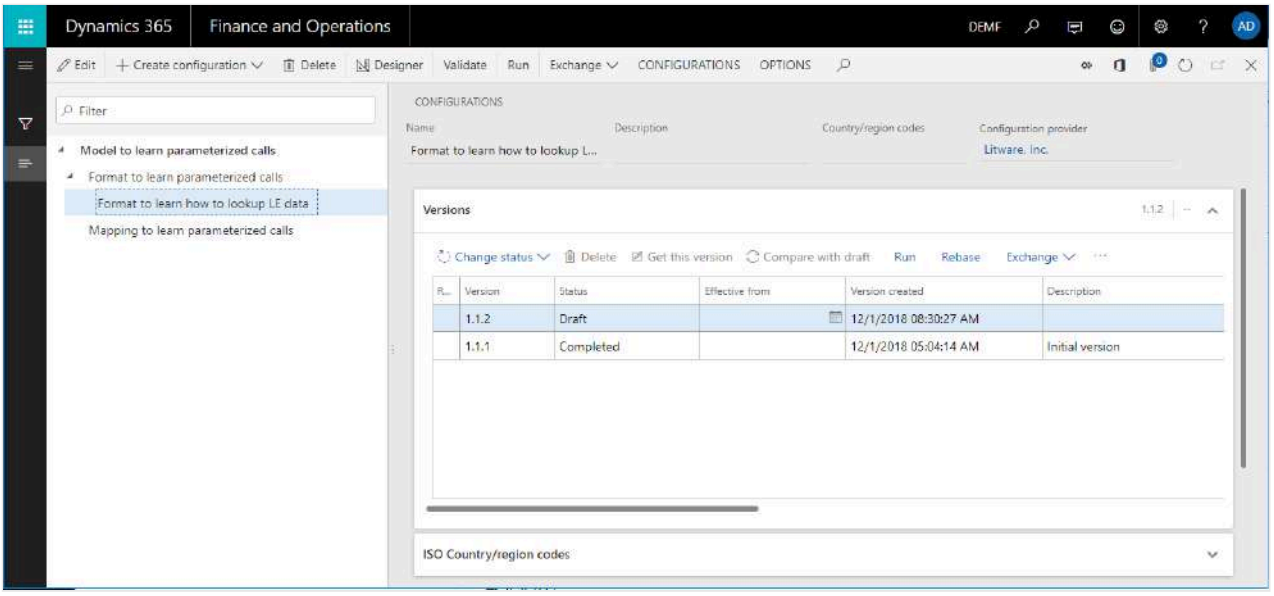
- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

Import ER configurations

To import ER configurations, follow these steps:

1. Sign in to your environment.
2. On the default dashboard, select **Electronic reporting**.
3. Select **Reporting configurations**.
4. In the current instance of Finance, import the configurations that you exported from Regulatory Configuration Services (RCS) while you were completing the steps in Configure ER formats to use parameters that are specified per legal entity. Follow these steps for each Electronic reporting (ER) configuration in the following order: data model, model mapping, and formats.
   a. Select **Exchange** > **Load from XML file**.
   b. Select **Browse** to select the file for the required ER configuration in XML format.
   c. Select **OK**.

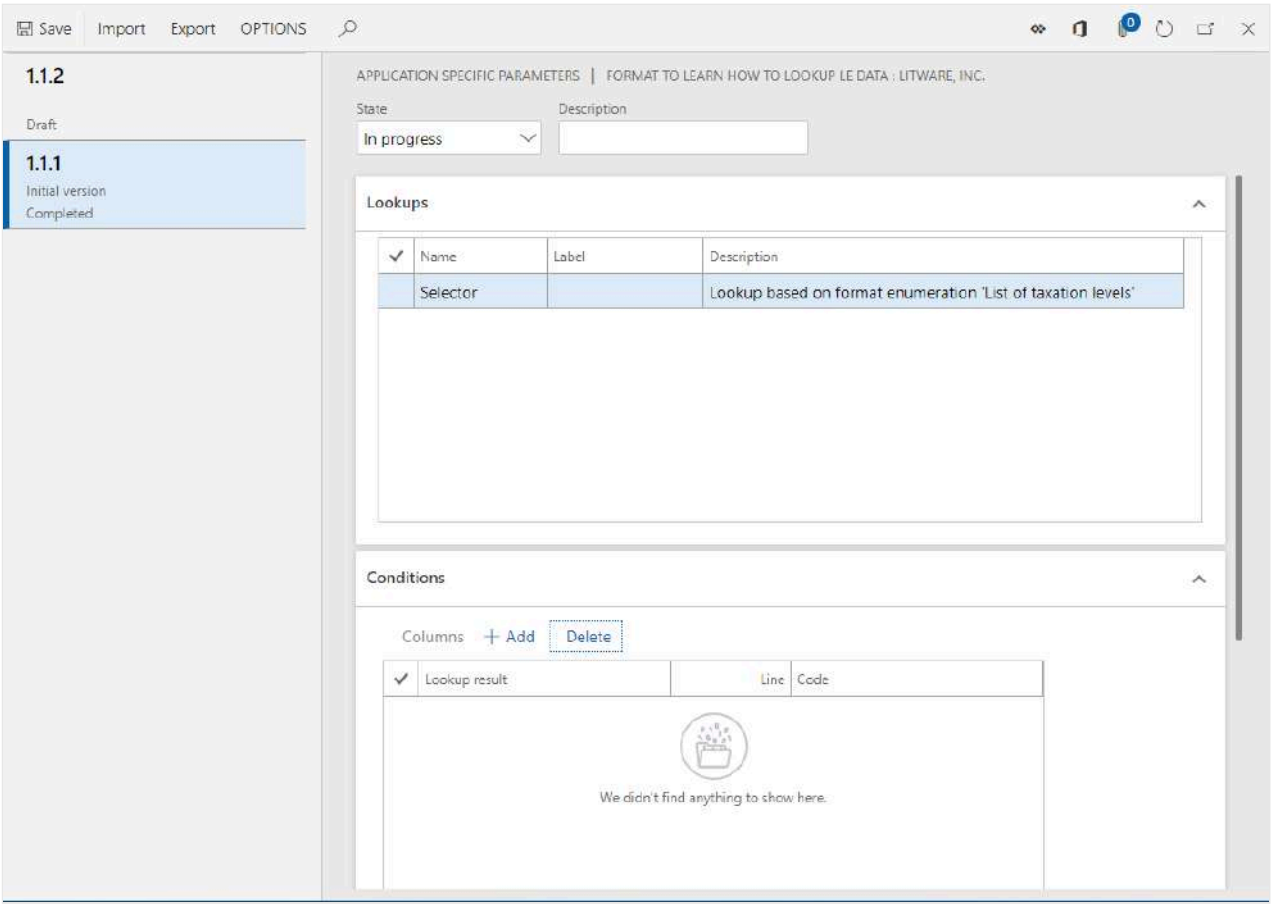
The following illustration shows the configurations that you must have when you finish.



Set up parameters for the DEMF company

You can use the ER framework to set up application-specific parameters for an ER format.

1. Select the **DEMF** legal entity.
2. In the configurations tree, select the **Format to learn how to lookup LE data** format.
3. On the Action Pane, on the **Configurations** tab, in the **Application specific parameters** group, select **Setup**.



On the **Application specific parameters** page, you can configure the rules for the **Selector** data source of the **Format to learn how to lookup LE data** format.

If the base ER format contains several data sources of the **Lookup** type, select the desired data source on the **Lookups** FastTab before you can start to configure the set of rules for the data source.

For each data source, you can configure separate rules for each version of the selected ER format.

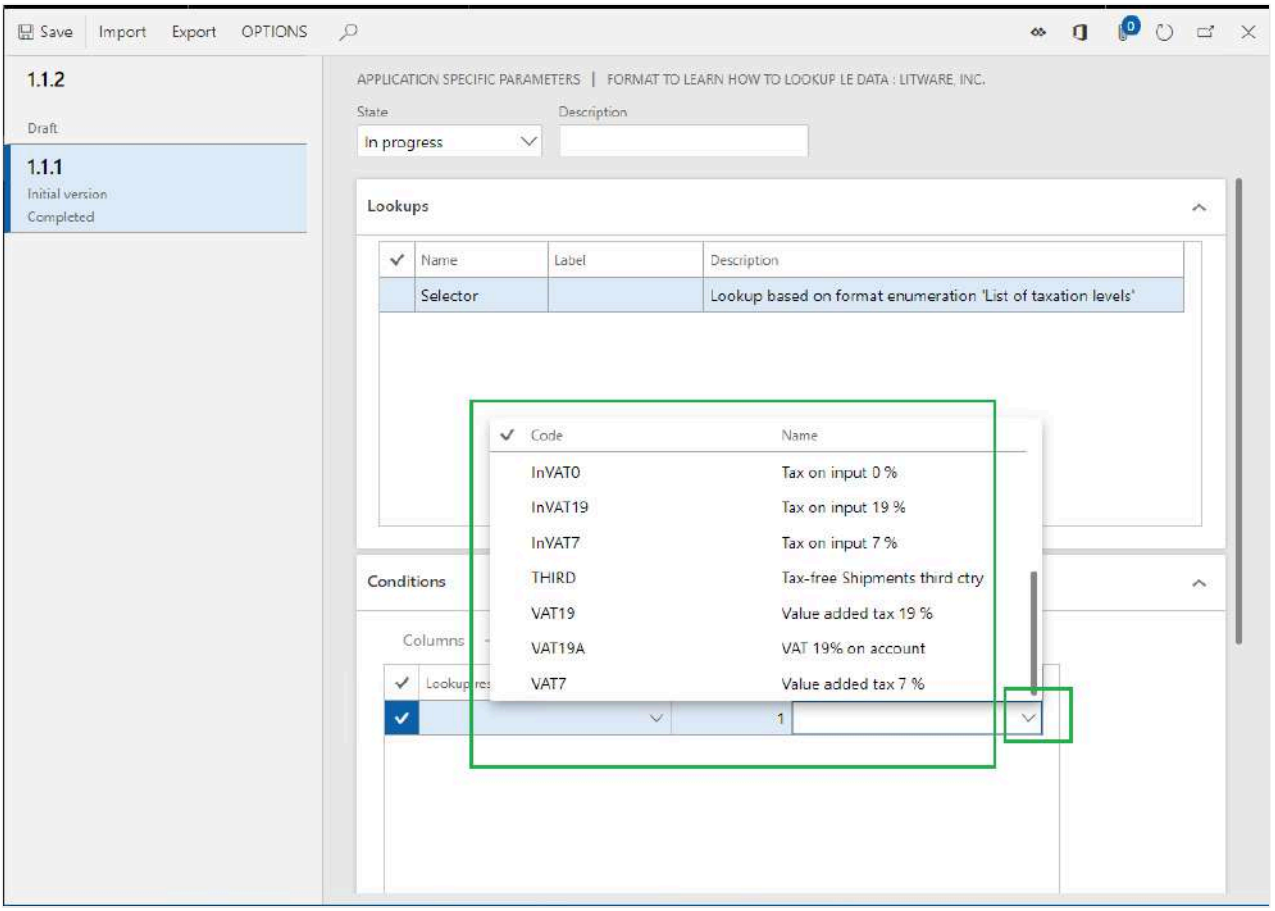
The whole set of rules for all lookup data sources that are available in the selected version of the base ER format makes up the application-specific parameters for the ER format.

4. Select version **1.1.1** of the ER format.

5. On the **Conditions** FastTab, select **Add**.

6. In the **Code** field of the new record, select the drop-down arrow to open the lookup.

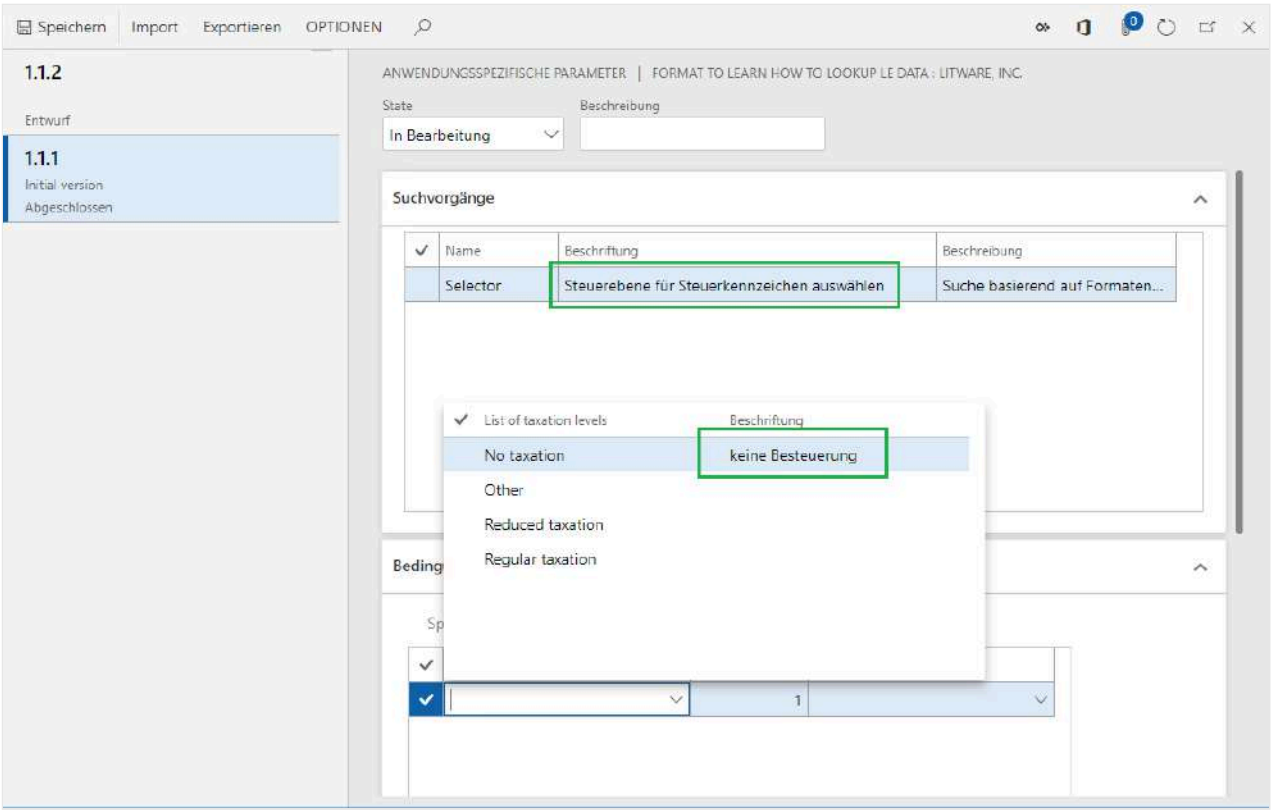
   The lookup presents the list of tax codes for selection. This list is returned by the **Model.Data.Tax** data source that's configured in the base ER format. Because this data source contains the **Name** field, the name of each tax code appears in the lookup.



7. Select the **VAT19** tax code.

8. In the **Lookup result** field of the new record, select the drop-down arrow to open the lookup. The lookup presents the list of values for the TaxationLevel format enumeration for selection.

   If you selected German as the preferred language for the user that you're signed in as, the labels of the values in the lookup appear in German, provided that they are translated in the base ER format. Additionally, if the label of a lookup data source is translated, that label appears in the user's preferred language on the **Lookups** tab.



9. Select the **Regular taxation** value.

   By adding this record, you define the following rule: When the **Selector** lookup data source is requested, and the **VAT19** tax code is passed as an argument, **Regular taxation** is returned as the requested taxation level.

10. Select **Add**, and then follow these steps:
    a. In the **Code** field, select the **InVAT19** tax code.
    b. In the **Lookup result** field, select the **Regular taxation** value.

11. Select **Add**, and then follow these steps:
    a. In the **Code** field, select the **VAT7** tax code.
    b. In the **Lookup result** field, select the **Reduced taxation** value.

12. Select **Add** , and then follow these steps:
    a. In the **Code** field, select the **InVAT7** tax code.
    b. In the **Lookup result** field, select the **Reduced taxation** value.

13. Select **Add**, and then follow these steps:
    a. In the **Code** field, select the **THIRD** tax code.
    b. In the **Lookup result** field, select the **No taxation** value.

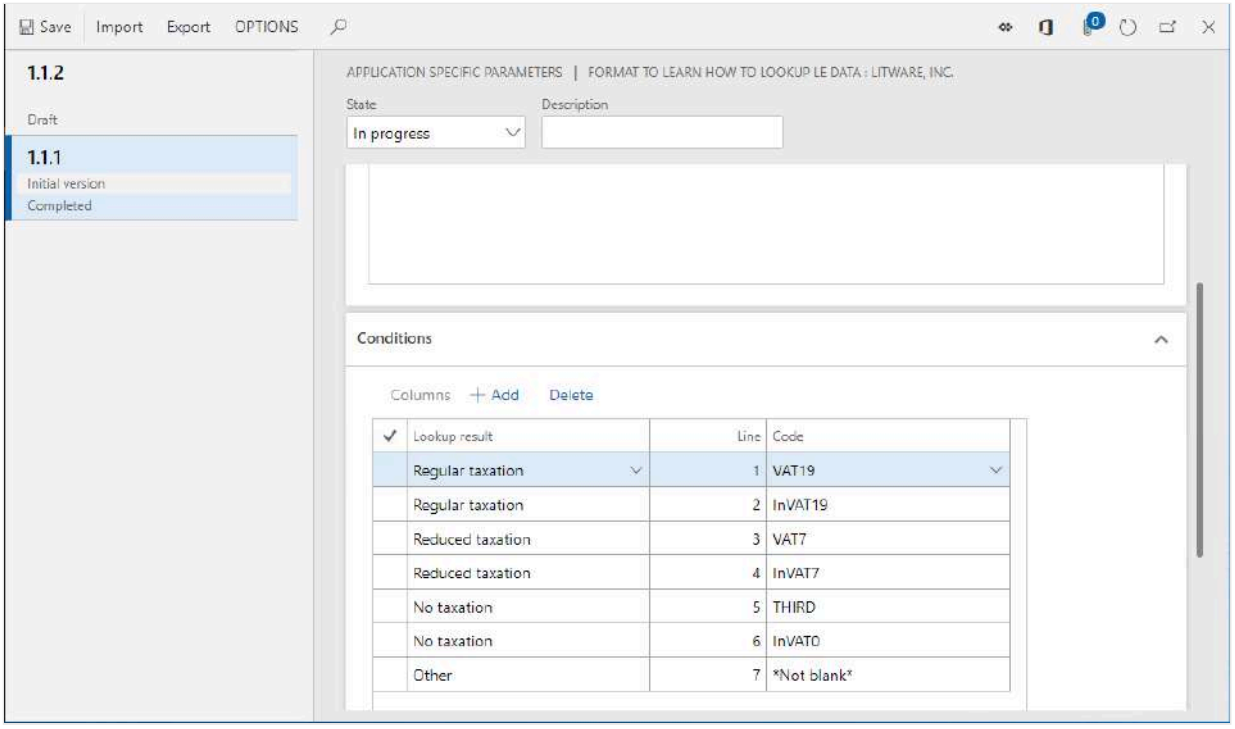
14. Select **Add**, and then follow these steps:
    a. In the **Code** field, select the **InVAT0** tax code.
    b. In the **Lookup result** field, select the **No taxation** value.

15. Select **Add**, and then follow these steps:

a. In the **Code** field, select the ***Not blank*** option.

b. In the **Lookup result** field, select the **Other** value.

By adding this last record, you define the following rule: When the tax code passed as an argument doesn't satisfy any of the previous rules, the lookup data source returns **Other** as the requested taxation level.



16. In the **State** field, select **Completed**.

    When you run an ER format version that has a status of either **Completed** or **Shared**, this set of rules must be in the **Completed** state. Otherwise, execution of the base ER format is interrupted when the format tries to load data from this set of rules while the **Selector** lookup data source is running.

    When you run an ER format version that has a status of **Draft**, the base ER format can access this set of rules, regardless of its state.

17. Select **Save**.

18. Close the **Application specific parameters** page.

Run the ER format in the DEMF company

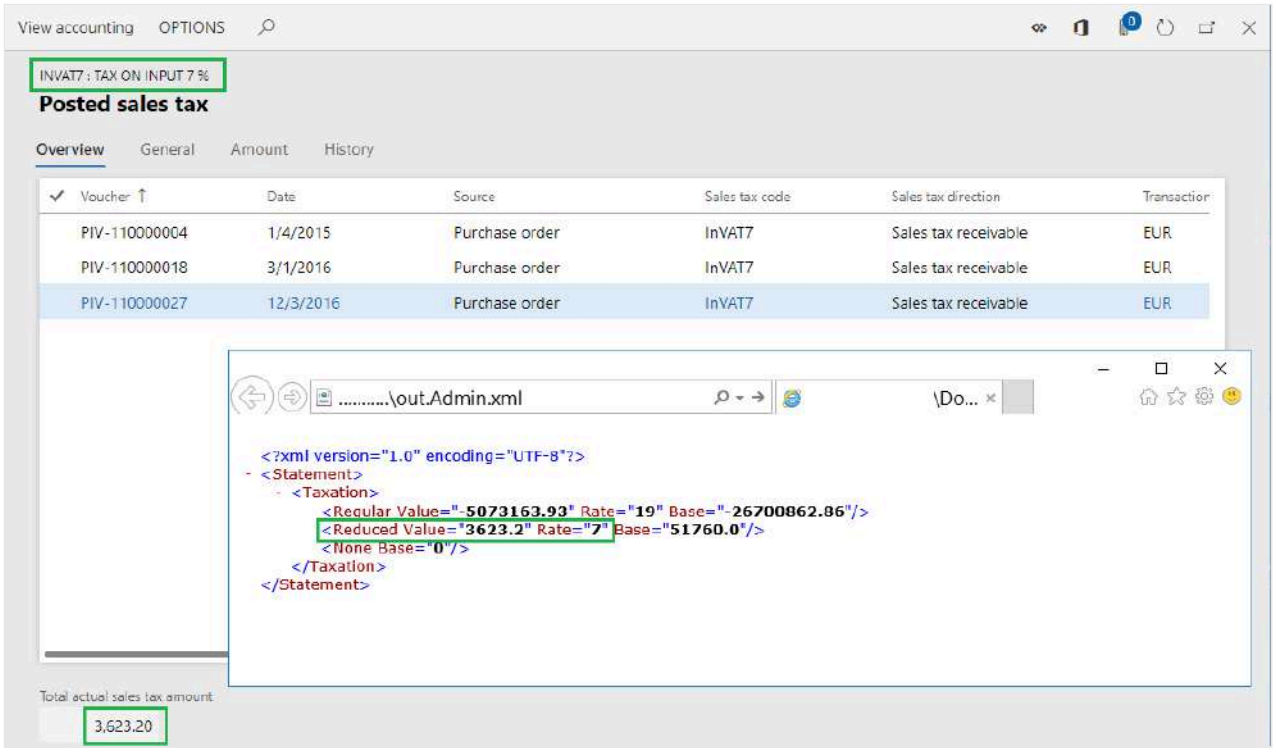
To run the ER format in the DEMF company, follow these steps:

1. In the configurations tree, select the **Format to learn how to lookup LE data** format.

2. On the action pane, select **Run**.

3. In the dialog box that appears, select **OK**.
4. Download the generated statement and store it locally.

   In the generated statement, the summary of the **InVAT7** tax code is on the **Reduced** level, and the summaries of the **VAT19** and **InVA19** tax codes are on the **Regular** level. The configuration in the legal entity–dependent set of rules determines this behavior.
5. Go to **Tax** > **Indirect taxes** > **Sales tax** > **Sales tax codes**.
6. Select the **InVAT7** tax code.
7. On the Action Pane, on the **Sales tax code** tab, in the **Inquiries** group, select **Posted sales tax** to view information about the tax value and applied tax rate per tax code.



8. Close the **Posted sales tax** page.

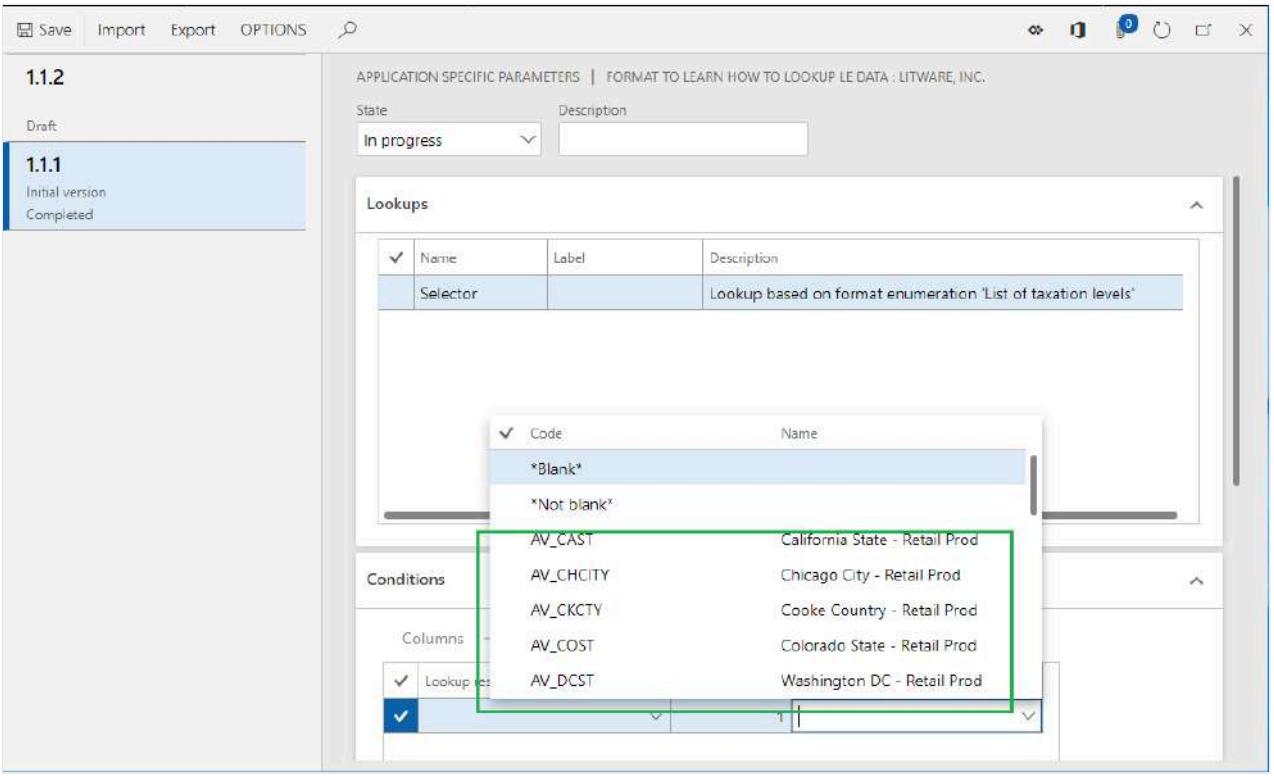
Set up parameters for the USMF company

To set up parameters for the USMF company, complete the following steps:

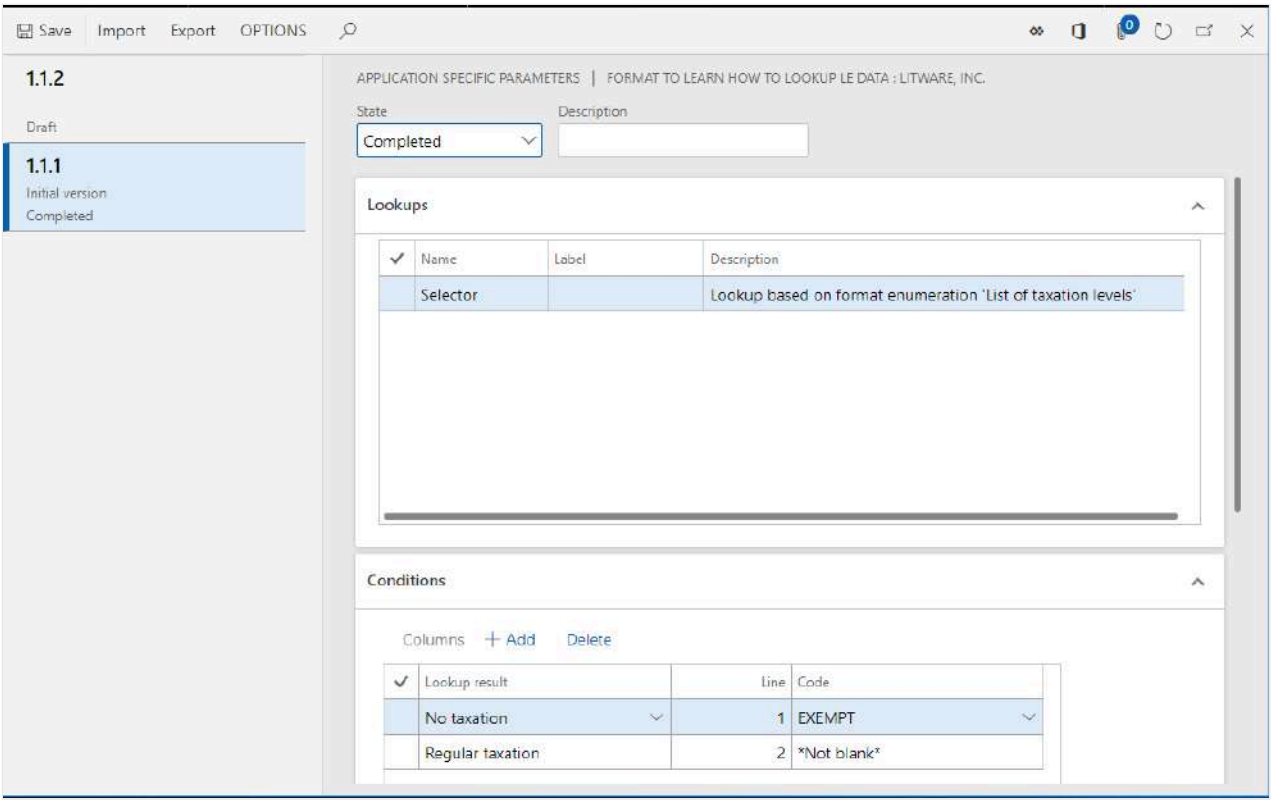
1. Select the **USMF** legal entity.
2. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
3. In the configurations tree, expand the **Model to learn parameterized calls** item, expand the **Format to learn parameterized calls** item, and select the **Format to learn how to lookup LE data** format.

4. On the **Configurations** tab, in the **Application specific parameters** group, select **Setup**.
5. Select version **1.1.1** of the selected ER format.
6. On the **Conditions** FastTab, select **Add**.
7. In the **Code** field of the new record, select the drop-down arrow to open the lookup.

   The lookup now presents the list of tax codes for the **USMF** company tax for selection.



8. Select the **EXEMPT** tax code.
9. In the **Lookup result** field of the new record, select the **No taxation** value.
10. Select **Add**.
11. In the **Code** field of the new record, select the ***Not blank*** option.
12. In the **Lookup result** field of the new record, select the **Regular taxation** value.
13. In the **State** field, select **Completed**.
14. Select **Save**.



15. Close the **Application specific parameters** page.

Run the ER format in the USMF company

To run the ER format in the USMF company, complete the following steps:

1. In the configurations tree, select the **Format to learn how to lookup LE data** format.
2. On the action pane, select **Run**.
3. In the dialog box that appears, select **OK**.
4. Download the generated statement and store it locally.

   In the generated statement, observe that you reused the same ER format for a different legal entity, but you didn't make any adjustments to the ER format.

Reuse legal entity–dependent parameters

Duplicate existing parameters

Export parameters

To export parameters, complete the following steps:

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. In the configurations tree, select the **Format to learn how to lookup LE data** format.
4. On the **Configurations** tab, in the **Application specific parameters** group, select **Setup**.
5. Select version **1.1.1** of the ER format.
6. On the Action Pane, select **Export**.
7. Download the generated file and store it locally.

   The configured set of application-specific parameters is exported as an XML file.

Import parameters

To import parameters, complete the following steps:

1. Select version **1.1.2** of the ER format.
2. On the Action Pane, select **Import**.
3. Select **Yes** to confirm that you want to override the existing application-specific parameters for this format version.
4. Select **Browse** to find the file that contains the exported application-specific parameters for version **1.1.1**.
5. Select **OK**.

   Version **1.1.2** of the ER format now has the same application-specific parameters that you originally configured for version **1.1.1**.

Applicability considerations

The application-specific parameters of an ER format are legal entity–dependent. To reuse the application-specific parameters that are configured for one legal entity in a different legal entity, export them while you're signed in to the first legal entity. Then import them after you sign in to the other legal entity.

You can also use this export-import approach to transfer ER format–related application-specific parameters originally configured in one instance of Finance to another instance of Finance.

If you configure application-specific parameters for one version of an ER format and then import a later version of the same format into the current Finance instance, the existing application-specific parameters aren't applied to the imported version unless you use the **Use application specific parameters from previous versions of ER formats** feature. For more information, see the Reuse existing parameters section later in this article.

When you select a file for import, the structure of the application-specific parameters in that file is compared with the structure of the corresponding data sources of the **Lookup** type in the ER format selected for import. By default, the import completes only if the structure of each application-specific parameter matches the structure of the corresponding data source in the ER format selected for import. If the structures don't match, a warning message informs you that the import can't be completed. If you force the import, the existing application-specific parameters for the selected ER format are cleaned up, and you must set them up from the beginning.

As of Finance version 10.0.24, you can change the default behavior and avoid receiving a warning message by enabling the **Align ER application specific parameters while importing** feature in the **Feature management** workspace. When this feature is enabled, if the structure of application-specific parameters that you're importing differs from the structure of the corresponding data sources in the target ER format selected for import, the import succeeds in the following cases:

- The structure of the target ER format is changed by adding new condition columns to any existing data sources of the **Lookup** type. When the import completes, the application-specific parameters are updated. In all the imported records of application-specific parameters, the values in every added condition column are initialized with the default value for the data type of that column.
- The structure of the target ER format is changed by removing some condition columns from any existing data sources of the **Lookup** type. When the import completes, the application-specific parameters are updated. In all the imported records of application-specific parameters, the values in every removed condition column are deleted.
- The structure of the target ER format is changed by adding new data sources of the **Lookup** type. When the import completes, the added lookups are appended to the application-specific parameters.
- The structure of the target ER format is changed by removing some of the existing data sources of the **Lookup** type. When the import completes, all artifacts that are related to the data sources of the **Lookup** type that were removed from the target ER format are deleted from the imported application-specific parameters.

When the import completes, in addition to the changes just described, the state of the imported application-specific parameters is changed to **In progress**. A warning message

informs you that you must manually edit the automatically adjusted application-specific parameters.

Replicate parameters

As of Finance version 10.0.27, you can copy the parameters that you configured in one company to other companies at the same time.

To copy parameters, complete the following steps.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. In the configurations tree, select the **Format to learn how to lookup LE data** format.
4. On the **Configurations** tab, in the **Application specific parameters** group, select **Setup**.
5. Select version **1.1.1** of the ER format.
6. On the Action Pane, select **Replicate**.
7. In the **Replicate** dialog box, on the **Companies** tab, select the companies that you want to copy parameters to.

   > ⓘ **Note**
   >
   > You see the list of target companies only if you're assigned a security role that grants access to all organizations.

8. Select **OK**.

   > ⓘ **Note**
   >
   > The confirmation dialog box informs you if some target companies contain previously configured parameters for the selected version of an ER format. Select **Yes** to override the parameters by copying them from the current company.

   The configured set of application-specific parameters is now copied to the selected companies.

Reuse existing parameters

Starting with Finance version 10.0.23, you can reuse application-specific parameters configured for one version of an ER format when you run a higher version of the same format. To reuse existing parameters, enable the **Use application specific parameters from previous versions of ER formats** feature in the **Feature management** workspace. When you enable this feature and run one version of an ER format that tries to read application-specific parameters, ER tries to find application-specific parameters that are configured for the running version of the format. If they aren't available, ER tries to find them for the nearest lower version of the format.

> ⓘ **Note**
>
> You can reuse application-specific parameters only in the scope of the current legal entity.
>
> An error is displayed at runtime when you run a higher version of an ER format that tries to reuse application-specific parameters configured for a lower version of the same format and the structure of at least one data source of the **Lookup** type in the higher format version changed.

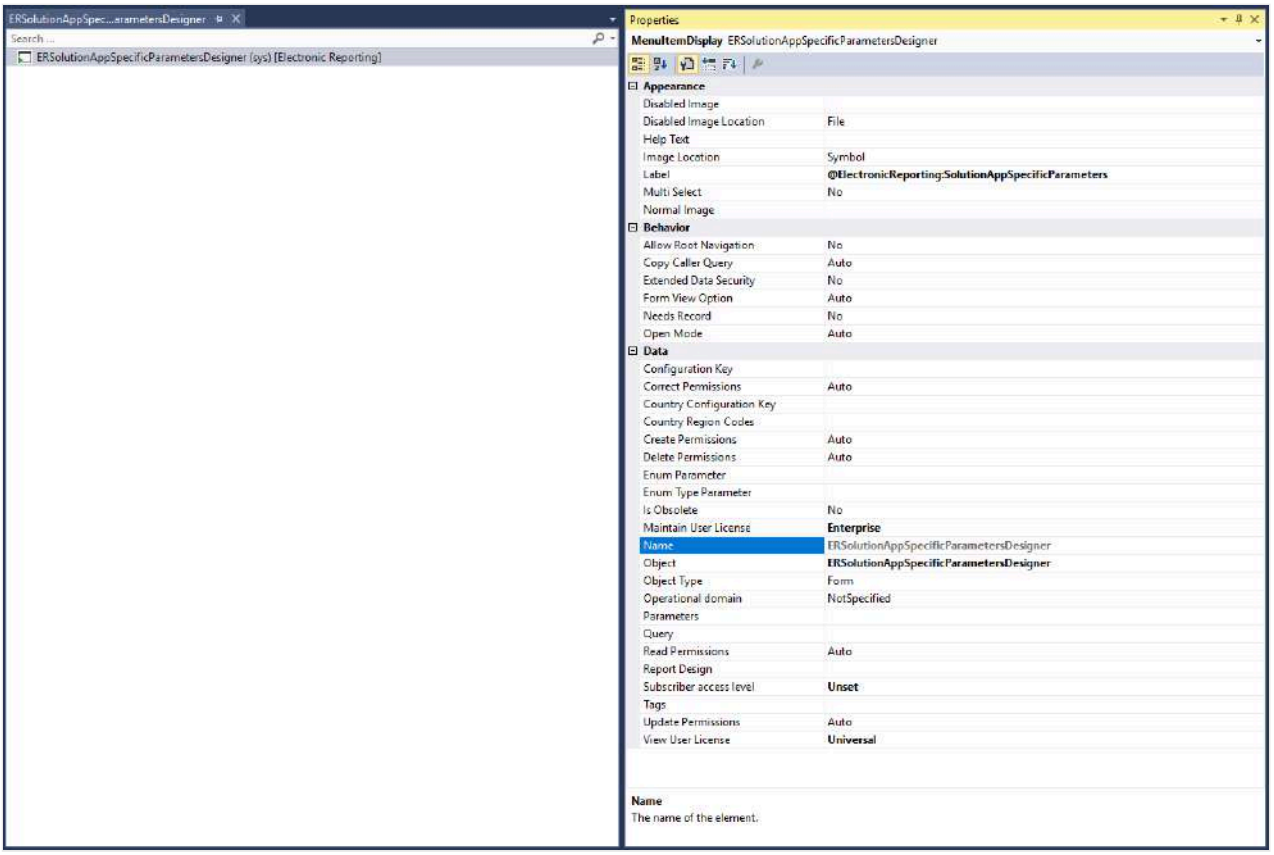
Relationship between application-specific parameters and an ER format

The relationship between an ER format and its application-specific parameters is established by the ER format's instance-independent unique identification code. Therefore, when you remove an ER format from Finance, the application-specific parameters configured for the ER format are kept in the current instance of Finance. You can access them on reimporting the base ER format into this instance of Finance.

Access application-specific parameters by using the ER framework

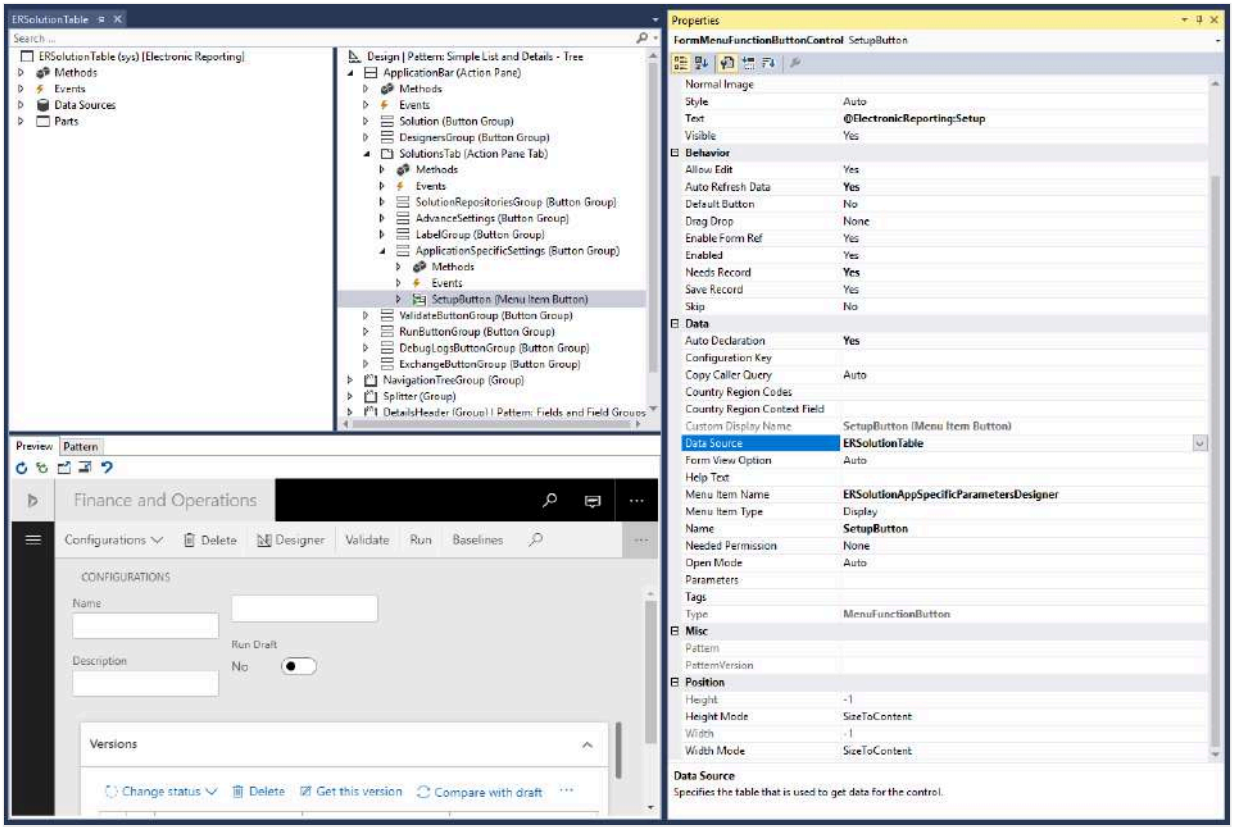
In the preceding example, you accessed application-specific parameters of an ER format by using the ER framework. This approach doesn't let you restrict access to the application-specific parameters of a specific ER format. If you need to apply such restrictions, follow these steps:

1. Either reuse an existing **ERSolutionAppSpecificParametersDesigner** menu item, or implement your own **ERSolutionAppSpecificParametersDesigner** menu item.



2. Follow one of these steps:

a. Create a new menu item button, and link it to the corresponding record from the **ERSolutionTable** table by setting its **Data Source** property to **ERSolutionTable**.



b. Create a simple button, and override the **Clicked** method as shown in the following example.

By using this approach, you can specify a unique solution ID (defined through the **GUID** value) to allow access to the application-specific parameters of only a specific ER format and descendant copies that are derived from it.

X++

```
public void clicked()
    {
        super();

        ERSolutionTable solutionTableRecord =
ERSolutionTable::findByGUID(str2Guid('ADACCB2F-EFD1-4C90-877D-
7E1E5D1AEE92'));

        Args args = new Args();
        args.record(solutionTableRecord);
        args.caller(this);

        new
MenuFunction(menuItemDisplayStr(ERSolutionAppSpecificParametersDesigner),
MenuItemType::Display)
            .run(args);
    }
```

Defer the execution of sequence elements in ER formats

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Overview

Use the Operations designer of the Electronic reporting (ER) framework to configure the format component of an ER solution that generates outbound documents in a text format. The hierarchical structure of the configured format component consists of format elements of various types. These format elements fill generated documents with the required information at runtime. By default, when you run an ER format, the format elements run in the same order as they appear in the format hierarchy: one by one, from top to bottom. However, at design time, you can change the execution order for any sequence elements of the configured format component.

When you turn on the **Deferred execution** option for a sequence format element in the configured format, you defer (postpone) the execution of that element. The element isn't run until all other elements of its parent are run.

To learn more about this feature, complete the example in this article.

Limitations

The **Deferred execution** option supports only sequence elements configured for an ER format that generates **outbound** documents in text format.

The **Deferred execution** option isn't applicable to sequences configured as trimmed sequences where the maximum length is limited.

Example: Defer the execution of a sequence element in an ER format

The following steps explain how a user in the System administrator or Electronic reporting functional consultant role can configure an ER format that contains a sequence element where order of execution differs from the order in the format hierarchy.

You can perform these steps in the **USMF** company in Microsoft Dynamics 365 Finance.

Prerequisites

To complete this example, you must have access to the **USMF** company in Finance for one of the following roles:

- Electronic reporting functional consultant
- System administrator

If you didn't yet complete the example in the Defer the execution of XML elements in ER formats article, download the following configurations of the sample ER solution.

Expand table

Content description	File name
ER data model configuration	Model to learn deferred elements.version.1.xml
ER model mapping configuration	Mapping to learn deferred elements.version.1.1.xml

Before you begin, download and save the following configuration of the sample ER solution.

Expand table

Content description	File name
ER format configuration	Format to learn deferred sequences.version.1.1.xml

Import the sample ER configurations

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.

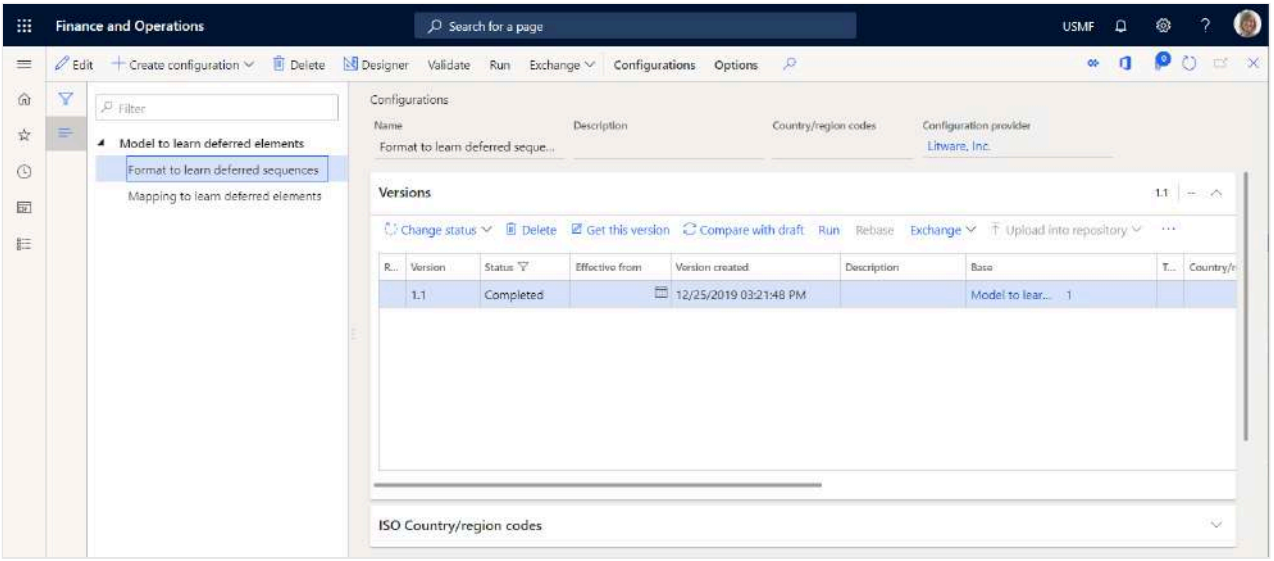
3. On **Configurations**, if the **Model to learn deferred elements** configuration isn't available in the configuration tree, import the ER data model configuration:
   a. Select **Exchange**, and then select **Load from XML file**.
   b. Select **Browse**, find and select the **Model to learn deferred elements.1.xml** file, and then select **OK**.

4. If the **Mapping to learn deferred elements** configuration isn't available in the configuration tree, import the ER model mapping configuration:
   a. Select **Exchange**, and then select **Load from XML file**.
   b. Select **Browse**, find and select the **Mapping to learn deferred elements.1.1.xml** file, and then select **OK**.

5. Import the ER format configuration:
   a. Select **Exchange**, and then select **Load from XML file**.
   b. Select **Browse**, find and select the **Format to learn deferred sequences.1.1.xml** file, and then select **OK**.

6. In the configuration tree, expand **Model to learn deferred elements**.

7. Review the list of imported ER configurations in the configuration tree.

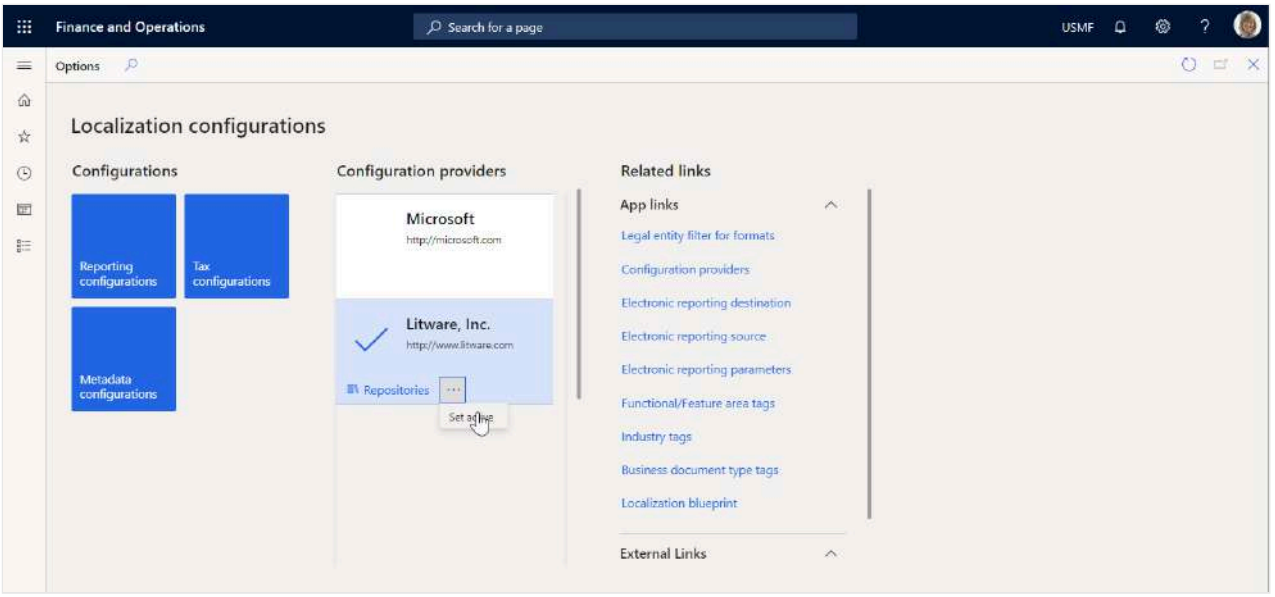


Activate a configurations provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

2. On **Localization configurations**, in the **Configuration providers** section, make sure that the configuration provider for the Litware, Inc. (`http://www.litware.com`) sample company is listed and marked as active. If this configuration provider isn't listed, or if it isn't marked

as active, follow the steps in the Create a configuration provider and mark it as active article.

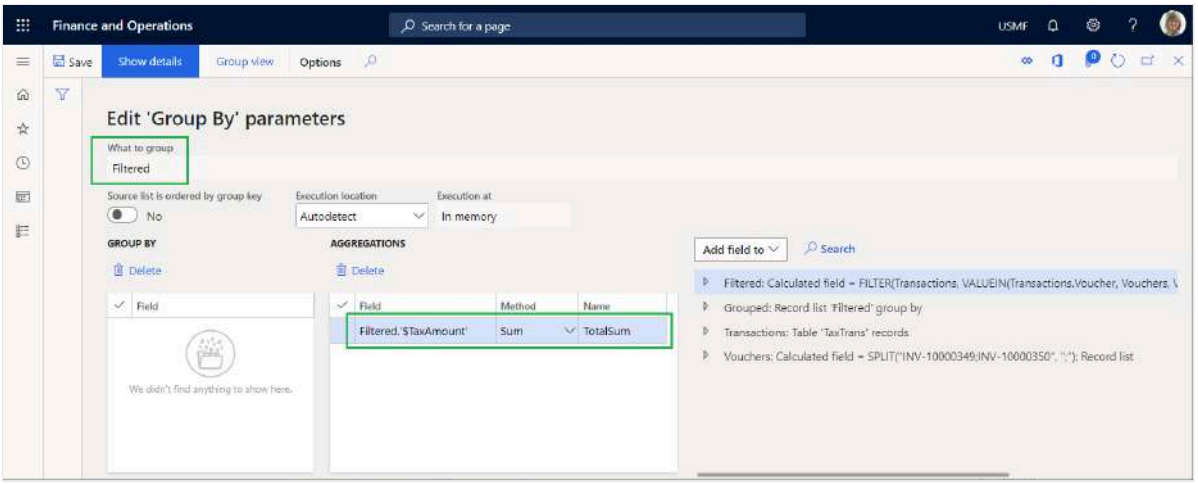


Review the imported model mapping

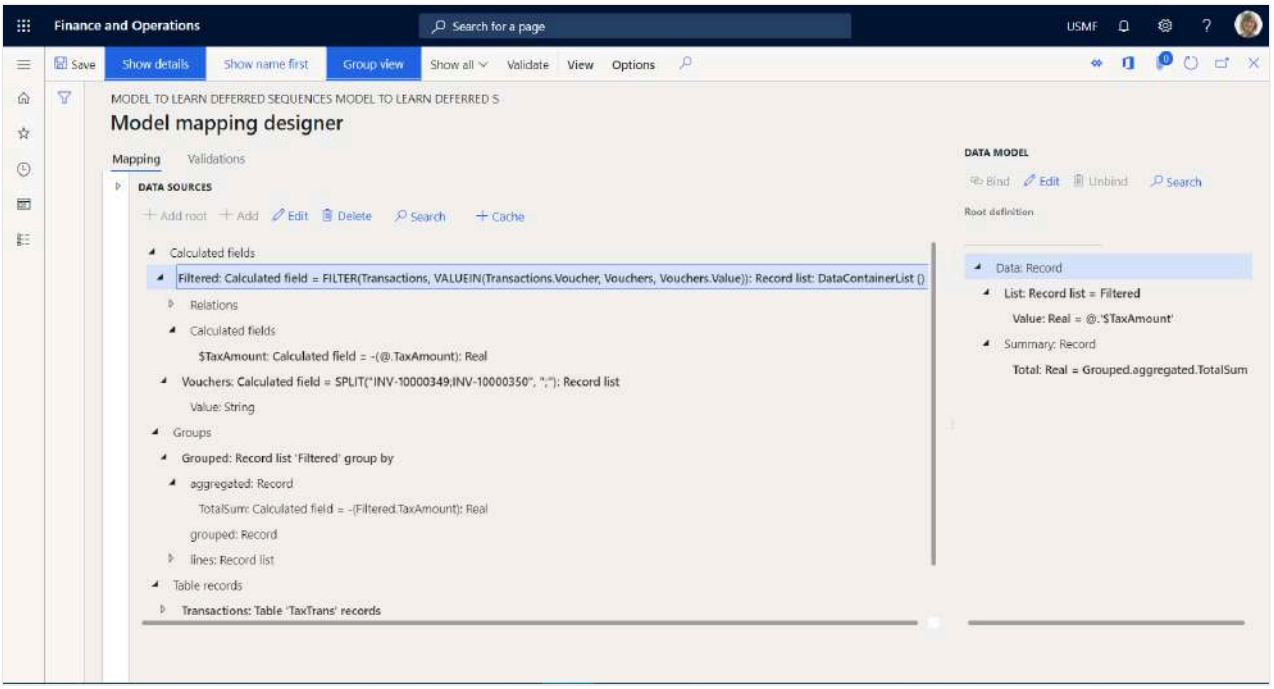
Review the settings of the ER model mapping component configured to access tax transactions and expose accessed data on request.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. On **Configurations**, in the configuration tree, expand **Model to learn deferred elements**.
4. Select the **Mapping to learn deferred elements** configuration.
5. Select **Designer** to open the list of mappings.
6. Select **Designer** to review the mapping details.
7. Select **Show details**.
8. Review the data sources configured to access tax transactions:
    - The **Transactions** data source of the *Table record* type is configured to access records of the **TaxTrans** application table.
    - The **Vouchers** data source of the *Calculated field* type is configured to return the required voucher codes (**INV-10000349** and **INV-10000350**) as a list of records.

- The **Filtered** data source of the *Calculated field* type is configured to select, from the **Transactions** data source, only tax transactions of the required vouchers.
- The **$TaxAmount** field of the *Calculated field* type is added for the **Filtered** data source to expose the tax value that has the opposite sign.
- The **Grouped** data source of the *Group By* type is configured to group filtered tax transactions of the **Filtered** data source.
- The **TotalSum** aggregation field of the **Grouped** data source is configured to summarize values of the **$TaxAmount** field of the **Filtered** data source for all filtered tax transactions of that data source.



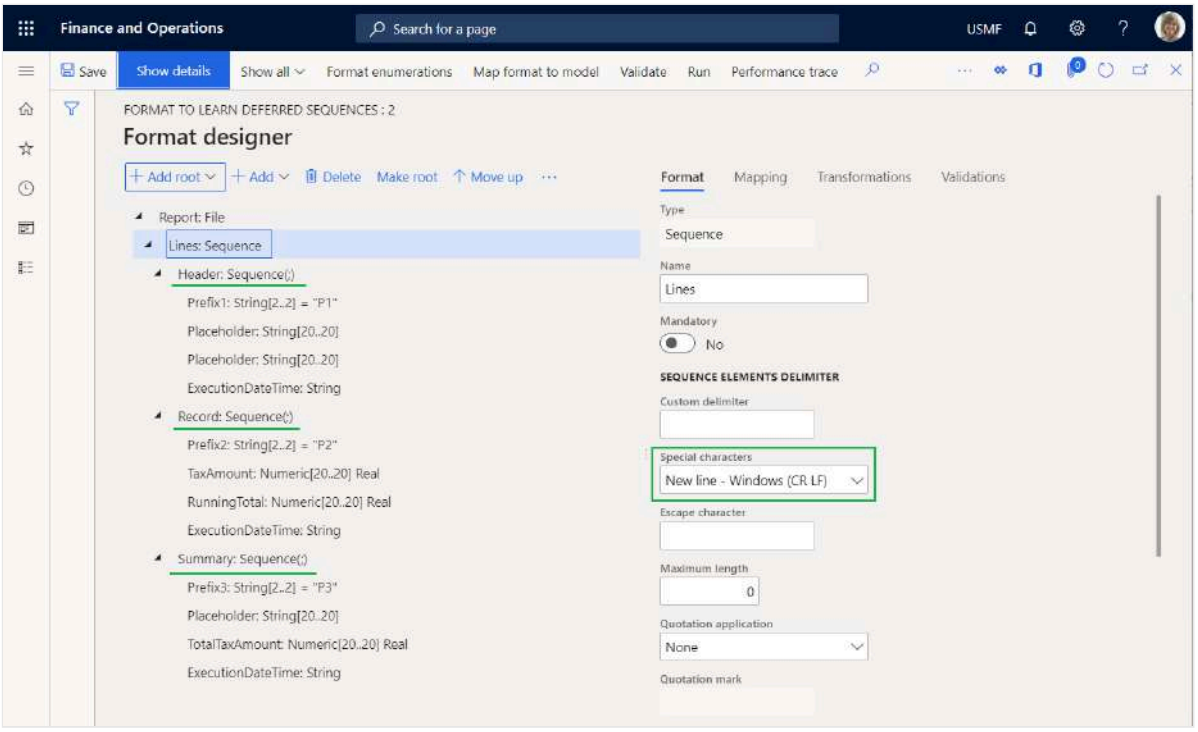
9. Review how the configured data sources are bound to the data model, and how they expose accessed data to make it available in an ER format:
   - The **Filtered** data source is bound to the **Data.List** field of the data model.
   - The **$TaxAmount** field of the **Filtered** data source is bound to the **Data.List.Value** field of the data model.
   - The **TotalSum** field of the **Grouped** data source is bound to the **Data.Summary.Total** field of the data model.



10. Close the **Model mapping designer** and **Model mappings** pages.

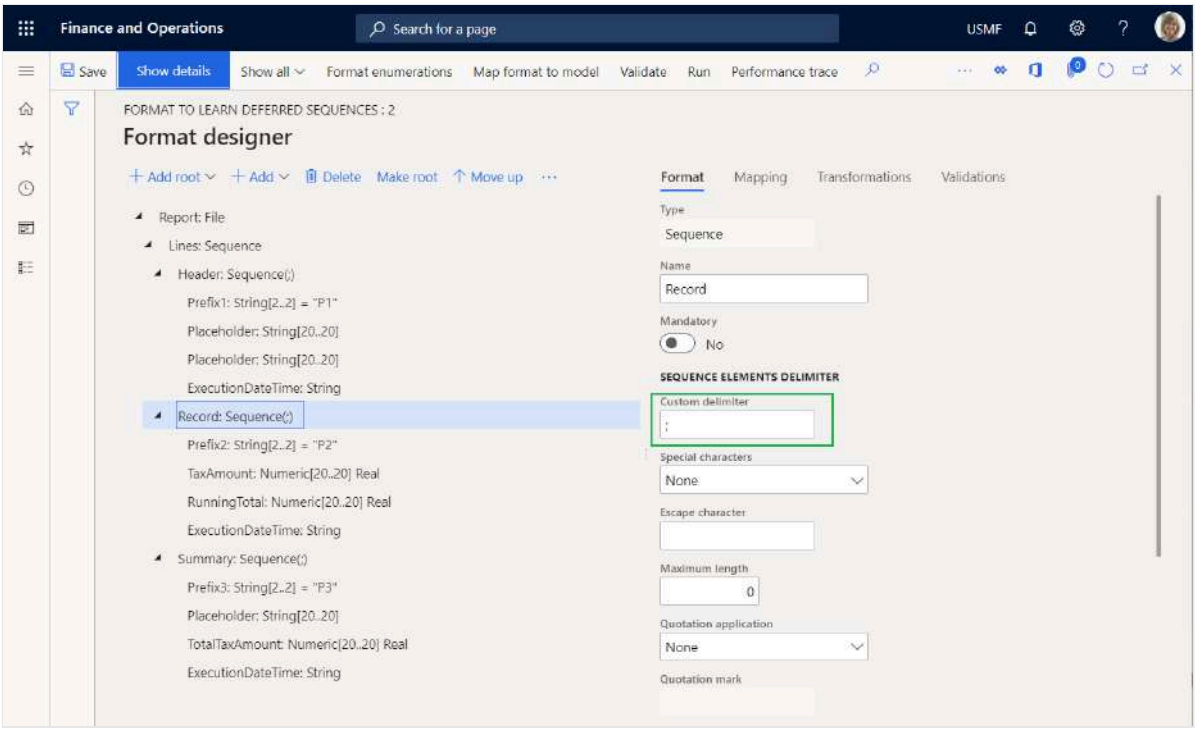
Review the imported format

1. On **Configurations**, in the configuration tree, select the **Format to learn deferred sequences** configuration.
2. Select **Designer** to review the format details.
3. Select **Show details**.
4. Review the settings of the ER format components that are configured to generate an outbound document in text format that includes details of the tax transactions:
    - The **Report\Lines** sequence format element is configured to fill the outbound document with a single line that is generated from the nested sequence elements (**Header**, **Record**, and **Summary**).



- The **Report\Lines\Header** sequence format element is configured to fill the outbound document with a single header line that shows the date and time when the processing starts.

- The **Report \Lines\Record** sequence format element is configured to fill the outbound document with a single line that shows the details of individual tax transactions. These tax transactions are separated by a semicolon.

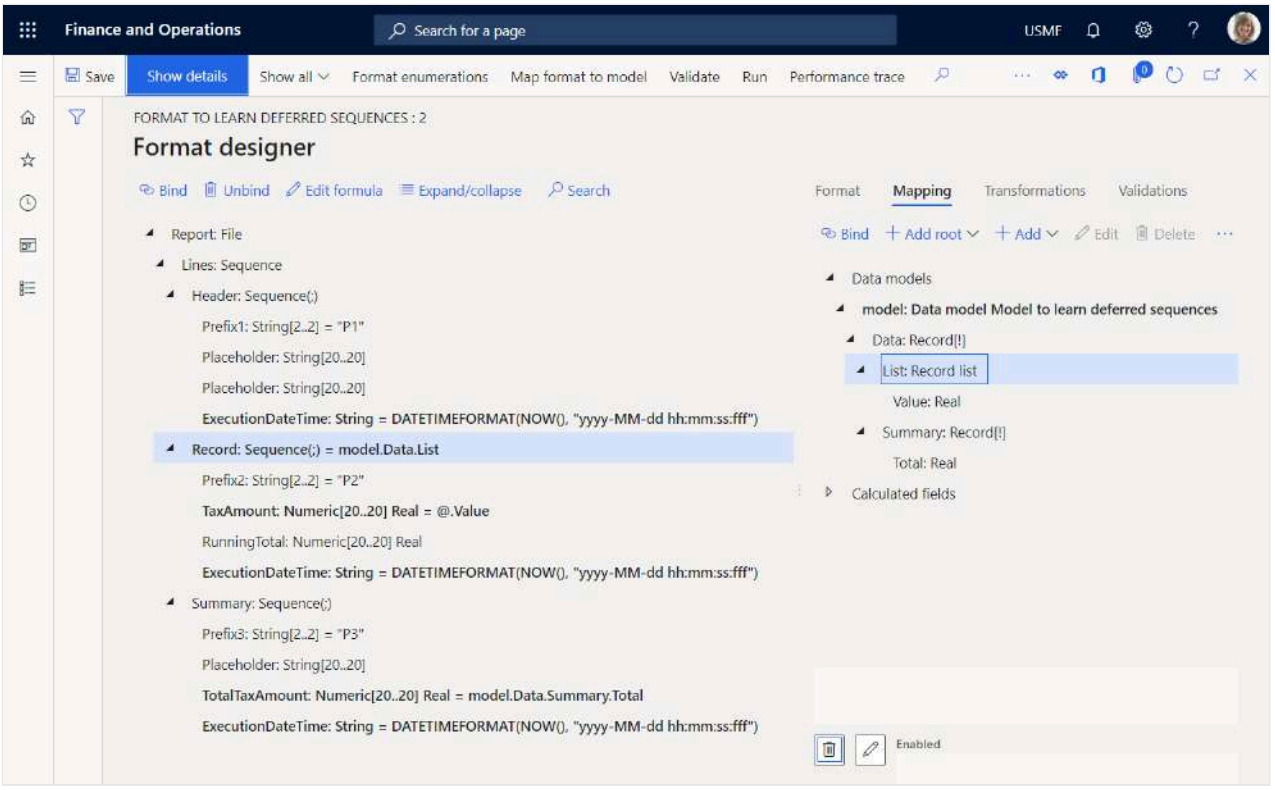


- The **Report\Lines\Summary** sequence format element is configured to fill the outbound document with a single summary line that includes the sum of the tax

values from the processed tax transactions.

5. On the **Mapping** tab, review the following details:

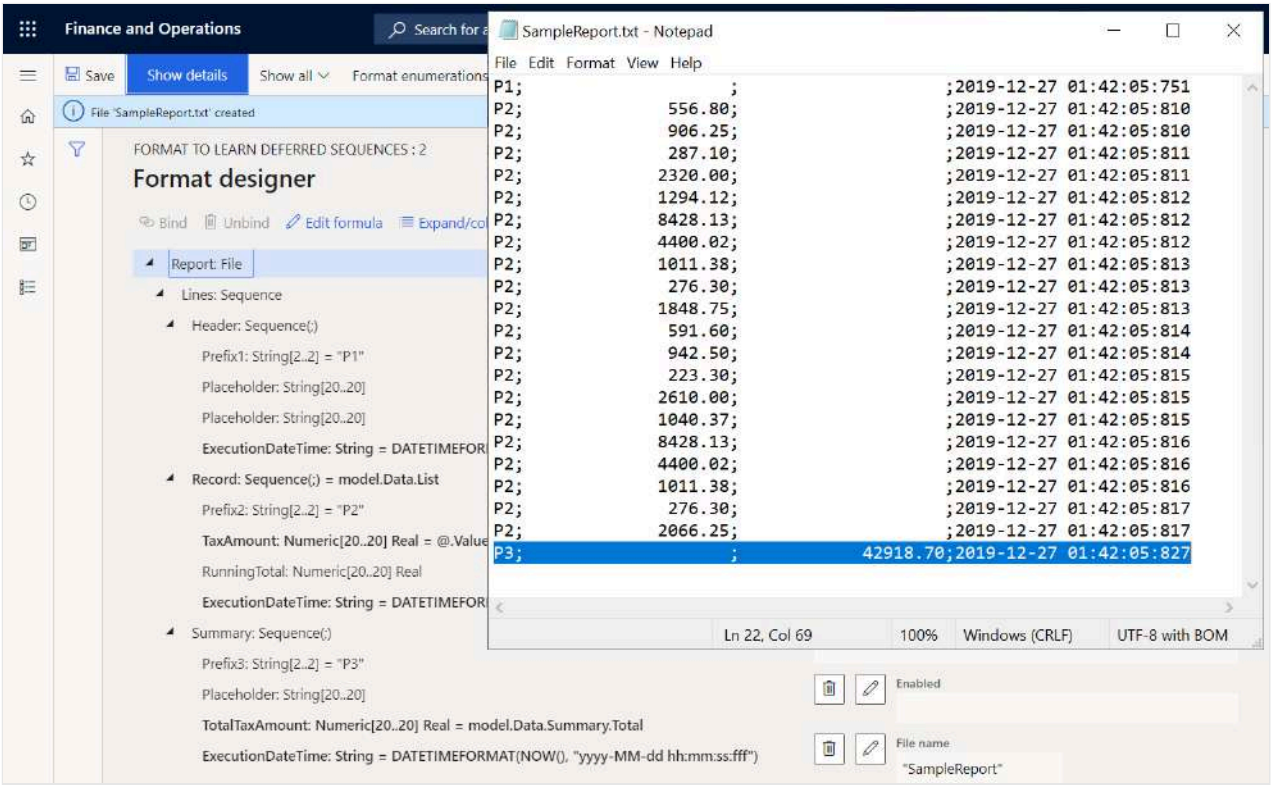
- The **Report\Lines\Header** element doesn't need to be bound to a data source to generate a single line in an outbound document.
- The **Prefix1** element generates **P1** symbols to indicate that the line that is added is the report header line.
- The **ExecutionDateTime** element generates the date and time (including milliseconds) when the header line is added.
- The **Report\Lines\Record** element is bound to the **model.Data.List** list to generate a single line for every record from the bound list.
- The **Prefix2** element generates **P2** symbols to indicate that the line that is added is for the tax transaction details.
- The **TaxAmount** element is bound to **model.Data.List.Value** (which is shown as **@.Value** in the relative path view) to generate the tax value of the current tax transaction.
- The **RunningTotal** element is a placeholder for the running total of the tax values. Currently, this element has no output, because neither a binding nor a default value is configured for it.
- The **ExecutionDateTime** element generates the date and time (including milliseconds) when the current transaction is processed in this report.
- The **Report\Lines\Summary** element doesn't need to be bound to a data source to generate a single line in an outbound document.
- The **Prefix3** element generates **P3** symbols to indicate that the line that is added contains the total tax value.
- The **TotalTaxAmount** element is bound to **model.Data.Summary.Total** to generate the sum of the tax values of the processed tax transactions.
- The **ExecutionDateTime** element generates the date and time (including milliseconds) when the summary line is added.



Run the imported format

1. On **Format designer**, select **Run**.

2. Download the file that the web browser offers, and open it for review.



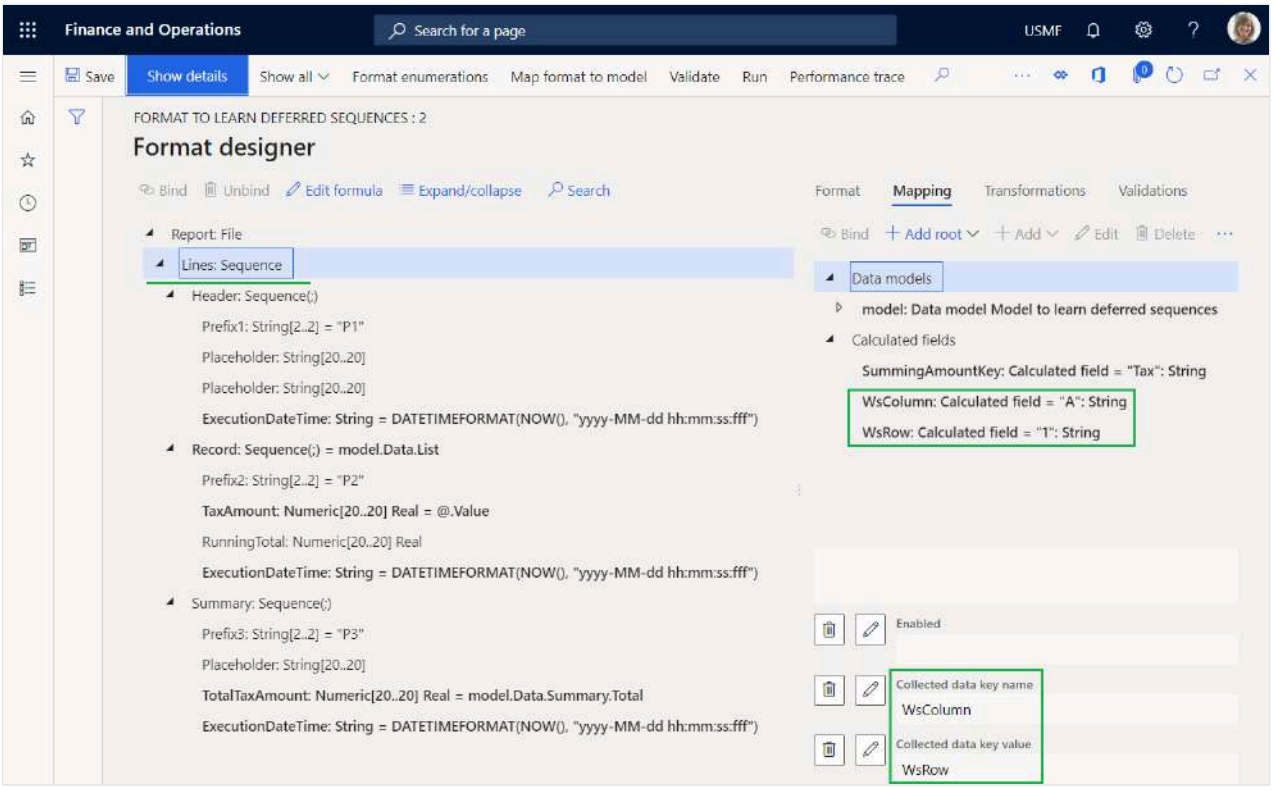
Summary line 22 presents the sum of the tax values for the processed transactions. Because the format uses the **model.Data.Summary.Total** binding to return this sum, the sum is calculated

by calling the **TotalSum** aggregation of the **Grouped** data source of the *GroupBy* type that uses the model mapping. To calculate this aggregation, model mapping iterates over all transactions selected in the **Filtered** data source. By comparing the execution times of lines 21 and 22, you can determine that calculation of the sum took 10 milliseconds (ms). By comparing the execution times of lines 2 and 21, you can determine that generation of all transactional lines took 7 ms. Therefore, a total of 17 ms was required.

Modify the format so that the summing is based on generated output

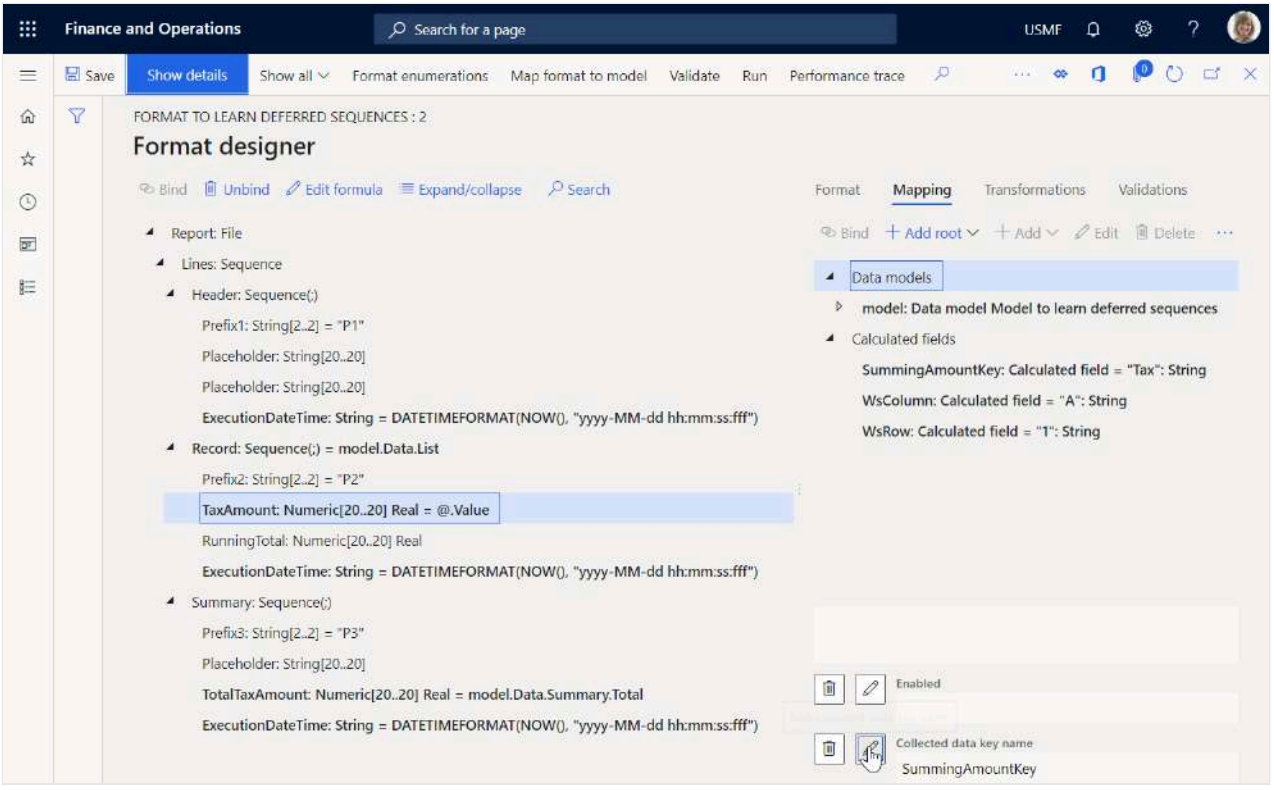
If the volume of transactions is much larger than the volume in the current example, the summing time might increase and cause performance issues. By changing the setting of the format, you can help prevent these performance issues. Because you access tax values to include them in the generated report, you can reuse this information to sum tax values. For more information, see Configure format to do counting and summing.

1. On the **Format designer** page, on the **Format** tab, select the **Report** file element in the format tree.
2. Set the **Collect output details** option to **Yes**. You can now configure this format by using the content of an existing report as a data source that can be accessed by using the built-in ER functions in the Data collection category.
3. On the **Mapping** tab, select the **Report\Lines** sequence element.
4. Configure the **Collected data key name** expression as `WsColumn`.
5. Configure the **Collected data key value** expression as `WsRow`.



6. Select the **Report\Lines\Record\TaxAmount** numeric element.

7. Configure the **Collected data key name** expression as `SummingAmountKey`.

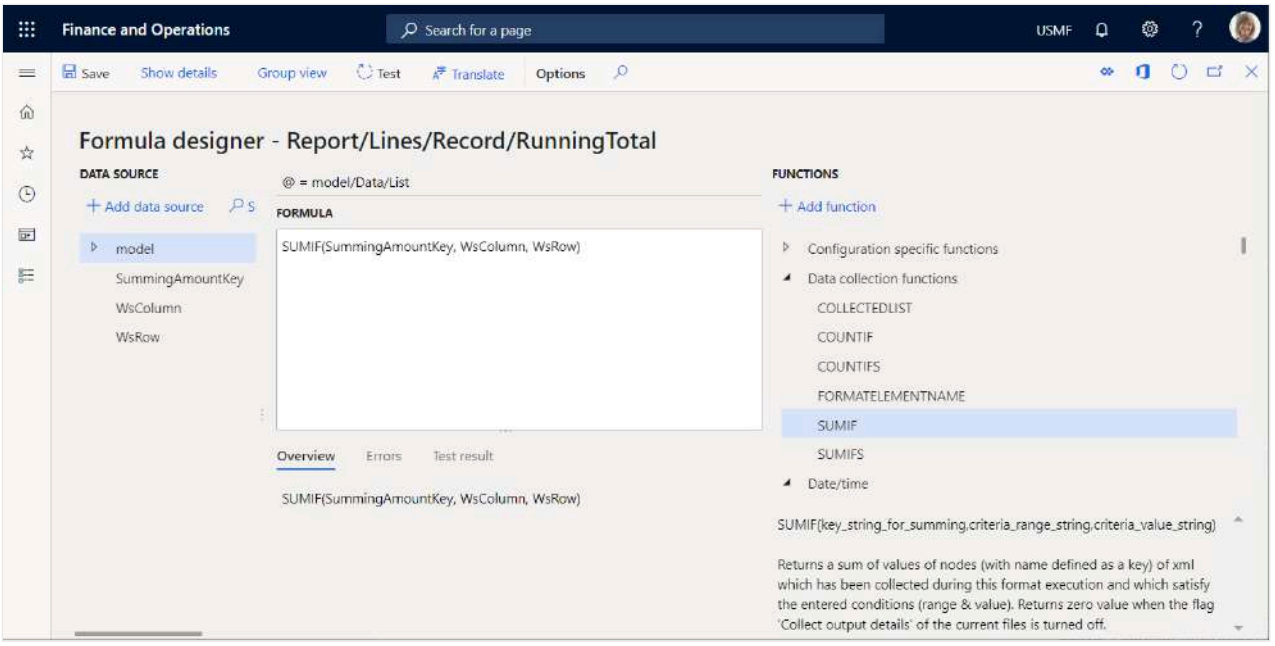


You can consider this setting the fulfillment of a virtual worksheet, where the value of cell A1 is appended with the value of the tax amount from every processed tax transaction.

8. Select the **Report\Lines\Record\RunningTotal** numeric element, and then select **Edit formula**.

9. Configure the `SUMIF(SummingAmountKey, WsColumn, WsRow)` expression by using the built-in SUMIF ER function.

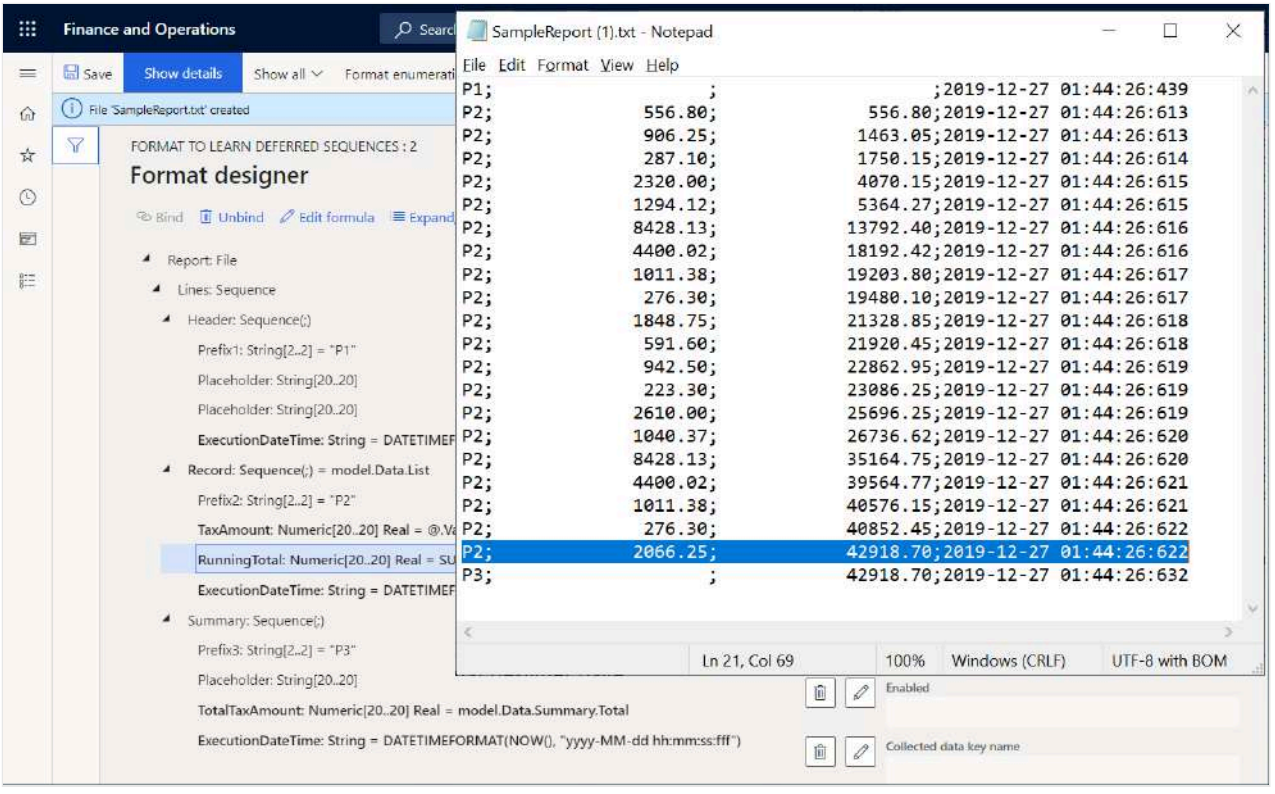
10. Select **Save**.



11. Close the **Formula designer** page.

12. Select **Save**, and then select **Run**.

13. Download and review the file that the web browser offers.



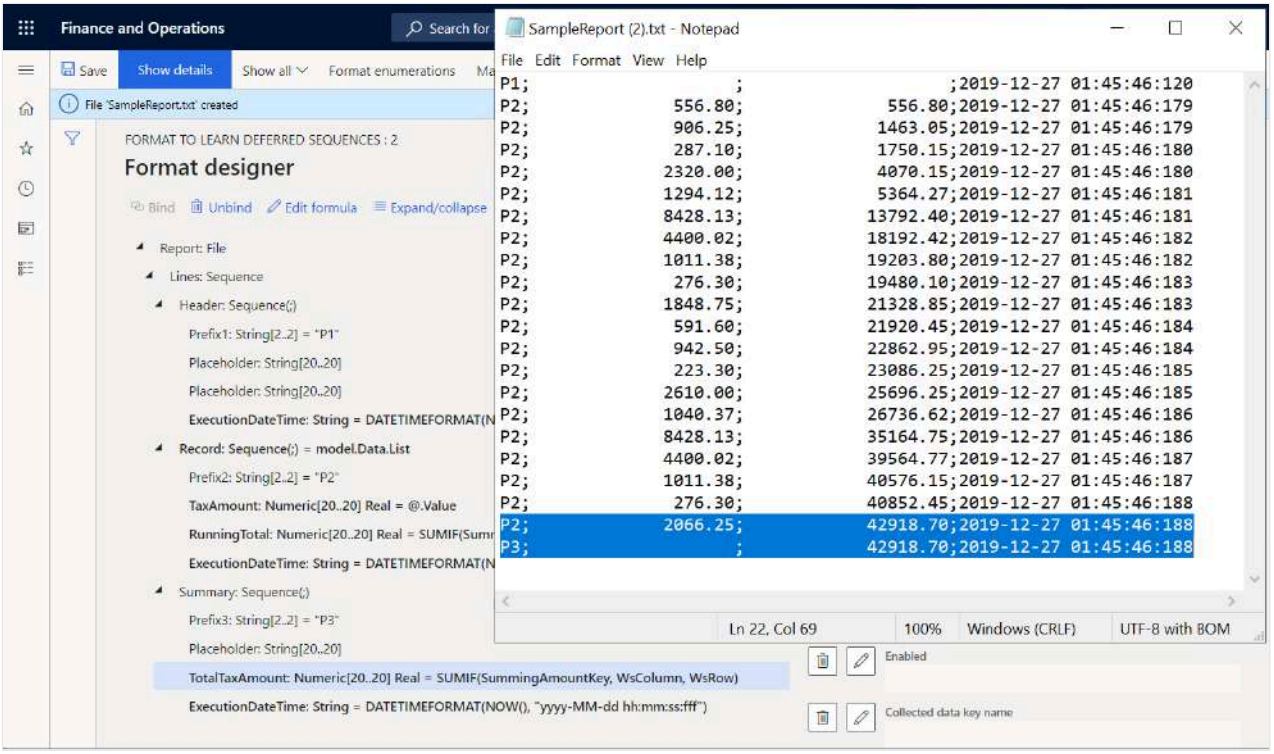
Line 21 contains the running total of tax values that is calculated for all processed transactions by using the generated output as a data source. This data source starts from the beginning of the report and continues through the last tax transaction. Line 22 contains the sum of the tax values for all processed transactions that are calculated in the model mapping by using the data source of the *GroupBy* type. Notice that these values are equal. Therefore, you can use output-based summing instead of **GroupBy**. By comparing the execution times of lines 2 and 21, you can determine that generation of all the transactional lines and summing took 9 ms. Therefore, as far as the generation of detailed lines and the summing of tax values are concerned, the modified format is approximately two times faster than the original format.

14. Select the **Report\Lines\Summary\TotalTaxAmount** numeric element, and then select **Edit formula**.

15. Enter the `SUMIF(SummingAmountKey, WsColumn, WsRow)` expression instead of the existing expression.

16. Select **Save**, and then select **Run**.

17. Download and review the file that the web browser offers.

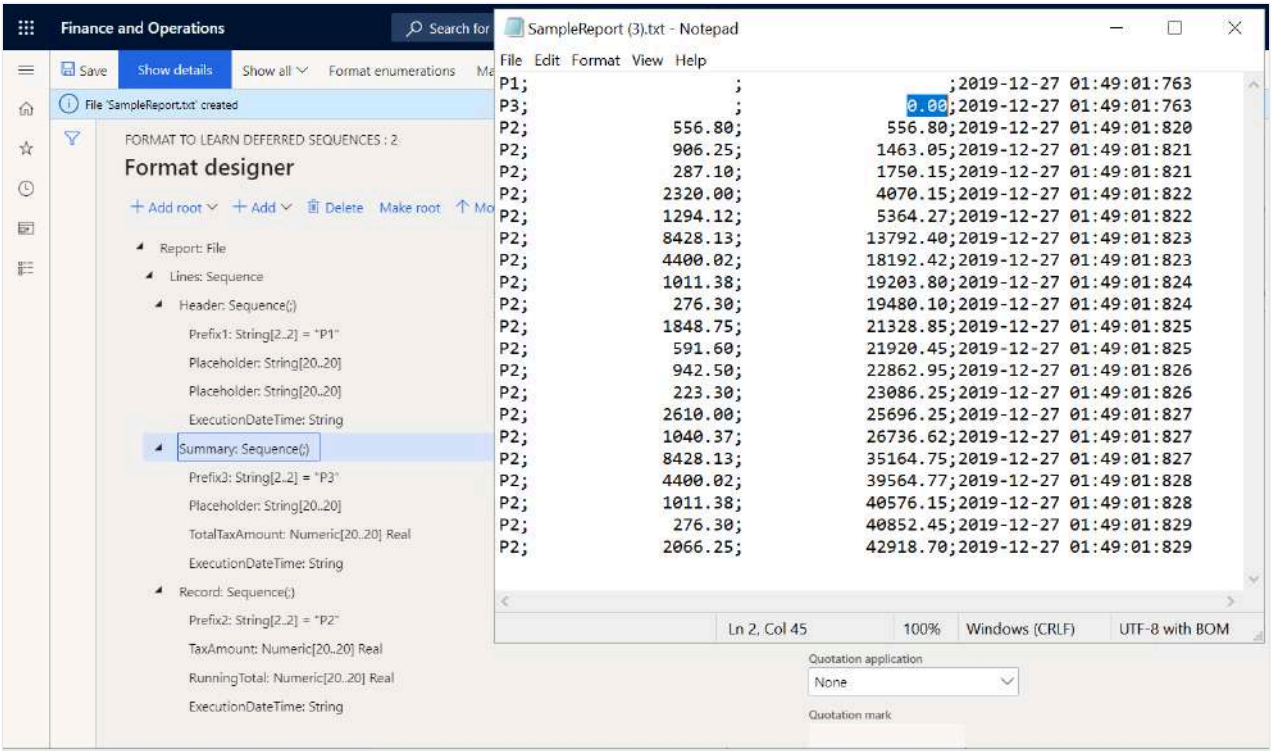


Notice that the running total of tax values on the last transaction details line now equals the sum on the summary line.

Put values of output-based summing in the report header

If, for example, you need to present the sum of tax values in the header of your report, you can modify your format.

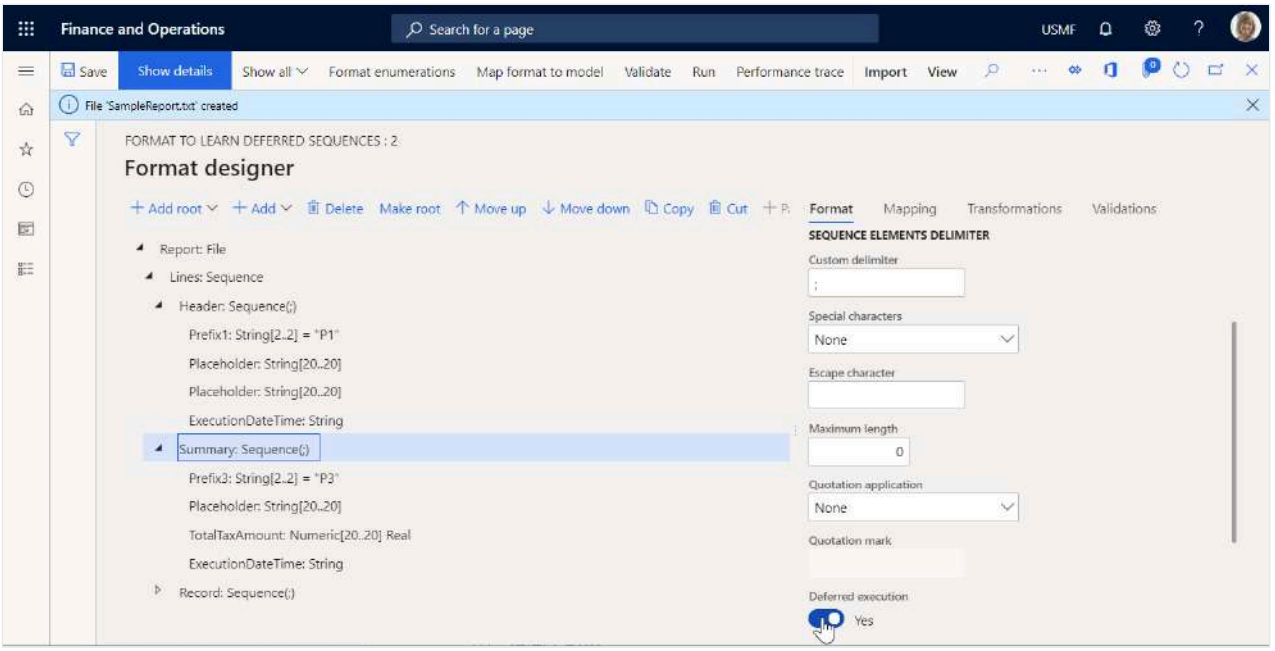
1. On the **Format designer** page, on the **Format** tab, select the **Report\Lines\Summary** sequence element.
2. Select **Move up**.
3. Select **Save**, and then select **Run**.
4. Download and review the file that the web browser offers.



The sum of tax values on summary line 2 now equals 0 (zero), because this sum is now calculated based on the generated output. When line 2 is generated, the generated output doesn't yet contain lines that have transaction details. You can configure this format to defer the execution of the **Report\Lines\Summary** sequence element until the **Report\Lines\Record** sequence element runs for all tax transactions.

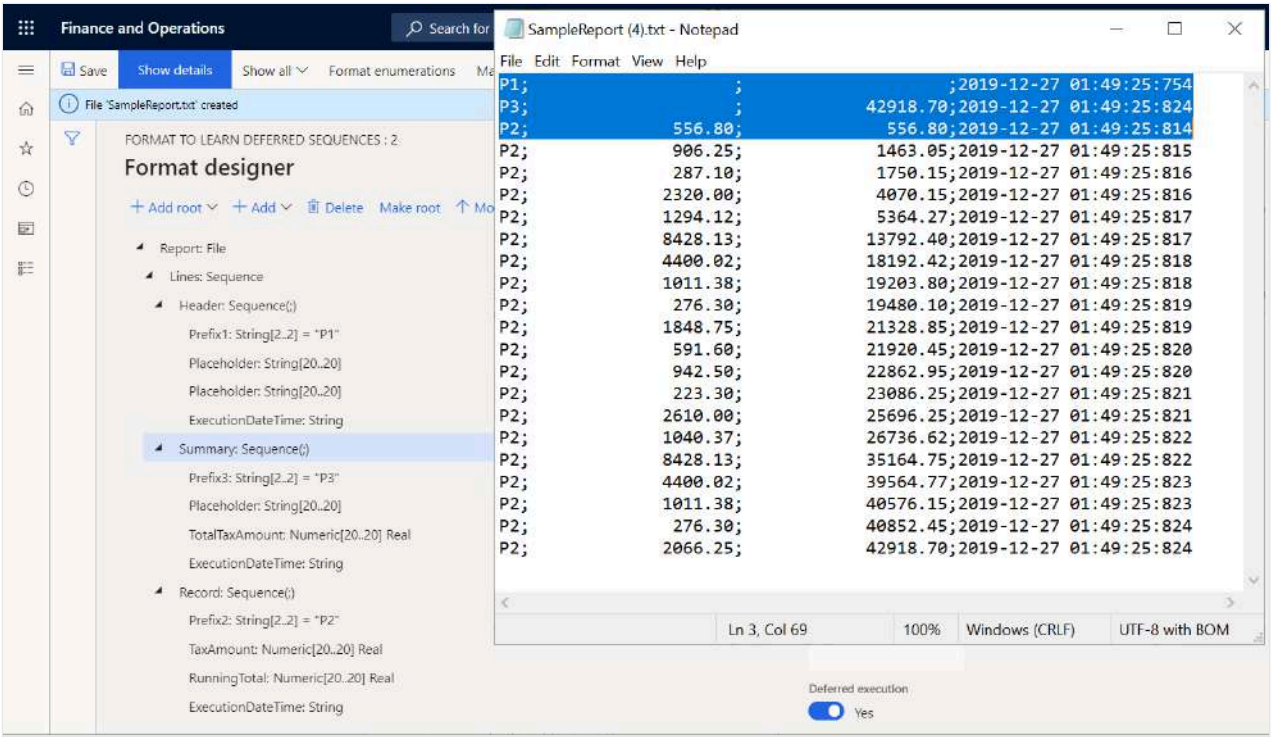
Defer the execution of the summary sequence so that the calculated total is used

1. On the **Format designer** page, on the **Format** tab, select the **Report\Lines\Summary** sequence element.
2. Set the **Deferred execution** option to **Yes**.



3. Select **Save**, and then select **Run**.

4. Download and review the file that the web browser offers.



The **Report\Lines\Summary** sequence element now runs only after all other items that are nested under its parent element, **Report\Lines**, run. Therefore, it runs after the **Report\Lines\Record** sequence element runs for all tax transactions of the **model.Data.List** data source. The execution times of lines 1, 2, and 3, and of the last line, 22, reveal this fact.

Defer the execution of XML elements in ER formats

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Overview

Use the Operations designer of the Electronic reporting (ER) framework to configure the format component of an ER solution that generates outbound documents in XML format. The hierarchical structure of the configured format component consists of format elements of various types. These format elements fill generated documents with the required information at runtime. By default, when you run an ER format, the format elements run in the same order as they appear in the format hierarchy: one by one, from top to bottom. However, at design time, you can change the execution order for any XML elements of the configured format component.

When you turn on the **Deferred execution** option for an XML element in the configured format, you defer (postpone) the execution of that element. In this case, the element isn't run until all other elements of its parent run.

To learn more about this feature, complete the example in this article.

Limitations

The **Deferred execution** option supports only XML elements that are configured for an ER format that generates **outbound** documents in XML format.

The **Deferred execution** option supports only XML elements that reside in one other XML element. Therefore, it doesn't apply to XML elements that reside in other types of format elements (for example, in an **XML sequence** element).

The **Deferred execution** option isn't supported for XML elements that reside in the **Common\File** format element when the **Split file** option is set to **Yes**. For more information about how to split XML files, see Split generated XML files based on file size and content quantity.

Example: Defer the execution of an XML element in an ER format

The following steps explain how a user in the System administrator or Electronic reporting functional consultant role can configure an ER format that contains an XML element where the order of execution differs from the order in the format hierarchy.

You can perform these steps in the **USMF** company in Microsoft Dynamics 365 Finance.

Prerequisites

To complete this example, you must have access to the **USMF** company in Finance for one of the following roles:

- Electronic reporting functional consultant
- System administrator

If you didn't yet complete the example in the Defer the execution of sequence elements in ER formats article, download the following configurations of the sample ER solution.

Expand table

Content description	File name
ER data model configuration	Model to learn deferred elements.version.1.xml
ER model mapping configuration	Mapping to learn deferred elements.version.1.1.xml

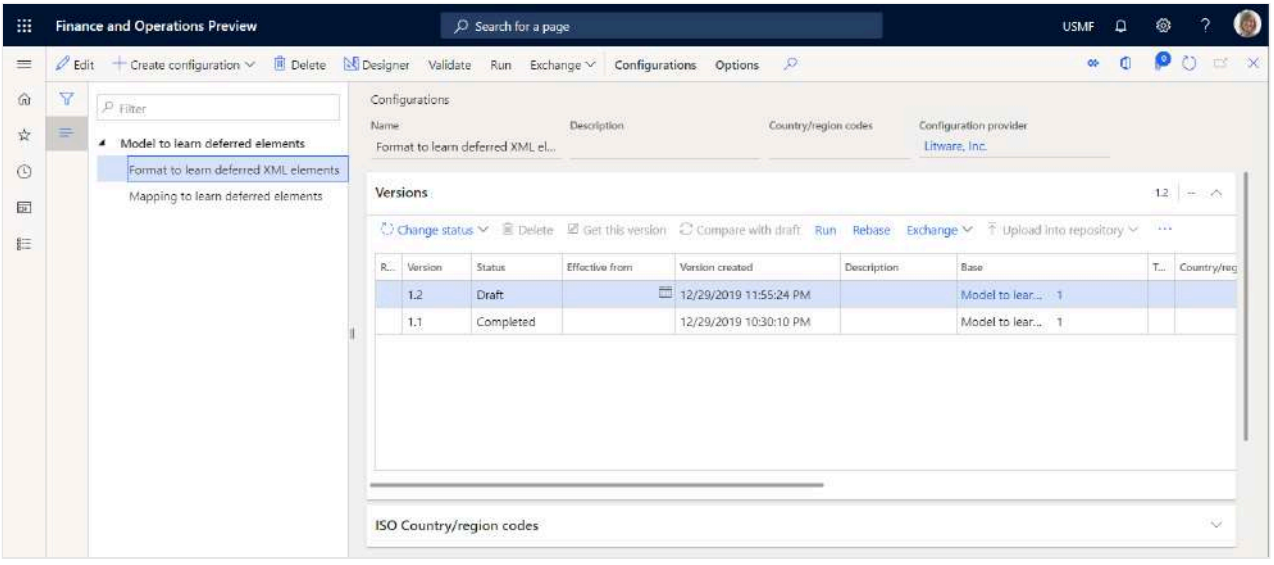
Before you begin, also download and save the following configuration of the sample ER solution to your local computer.

Expand table

Content description	File name
ER format configuration	Format to learn deferred XML elements.version.1.1.xml

Import the sample ER configurations

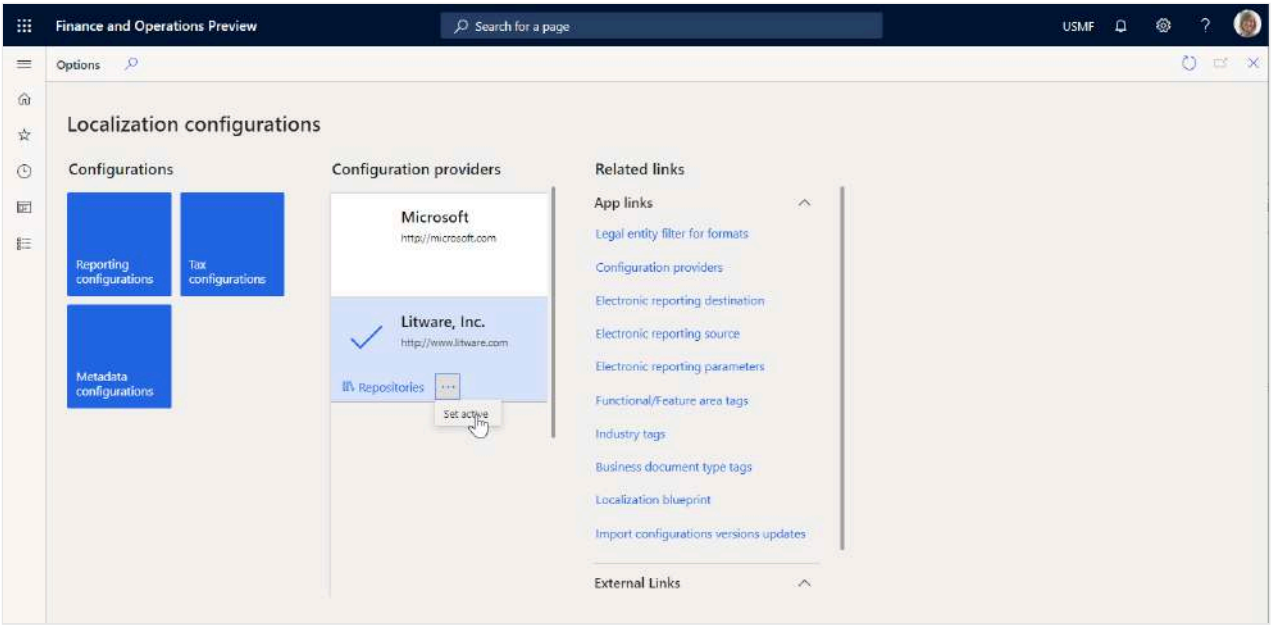
1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. On **Configurations**, if the **Model to learn deferred elements** configuration isn't available in the configuration tree, import the ER data model configuration:
   a. Select **Exchange**, and then select **Load from XML file**.
   b. Select **Browse**, find and select the **Model to learn deferred elements.1.xml** file, and then select **OK**.
4. If the **Mapping to learn deferred elements** configuration isn't available in the configuration tree, import the ER model mapping configuration:
   a. Select **Exchange**, and then select **Load from XML file**.
   b. Select **Browse**, find and select the **Mapping to learn deferred elements.1.1.xml** file, and then select **OK**.
5. Import the ER format configuration:
   a. Select **Exchange**, and then select **Load from XML file**.
   b. Select **Browse**, find and select the **Format to learn deferred XML elements.1.1.xml** file, and then select **OK**.
6. In the configuration tree, expand **Model to learn deferred elements**.
7. Review the list of imported ER configurations in the configuration tree.



Activate a configuration provider

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

2. On **Localization configurations**, in the **Configuration providers** section, make sure that the configuration provider for the Litware, Inc. (`http://www.litware.com`) sample company is listed and marked as active. If this configuration provider isn't listed, or if it isn't marked as active, follow the steps in the Create a configuration provider and mark it as active article.



Review the imported model mapping

Review the settings of the ER model mapping component that you configured to access tax transactions and expose accessed data on request.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

2. Select **Reporting configurations**.

3. On **Configurations**, in the configuration tree, expand **Model to learn deferred elements**.

4. Select the **Mapping to learn deferred elements** configuration.

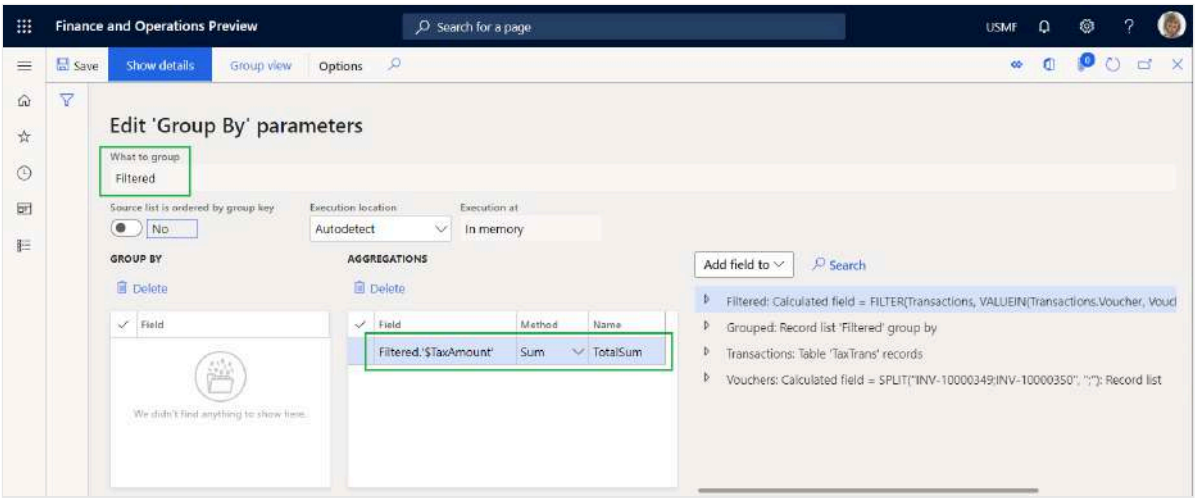
5. Select **Designer** to open the list of mappings.

6. Select **Designer** to review the mapping details.

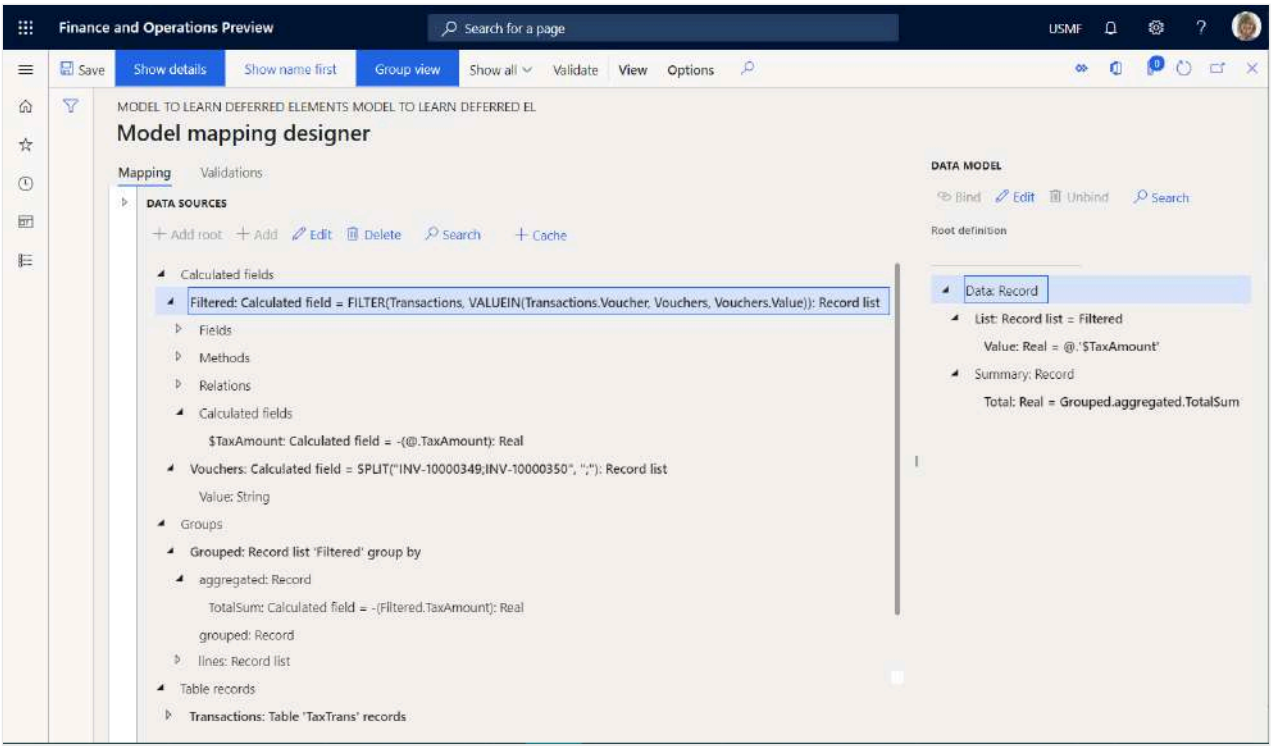
7. Select **Show details**.

8. Review the data sources that are configured to access tax transactions:

- The **Transactions** data source of the *Table record* type is configured to access records of the **TaxTrans** application table.
- The **Vouchers** data source of the *Calculated field* type is configured to return the required voucher codes (**INV-10000349** and **INV-10000350**) as a list of records.
- The **Filtered** data source of the *Calculated field* type is configured to select, from the **Transactions** data source, only tax transactions of the required vouchers.
- The **$TaxAmount** field of the *Calculated field* type is added for the **Filtered** data source to expose the tax value that has the opposite sign.
- The **Grouped** data source of the *Group By* type is configured to group filtered tax transactions of the **Filtered** data source.
- The **TotalSum** aggregation field of the **Grouped** data source is configured to summarize values of the **$TaxAmount** field of the **Filtered** data source for all filtered tax transactions of that data source.



9. Review how the configured data sources are bound to the data model, and how they expose accessed data to make it available in an ER format:
   - The **Filtered** data source is bound to the **Data.List** field of the data model.
   - The **$TaxAmount** field of the **Filtered** data source is bound to the **Data.List.Value** field of the data model.
   - The **TotalSum** field of the **Grouped** data source is bound to the **Data.Summary.Total** field of the data model.



10. Close the **Model mapping designer** and **Model mappings** pages.

Review the imported format

1. On **Configurations**, in the configuration tree, select the **Format to learn deferred XML elements** configuration.

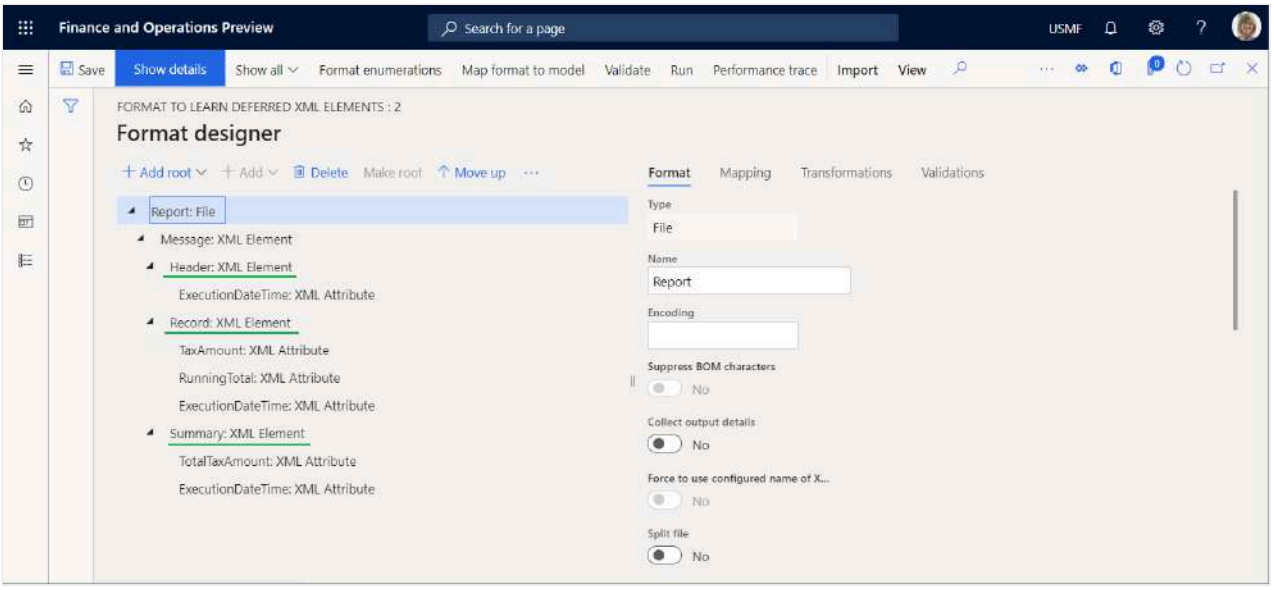
2. Select **Designer** to review the format details.

3. Select **Show details**.

4. Review the settings of the ER format components that are configured to generate an outbound document in XML format that includes details of the tax transactions:

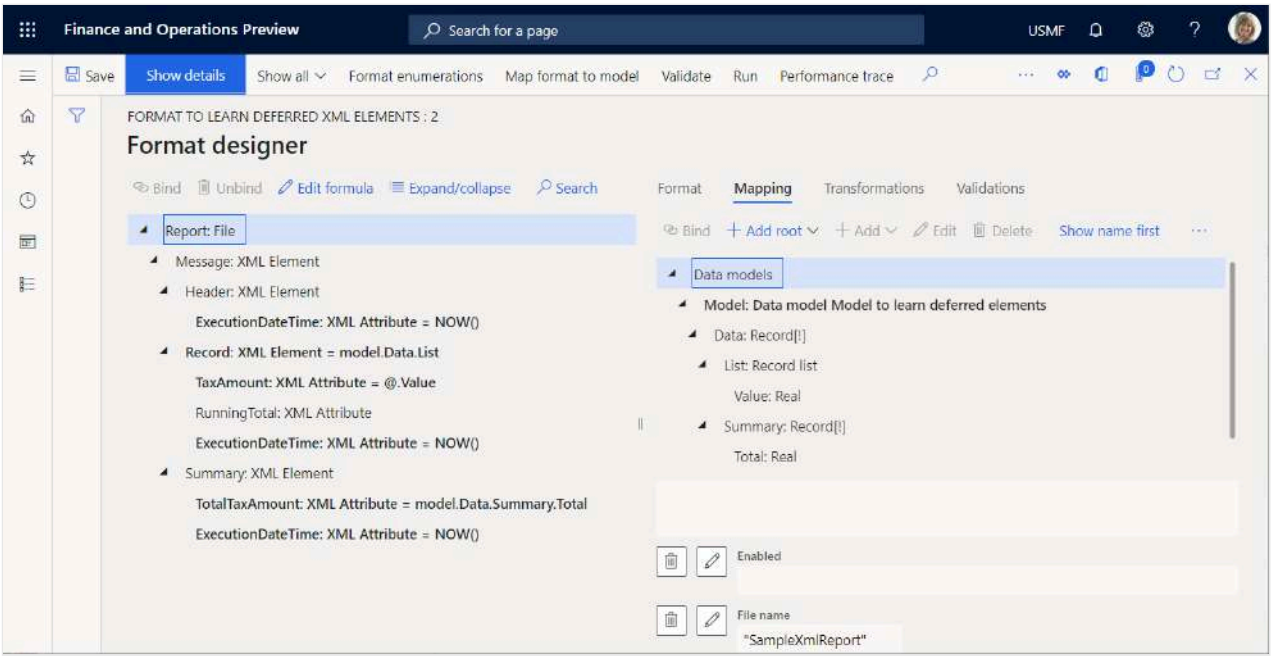
    - The **Report\Message** XML element is configured to fill the outbound document with a single node that includes the nested XML elements (**Header**, **Record**, and **Summary**).
    - The **Report\Message\Header** XML element is configured to fill the outbound document with a single header node that shows the date and time when the processing starts.
    - The **Report \Message\Record** XML element is configured to fill the outbound document with a single record node that shows the details of a single tax transaction.
    - The **Report\Message\Summary** XML element is configured to fill the outbound document with a single summary node that includes the sum of the tax values from

the processed tax transactions.



5. On the **Mapping** tab, review the following details:

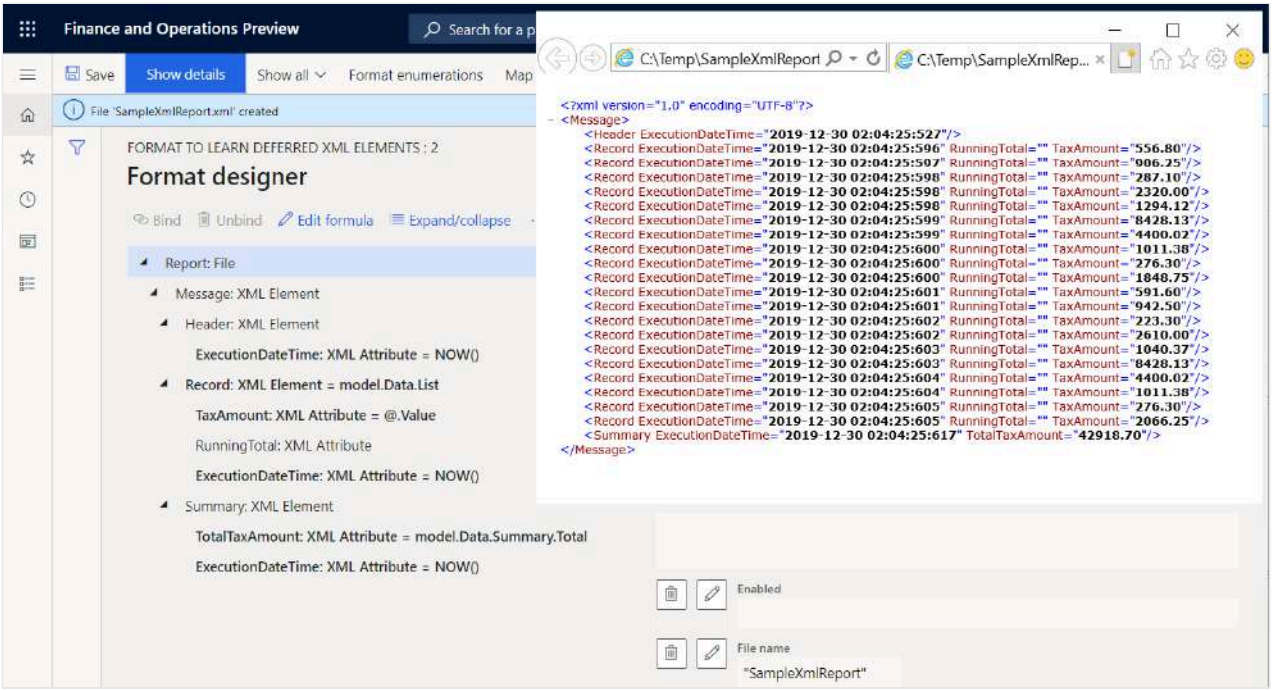
- The **Report\Message\Header** element doesn't need to be bound to a source to generate a single node in an outbound document.
- The **ExecutionDateTime** attribute generates the date and time (including milliseconds) when the header node is added.
- The **Report\Message\Record** element is bound to the **model.Data.List** list to generate a single record node for every record from the bound list.
- The **TaxAmount** attribute is bound to **model.Data.List.Value** (which is shown as **@.Value** in the relative path view) to generate the tax value of the current tax transaction.
- The **RunningTotal** attribute is a placeholder for the running total of the tax values. Currently, this attribute has no output, because neither a binding nor a default value is configured for it.
- The **ExecutionDateTime** attribute generates the date and time (including milliseconds) when the current transaction is processed in this report.
- The **Report\Message\Summary** element doesn't need to be bound to a data source to generate a single node in an outbound document.
- The **TotalTaxAmount** attribute is bound to **model.Data.Summary.Total** to generate the sum of the tax values of the processed tax transactions.
- The **ExecutionDateTime** attribute generates the date and time (including milliseconds) when the summary node is added.



Run the imported format

1. On **Format designer**, select **Run**.

2. Download the file that the web browser offers, and open it for review.



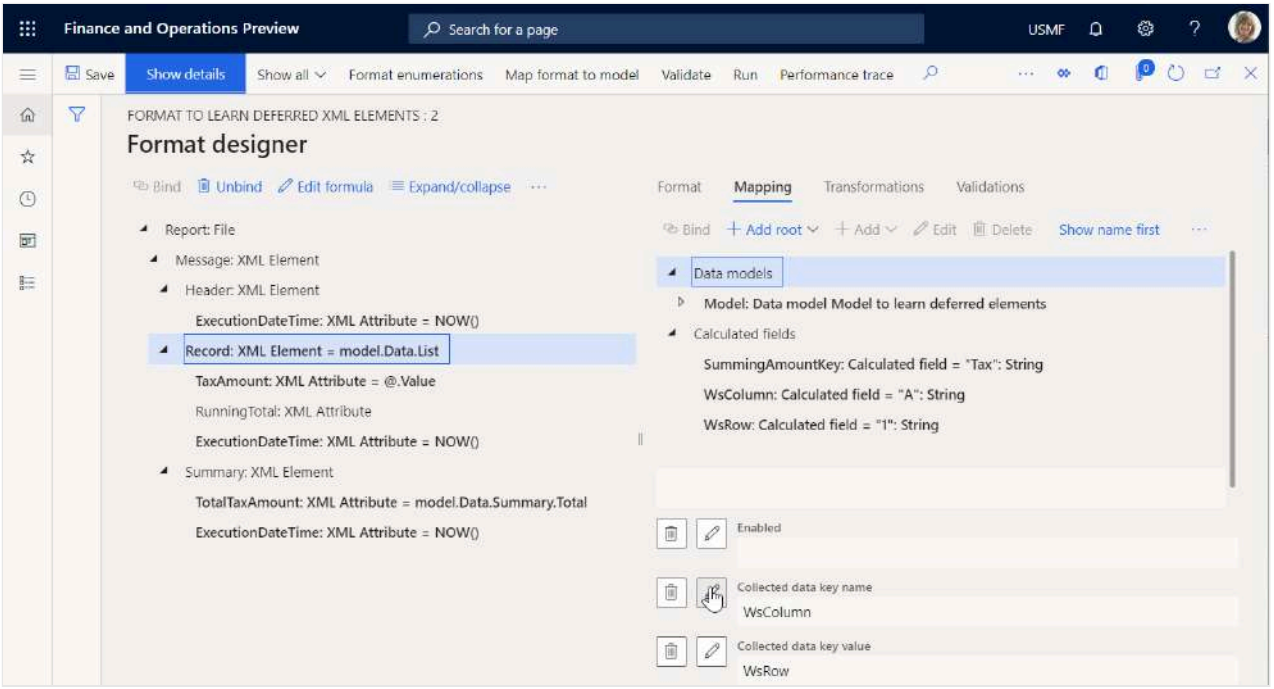
The summary node presents the sum of the tax values for the processed transactions. Because the format uses the **model.Data.Summary.Total** binding to return this sum, the sum is calculated by calling the **TotalSum** aggregation of the **Grouped** data source of the *GroupBy* type in the model mapping. To calculate this aggregation, the model mapping iterates over all transactions that you select in the **Filtered** data source. By comparing the execution times of the summary node and the last record node, you can determine that calculation of the sum

took 12 milliseconds (ms). By comparing the execution times of the first and last record nodes, you can determine that generation of all record nodes took 9 ms. Therefore, a total of 21 ms was required.

Modify the format so that the calculation is based on generated output

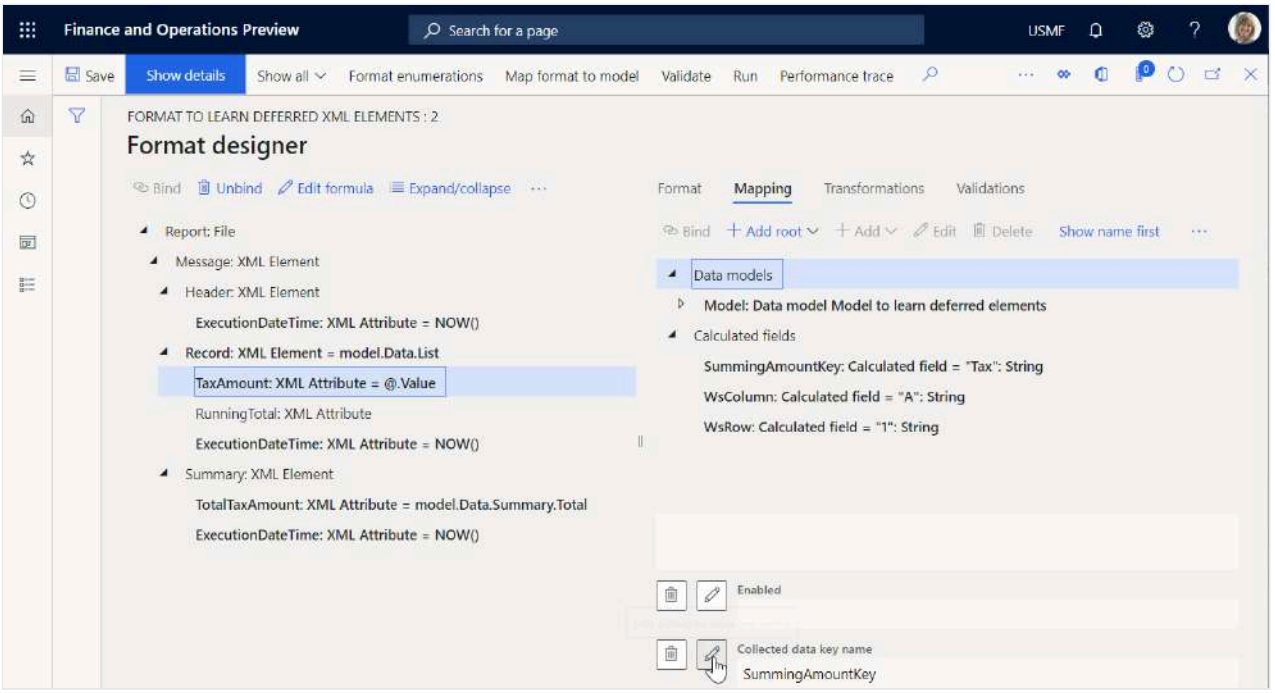
If the transaction volume is much larger than the volume in the current example, the calculation time might increase and cause performance problems. By changing the setting of the format, you can help prevent these performance problems. Because you access tax values to include them in the generated report, you can reuse this information to calculate tax values. For more information, see Configure format to do counting and summing.

1. On the **Format designer** page, on the **Format** tab, select the **Report** file element in the format tree.
2. Set the **Collect output details** option to **Yes**. You can now configure this format by using the content of a generated report as a data source that the built-in ER functions in the Data collection category can access.
3. On the **Mapping** tab, select the **Report\Message\Record** XML element.
4. Configure the **Collected data key name** expression as `WsColumn`.
5. Configure the **Collected data key value** expression as `WsRow`.



6. Select the **Report\Message\Record\TaxAmount** attribute.

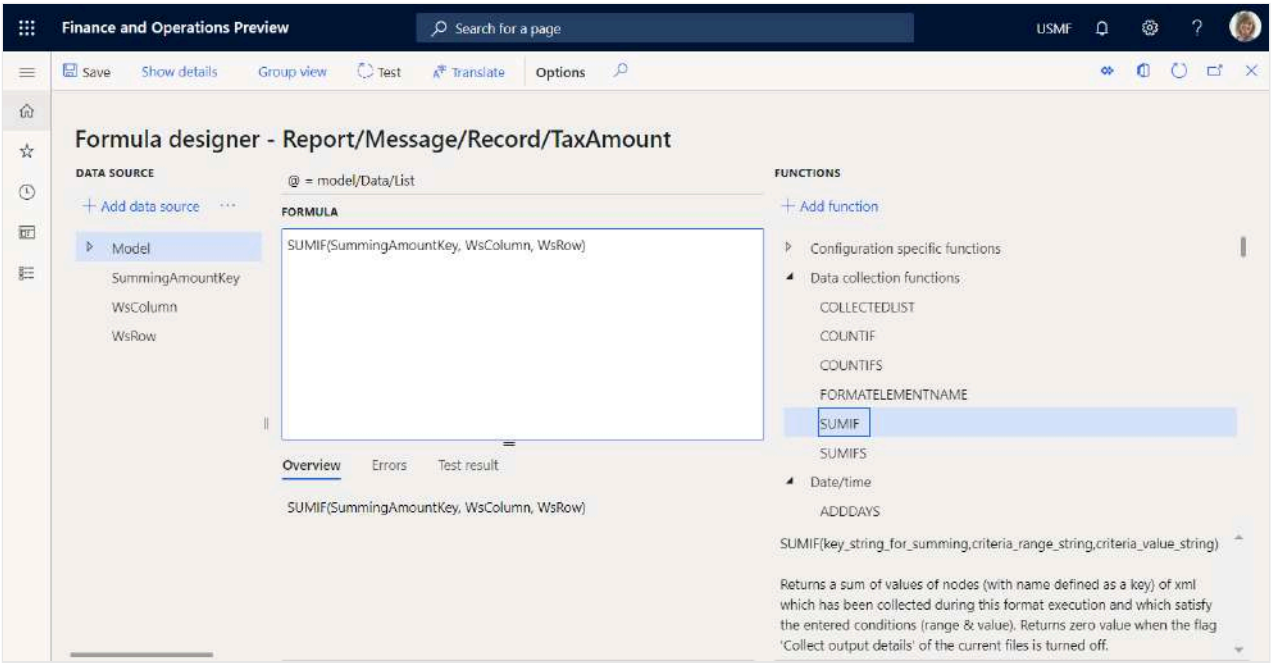
7. Configure the **Collected data key name** expression as `SummingAmountKey`.



You can consider this setting the fulfillment of a virtual worksheet, where the value of cell A1 is appended with the value of the tax amount from every processed tax transaction.

8. Select the **Report\Message\Record\RunningTotal** attribute, and then select **Edit formula**.

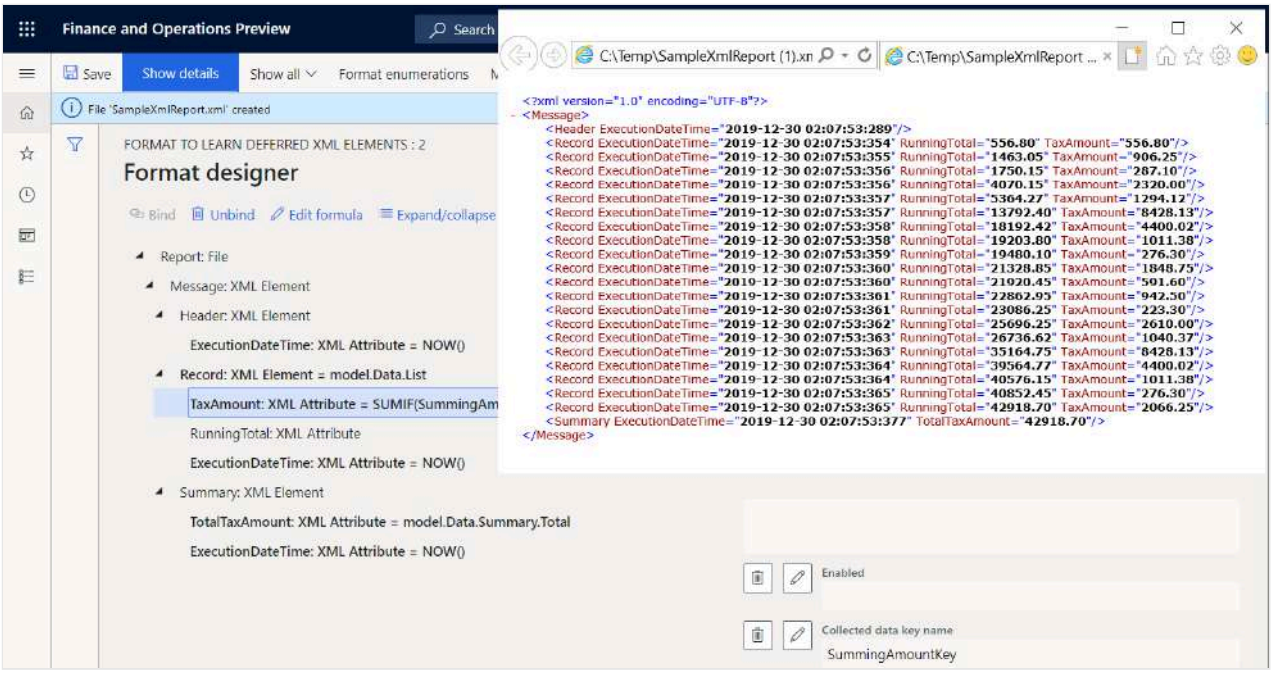
9. Configure the `SUMIF(SummingAmountKey, WsColumn, WsRow)` expression by using the built-in SUMIF ER function, and then select **Save**.



10. Close the **Formula designer** page.

11. Select **Save**, and then select **Run**.

12. Download and review the file that the web browser offers.



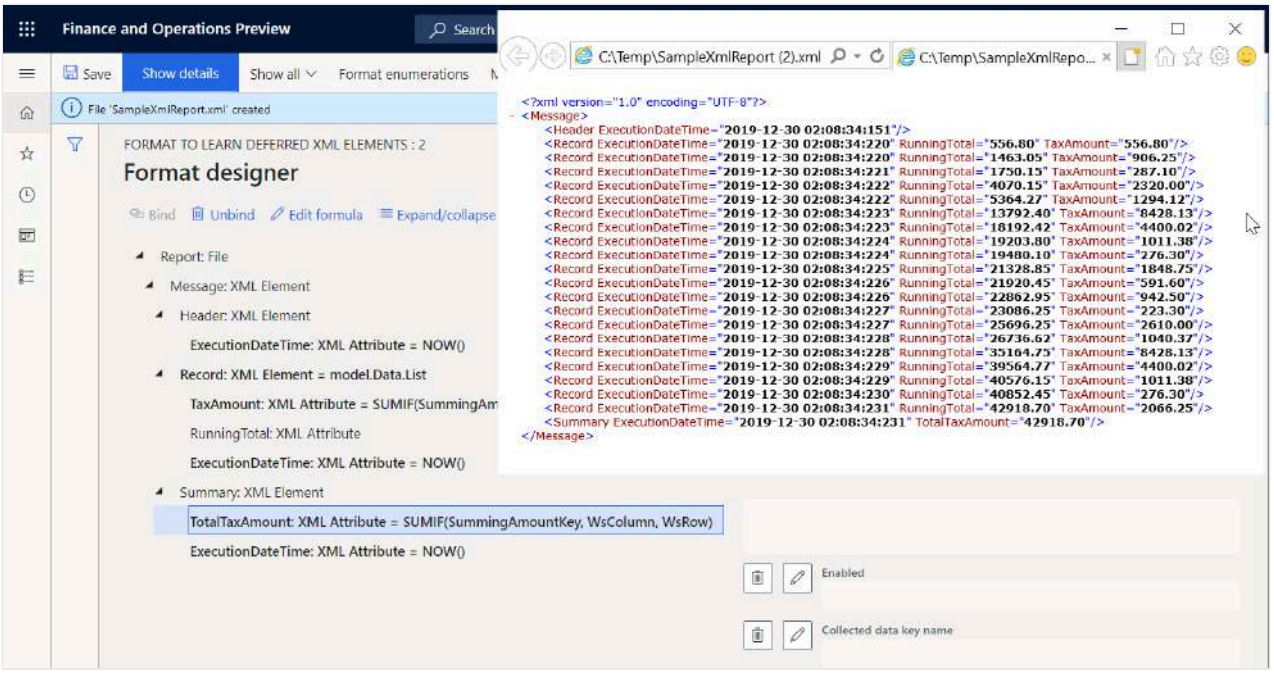
The last record node contains the running total of tax values that is calculated for all processed transactions by using the generated output as a data source. This data source starts from the beginning of the report and continues through the last tax transaction. The summary node contains the sum of the tax values for all processed transactions that are calculated in the model mapping by using the data source of the *GroupBy* type. Notice that these values are equal. Therefore, you can use output-based summing instead of **GroupBy**. By comparing the execution times of the first record node and the summary node, you can determine that generation of all the record nodes and summing took 11 ms. Therefore, as far as the generation of record nodes and the summing of tax values are concerned, the modified format is approximately two times faster than the original format.

13. Select the **Report\Message\Summary\TotalTaxAmount** attribute, and then select **Edit formula**.

14. Enter the `SUMIF(SummingAmountKey, WsColumn, WsRow)` expression instead of the existing expression.

15. Select **Save**, and then select **Run**.

16. Download and review the file that the web browser offers.

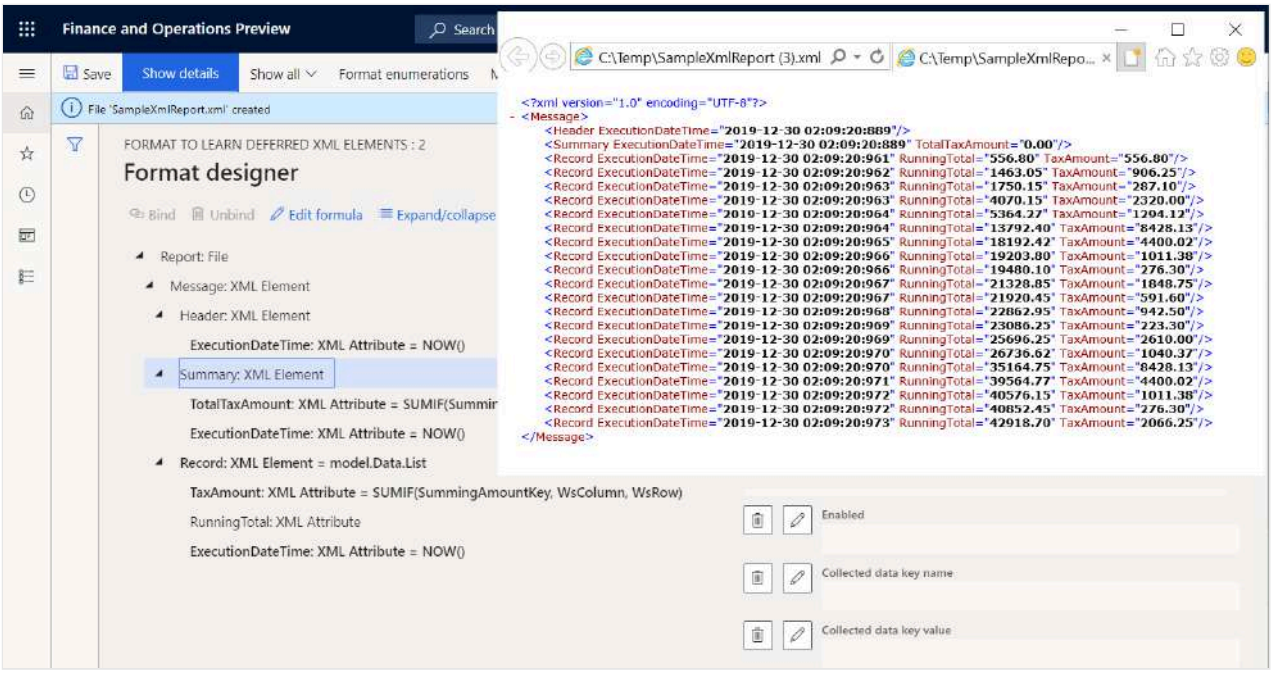


Notice that the running total of tax values in the last record node now equals the sum in the summary node.

Put values of output-based summing in the report header

If you need to present the sum of tax values in the header of your report, you can modify your format.

1. On the **Format designer** page, on the **Format** tab, select the **Report\Message\Summary** XML element.
2. Select **Move up**.
3. Select **Save**, and then select **Run**.
4. Download and review the file that the web browser offers.

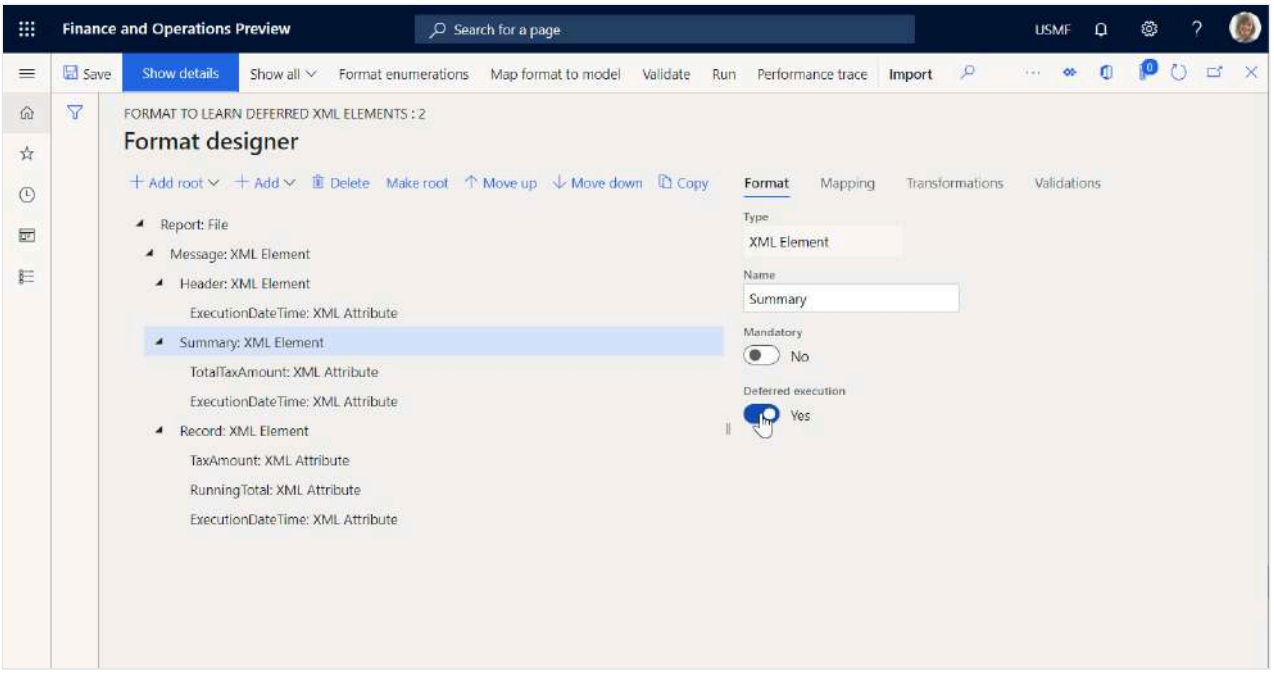


The sum of tax values in the summary node now equals 0 (zero), because this sum is now calculated based on the generated output. When the first record node is generated, the generated output doesn't yet contain record nodes that have transaction details. You can configure this format to defer the execution of the **Report\Message\Summary** element until the **Report\Message\Record** element runs for all tax transactions.

Defer the execution of the summary XML element so that the calculated total is used

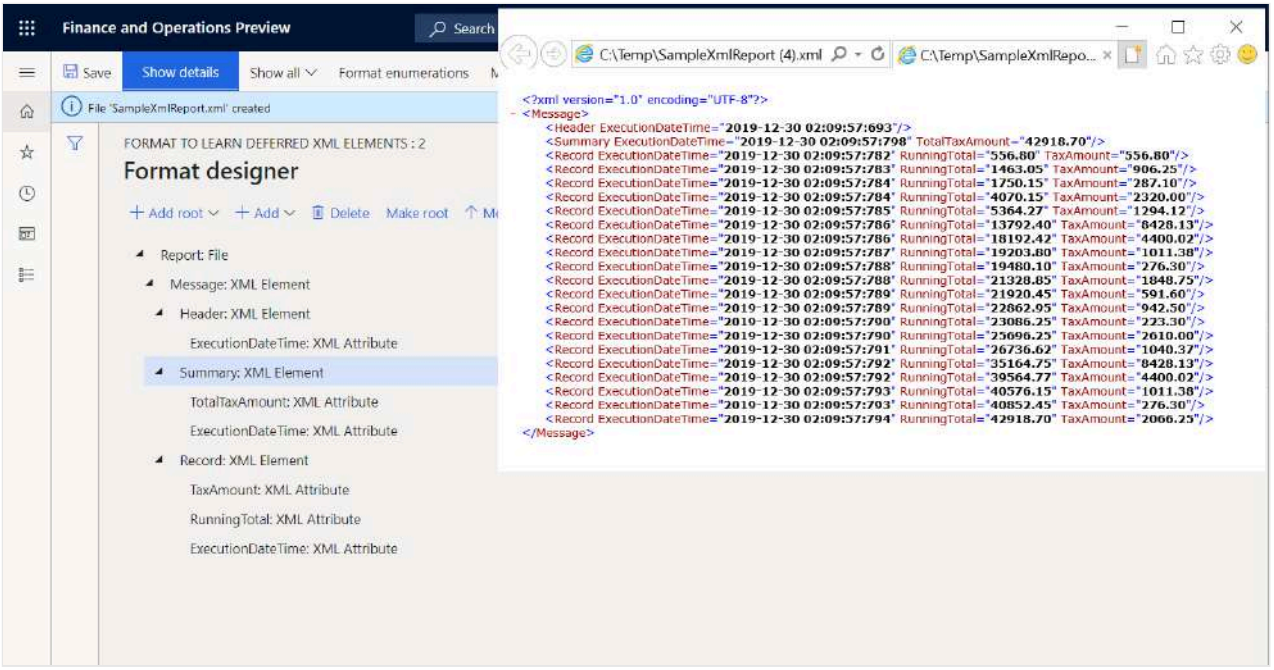
1. On the **Format designer** page, on the **Format** tab, select the **Report\Message\Summary** XML element.

2. Set the **Deferred execution** option to **Yes**.



3. Select **Save**, and then select **Run**.

4. Download and review the file that the web browser offers.



The **Report\Message\Summary** element now runs only after all other items that are nested under its parent element, **Report\Message**, run. Therefore, it runs after the **Report\Message\Record** element runs for all tax transactions of the **model.Data.List** data source. The execution times of the first and last record nodes, and of the header and summary nodes, reveal this fact.

Design multilingual reports in Electronic reporting

10/02/2025

Overview

As a business user, you can use the Electronic reporting (ER) framework to configure formats for outbound documents that must be generated in accordance with the legal requirements of various countries or regions. When these requirements demand that outbound documents be generated in different languages for different countries or regions, you can configure a single ER format that contains language-dependent resources. In that way, you can reuse the format to generate outbound documents for various countries or regions. You might also want to use a single ER format to generate an outbound document in different languages for corresponding customers, vendors, subsidiaries, or any other parties.

You can configure ER data models and model mappings as the data sources of configured ER formats to define the data flow that specifies what application data is put into generated documents. As an ER configuration provider, you can publish configured data models, model mappings, and formats as components of an ER solution to generate specific outbound documents. You can also allow customers to upload the published ER solution so that it can be used and customized. If you expect that customers might speak other languages, you can configure the ER components so that they contain language-dependent resources. In that way, the content of an editable ER component can be presented in a customer's user-preferred language at design time.

You can configure language-dependent resources as ER labels. You can then use those labels to configure ER components for the following purposes:

- At design time:
  - Present the content of configured ER components in the user-preferred language.
- At runtime:
  - Generate language-dependent content for outbound documents.
  - Provide warning and error messages in the user-preferred language.
  - Prompt for required fields in the user-preferred language.

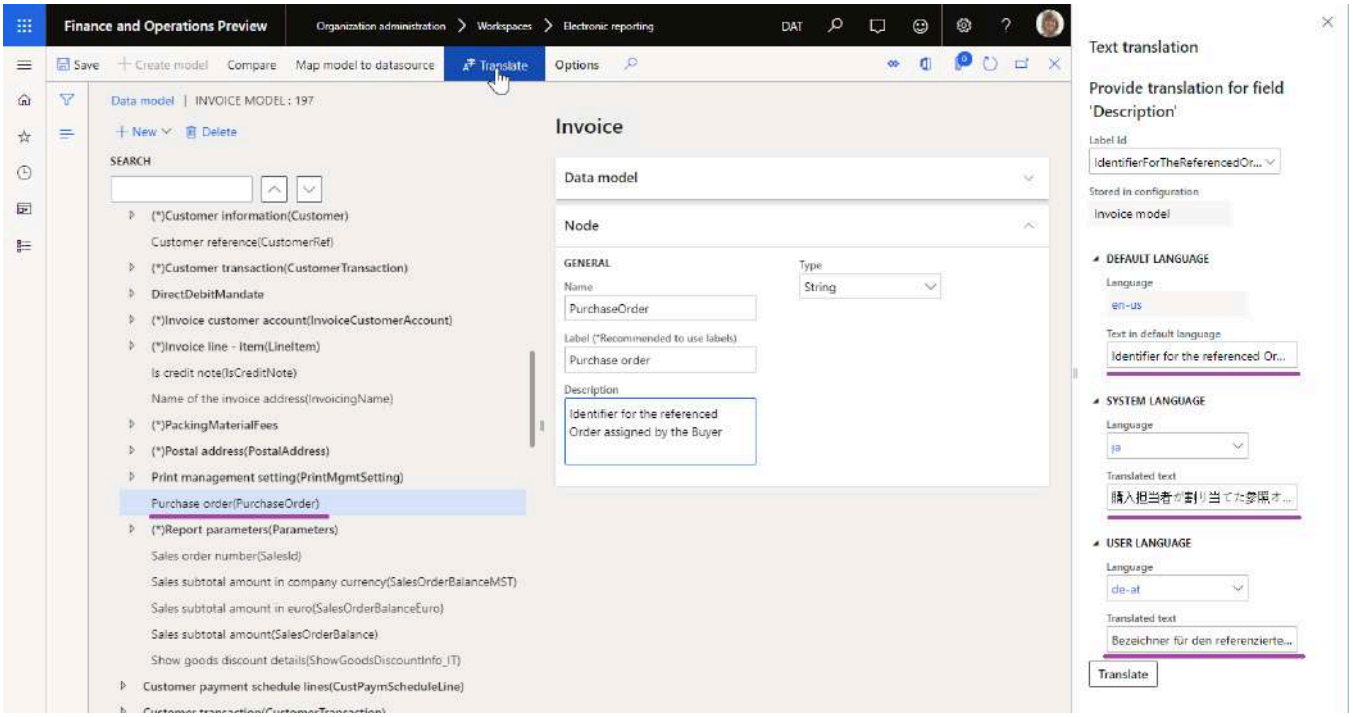
ER labels can be configured in every ER configuration that contains different components. The labels can be maintained independently of the configured logic of ER data models, ER model mappings, and ER format components.

Every ER label is identified by an ID that is unique in the scope of the ER configuration that holds that label. Every label can contain label text for every language that is supported in the current instance of Microsoft Dynamics 365 Finance. These supported languages include the languages of deployed customizations.

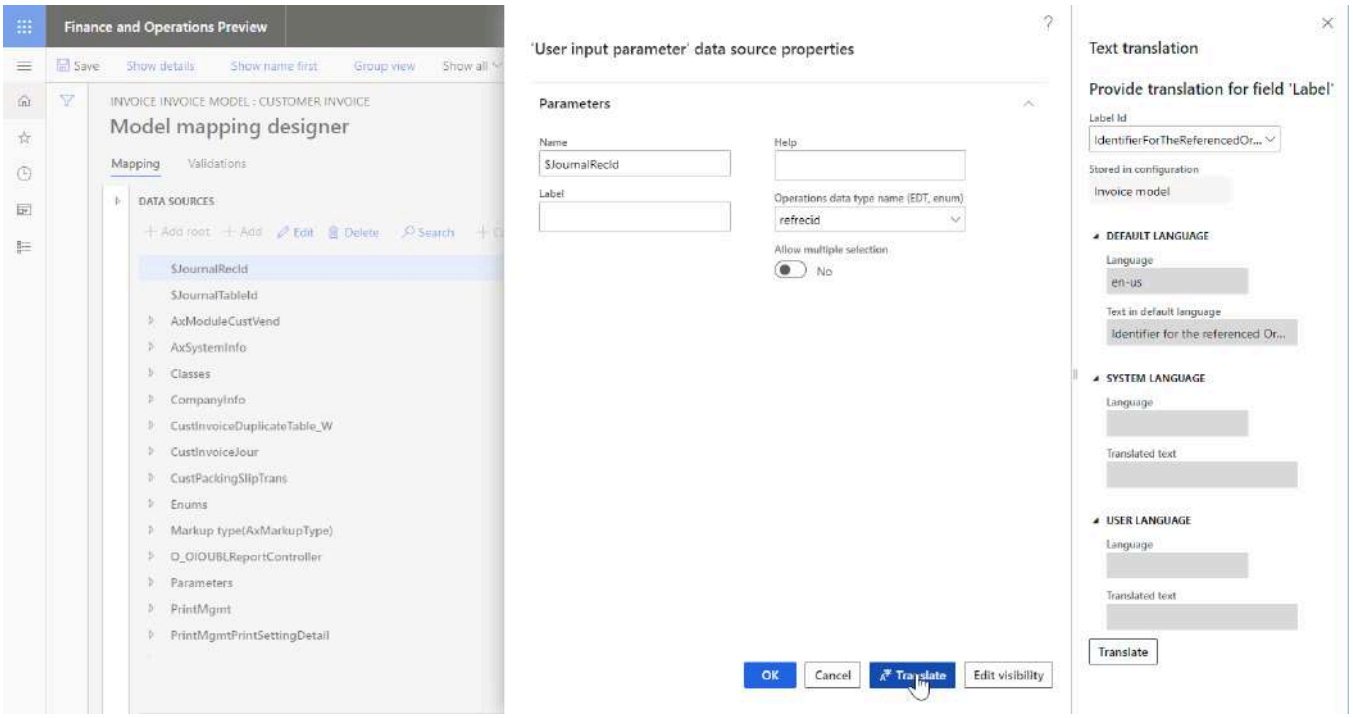
Entry

When you design an ER data model, an ER model mapping, or an ER format, the **Translate** option is shown whenever you select a field that might contain the translatable context. When you select this option, you can link the selected field to an ER label on the **Text translation** pane. You can select an existing ER label, or you can add a new ER label if it isn't available yet. When you select or add an ER label, you can add related text for every language that is supported in the current Finance instance.

The following illustration shows how this translation is done in an editable ER data model. In this example, the **Description** attribute of the **PurchaseOrder** field for the editable **Invoice model** is translated into the Austrian German (DE-AT) and Japanese (JA) languages.



Only label text for labels that reside in an editable ER component can be translated. For example, if you select **Translate** for the label attribute of an ER model mapping data source, and you then select an ER label that resides in the parent ER data model, you will see the content of the label, but you can't change it. In these cases, the **Translated text** field is unavailable, as shown in the following illustration.



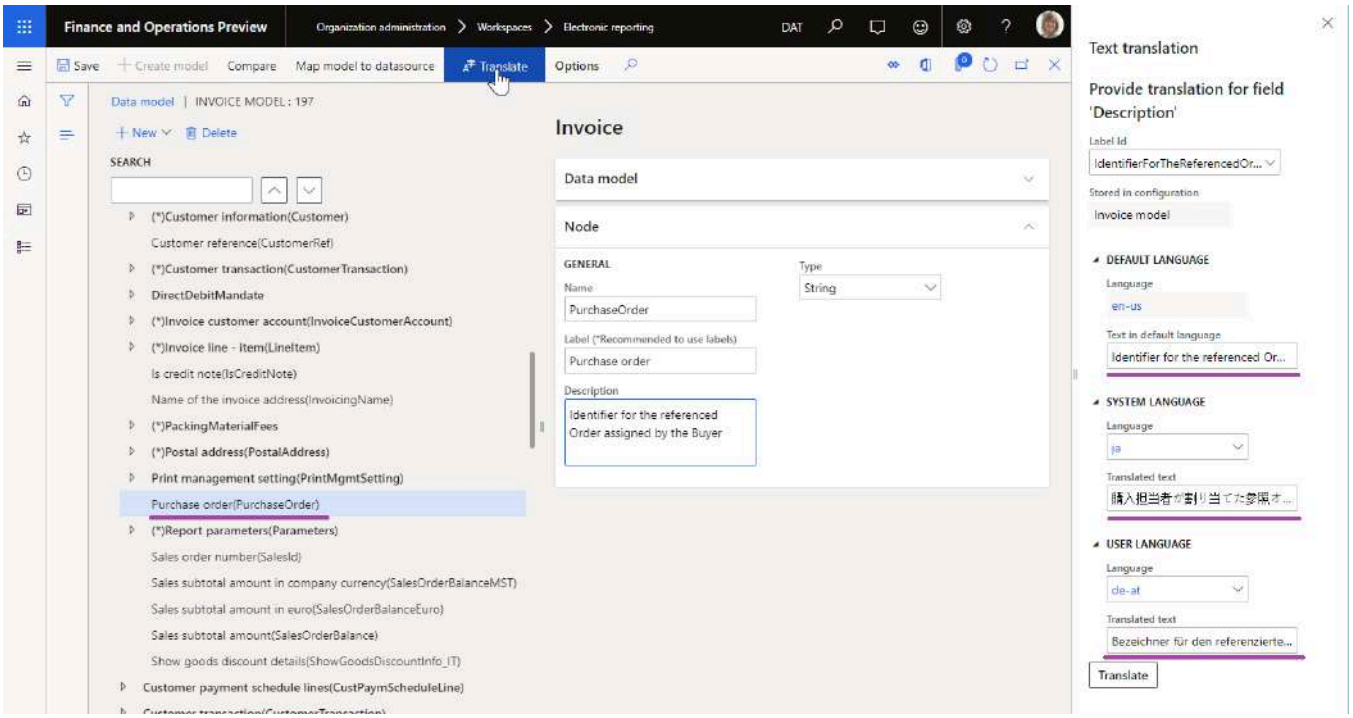
> **Note**
>
> You can't use the designers to delete label that has been entered in an editable ER component.

Scope

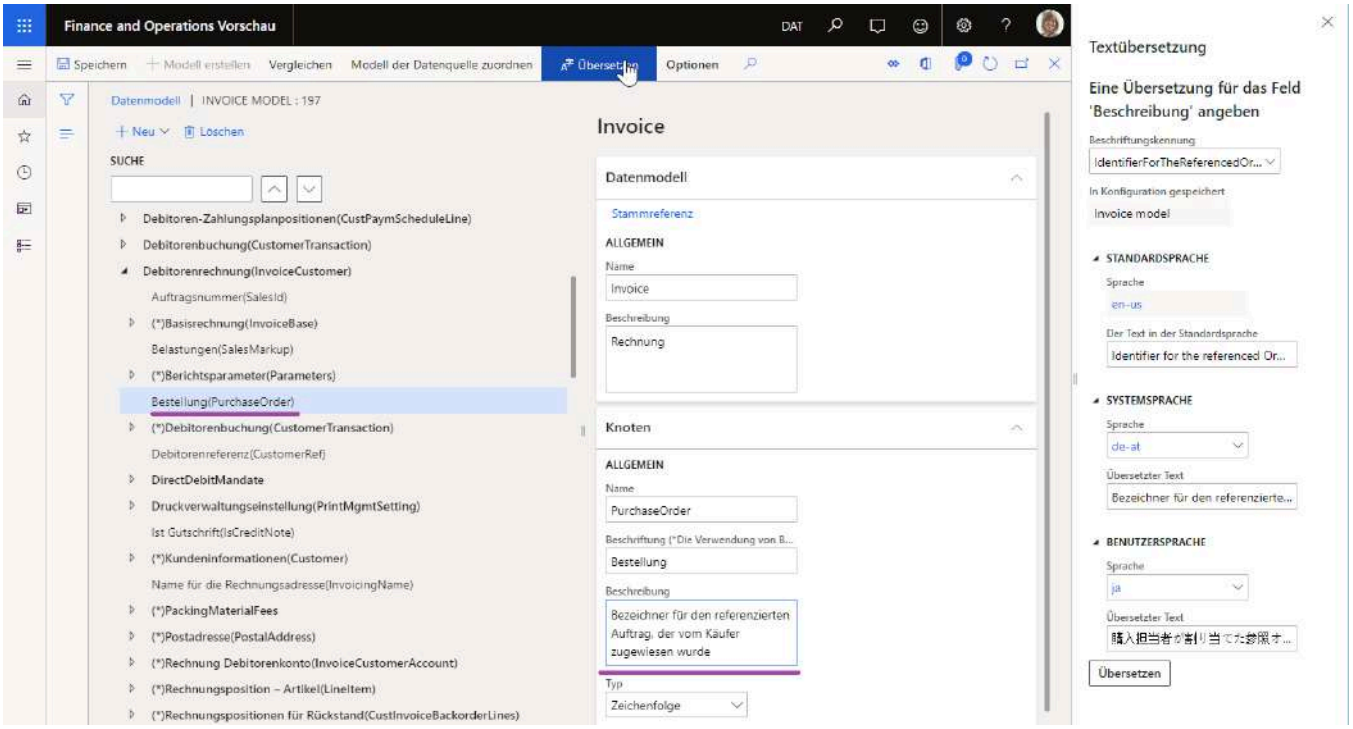
ER labels can be referred to in several translatable attributes of ER components.

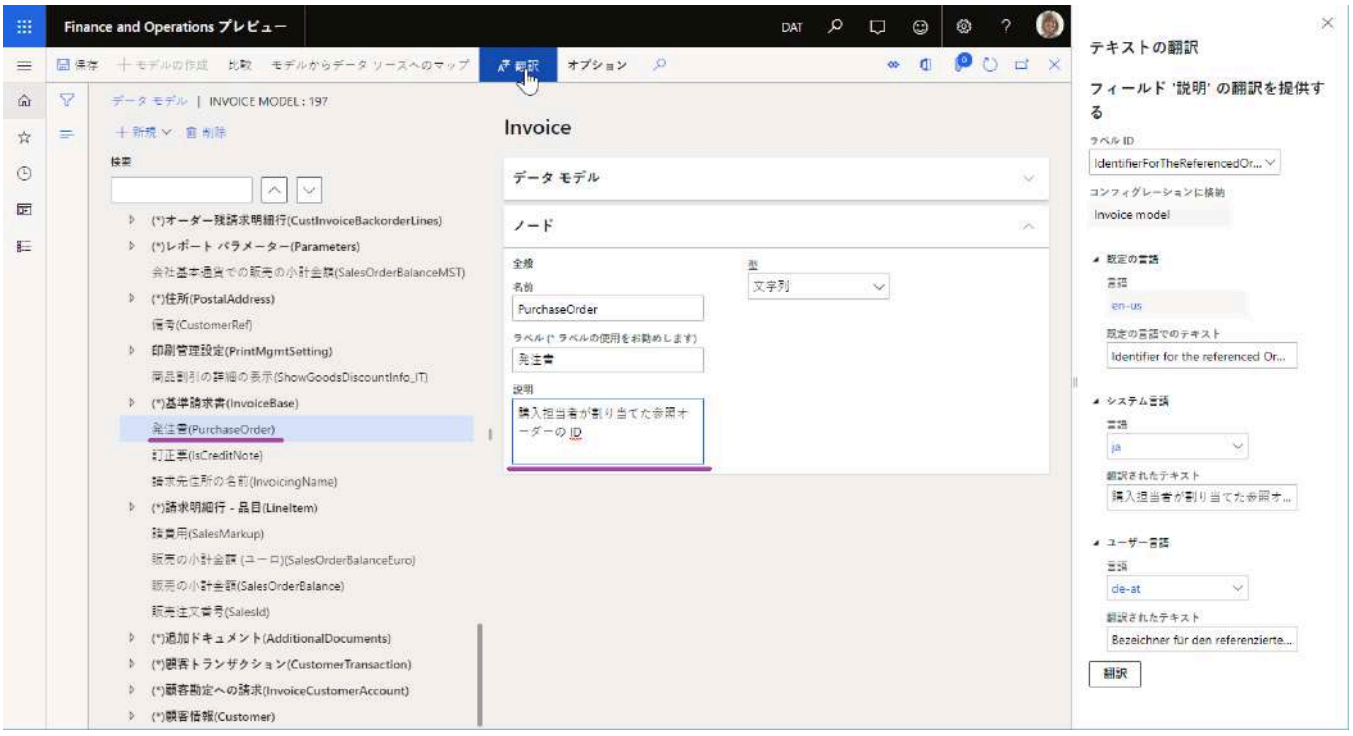
Data model component

When you configure an ER data model, you can add ER labels for it. **Label** and **Description** attributes of the model item, every model's field, and every model enumeration value can be linked to an ER label that is added to the ER data model.



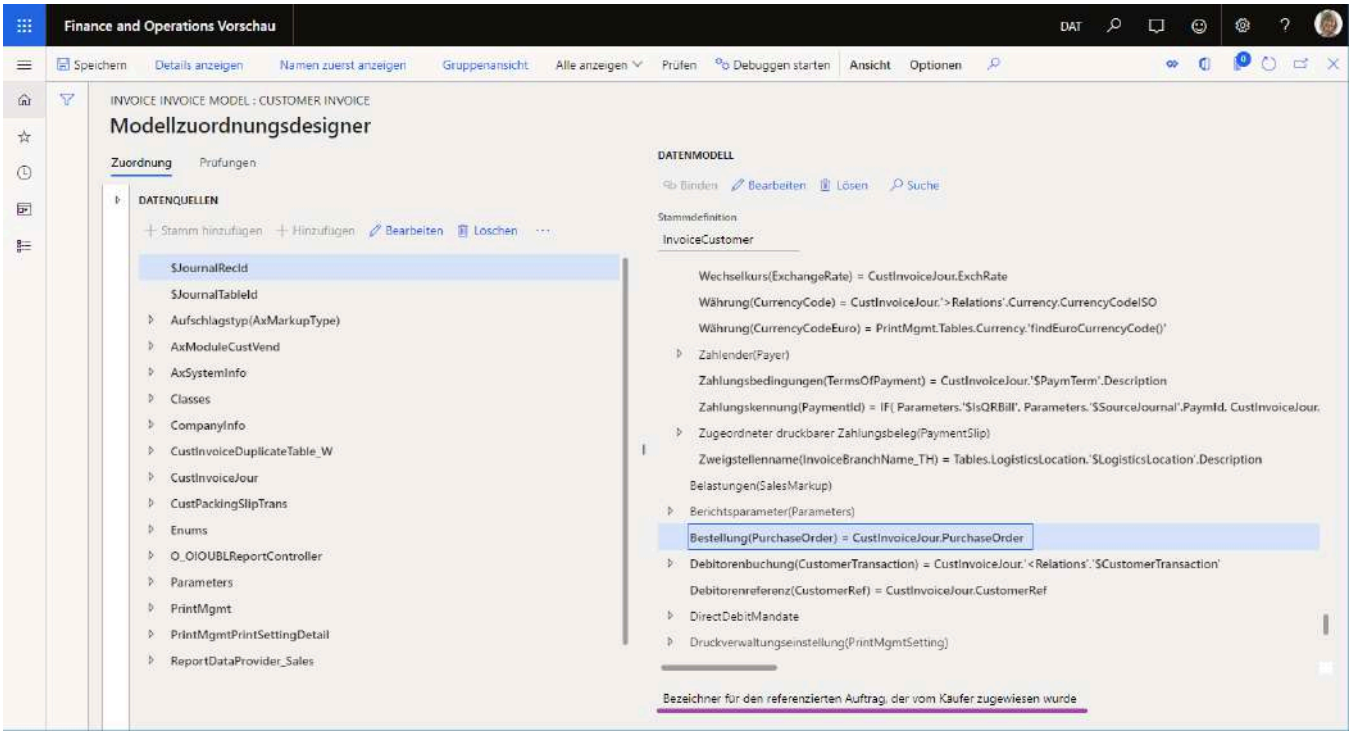
When an ER data model is configured in this way, its content will be presented to users of the ER data model designer in each user's preferred language. Therefore, model maintenance is simplified. The following illustrations show how this functionality works for users who have DE-AT and JA set as their preferred language.





Model mapping component

Because the ER model mapping is based on an ER data model, the labels of the data model elements that are referred to appear in the user's preferred language in the model mapping designer. The following illustration shows how the meaning of the **PurchaseOrder** field is explained in the editable model mapping by using the label of the **Description** attribute that has been added to the configured data model. Notice that this label is presented in the user's preferred language (DE-AT in this example).



When the **Label** attribute of the **User input parameter** data source is configured as linked to an ER label, the parameter field that corresponds to this data source is presented in the user dialog box at runtime to users in their preferred language.

Format component

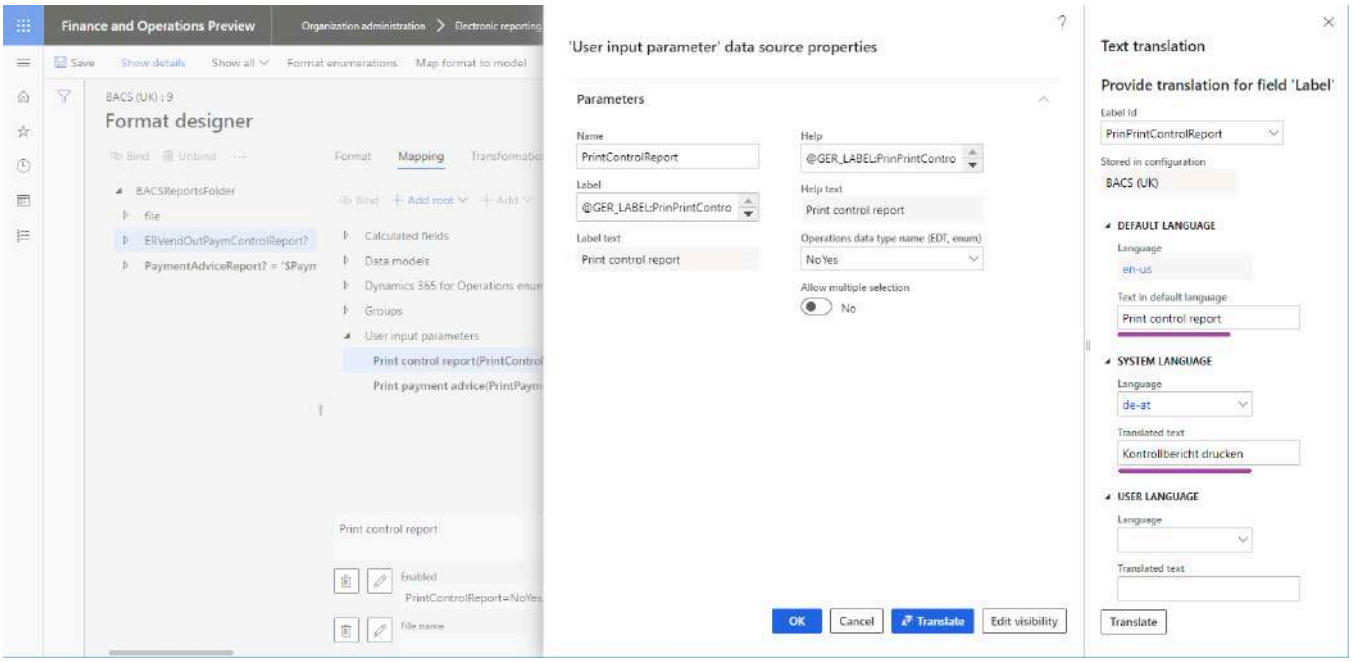
When you configure an ER format, you can add ER labels for it. The **Label** and **Help text** attributes of every configured data source can be linked to an ER label that is added to the ER format. The **Label** and **Description** attributes of every format enumeration value can also be linked to an ER label that is accessible from the editable ER format.

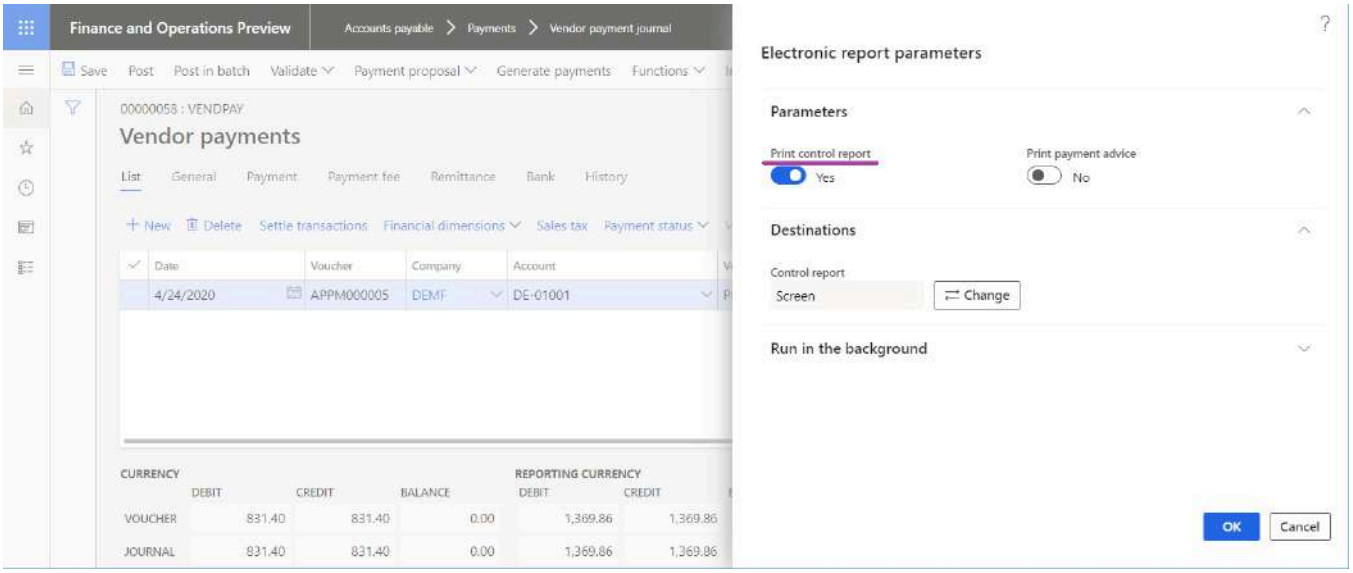
> **Note**
>
> You can also link these attributes to an ER label of the parent ER data model that reuses the model's labels in every ER format that is configured for this ER data model.

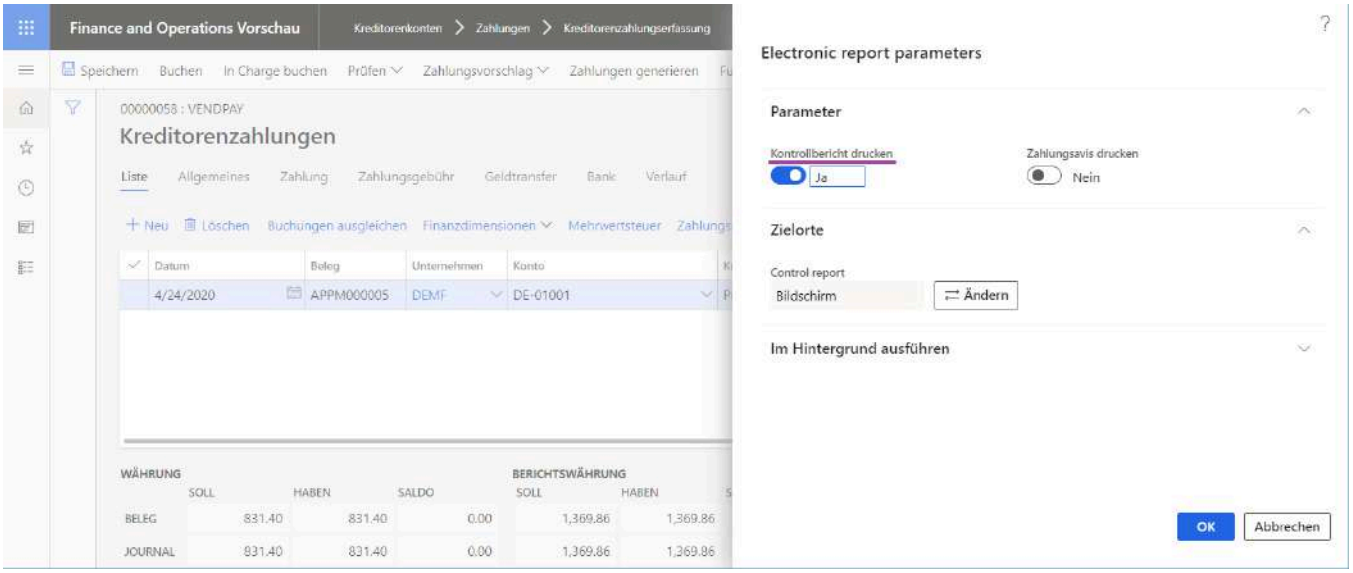
When an ER format is configured in this way, the content of the format will be presented to users of the ER Operation designer in each user's preferred language. Therefore, format maintenance and analysis of the configured logic are simplified.

Because an ER format is based on an ER data model, the labels that are referred to in the data model elements are presented in the ER format designer in the user-preferred language.

When the **Label** attribute of the **User input parameter** data source is linked to an ER label, the field that corresponds to the parameter in the user dialog box at runtime is presented to the user as a prompt. The following illustrations show how you can link the **Label** attribute of the **User input parameter** data source at design time to an ER label, so that users are prompted for the parameter in different user-preferred languages (shown for English United States (EN-US) and DE-AT languages) at runtime.

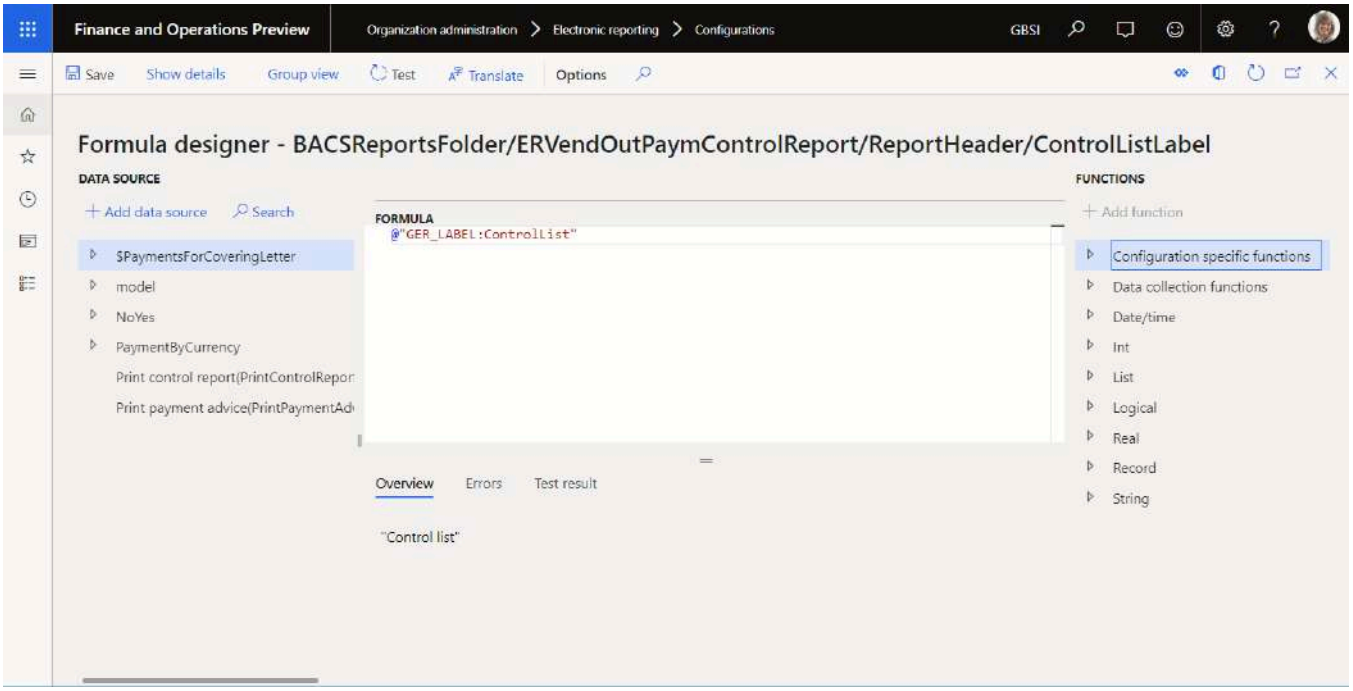




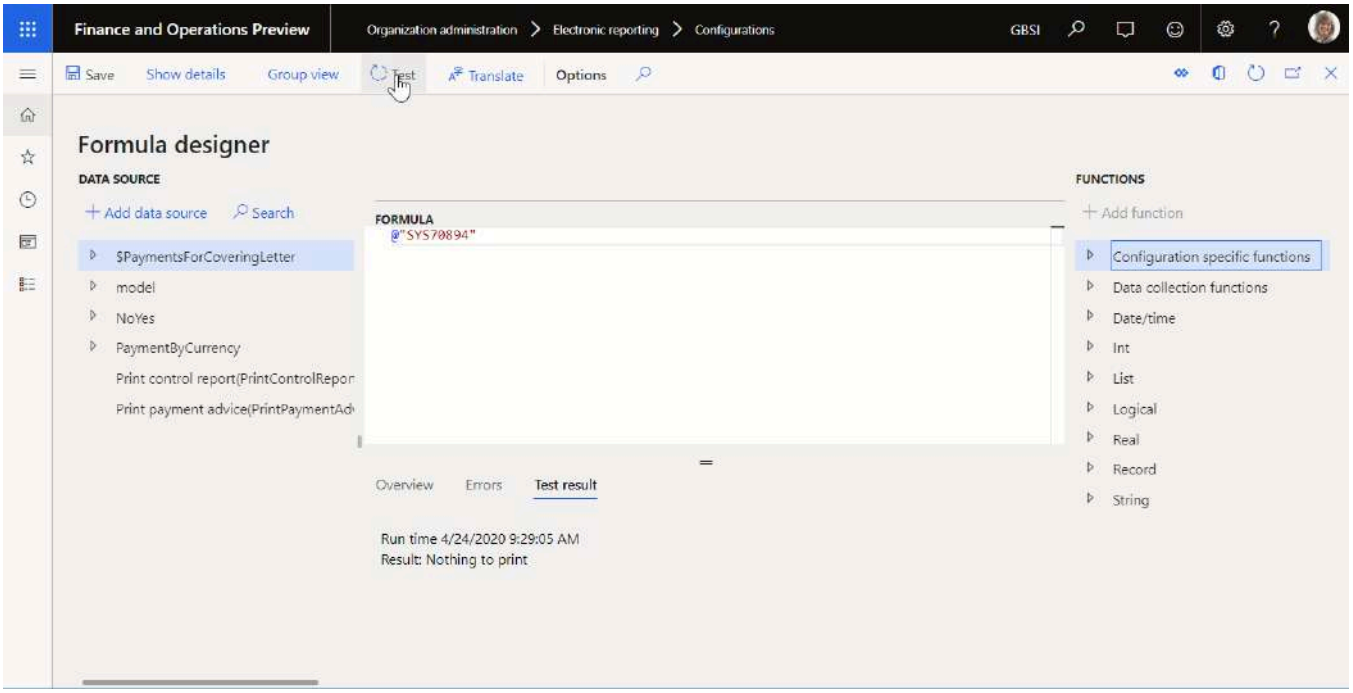


Expressions

To use a label in an ER expression, you must use the syntax @"**GER_LABEL:X**", where the prefix @ indicates that the operand refers to a label, **GER_LABEL** indicates that an ER label is involved, and **X** is the ER label ID.



To refer to a system (application) label, use the syntax @"**X**", where the prefix @ indicates that the operand refers to a label, and **X** is the system label ID.



Model mapping

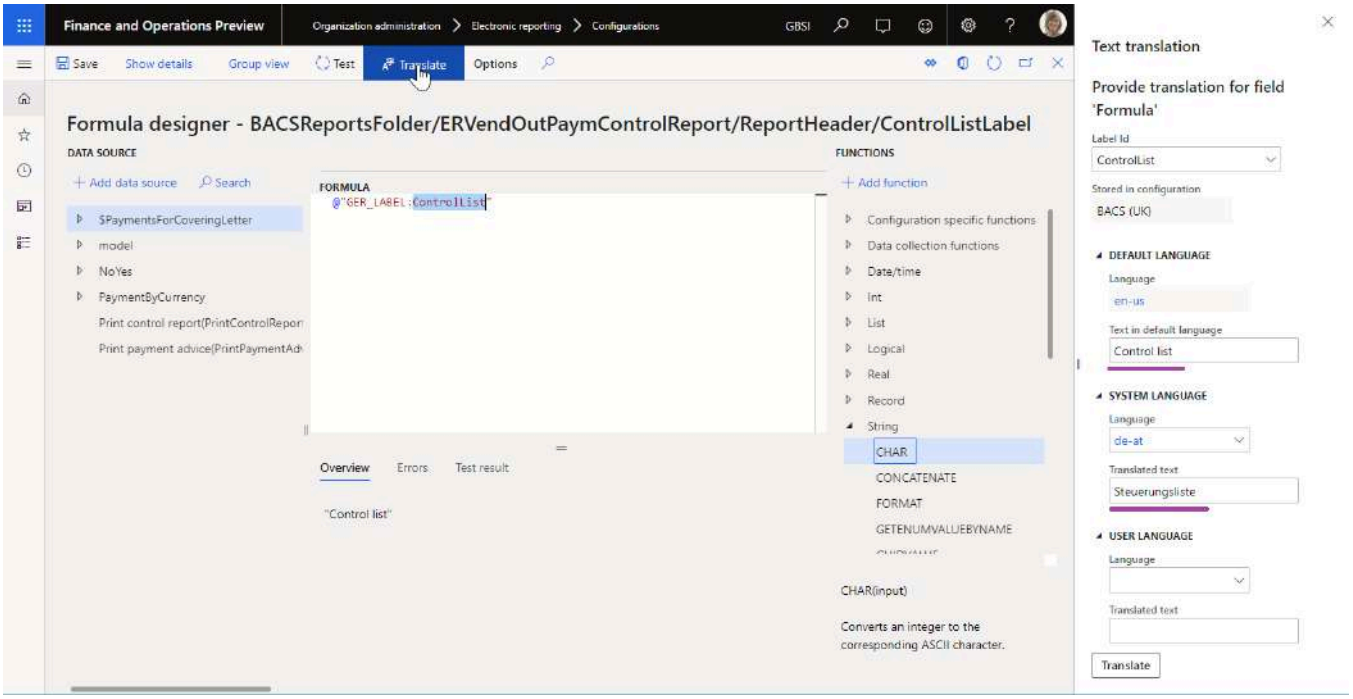
An expression of an ER model mapping can be configured by using a label. When this mapping is called by an ER format that is run to generate an outbound document, the context of the

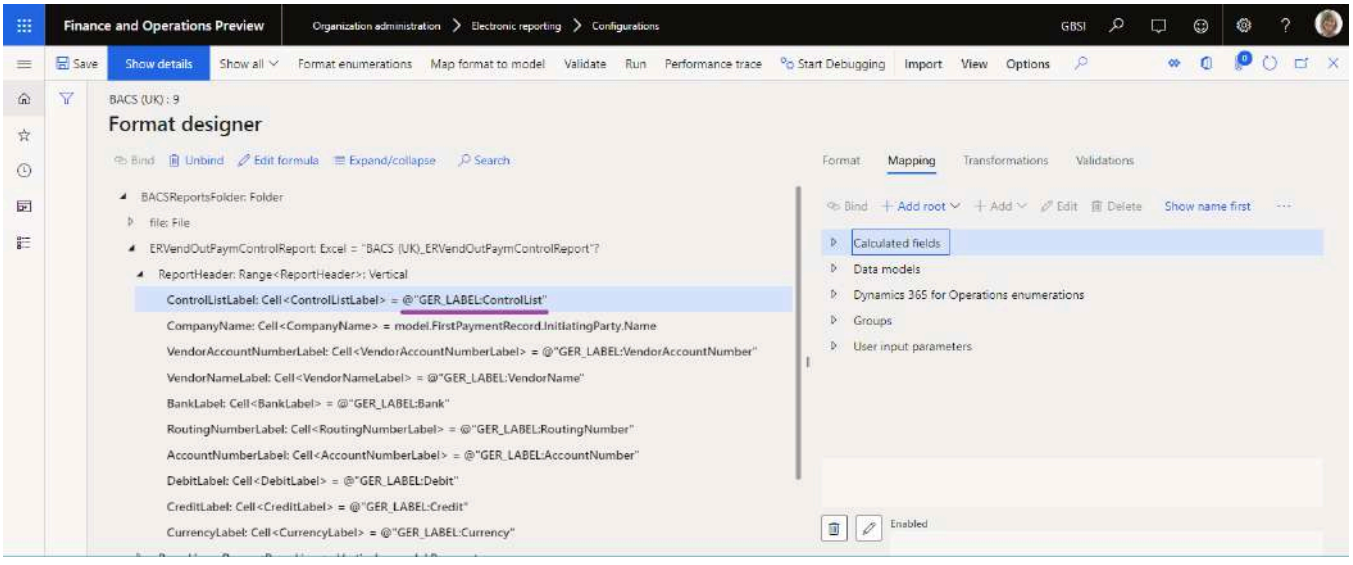
execution includes a language code. A configured expression label will be filled in with the label text that has been configured for the language of that context.

If a referenced label has no translation for the language of the format execution context that calls the model mapping, the label text in the EN-US language is used instead.

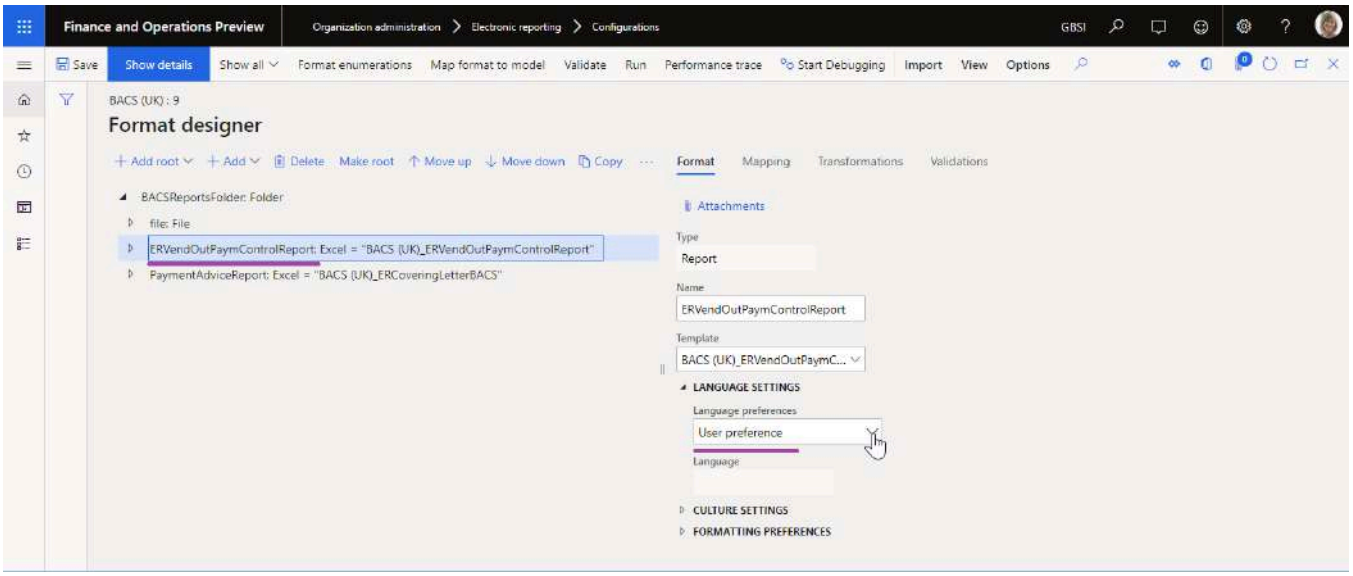
Format

An ER expression of an ER format can be configured by using labels. When this format is run to generate an outbound document, the context of the execution includes a language code. A configured expression label will be filled in with the label text that has been configured for the language of that context.

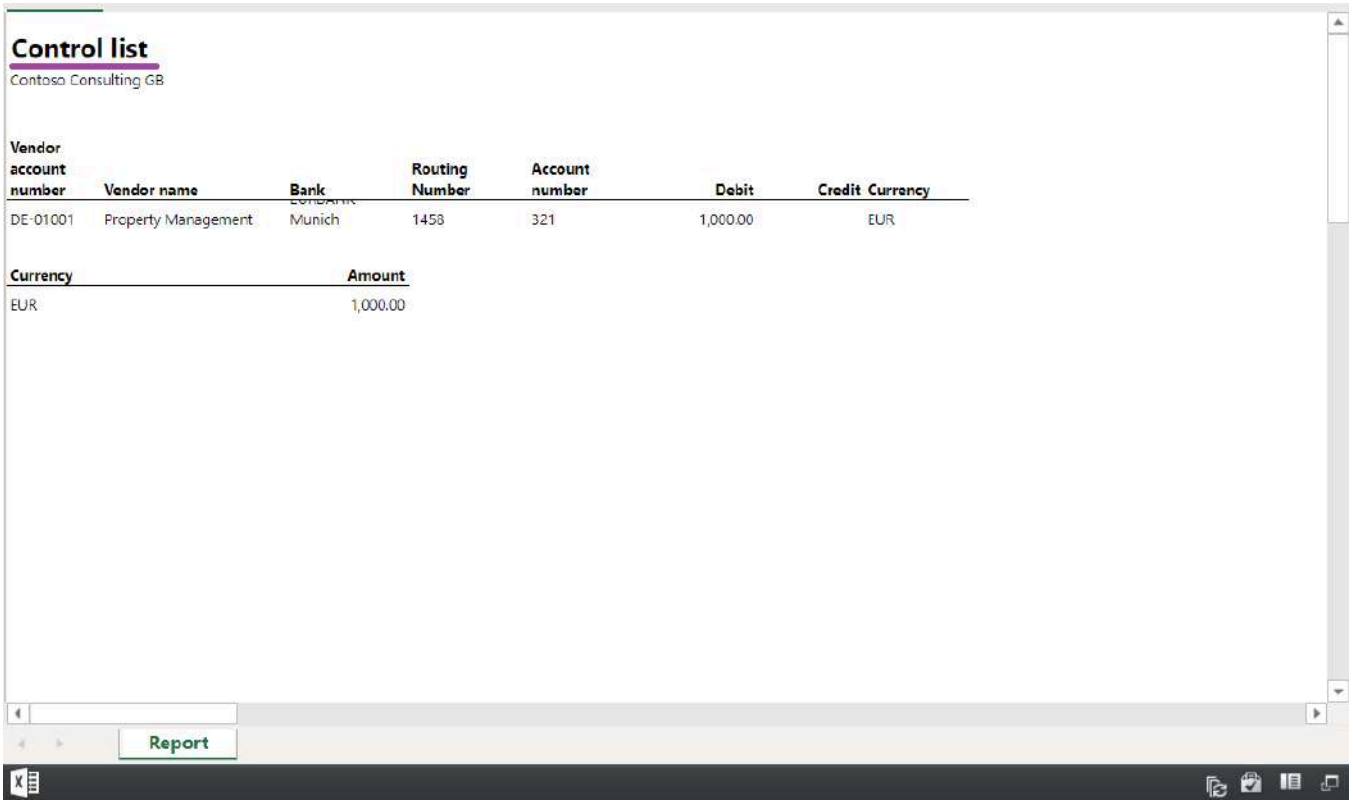


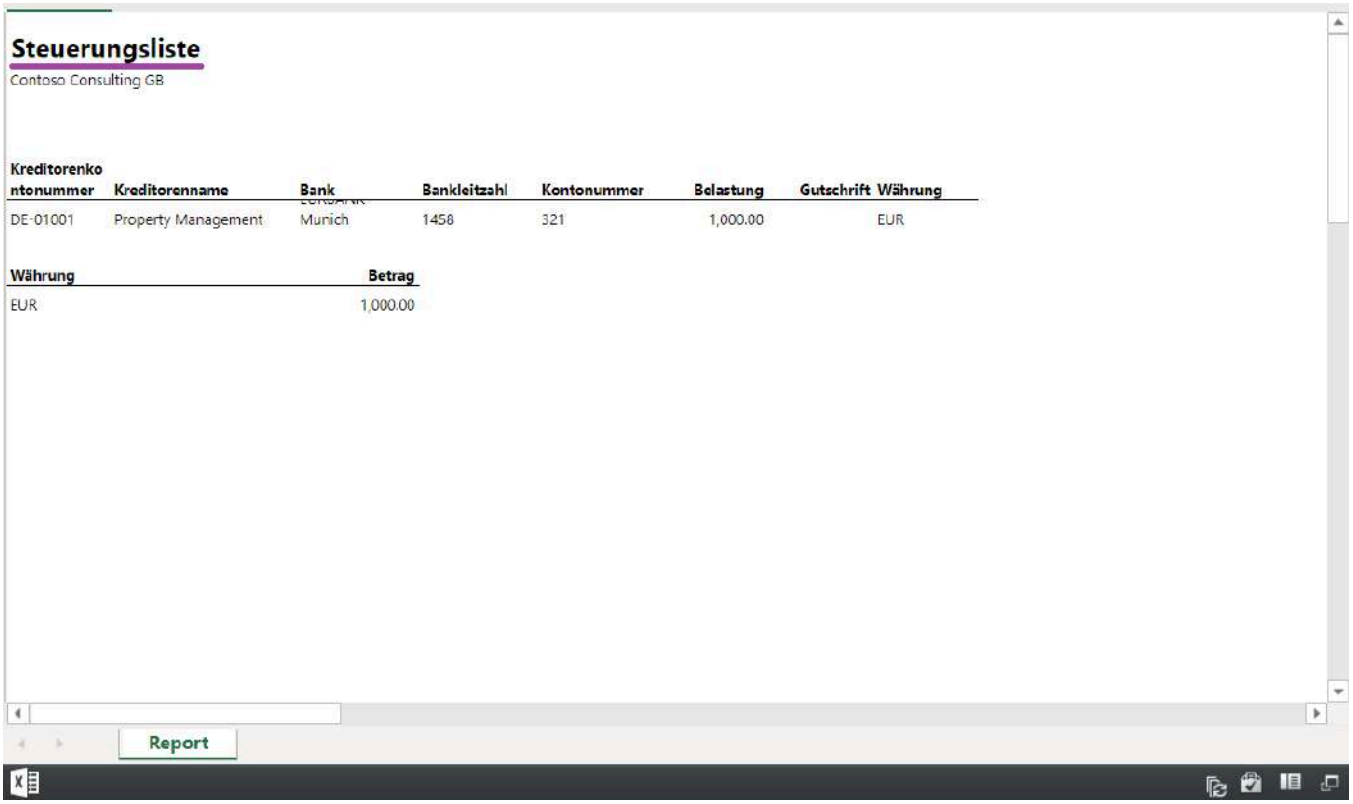


You can configure the **FILE** component of an ER format to generate the report in the user's preferred language.



If you configure an ER format in this way, the report is generated by using the corresponding text of the ER labels. The following illustrations show examples of reports for the EN-US and DE-AT user languages.





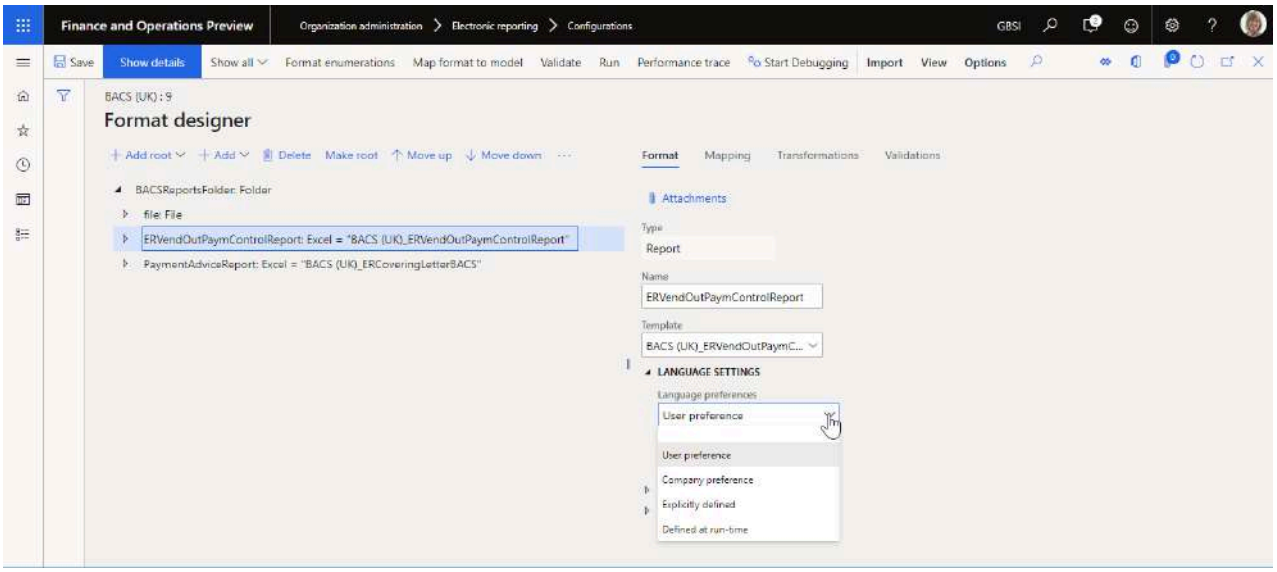
If a referenced label has no translation for the language of the format execution context, the label text in the EN-US language is used instead.

> **Tip**
>
> You can use the **FOLDER** and distinct types of **FILE** components in the editable ER format to specify how an outbound file is generated. To name a generated file, configure the ER expression for the **File name** parameter of the component. You can use labels in the configured expression. Because the **File name** parameter is language agnostic by default, the text of all labels that you refer to in this expression are exposed in the default EN-US language at runtime. However, in version 10.0.28 and later, you can enable the **Apply the 'Language preference' parameter to the 'File name' expression** feature. The **File name** expression then takes the **Language preferences** parameter into account when it's computed.

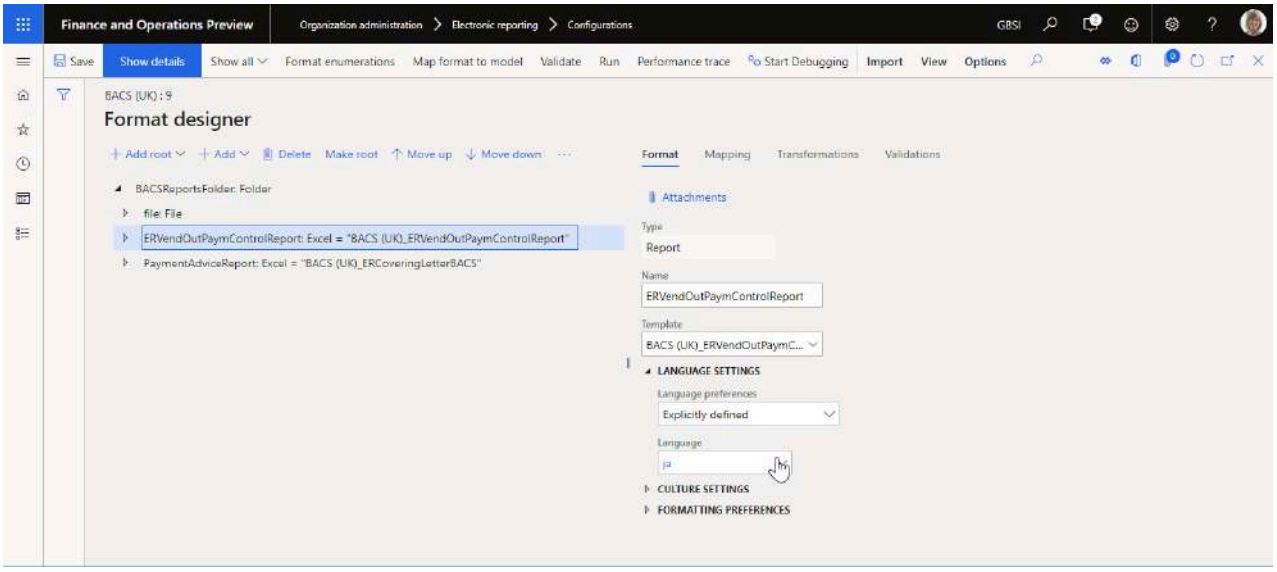
Language

ER supports different ways to specify a language for a generated report. In the **Language preferences** field on the **Format** tab, you can select the following values:

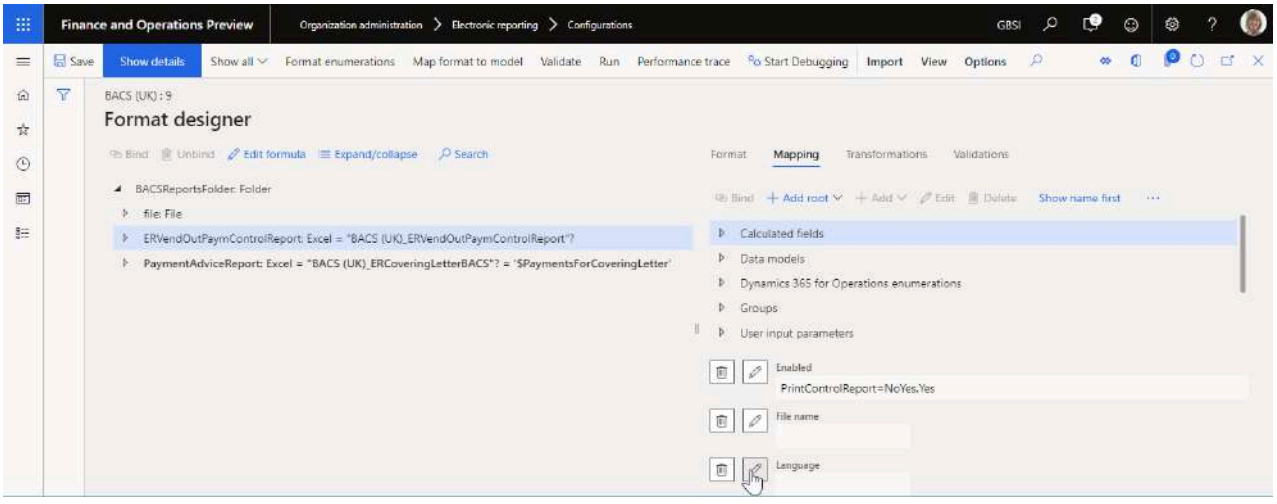
- **Company preference** – Generate a report in a company-specified language.



- **User preference** – Generate a report in the user's preferred language.
- **Explicitly defined** – Generate a report in a language that is specified at design time.



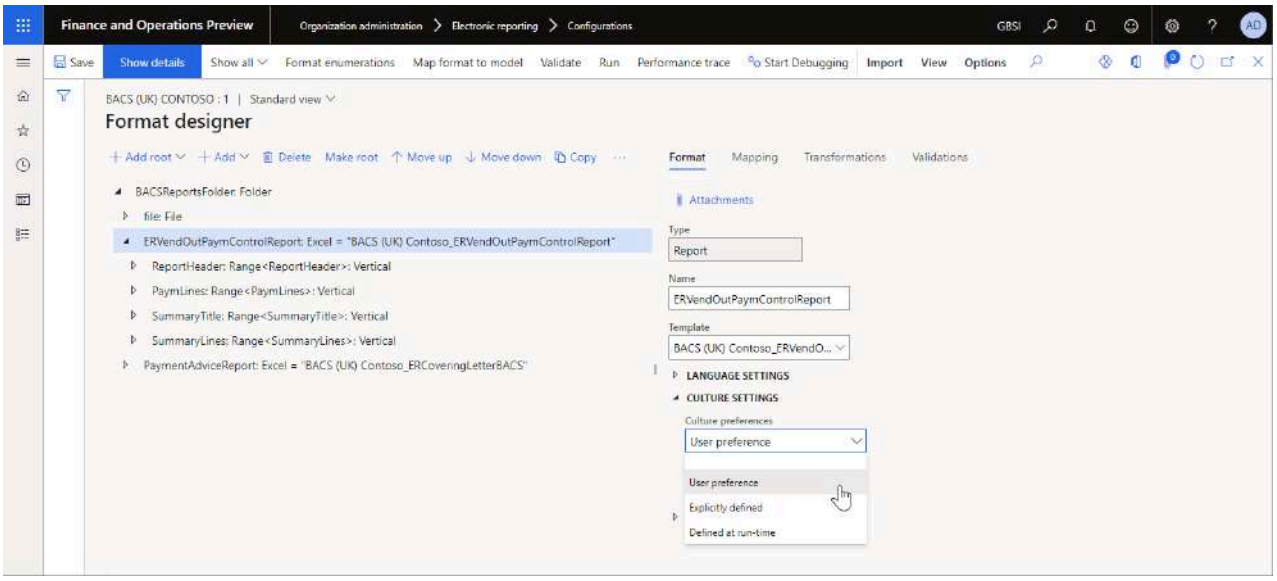
- **Defined at run-time** – Generate a report in a language that is specified at runtime. If you select this value, in the **Language** field, configure an ER expression that returns the language code for the language, such as the language of the corresponding customer.



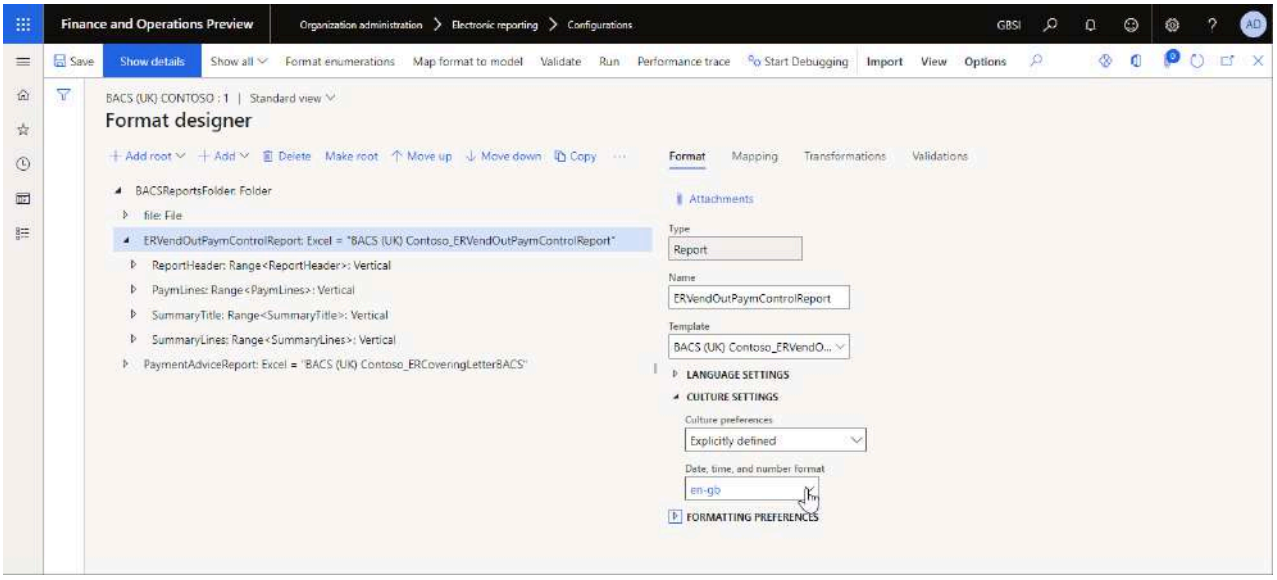
Culture-specific formatting

ER supports different ways to specify the culture for a generated report. Therefore, the correct culture-specific formatting can be used for date, time, and numeric values. When you design an ER format, on the **Format** tab, in the **Culture preferences** field, you can select one of the following values for every format component of the **Common\File**, **Excel\File**, **PDF\File**, or **PDF\Merger** type:

- **User preference** – Format the values according to the user's preferred culture. That culture is defined in the **Date, time, and number format** field on the **Preferences** tab of the **User options** page.

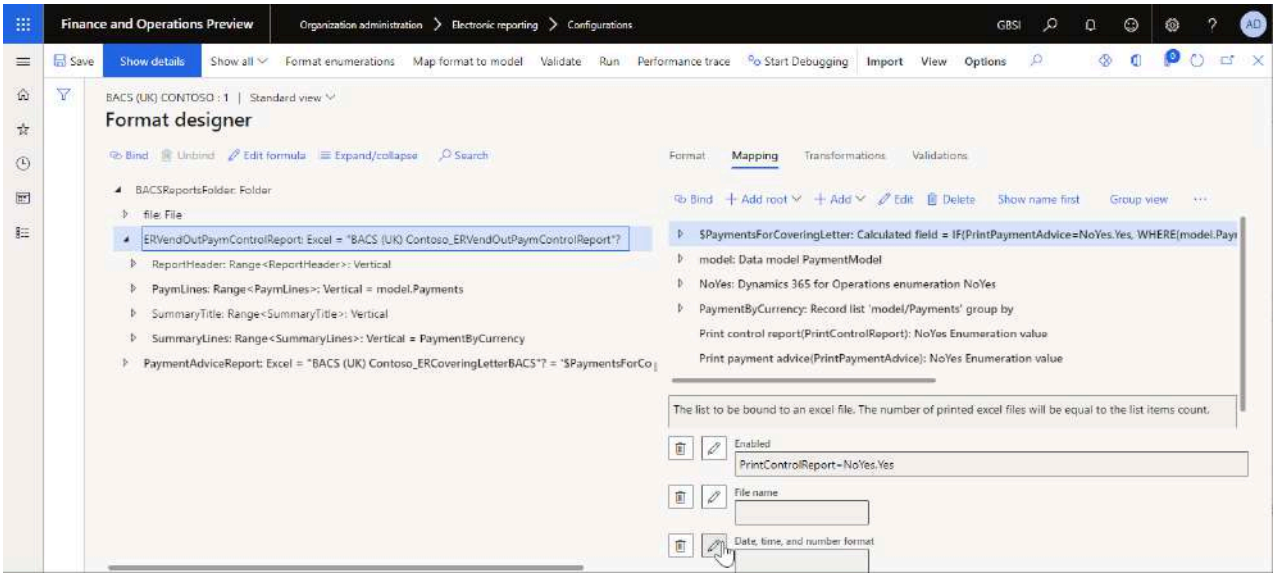


- **Explicitly defined** – Format the values according to the culture that is specified at design time.



- **Defined at run-time** – Format the values according to the culture that is specified at runtime. If you select this value, on the **Mapping** tab, in the **Date, time, and number**

format field, configure an ER expression that returns the culture code for the culture, such as the culture of the corresponding customer.



> **Note**
>
> An ER component that you define a specific culture for might contain child ER components that were configured to fill in a text value. By default, the culture of the parent component is used to format the values of those components. You can use the following built-in ER functions to configure bindings for those components and apply an alternative culture for value formatting:
>
> - DATEFORMAT
> - DATETIMEFORMAT
> - NUMBERFORMAT
>
> In version 10.0.20 and later, the locale of format components of the **Common\File** and **Excel\File** types is used to format values during PDF conversion of a generated document.

Translation

You can add required ER labels to an editable ER component. When an ER label is added, it can be translated in two ways: manually and automatically.

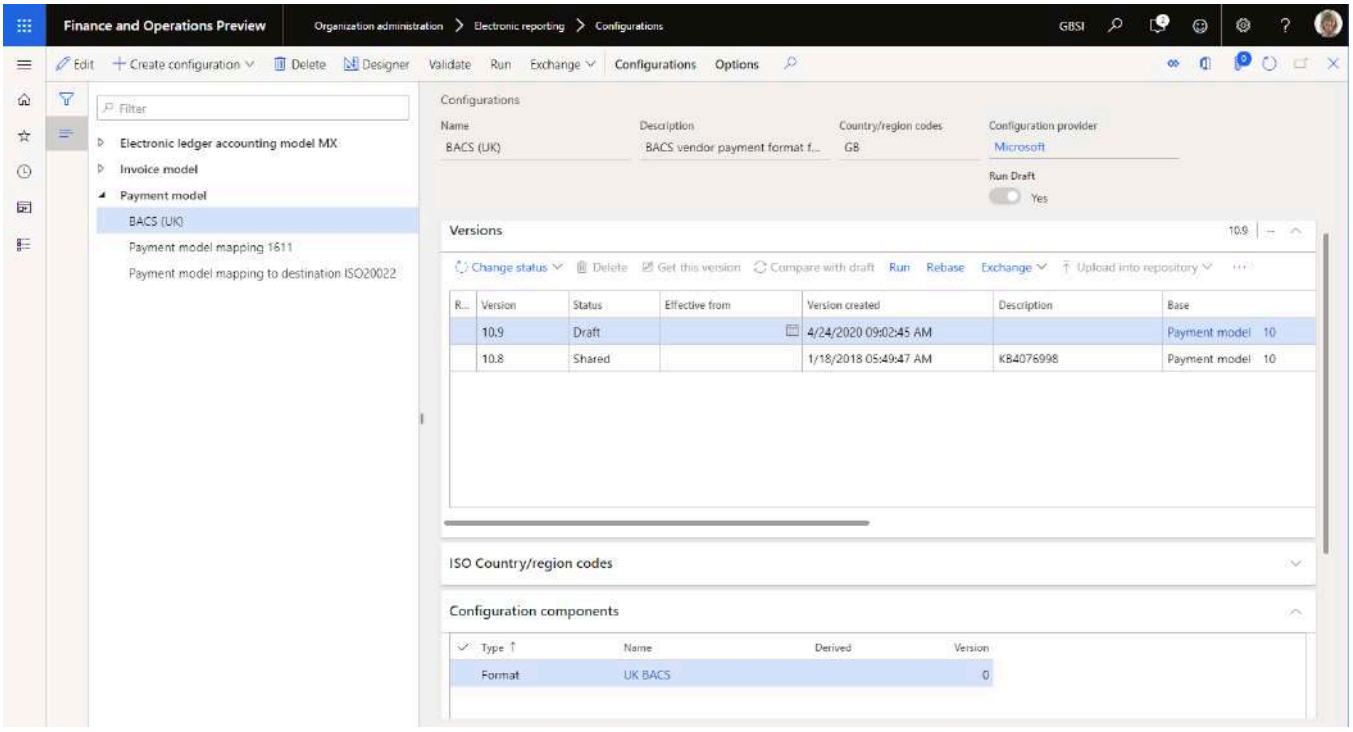
Manual translation

When you add an ER label on the **Text translation** pane, you can manually translate it into all languages that are supported in the current Finance instance. You can select the preferred language in the **Language** field in the **System language** or **User language** section, enter the

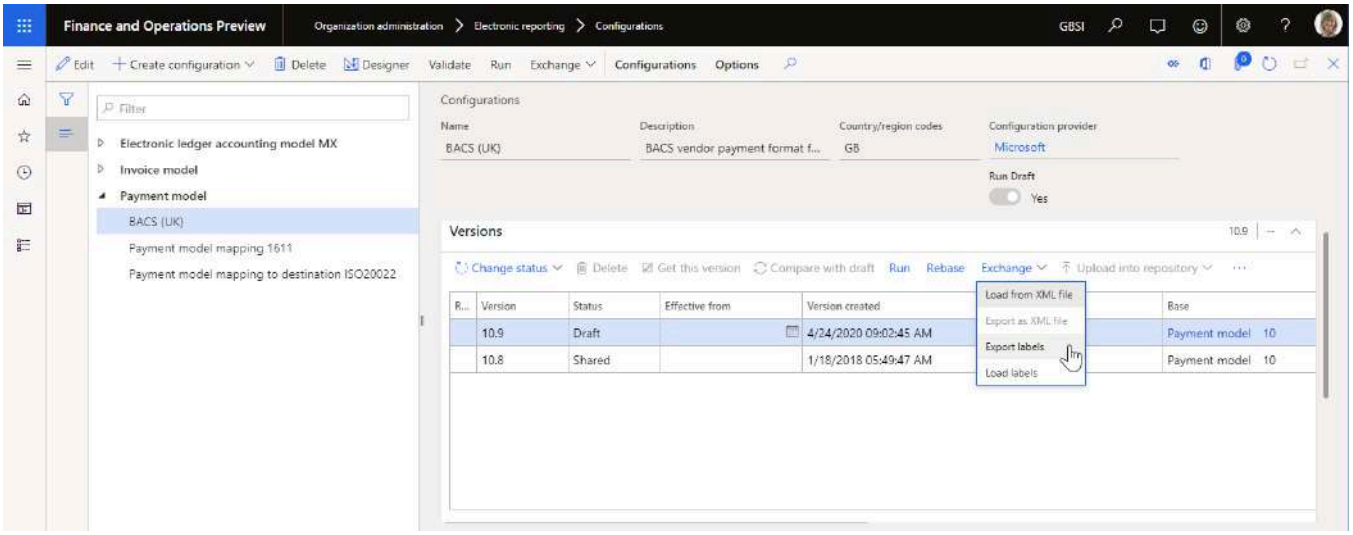
appropriate text in the corresponding **Translated text** field, and then select **Translate**. This process must be repeated for every required language and every label that you add.

Automatic translation

Configuration of an ER component is done in the draft version of the ER configuration that the editable ER component resides in.



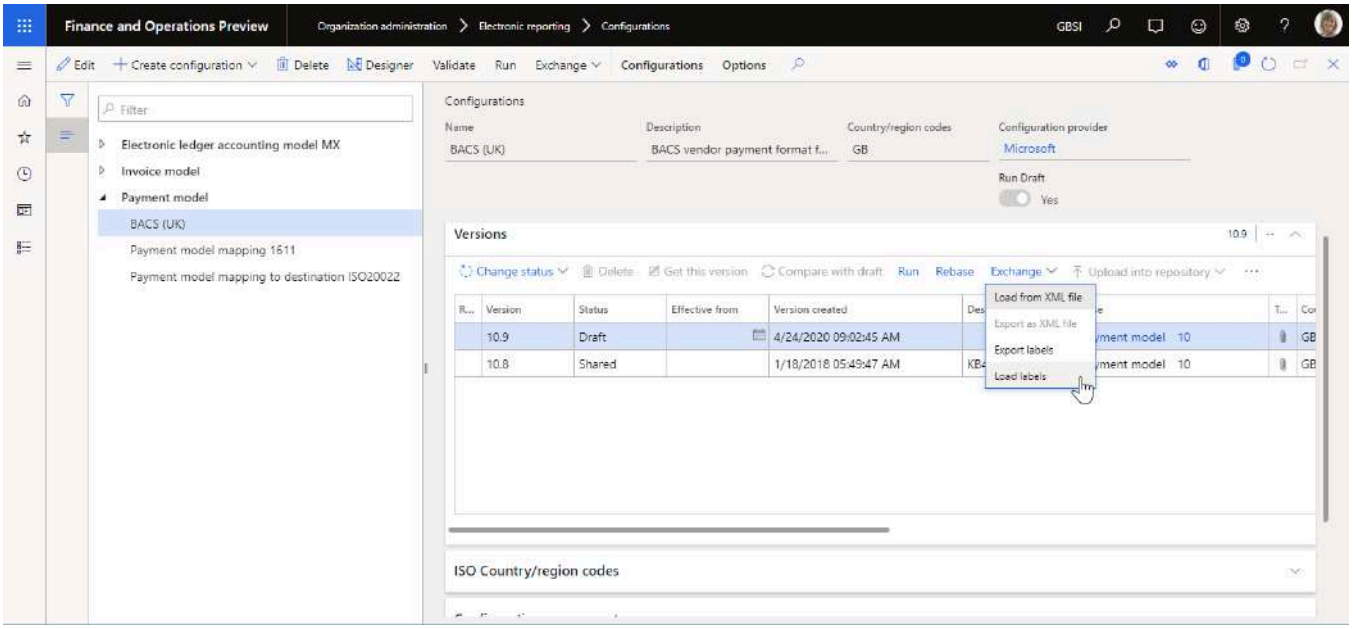
As described earlier in this article, you can add required ER labels to an editable ER component. In this way, you can specify the text of the ER labels in the EN-US language. You can then export the labels of the ER component by using the built-in ER function. Select the draft version of an ER configuration that contains the editable ER component, and then select **Exchange** > **Export labels**.



You can export either all labels or the labels for a single language that you specify at the beginning of export. Labels are exported as a zip file that contains XML files. Every XML file contains labels for a single language.

```
<?xml version="1.0" encoding="UTF-8"?>
- <StringResources>
  - <String _locID="guid{423CC719-54A0-4B2B-AD78-E5AC9F86DCEE}">
        <!--_locComment_text="Label file for configuration BACS (UK)"-->
      de-AT
    </String>
  - <String _locID="AccountNumber">
        <!--_locComment_text=""-->
      Kontonummer
    </String>
  - <String _locID="Bank">
        <!--_locComment_text=""-->
      Bank
    </String>
  - <String _locID="ControlList">
        <!--_locComment_text=""-->
      Steuerungsliste
    </String>
  - <String _locID="DiscountUsed">
        <!--_locComment_text=""-->
      Gewährter Rabatt
    </String>
  - <String _locID="FirstPaymentRecord">
        <!--_locComment_text=""-->
      Erster Zahlungsdatensatz
    </String>
  - <String _locID="Giro">
        <!--_locComment_text=""-->
      Girokonto
    </String>
  - <String _locID="InvoiceAmount">
        <!--_locComment_text=""-->
      Rechnungsbetrag
    </String>
```

This format is used for automatic translation of labels by external translation services such as Dynamics 365 Translation Service. When you receive the translated labels, you can import them back into the draft version of an ER configuration that contains the ER components that own those labels. Select the draft version of an ER configuration that contains the editable ER component, and select **Exchange** > **Load labels**.



Translated labels will be imported into the selected ER configuration. Translated labels that exist in this ER configuration are replaced. If any translated label is missing in the ER configuration, it's appended.

Lifecycle

Labels of an ER component that can be edited are kept, together with other content for the component, in the appropriate version of an ER configuration.

Labels of a base ER component can be referred to in a derived version of the ER component that you create to introduce your modifications.

> **Tip**
>
> When you design a ER solution, you can derive your own ER **data model** component from the one that is provided. In this derived data model, you can introduce your own ER labels and use them in all ER formats that will use the data model as the data source. You can then derive your own ER **format** component from the one that is provided by selecting your derived ER data model instead of the provided one. In version 10.0.28 and later, you can enable the **Enhanced access to labels of the ascendent ER data model** feature to access labels of an ascendent ER data model in derived ER format components, even when the ER data model that you selected for the derived ER component differs from the one that was used in the base ER component.
>
> When the same label name is used in your derived component and its ascendent components, your translation of that label is used as the most relevant one.

ER versioning controls label assignment to any attribute in an ER component. Changes to the label assignment are recorded in the list of changes (delta) of an editable ER component that has been created as a derived version of the provided ER component. These changes will be validated when a derived version is rebased to a new base version.

Functions

The built-in LISTOFFIELDS ER function can access ER labels that have been configured for some items of ER components.

As described earlier in this article, the **Label** and **Description** attributes of every model or format ER enumeration's value can be linked to an ER label that is accessible in the appropriate ER component. You can configure an ER expression where you call the **LISTOFFIELDS** function by using the ER enumeration as an argument. This expression returns a list that contains a record for every value of an ER enumeration that has been defined as an argument of this function. Every record contains the value of an ER label that is linked to an ER enumeration value:

- The value of an ER label that is linked to the **Label** attributes is stored in the **Label** field of the returned record.
- The value of an ER label that is linked to the **Description** attributes is stored in the **Description** field of the returned record.

Performance

When you configure an ER format component to generate a report in your preferred language, or to import an inbound document where the content is parsed by your preferred language, we recommend that you enable the **Cache the preferred language of the current user for ER runs** feature in the Feature management workspace. This feature helps improve performance, especially for ER format components that contain multiple references to labels in ER formulas and bindings and many validation rules to generate user messages in your preferred language.

When you change the status of an ER configuration version from **Draft** to **Completed**, if the configuration version contains ER labels, those labels are stored in the application database. The storage schema depends on the state of the **Accelerate the ER labels storage** feature:

- If the feature isn't enabled, all labels are stored in the **LABELXML** field of the **ERSOLUTIONVERSIONTABLE** table as a single XML snippet.
- If the feature is enabled, a separate record is created for each language in the **ERSOLUTIONVERSIONLABELSTABLE** table. The **CONTENTS** field of this table stores labels per language as a compressed XML snippet.

We recommend that you enable the **Accelerate the ER labels storage** feature in the **Feature management** workspace. This feature helps improve network bandwidth utilization and overall system performance because, in most cases, ER labels of a single language are used when you work with a single ER configuration.

To apply the selected storage schema for keeping labels of all ER configurations in the current Finance instance, complete the following steps.

1. Go to **Organization administration** > **Periodic** > **Apply the selected labels storing schema for all ER configurations**.
2. Select **OK**.

Compress large documents that are generated in Electronic reporting

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can use the Electronic reporting (ER) framework) to configure a solution that fetches transactional data to generate an outbound document. This generated document might be quite large. When this type of document is generated, the Application Object Server (AOS) memory is used to hold it. At some point, you must download the document from your Microsoft Dynamics 365 Finance application. Currently, the maximum size of a single document that generated in ER is limited to 2 gigabytes (GB). Additionally, Finance currently limits the size of a downloaded file to 1 GB. Therefore, you must configure an ER solution that reduces the likelihood that these limitations might be exceeded and that you receive a **Stream was too long** or **Overflow or underflow in the arithmetic operation** exception.

When you configure a solution, you can adjust your ER format in the Operations designer by adding a root element of the **Folder** type to compress the content that any of its nested elements generates. Compression works "just in time," so it reduces peak memory usage and the size of the file that you download.

> **Note**
>
> File compression takes an additional percentage of CPU usage.

To learn more about this approach, complete the example in this article.

Example: Compress an outbound document

This example shows how a user assigned to the **System administrator** or **Electronic reporting functional consultant** role can configure an ER format to compress a generated document.

Prerequisites

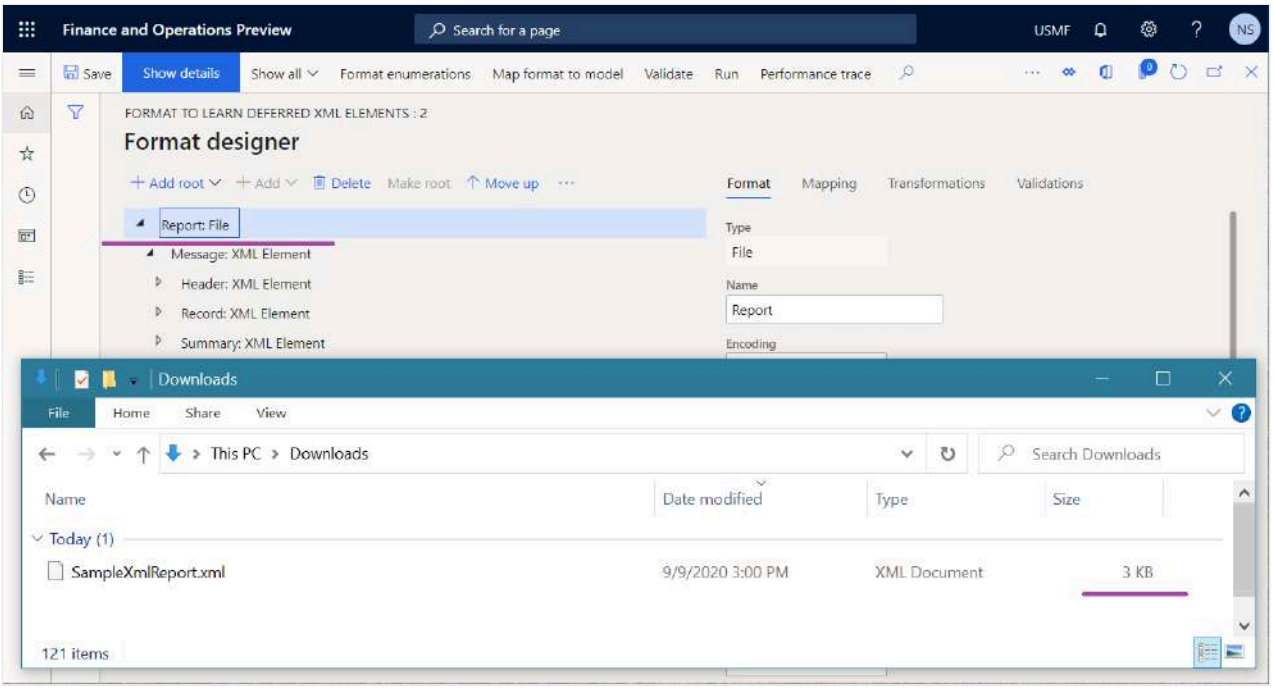
Before you complete the procedures in this article, complete the following steps.

1. Activate a configuration provider.
2. Import the sample ER configurations.
3. Review the imported format.

> **Note**
>
> Currently, the format structure starts from the **Report** element of the **File** type and contains XML elements. Therefore, an outbound document is generated in XML format, and it doesn't use compression.

Generate an ER format to get an uncompressed document

1. Run the imported format.
2. Notice that the size of the generated document in XML format is 3 kilobytes (KB).



Modify the format to compress the generated output

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, in the configuration tree, expand **Model to learn deferred elements**.
3. Select the **Format to learn deferred XML elements** configuration.

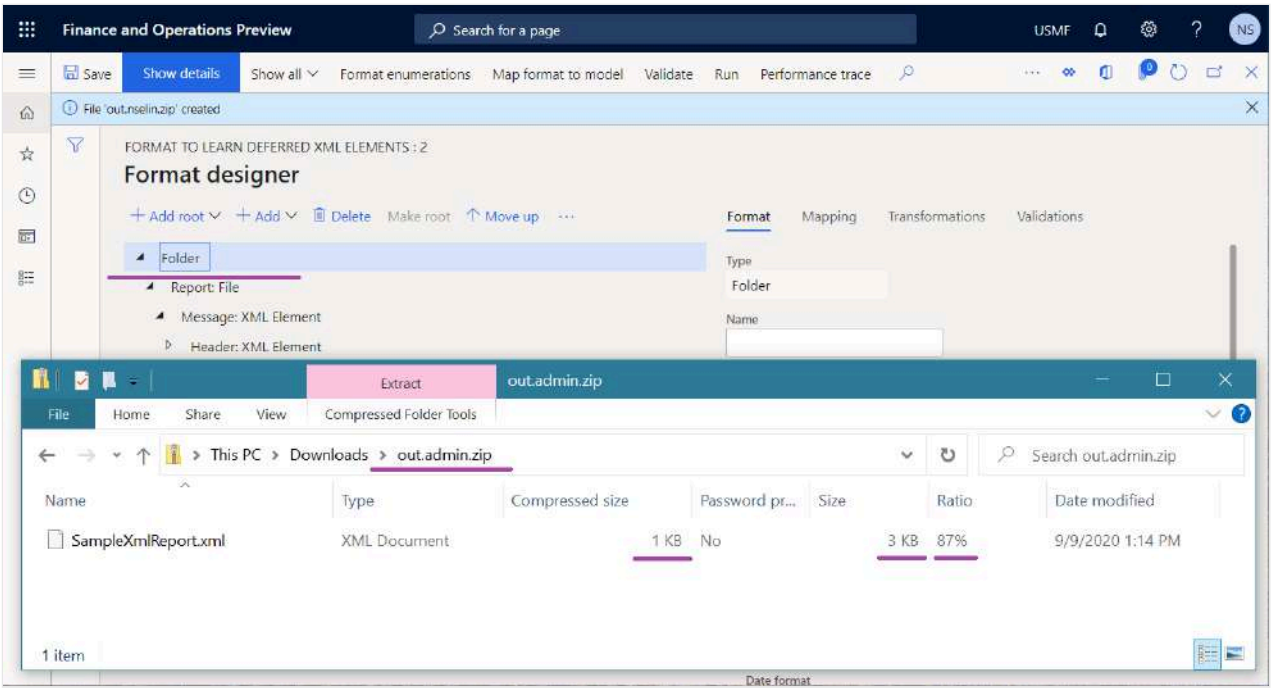
4. Select **Designer** to modify the format structure.
5. On the **Format designer** page, on the **Format** tab, select **Add root** to add a root format element.
6. In the **Add** dialog box, select **Common\Folder**.
7. Select **OK** to confirm the addition of the new root element.
8. Select **Save**.

> ⓘ **Note**
>
> The format structure starts from the element of the **Folder** type. This element generates output as a compressed (zip) file. When a document that the **Report** element generates is placed in an outbound zip file, the content is compressed to reduce the size of the outbound file.

Generate an ER format to get a compressed document

1. On the **Format designer** page, select **Run**.
2. Download the ZIP file that the web browser offers, and open it for review.
3. Notice that the size of the generated document in ZIP format is 1 KB.

   > ⓘ **Note**
   >
   > The compression ratio of the XML file that this ZIP file holds is 87 percent. The compression ratio depends on the data that is being compressed.



> **Note**
>
> If the ER destination is configured for the format element that generates output (the **Report** element in this example), compression of the output is bypassed.

Electronic reporting (ER) destinations

Defer the execution of XML elements in ER formats

Last updated on 04/15/2026

Validate ER format and model mapping to prevent runtime issues

You can validate each configured Electronic reporting (ER) format and model mapping at design time. During this validation, a consistency check runs to help prevent runtime problems, such as execution errors and performance degradation. For every problem that the check finds, it provides the path of a problematic element. For some problems, an automatic fix is available.

By default, the validation automatically runs in the following cases for an ER configuration that contains the previously mentioned ER components:

- You import a new version of an ER configuration into your instance of Microsoft Dynamics 365 Finance.
- You change the status of the editable ER configuration from **Draft** to **Completed**.
- You rebase an editable ER configuration by applying a new base version.

Starting in version 10.0.49, enhanced validation management lets you validate multiple completed configuration versions in a single operation, run that validation in the background as a batch job, and review the results later through a persistent validation history.

> **Note**
>
> Enhanced validation management is a feature that you turn on in **Feature management**.
>
> 1. Go to **Workspaces** > **Feature management**.
> 2. In the list, find and select **Enhanced validation management for Electronic Reporting configurations**.
> 3. Select **Enable now**.

Validate a single configuration version

To validate one version of a configuration, follow these steps:

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the configurations tree in the left pane, select the desired ER configuration that contains the ER format or ER model mapping component.
3. On the **Versions** FastTab, select the version of the selected ER configuration.

4. On the **Versions** FastTab or on Action Pane (if **Enhanced validation management for Electronic Reporting configurations** feature is disabled), select **Validate**.

The system validates the selected version and reports any errors or warnings.

> ⓘ **Note**
>
> When the **Enhanced validation management for Electronic Reporting configurations** feature is disabled, the **Validate** button is available on Action Pane and validates the selected version of the selected configuration.
>
> When the **Enhanced validation management for Electronic Reporting configurations** feature is enabled, the **Validate** button is available on the **Versions** FastTab and validates the selected version of the selected configuration.

Validate multiple configurations

> ⓘ **Note**
>
> This function is available starting in version 10.0.49 when the **Enhanced validation management for Electronic Reporting configurations** feature is enabled.

When you turn on the feature, the Action Pane on the **Configuration repository** page includes a **Validation** menu that you can use to validate several configurations at once.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the Action Pane, select **Validation** > **Validate configurations**.
3. In the **Configuration validation** dialog box, select the completed configuration versions that you want to validate.
4. Choose how to run the validation:
    - To run validation immediately in interactive mode, start the validation and confirm when prompted. Interactive validation can take some time, depending on how many configurations you select.
    - To run validation in the background, schedule it as a batch job by using the **Batch** button. When the job is queued, a notification confirms that the ER configuration validation job is added to the batch queue.

> **Tip**
>
> Run validation as a batch job when you select many configurations or large configurations, so that the work doesn't block your interactive session.

Only completed configuration versions are available for validation.

Validate ER format in the Designer

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the configurations tree in the left pane, select the desired ER configuration that contains the ER format component.
3. On the **Versions** FastTab, select the version of the selected ER configuration.
4. On the Action Pane, select **Designer**.
5. On the **Format designer** page, on the Action Pane, select **Validate**.

Validate ER model mapping in the Designer

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the configurations tree in the left pane, select the ER configuration that contains the ER model mapping component.
3. On the **Versions** FastTab, select the version of the selected ER configuration.
4. On the Action Pane, select **Designer**.
5. On the **Model to datasource mapping** page, on the Action Pane, select **Designer**.
6. On the **Model mapping designer** page, on the Action Pane, select **Validate**.

Skip the validation when importing the configuration

To skip the validation when importing the configuration, follow these steps:

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. Set the **Validate the configuration after importing** option to **No**.

Skip the validation when you change or rebase the version's status

To skip the validation when you change or rebase the version's status, follow these steps:

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. Set the **Skip validation at configuration's status change and rebase** option to **Yes**.

ER uses the following categories to group consistency check inspections:

- **Executability** – Inspections that detect critical issues that might occur at runtime. These issues are mostly at an **Error** level.
- **Performance** – Inspections that detect issues that might cause inefficient execution of configured ER components. These issues are mostly at a **Warning** level.
- **Data integrity** – Inspections that detect issues that might cause data loss or runtime issues. These issues are mostly at a **Warning** level.

List of validations

The following table provides an overview of the validations that ER provides. For more information about these validations, use the links in the first column to go to the relevant sections of this article. Those sections explain the types of components that ER provides inspections for and how you can reconfigure ER components to help prevent issues.

Expand table

Name	Category	Level	Message
Type conversion	Executability	Error	Can't convert expression of type <type> to field of type <type>. **Runtime error:** Exception for type
Type compatibility	Executability	Error	The configured expression can't be used as the binding of the current format element to a data source as this expression returns value of the data type <type> that is beyond the scope of data types that are supported by the current format element of type <type>. **Runtime error:** Exception of type
Missing configuration element	Executability	Error	Path not found <path>. **Runtime error:** Element of the configuration <path> not found
Executability of an expression with FILTER function	Executability	Error	The list expression of FILTER function isn't queryable. **Runtime error:** Filtering isn't supported. Validate the configuration to get more details about this.
Executability of a GROUPBY data source	Executability	Error	Path <path> doesn't support querying.
Executability of a GROUPBY data source	Executability	Error	Group by function can't be executed with query. **Runtime error:** Group by function can't be executed with query.
Executability of a JOIN data source	Executability	Error	Can't join a list <path> that isn't a filter in query. **Runtime error:** Function Joined datasource should be a

Name	Category	Level	Message
			filter expression calculated field has been incorrectly called.
Preferability of FILTER vs WHERE function	Performance	Warning	Using FILTER function for the expression is preferable than WHERE from the performance perspective. Select Fix to replace it automatically.
Preferability of ALLITEMSQUERY vs ALLITEMS function	Performance	Warning	Using ALLITEMSQUERY function for the expression is preferable than ALLITEMS from the performance perspective. Select Fix to replace it automatically.
Consideration of empty list cases	Executability	Warning	List <path> doesn't have any check for empty list case, it can result an error at run time. Add a check for empty list case. **Runtime error:** List is empty at <path> **Potential issue:** Line is getting populated once while a data source it's populated from contains multiple records
Executability of an expression with FILTER function (caching)	Executability	Error	FILTER function can't be applied to the selected type of data source. A data source of the Table records type is applicable only when it isn't cached and has no manually added nested data sources. **Runtime error:** Filtering isn't supported. Validate the configuration to get more details about this.
Missing binding	Executability	Warning	Path <path> has no binding to any datasource in using model's mapping. **Runtime error:** Path <path> isn't bound
Not linked template	Data integrity	Warning	File <name> isn't linked to any file components and will be removed after changing status of configuration version.
Not synced format	Data integrity	Warning	Defined name <component name> doesn't exist in Excel sheet <sheet name>
Not synced format	Data integrity	Warning	<Tagged Word content control> tag doesn't exist in Word template file **Runtime error:** <Tagged Word content control> tag doesn't exist in Word template file.
No default mapping	Data integrity	Error	More than one model mapping exists for the <model name (root descriptor)> data model in the

Name	Category	Level	Message
			configurations <configuration names separated by comma>. Set one of the configurations as default **Runtime error:** More than one model mapping exists for the <model name (root descriptor)> data model in the configurations <configuration names separated by comma>. Set one of the configurations as default.
Inconsistent setting of Header or Footer components	Data integrity	Error	Headers/footers (<component type: Header or Footer>) are inconsistent **Runtime:** The last configured component is used at runtime if the draft version of the configured ER format is executed.
Inconsistent setting of Page component	Data integrity	Error	There are more than two range components without replication. Remove unnecessary components.
Executability of an expression with ORDERBY function	Executability	Error	The list expression of ORDERBY function isn't queryable. **Runtime error:** Sorting isn't supported. Validate the configuration to get more details about this.
Obsolete application artifact	Data integrity	Warning	The element <path> is marked as obsolete. or The element <path> is marked as obsolete with message <message text>. **Runtime error sample:** Class '<path>' not found.

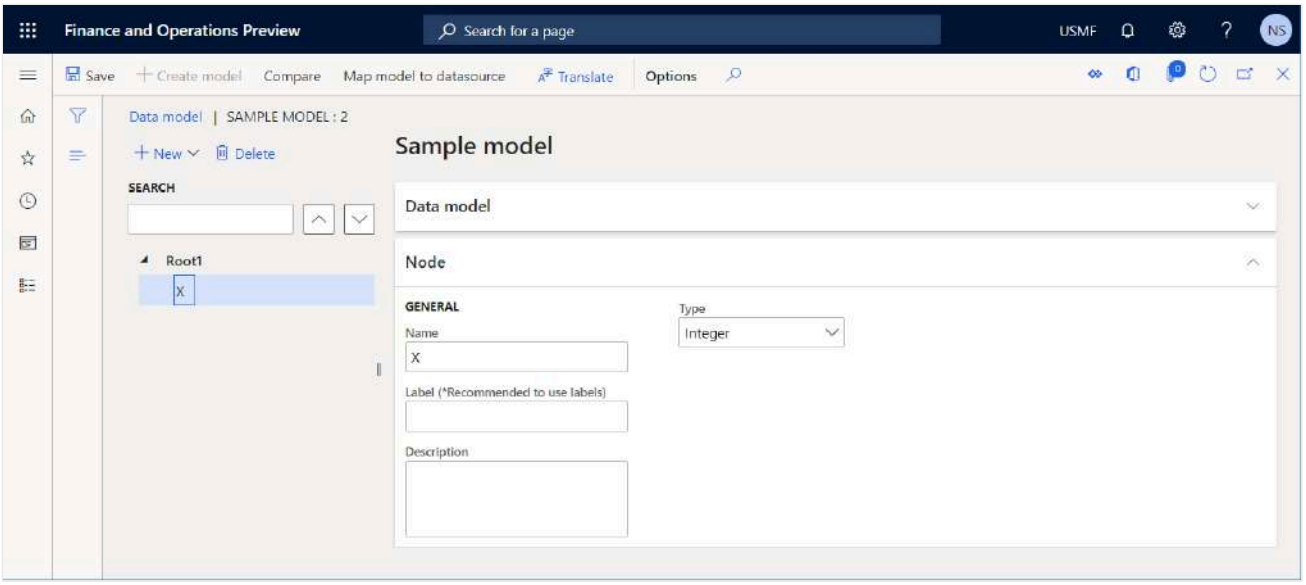
Type conversion

ER checks whether the data type of a data model field is compatible with the data type of an expression that you configure as the binding for that field. If the data types are incompatible, the ER model mapping designer shows a validation error. The error message states that ER can't convert an expression of type A to a field of type B.

The following steps show how this issue might occur.

1. Start to configure the ER data model and the ER model mapping components simultaneously.

2. In the data model tree, add a field that you name **X**, and select **Integer** as the data type.



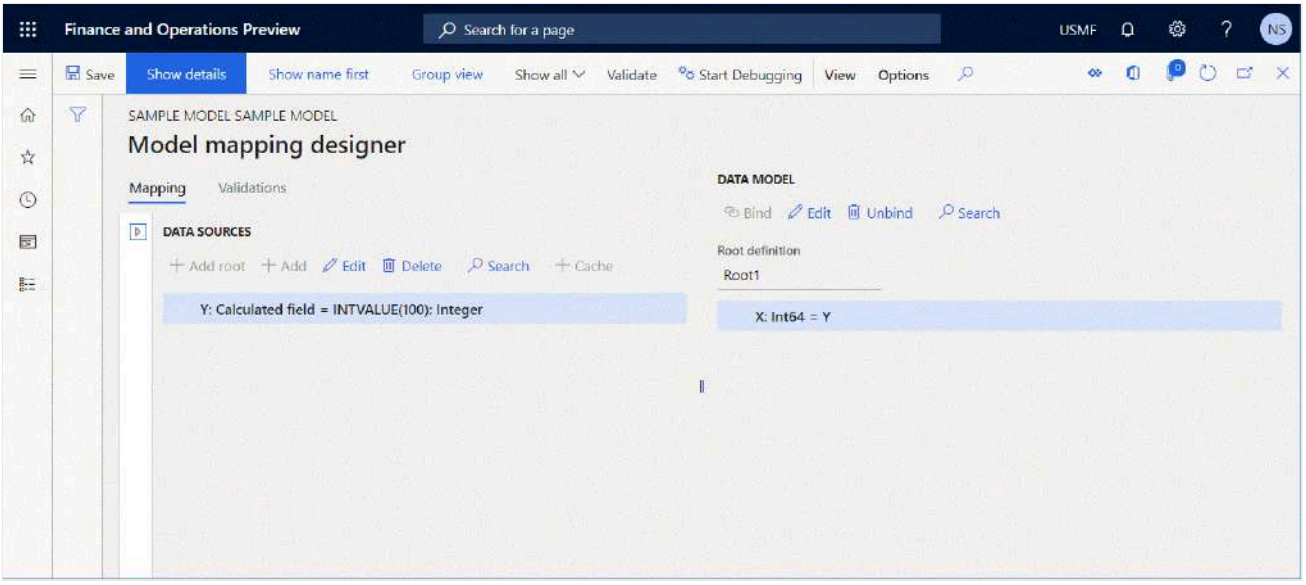
3. In the model mapping designer, in the **Data sources** pane, add a data source of the **Calculated field** type.

4. Name the new data source **Y**, and configure it so that it contains the expression `INTVALUE(100)`.

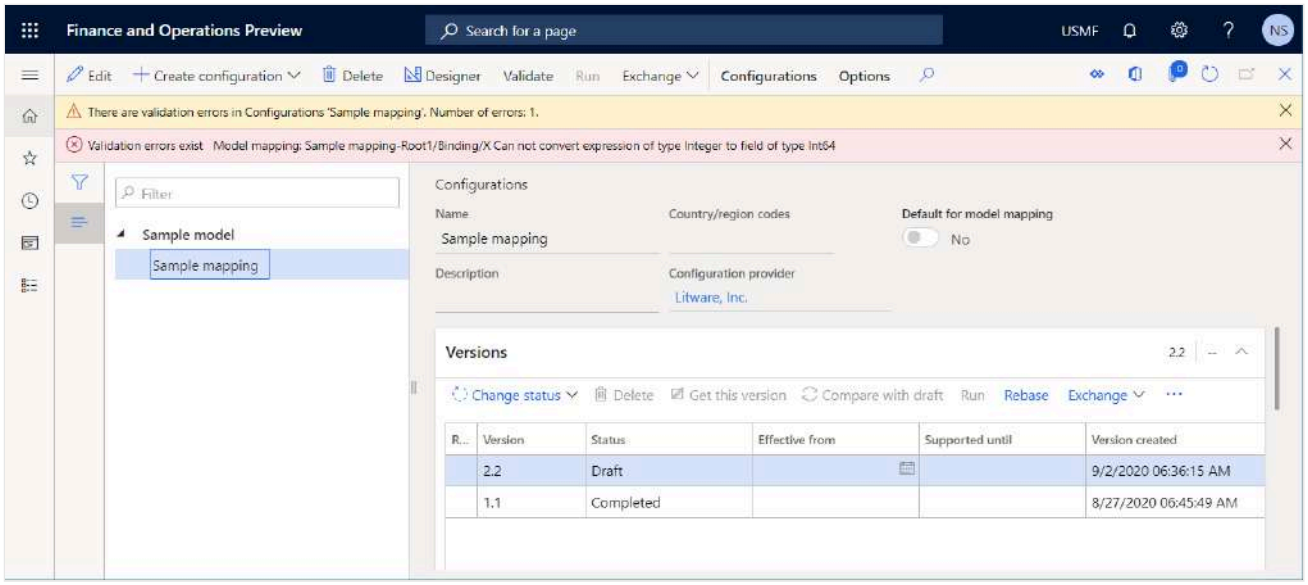
5. Bind **X** to **Y**.

6. In the data model designer, change the data type of the **X** field from **Integer** to **Int64**.

7. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page.

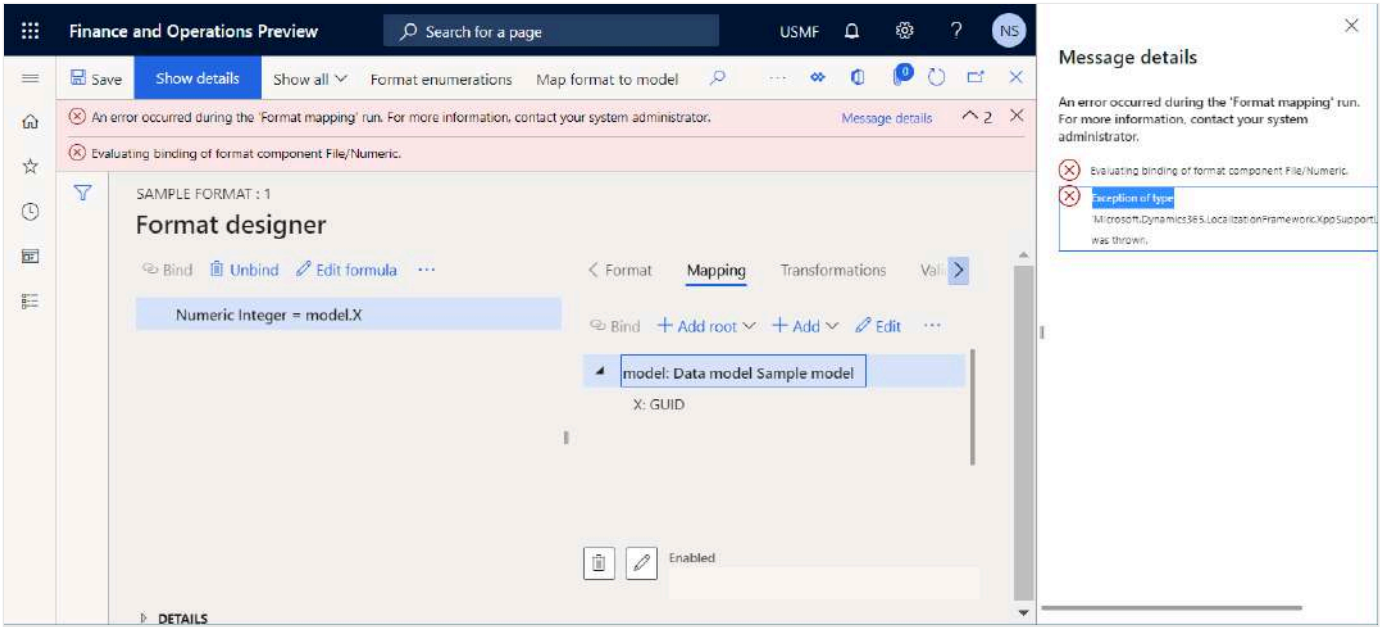


8. Select **Validate** to inspect the model mapping component of the selected ER configuration on the **Configurations** page.



9. Notice that a validation error occurs. The message states that the value of the **Integer** type that the `INTVALUE(100)` expression of the **Y** data source returns can't be stored in the **X** data model field of the **Int64** type.

The following illustration shows the runtime error that occurs if you ignore the warning and select **Run** to run a format that is configured to use the model mapping.



Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Update the data model structure by changing the data type of the data model field so that it matches the data type of the expression that you configure for the binding of that field. For the preceding example, change the data type of the **X** field back to **Integer**.

Option 2

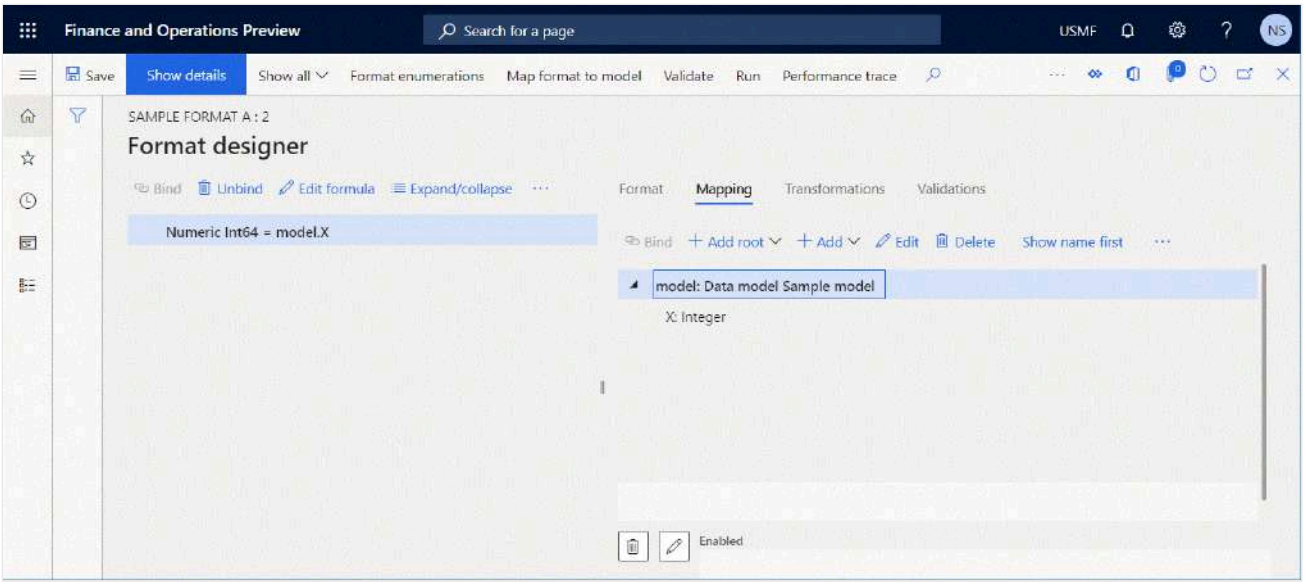
Update the model mapping by changing the expression of the data source that you bind to the data model field. For the preceding example, change the expression of the **Y** data source to `INT64VALUE(100)`.

Type compatibility

ER checks whether the data type of a format element is compatible with the data type of an expression that you configure as the binding of that format element. If the data types are incompatible, a validation error occurs in the ER Operations designer. The message that you receive states that the configured expression can't be used as the binding of the current format element to a data source, because the expression returns a value of data type A that is beyond the scope of the data types that the current format element of type B supports.

The following steps show how this issue might occur.

1. Start to configure the ER data model and the ER format components simultaneously.
2. In the data model tree, add a field that you name **X**, and select **Integer** as the data type.
3. In the format structure tree, add a format element of the **Numeric** type.
4. Name the new format element **Y**. In the **Numeric type** field, select **Integer** as the data type.
5. Bind **X** to **Y**.
6. In the format structure tree, change the data type of the **Y** format element from **Integer** to **Int64**.
7. Select **Validate** to inspect the editable format component on the **Format designer** page.



8. Notice that a validation error occurs. The message states that the configured expression can accept only **Int64** values. Therefore, the value of the **X** data model field of the **Integer** type can't be entered in the **Y** format element.

Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Update the format structure by changing the data type of the **Numeric** format element so that it matches the data type of the expression that you configured for the binding of that element. In the preceding example, change the **Numeric type** value of the **X** format element back to **Integer**.

Option 2

Update the format mapping of the **X** format element by changing the expression from `model.X` to `INT64VALUE(model.X)`.

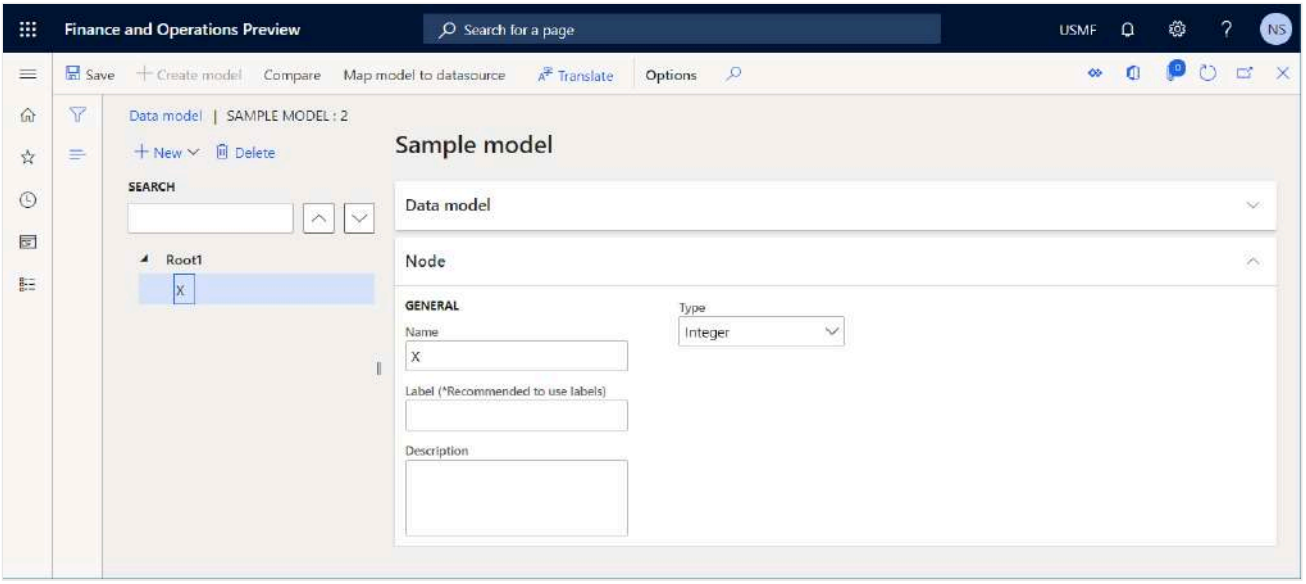
Missing configuration element

ER checks whether the binding expressions contain only data sources that the editable ER component configures. For every binding that contains a data source that the editable ER component is missing, a validation error occurs in the ER Operations designer or the ER model mapping designer.

The following steps show how this issue might occur.

1. Start to configure the ER data model and the ER model mapping components simultaneously.

2. In the data model tree, add a field that you name **X**, and select **Integer** as the data type.



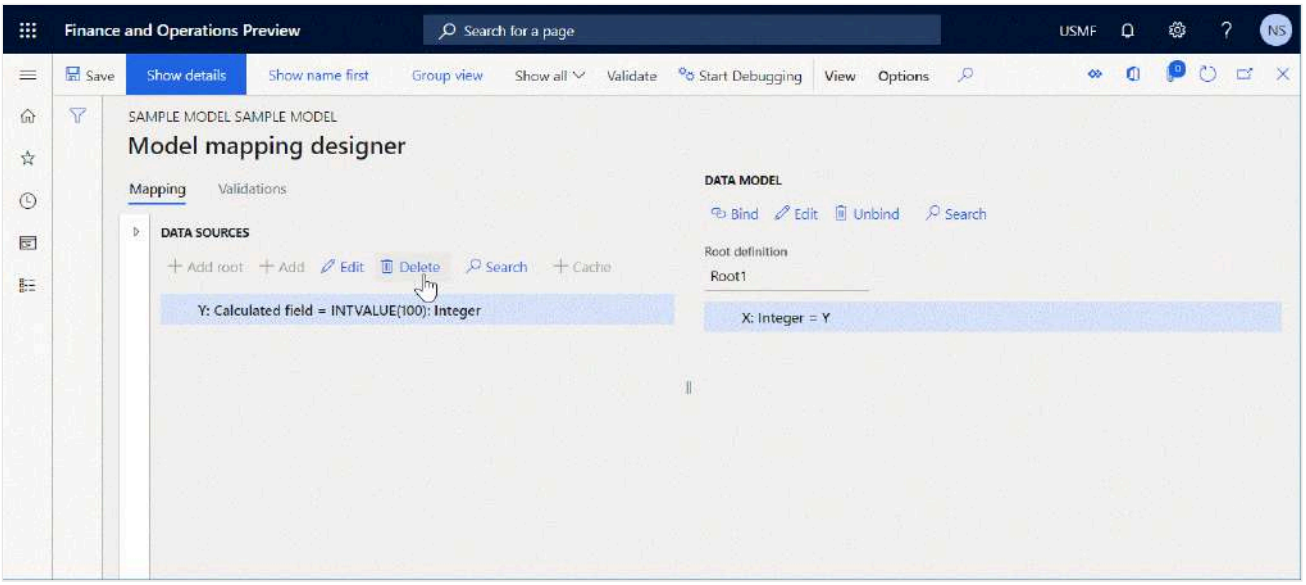
3. In the model mapping designer, in the **Data sources** pane, add a data source of the **Calculated field** type.

4. Name the new data source **Y**, and configure it so that it contains the expression `INTVALUE(100)`.

5. Bind **X** to **Y**.

6. In the model mapping designer, in the **Data sources** pane, delete the **Y** data source.

7. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page.



8. Notice that a validation error occurs. The message states that the binding of the **X** data model field contains the path that refers to the **Y** data source, but this data source isn't found.

Automatic resolution

Select **Unbind** to automatically fix this issue by removing the missing data source binding.

Manual resolution

Option 1

Unbind the **X** data model field to stop referring to the nonexistent **Y** data source.

Option 2

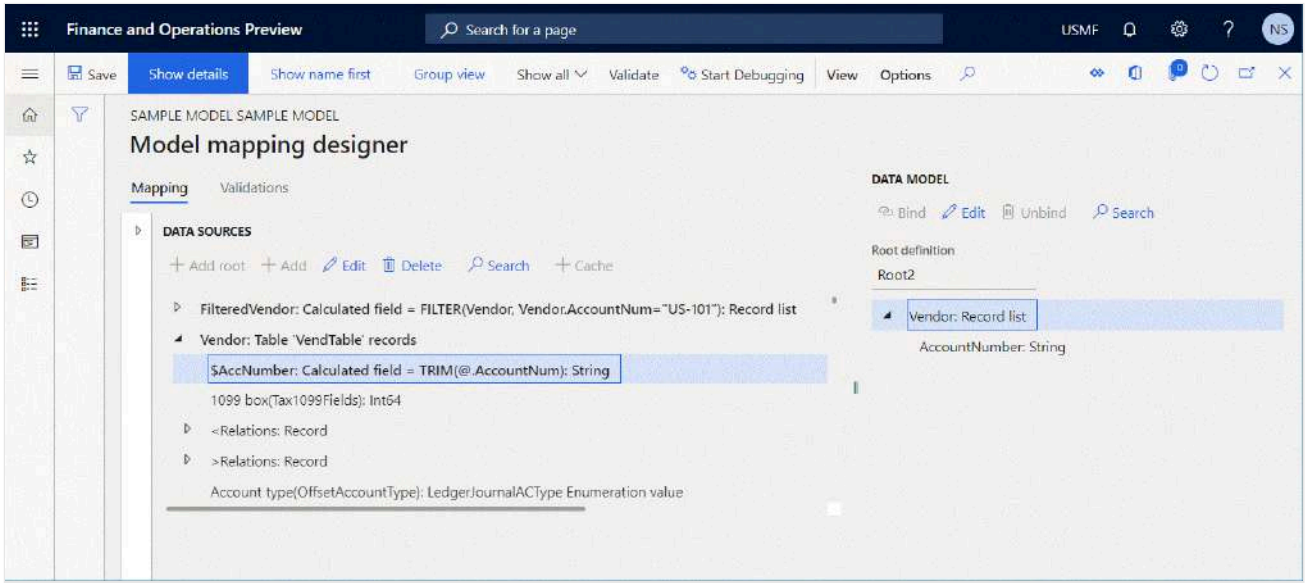
In the model mapping designer, in the **Data sources** pane, add the **Y** data source again.

Executability of an expression with FILTER function

Use the built-in FILTER ER function to access application tables, views, or data entities. The function places a single SQL call to get the required data as a list of records. Use a data source of the **Record list** type as an argument of this function to specify the application source for the call. ER checks whether a direct SQL query can be established to a data source that you refer to in the `FILTER` function. If a direct query can't be established, the ER model mapping designer shows a validation error. The error message states that the ER expression that includes the `FILTER` function can't be run at runtime.

The following steps show how this issue might occur.

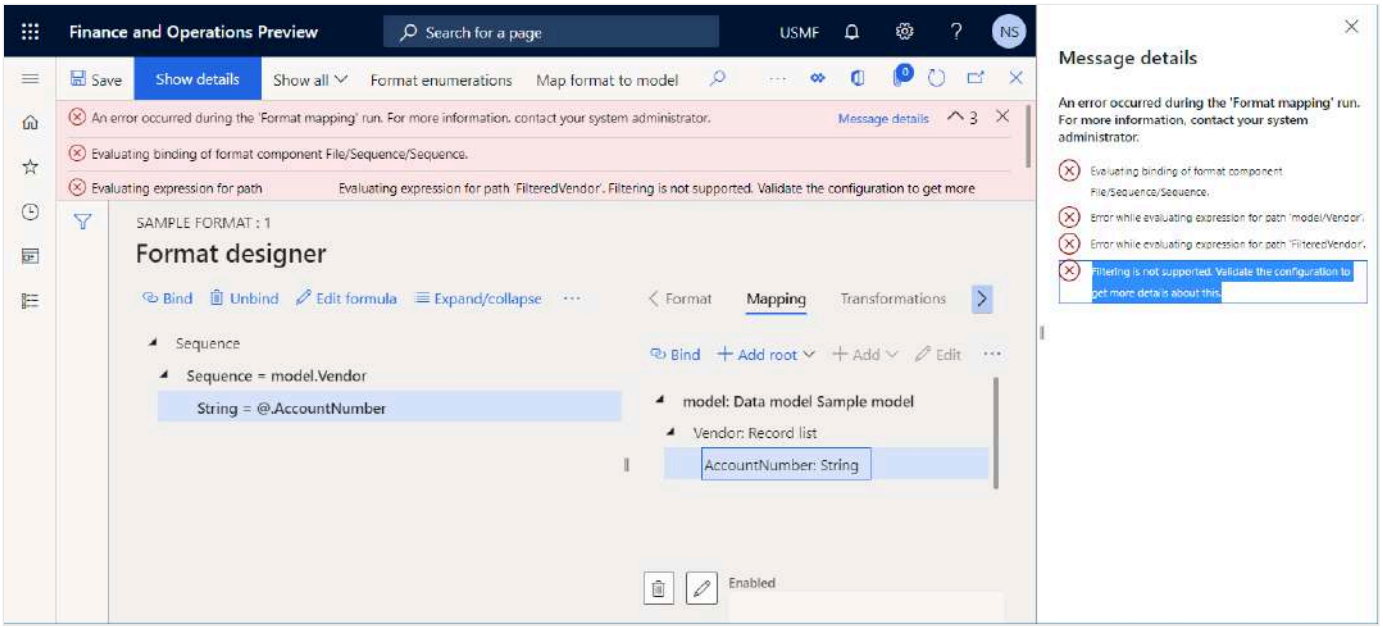
1. Start to configure the ER model mapping component.
2. Add a data source of the **Dynamics 365 for Operations \ Table records** type.
3. Name the new data source **Vendor**. In the **Table** field, select **VendTable** to specify that this data source requests the VendTable table.
4. Add a data source of the **Calculated field** type.
5. Name the new data source **FilteredVendor**, and configure it so that it contains the expression `FILTER(Vendor, Vendor.AccountNum="US-101")`.
6. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page and verify that the `FILTER(Vendor, Vendor.AccountNum="US-101")` expression in the **Vendor** data source can be queried.
7. Modify the **Vendor** data source by adding a nested field of the **Calculated field** type to get the trimmed vendor account number.
8. Name the new nested field **$AccNumber**, and configure it so that it contains the expression `TRIM(Vendor.AccountNum)`.
9. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page and verify that the `FILTER(Vendor, Vendor.AccountNum="US-101")` expression in the **Vendor** data source can be queried.



10. Notice that a validation error occurs, because the **Vendor** data source contains a nested field of the **Calculated field** type that doesn't allow the expression of the **FilteredVendor**

data source to be translated to the direct SQL statement.

The following illustration shows the runtime error that occurs if you ignore the warning and select **Run** to run a format that is configured to use the model mapping.



Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Instead of adding a nested field of the **Calculated field** type to the **Vendor** data source, add the **$AccNumber** nested field to the **FilteredVendor** data source, and configure it so that it contains the expression `TRIM(FilteredVendor.AccountNum)`. By using this approach, you can run the `FILTER(Vendor, Vendor.AccountNum="US-101")` expression at the SQL level and calculate the **$AccNumber** nested field afterward.

Option 2

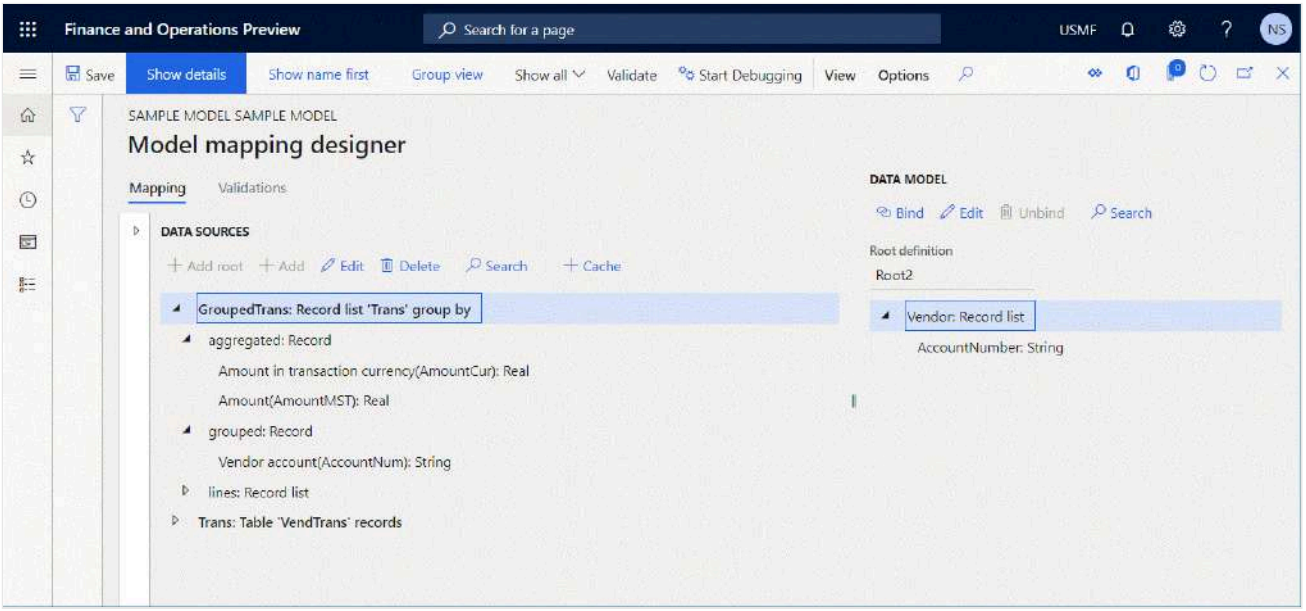
Change the expression of the **FilteredVendor** data source from `FILTER(Vendor, Vendor.AccountNum="US-101")` to `WHERE(Vendor, Vendor.AccountNum="US-101")`. Don't change the expression for a table that has a large volume of data (transactional table), because this change fetches all records and selects the required records in memory. Therefore, this approach can cause poor performance. For more information, see WHERE ER function.

Executability of a GROUPBY data source

The **GROUPBY** data source divides the query result into groups of records, usually to perform one or more aggregations on each group. You can configure every **GROUPBY** data source to run either at the database level or in memory. When you configure a **GROUPBY** data source to run at the database level, ER checks whether it can create a direct SQL query to a data source that the **GROUPBY** data source refers to. If ER can't create a direct query, the ER model mapping designer shows a validation error. The error message states that the configured **GROUPBY** data source can't run at runtime.

The following steps show how this issue might occur.

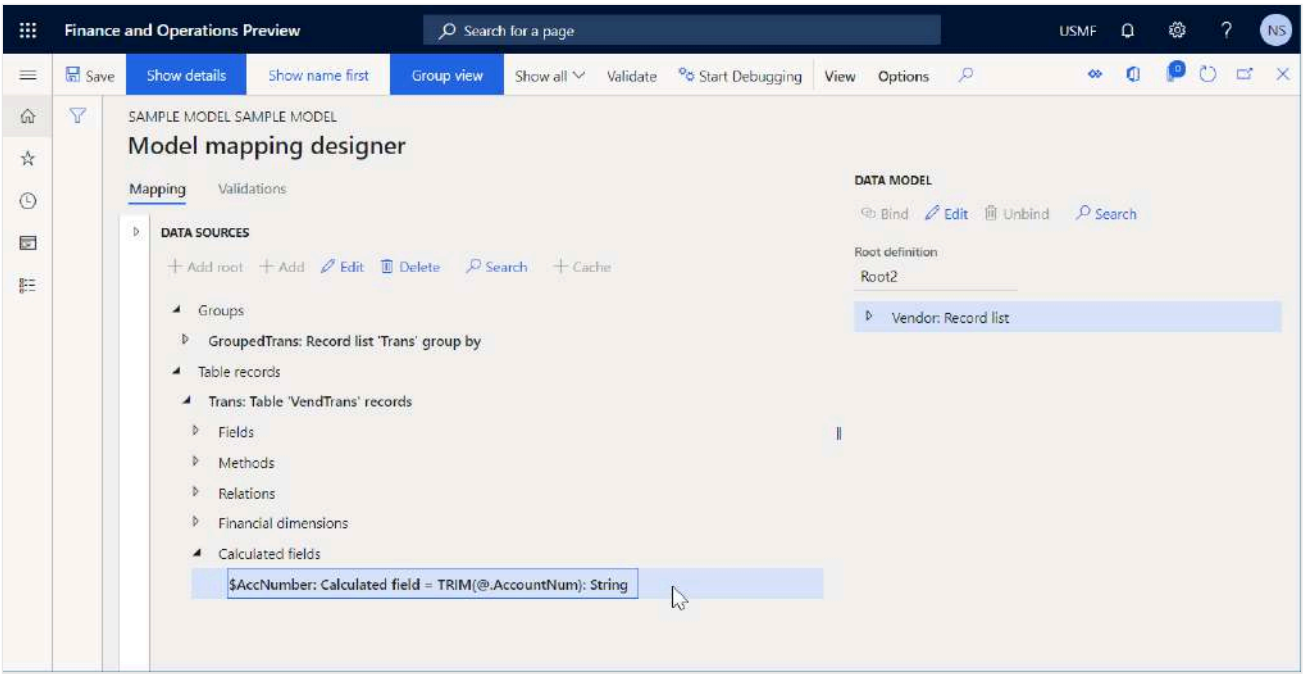
1. Start to configure the ER model mapping component.
2. Add a data source of the **Dynamics 365 for Operations \ Table records** type.
3. Name the new data source **Trans**. In the **Table** field, select **VendTrans** to specify that this data source requests the VendTrans table.
4. Add a data source of the **Group by** type.
5. Name the new data source **GroupedTrans**, and configure it in the following way:
    - Select the **Trans** data source as the source of records that should be grouped.
    - In the **Execution location** field, select **Query** to specify that you want to run this data source at the database level.



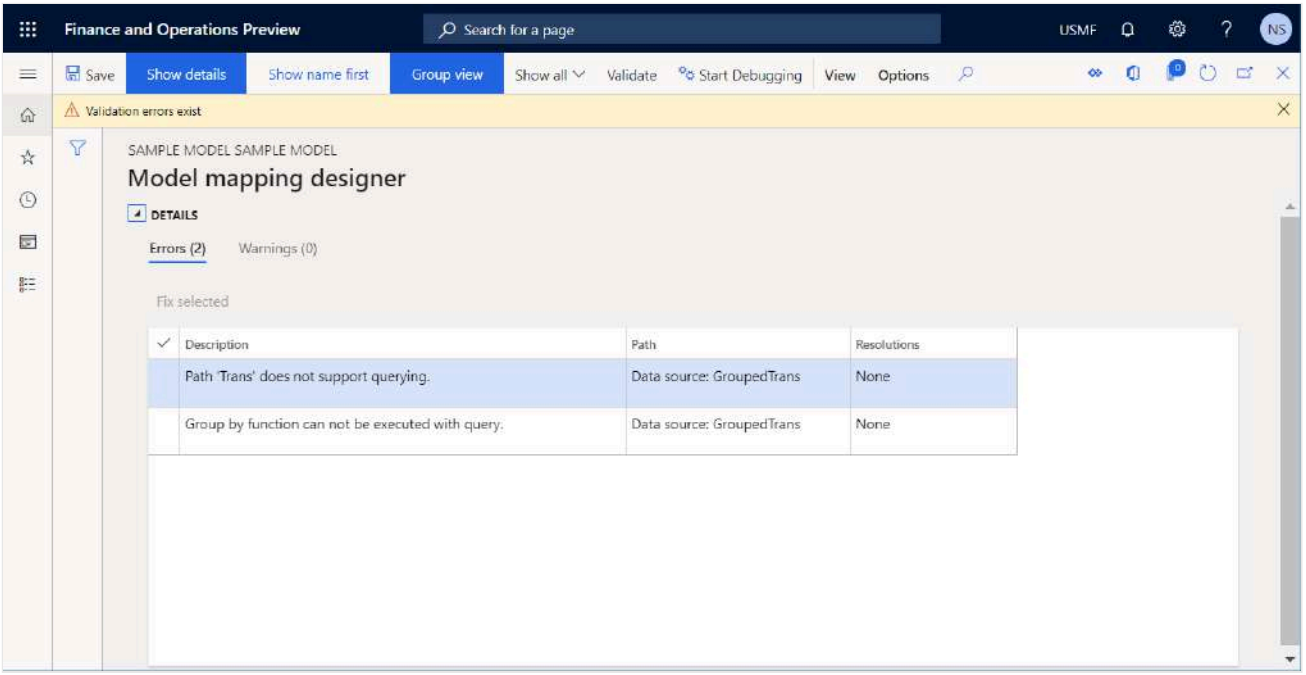
6. Select **Validate** to check the editable model mapping component on the **Model mapping designer** page and verify that the configured **GroupedTrans** data source can be queried.

7. Modify the **Trans** data source by adding a nested field of the **Calculated field** type to get the trimmed vendor account number.

8. Name the new data source **$AccNumber**, and configure it so that it contains the expression `TRIM(Trans.AccountNum)`.

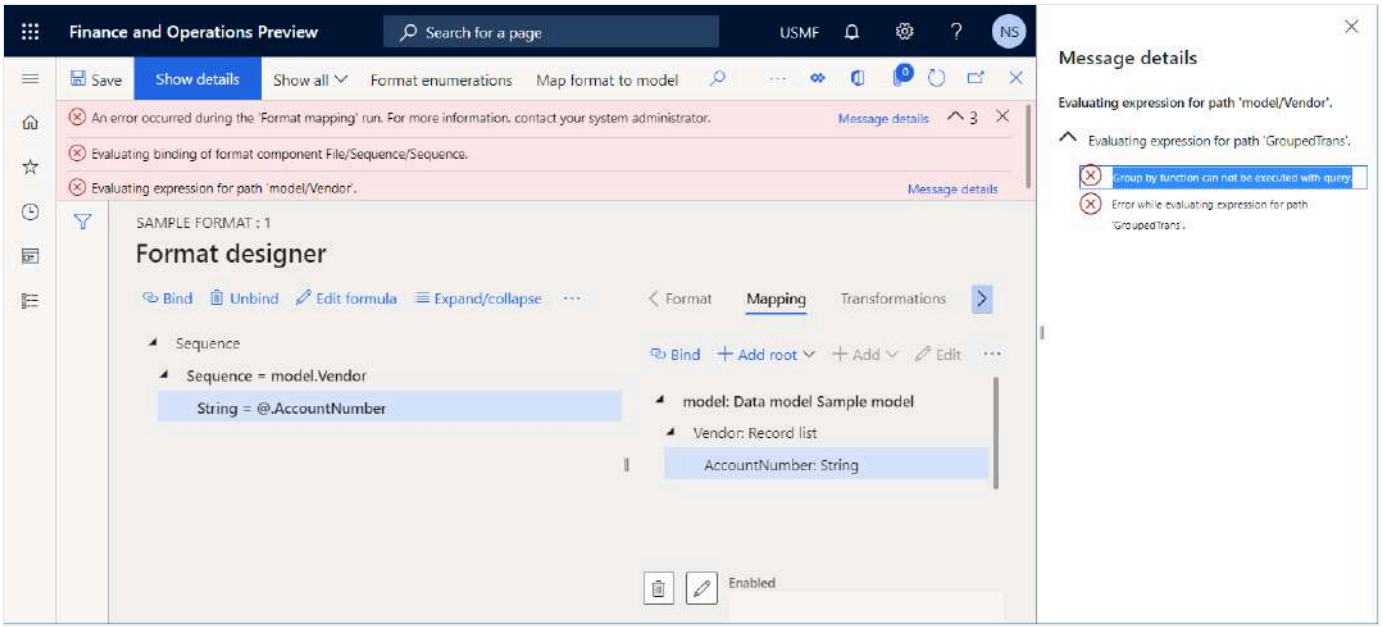


9. Select **Validate** to check the editable model mapping component on the **Model mapping designer** page and verify that the configured **GroupedTrans** data source can be queried.



10. Notice that a validation error occurs, because the **Trans** data source contains a nested field of the **Calculated field** type that doesn't allow the call for the **GroupedTrans** data source to be translated to the direct SQL statement.

The following illustration shows the runtime error that occurs if you ignore the warning and select **Run** to run a format that is configured to use the model mapping.



Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Instead of adding a nested field of the **Calculated field** type to the **Trans** data source, add the **$AccNumber** nested field for the **GroupedTrans.lines** item of the **GroupedTrans** data source, and configure it so that it contains the expression `TRIM(GroupedTrans.lines.AccountNum)`. In this way, you can run the **GroupedTrans** data source at the SQL level and calculate the **$AccNumber** nested field afterward.

Option 2

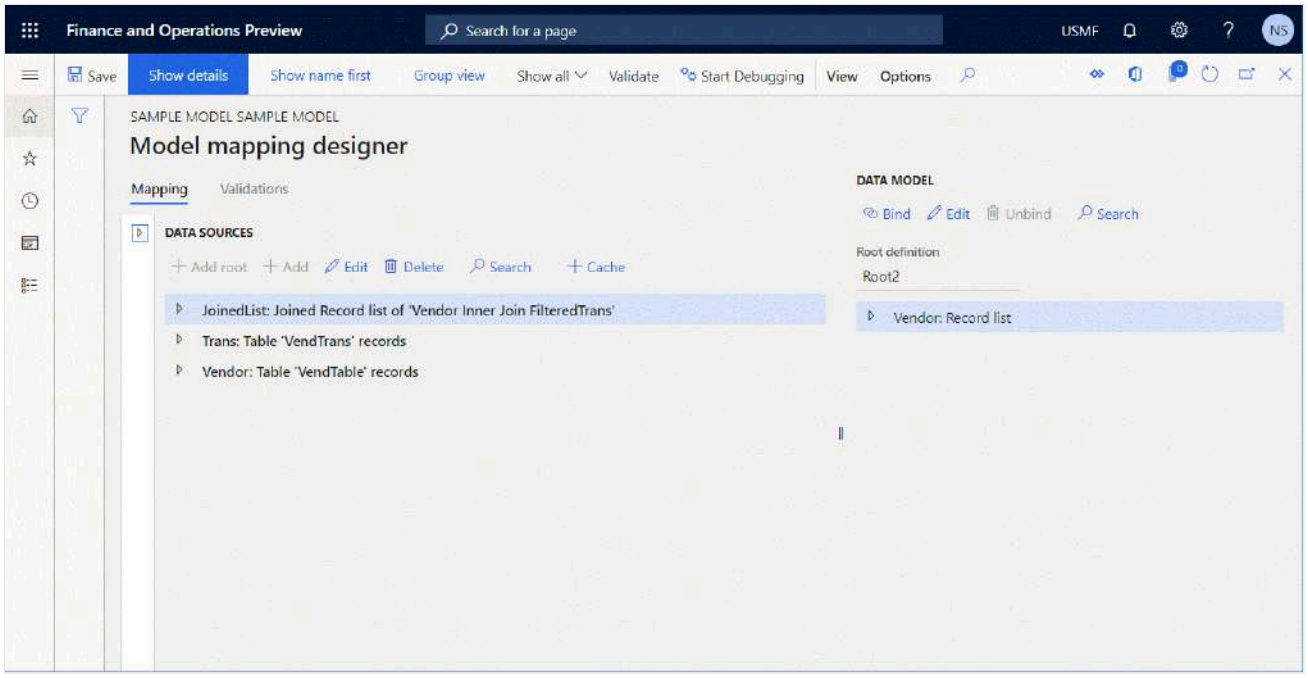
Change the value of the **Execution location** field for the **GroupedTrans** data source from **Query** to **In memory**. Don't change the value for a table that has a large volume of data (transactional table), because this change fetches all records and does grouping and aggregation in memory. Therefore, this approach can cause poor performance.

Executability of a JOIN data source

The JOIN data source combines records from two or more database tables, based on related fields. You can configure every **JOIN** data source to run either at the database level or in memory. When you configure a **JOIN** data source to run at the database level, ER checks whether it can create a direct SQL query to data sources that the data source refers to. If ER can't create a direct SQL query to at least one referenced data source, the ER model mapping designer shows a validation error. The error message states that the configured **JOIN** data source can't run at runtime.

The following steps show how this issue might occur.

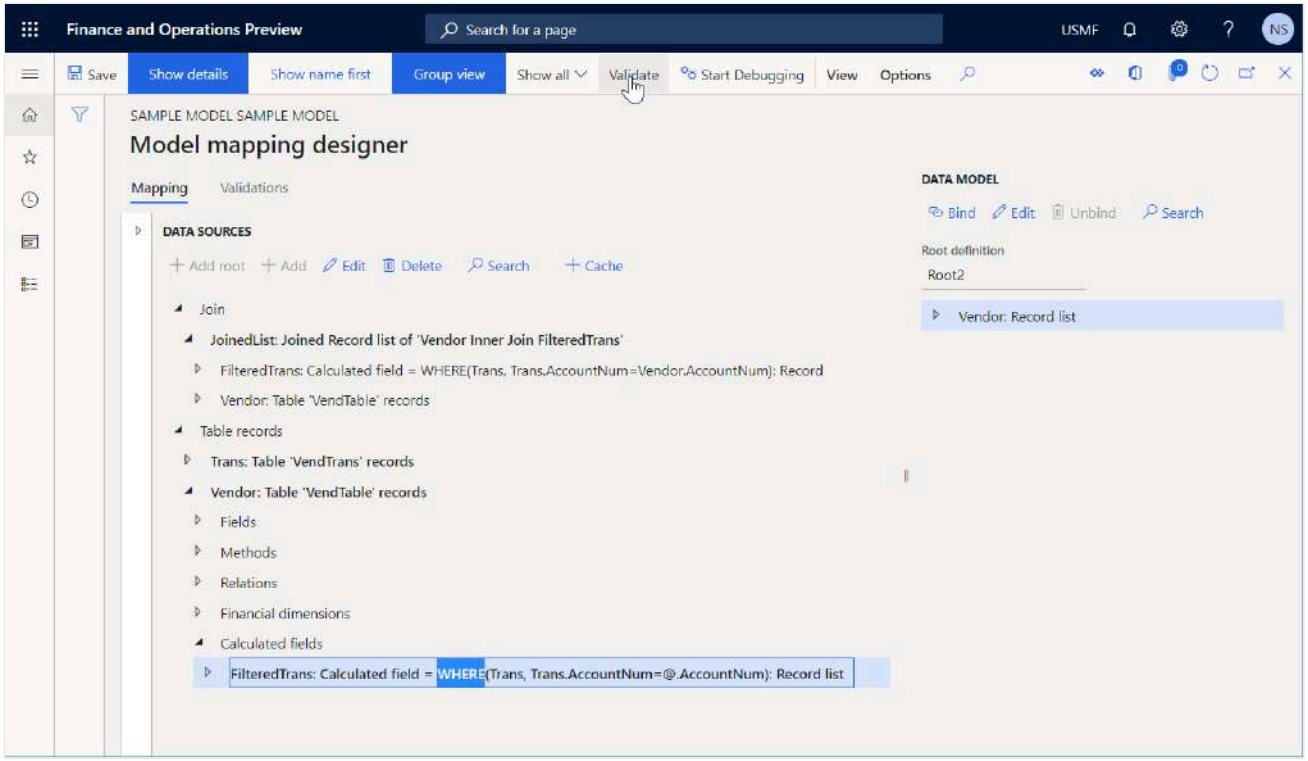
1. Start to configure the ER model mapping component.
2. Add a data source of the **Dynamics 365 for Operations \ Table records** type.
3. Name the new data source **Vendor**. In the **Table** field, select **VendTable** to specify that this data source requests the VendTable table.
4. Add a data source of the **Dynamics 365 for Operations \ Table records** type.
5. Name the new data source **Trans**. In the **Table** field, select **VendTrans** to specify that this data source requests the VendTrans table.
6. Add a data source of the **Calculated field** type as the nested field of the **Vendor** data source.
7. Name the new data source **FilteredTrans**, and configure it so that it contains the expression `FILTER(Trans, Trans.AccountNum=Vendor.AccountNum)`.
8. Add a data source of the **Join** type.
9. Name the new data source **JoinedList**, and configure it in the following way:
   a. Add the **Vendor** data source as the first set of records to join.
   b. Add the **Vendor.FilteredTrans** data source as the second set of records to join. Select **INNER** as the type.
   c. In the **Execute** field, select **Query** to specify that you want to run this data source at the database level.



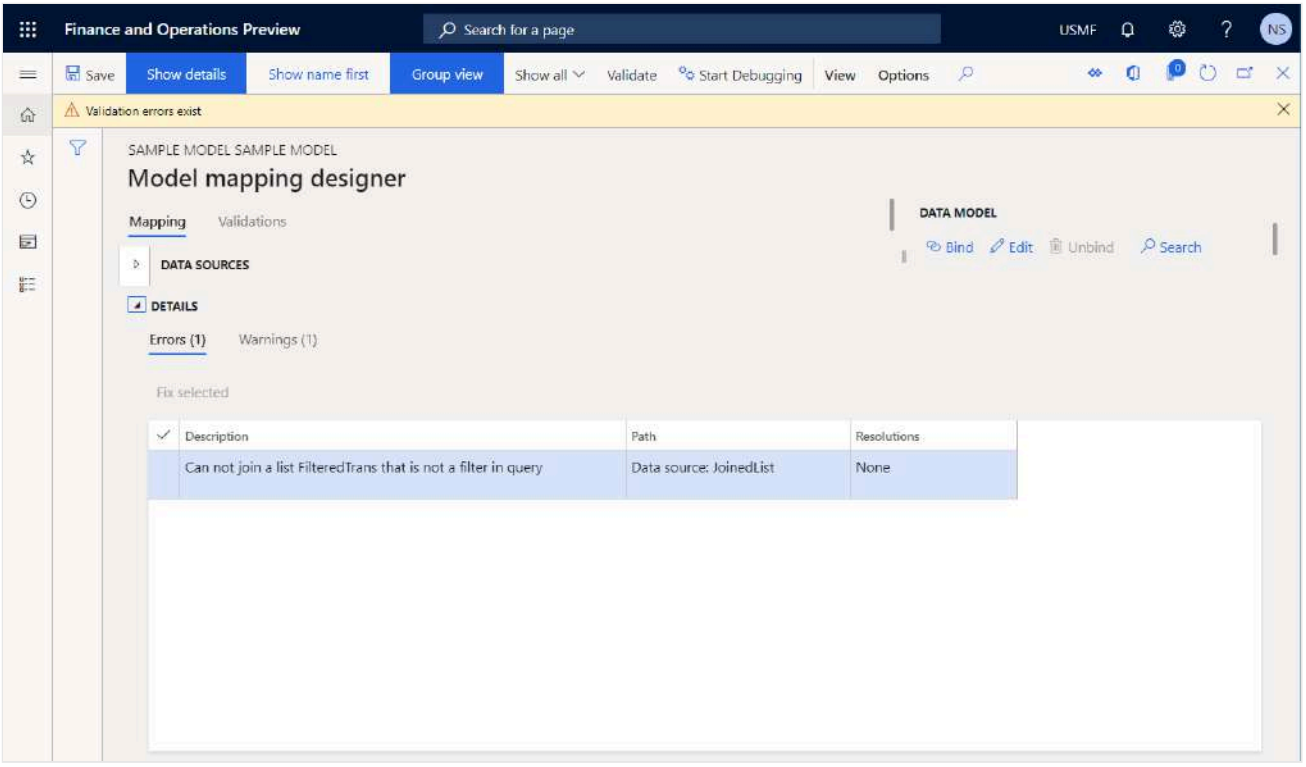
10. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page and verify that the configured **JoinedList** data source can be queried.

11. Change the expression of the **Vendor.FilteredTrans** data source from `FILTER(Trans, Trans.AccountNum=Vendor.AccountNum)` to `WHERE(Trans, Trans.AccountNum=Vendor.AccountNum)`.

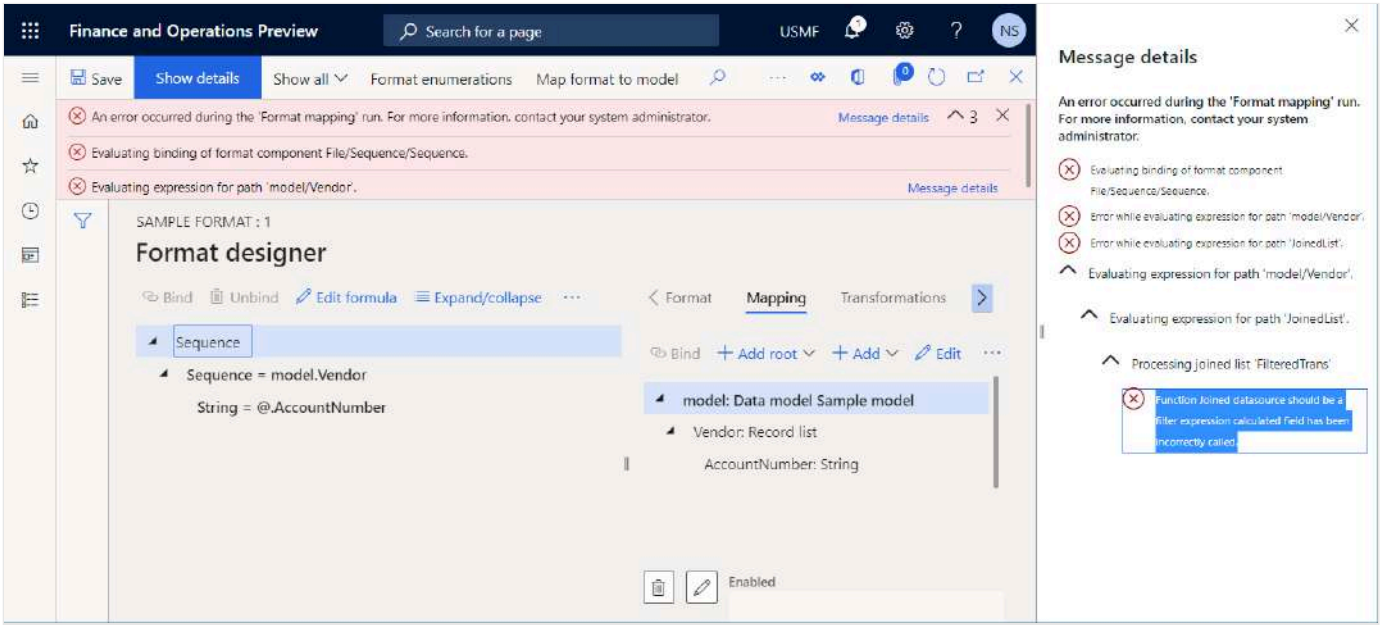
12. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page and verify that the configured **JoinedList** data source can be queried.



13. Notice that a validation error occurs, because the expression of the **Vendor.FilteredTrans** data source can't be translated to the direct SQL call. Additionally, the direct SQL call doesn't allow the call for the **JoinedList** data source to be translated to the direct SQL statement.



The following illustration shows the runtime error that occurs if you ignore the warning and select **Run** to run a format that is configured to use the model mapping.



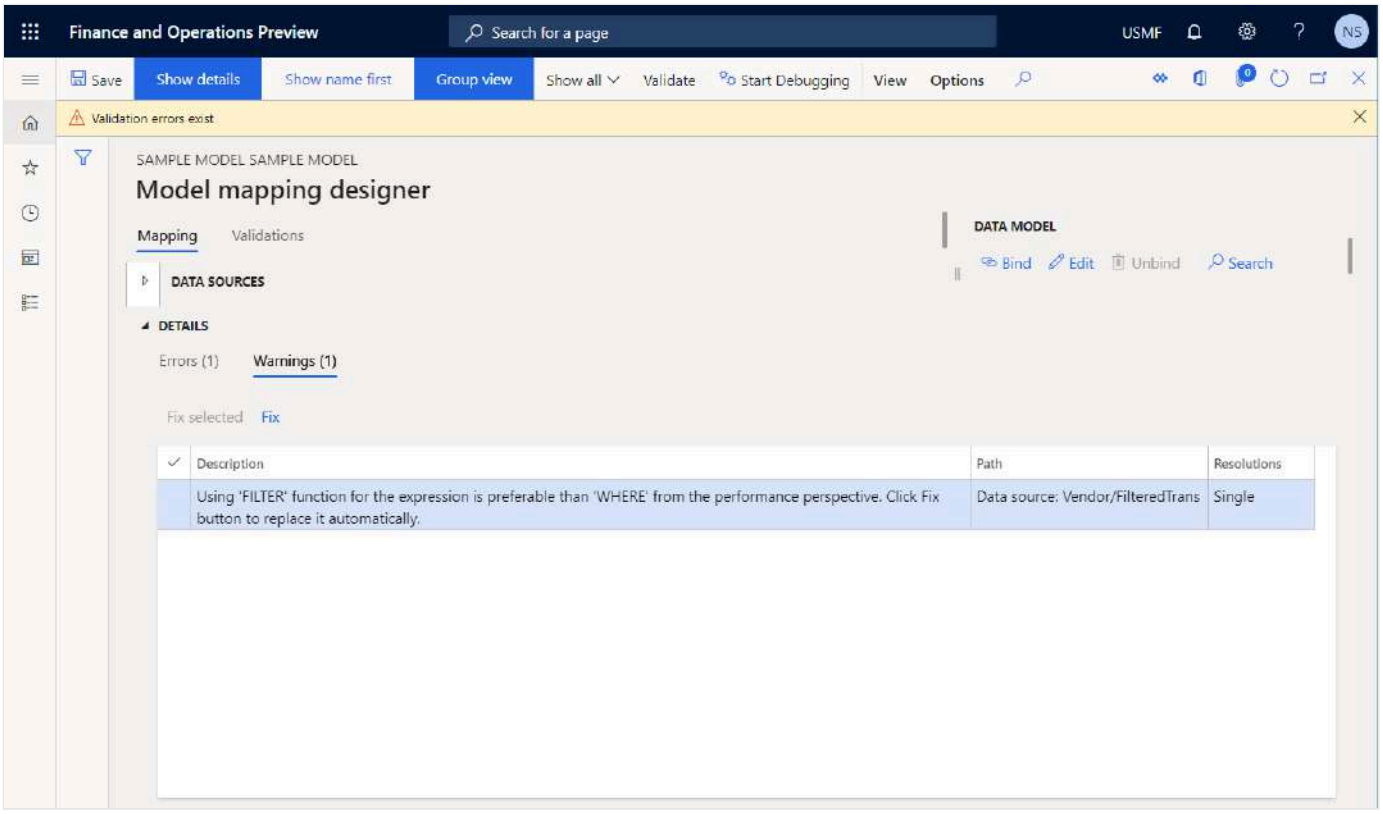
Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Change the expression of the **Vendor.FilteredTrans** data source from `WHERE(Trans, Trans.AccountNum=Vendor.AccountNum)` back to `FILTER(Trans, Trans.AccountNum=Vendor.AccountNum)`, as the warning advises.



Option 2

Change the value of the **Execute** field for the **JoinedList** data source from **Query** to **In memory**. Don't change the value for a table that has a large volume of data (transactional table), because this change fetches all records, and the join happens in memory. Therefore, this approach can cause poor performance. A validation warning informs you about this risk.

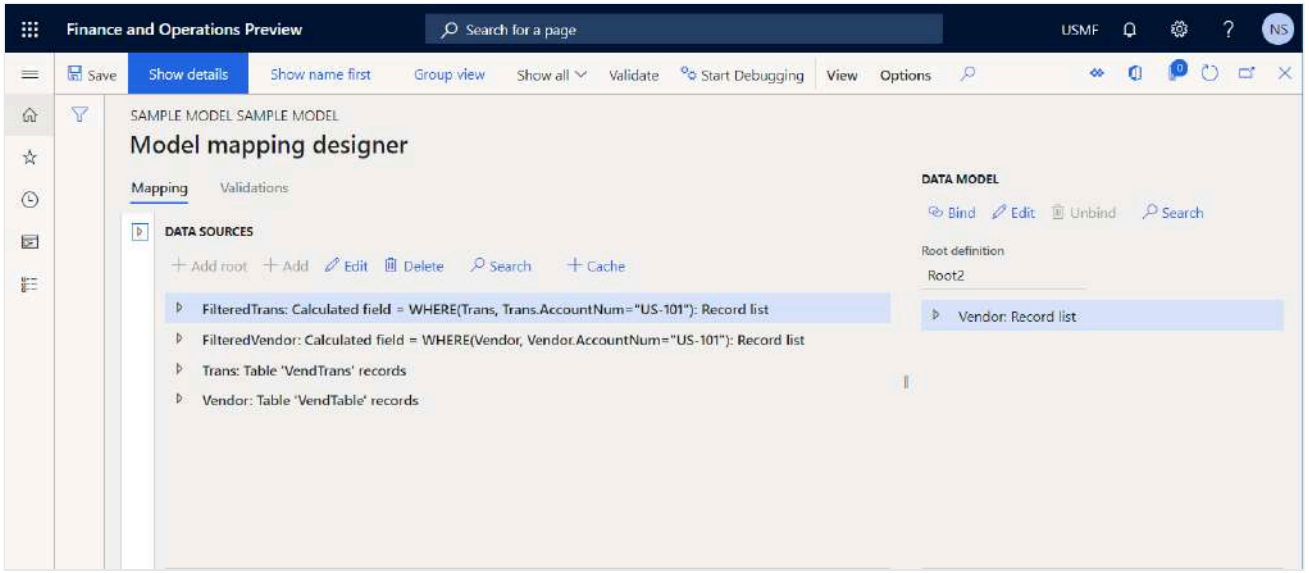
Preferability of FILTER vs WHERE function

Use the built-in FILTER ER function to access application tables, views, or data entities. It places a single SQL call to get the required data as a list of records. The WHERE function fetches all records from the given source and does record selection in memory. Both functions use a data source of the **Record list** type as an argument and specify a source for getting records. ER checks whether a direct SQL call can be established to a data source that you refer to in the **WHERE** function. If a direct call can be established, a validation warning occurs in the ER model mapping

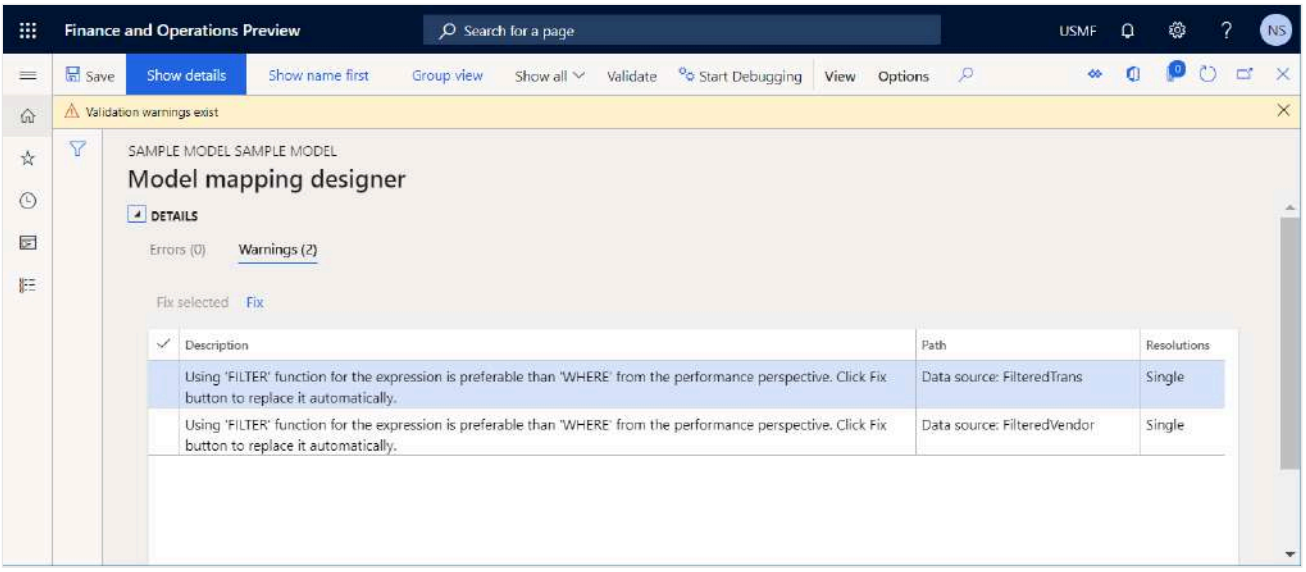
designer. The message that you receive recommends that you use the **FILTER** function instead of the **WHERE** function to help improve efficiency.

The following steps show how this issue might occur.

1. Start to configure the ER model mapping component.
2. Add a data source of the **Dynamics 365 for Operations \ Table records** type.
3. Name the new data source **Trans**. In the **Table** field, select **VendTrans** to specify that this data source requests the VendTrans table.
4. Add a data source of the **Calculated field** type as the nested field of the **Vendor** data source.
5. Name the new data source **FilteredTrans**, and configure it so that it contains the expression `WHERE(Trans, Trans.AccountNum="US-101")`.
6. Add a data source of the **Dynamics 365 for Operations \ Table records** type.
7. Name the new data source **Vendor**. In the **Table** field, select **VendTable** to specify that this data source requests the VendTable table.
8. Add a data source of the **Calculated field** type.
9. Name the new data source **FilteredVendor**, and configure it so that it contains the expression `WHERE(Vendor, Vendor.AccountNum="US-101")`.
10. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page.



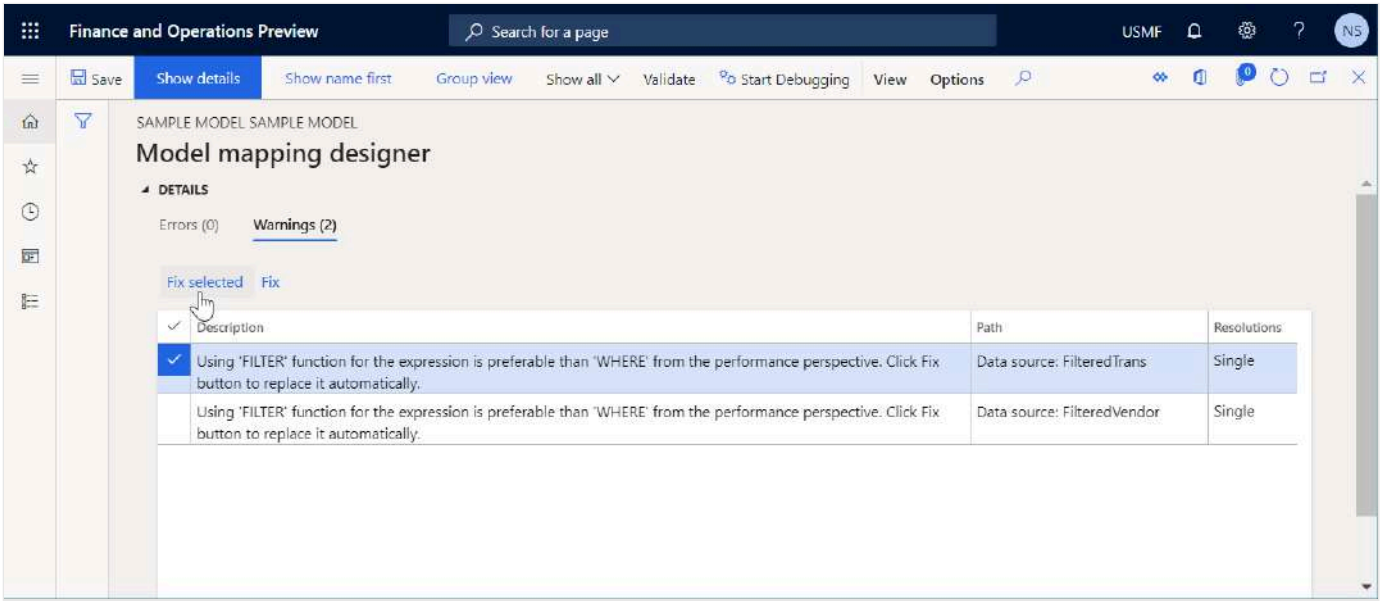
11. Notice that validation warnings recommend that you use the **FILTER** function instead of the **WHERE** function for the **FilteredVendor** and **FilteredTrans** data sources.



Automatic resolution

Select **Fix** to automatically replace the **WHERE** function with the **FILTER** function in the expression of all data sources that appear in the grid on the **Warnings** tab for this type of inspection.

Alternatively, select the row for a single warning in the grid and then select **Fix selected**. In this case, the expression is automatically changed only in the data source that the selected warning mentions.



Manual resolution

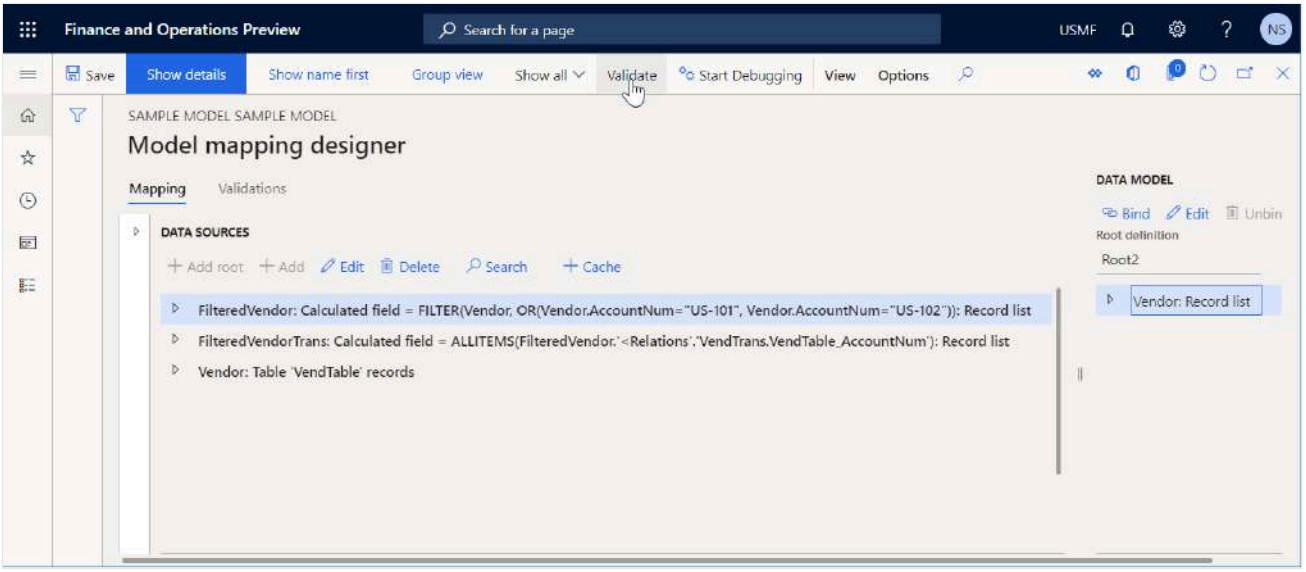
Manually adjust the expressions of all the data sources in the validation grid by replacing the **WHERE** function with the **FILTER** function.

Preferability of ALLITEMSQUERY vs ALLITEMS function

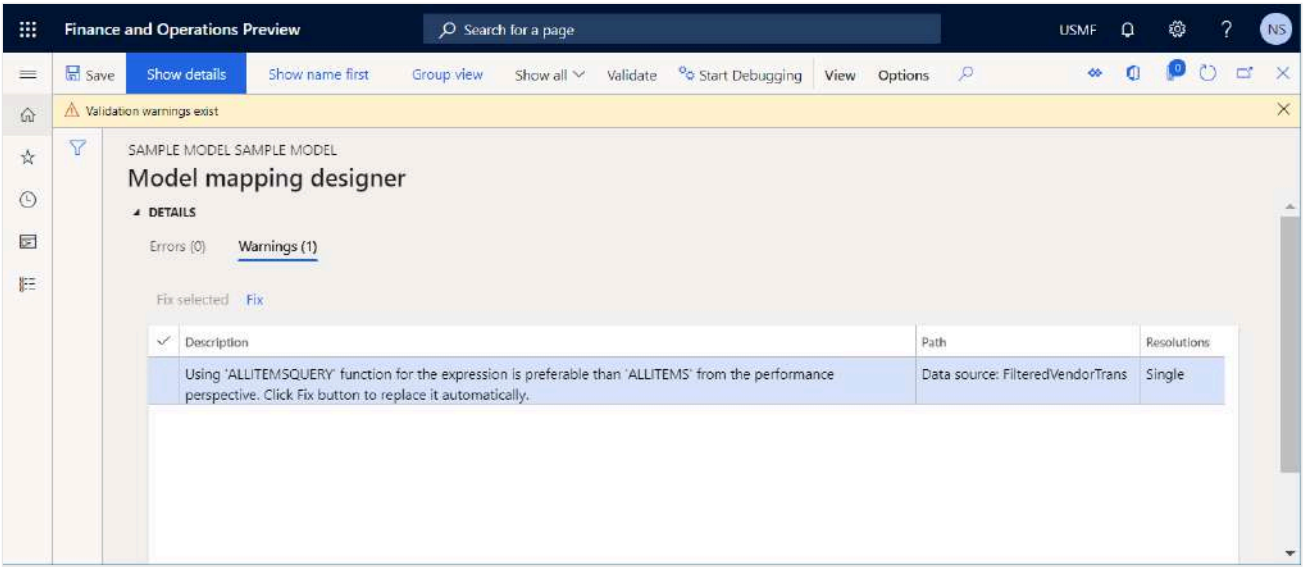
The built-in ALLITEMS and ALLITEMSQUERY ER functions return a flattened **Record list** value that consists of a list of records that represent all items that match the specified path. ER checks whether it can establish a direct SQL call to a data source that the **ALLITEMS** function refers to. If ER can establish a direct call, a validation warning occurs in the ER model mapping designer. The message that you receive recommends that you use the **ALLITEMSQUERY** function instead of the **ALLITEMS** function to help improve efficiency.

The following steps show how this issue might occur.

1. Start to configure the ER model mapping component.
2. Add a data source of the **Dynamics 365 for Operations \ Table records** type.
3. Name the new data source **Vendor**. In the **Table** field, select **VendTable** to specify that this data source requests the VendTable table.
4. Add a data source of the **Calculated field** type to get records for several vendors.
5. Name the new data source **FilteredVendor**, and configure it so that it contains the expression `FILTER(Vendor, OR(Vendor.AccountNum="US-101",Vendor.AccountNum="US-102"))`.
6. Add a data source of the **Calculated field** type to get the transactions of all filtered vendors.
7. Name the new data source **FilteredVendorTrans**, and configure it so that it contains the expression `ALLITEMS(FilteredVendor.'<Relations'.'VendTrans.VendTable_AccountNum')`.
8. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page.



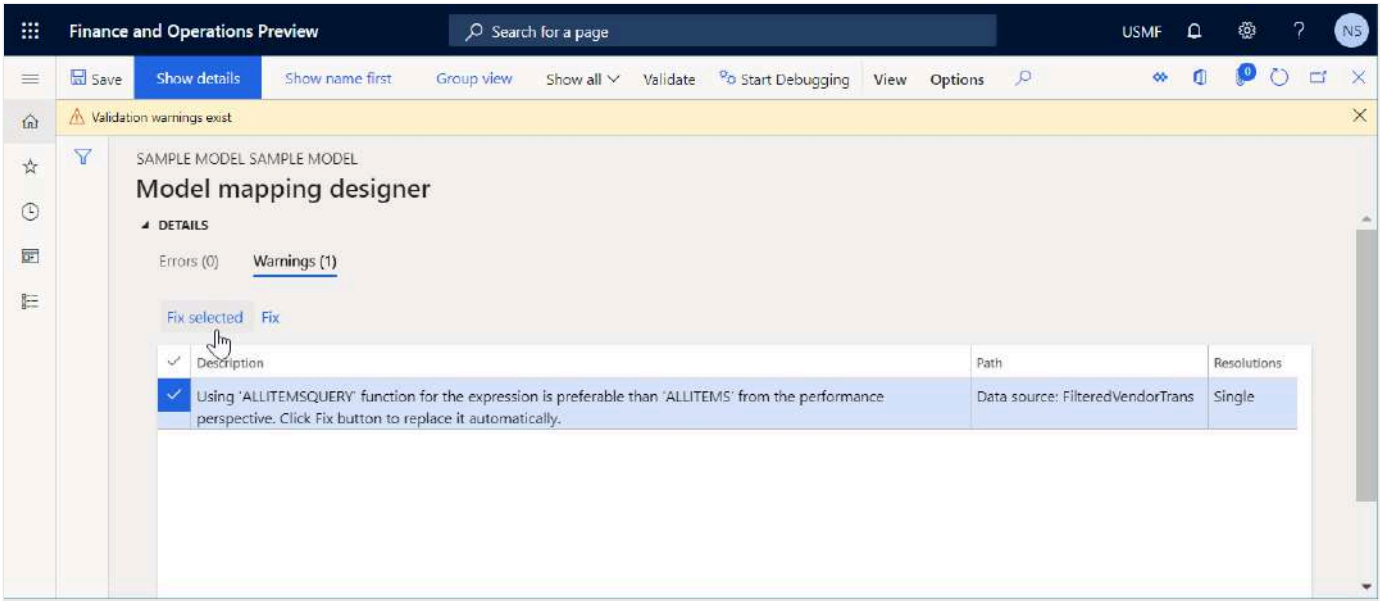
9. Notice that a validation warning occurs. The message recommends that you use the **ALLITEMSQUERY** function instead of the **ALLITEMS** function for the **FilteredVendorTrans** data source.



Automatic resolution

Select **Fix** to automatically replace the **ALLITEMS** function with the **ALLITEMSQUERY** function in the expression of all data sources that appear in the grid on the **Warnings** tab for this type of inspection.

Alternatively, select the row for a single warning in the grid and then select **Fix selected**. In this case, the expression is automatically changed only in the data source that the selected warning mentions.



Manual resolution

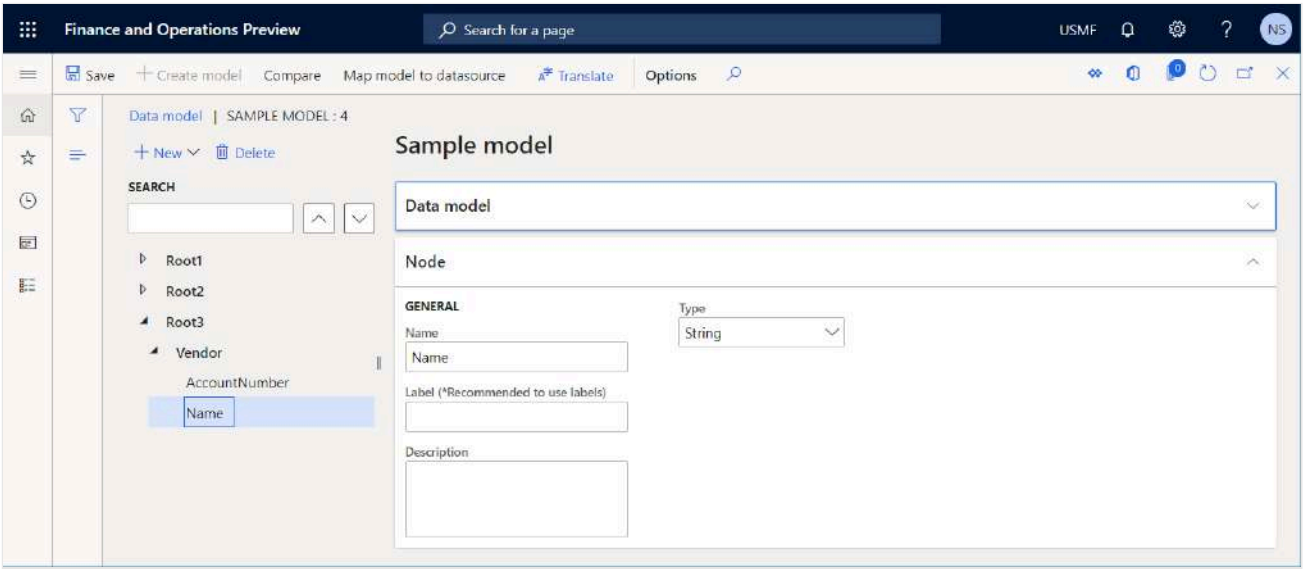
To resolve the issue, manually adjust the expressions for all data sources mentioned in the validation grid. Replace the **ALLITEMS** function with the **ALLITEMSQUERY** function.

Consider empty list cases

You can configure your ER format or model mapping component to get the field value of a data source of the **Record list** type. ER checks whether your design considers the case where a data source that you call contains no records (that is, it's empty). This check prevents runtime errors when a value is fetched from a field of a nonexistent record.

The following steps show how this issue might occur.

1. Start to configure the ER data model, the ER model mapping, and the ER format components simultaneously.
2. In the data model tree, add a root item that you name **Root3**.
3. Modify the **Root3** item by adding a nested item of the **Record list** type.
4. Name the new nested item **Vendor**.
5. Modify the **Vendor** item in the following way:
    - Add a nested field of the **String** type, and name it **Name**.
    - Add a nested field of the **String** type, and name it **AccountNumber**.



6. In the model mapping designer, in the **Data sources** pane, add a data source of the **Dynamics 365 for Operations \ Table records** type.

7. Name the new data source **Vendor**. In the **Table** field, select **VendTable** to specify that this data source requests the VendTable table.

8. Add a data source of the **General \ User input parameter** type to search for a vendor account in the runtime dialog box.

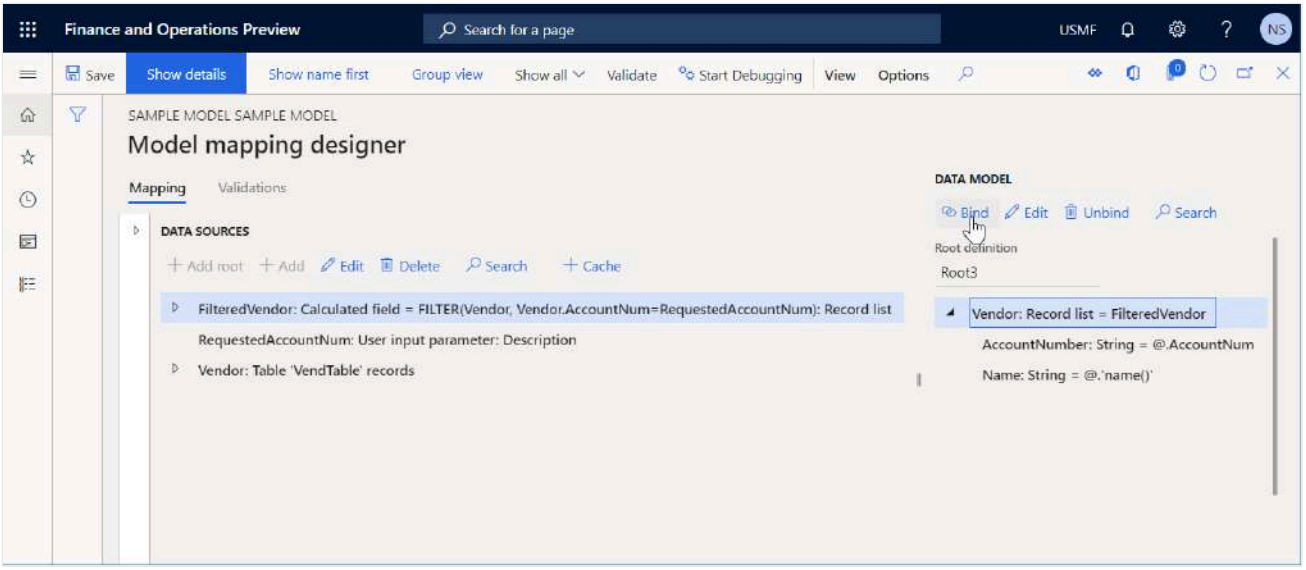
9. Name the new data source **RequestedAccountNum**. In the **Label** field, enter **Vendor account number**. In the **Operations data type name** field, keep the default value, **Description**.

10. Add a data source of the **Calculated field** type to filter a vendor that the user inquires about.

11. Name the new data source **FilteredVendor**, and configure it so that it contains the expression `FILTER(Vendor, Vendor.AccountNum=RequestedAccountNum)`.

12. Bind the data model items to configured data sources in the following way:

    - Bind **FilteredVendor** to **Vendor**.
    - Bind **FilteredVendor.AccountNum** to **Vendor.AccountNumber**.
    - Bind **FilteredVendor.'name()'** to **Vendor.Name**.



13. In the format structure tree, add the following items to generate an outbound document in XML format that contains the vendor details:

    a. Add the **Statement** root XML element.

    b. For the **Statement** XML element, add the nested **Party** XML element.

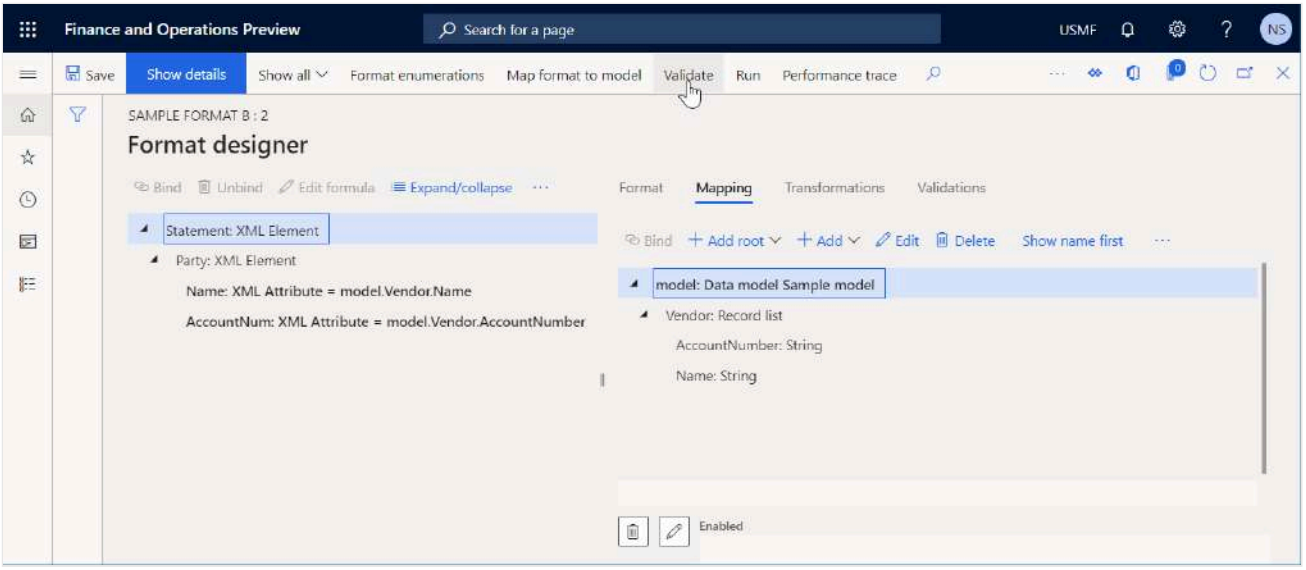
    c. For the **Party** XML element, add the following nested XML attributes:

- Name
- AccountNum

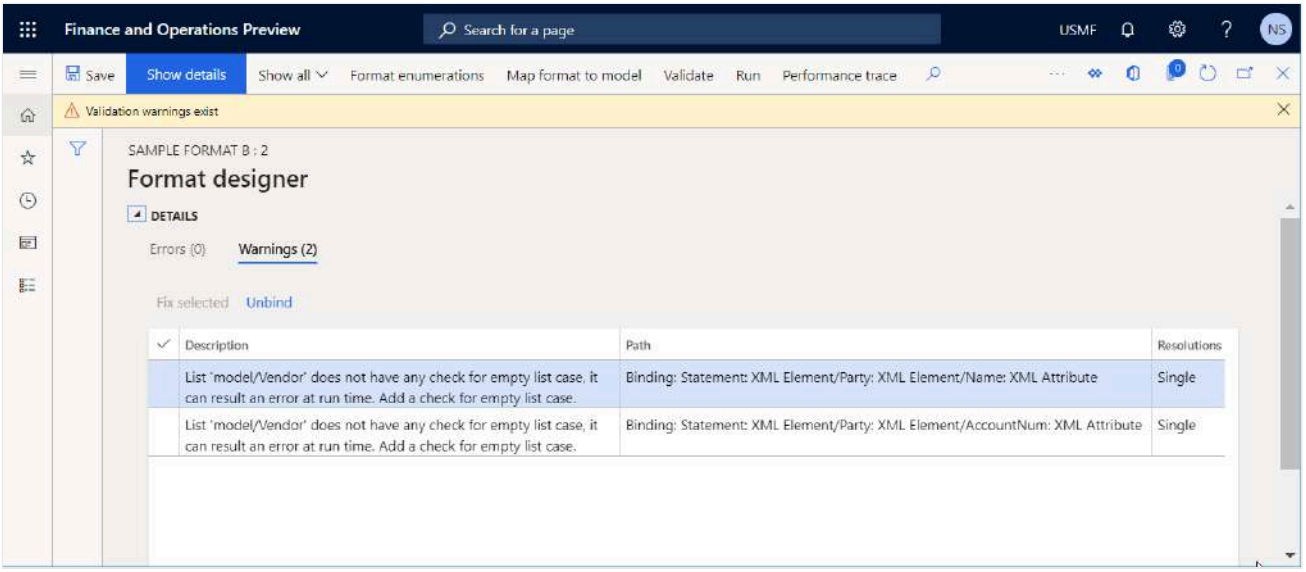
14. Bind format elements to provided data sources in the following way:

    - Bind the **Statement\Party\Name** format element to the **model.Vendor.Name** data source field.
    - Bind the **Statement\Party\AccountNum** format element to the **model.Vendor.AccountNumber** data source field.

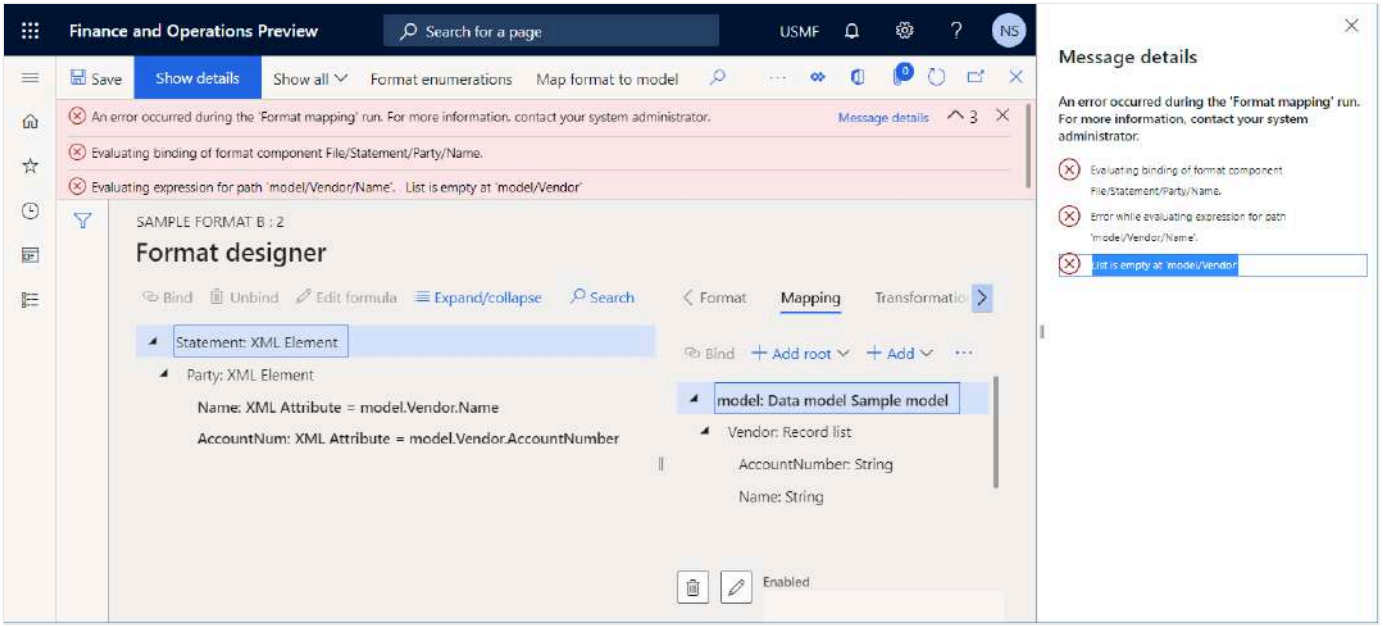
15. Select **Validate** to inspect the editable format component on the **Format designer** page.



16. Notice that a validation error occurs. The message states that an error might be thrown for the configured **Statement\Party\Name** and **Statement\Party\AccountNum** format components at runtime if the `model.Vendor` list is empty.



The following illustration shows the runtime error that occurs if you ignore the warning, select **Run** to run the format, and select the account number of a nonexistent vendor. Because the requested vendor doesn't exist, the `model.Vendor` list is empty (that is, it contains no records).



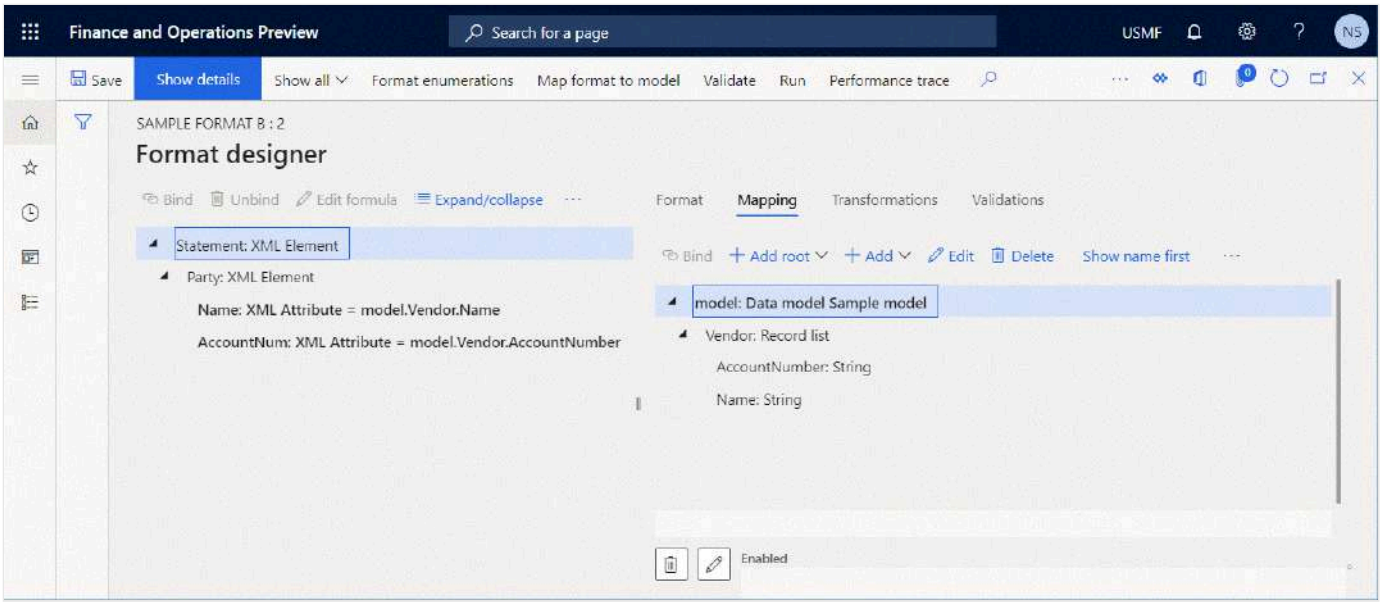
Automatic resolution

For the selected row in the grid on the **Warnings** tab, select **Unbind**. This action automatically removes the binding from the format elements that the **Path** column points to.

Manual resolution

Option 1

Bind the **Statement\Party\Name** format element to the `model.Vendor` data source item. At runtime, this binding calls the `model.Vendor` data source first. When `model.Vendor` returns an empty record list, the nested format elements don't run. Therefore, no validation warnings occur for this format configuration.

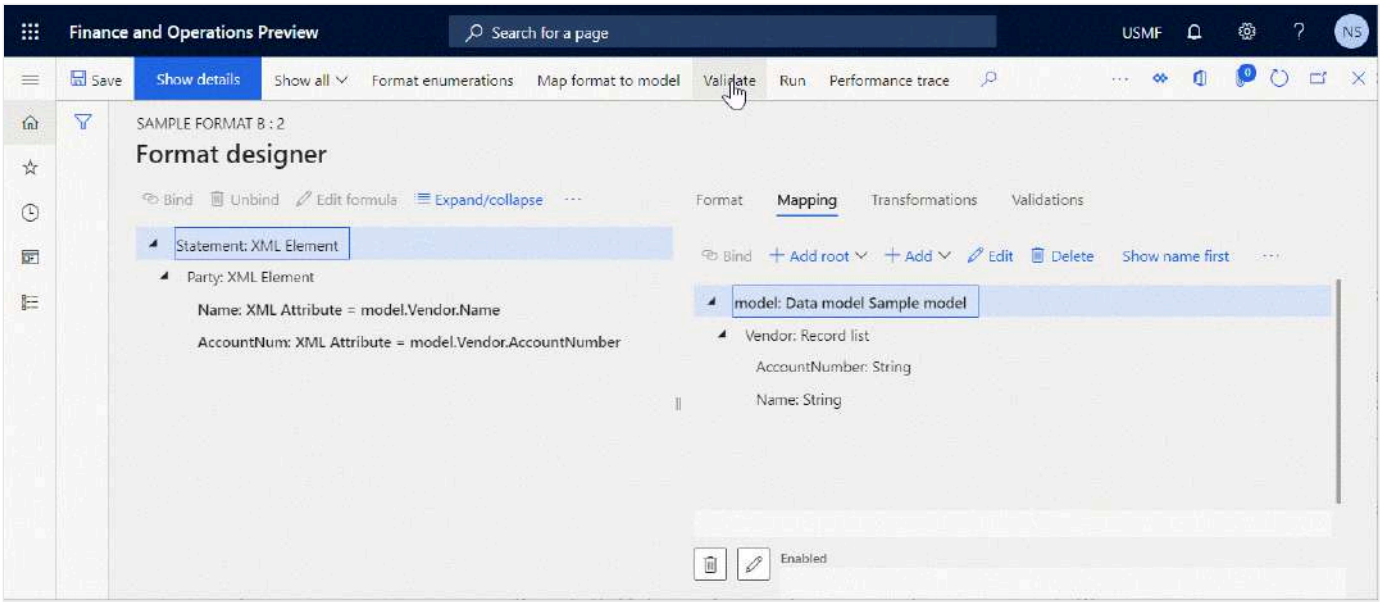


Option 2

Change the binding of the **Statement\Party\Name** format element from `model.Vendor.Name` to `FIRSTORNULL(model.Vendor).Name`. The updated binding conditionally converts the first record of the `model.Vendor` data source of the **Record list** type to a new data source of the **Record** type. This new data source contains the same set of fields.

- If at least one record is available in the `model.Vendor` data source, the fields of that record are filled with the values of the fields of the first record of the `model.Vendor` data source. In this case, the updated binding returns the vendor name.
- Otherwise, every field of the record that is created is filled with the default value for the data type of that field. In this case, the blank string is returned as the default value of the **String** data type.

Therefore, no validation warnings occur for the **Statement\Party\Name** format element when it's bound to the `FIRSTORNULL(model.Vendor).Name` expression.



Option 3

If you want to explicitly specify the data that's entered in a generated document when the `model.Vendor` data source of the **Record list** type returns no records (the text **Not available** in this example), change the binding of the **Statement\Party\Name** format element from `model.Vendor.Name` to `IF(NOT(ISEMPTY(model.Vendor)), model.Vendor.Name, "Not available")`. You can also use the expression `IF(COUNT(model.Vendor)=0, model.Vendor.Name, "Not available")`.

Additional consideration

The inspection also warns you about another potential problem. By default, when you bind the **Statement\Party\Name** and **Statement\Party\AccountNum** format elements to the appropriate fields of the `model.Vendor` data source of the **Record list** type, you run those bindings and take the values from the appropriate fields of the first record of the `model.Vendor` data source, if that list isn't empty.

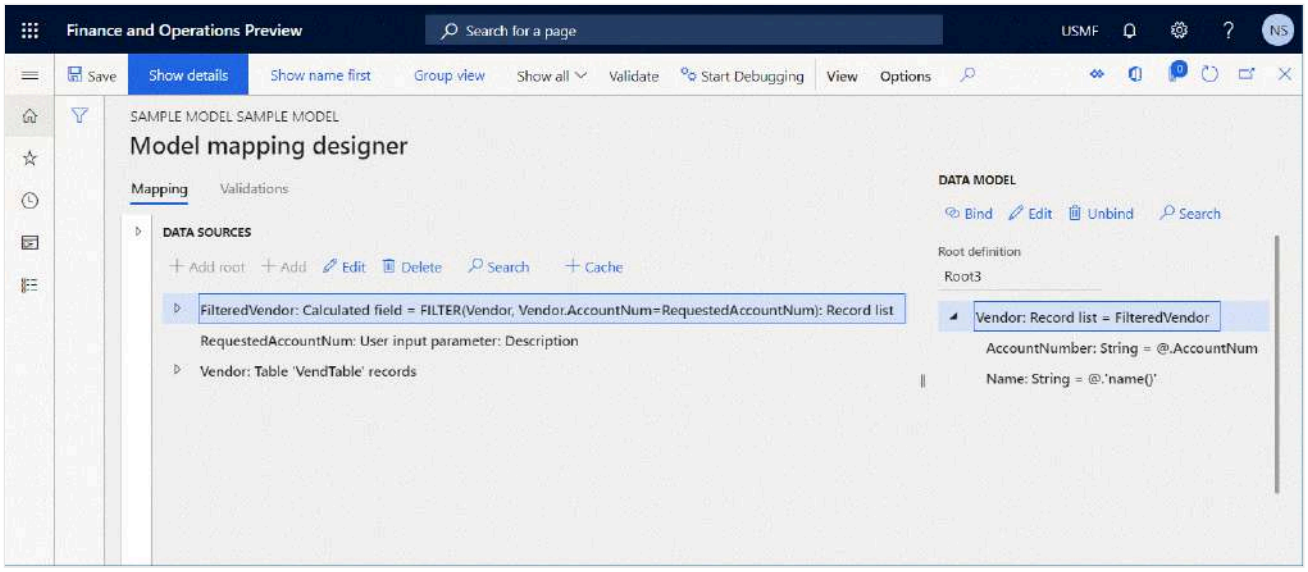
If you don't bind the **Statement\Party** format element with the `model.Vendor` data source, the **Statement\Party** element doesn't iterate for every record of the `model.Vendor` data source during format execution. Instead, the generated document fills with information from only the first record of the record list, if that list contains multiple records. To fix this problem, bind the **Statement\Party** element with the `model.Vendor` data source.

Executability of an expression with FILTER function (caching)

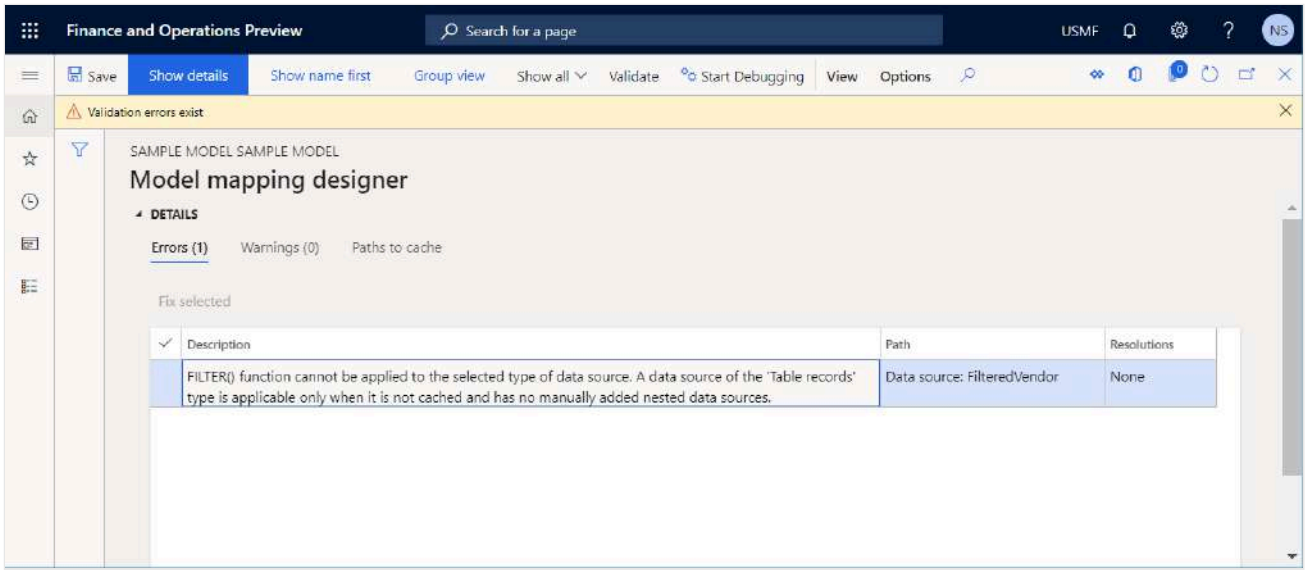
To access application tables, views, or data entities, several built-in ER functions, including FILTER and ALLITEMSQUERY, make a single SQL call to get the required data as a list of records. You use a data source of the **Record list** type as an argument for each of these functions to specify an application source for the call. ER checks whether it can establish a direct SQL call to a data source that you refer to in one of these functions. If ER can't establish a direct call because you marked the data source as cached, the ER model mapping designer shows a validation error. The message states that the ER expression that contains one of these functions can't run at runtime.

The following steps show how this issue might occur.

1. Start to configure the ER model mapping component.
2. Add a data source of the **Dynamics 365 for Operations \ Table records** type.
3. Name the new data source **Vendor**. In the **Table** field, select **VendTable** to specify that this data source requests the VendTable table.
4. Add a data source of the **General \ User input parameter** type to search for a vendor account in the runtime dialog box.
5. Name the new data source **RequestedAccountNum**. In the **Label** field, enter **Vendor account number**. In the **Operations data type name** field, keep the default value, **Description**.
6. Add a data source of the **Calculated field** type to filter a vendor that the user inquires about.
7. Name the new data source **FilteredVendor**, and configure it so that it contains the expression `FILTER(Vendor, Vendor.AccountNum=RequestedAccountNum)`.
8. Mark the configured **Vendor** data source as cached.

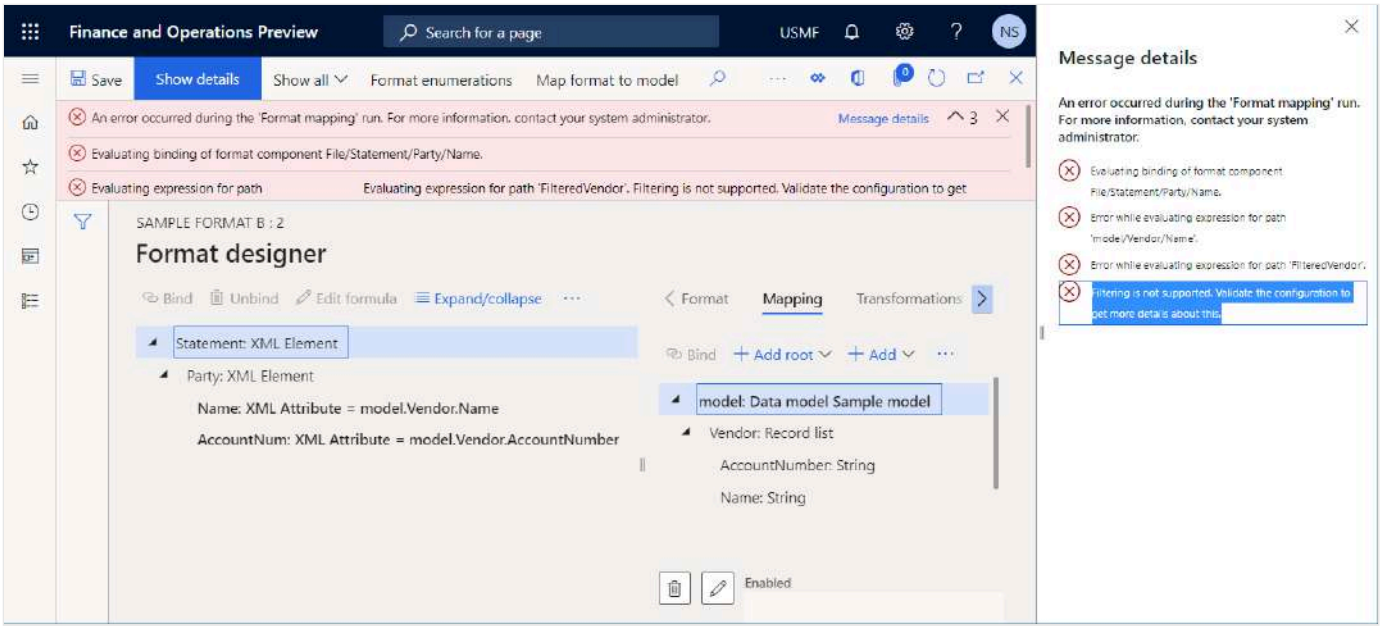


9. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page.



10. Notice that a validation error occurs. The message states that the **FILTER** function can't be applied to the cached **Vendor** data source.

The following illustration shows the runtime error that occurs if you ignore the warning and select **Run** to run the format.



Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Remove the **Cache** flag from the **Vendor** data source. The **FilteredVendor** data source then becomes executable, but the **Vendor** data source that the VendTable table refers to is accessed every time the **FilteredVendor** data source is called.

Option 2

Change the expression of the **FilteredVendor** data source from `FILTER(Vendor, Vendor.AccountNum="US-101")` to `WHERE(Vendor, Vendor.AccountNum="US-101")`. In this case, the **Vendor** data source that the VendTable table refers to is accessed only during the first call of the **Vendor** data source. However, the selection of records is done in memory. Therefore, this approach can cause poor performance.

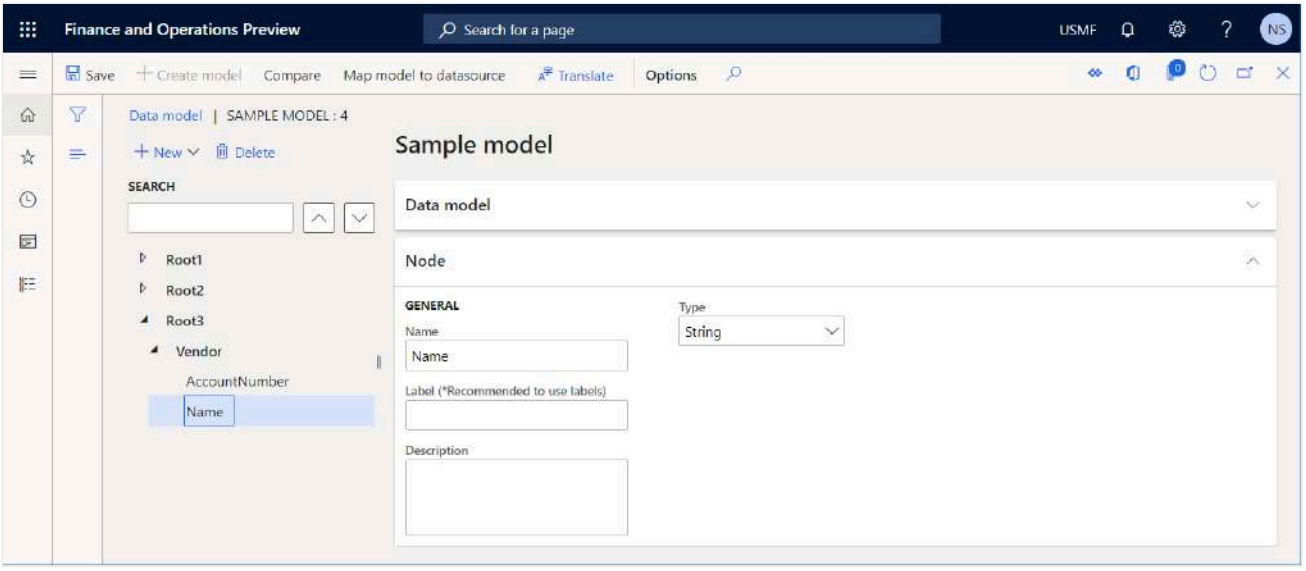
Missing binding

When you configure an ER format component, the base ER data model is the default data source for the ER format. When you run the configured ER format, the default model mapping for the base model fills the data model with application data. The ER format designer shows a warning if you bind a format element to a data model item that isn't bound to any data source in the model mapping currently selected as the default model mapping for the editable format. You can't run

this type of binding at runtime, because the format that runs can't fill a bound element with application data. Therefore, an error occurs at runtime.

The following steps show how this issue might occur.

1. Start to configure the ER data model, the ER model mapping, and the ER format components simultaneously.
2. In the data model tree, add a root item that you name **Root3**.
3. Modify the **Root3** item by adding a new nested item of the **Record list** type.
4. Name the new nested item **Vendor**.
5. Modify the **Vendor** item in the following way:
    - Add a nested field of the **String** type, and name it **Name**.
    - Add a nested field of the **String** type, and name it **AccountNumber**.



6. In the model mapping designer, in the **Data sources** pane, add a data source of the **Dynamics 365 for Operations \ Table records** type.
7. Name the new data source **Vendor**. In the **Table** field, select **VendTable** to specify that this data source requests the VendTable table.
8. Add a data source of the **General \ User input parameter** type to inquire about a vendor account in the runtime dialog box.
9. Name the new data source **RequestedAccountNum**. In the **Label** field, enter **Vendor account number**. In the **Operations data type name** field, keep the default value, **Description**.

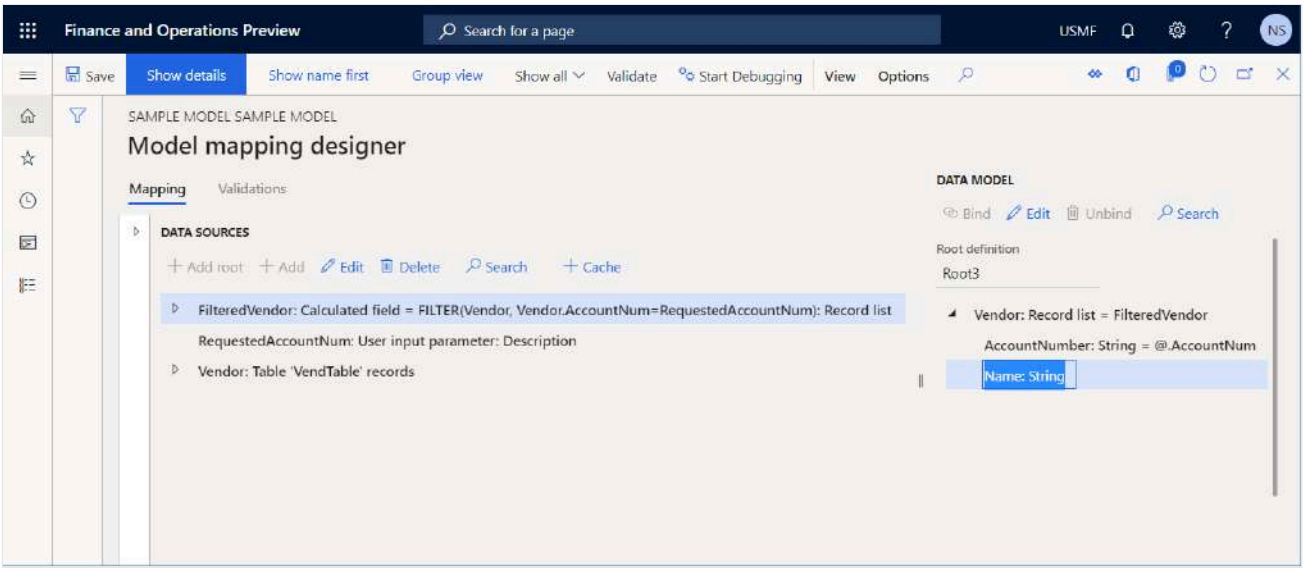
10. Add a data source of the **Calculated field** type to filter a vendor that the user inquires about.

11. Name the new data source **FilteredVendor**, and configure it so that it contains the expression `FILTER(Vendor, Vendor.AccountNum=RequestedAccountNum)`.

12. Bind the data model items to configured data sources in the following way:

    - Bind **FilteredVendor** to **Vendor**.
    - Bind **FilteredVendor.AccountNum** to **Vendor.AccountNumber**.

    > **Note**
    >
    > The **Vendor.Name** data model field remains unbound.



13. In the format structure tree, add the following items to generate an outbound document in XML format that contains the details of the vendors that the user inquires about:

    a. Add the **Statement** root XML element.

    b. For the **Statement** XML element, add the nested **Party** XML element.

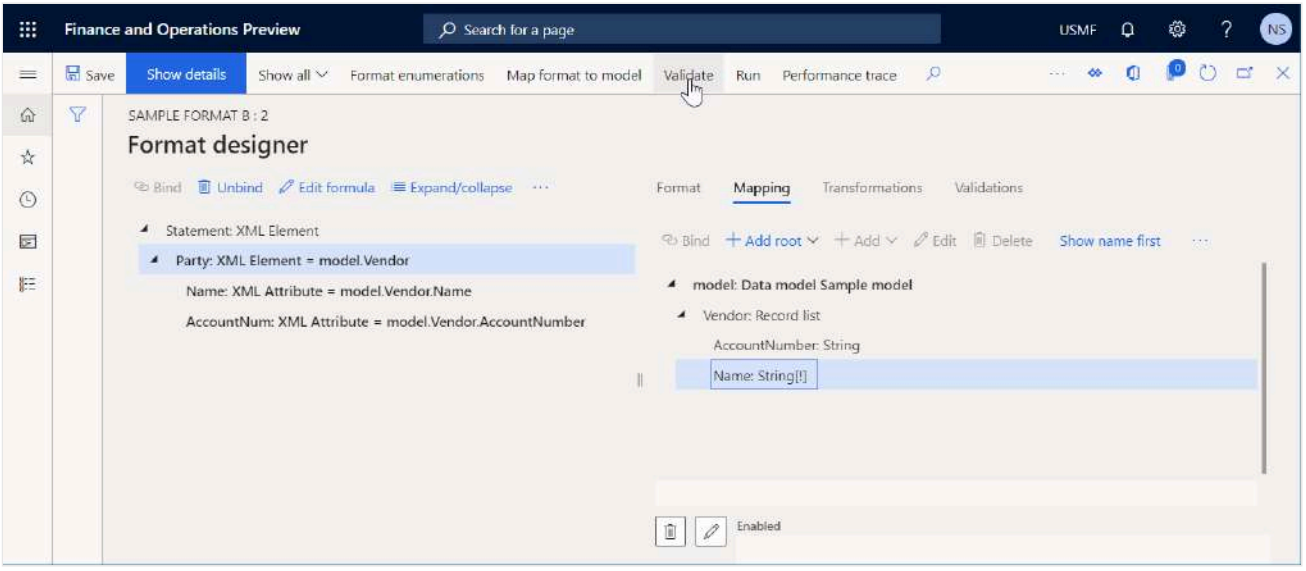
    c. For the **Party** XML element, add the following nested XML attributes:

    - Name
    - AccountNum

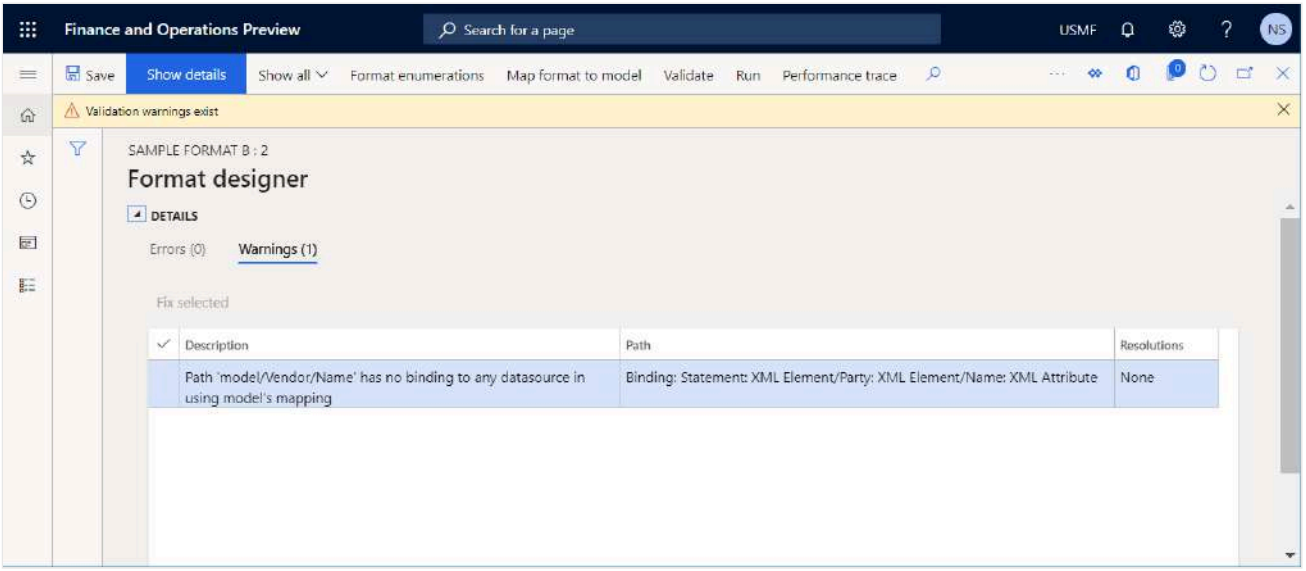
14. Bind the format elements to provided data sources in the following way:

- Bind the **Statement\Party** format element to the `model.Vendor` data source item.
- Bind the **Statement\Party\Name** format element to the **model.Vendor.Name** data source field.
- Bind the **Statement\Party\AccountNum** format element to the **model.Vendor.AccountNumber** data source field.

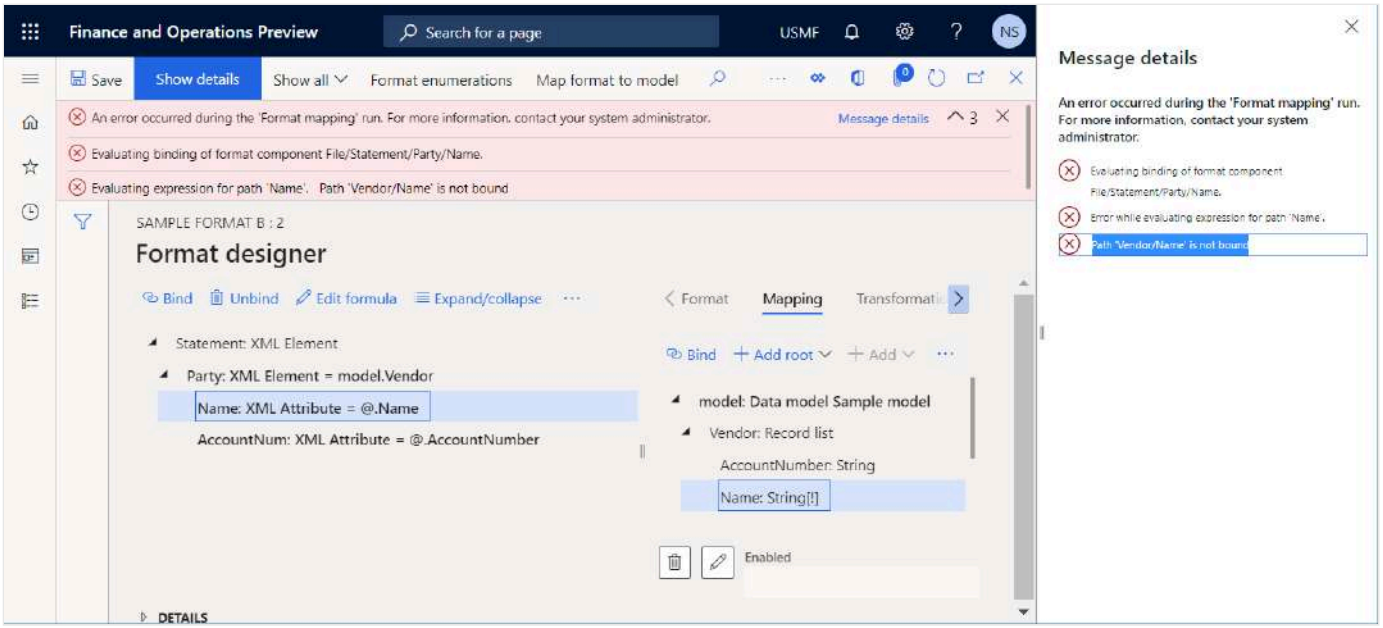
15. Select **Validate** to inspect the editable format component on the **Format designer** page.



16. Notice that a validation warning occurs. The message states that the **model.Vendor.Name** data source field isn't bound to any data source in the model mapping that you configured to be used by the format. Therefore, the **Statement\Party\Name** format element might not be filled at runtime, and a runtime exception might occur.



The following illustration shows the runtime error that occurs if you ignore the warning and select **Run** to run the format.



Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Modify the configured model mapping by adding a binding for the **model.Vendor.Name** data source field.

Option 2

Modify the configured format by removing the binding for the **Statement\Party\Name** format element.

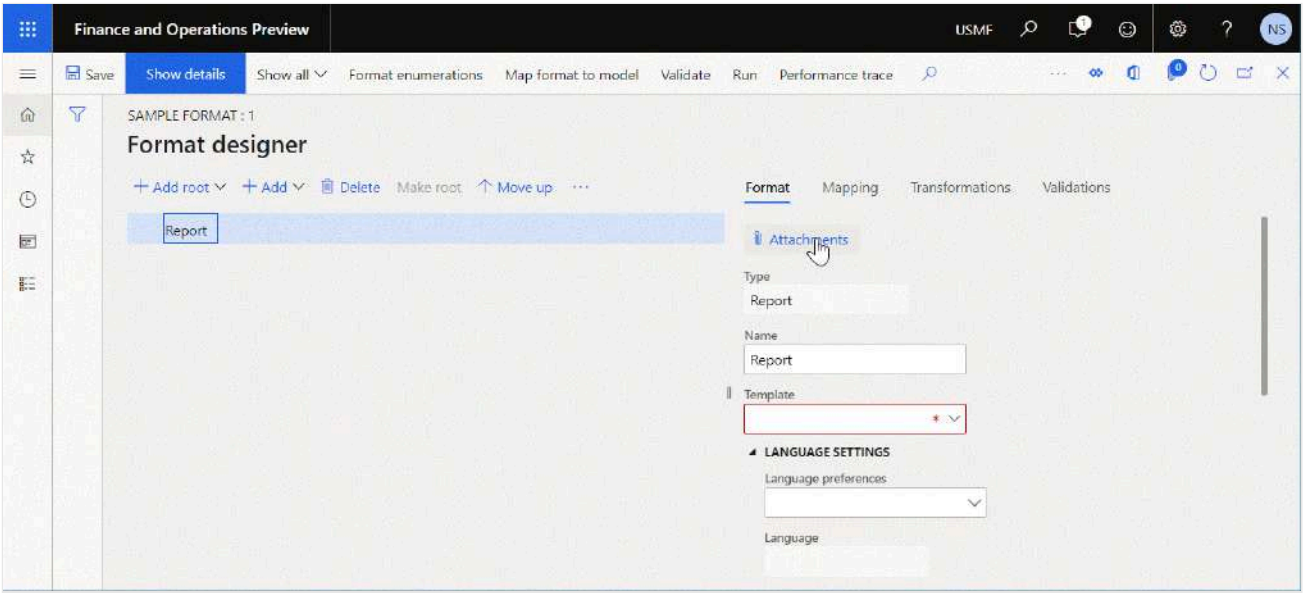
Not linked template

When you manually configure an ER format component to use a template to generate an outbound document, you must manually add the **Excel\File** element, add the required template as an attachment of the editable component, and select that attachment in the added **Excel\File** element. By using this process, you indicate that the added element fills the selected template at runtime. When you configure a format component version in **Draft** status, you can add several templates to the editable component and then select each template in the **Excel\File** element to run the ER format. By using this process, you can see how different templates are filled at runtime. If you have templates that aren't selected in any **Excel\File** elements, the ER format

designer warns you that those templates are deleted from the editable ER format component version when its status changes from **Draft** to **Completed**.

The following steps show how this issue might occur.

1. Start to configure the ER format component.
2. In the format structure tree, add the **Excel\File** element.
3. For the **Excel\File** element that you just added, add an Excel workbook file, **A.xlsx**, as an attachment. Use the document type that is configured in the ER parameters to specify the storage of ER format templates.
4. For the **Excel\File** element, add another Excel workbook file, **B.xlsx**, as an attachment. Use the same document type that you used for workbook file A.
5. In the **Excel\File** element, select workbook file A.
6. Select **Validate** to inspect the editable format component on the **Format designer** page.



7. Notice that a validation warning occurs. The message states that workbook file B.xlsx isn't linked to any components, and that it's removed after the status of the configuration version changes.

Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Modify the configured format by removing all templates that aren't linked to any **Excel\File** element.

Not synced format

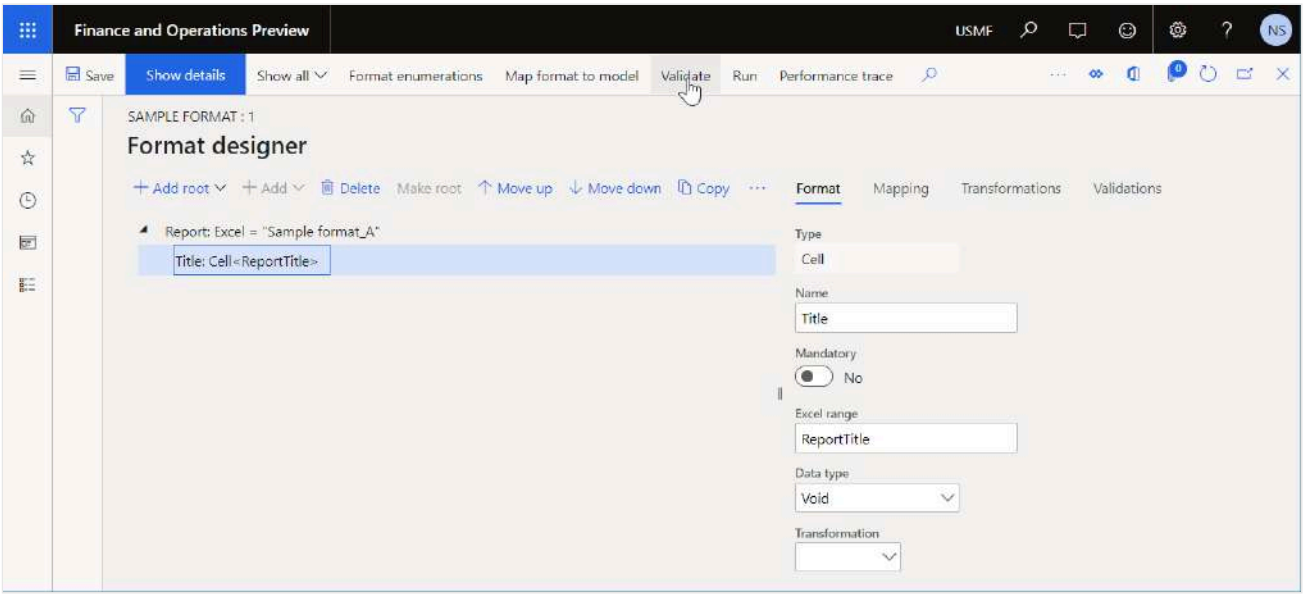
When you configure an ER format component to use an Excel template to generate an outbound document, you can manually add the **Excel\File** element, add the required template as an attachment of the editable component, and select that attachment in the added **Excel\File** element. In this way, you indicate that the added element fills the selected template at runtime. Because you designed the added Excel template externally, the editable ER format might contain Excel names that are missing from the added template. The ER format designer warns you about any inconsistencies between the properties of the ER format elements and the names that aren't included in the added Excel template.

The following steps show how this issue might occur.

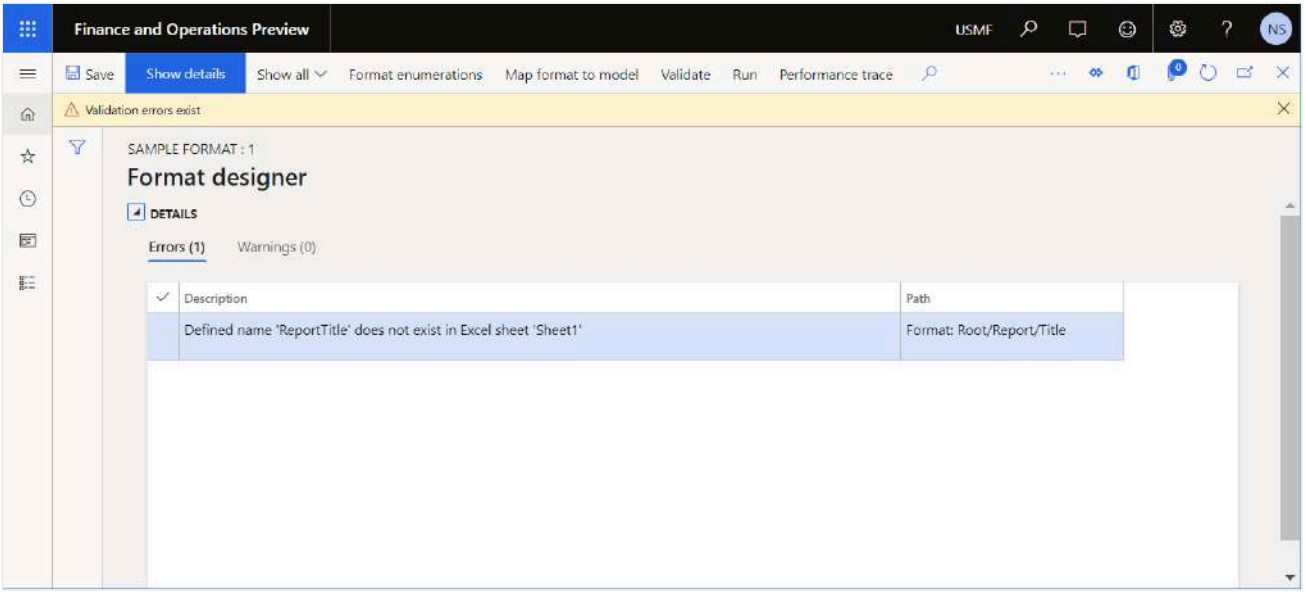
1. Start to configure the ER format component.
2. In the format structure tree, add the **Excel\File** element **Report**.
3. For the **Excel\File** element that you just added, add an Excel workbook file, **A.xlsx**, as an attachment. Use the document type that is configured in the ER parameters to specify the storage of ER format templates.

   > ⓘ **Important**
   >
   > Make sure that the added Excel workbook doesn't contain the name **ReportTitle**.

4. Add the **Excel\Cell** element **Title** as a nested element of the **Report** element. In the **Excel range** field, enter **ReportTitle**.
5. Select **Validate** to inspect the editable format component on the **Format designer** page.



6. Notice that a validation warning occurs. The message states that the name **ReportTitle** doesn't exist on sheet **Sheet1** of the Excel template that you're using.



Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Modify the configured format by removing all elements that refer to Excel names that are missing from the template.

Option 2

Update the editable ER format by importing an Excel template. The structure of the editable ER format is synced with the structure of the imported Excel template.

Additional consideration

To learn how the format structure can be synced with an ER template in the template editor of Business document management, see Update the structure of a business document template.

Not synced with a Word template format

When you configure an ER format component to use a Word template to generate an outbound document, you can manually add the **Excel\File** element, add the required Word template as an attachment of the editable component, and select that attachment in the added **Excel\File** element.

> **Note**
>
> When the Word document is attached, the ER format designer presents the editable element as **Word\File**.

In this way, you indicate that the added element fills the selected template at runtime. Because you externally design the added Word template, the editable ER format might contain references to Word content controls that are missing from the added template. The ER format designer warns you about any inconsistencies between the properties of the ER format elements and the content controls that aren't included in the added Word template.

For an example that shows how this issue might occur, see Configure the editable format to suppress the summary section.

Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Modify the configured format by deleting the **Removed** formula from the format element that the validation warning mentions.

Option 2

Modify the Word template by adding the required tag to the relevant Word content control.

No default mapping

When the Missing binding inspection runs, it evaluates the inspected format bindings against the bindings of the relevant model mapping component. You can import several ER model mapping configurations to your Finance instance, and each configuration might contain the applicable model mapping component. You must select one configuration as the default configuration. Otherwise, an exception occurs when you try to run, edit, or validate the inspected ER format. You receive the following message: "More than one model mapping exists for the <model name (root descriptor)> data model in the configurations <configuration names separated by comma>. Set one of the configurations as default."

For an example that shows how this issue might occur and how it can be fixed, see Manage several derived mappings for a single model root.

Inconsistent setting of Header or Footer components

When you configure an ER format component to use an Excel template to generate an outbound document, you can add the **Excel\Header** component to fill in headers at the top of a worksheet in an Excel workbook. You can also add the **Excel\Footer** component to fill in footers at the bottom of a worksheet. For every **Excel\Header** or **Excel\Footer** component that you add, you must set the **Header/footer appearance** property to specify the pages that the component runs for. Because you can configure several **Excel\Header** or **Excel\Footer** components for a single **Sheet** component, and you can generate different headers or footers for different type of pages in an Excel worksheet, you must configure a single **Excel\Header** or **Excel\Footer** component for a specific value of the **Header/footer appearance** property. If you configure more than one **Excel\Header** or **Excel\Footer** component for a specific value of the **Header/footer appearance** property, a validation error occurs, and you receive the following error message: "Headers/footers (<component type: Header or Footer>) are inconsistent."

Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Modify the configured format by deleting one of the inconsistent **Excel\Header** or **Excel\Footer** components.

Option 2

Modify the value of the **Header/footer appearance** property for one of the inconsistent **Excel\Header** or **Excel\Footer** components.

Inconsistent setting of Page component

When you configure an ER format component to use an Excel template to generate an outbound document, you can add the **Excel\Page** component to paginate a generated document by using ER formulas. For every **Excel\Page** component that you add, you can add many nested Range components and still remain compliant with the following structure:

- The first nested **Range** component can have the **Replication direction** property set to **No replication**. Use this range to make page headers in generated documents.
- You can add many other nested **Range** components where the **Replication direction** property is set to **Vertical**. Use these ranges to fill in generated documents.
- The last nested **Range** component can have the **Replication direction** property set to **No replication**. Use this range to make page footers in generated documents and to add the required page breaks.

If you don't follow this structure for an ER format in the ER format designer at design time, a validation error occurs, and you receive the following error message: "There are more than two range components without replication. Remove unnecessary components."

Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Modify the configured format by changing the **Replication direction** property for all inconsistent **Excel\Range** components.

Executability of an expression with ORDERBY function

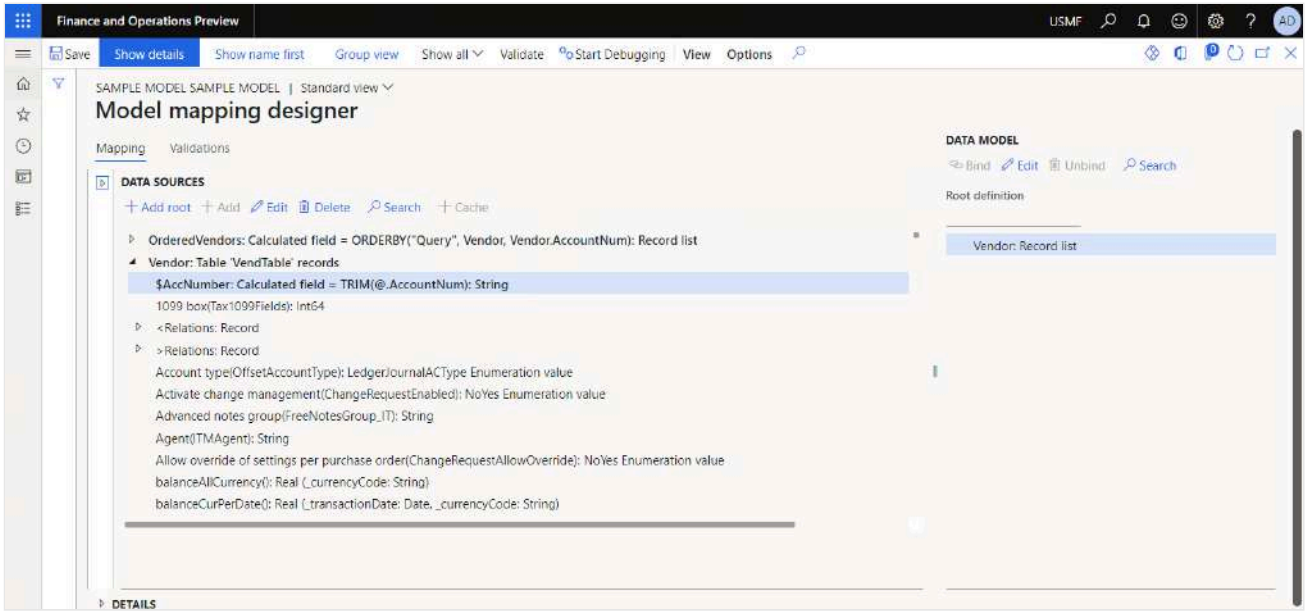
Use the built-in ORDERBY ER function to sort the records of an ER data source of the **Record list** type. You specify the data source as an argument of the function.

Specify arguments of the `ORDERBY` function to sort records of application tables, views, or data entities. By using this function, you make a single database call to get the sorted data as a list of records. Use a data source of the **Record list** type as an argument of the function to specify the application source for the call.

ER checks whether it can establish a direct database query to a data source that you refer to in the `ORDERBY` function. If ER can't establish a direct query, a validation error occurs in the ER model mapping designer. The message that you receive states that the ER expression that includes the `ORDERBY` function can't be run at runtime.

The following steps show how this issue might occur.

1. Start to configure the ER model mapping component.
2. Add a data source of the **Dynamics 365 for Operations \ Table records** type.
3. Name the new data source **Vendor**. In the **Table** field, select **VendTable** to specify that this data source requests the **VendTable** table.
4. Add a data source of the **Calculated field** type.
5. Name the new data source **OrderedVendors**, and configure it so that it contains the expression `ORDERBY("Query", Vendor, Vendor.AccountNum)`.

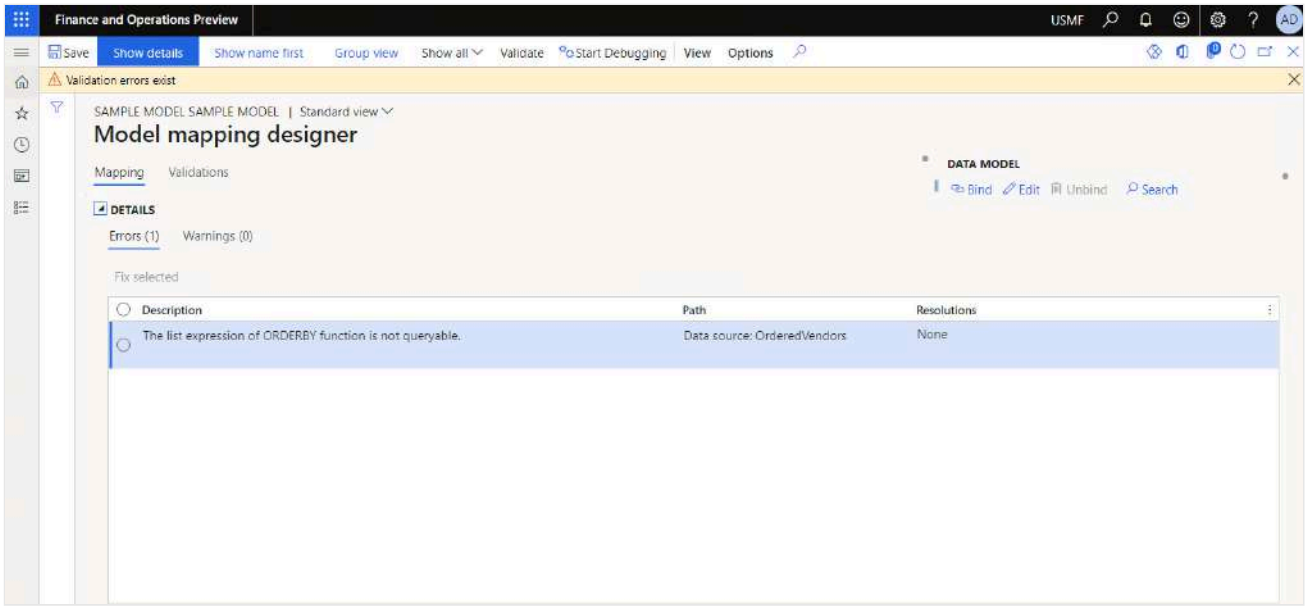


6. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page and verify that the expression in the **OrderedVendors** data source can be queried.

7. Modify the **Vendor** data source by adding a nested field of the **Calculated field** type to get the trimmed vendor account number.

8. Name the new nested field **$AccNumber**, and configure it so that it contains the expression `TRIM(Vendor.AccountNum)`.

9. Select **Validate** to inspect the editable model mapping component on the **Model mapping designer** page and verify that the expression in the **Vendor** data source can be queried.



10. Notice that a validation error occurs, because the **Vendor** data source contains a nested field of the **Calculated field** type. This nested field doesn't allow the expression of the **OrderedVendors** data source to be translated to the direct database statement. The same error occurs at runtime if you ignore the validation error and select **Run** to run this model mapping.

Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Option 1

Instead of adding a nested field of the **Calculated field** type to the **Vendor** data source, add the **$AccNumber** nested field to the **FilteredVendors** data source, and configure the field so that it contains the expression `TRIM(FilteredVendor.AccountNum)`. By using this approach, you can run the `ORDERBY("Query", Vendor, Vendor.AccountNum)` expression at the database level, and you can calculate the **$AccNumber** nested field after.

Option 2

Change the expression of the **FilteredVendors** data source from `ORDERBY("Query", Vendor, Vendor.AccountNum)` to `ORDERBY("InMemory", Vendor, Vendor.AccountNum)`. Don't change the expression for a table that has a large volume of data (transactional table), because this change fetches all records and orders the required records in memory. Therefore, this approach can cause poor performance.

Obsolete application artifact

When you design an ER model mapping component or an ER format component, you can configure an ER expression to call an application artifact in ER, such as a database table, a method of a class, and more. In Finance version 10.0.30 and later, you can configure ER to warn you when the referred application artifact is marked in source code as obsolete. This warning is useful because usually, obsolete artifacts are eventually removed from source code. Being informed about an artifact's status can stop you from using the obsolete artifact in the editable ER component before its removal from the source code. This action helps prevent errors of calling non-existing application artifacts from an ER component at runtime.

To start evaluating the obsolete attribute of application artifacts during the inspection of an editable ER component, enable the **Validate obsolete elements of Electronic Reporting data sources** feature in the **Feature management** workspace. The obsolete attribute is currently evaluated for the following types of application artifacts:

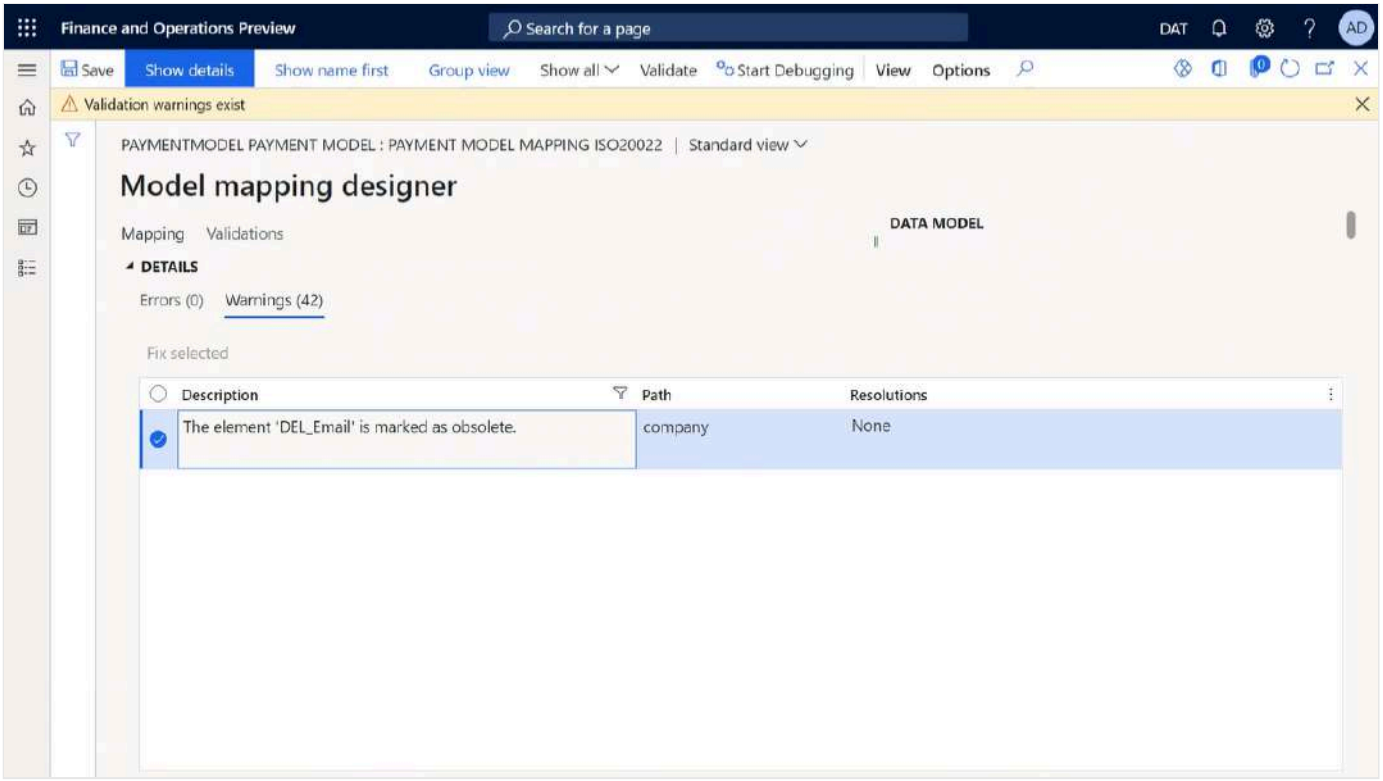
- Database table
  - Field of a table
  - Method of a table
- Application class
  - Method of a class

> ⓘ **Note**

A warning occurs during the inspection of the editable ER component for a data source that refers to an obsolete artifact only when this data source is used in at least one binding of this ER component.

> **Tip**
>
> When the SysObsoleteAttribute class is used to notify the compiler to issue warning messages instead of errors, the inspection warning presents the specified in source code warning at design time in the **Details** FastTab on the **Model mapping designer** or **Format designer** page.

The following illustration shows the validation warning that occurs when the obsolete `DEL_Email` field of the `CompanyInfo` application table is bound to a data model field by using the configured `company` data source.



Automatic resolution

No option to automatically fix this issue is available.

Manual resolution

Modify the configured model mapping or format by removing all bindings to a data source that refers to an obsolete application artifact.

Review Electronic reporting (ER) validation history

This article describes how to review the validation history for Electronic reporting (ER) configurations. Validation history lets you return to previous validation runs to confirm which configuration versions were validated, when they were validated, and what errors or warnings were reported.

Overview

When you validate ER configurations, the system retains the results in a persistent validation history. Instead of re-running validation to confirm a configuration's state, you can open the history at any time and review the outcome of earlier runs.

The history is organized by configuration and by version, so you can review the individual errors and warnings that were reported for that run. Because the history is persistent and shared, you and other users in the environment see the same results.

Validation history is part of the enhanced validation management feature that's introduced in version 10.0.49. For information about turning on the feature and running validation, see Validate ER format and model mapping to prevent runtime issues.

Prerequisites

- Turn on the **Enhanced validation management for Electronic Reporting configurations** feature in **Feature management**.
- Complete at least one validation run so that there are results to review.

Open the validation history

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the Action Pane, select **Validation** > **Validation history**.

The **Validation history** opens and lists the validation runs that are completed in the current environment.

Review validation runs

The **History** tab shows every validation run that completed in the current environment. Each row provides the following information.

Expand table

Column	Description
Completed	The date and time when the validation run finished.
Created by	The user who started the validation run.
Mode	How the run was performed - **Interactive** or **Batch**.
Batch job	The ID of the batch job, when the run was performed in batch mode.
Configurations checked	The number of configurations that the run validated.
Passed	The number of configurations that passed validation.
Warnings	The number of configurations that reported warnings.
Failed	The number of configurations that failed validation.

To review a run, select its row in the **History** grid. The configurations that the run checked appear in the lower **Configurations** grid.

Review the configurations that were checked

When you select a run on the **History** tab, the **Configurations** grid lists the configurations that the run validated. Each row provides the following information.

Expand table

Column	Description
Configuration	The name of the validated ER configuration.
Version	The configuration version that the run validated.
Status	The status of the version, such as **Draft** or **Completed**.
Configuration type	The component type - for example, **Format**, **Model mapping**, or **Data model**.
Result	The validation result for the version, such as **Valid**.
Messages	The number of validation messages that the run reported for the version.

Show message details

To review the individual errors and warnings that a validation run reported, select **Show message details**. You can use this action in both the **History** grid and the **Configurations** grid. You can review messages for an entire run or for a single configuration version.

Delete validation runs

To remove a validation run from the history, select the run in the **History** grid, and then select **Delete**.

Because the system tracks validation for each configuration version, both users and system processes can identify which versions are already validated in the current environment. This information helps you avoid redundant validation runs and focus on the versions that still need attention.

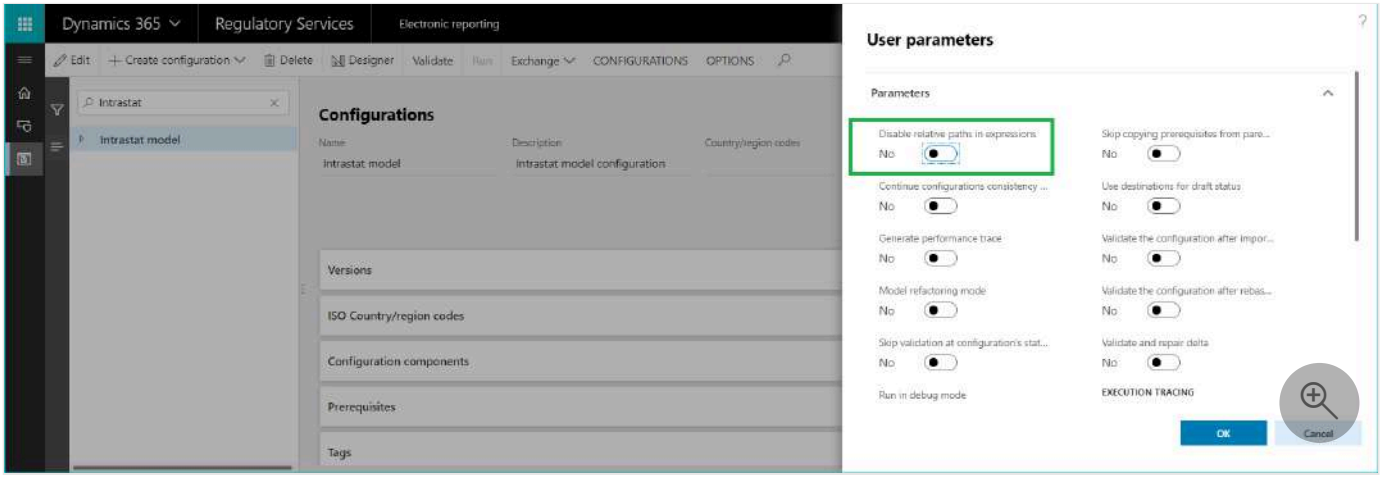
Use a relative path in data bindings of ER models and formats

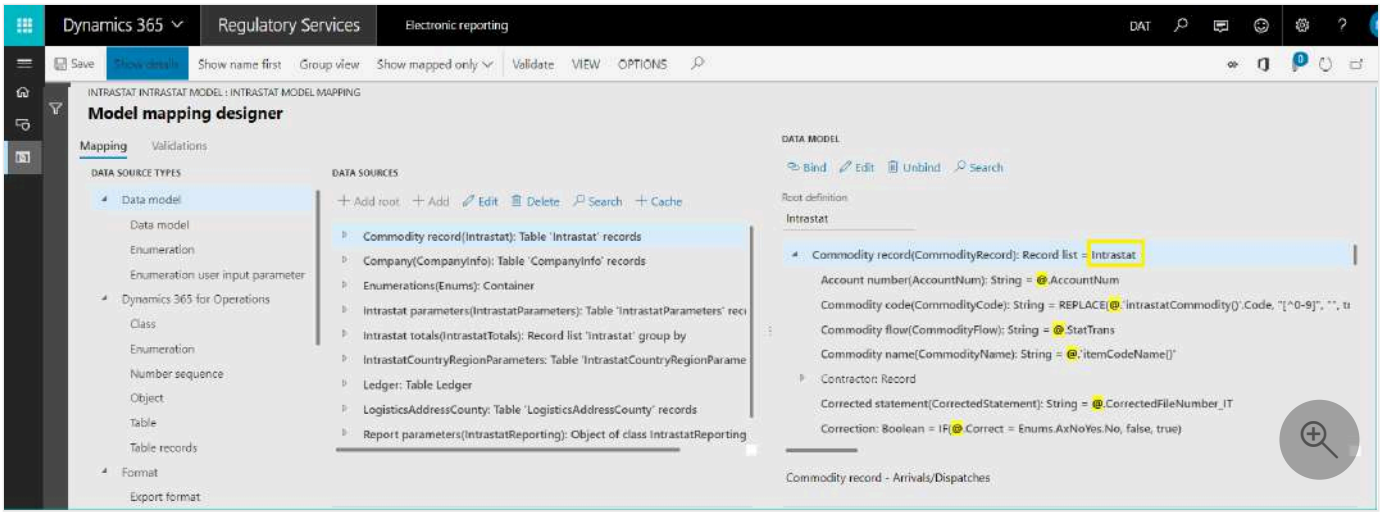
The Electronic reporting (ER) tool lets you define electronic format structures and then describe how to fill those structures by using data and algorithms that exist in the application. For more information, see Create Electronic reporting (ER) configurations. To specify the data flow for retrieving finance and operations data and using it to generate an electronic document, complete the following steps:

- Bind configured data sources to elements of the designed domain-specific data model. The model structure and selected data sources might be part of a complex hierarchical structure. Because of this complexity, final bindings can be quite large and contain many elements of different types, such as relations, tables, and methods. The bindings can become less readable and quite complex to review and understand, especially for non-owners.
- Bind data model elements with format components to define what data populates from the data model to the generated format's output.

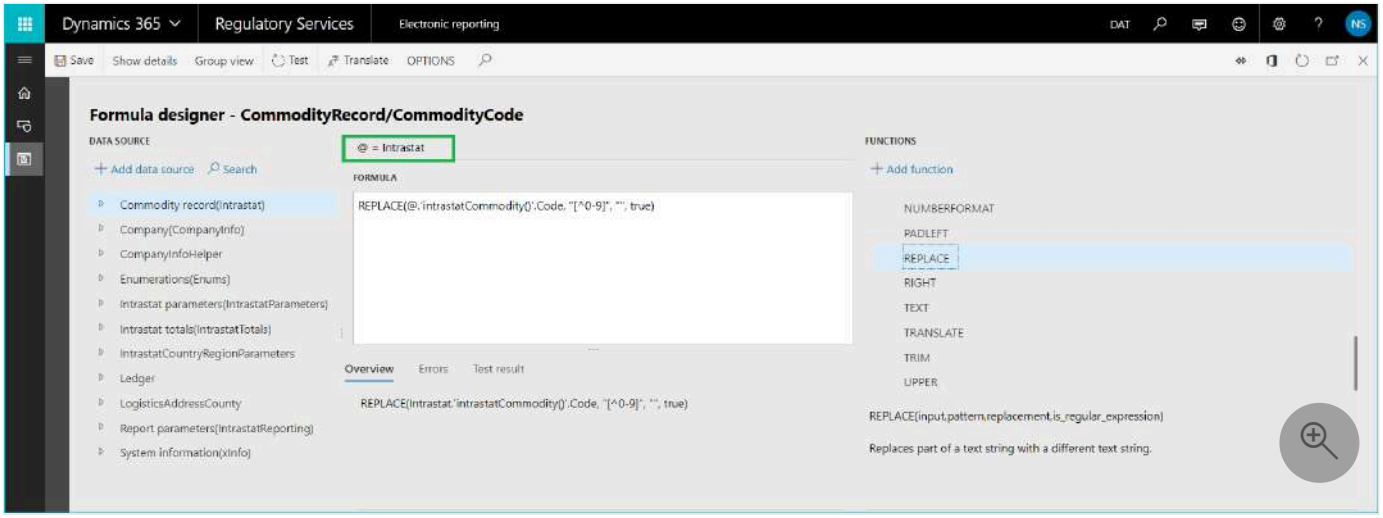
To improve the usability of ER mapping designers, the relative path feature was released. By default, the relative path representation option is turned on for any new instance of the application where ER design experience is enabled (Microsoft Dynamics 365 Finance, Microsoft Regulatory Configuration Service). The relative path parameter enables users to keep using the full path when working with this presentation of ER bindings.



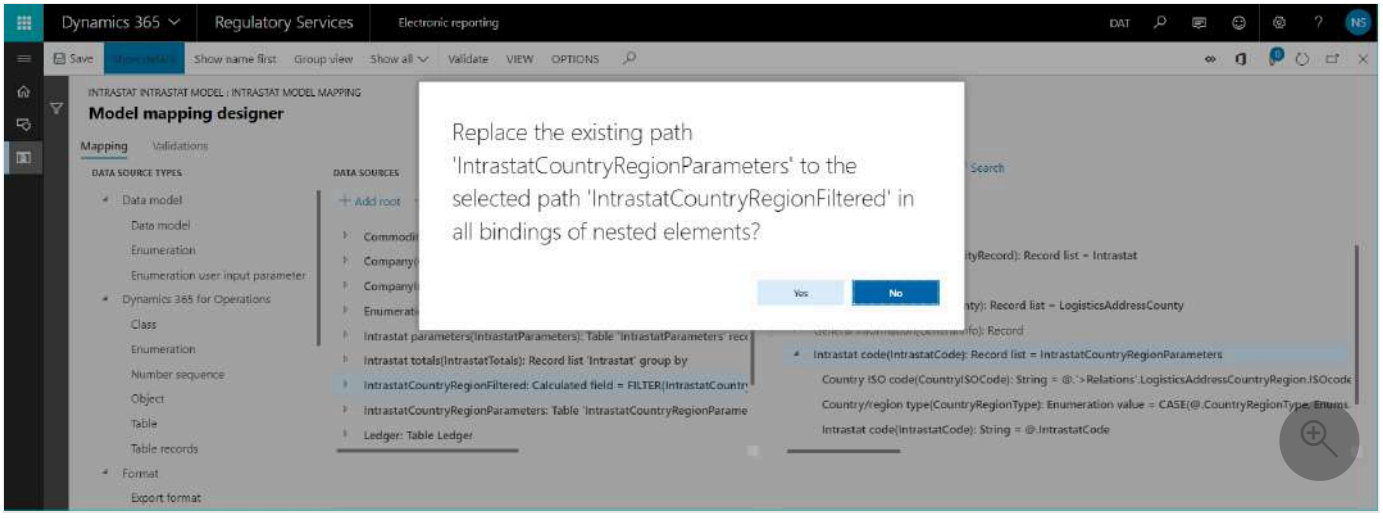
When you turn on the relative path usage parameter, a single `@` character replaces the path to the parent item in the binding of the current model element. The entire binding path becomes shorter, which makes the entire mapping more obvious and easier to understand. In most cases, no additional scrolling is required in the ER designer to view all the bindings of the data model.



When you start designing a new ER expression, you need to enter only one character to define a binding to a field of the parent item.



When you decide to change the data source of the parent model item, with absolute path usage, you have to manually rebind this model item, as well as all nested items, to a new data source. When you turn on relative path usage and select a new data source to bind to a parent item, you are offered an option to automatically rebind all nested elements of this parent item with one click.



If you confirm rebinding of nested items, the new parent item is placed to the path of each nested item containing the existing parent item. This feature doesn't break the backward compatibility of the ER framework. All previously designed ER configurations work with this new feature, and no upgrades or conversions are required.

> **Note**
>
> All changes that are introduced by mass modification of bindings of nested elements in model mappings are correctly saved in a configuration delta (trace of changes). This process allows customers to rebase their derived version of model mappings to any new base version of it that is modified by using this new feature.

Design ER expressions to call application class methods

This article describes how to reuse existing application logic in Electronic reporting (ER) configurations by calling required methods of application classes in ER expressions. You can dynamically define values of arguments for calling classes at runtime. For example, you can base values on information in the parsing document to ensure its correctness.

For the example in this article, you design a process that parses incoming bank statements for an application data update. You receive the incoming bank statements as text (.txt) files that contain International Bank Account Number (IBAN) codes. As part of the process of importing the bank statements, you must validate the correctness of the IBAN code by using the logic that's already available.

Prerequisites

The procedures in this article are intended for users who are assigned the **System administrator** or **Electronic reporting developer** role.

You can complete the procedures by using any data set.

To complete the procedures, you must download and save the following file: SampleIncomingMessage.txt .

In this article, you will create the required ER configurations for the Litware, Inc. sample company. Therefore, before you complete the procedures in this article, you must follow these steps:

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On the **Localization configurations** page, verify that the configuration provider for the **Litware, Inc.** sample company is available and marked as active. If you don't see this configuration provider, you must first complete the steps in Create configuration providers and mark them as active.

Import a new ER model configuration

1. On **Localization configurations**, in the **Configuration providers** section, select the tile for the **Microsoft** configuration provider.

2. Select **Repositories**.
3. On **Localization repositories**, select **Show filters**.
4. To select the Global repository record, add a **Name** filter field.
5. In the **Name** field, enter **Global**. Then select the **contains** filter operator.
6. Select **Apply**.
7. Select **Open** to review the list of ER configurations in the selected repository.
8. On **Configuration repository**, in the configuration tree, select **Payment model**.
9. On the **Versions** FastTab, if the **Import** button is available, select it, and then select **Yes**.

   If the **Import** button isn't available, you already imported the selected version of the **Payment model** ER configuration.
10. Close **Configuration repository**, and then close **Localization repositories**.

Add a new ER format configuration

Add a new ER format to parse incoming bank statements in TXT format.

1. On **Localization configurations**, select the **Reporting configurations** tile.
2. On **Configurations**, in the configuration tree in the left pane, select **Payment model**.
3. Select **Create configuration**.
4. In the drop-down dialog box, follow these steps:
   a. In the **New** field, enter **Format based on data model PaymentModel**.
   b. In the **Name** field, enter **Bank statement import format (sample)**.
   c. In the **Supports data import** field, select **Yes**.
   d. Select **Create configuration** to finish creating the configuration.

Design the ER format configuration – Format

Design an ER format that represents the expected structure of the external file in TXT format.

1. For the **Bank statement import format (sample)** format configuration that you added, select **Designer**.

2. On the **Format designer** page, in the format structure tree in the left pane, select **Add root**.

3. In the dialog box that appears, follow these steps:
   a. In the tree, select **Text\Sequence** to add a **Sequence** format component.
   b. In the **Name** field, enter **Root**.
   c. In the **Special characters** field, select **New line - Windows (CR LF)**. Based on this setting, each line in the parsing file is a separate record.
   d. Select **OK**.

4. Select **Add**.

5. In the dialog box that appears, follow these steps:
   a. In the tree, select **Text\Sequence**.
   b. In the **Name** field, enter **Rows**.
   c. In the **Multiplicity** field, select **One many**. Based on this setting, the parsing file contains at least one line.
   d. Select **OK**.

6. In the tree, select **Root\Rows**, and then select **Add Sequence**.

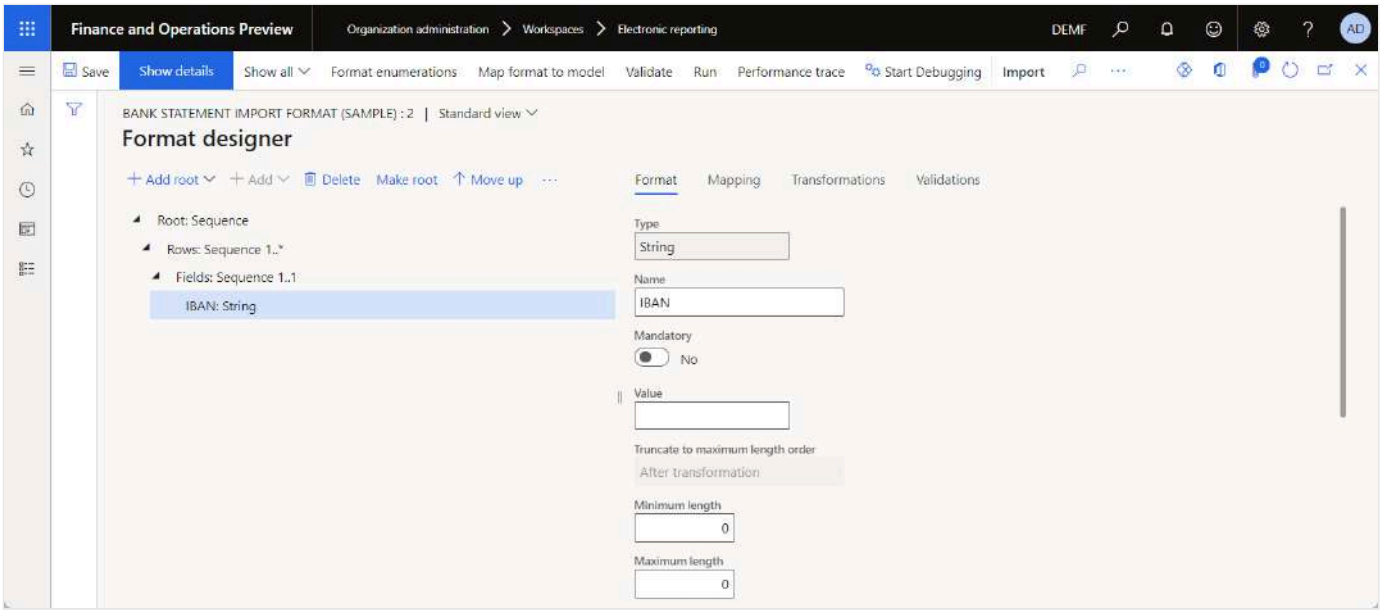
7. In the dialog box that appears, follow these steps:
   a. In the **Name** field, enter **Fields**.
   b. In the **Multiplicity** field, select **Exactly one**.
   c. Select **OK**.

8. In the tree, select **Root\Rows\Fields**, and then select **Add**.

9. In the dialog box that appears, follow these steps:
   a. In the tree, select **Text\String**.
   b. In the **Name** field, enter **IBAN**.
   c. Select **OK**.

10. Select **Save**.

The configuration is now set up so that each line in the parsing file contains only the IBAN code.



Design the ER format configuration – Mapping to a data model

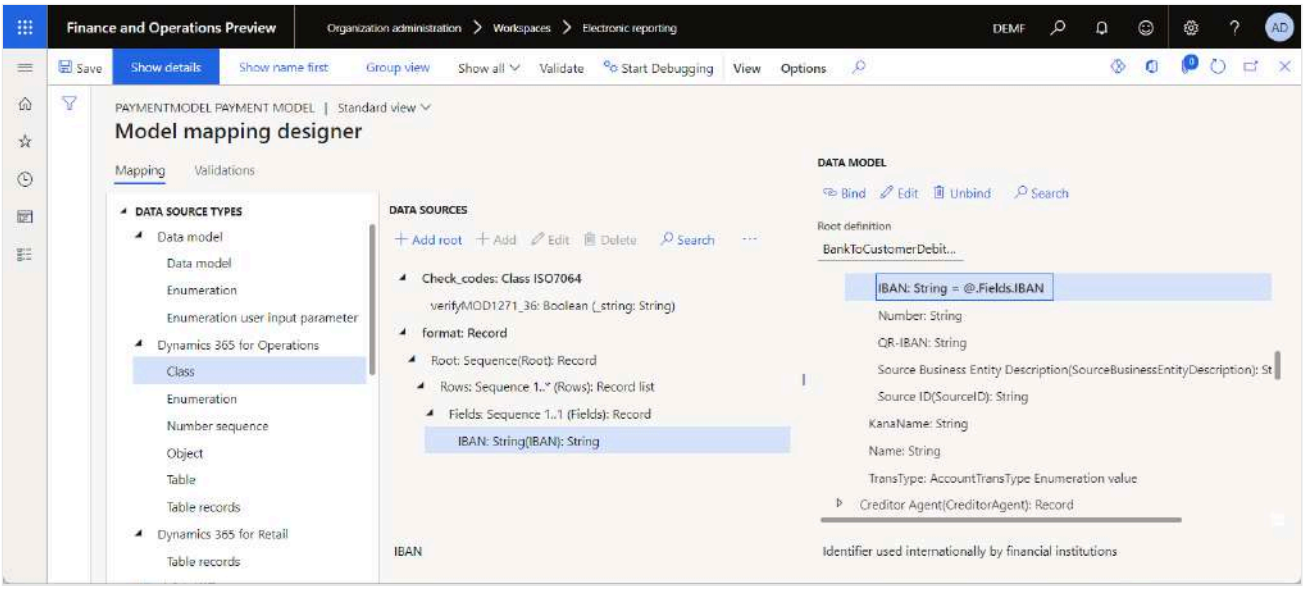
Design an ER format mapping that uses information from the parsing file to fill in a data model.

1. On the **Format designer** page, on the Action Pane, select **Map format to model**.
2. On the **Model to datasource mapping** page, on the Action Pane, select **New**.
3. In the **Definition** field, select **BankToCustomerDebitCreditNotificationInitiation**.
4. In the **Name** field, enter **Mapping to data model**.
5. Select **Save**.
6. Select **Designer**.
7. On the **Model mapping designer** page, in the **Data source types** tree, select **Dynamics 365 for Operations\Class**.
8. In the **Data sources** section, select **Add root** to add a data source that calls the existing application logic for IBAN codes validation.
9. In the dialog box that appears, follow these steps:
   a. In the **Name** field, enter **Check_codes**.
   b. In the **Class** field, enter or select **ISO7064**.
   c. Select **OK**.
10. In the **Data source types** tree, follow these steps:

a. Expand the **format** data source.
b. Expand **format\Root: Sequence(Root)**.
c. Expand **format\Root: Sequence(Root)\Rows: Sequence 1..* (Rows)**.
d. Expand **format\Root: Sequence(Root)\Rows: Sequence 1..* (Rows)\Fields: Sequence 1..1 (Fields)**.

11. In the **Data model** tree, follow these steps:
    a. Expand the **Payments** field of the data model.
    b. Expand **Payments\Creditor Account(CreditorAccount)**.
    c. Expand **Payments\Creditor Account(CreditorAccount)\Identification**.
    d. Expand **Payments\Creditor Account(CreditorAccount)\Identification\IBAN**.

12. Follow these steps to bind components of the configured format to data model fields:
    a. Select **format\Root: Sequence(Root)\Rows: Sequence 1..* (Rows)**.
    b. Select **Payments**.
    c. Select **Bind**. Based on this setting, each line in the parsing file is a single payment.
    d. Select **format\Root: Sequence(Root)\Rows: Sequence 1..* (Rows)\Fields: Sequence 1..1 (Fields)\IBAN: String(IBAN)**.
    e. Select **Payments\Creditor Account(CreditorAccount)\Identification\IBAN**.
    f. Select **Bind**. Based on this setting, the **IBAN** field of the data model is filled with the value from the parsing file.



13. On the **Validations** tab, follow these steps to add a validation rule that shows an error message for any line in the parsing file that contains an invalid IBAN code:
    a. Select **New**, and then select **Edit condition**.
    b. On the **Formula designer** page, in the **Data source** tree, expand the **Check_codes** data source that represents the **ISO7064** application class to view the available methods of

this class.

c. Select **Check_codes\verifyMOD1271_36**.

d. Select **Add data source**.

e. In the **Formula** field, enter the following expression: **Check_codes.verifyMOD1271_36(format.Root.Rows.Fields.IBAN)**.

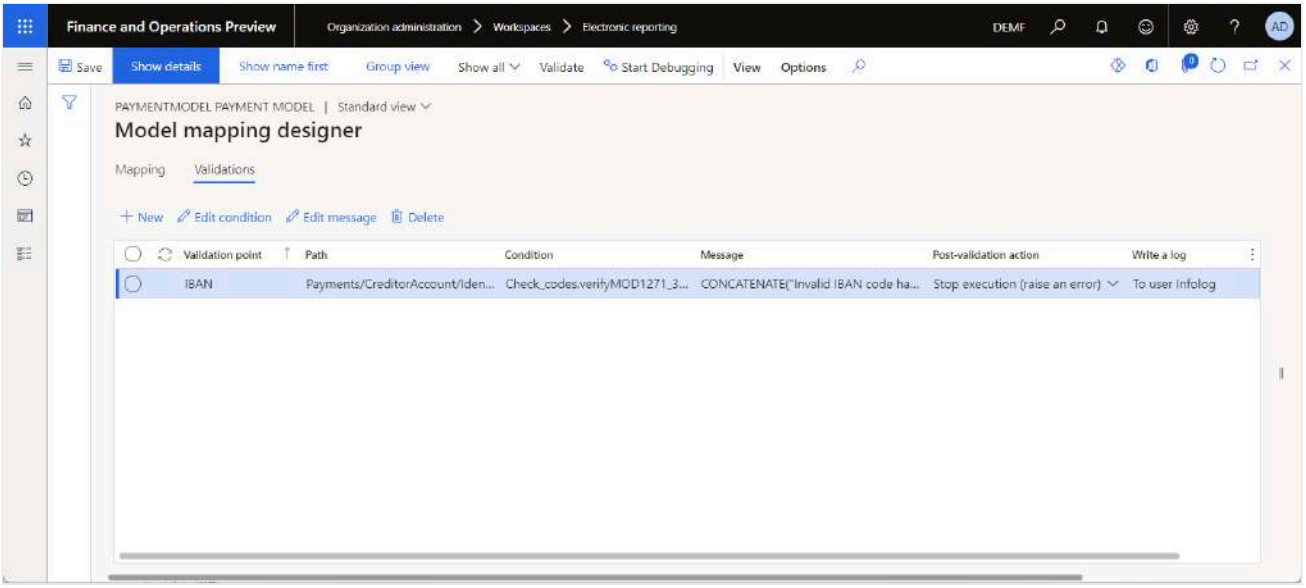
f. Select **Save**, and then close the page.

g. Select **Edit message**.

h. On the **Formula designer** page, in the **Formula** field, enter **CONCATENATE("Invalid IBAN code has been found: ", format.Root.Rows.Fields.IBAN)**.

i. Select **Save**, and then close the page.

Based on these settings, the validation condition returns *FALSE* for any invalid IBAN code by calling the existing **verifyMOD1271_36** method of the **ISO7064** application class. The value of the IBAN code is dynamically defined at runtime as the argument of the calling method, based on the content of the parsing text file.



14. Select **Save**.

15. Close the **Model mapping designer** page, and then close the **Model to datasource mapping** page.

Run the format mapping

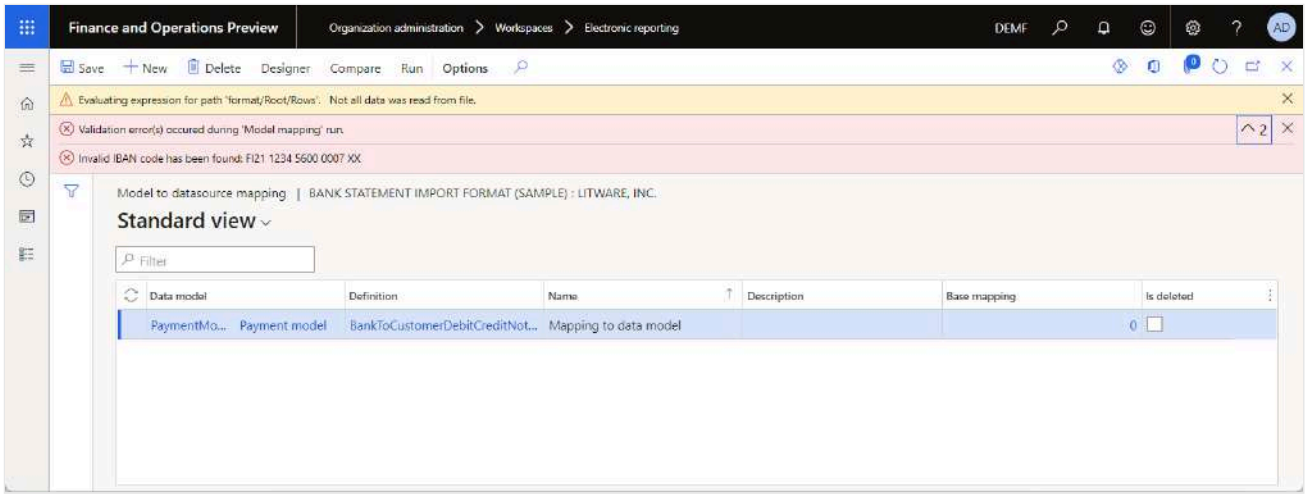
For testing purposes, run the format mapping by using the SampleIncomingMessage.txt file that you downloaded earlier. The generated output includes data that the process imports from the selected text file and ports to the custom data model during the real import.

1. On **Model to datasource mapping**, select **Run**.

2. On **Electronic report parameters**, select **Browse**, browse to the **SampleIncomingMessage.txt** file that you downloaded, and select it.

3. Select **OK**.

4. The **Model to datasource mapping** page shows an error message about an invalid IBAN code.



5. Review the output in XML format that represents the data imported from the selected file and ported to the data model. Notice that the process handles only three lines of the imported text file without errors. The IBAN code on line 4 isn't valid and is skipped.

Configure the Electronic reporting (ER) framework

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to set up the basic functionality for Electronic reporting (ER). It also describes the steps that you must complete before you can set up ER.

Prerequisites for ER setup

Before you can set up ER, you must set up the required document types in Document management:

- A document type for Microsoft Office documents that are used as templates for ER reports.
- A document type that is used to store the output of ER reports in the jobs archive.
- A document type that is used to store the output of ER reports so that they can be viewed in other programs.
- A document type that is used to keep baselines of outputs of ER configurations.
- A document type that is used to handle files in the ER framework for all other purposes.

For each document type, the following attribute values can be selected.

Expand table

Attribute name	Attribute value
Class	**Attach file**
Group	**File**
Location	**Azure storage** or **SharePoint**

Set up ER

Use the following procedure to set up the basic functionality of ER for all legal entities.

1. Open the **Electronic reporting** workspace page.
2. Click **Electronic reporting parameters**.

Main parameters

On the **General** tab of the **Electronic reporting parameters** page, set the following ER parameters:

- **Enable design mode**
  - Set this option to **Yes** to enable embedded ER designers, so that users can create their own ER configurations.
  - Set this option to **No** to require that users access the functionality of ER designers by signing up for Configuration service.

- **Disable tracing of ER performance in data handling**
  - Set this option to **No** to allow Microsoft Telemetry to collect information about the average time that is required to process a single incoming or outgoing record as an ER configuration. This information is tracked as a specific health metric of the environment, and it will help Microsoft quickly identify and address issues that affect customers who use the ER framework.
  - Set this option to **Yes** to stop collecting telemetry information.

Parameters to manage documents

On the **Attachments** tab of the **Electronic reporting parameters** page, set the following ER parameters:

- **Configurations** – Select a document type to specify the storage of templates of ER formats. This document type is selected within the scope of a specific company. This document type will be used, regardless of the company that a user is signed in to while an ER format is being used.

- **Job archive** – Select a document type to specify the storage of generated documents that are attached to the records of the ER jobs archive. This document type is selected as a company-specific document type. You must make sure that the selected document type is

configured for every company that you plan to run ER formats for, and then store the results in the ER jobs archive.

- **Temporary** – Select a document type to specify the storage of generated documents that are used for other purposes. For example, documents might be generated for preview by other services. This document type is selected as a company-specific document type. You must make sure that the selected document type is configured for every company that you plan to run ER formats for, and then store the results in the ER jobs archive.
- **Baseline** – Select a document type to specify the storage of documents that are used as baselines during the automated testing of ER configurations. This document type is selected as a company-specific document type. You must make sure that the selected document type is configured for every company that you plan to run ER formats for, and then store the results in the ER jobs archive.
- **Others** – Select a document type to specify the storage of generated documents that are used for all other purposes. This document type is selected as a company-specific document type. You must make sure that the selected document type is configured for every company that you plan to run ER formats for, and then store the results in the ER jobs archive.
- **Stop making backup copies of templates**
    - Set this option to **No** to automatically create a backup copy of any ER format configuration template and store the copy in the database storage.
    - Set this option to **Yes** to stop making backup copies of ER formation configuration templates.

      For more information, see Backup storage of ER templates.

Runtime parameters

On the **Runtime** tab of the **Electronic reporting parameters** page, set the following ER parameters:

- **Autofit row height** - When selected, this setting ensures that the height of a row configured in an Excel template as an *AutoFit Row Height* and containing at least one merged cell with wrap text alignment, is automatically adjusted at runtime. This adjustment occurs when the merged cell is filled with large text, allowing all wrapped content to be fully visible without manual resizing.

- **Query timeout (seconds)** - As of version 10.0.46 of Finance, the ER engine supports manual configuration of query timeouts during runtime. The default value of 0 retains the system's standard timeout, but users can now define custom duration for queries in ER runtime, improving flexibility and execution control.

Active ER configurations provider

On the **Configuration provider table** page, create ER provider records. Each provider can be marked as **Active**. The active provider's name and internet address are stored in an ER configuration, as attributes of the configuration owner.

Optional setup for ER

In addition to the basic functionality, ER has other functionality that you can set up.

- On the **Electronic reporting destination** page, define the ER output destinations for each file output of each ER format configuration. Use the document types of the Document management framework that you set up earlier. You can also use this page to set up the optional ER functionality for each legal entity. For more information, see Electronic reporting (ER) destinations.
- When you add new Application Object Tree (AOT) artifacts or update existing AOT artifacts that are used as data sources (tables, views, or data entities) in ER, use the **Rebuild table references** menu item (**Organization administration** > **Electronic reporting** > **Rebuild table references**) to bring your AOT changes into the ER metadata.

Frequently asked questions

Question: I have added a custom table to the AOT. I created a new ER model mapping configuration for my ER data model. During the design of the model mapping, I tried to add a new data source type, **Table records**, that refers to my table. I could manually add my table name to the **Table** lookup, and the ER model mapping accepted it without errors or warnings. However, my table's name isn't included in the list of available choices that the **Table** lookup of this data source offers. How do I include the name of my table?

Answer: To include the name of your custom table in the **Table** lookup, use the **Rebuild table references** menu item as described in the "Optional setup for ER" section earlier in this article.

Question: Why can't I mark the Microsoft provider as **Active** in the **Electronic reporting** workspace in my production environment?

Answer: The Microsoft provider is used to mark ER configurations that have been designed and maintained by Microsoft. We expect that Microsoft will release new versions of the configurations in the future. We recommend that you not mark the Microsoft provider as **Active**. Otherwise, you can update the configurations. (For example, you can change the content and register new versions.) These updates will cause issues in the future, when Microsoft provides new versions of the configurations, and those new versions must be imported and adopted. Instead, register a new ER provider for your company, and use it for your ER configurations maintenance. To reuse a Microsoft configuration, select it as the base for your derived copy. To incorporate changes that are provided by Microsoft, rebase your configuration to a new version of the Microsoft configuration when it becomes available.

Question: I successfully ran an ER format in one company. However, when I ran the same ER format in another company and used the same settings, I received the following error message: "The provided document type is not a File type." Why?

Answer: Most likely, the second company doesn't contain document types that have been selected in the **Job archive**, **Temporary**, **Baseline**, and **Others** ER parameters. To fix this issue, configure these document types in the second company.

Backup storage of ER templates

By using the Electronic reporting (ER) overview, business users can configure formats for outbound documents that meet the legal requirements of various countries and regions. Configured ER formats can use predefined templates to generate outbound documents in various formats, such as Microsoft Excel workbooks, Microsoft Word documents, or PDF documents. The templates are filled with data that the configured dataflow for generated documents requires.

You can publish each configured format as part of an ER solution. You can export each ER solution from one instance of finance and operations and import it into another instance.

The ER framework uses the Configure document management to keep the required templates for the current finance and operations instance. Depending on the settings of the ER framework, Microsoft Azure Blob storage or a Microsoft SharePoint folder can be selected as the physical primary storage location for templates. (For more information, see Configure the Electronic reporting (ER) framework.) The DocuValue table holds an individual record for each template. In each record, the **AccessInformation** field stores the path of a template file that is located in the configured storage location.

When you manage your finance and operations instances, you might decide to migrate the current instance to another location. For example, you might migrate your production instance to a new sandbox environment. If you configure the ER framework to store templates in Blob storage, the DocuValue table in the new sandbox environment refers to the instance of Blob storage in the production environment. However, you can't access this instance from the sandbox environment, because the migration process doesn't support the migration of artifacts in Blob storage. Therefore, if you try to run an ER format that uses a template to generate business documents, an exception occurs, and you're notified about the missing template. You're also guided to use the ER cleanup tool to delete and then re-import the ER format configuration that contains the template. Because you might have several ER format configurations, this process can be time consuming.

The Backup storage of ER templates feature can help you make your templates always available to generate business documents.

> ⓘ **Note**

You can use this feature only when Blob storage is selected as the physical storage location for ER templates.

Automated recovery and notification

For this feature, every template of a new ER format configuration in the current environment is automatically saved to the backup storage location for templates (the ERDocuDatabaseStorage database table) when the following events occur:

- You import a new ER format configuration that contains a template.
- You complete the draft version of an ER format configuration that contains a template.

Backup copies of templates are migrated to a new instance of finance and operations as part of the application database.

If an ER format template is required to generate outbound documents, such as to process vendor payments including generation of payment advice and control reports, but the required template isn't found in the primary storage location, the following events occur:

- If the template is available in the backup storage location, it is automatically taken from the backup storage location, restored to the primary storage location, and used for the current execution.

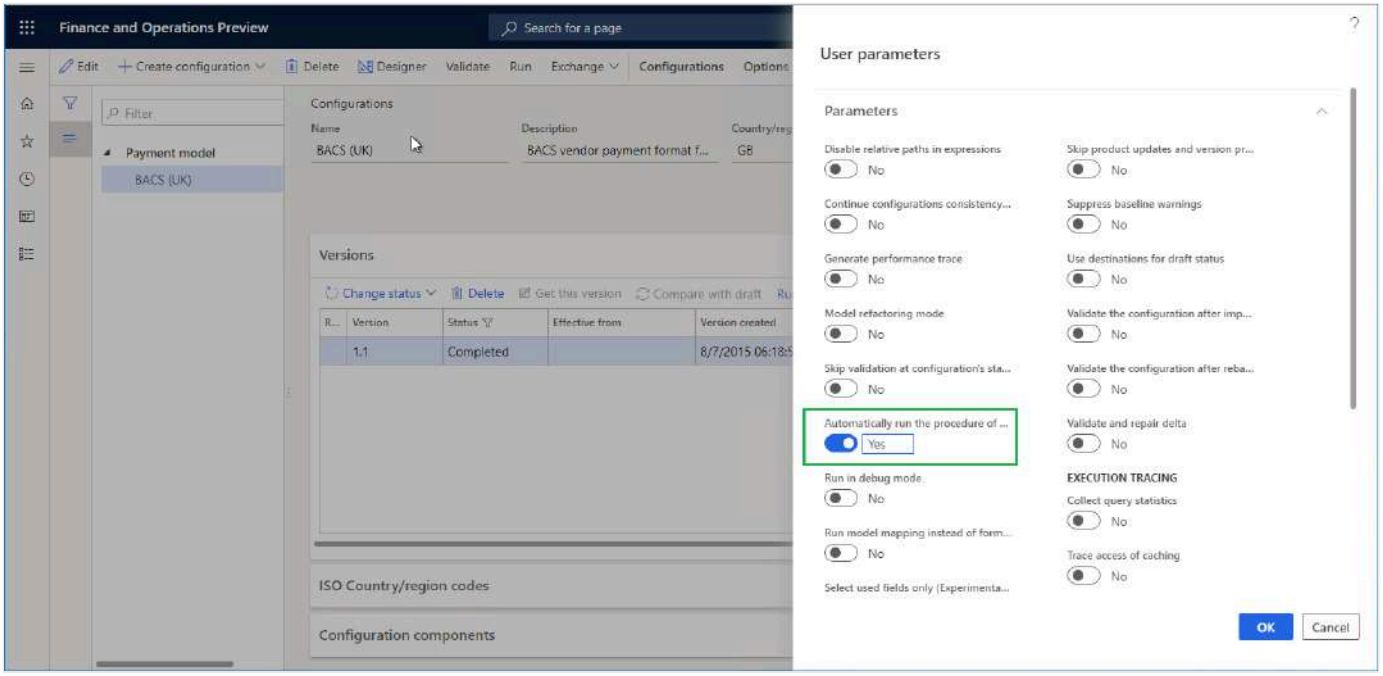
- Every user who is assigned to the **Electronic reporting developer** or **System administrator** role is notified about the missing template issue through the Action center. The message that appears depends on the value of the **Automatically run the procedure of restoring the broken templates in batch** parameter:
  - If this parameter is set to **Off**, the message recommends that you start the batch process to automatically fix similar issues for other ER format configuration templates. The message includes a link that you can use to start the batch process.
  - If this parameter is set to **On**, the message notifies you that a missing templates issue has been discovered, and that a new batch process, **Restore broken templates from internal database backup**, has been automatically scheduled. This batch process automatically fixes similar issues for other templates.

To set up the **Automatically run the procedure of restoring the broken templates in batch** parameter, complete the following steps:

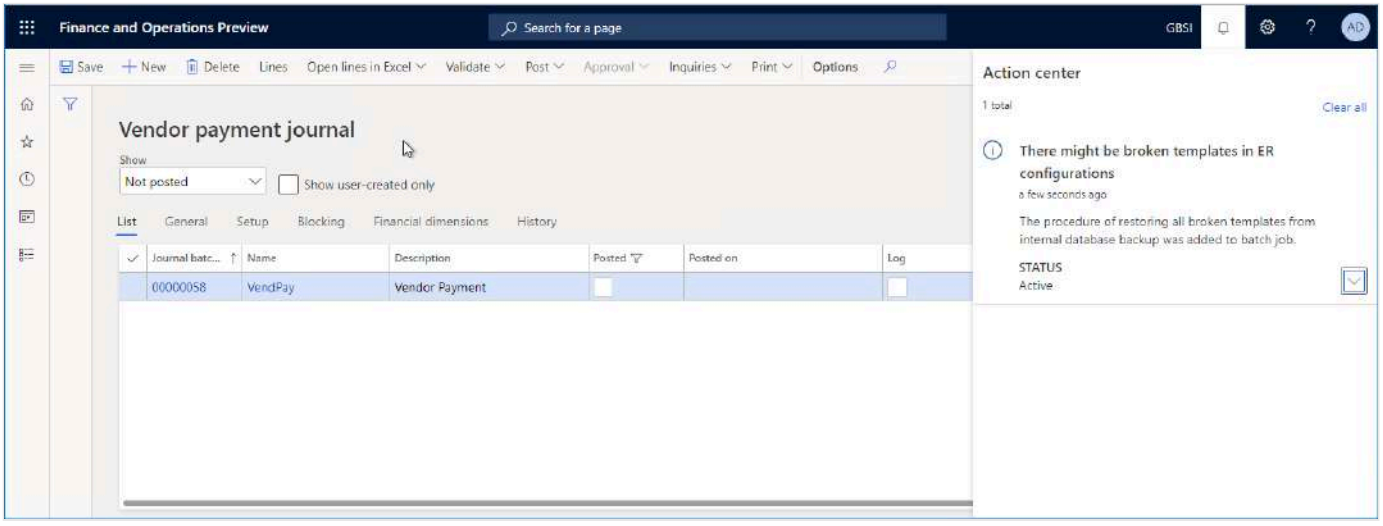
1. In Finance and Operations, open the **Organization administration** > **Electronic reporting** > **Configurations** page.

2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, set the required value for the **Automatically run the procedure of restoring the broken templates in batch** parameter.

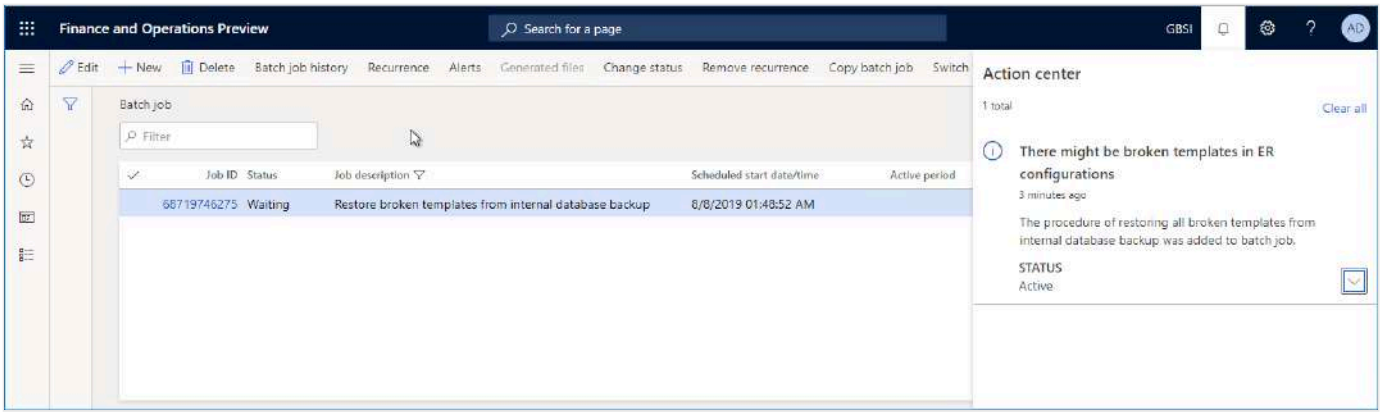
> **Note**
>
> This parameter is defined as application user and logged company specific.



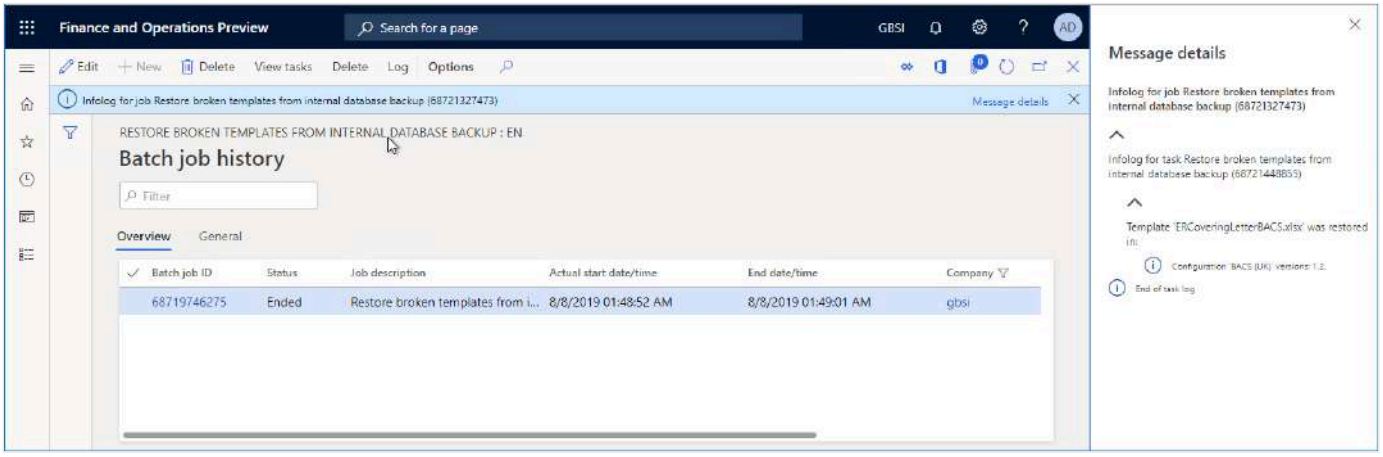
The following illustration shows an example of the message that appears when the **Automatically run the procedure of restoring the broken templates in batch** parameter is set to **On**.



The following illustration shows the **Restore broken templates from internal database backup** batch process on the **Batch job** page.



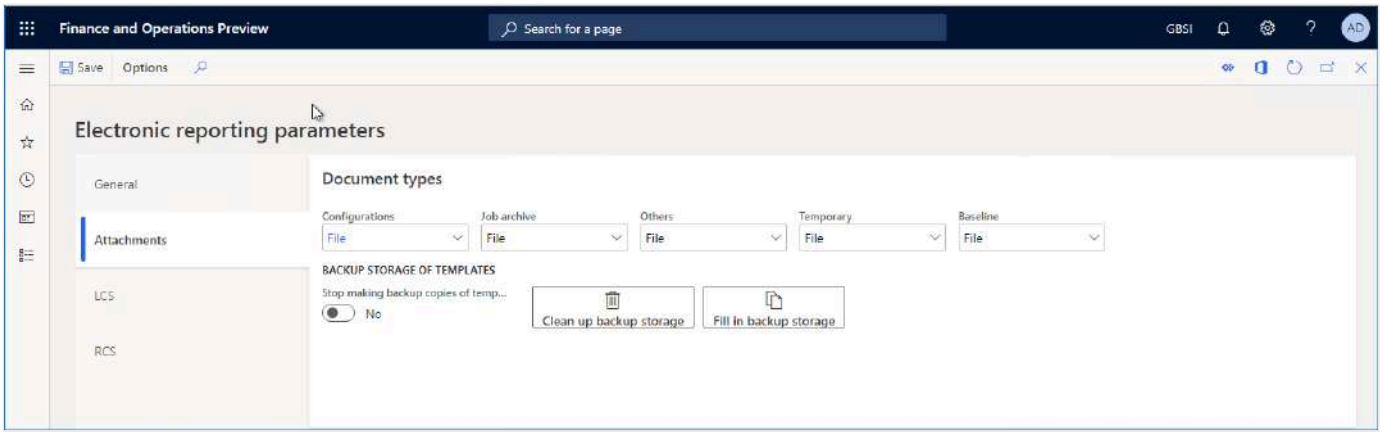
The execution log of the completed **Restore broken templates from internal database backup** batch process includes information about the templates that the process restores from the backup storage location to the primary storage location.



By default, the process of automatically creating backup copies of templates that reside in ER format configurations is turned on. To stop making backup copies of templates, set the **Stop making backup copies of template** option to **Yes** on the **Attachments** tab of the **Electronic reporting parameters** page. You can open this page from the **Electronic reporting** workspace.

If you set the **Stop making backup copies of templates** option to **Yes** and don't want to keep the backup copies that were previously made of templates, select **Clean up backup storage** on the **Electronic reporting parameters** page.

If you upgraded your environment to Finance and Operations version 10.0.5 (October 2019) and want to migrate to a new environment that includes ER format configurations that can be run, select **Fill in backup storage** on the **Electronic reporting parameters** page before the migration occurs. This button starts the process of making backup copies of all available templates, so that they can be stored in the ER backup storage location for templates.



Manual recovery

Go to **Organization administration** > **Electronic reporting** > **Restore broken templates** to manually restore ER templates from the backup storage location to the primary storage location. Before you start this process, use the **Restore broken templates** page to specify whether to perform the restoration interactively or schedule it as a batch process.

Supported deployments

In finance and operations version 10.0.5, the **Backup storage of ER templates** feature is available only in cloud deployments.

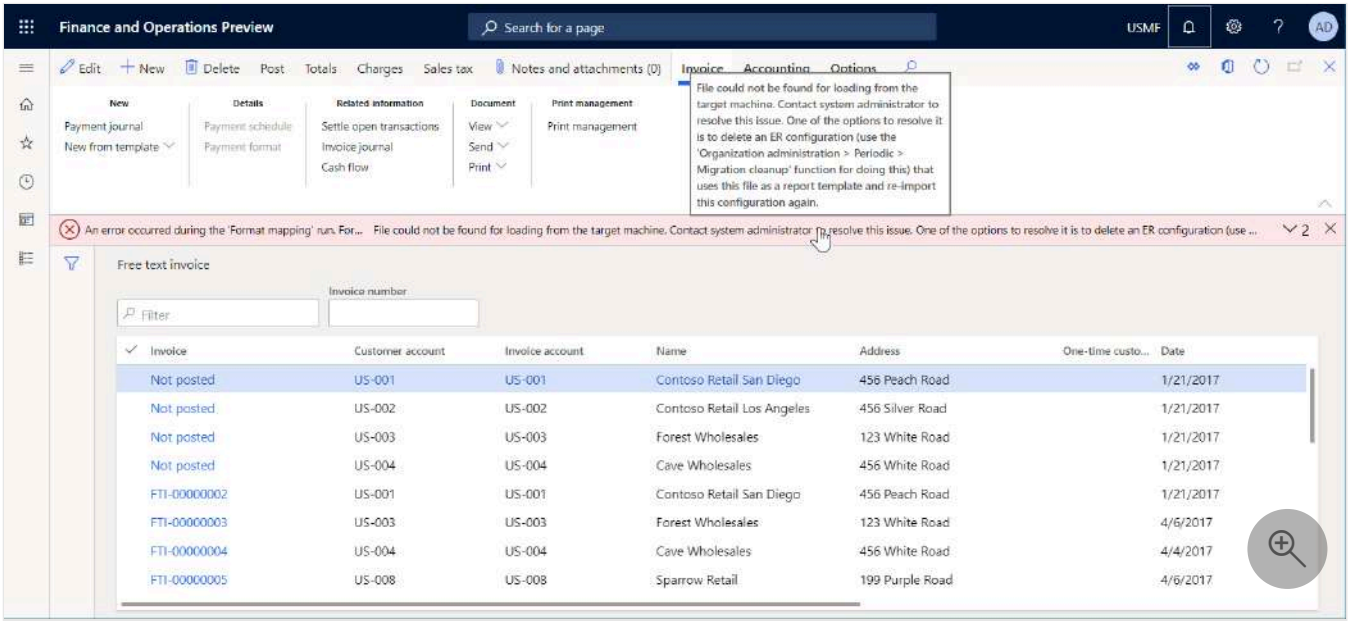
Last updated on 06/26/2026

ER migration cleanup

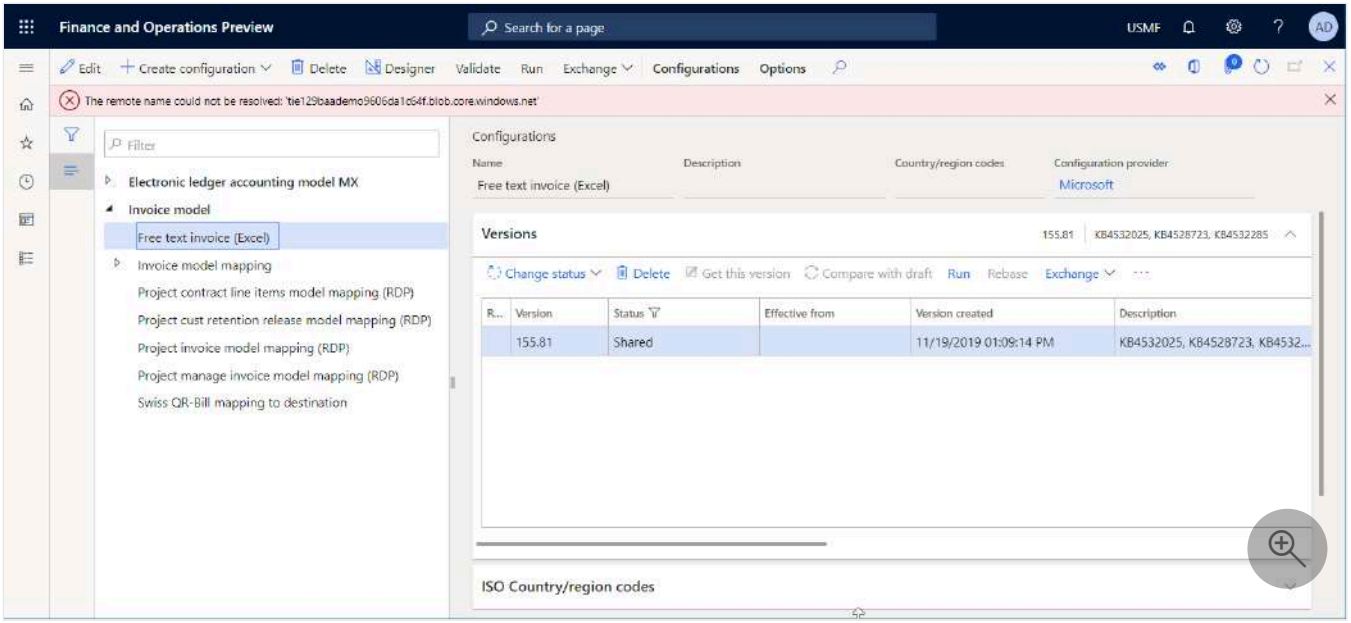
> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you manage your Finance instances, you might decide to migrate your current instance to another location. For example, you might migrate your production instance to a new sandbox environment. If you configured the Electronic reporting (ER) framework to store templates in Microsoft Azure Blob storage, the **DocuValue** table in the new sandbox environment refers to the instance of Blob storage in the production environment. However, you can't access this instance from the sandbox environment because the migration process doesn't support the migration of artifacts in Blob storage. Instead, in the new sandbox environment, you refer to the instance of Blob storage in the sandbox environment that doesn't yet have the ER templates.

If you try to run an ER format that uses a template to generate business documents, an exception occurs, and you're notified about the missing template. You're also guided to use the ER migration cleanup option to delete and then re-import the ER format configuration that contains the template.



You receive a similar error if you go to the **Configurations** page (**Organization administration** > **Electronic reporting** > **Configurations**) and in the configurations tree, try to delete an ER format configuration that uses a template.



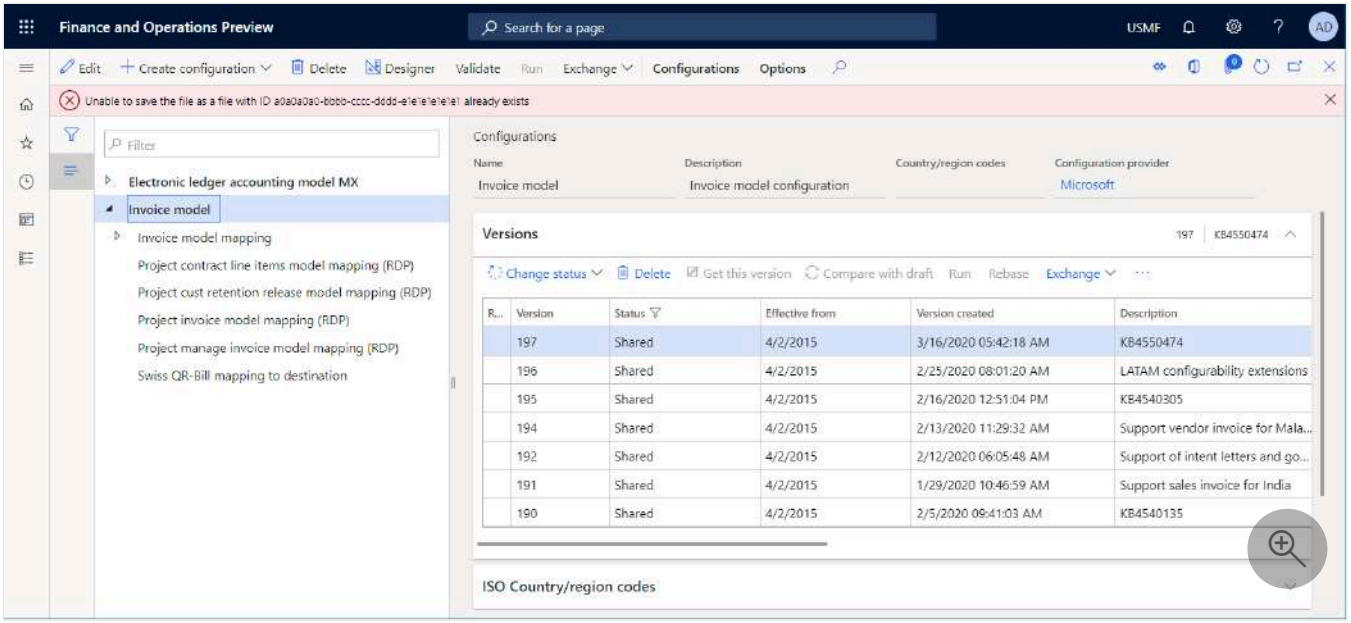
Complete the following steps to resolve issues with ER templates that you can't access.

1. Go to **Organization administration** > **Periodic** > **Migration cleanup**.
2. Select an ER format configuration that you can't execute or delete.
3. Select **Delete**.
4. Confirm the deletion of the selected ER format configuration.
5. Import the deleted ER format configuration to the current Finance instance.

Applicability

> **Important**
>
> The **Migration cleanup** option is only for ER format configurations that contain non-accessible ER templates. When you use the **Migration cleanup** option to delete an ER format configuration, ER deletes the templates that are related to the configuration artifacts in the only application database. ER doesn't validate the existence of the appropriate physical files in Blob storage. Instead, ER assumes that there are none. Therefore, don't use the **Migration cleanup** option as an alternative to the ER configuration deletion option on the **Configurations** page. Use the **Migration cleanup** option only when the ER configuration deletion option on the **Configurations** page failed.
>
> If you use the **Migration cleanup** option to delete an ER format configuration when the referred template is available in the Blob storage, you only delete related configuration

artifacts in the application database. The physical file of the template in the Blob storage remains. File overwriting in Blob storage is no longer allowed. For more information, see KB4557217. Additionally, you can't re-import the configurations deleted by using the Migration cleanup in this environment. To resolve this issue, you need to find the corresponding file in Blob storage and manually delete it.



A similar problem can occur if you migrate your application instance to another location that you used as a migration target more than once and for which the Blob storage already contains ER template files.

Because you can have several ER format configurations, this process can be time consuming. Therefore, using the Backup storage of ER templates feature to automatically recover templates with broken references is preferred.

Last updated on 04/13/2026

Create configuration providers and mark them as active

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how a user assigned to the System Administrator or Electronic Reporting Developer role can create a configuration provider for Electronic reporting (ER). Each ER configuration refers to the provider as the author of the configuration. In this example, you create a configuration provider for sample company, Litware, Inc. You can perform these steps in any company because ER configuration providers are shared among all companies.

Create a provider

1. Go to the **navigation pane** in the upper left corner and select **Organization administration**.
2. Go to **Workspaces** > **Electronic reporting**.
3. Go to **Related links** > **Configuration providers**.
4. Select **New**.

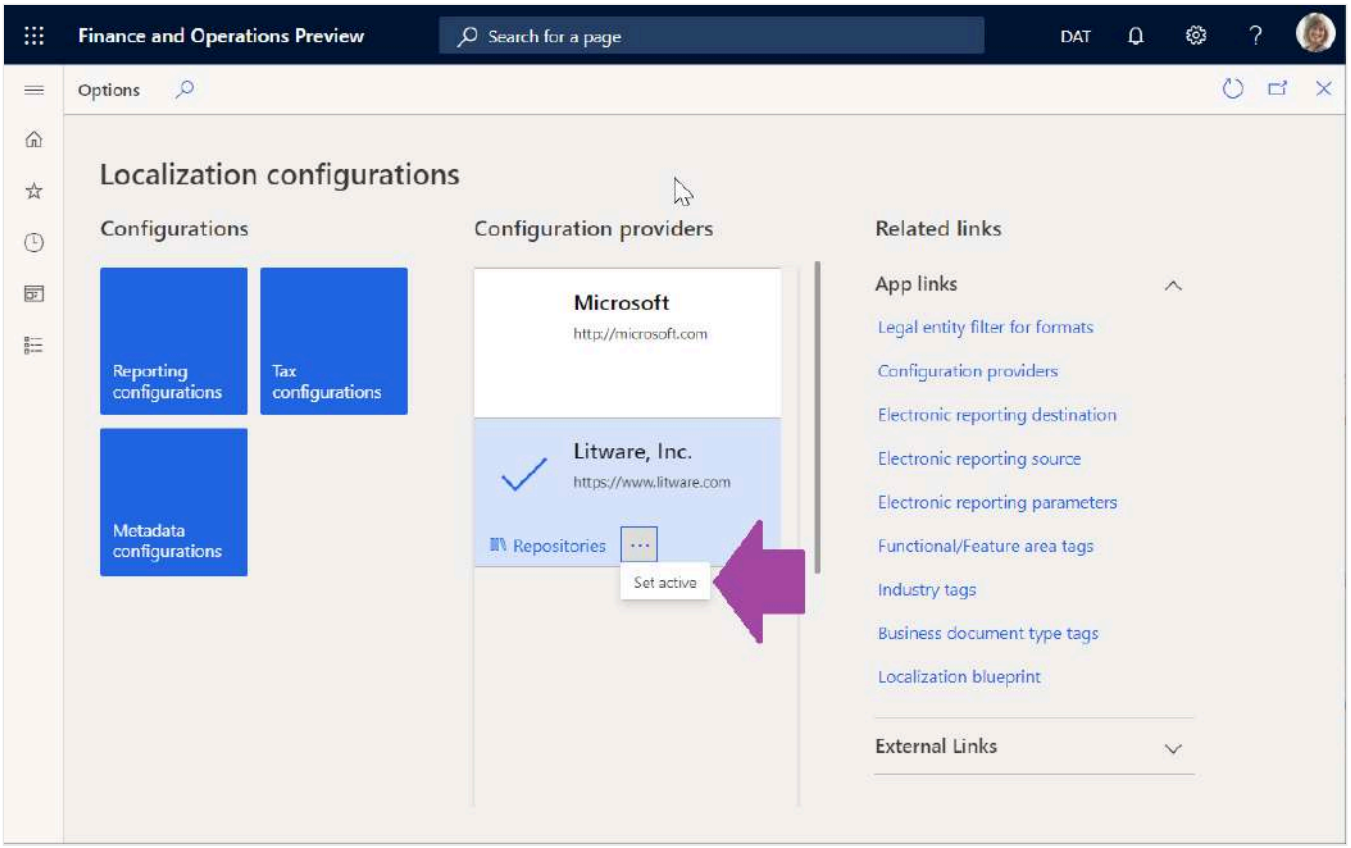
    - A provider record has a unique name and URL. Review the content of this page and skip this procedure if a record for Litware, Inc. (https://www.litware.com) already exists.

5. In the Name field, type `Litware, Inc.`.
6. In the Internet address field, type `https://www.litware.com`.
7. Select **Save**.
8. Close the page.

Select as an active provider

1. Select the Litware, Inc. provider.

2. Select **Set active**.



Last updated on 04/10/2026

Electronic reporting (ER) destinations

10/02/2025

You configure a destination for each Electronic reporting (ER) format configuration and its output component (a folder or a file). Users who have appropriate access rights can also modify destination settings at runtime. This article explains ER destination management, the types of destinations that are supported, and security considerations.

ER format configurations usually contain at least one output component: a file. Typically, configurations contain multiple file output components of different types (for example, XML, TXT, XLSX, DOCX, or PDF) that are grouped into either a single folder or multiple folders. ER destination management lets you preconfigure what occurs when each component runs. By default, when you run a configuration, a dialog box appears that lets you save or open the file. The same behavior also occurs when you import an ER configuration and don't configure any specific destinations for it. After you create a destination for a main output component, that destination overrides the default behavior, and the folder or file is sent according to the destination's settings.

Overview

You can set up destinations only for ER configurations that you import into the current Finance instance and for the formats that are available on the **Electronic reporting configurations** page. You can access ER destination management at **Organization administration** > **Electronic reporting** > **Electronic reporting destination**.

Default behavior

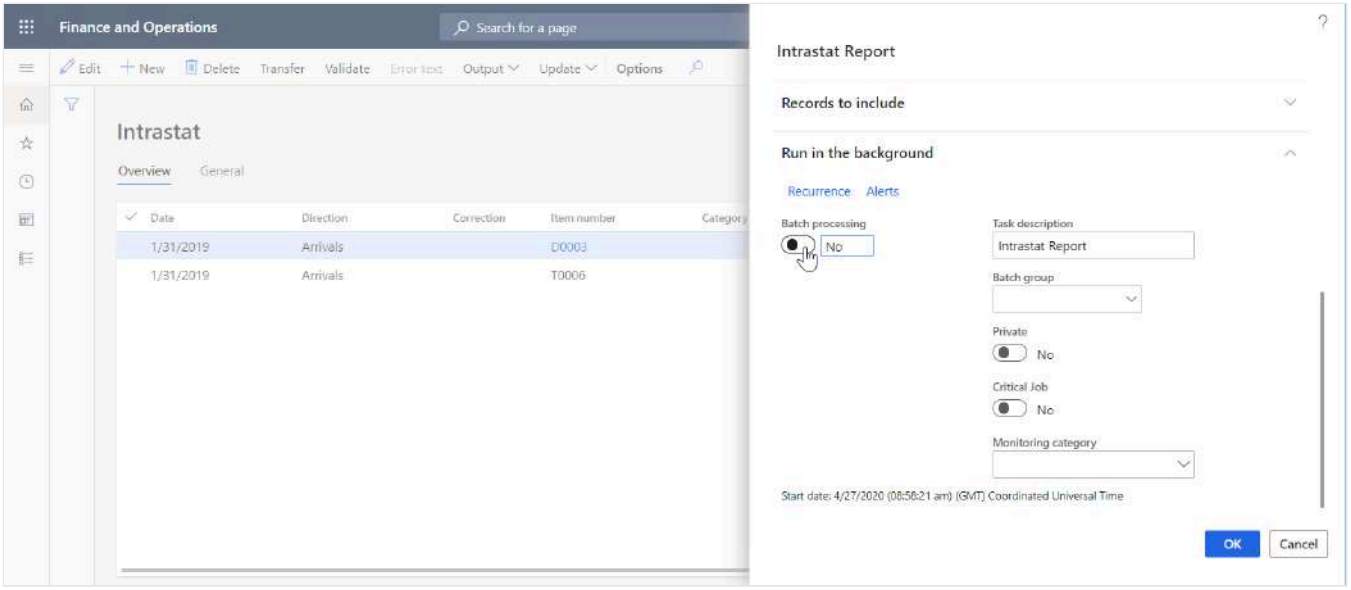
The default behavior for an ER format configuration depends on the execution type that you specify when an ER format starts.

For example, in the **Intrastat Report** dialog box, on the **Run in the background** FastTab, if you set the **Batch processing** option to **No**, an ER format runs immediately in interactive mode. When this execution completes successfully, a generated outbound document is available for download.

If you set the **Batch processing** option to **Yes**, an ER format runs in batch mode. The appropriate batch job is created based on the parameters that you specify on the **Run in the background** tab of the **ER parameters** dialog box.

> ⓘ **Note**

The job description informs you about the run of an ER format mapping. It also contains the name of the ER component that runs.

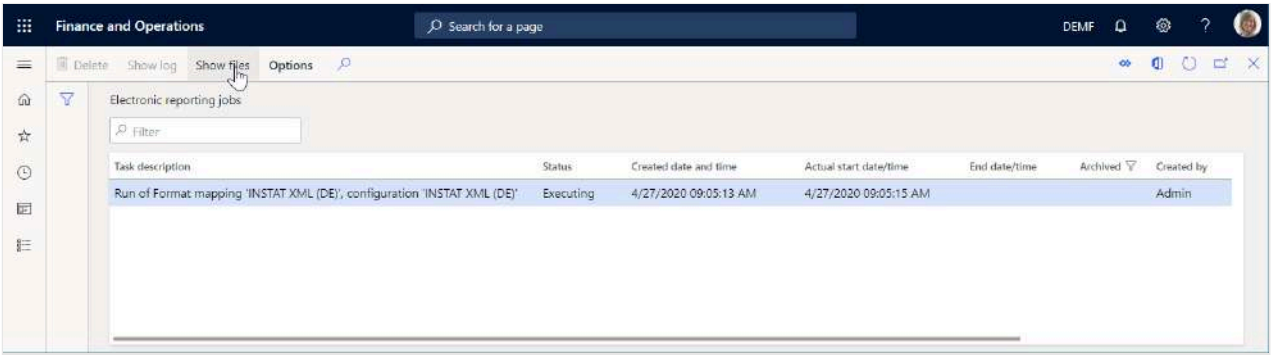


You can find information about this job in several places:

- Go to **Common** > **Inquiries** > **Batch jobs** > **My batch jobs** to check the status of the scheduled job.
- Go to **Organization administration** > **Electronic reporting** > **Electronic reporting jobs** to check the status of the scheduled job and the execution results of the completed job. When job execution completes successfully, select **Show files** on the **Electronic reporting jobs** page to get a generated outbound document.

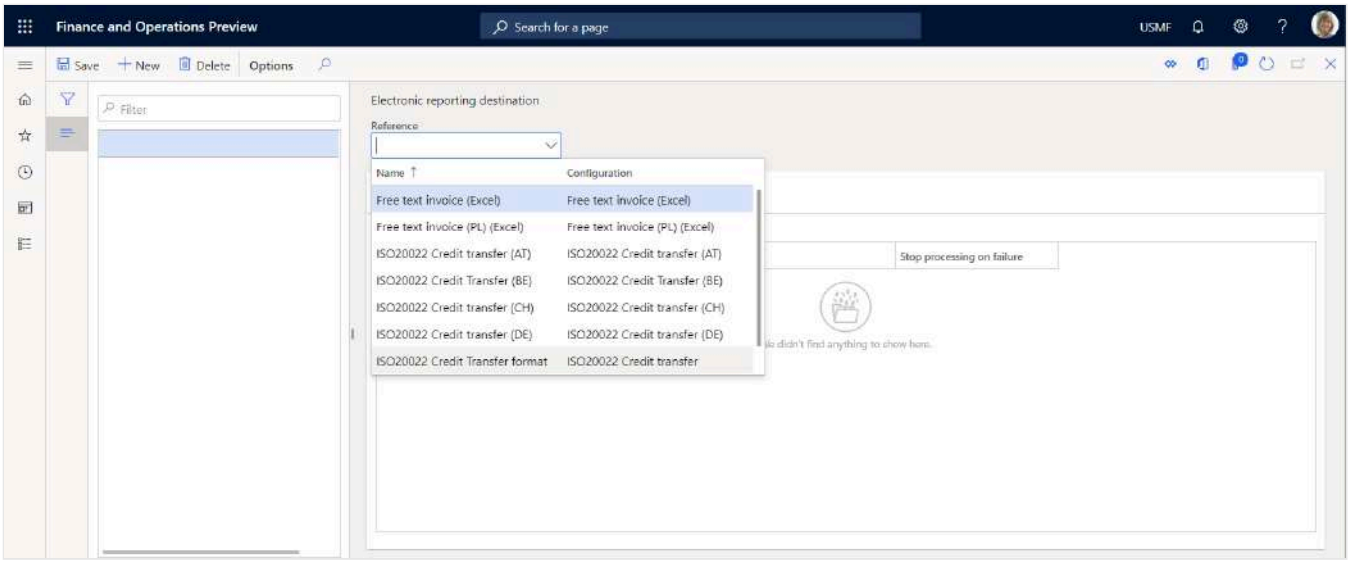
  > **Note**
  >
  > This document is stored as an attachment of the current job record and is controlled by the Document management framework. The document type that is used to store ER artifacts of this type is configured in the ER parameters.

- On the **Electronic reporting jobs** page, select **Show files** to view the list of any errors and warnings that were generated during job execution.

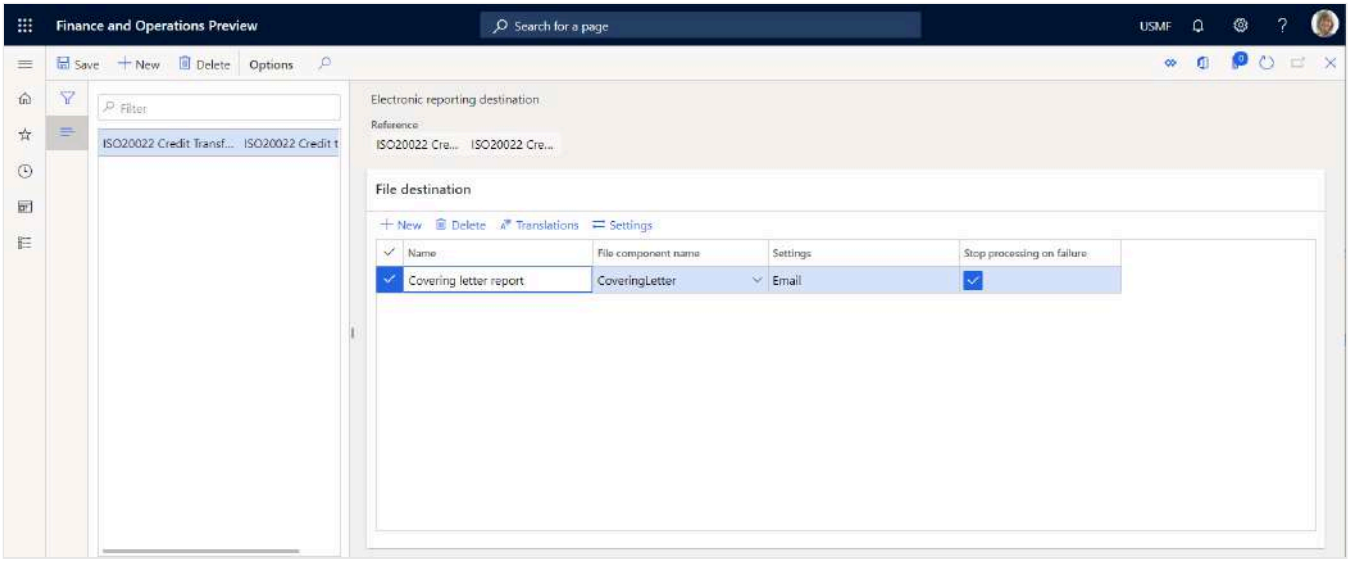


User-configured behavior

On the **Electronic reporting destination** page, you can override the default behavior for a configuration. Imported configurations don't appear on this page until you select **New** and then, in the **Reference** field, select a configuration to create destination settings for.



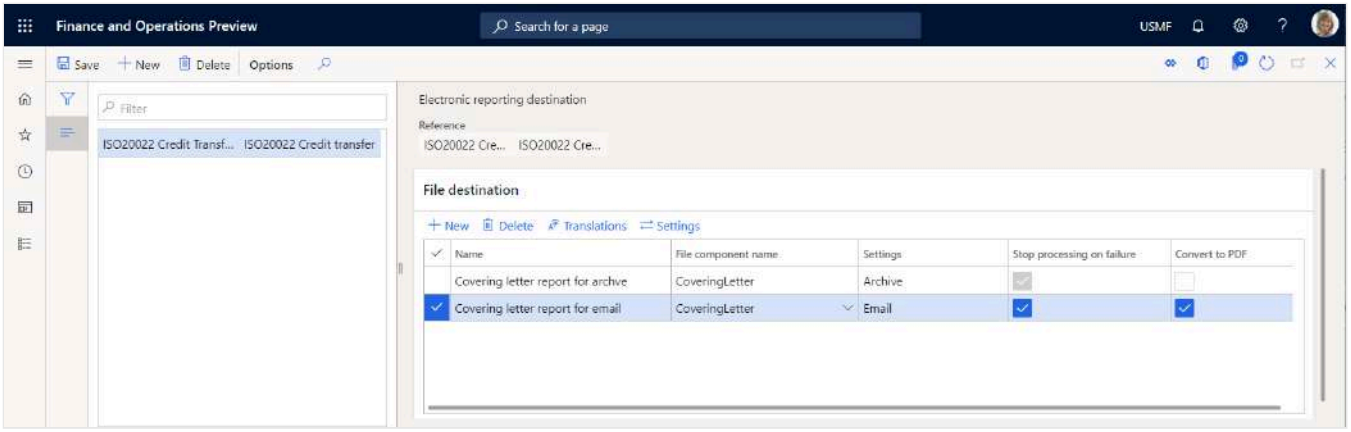
After you create a reference, you can create a file destination for each **Folder** or **File** output component of the referenced ER format.



Next, in the **Destination settings** dialog box, you can enable and disable individual destinations for the file destination. Use the **Settings** button to control all the destinations for a selected file destination. In the **Destination settings** dialog box, you can control each destination separately by setting the **Enabled** option for it.

You can create **multiple file destinations** for each output component of the same format. For example, you can use this capability to configure file destinations for a file component that's used to generate an outbound document in Excel format. One destination can be configured to store the original Excel file in the ER jobs archive, and another destination can be configured

to simultaneously convert the Excel file to PDF format and send the PDF file by email. Learn more in Archive, Email, and Convert.



When you run an ER format, the system always runs all destinations that you configured for components of the format. In addition, the ER destinations functionality lets you configure different sets of destinations for a single ER format. This configuration marks each set as configured for a particular user action. The ER API was extended so that an action can be provided that the user performs by running an ER format. The action code that is provided is passed to ER destinations. You can run different destinations of an ER format, depending on the action code that is provided. Learn more in Configure action-dependent ER destinations.

Destination types

The following destinations are currently supported for ER formats. You can disable or enable all types at the same time. In this way, you can either do nothing or send the component to all configured destinations.

- Email
- Archive
- File
- Screen
- Power BI
- Print

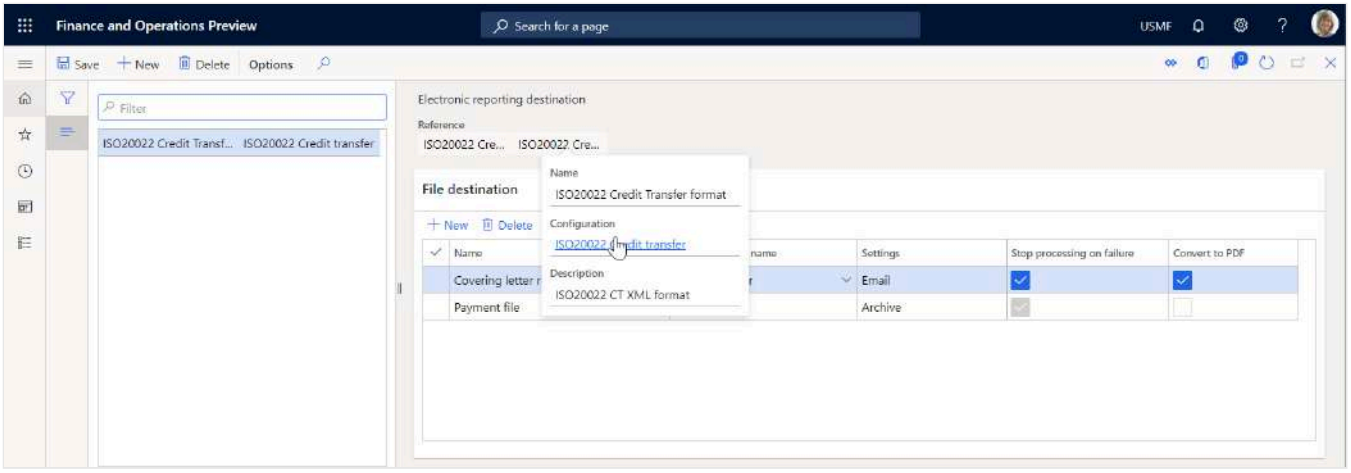
Applicability

You can set up destinations only for ER configurations that you import and for the formats that are available on the **Electronic reporting configurations** page.

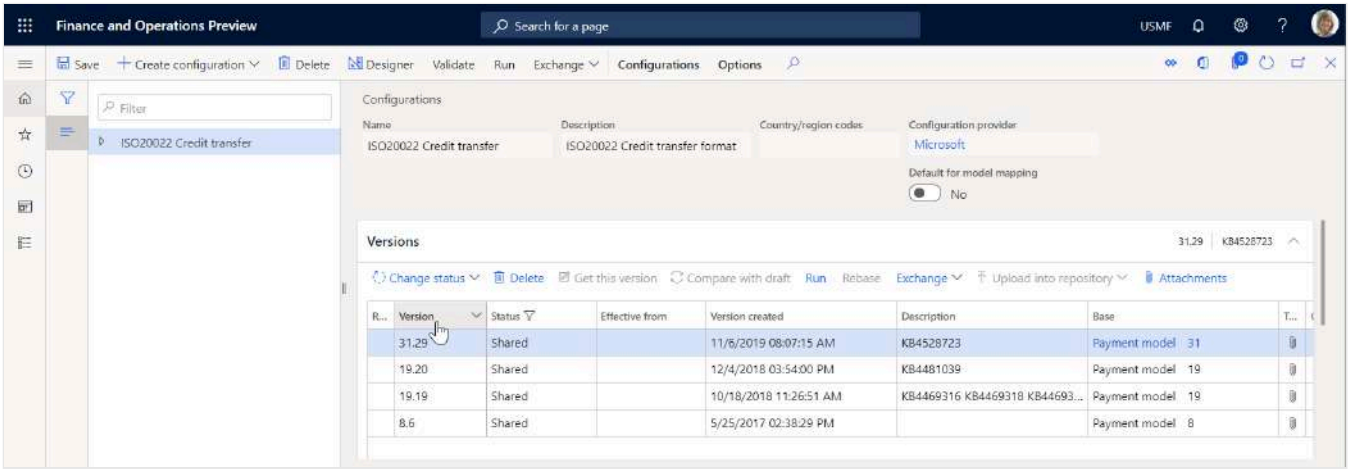
> ⓘ **Note**

Configured destinations are company-specific. If you plan to use an ER format in different companies of the current Finance instance, you must configure destinations for that ER format for each of those companies.

When you configure file destinations for a selected format, you configure them for the whole format.



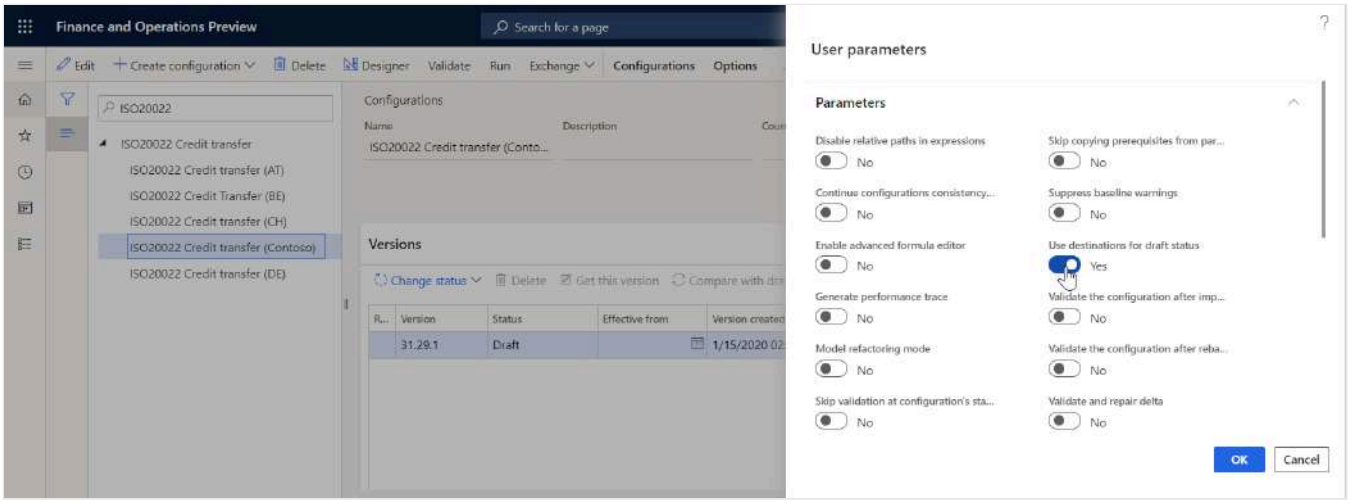
At the same time, you might have multiple versions of the format that you import into the current Finance instance. You can view them if you select the **Configuration** link that is offered when you select the **Reference** field.



By default, configured destinations are applied only when you run an ER format version that has a status of either **Completed** or **Shared**. However, you sometimes must use configured destinations when you run the draft version of an ER format. For example, you modify a draft version of your format, and you want to use configured destinations to test how the system delivers generated . Follow these steps to apply destinations for an ER format when the draft version is run.

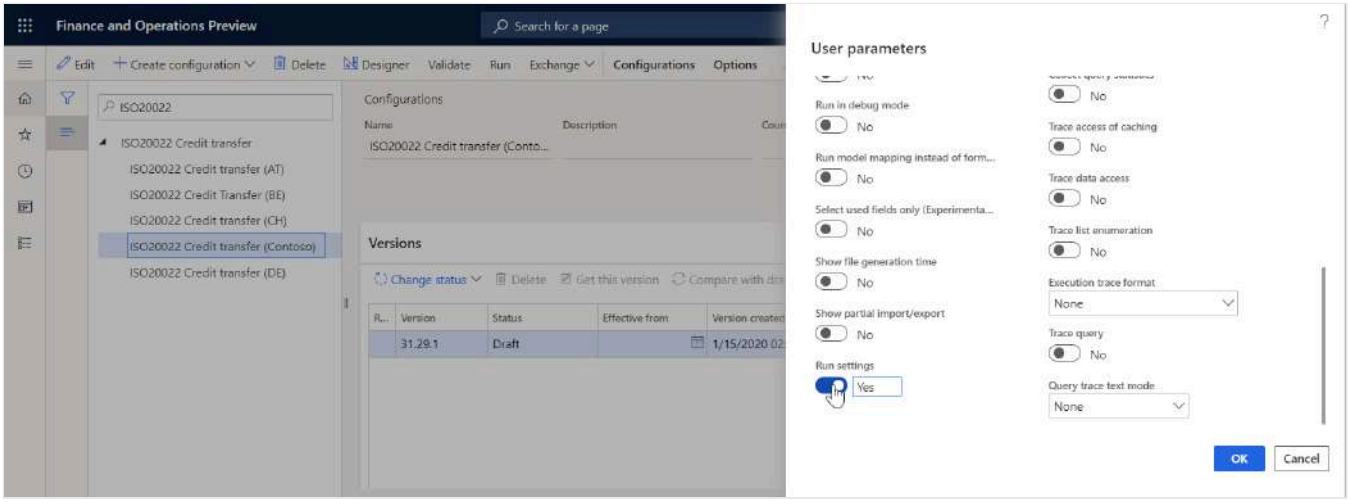
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.

3. Set the **Use destinations for draft status** option to **Yes**.

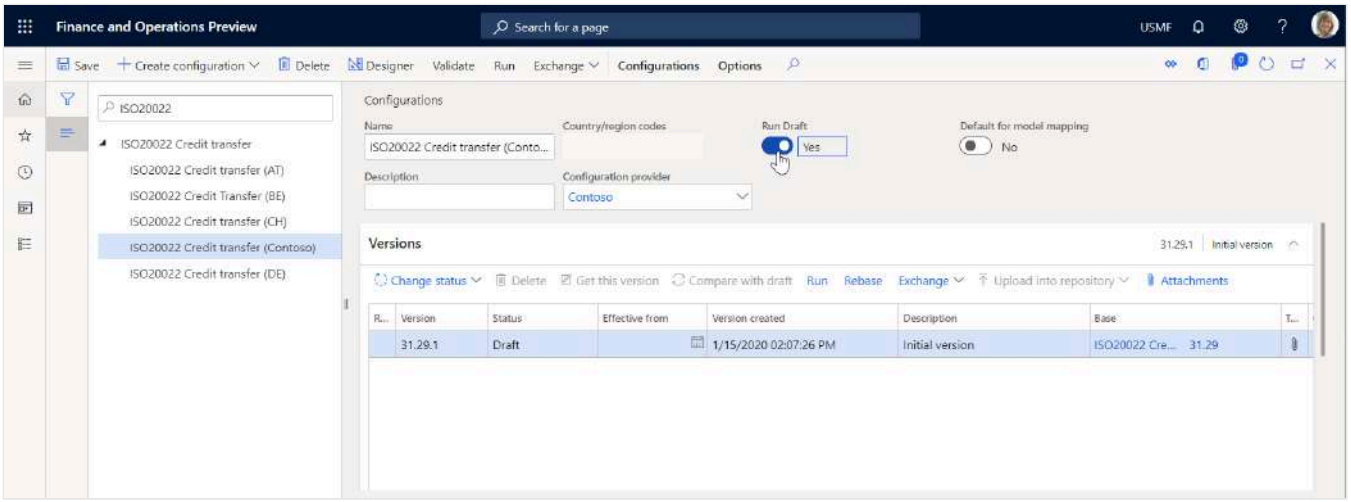


To use the draft version of an ER format, you must mark the ER format accordingly.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. Set the **Run setting** option to **Yes**.



After you complete this setup, the **Run draft** option is available for ER formats that you modify. Set this option to **Yes** to start to use the draft version of the format when the format is run.



Security considerations

Two types of privileges and duties are used for ER destinations. One type controls a user's overall ability to maintain the destinations configured for a legal entity (that is, it controls access to the **Electronic reporting destinations** page). The other type controls an application user's ability to override the destination settings that an ER developer or ER functional consultant configures at runtime.

Expand table

Role (AOT name)	Role name	Duty (AOT name)	Duty name
ERDeveloper	Electronic reporting developer	ERFormatDestinationConfigure	Configure electronic reporting format destination
ERFunctionalConsultant	Electronic reporting functional consultant	ERFormatDestinationConfigure	Configure electronic reporting format destination

Frequently asked questions

I imported electronic configurations, and I see them on the Electronic reporting configurations page. But why don't I see them on the Electronic reporting destinations page?

Make sure that you select **New** and then select a configuration in the **Reference** field. The **Electronic reporting destinations** page shows only configurations that you configure destinations for.

Is there any way to define which Microsoft Azure Storage account and Azure Blob storage are used?

No. The default Microsoft Azure Blob storage that is defined and used for the document management system is used.

What is the purpose of the File destination in the destination settings? What does that setting do?

The **File** destination controls a dialog box of your web browser when you run an ER format in interactive mode. If you enable this destination, or if you don't define a destination for a configuration, an open or save dialog box appears in your web browser after an file is created.

Can you give me an example of the formula that refers to a vendor account that I can send email to?

The formula is specific to the ER configuration. For example, if you use the ISO 20022 Credit Transfer configuration, you can use **'$PaymentsForCoveringLetter'.Creditor.Identification.SourceID** or **model.Payments.Creditor.Identification.SourceID** to get an associated vendor account.

One of my format configurations contains multiple files that are grouped into one folder (for example, Folder1 contains File1, File2, and File3). How do I set up destinations so that Folder1.zip isn't created at all, File1 is sent by email, File2 is sent to SharePoint, and I can open File3 immediately after the configuration runs?

Your format must first be available in the ER configurations. If this prerequisite is met, open the **Electronic reporting destination** page and create a new reference to the configuration. You must then have four file destinations, one for each component. Create the first file destination, give it a name such as **Folder**, and select a file name that represents a folder in your configuration. Then select **Settings**, and make sure that all the destinations are disabled. For this file destination, the folder isn't created. By default, because of hierarchical dependencies between files and parent folders, the files behave in the same way. In other words, they aren't sent anywhere. To override that default behavior, you must create three more file destinations, one for each file. In the destination settings for each, you must enable the destination that the file should be sent to.

More information

Electronic reporting (ER) overview

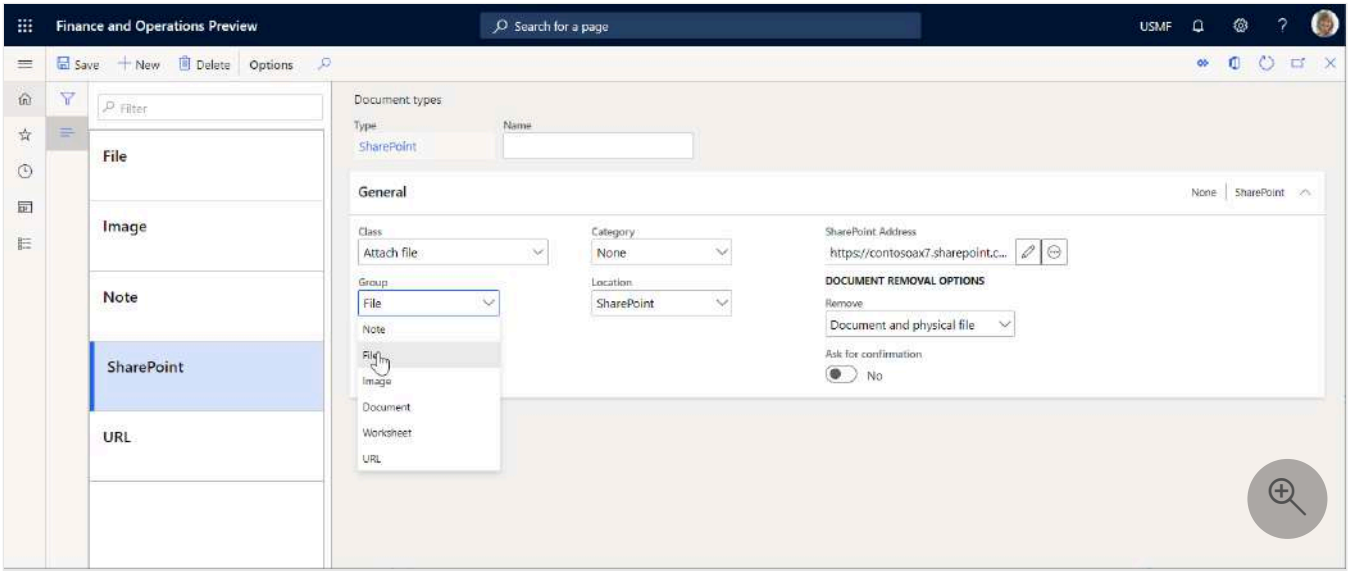
Configure action-dependent ER destinations

Archive ER destination type

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can configure an archive destination for each **Folder** or **File** component of an Electronic reporting (ER) format configured to generate outbound documents. Based on the destination setting, the system stores a generated document as an attachment of a record in the ER jobs list. To view the results, go to **Organization administration** > **Electronic reporting** > **Electronic reporting jobs**.

Use this option to send the generated document to a Microsoft SharePoint folder or Microsoft Azure Storage. Set **Enabled** to **Yes** to send output to a destination that the selected document type defines. You can only select document types where the group is set to **File**. You define document types at **Organization administration** > **Document management** > **Document types**. The configuration for ER destinations is the same as the configuration for the document management system.

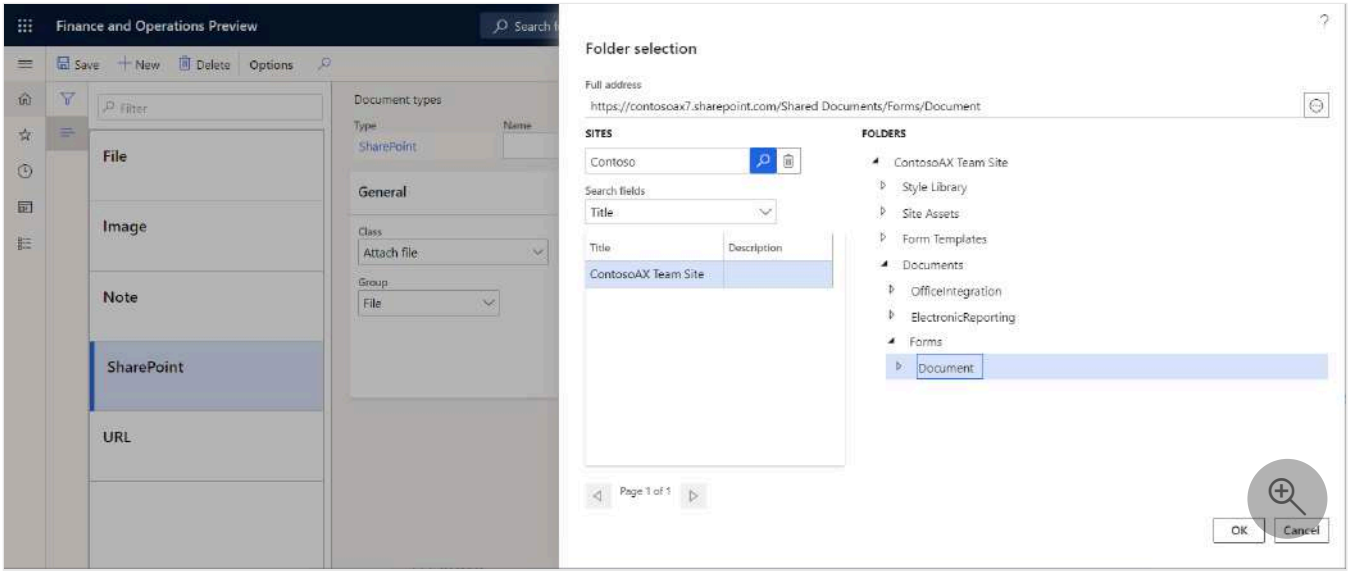


The location determines where the file is saved. After you enable the **Archive** destination, the results can be saved in the Job archive. You can view the results at **Organization administration** > **Electronic reporting** > **Electronic reporting archived jobs**.

> **Note**
>
> Select a document type for the Job archive by navigqting to **Organization administration** > **Workspaces** > **Electronic reporting** > **Electronic reporting parameters**. For more information, see Configure the Electronic reporting (ER) framework.

SharePoint

You can save a file in a designated SharePoint folder. To define the default SharePoint server, go to **Organization administration** > **Document management** > **Document management parameters**. On the **SharePoint** tab, configure the SharePoint folder. Then, you can select it as the folder where the ER output is saved. You must select the **SharePoint** location in this document type.



Azure Storage

When the document type location is set to **Azure storage**, you can save a file to Azure Storage.

> **Note**
>
> Unlike the Data management framework, which applies a seven-day retention policy for documents that must be processed, the ER framework permanently stores files in Azure Blob storage. For more information, see API for getting message status and Status check API. The ER-related files are stored in Azure Blob storage as attachments of application

table records for as long as necessary. A single file is deleted from Azure Blob storage along with the application table record that this file was attached to.

Last updated on 04/15/2026

Email ER destination type

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you run an Electronic reporting (ER) format, you can generate one or more outbound documents. Use **Folder** or **File** format components in ER formats to specify the structure of outbound documents. You can configure an email destination for these types of components to send outbound documents as email attachments.

You can configure an email destination for each **Folder** or **File** component of an ER format. In this case, **each outbound document is emailed individually**. Based on this destination setting, a generated document is delivered as an attachment of an email.

> **Note**
>
> If no document is generated because the **Enabled** expression for the relevant **File** component returns a **False** Boolean value, no email is sent, even if an email destination an email destination is configured and enabled for the component.

You can also group several **Folder** or **File** components together, and then configure an email destination for all the components in the group. In this case, all outbound documents that components in the group generate **are sent as multiple attachments of a single email**. Based on this destination setting, each generated document is delivered as an attachment of a single email.

> **Note**
>
> If at least one document is generated by a **File** component in a group of components, an email is sent. If no document is generated by grouped components because the **Enabled** expression for each **File** component returns a **False** Boolean value, no email is sent, even if an email destination is configured and enabled for that group of components.

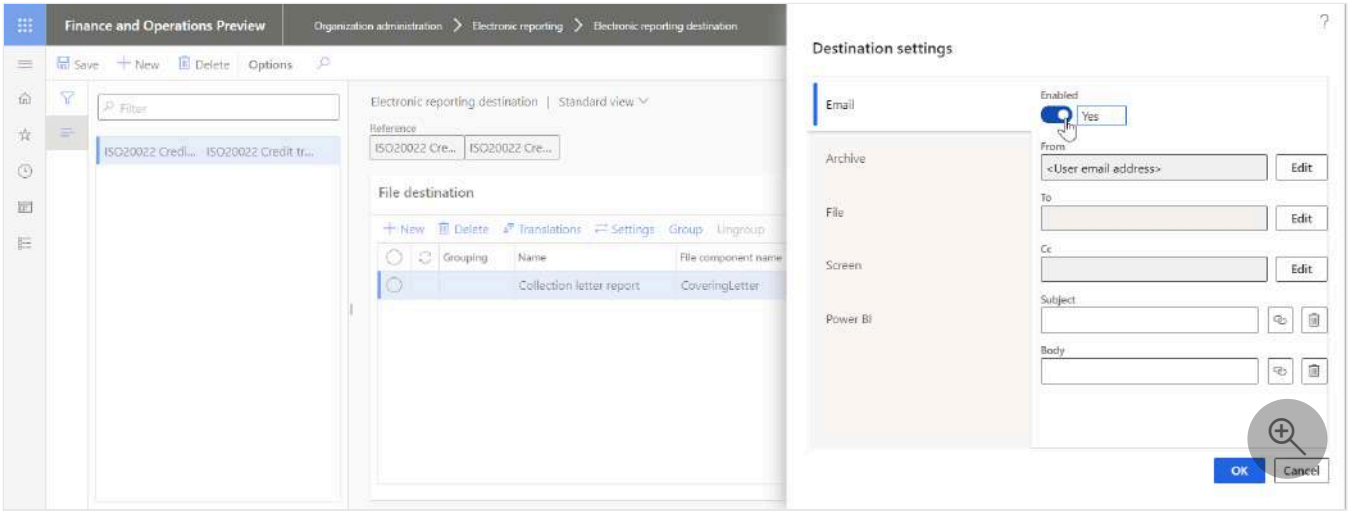
Email is the only destination that you can configure for a group of components. To deliver a document that is emailed based on the email destination setting for a group, add one more destination record, select the component that you want, and then configure another destination for this record.

You can configure multiple groups of components for a single ER format configuration. In this way, you can configure an email destination for every group of components and an email destination for every component.

Enable an email destination

To send one or more output files by email, follow these steps:

1. On the **Electronic reporting destination** page, on the **File destination** FastTab, select a component or group of components in the grid.
2. Select **Settings**, and then, in the **Destination settings** dialog box, on the **Email** tab, set the **Enabled** option to **Yes**.



Configure an email destination

Email content

You can edit the subject and body of the email message.

In the **Subject** field, enter the text of the email subject that should appear in the subject field of an electronic message that is generated at runtime. In the **Body** field, enter the text of the email body that should appear in the body field of an electronic message. You can set up constant text for the email subject and body, or you can use ER formulas to dynamically create email text at runtime. The configured formula must return a value of the String type.

The body of your email is composed in TEXT or HTML format, depending on the email client. You can use any layout, styling, and branding that HTML and inline Cascading Style Sheets (CSS) allow for.

> ⓘ **Note**
>
> Email clients impose layout and style limitations that might require adjustments to the HTML and CSS that you use for the message body. Familiarize yourself with the best practices for creating HTML that the most popular email clients support.
>
> Use the correct encoding to implement a carriage return, depending on the body formatting. For more information, see the definition of the **String** data type.

Email addresses

You can specify the email sender and email recipients. By default, an email is sent on behalf of the current user. To specify a different email sender, configure the **From** field.

> ⓘ **Note**
>
> When you configure an email destination, only users with the `ERFormatDestinationSenderEmailConfigure` security privilege, **Configure the sender email address for ER format destinations**, can see the **From** field.
>
> When an email destination is offered for modification at **runtime**, the **From** field is visible only to users who have the `ERFormatDestinationSenderEmailMaintain` security privilege, **Maintain the sender email address for ER format destination**.
>
> When you configure the **From** field to use an email address other than the current user's, you must correctly **set** either the **Send as** or **Send on behalf** permission in advance. Otherwise, the following exception is thrown at runtime: "Unable to send email as <from email account> from the <current user account> account, please check the 'Send as' permissions on the <from email account>."

You can configure the **From** field to return more than one email address. In this case, the first address in the list is used as the email sender address.

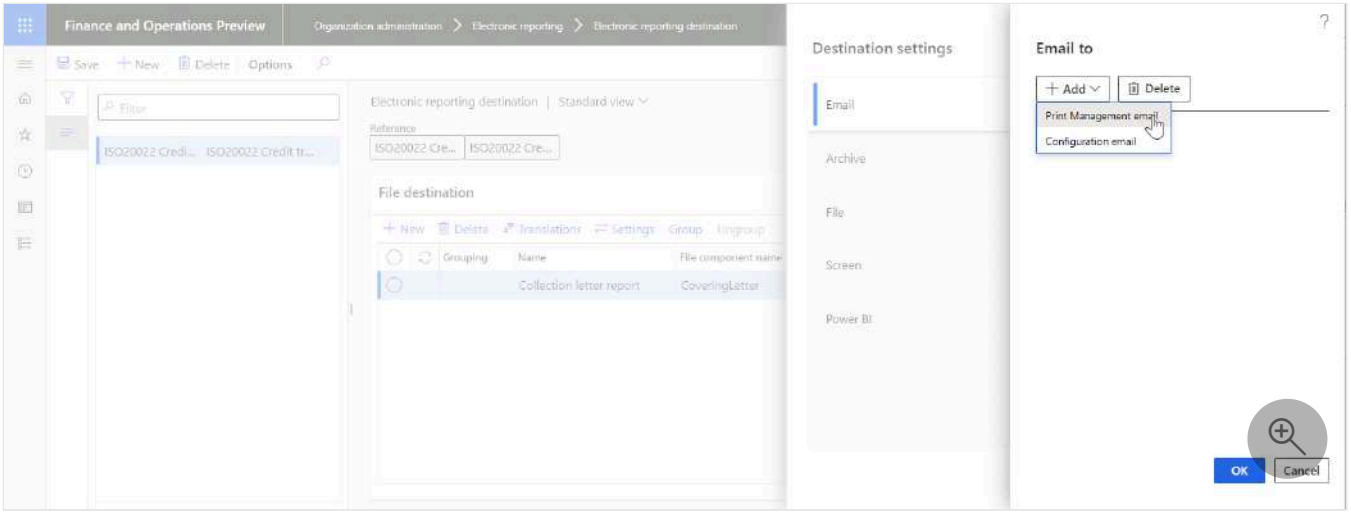
To specify email recipients, configure the **To** and **Cc** (optional) fields.

As of version 10.0.48, you can also configure **BCC** (optional) field.

You can configure email addresses for ER in two ways. You can complete the configuration in the same way as the Print Management feature, or you can resolve an email address by using a direct reference to the ER configuration through a formula.

Email address types

If you select **Edit** next to the **From**, **To**, **Cc**, or **BCC** field in the **Destination settings** dialog box, the appropriate **Email from**, **Email to**, **Email cc**, or **Email BCC** dialog box appears. You can configure the email sender and email recipients. Select **Add**, and then select the type of email address to use. Two types are currently supported: **Print Management email** and **Configuration email**.



Print Management email

If you select **Print Management email** as the email address type, enter fixed email addresses in the **Email from**, **Email to**, **Email cc**, or **Email BCC** dialog box by setting the following fields:

- In the **Email source** field, select **None**.
- In the **Additional email addresses, separated by ";"** field, enter the fixed email addresses.

Alternatively, you can get email addresses from the contact details of the party that you generate an outbound document for. To use email addresses that aren't fixed, in the **Email source** field, select the role of the party for a file destination. The following roles are supported:

- Customer
- Vendor
- Prospect
- Contact

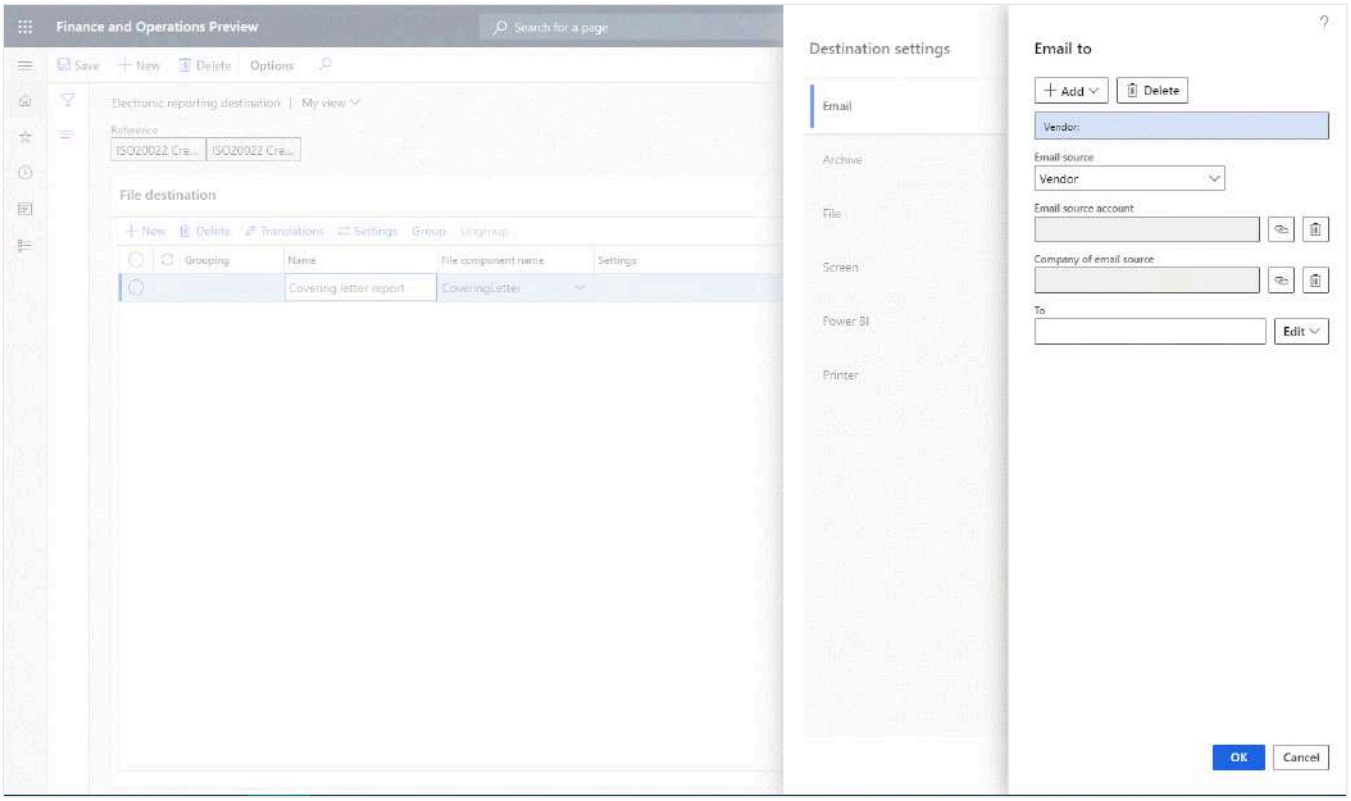
- Competitor
- Worker
- Applicant
- Prospective vendor
- Disallowed vendor
- Legal entity

For example, to configure an email destination for an ER format that is used to process vendor payments, select the **Vendor** role.

After you select the desired role, select the **Bind** button (chain symbol) next to the **Email source account** field to open the Formula designer page. You can then use this page to configure a formula that returns, at runtime, the account number of the party that is assigned to the configured role from the processed document to the email destination.

> **Note**
>
> Formulas are specific to the ER configuration.

On the **Formula designer** page, in the **Formula** field, enter a document-specific reference to a supported role. Instead of typing the reference, in the **Data source** pane, find and select the data source node that represents an account of the configured role, and then select **Add data source** to update the formula. For example, if you configure the email destination for the **ISO 20022 Credit Transfer** configuration that is used to process vendor payments, the node that represents a vendor account is `'$PaymentsForCoveringLetter'.Creditor.Identification.SourceID`.



If the account numbers of the configured role are unique for the whole instance of Microsoft Dynamics 365 Finance, the **Company of email source** field in the **Email to** dialog box can remain blank.

Alternatively, you might have a situation where different parties in the Global address book are registered in different companies (legal entities) in such a way that they all use the same account number to fill the configured role. In this case, account numbers for the configured role aren't unique for the whole Finance instance. Therefore, to explicitly select a party, you can't specify only an account number. You must also specify the company with the scope that the party is registered in to fill the configured role. Select the **Bind** button (chain symbol) next to the **Company of email source** field in the **Email to** dialog box to open the Formula designer page. You can then use this page to configure a formula that returns, at runtime, the code of the company that the desired source must be found in the scope of.

> **Tip**
>
> If you must use the company code to run an ER format, but the ER format doesn't provide any data source that the company code can be obtained from, configure the `GetCurrentCompany()` formula by using the built-in GETCURRENTCOMPANY ER function.

> **Note**

Formulas are specific to the ER configuration.

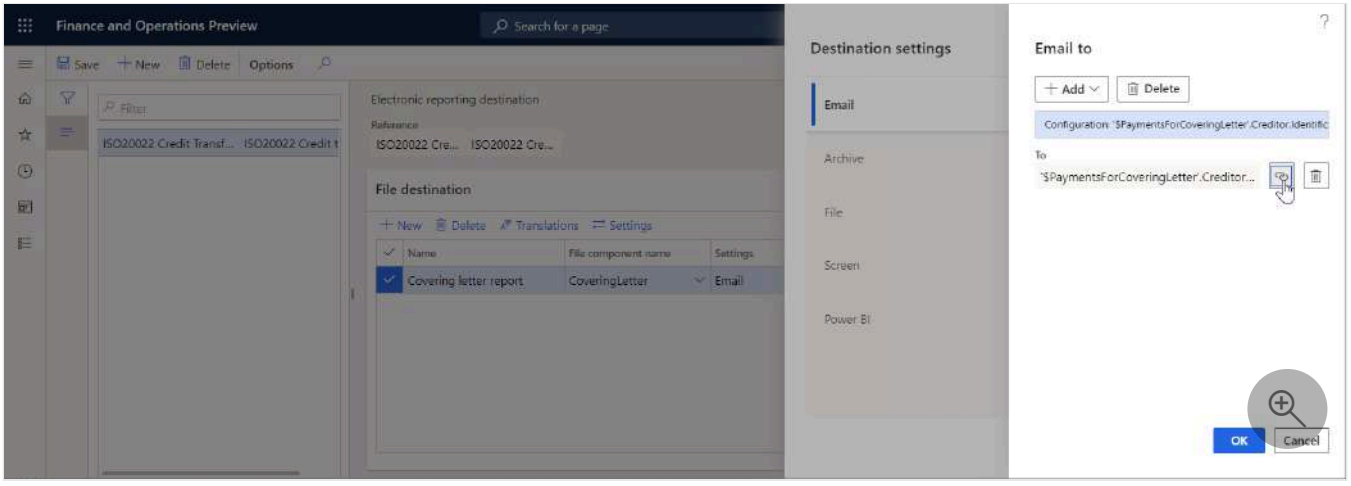
To specify the type of email addresses that must be used at runtime, in the **Email to** dialog box, select **Edit** next to the **To** field to open the **Assign email address** drop-down dialog box. Then set the following fields:

- In the **Purpose** field, select the desired purposes. Only email addresses of the selected purposes from contacts of the discovered party are used.
- Set the **Primary contact** option to **Yes** to use an email address that is configured for the discovered party as the primary email address.

> **Note**
>
> If you select purposes in the **Purpose** field and set the **Primary contact** option to **Yes** at the same time, every email that satisfies at least one configured criterion is used at runtime.

Configuration email

Select **Configuration email** as the email address type if the configuration that you use has a node in the data sources that returns either a single email address or multiple email addresses that are separated by semicolons (;). You can use data sources and functions in the formula designer to get a correctly formatted email address or correctly formatted email addresses that are separated by semicolons. For example, if you use the **ISO 20022 Credit Transfer** configuration, the node that represents the primary email address of a vendor from the vendor contact details that the covering letter should be sent to is `'$PaymentsForCoveringLetter'.Creditor.ContactDetails.Email`.



Group format components

To group format components, on the **Electronic reporting destination** page, on the **File destination** FastTab, select the components in the grid, and then select **Group**.

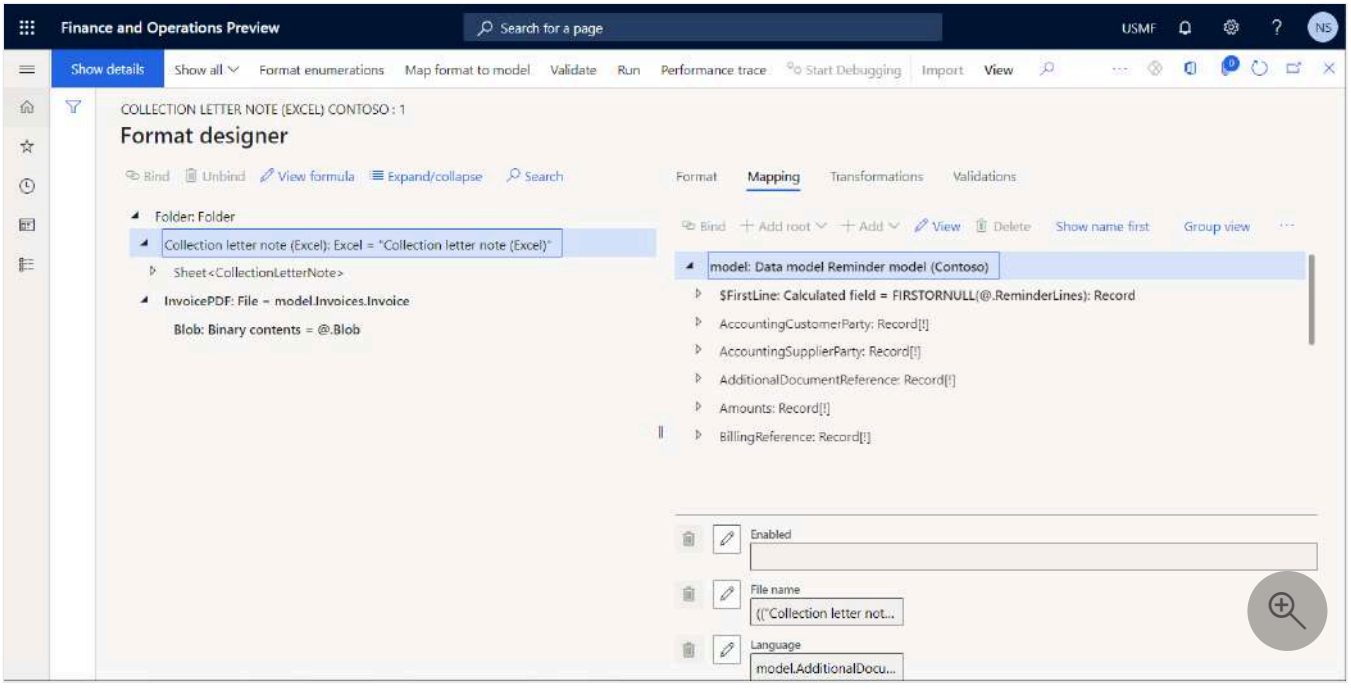
Email is the only previously configured destination that is still available for the selected components. No other previously configured destinations are available, because they're considered unsupported for a group of components. You're notified about these changes as appropriate.

The record that you previously added is considered the header of the created group. This header record holds the email destination settings for the group. Other records are group members that use the email destination settings of the group's header record.

To ungroup format components, on the **File destination** FastTab, select a record that belongs to the group, and then select **Ungroup**.

- If you select a header record, the whole group is ungrouped.
- If you select a member record, and it's the last member record in a group, the whole group is ungrouped.
- If you select a member record that isn't the last member record in a group, that record is excluded from the current group.

The following illustration shows the structure of an ER format configured to produce a zipped outbound file that contains a collection letter note and appropriate customer invoices in PDF format.



The following illustration shows the process, as described in this article, of grouping individual components and enabling the **Email** destination for the new group, so that a collection letter note is sent together with appropriate customer invoices as email attachments.

Power BI destination

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can configure a Microsoft Power BI destination for each folder or file component of an Electronic reporting (ER) format configured to generate outbound documents. Based on the setting of the destination, a generated document is stored in a previously configured SharePoint folder.

Set **Enabled** to **Yes** to use your ER configuration to arrange the transfer of data from your Dynamics 365 Finance instance to Microsoft Power BI services. The transferred files are stored on a Microsoft SharePoint Server instance that you must configure for that purpose. For more information, see Configure Electronic reporting (ER) to pull data into Power BI.

Printer destination

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can send a generated document directly to a network printer for direct printing.

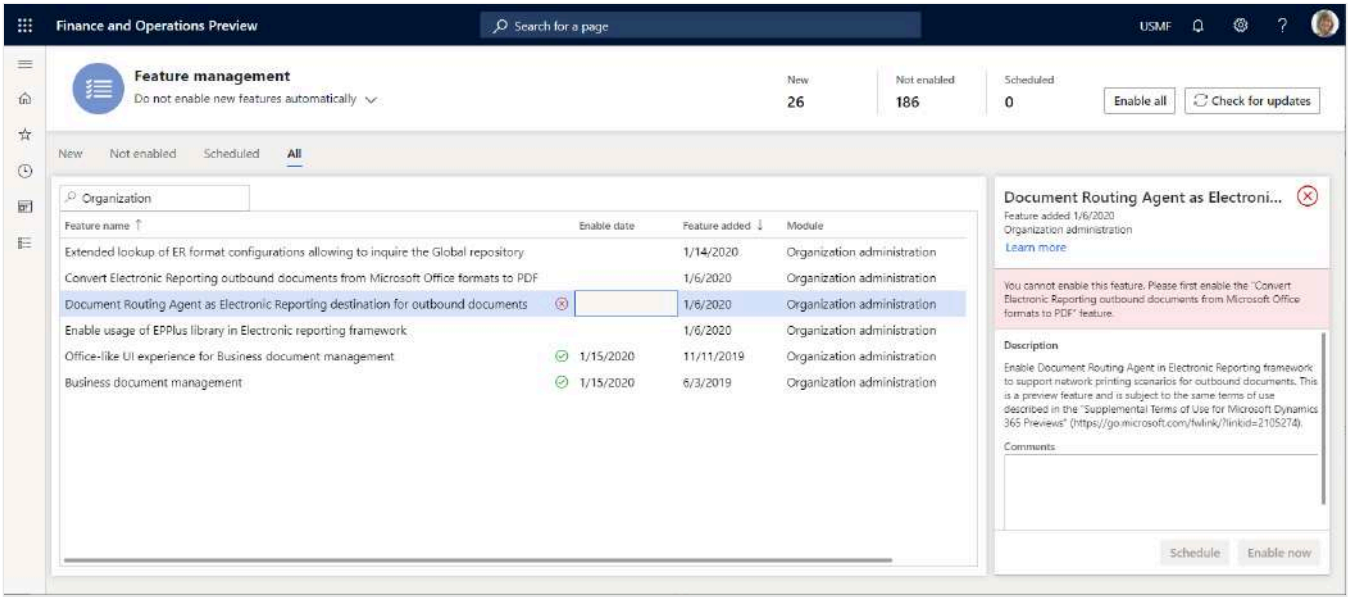
Prerequisites

Before you begin, install and configure the Document Routing Agent, and then register the network printers. For more information, see Install the Document Routing Agent to enable network printing.

Make the Printer destination available

To make the **Printer** destination available in the current instance of Microsoft Dynamics 365 Finance, go to the **Feature management** workspace, and turn on the following features, in this order:

1. Convert Electronic Reporting outbound documents from Microsoft Office formats to PDF
2. Document Routing Agent as Electronic Reporting destination for outbound documents

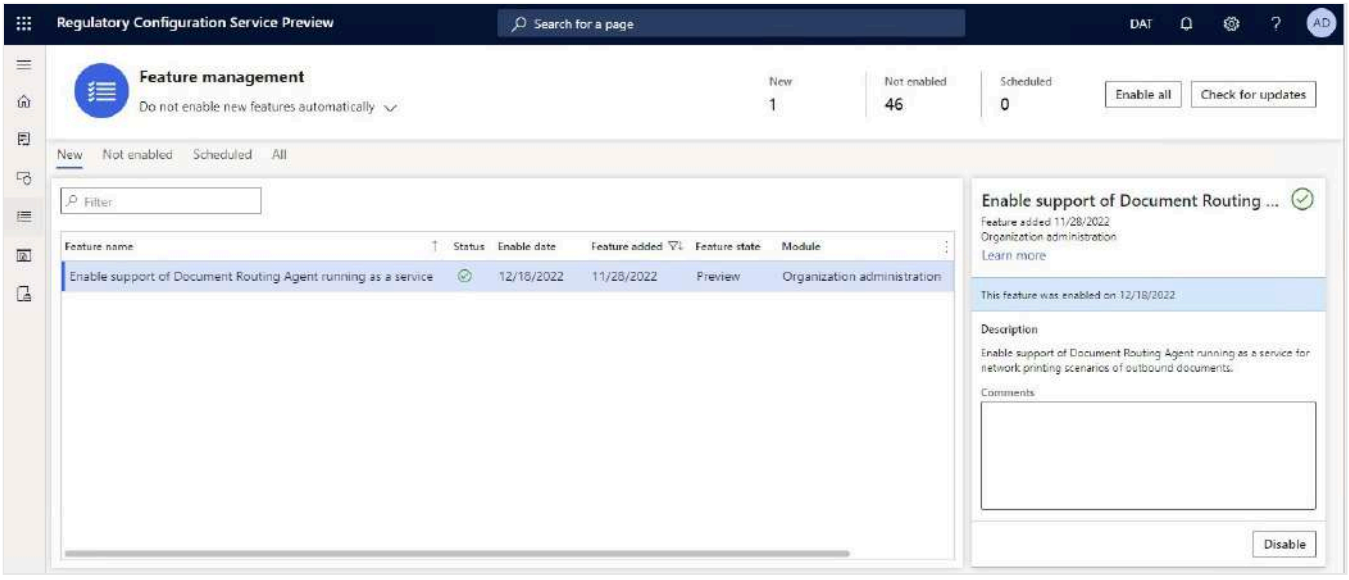


> **Note**
>
> As of Finance version 10.0.32, the **Convert Electronic Reporting outbound documents from Microsoft Office formats to PDF** and **Document Routing Agent as Electronic Reporting destination for outbound documents** features are removed. The functionality that these features controlled is now enabled by default.

Run the Document Routing Agent as a service

The Document Routing Agent lets you select the mode of execution. The process can run either as a desktop application or as a Windows service. For more information, see Run the Document Routing Agent as a Windows service.

As of Finance version 10.0.32, the capability to support running the Document Routing Agent as a Windows service is implemented. To activate this capability in the system, turn on the **Enable support of Document Routing agent running as a service** feature in the **Feature management** workspace.



Applicability

PDF printing

> **Note**
>
> You can print PDF documents directly to a network printer only if the Document Routing Agent is running as a desktop application. If the Document Routing Agent is running as a service, PDF documents aren't sent directly to a printer. Instead, they're stored in a target

folder. You must configure this folder in advance in the Document Routing Agent's parameters. For more information, see **Update the execution mode for the Document Routing Agent**.

To continue sending printable documents directly to a printer when the Document Routing Agent is running as a service, use **EMF printing**.

In versions of Finance before version 10.0.18, you can configure the **Printer** destination only for file components that generate output in printable PDF format (**PDF Merger** or **PDF file** format elements) or Microsoft Office Excel and Word format (**Excel file** format element). When you generate the output in PDF format, it's sent to a printer. When you generate the output in Office format by using the **Excel file** format element, it's automatically converted to PDF format and then sent to a printer.

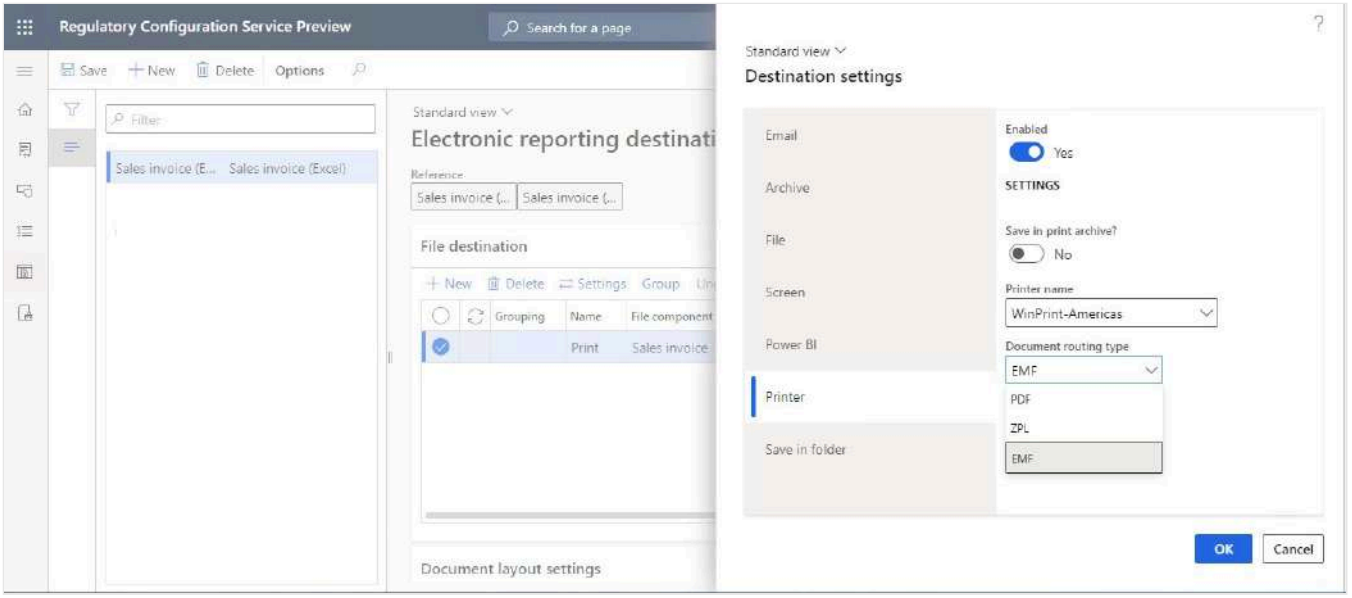
However, as of version 10.0.18, you can configure the **Printer** destination for the **Common file** format element. This format element mostly generates output in either TXT or XML format. You can configure an ER format that contains the **Common file** format element as the root format element and the **Binary contents** format element as the only nested element under it. In this case, the **Common file** format element produces output in the format that you specify by the binding that you configure for the **Binary contents** format element. For example, you can configure this binding to fill in this element with the content of a Document management attachment in PDF or Office (Excel or Word) format. You can print out the output by using the configured **Printer** destination.

> ⓘ **Note**
>
> When you select the **Common\File** format element to configure the **Printer** destination, there's no way to guarantee, at design time, that the selected element produces output in PDF format or output that can be converted to PDF format. Therefore, you receive the following warning message: "Please, make sure that the output that is generated by selected format component can be converted to PDF. Otherwise, uncheck the 'Convert to PDF' option." You must take steps to help prevent runtime issues when non-PDF or non-PDF-convertible output is provided for printing at runtime. If you expect to receive output in Office (Excel or Word) format, the **Convert to PDF** option must be selected.
>
> In version 10.0.26 and later, to use the **Convert to PDF** option, you must select **PDF** for the **Document routing type** parameter of the configured **Printer** destination.

EMF printing

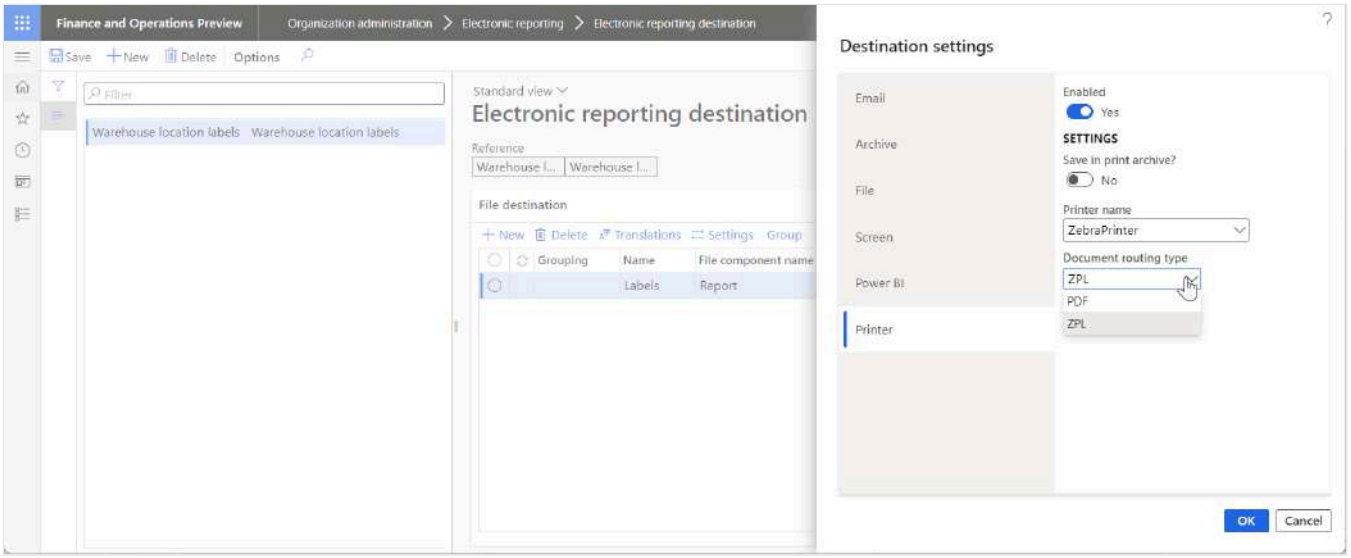
As of Finance version 10.0.32, the capability to generate outbound documents in Enhanced Metafile (EMF) format is implemented. To activate this capability, follow these configuration steps.

1. Make sure that the Enable support of Document Routing agent running as a service feature is turned on in Feature management.
2. Configure the **Printer** destination for the required format component by selecting **EMF** for the **Document routing type** parameter.



ZPL printing

In version 10.0.26 and later, you can configure the **Printer** destination for the **Common\File** format element by selecting **ZPL** for the **Document routing type** parameter. In this case, the **Convert to PDF** option is ignored at runtime, and the TXT or XML output is sent directly to a selected printer by using the Zebra Programming Language (ZPL) contract of the Document routing agent (DRA). Use this feature for an ER format that represents a ZPL II label layout to print various labels.



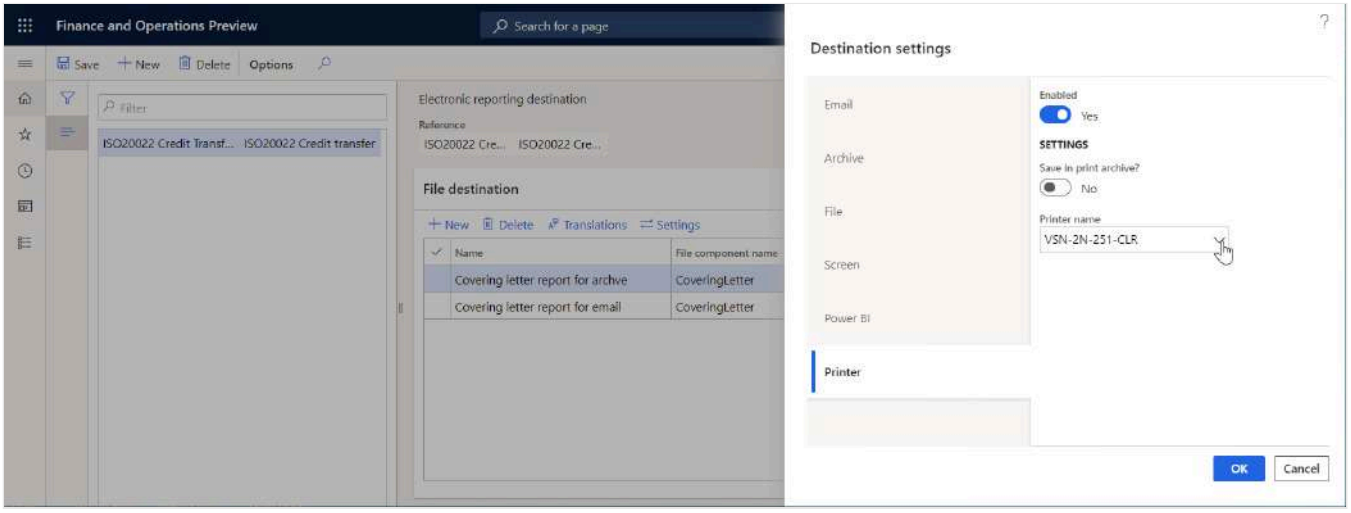
For more information about this feature, see Design a new ER solution to print ZPL labels.

Limitations

The **Printer** destination works only for cloud deployments.

Use the Printer destination

1. Set the **Enabled** option to **Yes** to send a generated document to a printer.
2. In the **Printer name** field, select the required network printer.
3. Set the **Save in print archive?** option to **Yes** to store the generated output in the print archive, so that it's available for further printing. To access archived output later, go to **Organization administration** > **Inquiries and reports** > **Report archive**.



> **Note**
>
> You don't need to turn on the **Convert to PDF** option when you configure the **Printer** destination. The PDF conversion for printing purposes happens even if the option is

turned off.

To use a specific page orientation when you print an outbound document in Excel format, you must turn on the **Convert to PDF** option. When you set the **Convert to PDF** option to **Yes**, the **Page orientation** field becomes available. In the **Page orientation** field, you can select a page orientation.

Additional resources

Last updated on 04/15/2026

ER Configure destinations

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure shows how to set up and use different destinations for Electronic reporting (ER) output components, such as a folder or a file. The demo data company used to create this procedure is DEMF. Germany is the country\region of the legal entity's primary address, but you can use any legal entity for this procedure.

The format used in this example is ISO20022 Credit transfer, but you can use any format that you already imported. This procedure is an example of a single file and a single destination setup. For more information about Electronic reporting destination management, see Dynamics 365 Finance Help.

1. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting destination**.
2. Select **New** to create a new set of destinations for a format.
3. In the **Reference** field, select a format for which you want to configure destinations.

    - If you don't see a value to select, it means that you didn't import any Electronic reporting format configurations. You must import a format configuration before setting up destinations.

4. Select **New** to create a new file destination.

    - You can create one file destination for each output component of the same format, such as a folder or a file. You can enable and disable destinations separately in the settings.

5. In the **Name** field, enter the user-friendly name of output component.

    - Use meaningful names, such as "Payment file" or "Control report". Users see these names at configuration runtime along with the destination settings.

6. In the **File name**, select a file or folder that is specific to the format.
7. Select **Settings**.
8. Select **Yes** in the **Enabled** field.

    - The **Enabled** check box on each tab enables and disables each destination separately. In this example, you enable sending an output file to a mail recipient when the file is generated.

9. Select **Edit**, to set up email recipients.
10. Select **Add**.
11. Select **Print Management email**.
12. In the **Email source** field, select an option.

    - You can select different email source types, such as a customer or a vendor type. This option defines the type of argument that the **Email source account** formula returns. The **Email source account** formula, described in a following step, is the place where you bind an email source. Select **Vendor** if your formula returns a vendor account. Use **Vendor** if you're using the ISO 20022 Credit Transfer configuration example.

13. Select **Email source** bind button.
14. In the **Formula**, enter a document-specific reference to a party type that you selected earlier.

    - Instead of typing, you can find a data source node that represents the party account, and select the **Add data source** button to update the formula. For example, if you use the ISO 20022 Credit Transfer configuration, the node representing a vendor account is `$PaymentsForCoveringLetter.Creditor.Identification.SourceID`. Otherwise, enter any string value, such as "DE-001", to save a formula.

15. Select **Save**.
16. Close the page.
17. Select **Edit** to configure contact details for the party.
18. Select **Yes** in the **Primary contact** field.

    - You can use different options to indicate what contact type of the party should be used as an email address for this destination. This example uses primary contact.

19. Select **OK**.
20. Select **OK**.

21. In the **Subject** field, type a value.
22. Select **OK**.

Configure action-dependent ER destinations

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can configure destinations for each output component (folder or file) of an Electronic reporting (ER) format configuration that helps generate an outbound document. Users who run an ER format of this type and have appropriate access rights can also change the configured destination settings at runtime.

In Microsoft Dynamics 365 Finance **version 10.0.17 and later**, an ER format can be run by provisioning an action code that the user performs by running that ER format. For example, in the **Accounts receivable** module, in the Print management settings, you can select an ER format that generates a specific business document, such as a free text invoice. You can then select **View** to preview the invoice or **Print** to send it to a printer. If a user action is passed for the running ER format at runtime, you can configure different ER destinations for different user actions. This article explains how to configure ER destinations for this type of ER format.

Make action-dependent ER destinations available

To configure action-dependent ER destinations in the current Finance instance and enable the new ER API, open the Feature management workspace, and turn on the **Configure specific ER destinations to be used for different PM actions** feature. To use configured ER destinations for reports at runtime, enable the **Route output of PM reports based on ER destinations that are user action specific (wave 1)** feature.

Configure action-dependent ER destinations

When you turn on the **Configure specific ER destinations to be used for different PM actions** feature, you can configure action-dependent ER destinations on the **File destination** FastTab of the **Electronic reporting destination** page. For each component, you can add a record and enable specific ER destinations. For each record, you must specify the type of document that the configured ER destinations should apply to. In the **Document type** field, select one of the following values:

- Select **Electronic** to apply the configured destinations if no user action code is provided at runtime.
- Select **Print management** to apply the configured destinations if a user action code is provided at runtime.
- Select **Any** to always apply the configured destinations, regardless of whether a user action is provided at runtime.

If you select the **Print management** document type, you must specify the user actions that the configured ER destinations should apply to. In the **Print management action** field, select one of the following values:

- Select **View** to apply the configured destinations if the **View** user action is provided at runtime.
- Select **Print** to apply the configured destinations if the **Print** user action is provided at runtime.
- Select **Send** to apply the configured destinations if the **Send** user action is provided at runtime.

> **Note**
>
> Multiple actions can be selected for a single destination record.

If you select the **Any** document type, **Autodetect** is automatically selected in the **Print management action** field as a user action, and the following behavior occurs:

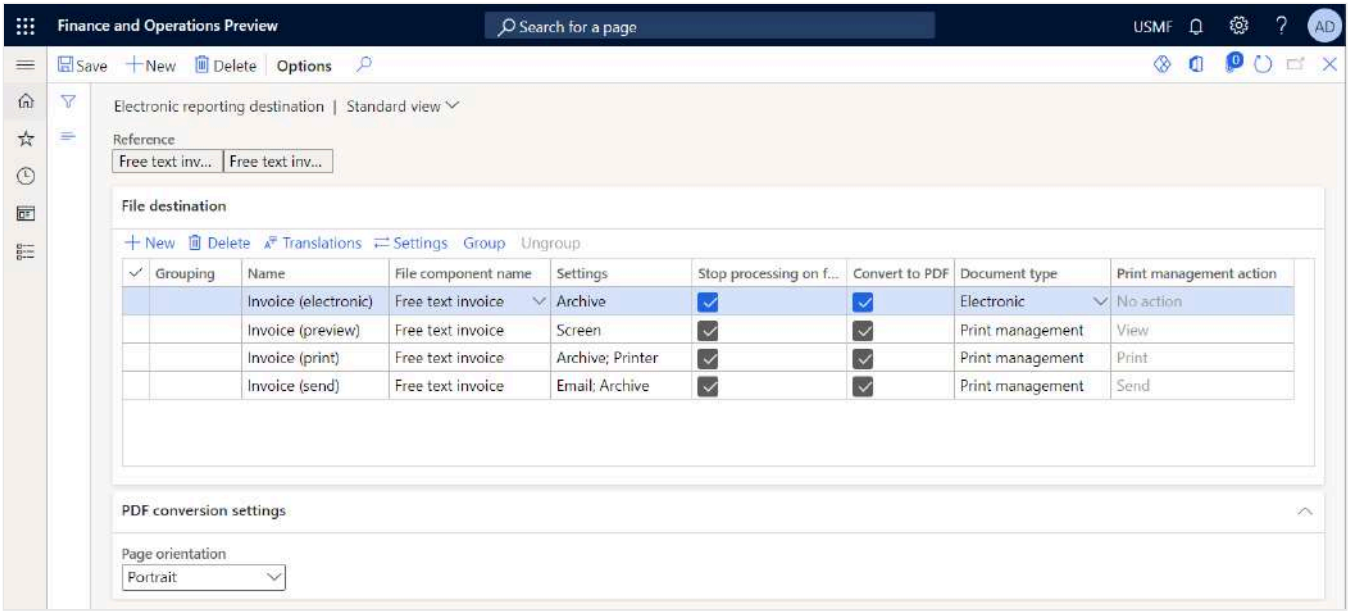
- If no user action code is provided at runtime, all configured ER destinations are applied.
- If a user action code is provided at runtime, an ER destination that is predefined for a specific action is applied, **regardless of whether it's enabled**:
  - When the **View** action is provided at runtime, the **Screen** ER destination is applied.
  - When the **Send** action is provided at runtime, the **Email** ER destination is applied.
  - When the **Print** action is provided at runtime, the **Printer** ER destination is applied.

For example, you can use the **Free text invoice (Excel)** ER format to print a free text invoice when you post it. To route a generated document, you must configure ER destinations for this ER format. For example, you might need to configure these ER destinations to perform the following actions on a generated document:

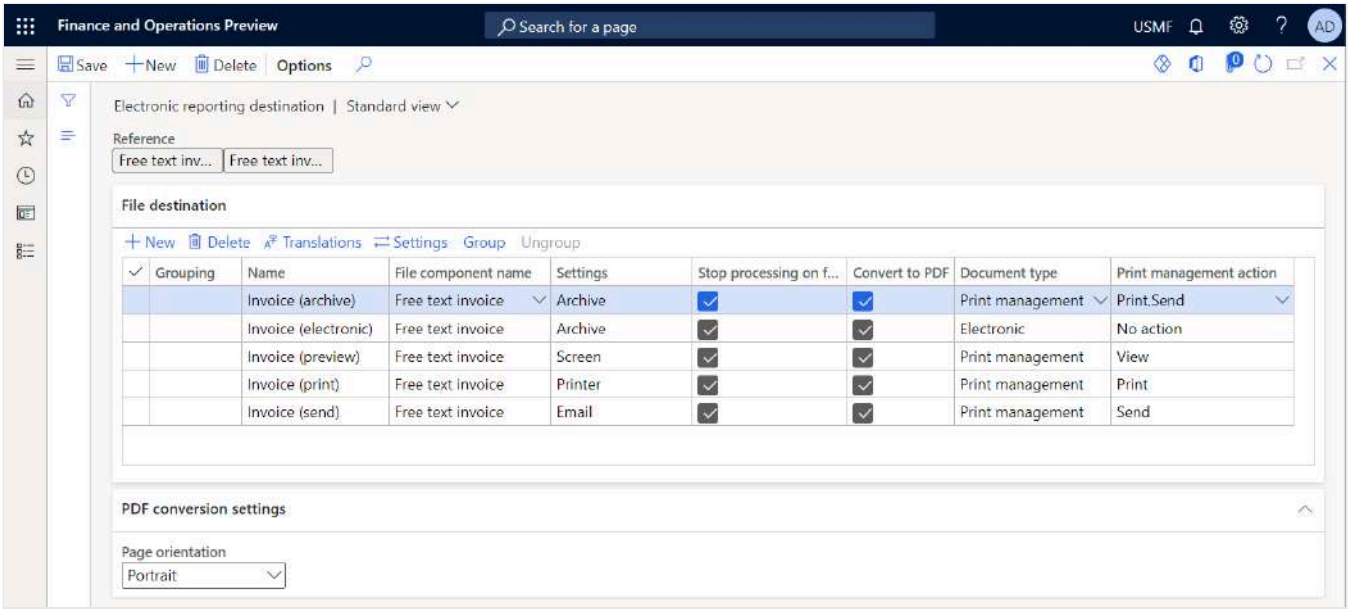
- Archive the document if the ER format is run but no action code is provided (for example, when the document is sent electronically).
- Preview the document in a web browser when a user performs the **View** action.
- Archive and print the document when a user performs the **Print** action.

- Archive the document and email it as the attachment of an outbound email message when a user performs the **Send** action.

The following illustration shows how you can achieve this by configuring ER destinations as the set of individual destination records when every record is configured for an individual user action:



The following illustration shows how you can achieve the same result by configuring ER destinations as the set of individual destination records when every record is configured for an individual destination:

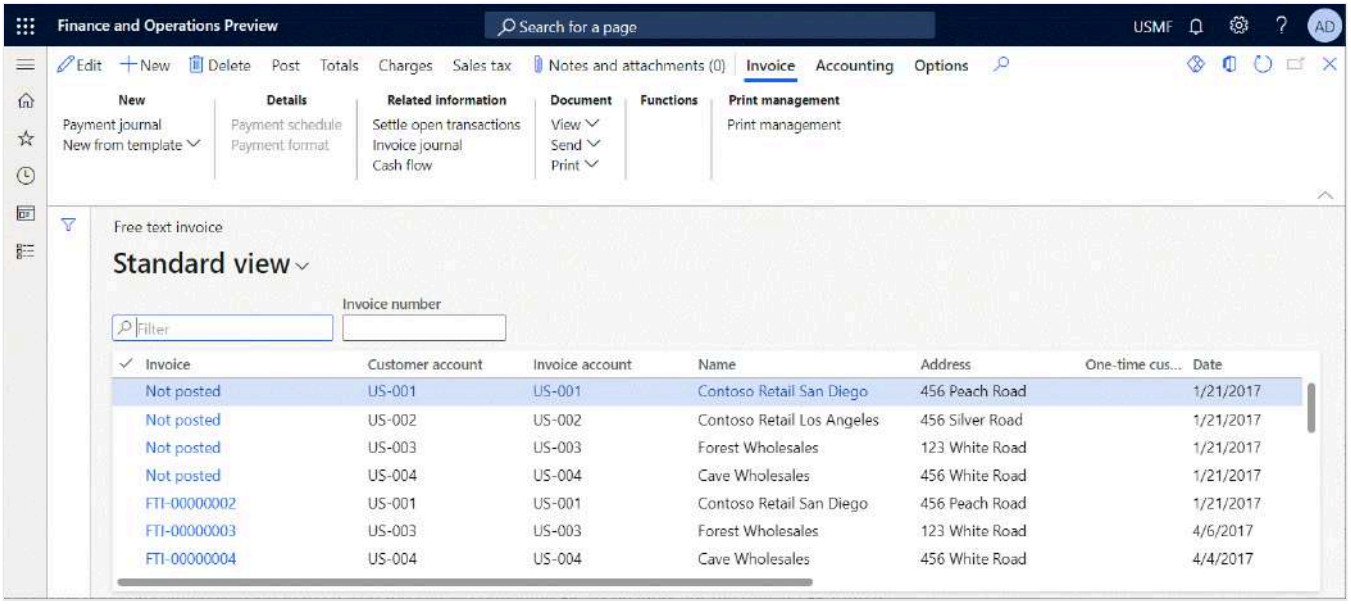


> **Note**
>
> If you provide an action code for the running ER format but don't configure destinations for that action code, the default destination behavior is applied.

Change action-dependent ER destinations at runtime

When an ER format runs, if you provision user actions and have the appropriate permissions to change the configured destination settings at run time, a dialog box appears providing you with the option to change the configured destination settings. This dialog box is optional, and its appearance depends on how you implement the call that the ER framework makes to run an ER format. If this dialog box appears, the corresponding ER destinations are enabled according to the provided user actions.

The following illustration shows an example of the **Electronic reporting format destinations** dialog box that appears when a free text invoice is posted and the **Free text invoice (Excel)** ER format is run to generate this document, if the **Printer** action was provisioned and ER destinations were configured for this format as shown earlier in this article.



> **Note**
>
> If you configured ER destinations for several components of the running ER format, an option will be offered separately for every configured component of the ER format.

If several ER formats are applicable as report templates for the selected document, all ER destinations for all applicable ER report templates are shown in the dialog box and available for manual adjustment at runtime.

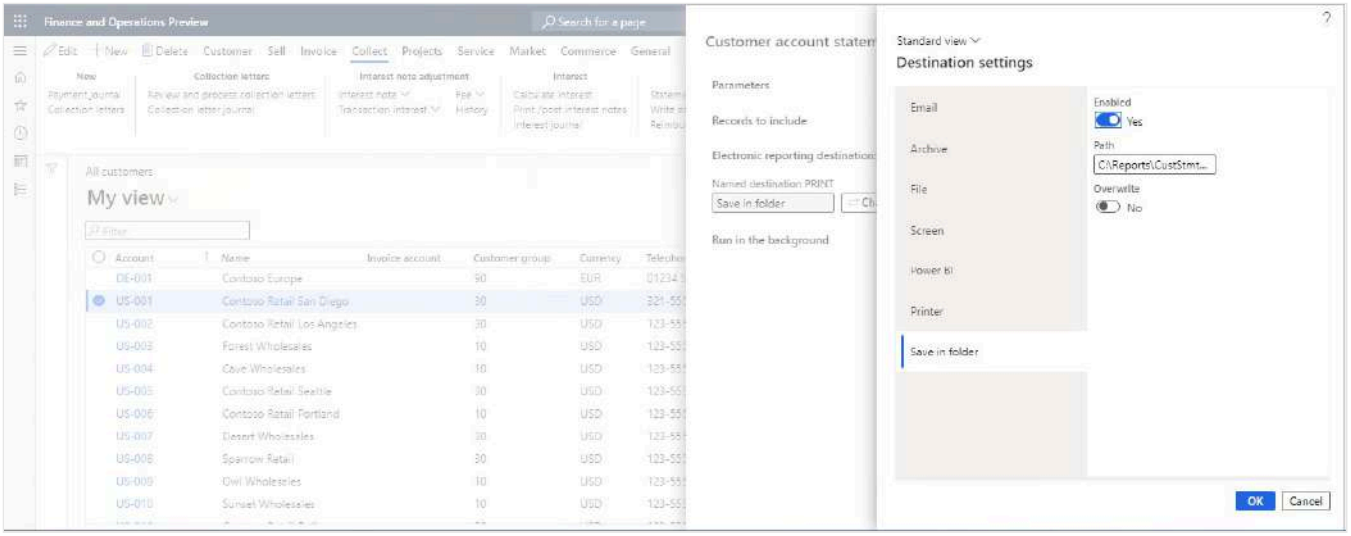
If no SQL Server Reporting Services (SSRS) report templates are applicable to the selected document, the standard selection of Print management destinations is dynamically hidden.

As of Finance version **10.0.31**, you can manually change the assigned ER destinations at runtime for the following business documents:

- Customer account statement
- Interest note
- Collection letter note
- Customer Payment advice
- Vendor Payment advice

To activate the capability to change ER destinations at runtime, enable the **Allow ER destinations adjustment at runtime** feature in the Feature management workspace.

> **Important**
>
> For the **Customer Payment advice** and **Vendor Payment advice** reports, the capability to manually change ER destinations is available only if the **ForcePrintJobSettings** flight is enabled.



> **Note**
>
> When the **Use print management destination** option is set to **Yes**, the system uses the default ER destinations that are configured for specific ER reports. All manual changes that are made in the dialog box are ignored. Set the **Use print management destination** option to **No** to process documents to the ER destinations that are defined in the dialog box immediately before you run the reports.

The following business documents don't assume explicit user selection of an action when they're run:

- Customer account statement

- Interest note
- Collection letter note
- Customer Payment advice
- Vendor Payment advice

The following logic is used to determine which action is used while the preceding reports are processed:

- If the **ForcePrintJobSettings** flight is enabled:
  - If the **Use print management destination** option is set to **Yes**, the **Print** action is used.
  - If the **Use print management destination** option is set to **No**, the **View** action is used.

- If the **ForcePrintJobSettings** flight isn't enabled:
  - If the **Use print management destination** option is set to **Yes**, the **Print** action is used for the **Customer Payment advice** and **Vendor Payment advice** reports.
  - If the **Use print management destination** option is set to **No**, the default SSRS report template is always used for the **Customer Payment advice** and **Vendor Payment advice** reports, regardless of any ER settings that are configured.
  - The **Print** action is always used for the **Customer account statement**, **Interest note**, and **Collection letter note** reports.

For the preceding logic, the **Print** or **View** actions can be used to configure action-dependent ER report destinations. At runtime, only ER destinations that are configured for a specific action are filtered in the dialog box.

Verify the provided user action

You can verify what user action, if any, is provided for the running ER format when you perform a specific user action. This verification is important when you must configure action-dependent ER destinations, but you aren't sure which user action code, if any, is provided. For example, when you start to post a free text invoice and set the **Print invoice** option to **Yes** in the **Post free text invoice** dialog box, you can set the **Use print management destination** option to **Yes** or **No**.

Follow these steps to verify the user action code that is provided.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, set the **Run in debug mode** option to **Yes**.

4. Perform a user action by running an ER format. Remember that ER user parameters are company-specific and user-specific.
5. Go to **Organization administration** > **Electronic reporting** > **Configuration debug logs**.
6. On the **Configuration debug logs** page, filter the ER run logs to find the log for your ER format run.
7. Review the log entries that must contain the record that presents the provided user action code, if any action has been provided for the ER format run.

Configure print management record-specific ER destinations

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how a user in the System Administrator or Accounts Receivable Clerk role can perform the following tasks:

- Configure named Electronic reporting (ER) destinations for an ER solution that generates free text invoices.
- Assign an ER destination to a single print management record.

Complete the procedures in the USMF company. No coding is required.

Introduction

You can configure destinations for each folder in the file output component of an ER format configuration that generates an outbound document. When you run an ER format of this type, if you have the appropriate access rights, you can also change the configured destination settings at runtime.

In Microsoft Dynamics 365 Finance **version 10.0.17 and later**, you can set up an action code for an ER format to specify the action that users perform by running that ER format. For example, in the **Accounts receivable** module, in the print management settings, you can select an ER format that generates a specific business document, such as a free text invoice. You can then select **View** to preview the invoice or **Print** to send it to a printer. If you pass an action for the running ER format at runtime, you can configure different ER destinations for different user actions.

In Finance **version 10.0.21 and later**, you can set up a named destination for an ER format and assign it to the print management record that the ER format processes when it runs. For

example, in the **Accounts receivable** module, in the print management settings, you want to configure the **Original** record to perform the following actions:

- Run an ER format.
- Email the generated invoice to a customer.
- Configure the **Copy** record to run the same format.
- Print a copy of the invoice to a network printer.

In this case, you must configure different ER destinations for the ER format that runs, and you must select the destinations for different print management records.

Prerequisites

Before you begin, the **Allow to set up ER destinations per print management item** feature must be turned on in the Feature management workspace. The source code must also be changed to allow for the configuration of named ER destinations in the current Finance instance and to enable the new ER API.

Additionally, the **Free text invoice (Excel)** ER configuration must be imported into your Finance instance.

Configure a new ER destination

1. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.

2. Select an invoice for customer account **US-001**.

3. On the **Free text invoice** page, on the **Invoice** tab, in the **Print management** group, select **Print management**.

4. On the **Print management setup** page, expand **Module - accounts receivable** > **Documents** > **Free text invoice**, select the **Original** record, and then follow these steps:
   a. Observe the current settings of the selected record:

      - The default SSRS report **FreeTextInvoice.Report** is selected in the **Report format** field.
      - The **<Default>** name is shown in the **Destination** field informing that there is no custom destination selected for the assigned SSRS report.

   b. In the **Report format** field, select the **Free text invoice (Excel)** ER format configuration.

- The name of the **Destination** field is changed to **Destination name**.
- The **<No named destination>** name is shown in the **Destination name** field informing that there is no named destination selected for the assigned ER format.

c. Select the arrow button to the right of the **Destination name** field.

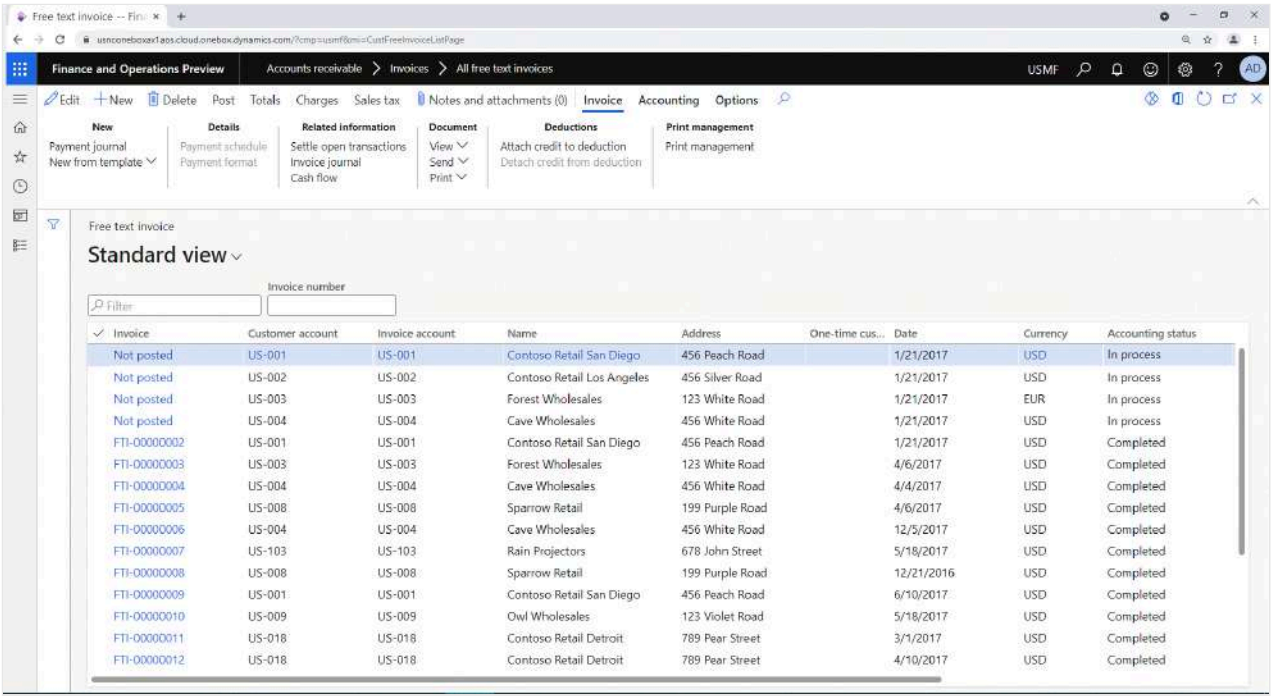
d. On the **Electronic reporting named destination** page, in the **Name** field, enter **Main destination**.

e. Select **Save**.

f. On the **File destination** FastTab, configure the **Email** destination for the **Report** component.

g. Close the **Electronic reporting named destination** page.

h. On the **Print management setup** page, in the **Destination name** field, select the **Main destination** named destination.



You've now configured the named ER destination **Main destination** for the **Free text invoice (Excel)** format and assigned it to the **Original** print management record under **Module - accounts receivable** > **Documents** > **Free text invoice**.

5. Expand **Module - accounts receivable** > **Account - US-001** > **Free text invoice**, select the **Original** record, and then follow these steps:

a. Select and hold (or right-click) the record, and then select **Override**.

b. Select the arrow button to the right of the **Destination name** field.

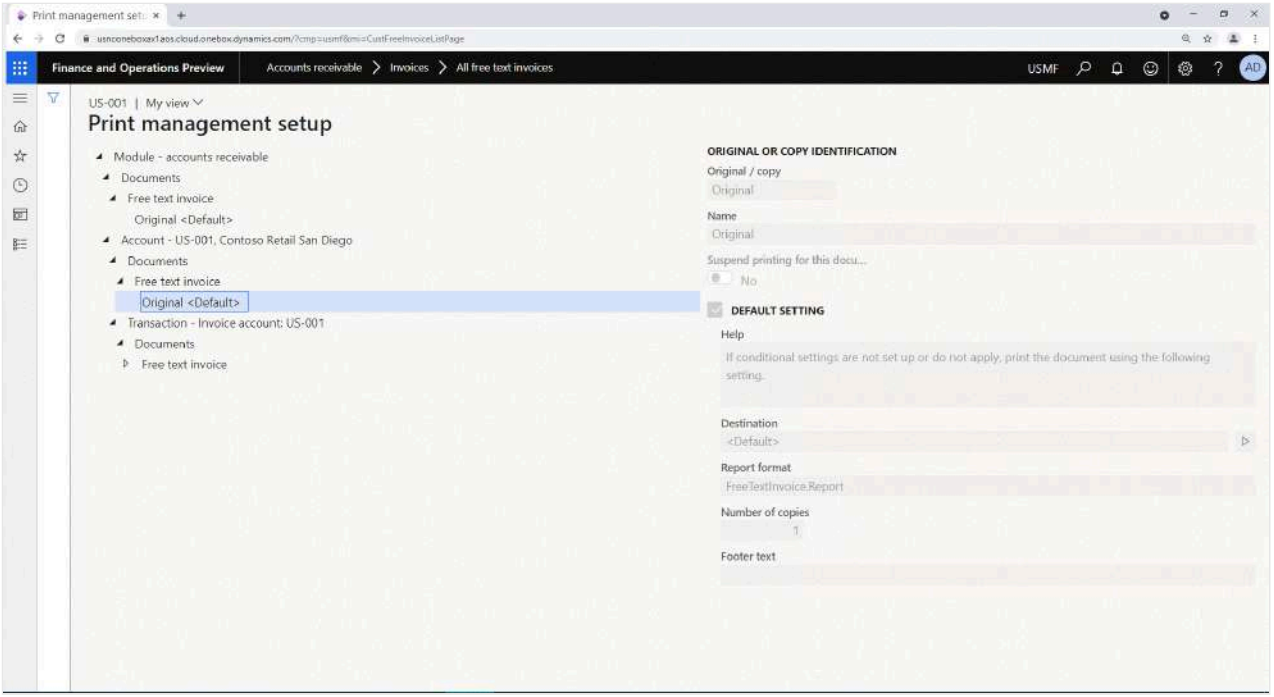
c. On the **Electronic reporting named destination** page, on the Action Pane, select **New**.

d. In the **Name** field, enter **US-001 destination**.

e. On the **File destination** FastTab, configure the **Printer** destination for the **Report** component.

f. Close the **Electronic reporting named destination** page.

g. On the **Print management setup** page, in the **Destination name** field, select the **US-001 destination** named destination.



You've now configured the named ER destination **US-001 destination** for the **Free text invoice (Excel)** format and assigned it to the **Original** print management record under **Module - accounts receivable** > **Account - US-001** > **Free text invoice**.

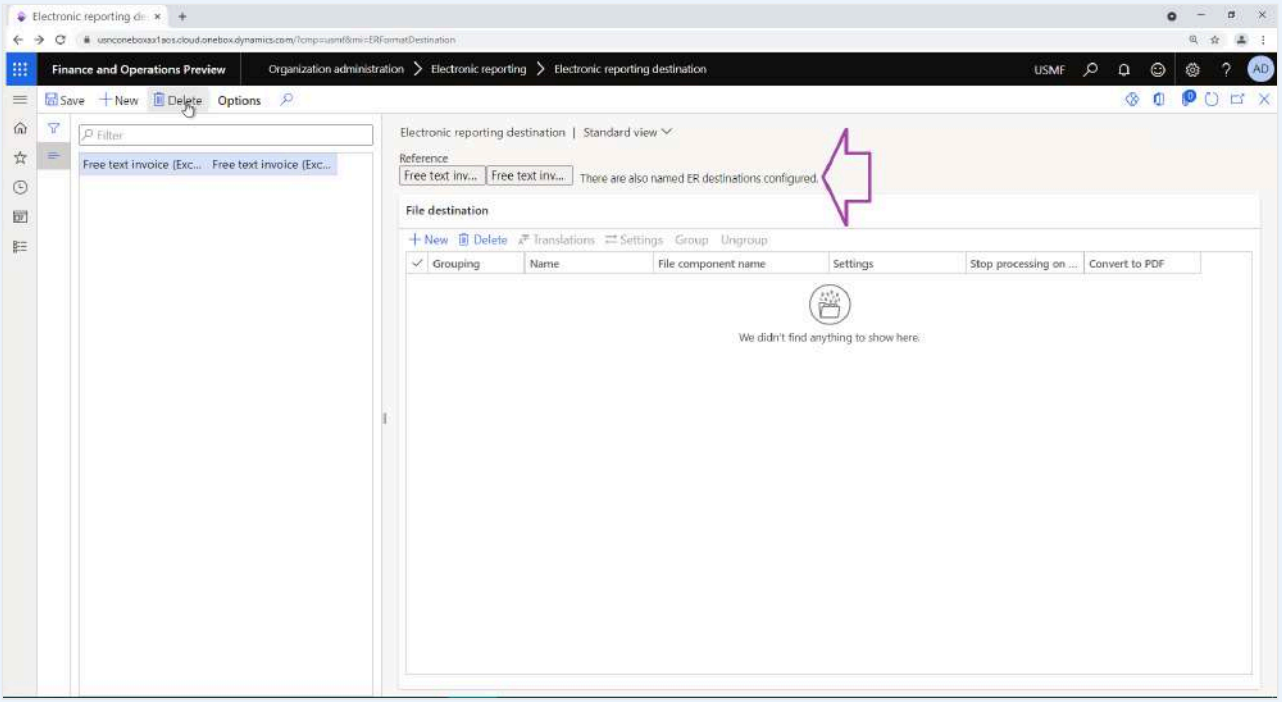
Now, when a free text invoice is processed, the **Free text invoice (Excel)** ER format is run, and one of the following events occurs:

- If the free text invoice is for a customer other than US-001, the generated document is sent by email.
- If the free text invoice is for customer US-001, the generated document is printed.

> ⓘ **Note**
>
> When a named destination hasn't been defined for a print management record that is processed at runtime, the default ER destinations are used if they are available for the ER format that is running.

> ⓘ **Important**
>
> On the **Electronic reporting destination** page (**Organization administration** > **Electronic reporting** > **Electronic reporting destination**), if you select an ER format that at least one

named destination was configured for, you're notified about the presence of named destinations.



If you delete the default destination, all named destinations are also deleted. If those named destinations were selected for print management records, the selection of those named destinations is canceled.

Copy an existing ER destination as a new named destination

When the default named ER destination is available for an ER format, it can be used as a template for new ER destinations. To create a new ER destination that is based on the default destination, select **Copy from default** on the **Electronic reporting named destination** page. The new destination is named **Default**. You can repeat this step as many times as required.

You can select any existing named destination as a template for a new named destination. To create a new named ER destination that is based on a selected named destination, select **Copy** on the **Electronic reporting named destination** page. The new destination has the same name as the selected named destination, but the suffix "Copy" is added. You can repeat this step as many times as required.

Security considerations

You can set up named ER destinations on the **Print management setup** page only if you have permission to perform this task. Permission can be granted to you if the **Configure electronic reporting format destination** duty is assigned to one of your security roles. For more information, see Security considerations.

Output unfolding for Folder component of ER format

When you configure a destination for the **Folder** component of your ER format, you specify how the output of that component is delivered to the configured destination.

Applicability

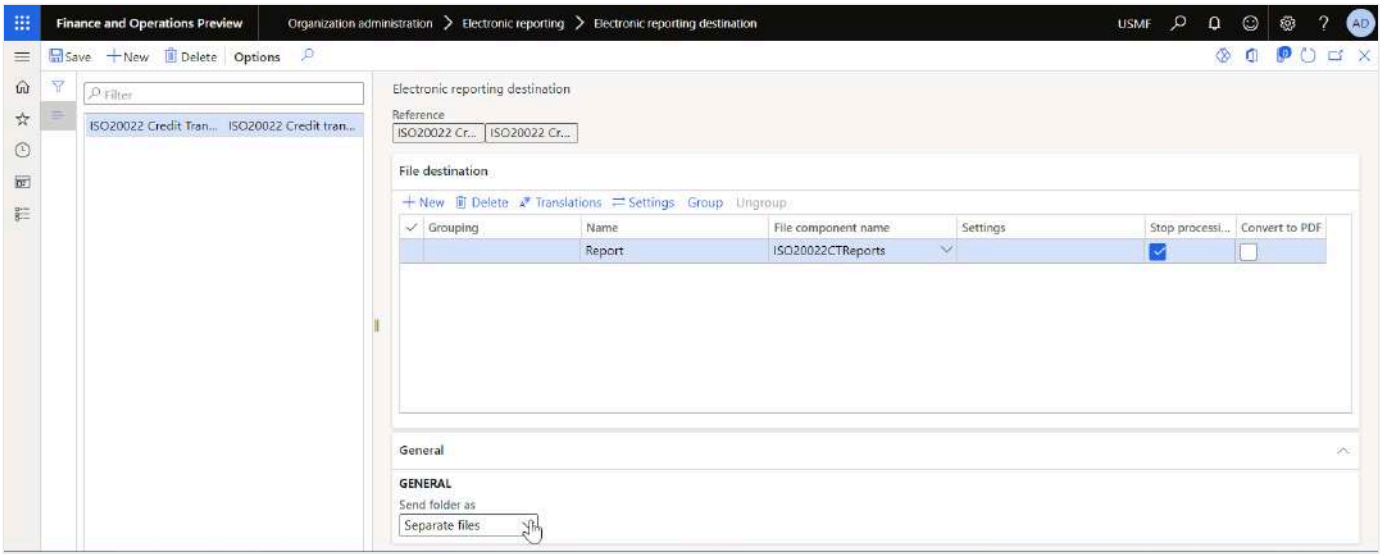
You can configure the output unfolding option only for the format components of the **Folder** type. When you start to configure a **Folder** component, the **General** FastTab is available on the **Electronic reporting destination** page.

Use the output unfolding option

On the **General** FastTab, in the **Send folder as** field, select one of the following values:

- **ZIP archive** – Deliver a generated file as a zip file.
- **Separate files** – Deliver every file of a generated zip file as an individual file.

> ⓘ **Note**
>
> When you select **Separate files**, the generated output is collected in memory in a zipped state. Therefore, the maximum file size limit is applied for zipped output when the real file size can exceed this limit. Select this value when you expect the size of the generated output to be large.



Limitations

If you set the **Send folder as** field to **Separate files** for a **Folder** component that contains other nested **Folder** components, the setting doesn't apply recursively to the nested **Folder** components.

Change page layout properties of a template in ER destinations

You can configure an ER destination for an ER format component that's designed to use a template in a Microsoft Office (Excel or Word) format for report generation. If you aren't the owner of this format and you need to change page layout properties of the format's template, you can change the page layout properties of the template at runtime to avoid creating and maintaining the derived format configuration. To do this, set up the desired properties as part of the settings of the configured ER destination. When you run an ER format and execute an ER destination that's configured to use certain page layout properties, the values of page layout properties of the executed destination are applied to the template you use, replacing the original template's properties. You can configure different destinations for the same format's component configuring different page layout properties for the template in use.

The following properties can be configured in an ER destination for a format component that's designed to use a template in Excel or Word format:

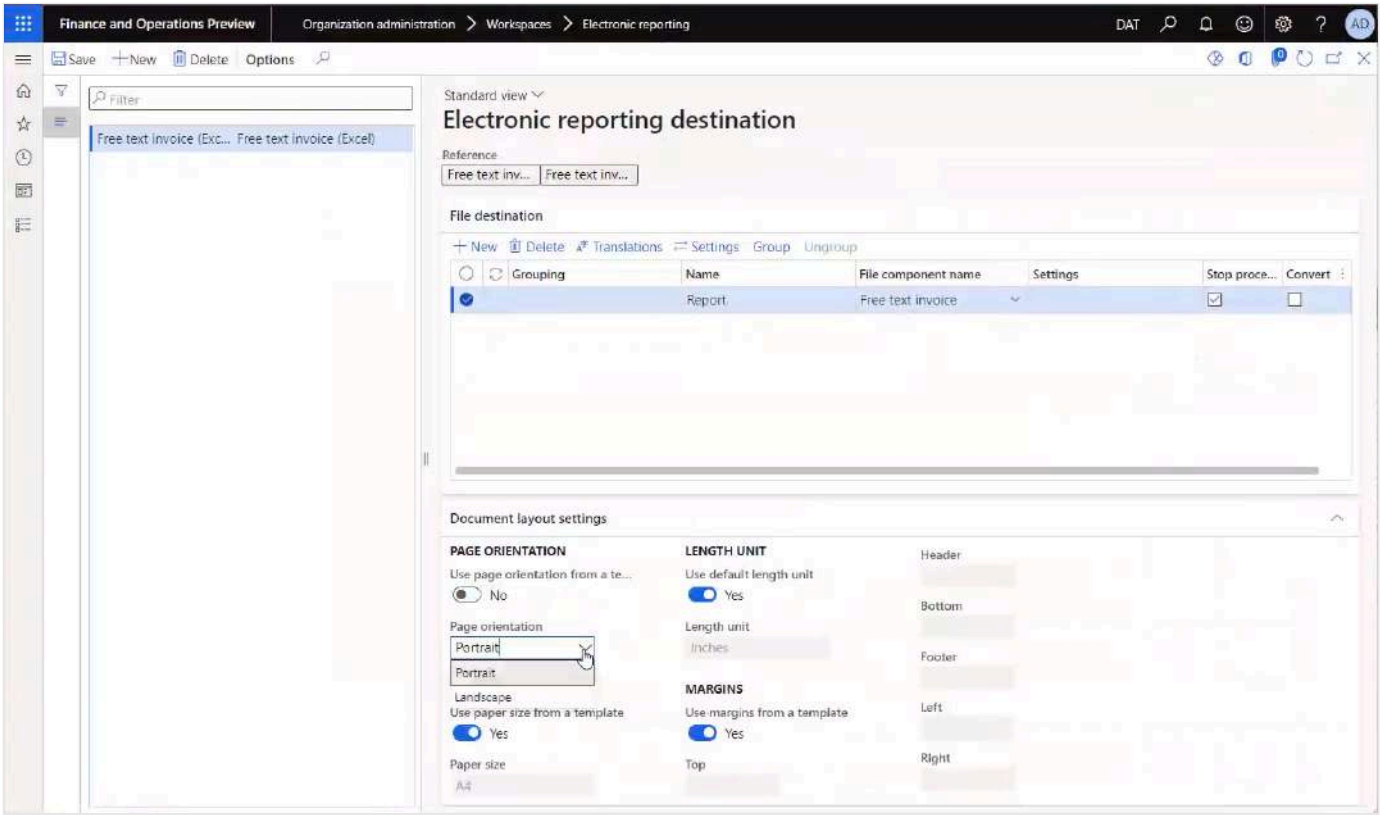
- Page orientation
  - Portrait
  - Landscape
- Paper size
  - A3
  - A4
  - A5
  - B4
  - B5
  - Executive
  - Legal
  - Letter
  - Statement
  - Tabloid
- Page margins
  - Top
    - Header
  - Bottom
    - Footer

- Left
- Right

> **Note**
>
> The page orientation of the template that's configured in this way must be aligned with the page orientation for PDF conversion if the PDF conversion is configured.

You must select the length unit for setting page margins:

- Inches
- Centimeters
- Millimeters



> **Tip**
>
> When you specify a margin value in centimeters with multiple decimals, the value is rounded at runtime to the nearest value with one decimal point.
>
> When you specify a margin value in millimeters with decimals for Excel, the value is rounded at runtime to the nearest integer value with no decimal point.

When you specify a margin value in millimeters with multiple decimals for Word, the value is rounded at runtime to the nearest value with one decimal point.

Last updated on 04/13/2026

Output conversion to PDF

Use the PDF conversion option to convert output in Microsoft Office (Excel or Word) format to PDF format.

Turn on the PDF conversion option for **Excel\File** and **Common\File** components that generate output in Office (Excel or Word) format. When you turn on this option, the output that you generate in Office format is automatically converted to PDF format.

> ⓘ **Note**
>
> Pay attention to the warning message that you receive when you turn on the PDF conversion option for an ER component of the **Common\File** type. This message informs you that there's no way to guarantee, at design time, that the selected file component exposes the content in PDF format or the PDF-convertible content at runtime. Therefore, turn on the option only if you're sure that the selected file component was configured to expose the content in PDF format or the PDF-convertible content at runtime.
>
> If you turn on the PDF conversion option for a format component, and if that component exposes content in a format other than PDF that can't be converted to PDF format, an exception occurs at runtime. The message that you receive informs you that the generated content can't be converted to PDF format.

Limitations

In versions earlier than Dynamics 365 Finance version 10.0.43, you can only convert PDFs outside the current Finance instance. A generated file is sent out of Finance to the conversion service, and that service returns the converted document. This solution has the following limitations:

- You can use the PDF conversion option for cloud deployments and on-premises deployment that has Internet connectivity enabled.
- The PDF document that you produce has a maximum length of 300 pages.

In Dynamics 365 Finance version **10.0.43** and later, you can enable the **In-App PDF conversion for Configurable Business Documents (CBD)** feature in **Feature management** to facilitate the seamless conversion of configurable business documents from Word or Excel formats to PDF.

> **Note**
>
> The **In-App PDF conversion for Configurable Business Documents (CBD) (preview)** feature is available in Finance version 10.0.43 and the 10.0.2095.**124** build and later of the 10.0.42 version.

This feature uses Application Object Server (AOS) resources to remove the need for external conversion services. By using in-app capabilities, you get efficient and secure document processing and reduce dependency on tools outside of Finance while maintaining high performance and reliability. This enhancement supports a wide range of business scenarios to provide users with the flexibility to generate and distribute professional-grade PDF documents directly within the application.

The following advantages come with in-app PDF conversion when you enable the **In-App PDF conversion for Configurable Business Documents (CBD)** feature:

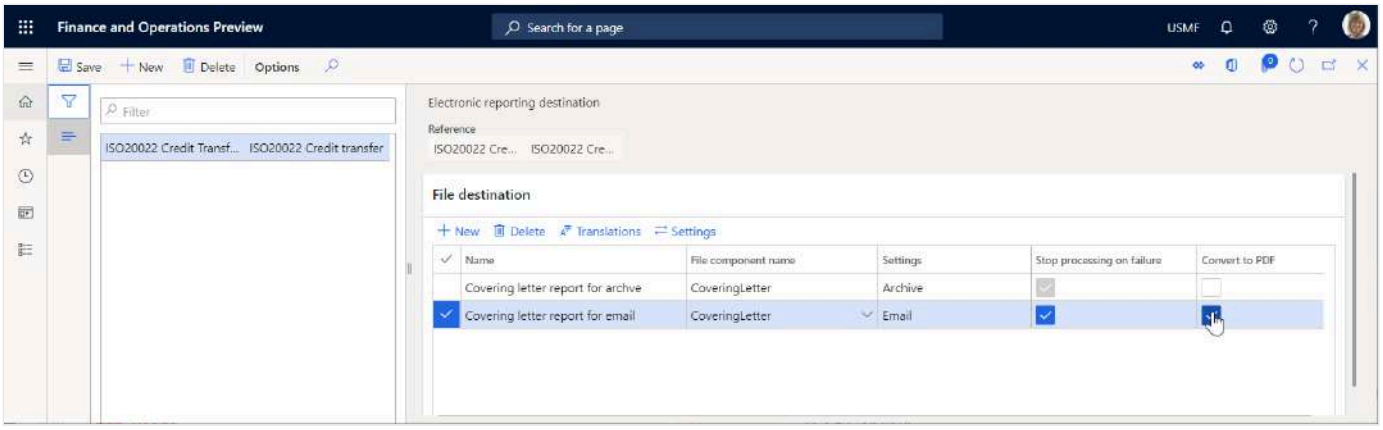
- The PDF document that you produce doesn't have a maximum of 300 pages.
- The Word document that you convert can have a large number of content controls.
- On-premises deployments don't require Internet connectivity.

> **Note**
>
> Only the common system fonts of the Windows operating system are used to convert output that contains no embedded fonts.

> **Tip**
>
> When using the **In-App PDF conversion for Configurable Business Documents (CBD)**, you might notice the font in the generated PDFs has a lighter weight compared to the one in Excel templates. This difference can result in small visual discrepancies between your original template and the final PDF output. Configuration engineers should preview the generated PDF before completing and sharing their configurations.

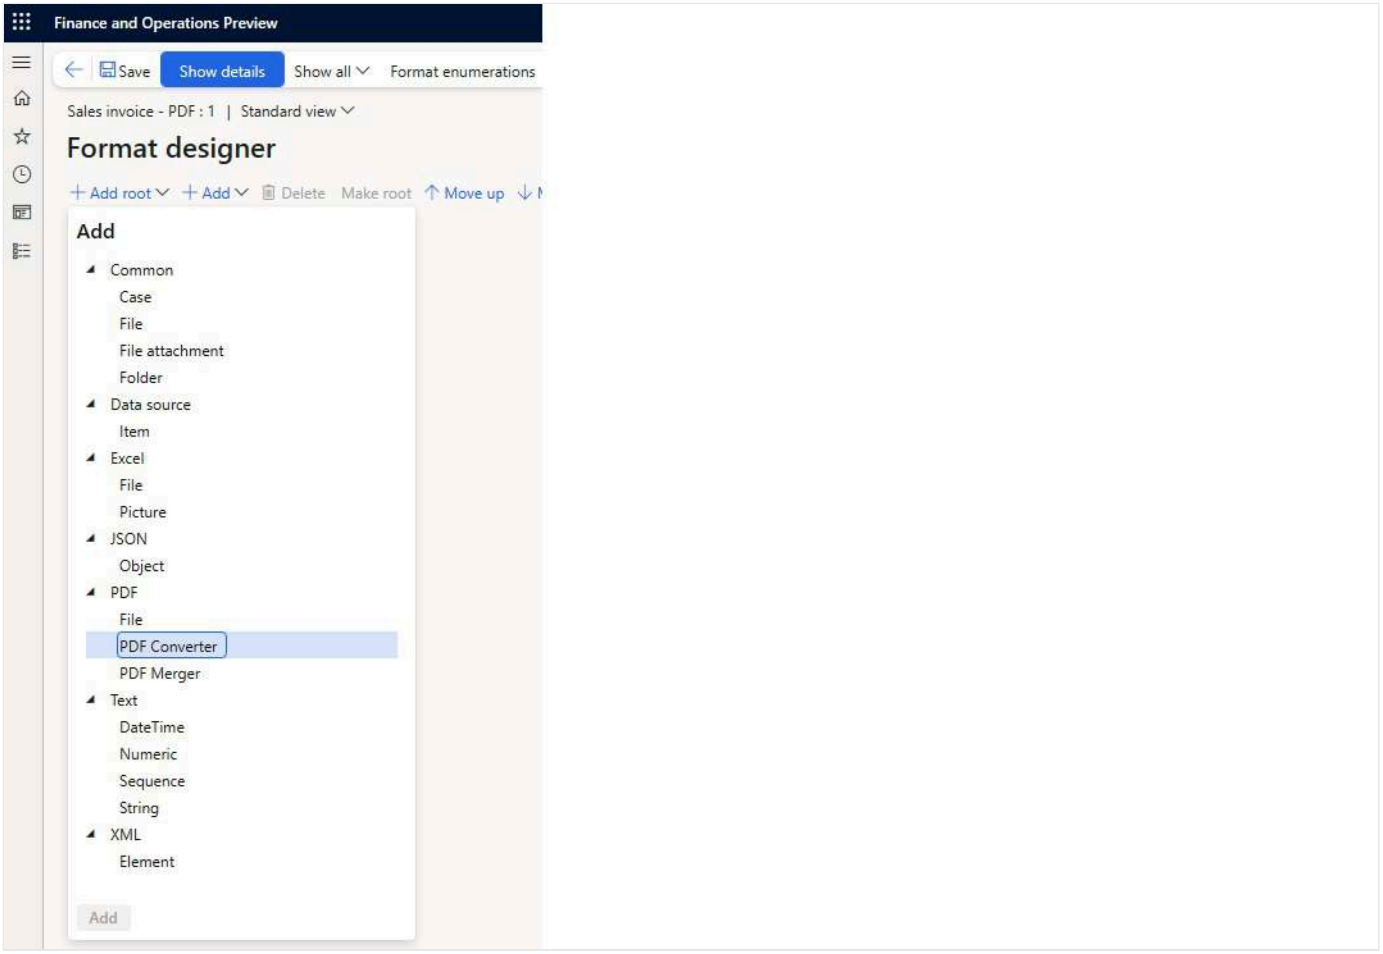
Use the PDF conversion option

To turn on PDF conversion for a file destination, select the **Convert to PDF** check box.



Use the PDF conversion component in ER format configurations

You can use PDF conversion directly in format configurations. In this case, you don't have to use the **Convert to PDF** checkbox on the **Electronic reporting destination** page. A format component, **PDF Converter**, is available.

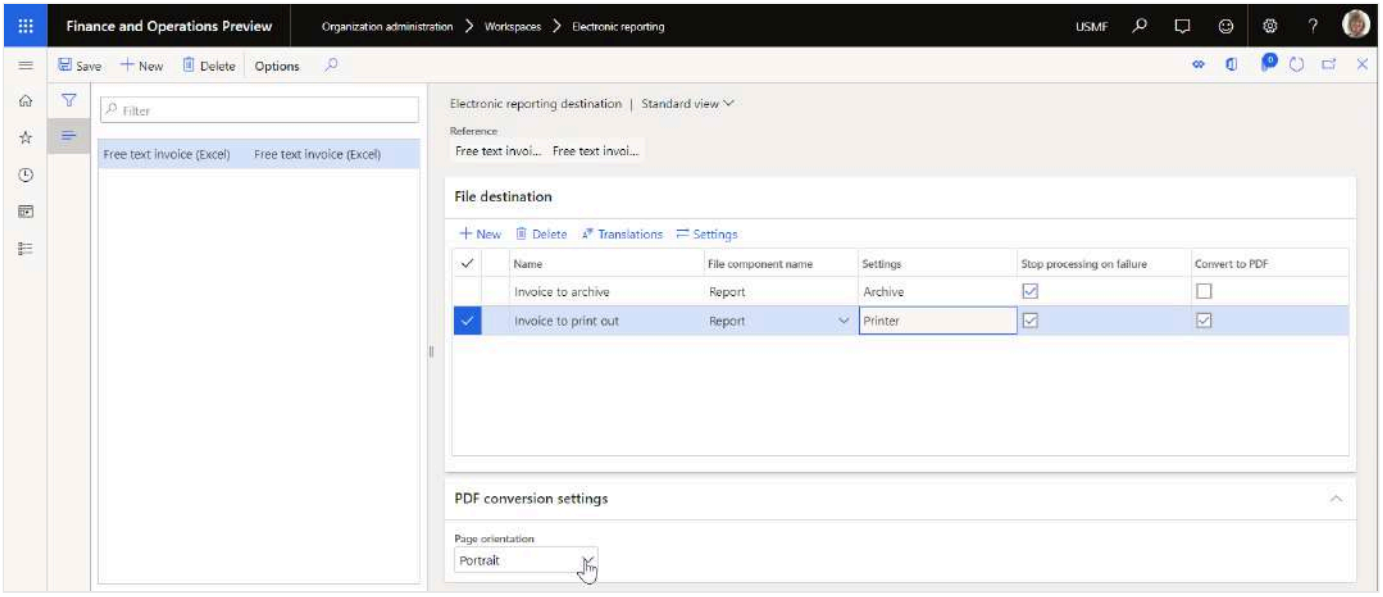


> **Note**
>
> You can add the **PDF Converter** component only in the format configurations of a **PDF** format type, or when the format type isn't explicitly defined but is left blank. The **PDF**

Converter component can contain only one **Excel\File** subcomponent.

Select a page orientation for PDF conversion

If you generate an ER configuration in Excel format and want to convert it to PDF format, you can specify the page orientation of the PDF document. When you select the **Convert to PDF** checkbox to turn on PDF conversion for a file destination that produces an output file in Excel format, the **Page orientation** field becomes available on the **PDF conversion settings** FastTab. In the **Page orientation** field, select your preferred orientation.



The following page orientation options are supported:

- Portrait
- Landscape
- Worksheet specific

The selected page orientation applies to all pages of an outbound document that you generate in Excel format and convert to PDF format. When you select the **Worksheet specific** option, every worksheet of a generated Excel workbook is converted to PDF using the page orientation that you configured for this worksheet in the Excel template. You might have a final PDF document containing portrait and landscape pages.

> ⓘ **Note**
>
> For ER configuration in Word format converted to PDF format, the page orientation of the PDF document always comes from the Word document.

Last updated on 10/02/2025

Export, import, and replicate ER destinations

As of version **10.0.46** of Microsoft Dynamics 365 Finance, you can use these capabilities to streamline the process of configuring destinations across multiple legal entities or environments.

- **Export and import** destination configurations by using the Data Management Framework (DMF).
- **Replicate** destinations across multiple legal entities within the same environment.

These capabilities reduce manual effort, improve consistency, and make ER destination setup more scalable.

Export and import ER destinations

You can now use a dedicated **Data entity** to export and import ER destination configurations between environments.

Expand table

Data entity name	Target data entity	Tables included
File destination	**ERFormatFileDestinationEntity**	ERFormatDestinationTable ERFormatFileDestinationTable ERFormatDestinationNamedTable

For more information about data entities in Finance, see Data entities overview.

Replicate ER destinations across legal entities

1. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting destination**.
2. In the list on the left, select one or more ER formats.
3. On the action pane, select the **Replicate** button.
4. Select one or more legal entities to copy destinations into.
5. (Optional) To also replicate **named destinations** that are used in **Print management** for configurable business documents, select the **Include named destinations** checkbox. For more information about named destinations used in **Print management**, see Configure print management record-specific ER destinations.
6. Select **OK** to replicate.

The process copies all destinations for the selected formats into the chosen companies, including those destinations that use container fields.

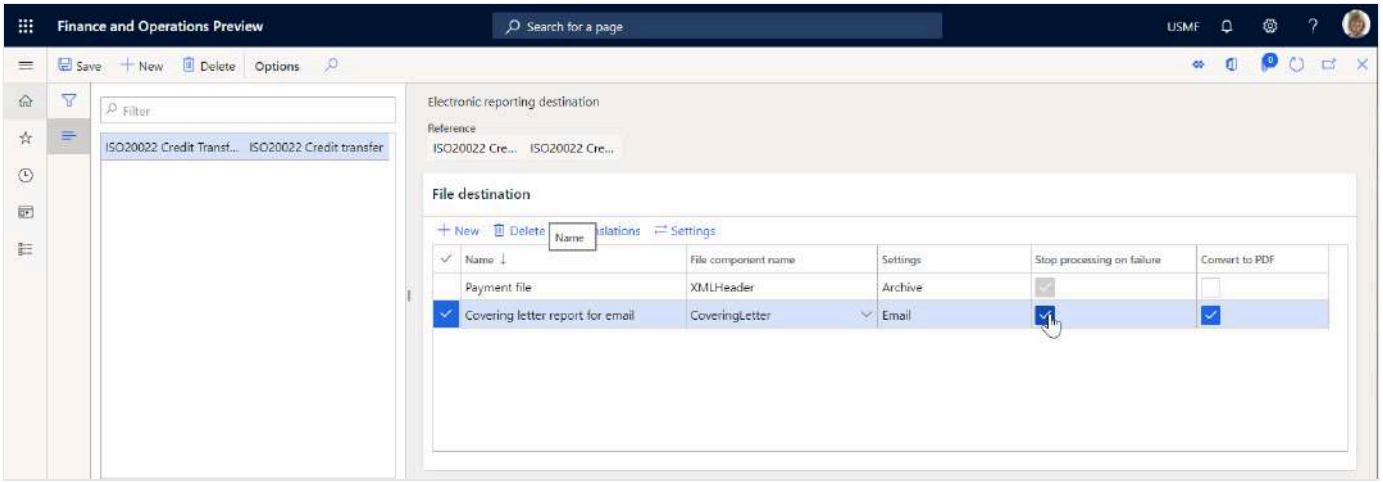
> **Note**
>
> You can apply replication to multiple formats and multiple legal entities in a single operation, which saves significant setup time.

Last updated on 10/02/2025

Electronic reporting destination failure handling

Usually, you run an ER format within the scope of a specific business process. However, sometimes you need to consider the delivery of an outbound document that the ER format generates during execution as part of that business process. In this case, if delivery of a generated outbound document to a configured destination isn't successful, you must cancel execution of the business process. To configure the appropriate ER destination, select the **Stop processing on failure** option.

For example, you configure vendor payment processing so that the **ISO20022 Credit Transfer** ER format runs to generate the payment file and supplementary documents (such as the covering letter and control report). If a payment should be considered successfully processed only if the covering letter is successfully delivered by email, you must select the **Stop processing on failure** checkbox for the **CoveringLetter** component in the appropriate file destination, as shown in the following illustration. In this case, the status of the payment that you select for processing changes from **None** to **Sent** only when the covering letter that's generated is successfully accepted for delivery by an email provider that's configured in the Finance instance.



If you clear the **Stop processing on failure** checkbox for the **CoveringLetter** component in the destination, a payment is considered successfully processed even if the covering letter isn't successfully delivered by email. The status of the payment changes from **None** to **Sent** even if the covering letter can't be sent because, for example, the email address of the recipient or sender is missing or incorrect.

Design a new ER solution to print ZPL labels

This article explains how a user in the System Administrator, Electronic Reporting Developer, or Electronic Reporting Functional Consultant role can configure parameters of the Electronic reporting (ER) framework, design the required ER configurations of a new ER solution to access the data of the Warehouse management system, and generate custom warehouse location labels in Zebra Programming Language (ZPL) II format. You can complete these steps in the **USRT** company.

Business scenario

You represent a company that implemented warehouse management in Microsoft Dynamics 365 Finance. Every warehouse location must be labeled with a self-adhesive label that includes a bar code. Warehouse workers use handheld bar code readers to scan the bar codes.

All warehouse locations are labeled in the scope of pre-go-live activities. However, you must also be able to print warehouse location labels on demand if existing labels become damaged or warehouse shelving is reconfigured. By using recently released ER functionality, you can configure a new ER solution that lets a warehouse supervisor print labels directly to a thermal label printer.

Configure the ER framework

Follow the steps in Configure the ER framework to set up the minimal set of ER parameters. You must complete this setup before you start to use the ER framework to design a new ER solution.

Design a domain-specific data model

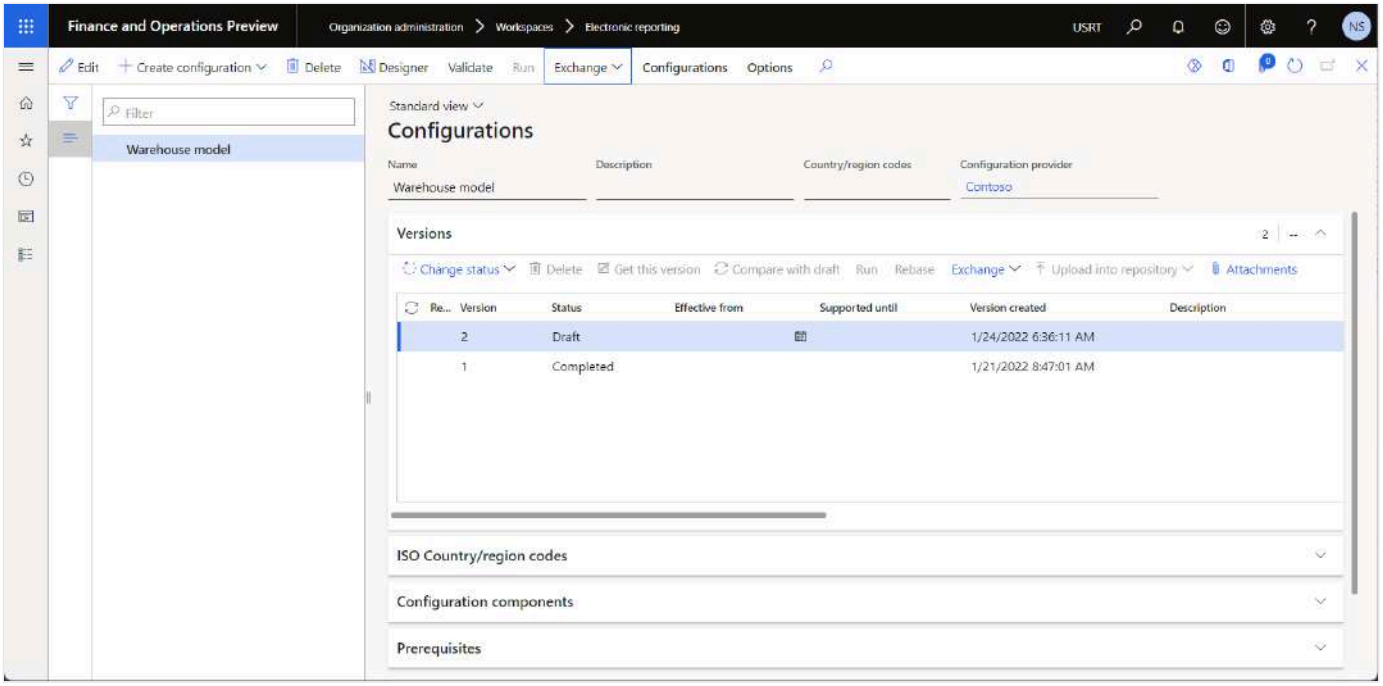
Create a new ER configuration that contains a data model component for the Warehouse management domain. You use this data model as a data source later, when you design an ER format to generate warehouse location labels.

Import a data model configuration

Follow these steps to import the required data model from an XML file that Microsoft provides. Alternatively, you can create your own data model as described in the next section.

1. Download the Warehouse model.version.1.xml file, and save it to your local computer.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

3. In the **Electronic reporting** workspace, select **Reporting configurations**.
4. On the **Configurations** page, on the Action Pane, select **Exchange** > **Load from XML file**.
5. Select **Browse**, and then find and select the **Warehouse model.version.1.xml** file.
6. Select **OK** to import the configuration.

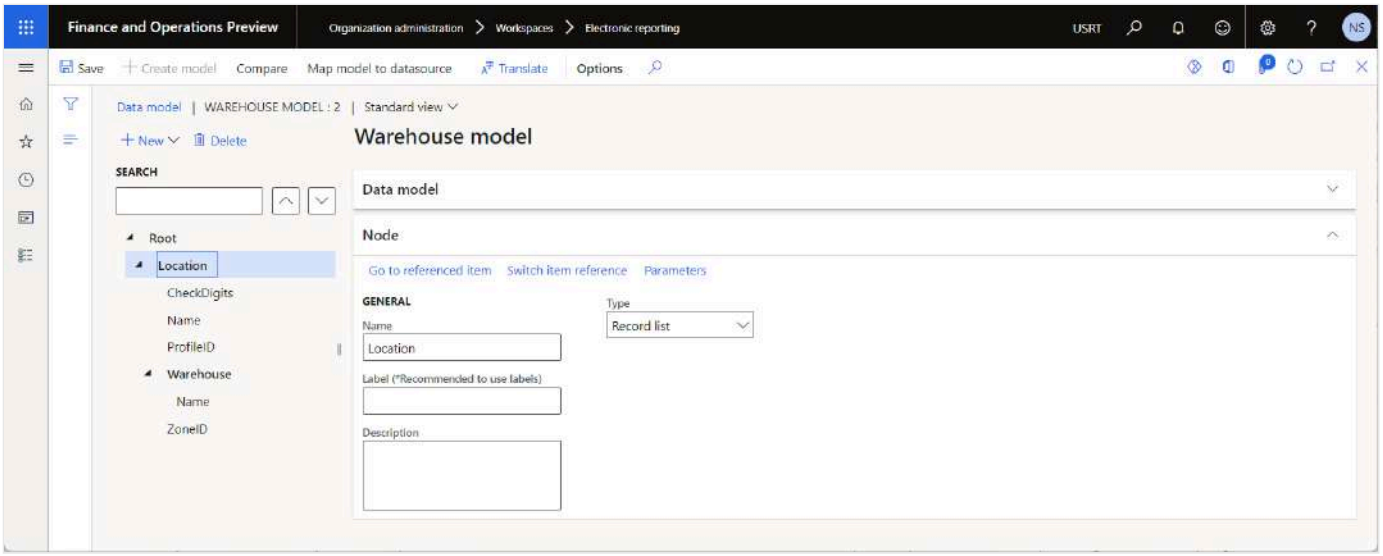


Create a data model configuration

Instead of importing the Microsoft-provided data model file, you can create a data model from scratch. For an example that shows how to complete this task, see Create a new data model configuration.

Review the data model

You can view an editable version of the configured data model on the **Data model designer** page.



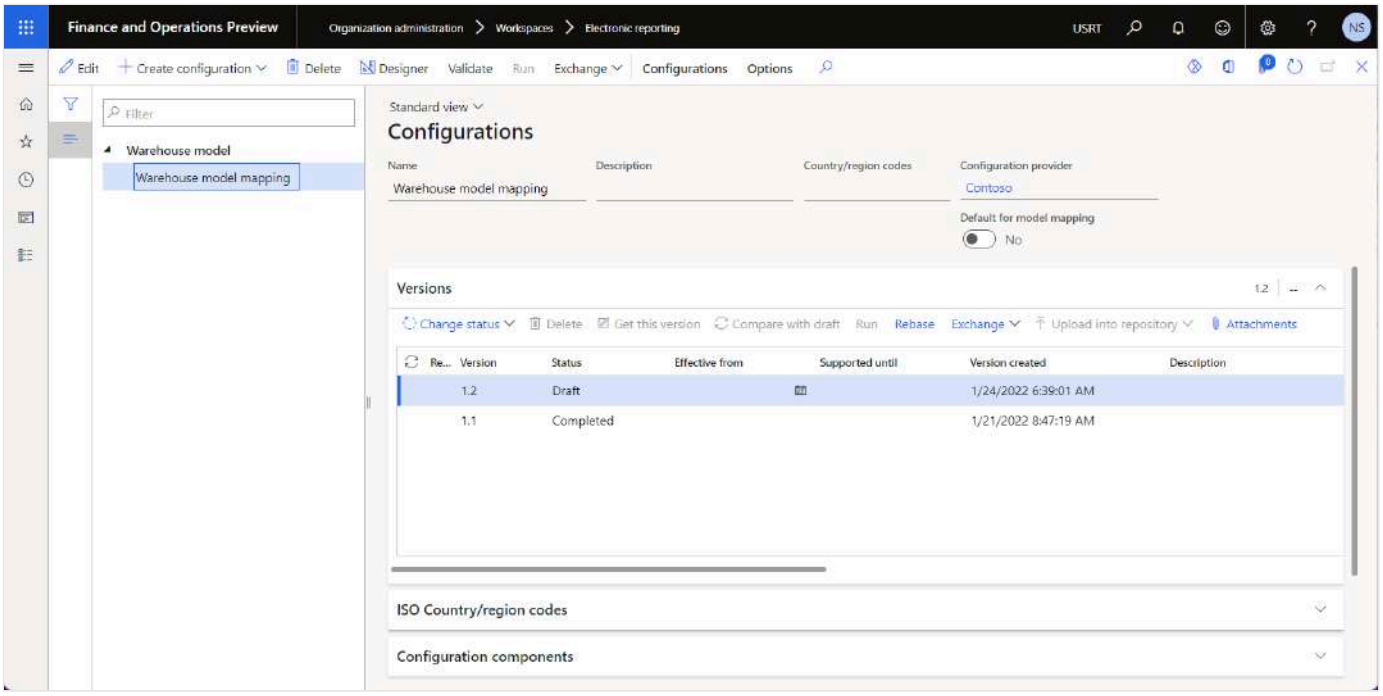
Design a model mapping for the configured data model

As a user in the Electronic Reporting Developer role, you must create a new ER configuration that contains a model mapping component for the Warehouse data model. This component implements the configured data model for Dynamics 365 Finance and is specific to that app. You must configure it to specify the application objects that fill the configured data model with application data at runtime. To complete this task, you must understand how the data structure of the Warehouse management business domain is implemented in Finance.

Import a model mapping configuration

Follow these steps to import the required model mapping from an XML file that Microsoft provides. Alternatively, you can create your own model mapping as described in the next section.

1. Download the Warehouse model mapping.version.1.1.xml file, and save it to your local computer.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. In the **Electronic reporting** workspace, select **Reporting configurations**.
4. On the **Configurations** page, on the Action Pane, select **Exchange** > **Load from XML file**.
5. Select **Browse**, and then find and select the **Warehouse model mapping.version.1.1.xml** file.
6. Select **OK** to import the configuration.

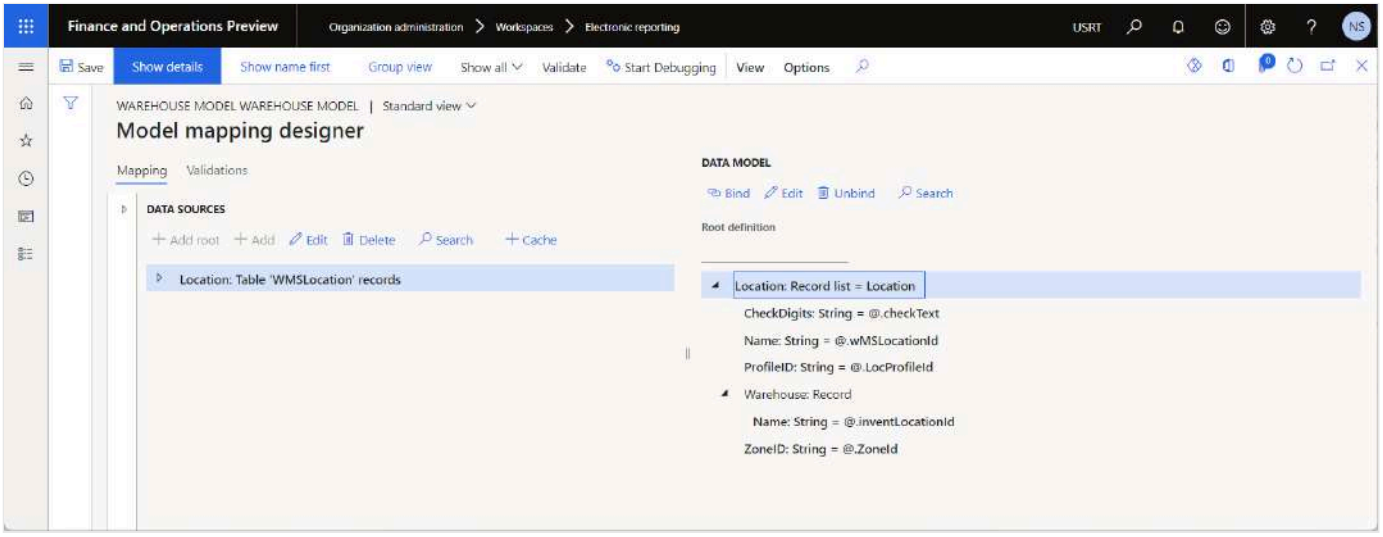


Create a model mapping configuration

Instead of importing the Microsoft-provided model mapping file, you can create a model mapping from scratch. For an example that shows how to complete this task, see Create a new model mapping configuration.

Review the model mapping

You can view an editable version of the configured model mapping on the **Model mapping designer** page.



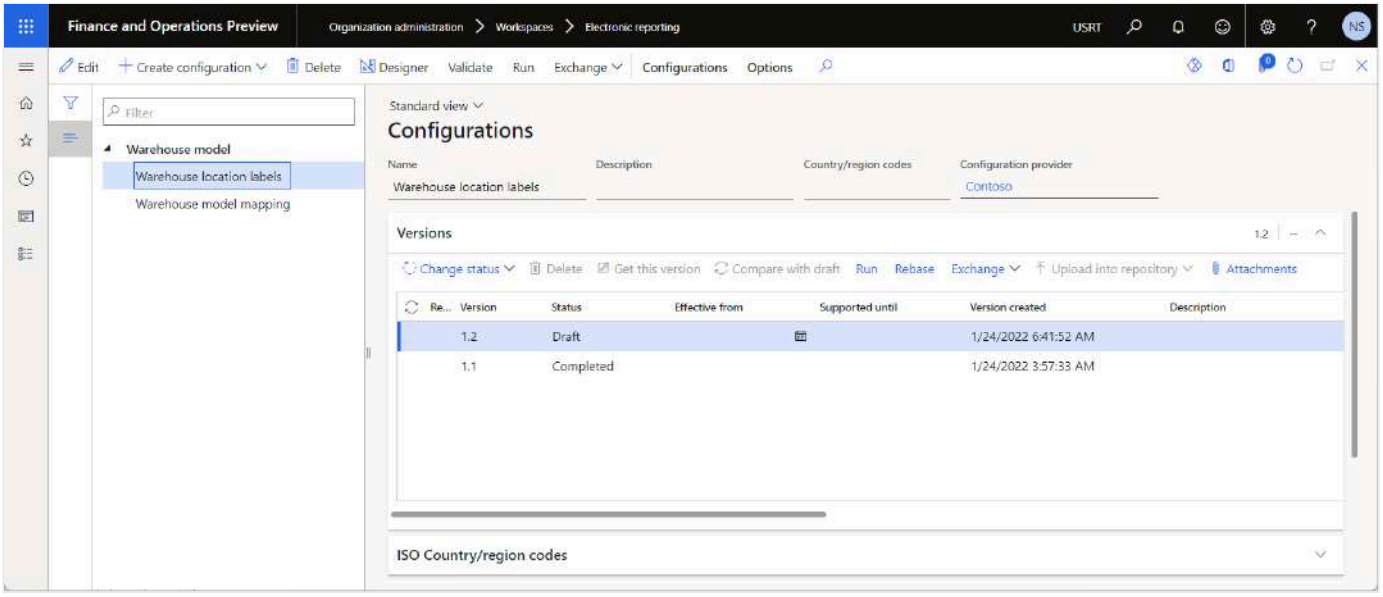
Design a format

As a user in the Electronic Reporting Functional Consultant role, you must create a new ER configuration that contains a format component. To configure this component, use ZPL II code to specify the layout of your warehouse location label.

Import a format configuration

Follow these steps to import the required format from an XML file that Microsoft provides. Alternatively, you can create your own format as described in the next section.

1. Download the Warehouse location labels.version.1.1.xml file, and save it to your local computer.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
3. In the **Electronic reporting** workspace, select **Reporting configurations**.
4. On the **Configurations** page, on the Action Pane, select **Exchange** > **Load from XML file**.
5. Select **Browse**, and then find and select the **Warehouse location labels.version.1.1.xml** file.
6. Select **OK** to import the configuration.

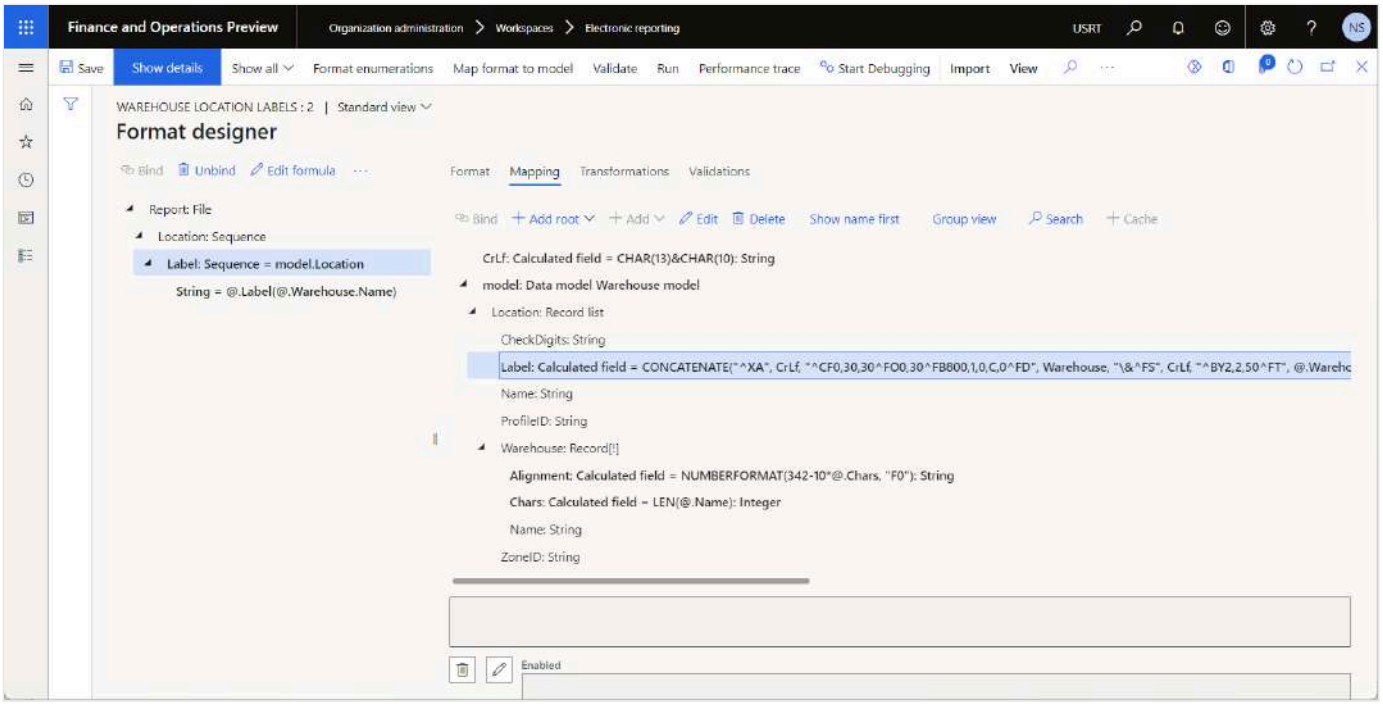


Create a format configuration

Instead of importing the Microsoft-provided format file, you can create a format from scratch. For an example that shows how to complete this task, see Create a new format configuration.

Review the format

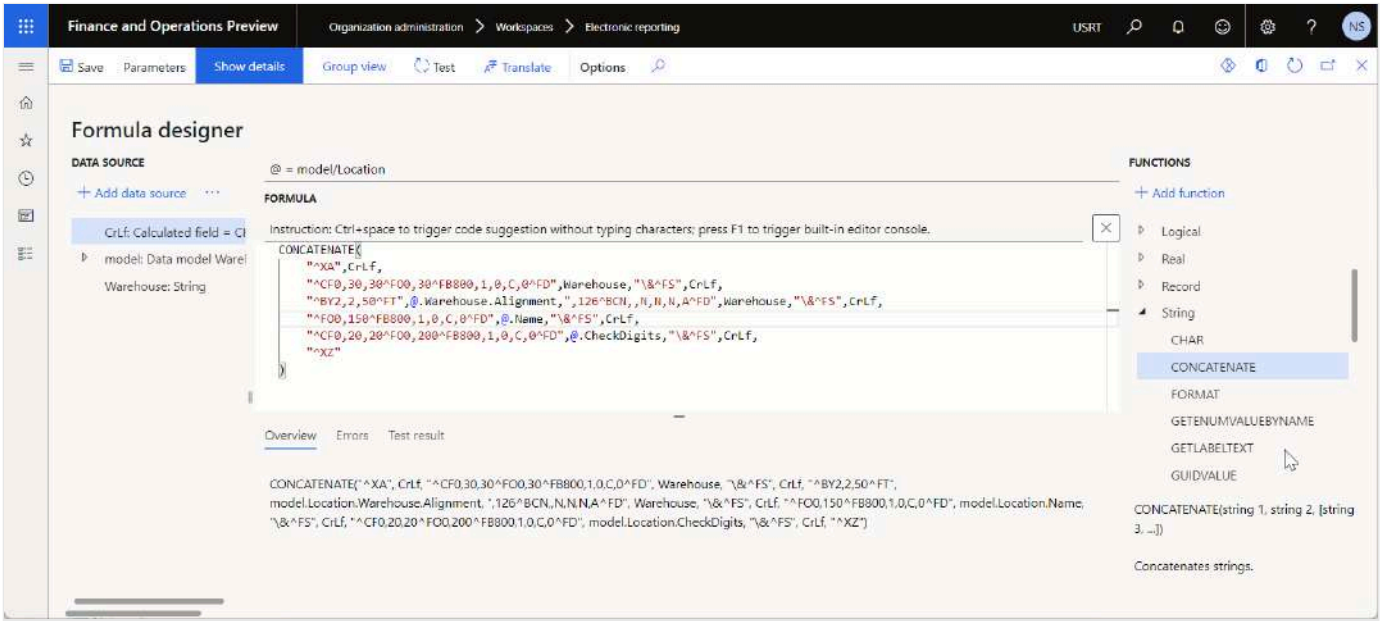
You can view an editable version of the configured format on the **Format designer** page.



The `model.Location.Label` data source of this format is configured to generate labels that contain the following information:

- The warehouse title as text
- The warehouse title as a bar code
- The location title
- Check digits

On the **Formula designer** page for the data source, the ER formula that generates labels includes a `CONCATENATE` function that combines the information in the desired layout.



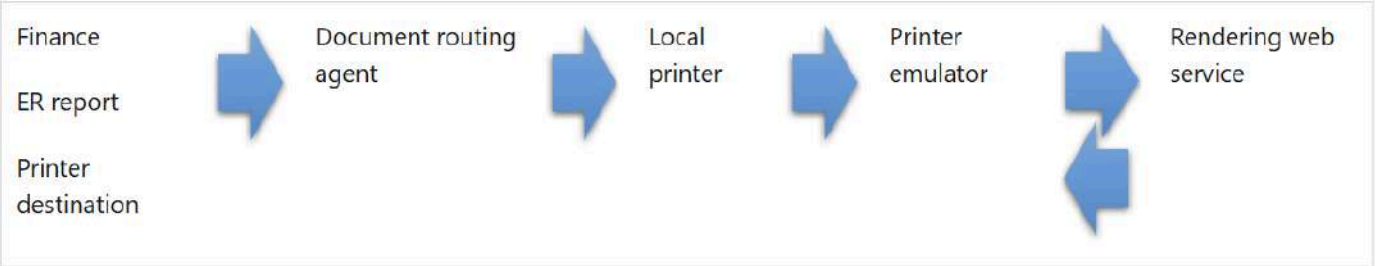
> **Tip**

The label layout is designed so that the location title and the check digits are aligned in the center of the label. However, ZPL II doesn't support center alignment for bar codes. Therefore, the formula of the `model.Location.Warehouse.Alignment` data source aligns the bar code in the center of the label. This formula calculates the left offset of the bar code, based on the number of characters in the warehouse title.

Prepare your environment for previewing generated labels

The following example uses a printer emulator application for ZPL labels to show a preview of generated labels on the screen. Follow these steps to enable this option.

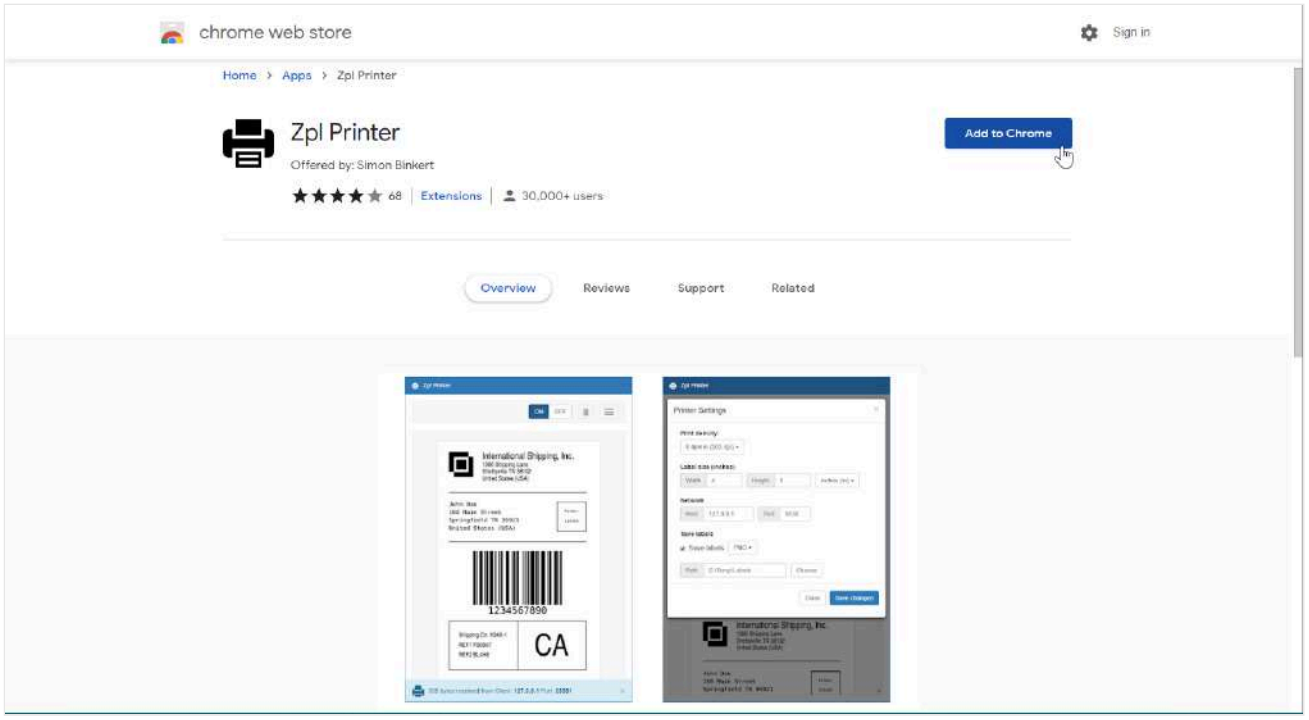
1. Add the Printer ER destination for the **Warehouse location label** ER format, and configure it to send generated labels from Finance to the Document routing agent (DRA).
2. Install and configure the DRA to route generated labels from Finance to a local printer that you can access from the current workstation.
3. Add a local printer for the current workstation, and configure it to pass generated labels from the DRA to a printer emulator application.
4. Install a printer emulator application as an extension of the Chrome web browser, and configure it to pass generated labels from a local printer to a web service that renders generated labels and returns them to the printer emulator for preview.



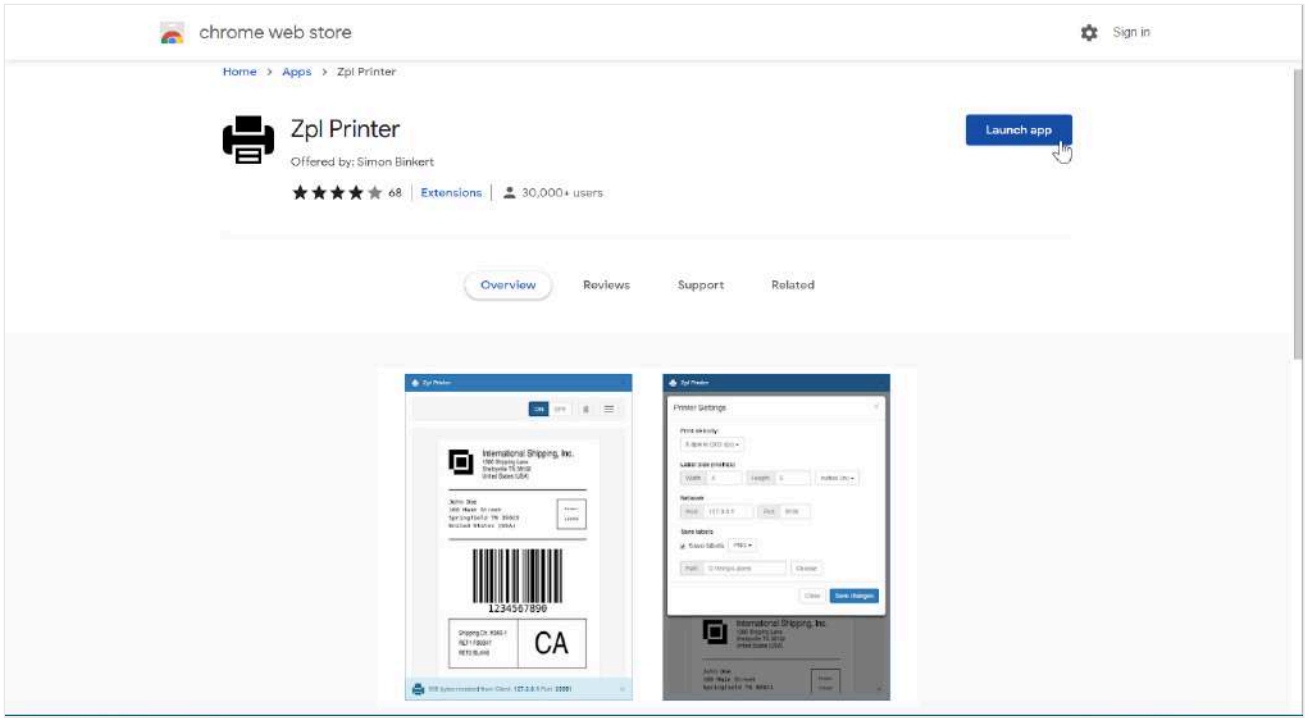
Install and configure a printer emulator application

Add a printer emulator application for the ZPL rendering engine to your Chrome web browser. This example uses the Zpl Printer emulator that is based on the Labelary ZPL web service. The printer emulator application passes generated labels in ZPL format from a local printer to the web service and then returns labels as PDF or PNG files for preview.

1. In the Chrome web store, find and select the printer emulator application that you want to use. Then select **Add to Chrome** to add it to your Chrome web browser.



2. Select **Launch app** to run the printer emulator application from the Chrome web browser.

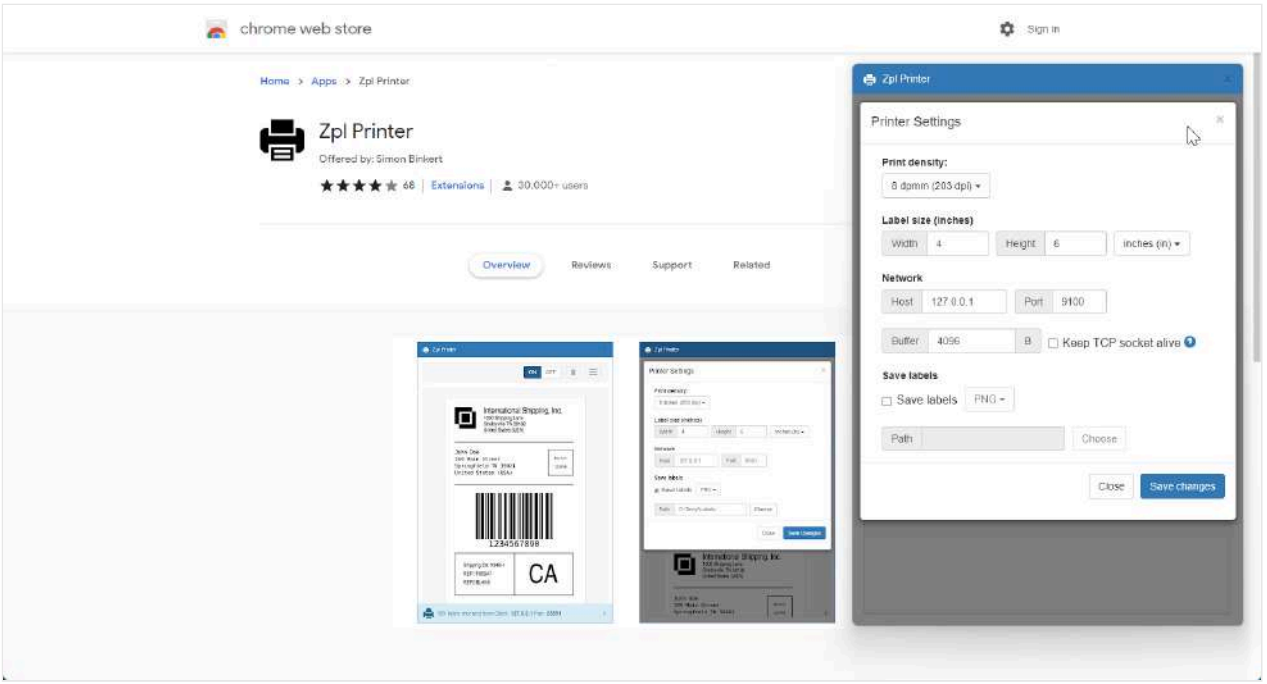


3. Configure the running application:

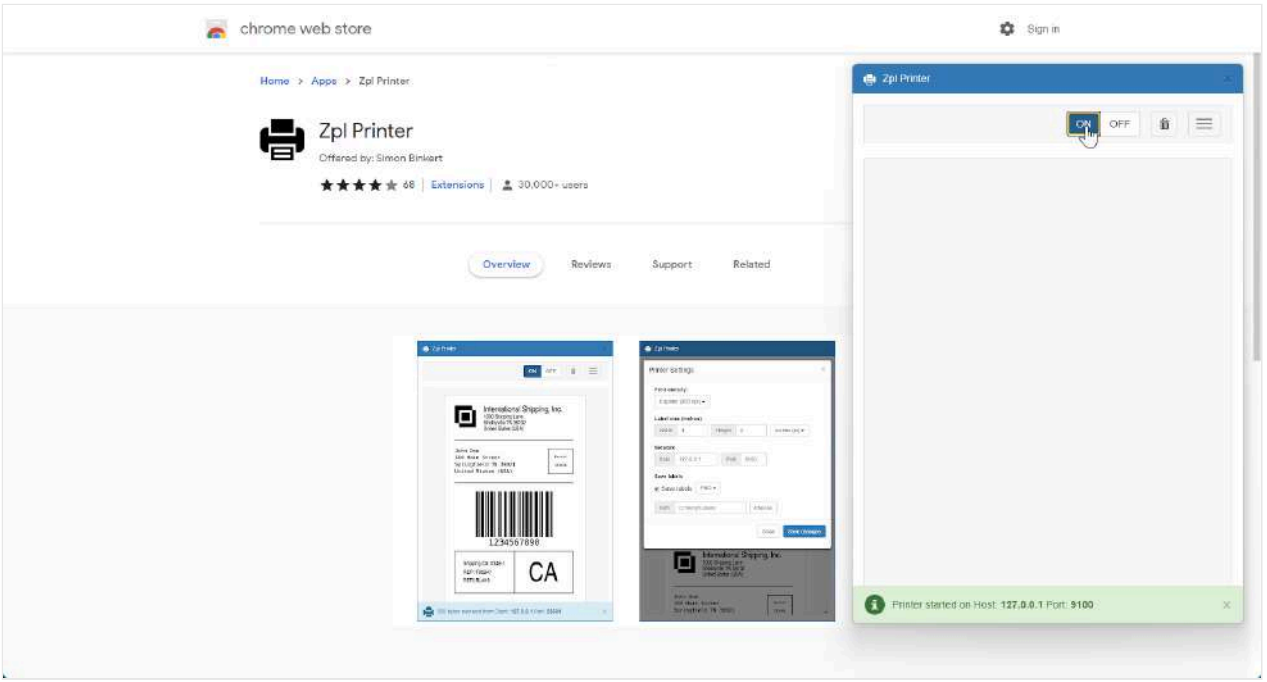
   a. Turn the application off.

   b. In the printer settings, set the host to **127.0.0.1**.

   c. Set the port to **9100**.



d. Turn the application back on. You receive a message that states that the printer was started on the specified host and port.

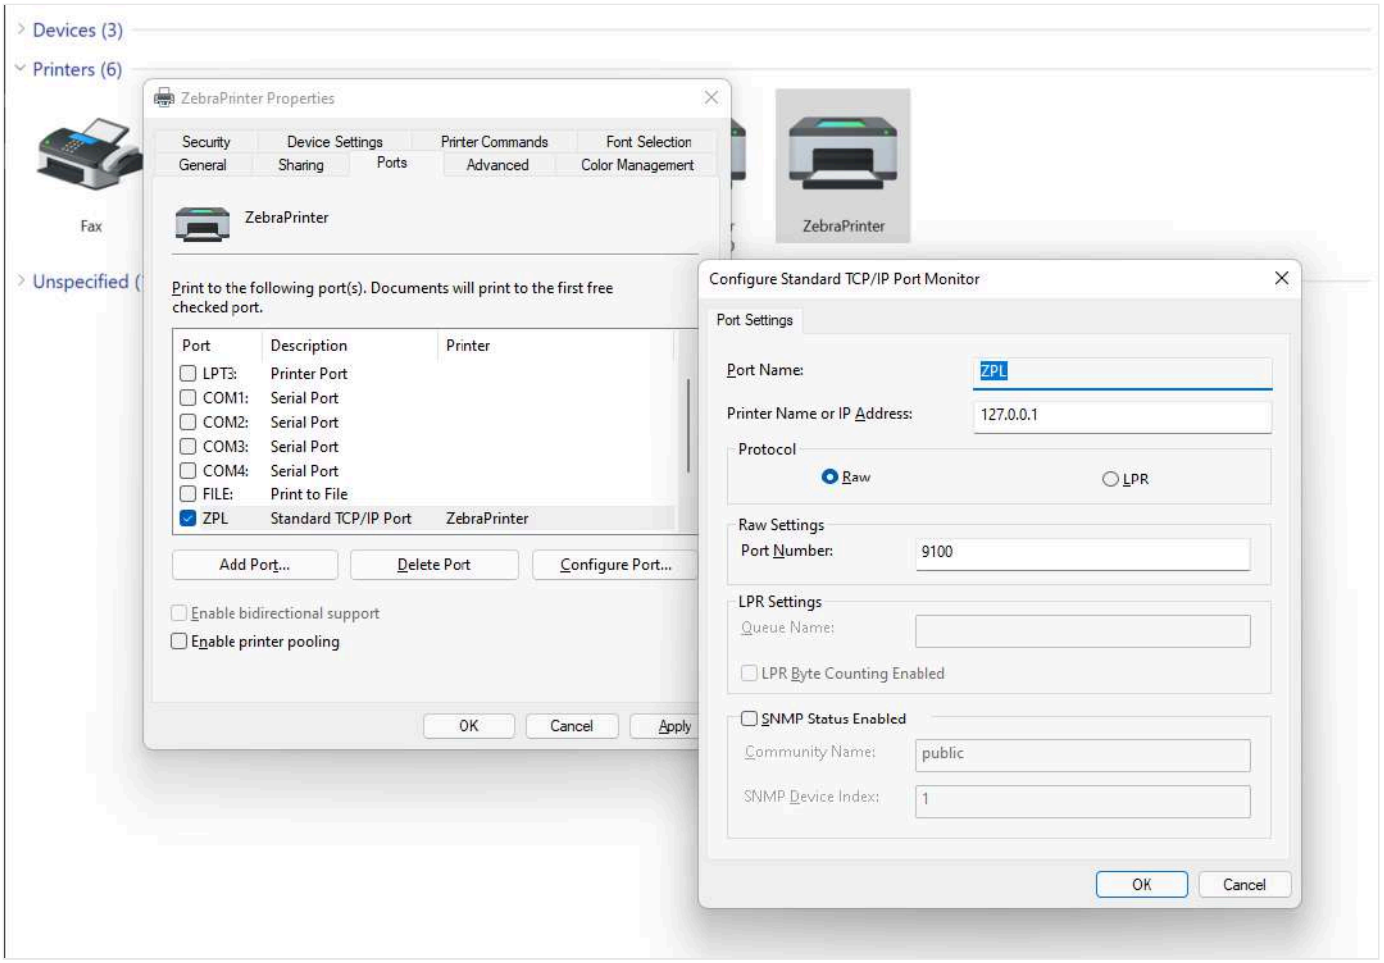


> **Note**
>
> Because the printer emulator application that this example uses relies on a web service to render labels, make sure that your security settings allow you to communicate with the service. Otherwise, the application doesn't receive the rendered labels, and no preview of those labels is available.

Add and configure a local printer

Add a new local printer that the current device can use to pass generated labels from the DRA to the printer emulator application.

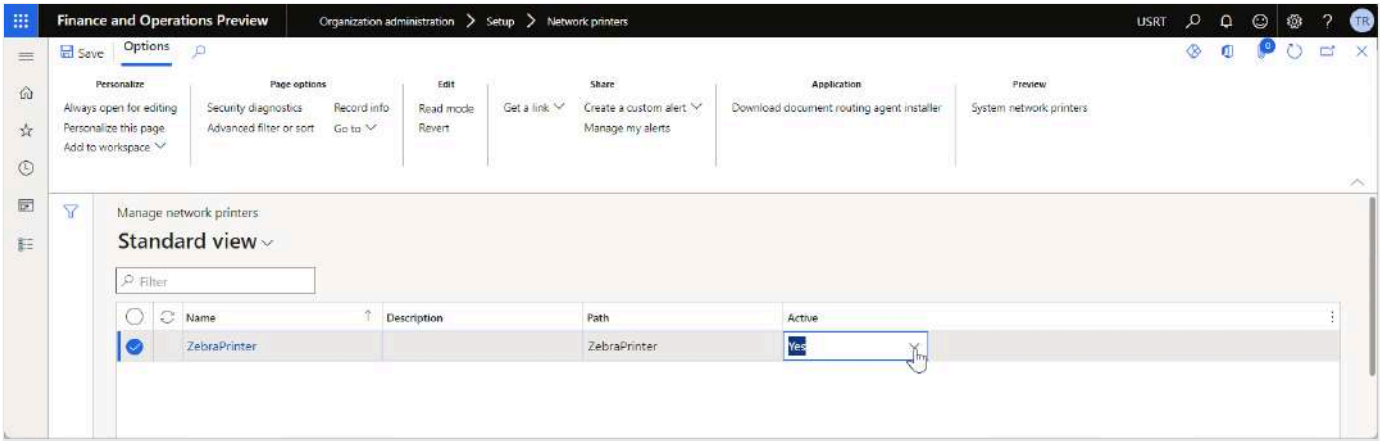
1. In Windows, select **Start** > **Settings** > **Devices** > **Printers & scanners**.
2. Select **Printers & scanners settings**.
3. For **Add a printer or scanner**, select **Add device**.
4. For **The printer that I want isn't listed**, select **Add manually**.
5. In the **Find a printer by other options** field, select **Add a local printer or network printer with manual settings**.
6. In the **Choose a printer port** field, select **Create a new port**, and then follow these steps:
   a. In the **Type of port** field, select **Standard TCP/IP Port**.
   b. In the **Hostname or IP address** field, enter **127.0.0.1**.
   c. In the **Port name** field, enter **ZPL**.
   d. Wait until the **Detecting TCP/IP port** operation completes.
   e. In the **Device type** field, select **Custom**, and then select **Settings**.
   f. Make sure that the following port settings are specified:
      - **Port name:** ZPL
      - **Printer name or IP address:** 127.0.0.1
      - **Protocol:** Raw
      - **Port number:** 9100
7. In the **Install the printer driver** field, select **Generic / Text only**.
8. In the **Printer name** field, enter **ZebraPrinter**.



Install and configure the DRA

Prepare the DRA to pass generated labels from Finance to the configured local printer.

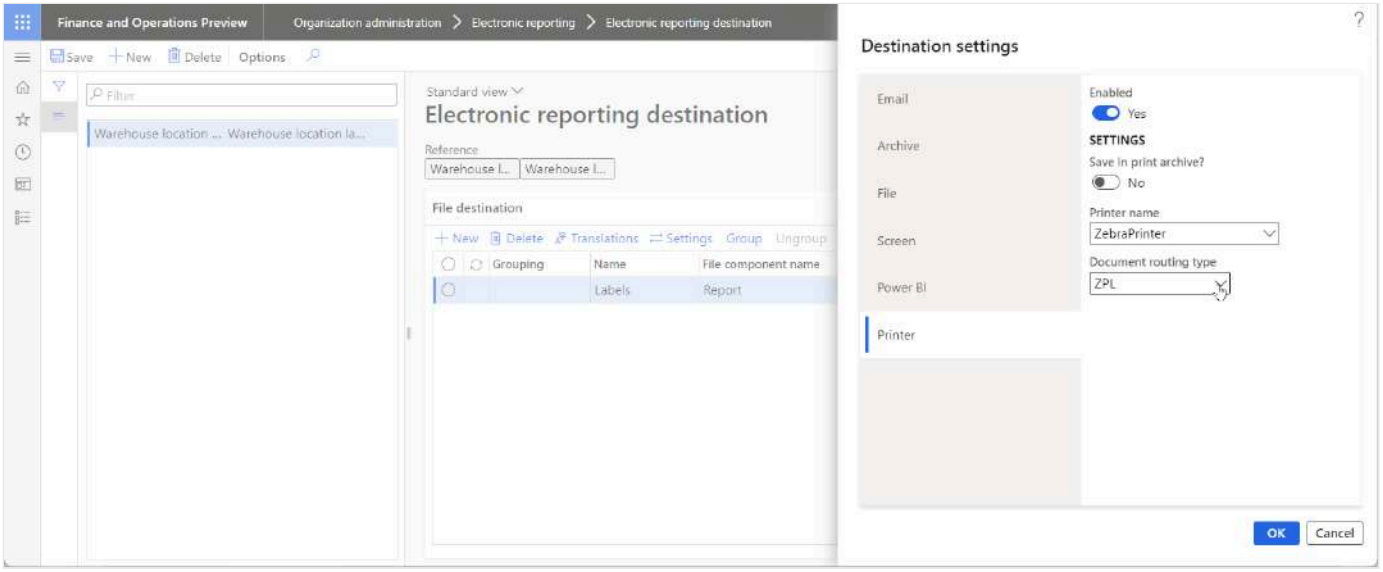
1. Install the DRA.
2. Configure the DRA.
3. Register the local printer in the DRA.
4. Activate the local printer in your Finance environment.



Configure the ER destination

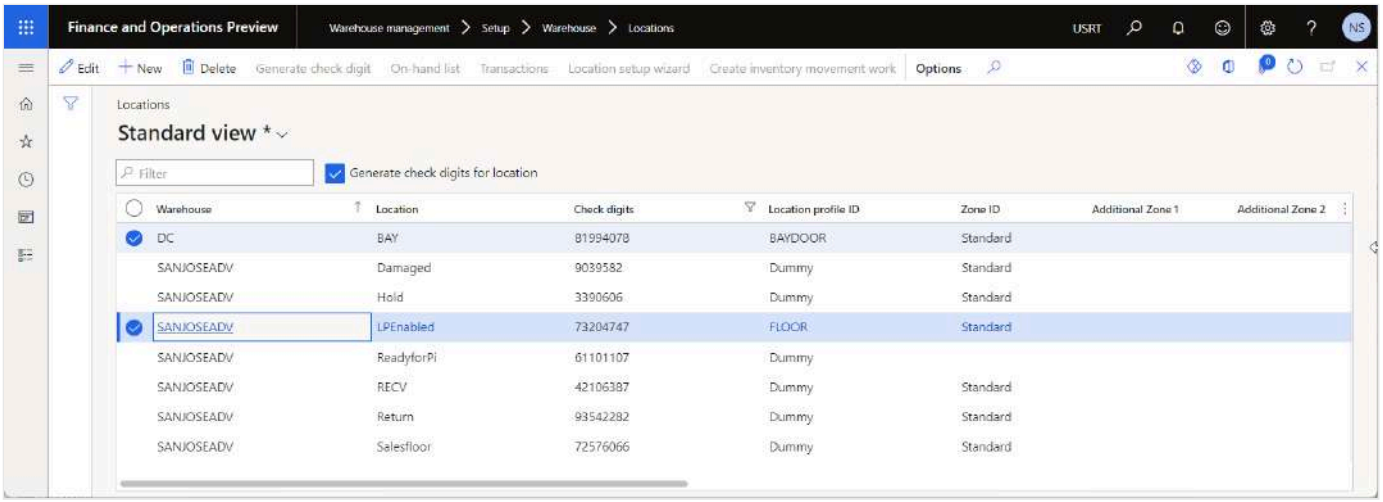
Prepare the ER destination to pass generated labels from Finance to the DRA.

1. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting destination**.
2. On the **Electronic reporting destination** page, on the Action Pane, select **New**.
3. In the **Reference** field, select **Warehouse location labels**.
4. On the **File destination** FastTab, select **New**.
5. In the **Name** field, enter **Labels**.
6. In the **File component name** field, select **Report**.
7. Select **Settings**.
8. In the **Destination settings** dialog box, on the **Printer** tab, set the **Enabled** option to **Yes**.
9. In the **Printer name** field, select **ZebraPrinter**.
10. In the **Document routing type** field, select **ZPL**.
11. Select **OK**.



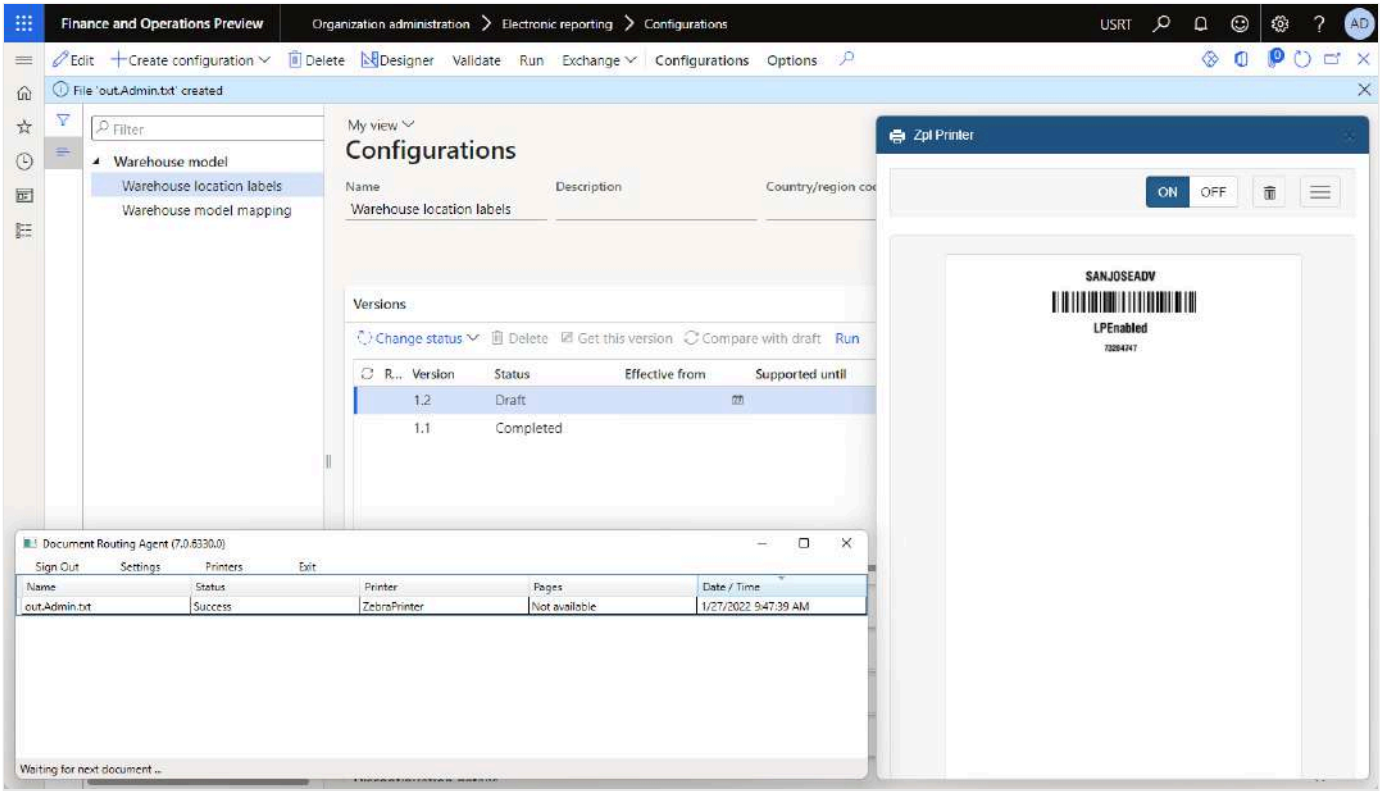
Review warehouse locations

1. Go to **Warehouse management** > **Setup** > **Warehouse** > **Locations**.
2. On **Locations**, filter to view only locations that have a value in the **Check digits** field.



Print warehouse location labels

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, in the configuration tree, expand **Warehouse model**, and select **Warehouse location labels**.
3. On the Action Pane, select **Run**.
4. In the **Electronic report parameters** dialog box, on the **Records to include** tab, select **Filter**.
5. On the **Range** tab, find the row where the **Table** field is set to **Locations** and the **Field** field is set to **Location**. In the **Criteria** field, enter **LPEnabled**.
6. Select **OK**.
7. Select **OK**. A label is generated and shown on the preview page in the printer emulator application.



Modify the layout of a label

You can change the current layout of your warehouse location labels. The following example shows how to change the layout so that generated labels include a location profile ID.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. Set the **Use destinations for draft status** ER user parameter to **Yes**.
3. On **Configurations**, in the configuration tree, expand **Warehouse model**, and select **Warehouse location labels**.
4. Select **Designer**.
5. On **Format designer**, on the **Mapping** tab, select the `model.Location.Label` data source.
6. In the **Data source properties** dialog box, select **Edit** > **Edit formula**.
7. On **Formula designer**, in the **Formula** field, review the ER formula that generates labels.

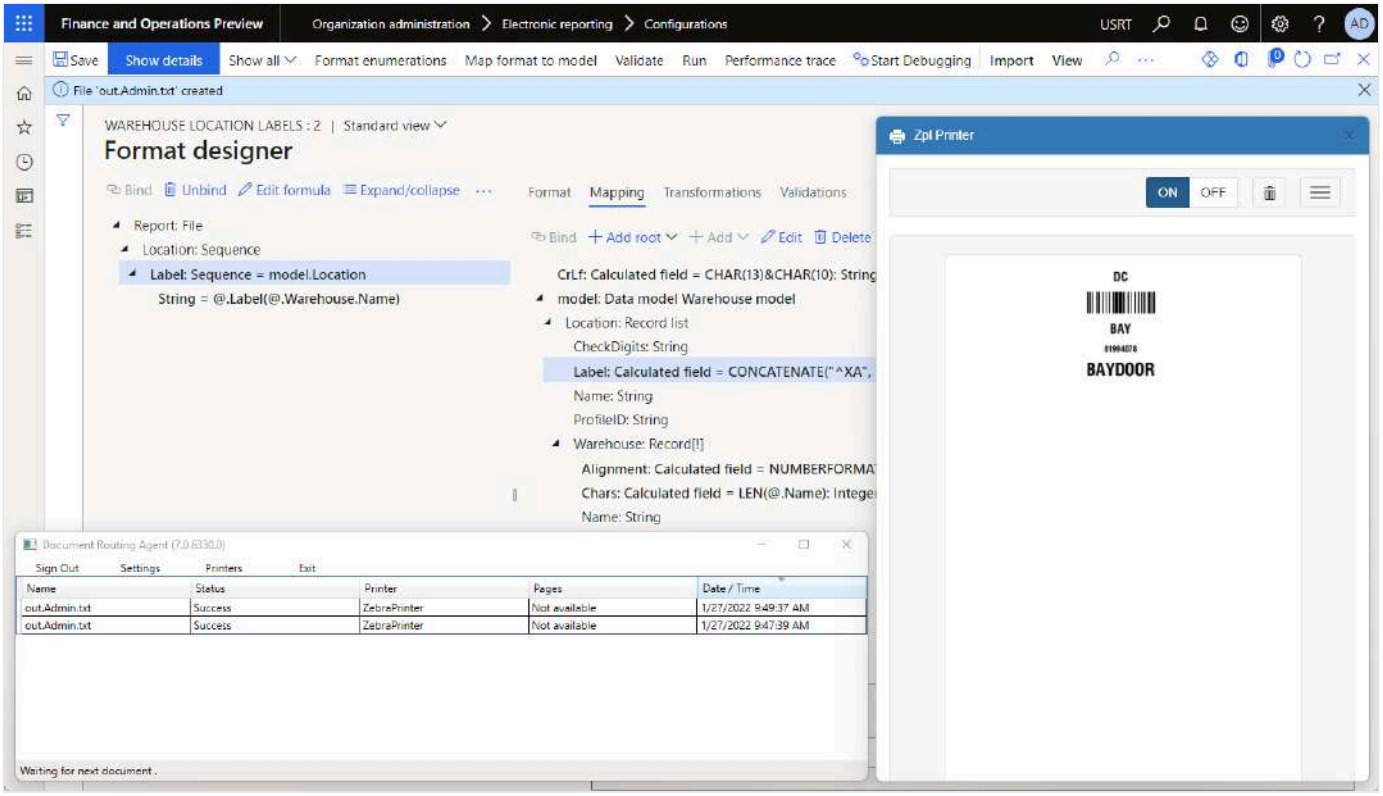
```VB
CONCATENATE(
"^XA",CrLf,
"^CF0,30,30^FO0,30^FB800,1,0,C,0^FD",Warehouse,"\&^FS",CrLf,
"^BY2,2,50^FT",@.Warehouse.Alignment,",126^BCN,,N,N,N,A^FD",Warehouse,"\&^FS",CrL
f,
"^FO0,150^FB800,1,0,C,0^FD",@.Name,"\&^FS",CrLf,
"^CF0,20,20^FO0,200^FB800,1,0,C,0^FD",@.CheckDigits,"\&^FS",CrLf,
"^XZ")
```

8. Update the formula to add a location profile ID to generated labels.

```VB
CONCATENATE(
"^XA",CrLf,
"^CF0,30,30^FO0,30^FB800,1,0,C,0^FD",Warehouse,"\&^FS",CrLf,
"^BY2,2,50^FT",@.Warehouse.Alignment,",126^BCN,,N,N,N,A^FD",Warehouse,"\&^FS",CrL
f,
"^FO0,150^FB800,1,0,C,0^FD",@.Name,"\&^FS",CrLf,
"^CF0,20,20^FO0,200^FB800,1,0,C,0^FD",@.CheckDigits,"\&^FS",CrLf,
"^CF0,40,40^FO0,240^FB800,1,0,C,0^FD",@.ProfileID,"\&^FS",CrLf,
"^XZ")
```

9. Select **Save**.

10. Select **OK**.
11. On the Action Pane, select **Run**.
12. In the **Electronic report parameters** dialog box, on the **Records to include** tab, select **Filter**.
13. On the **Range** tab, find the row where the **Table** field is set to **Locations** and the **Field** field is set to **Location**. In the **Criteria** field, enter **Bay**.
14. Select **OK**.
15. Select **OK**. A label is generated and shown on the preview page in the printer emulator application.



Encoding

> **Note**
>
> You must synchronize the encoding setting of the **Common\File** component of the editable ER format and the appropriate setting of the designed label. The value of the Encoding field of the **Common\File** component shouldn't contradict a ZPL command that controls the label's encoding (for example, the `^CI` command). ER doesn't validate that these settings are synchronized.

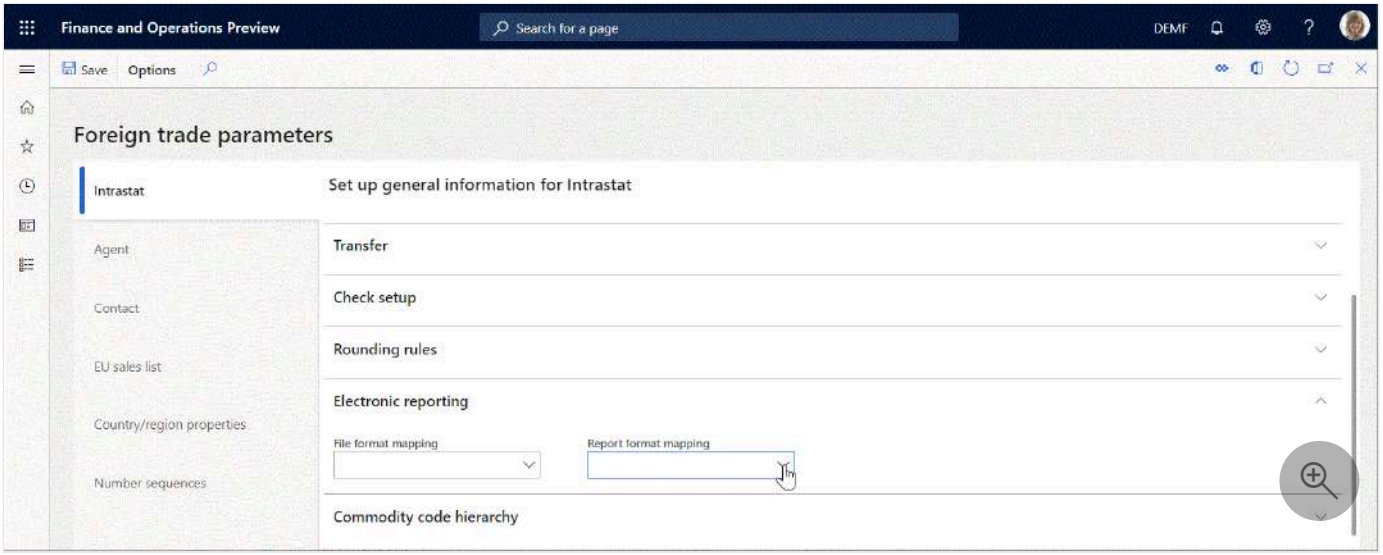
Allow users to set up an ER format reference by inquiring a format from the Global repository

Use the Electronic reporting (ER) framework to configure formats for outbound documents that comply with the legal requirements of various countries/regions. You can also use the ER framework to configure formats for parsing inbound documents and use the information from those documents to append or update application data. You can use each of these formats in your Dynamics 365 Finance instance for handling inbound or outbound business documents as part of a certain business process.

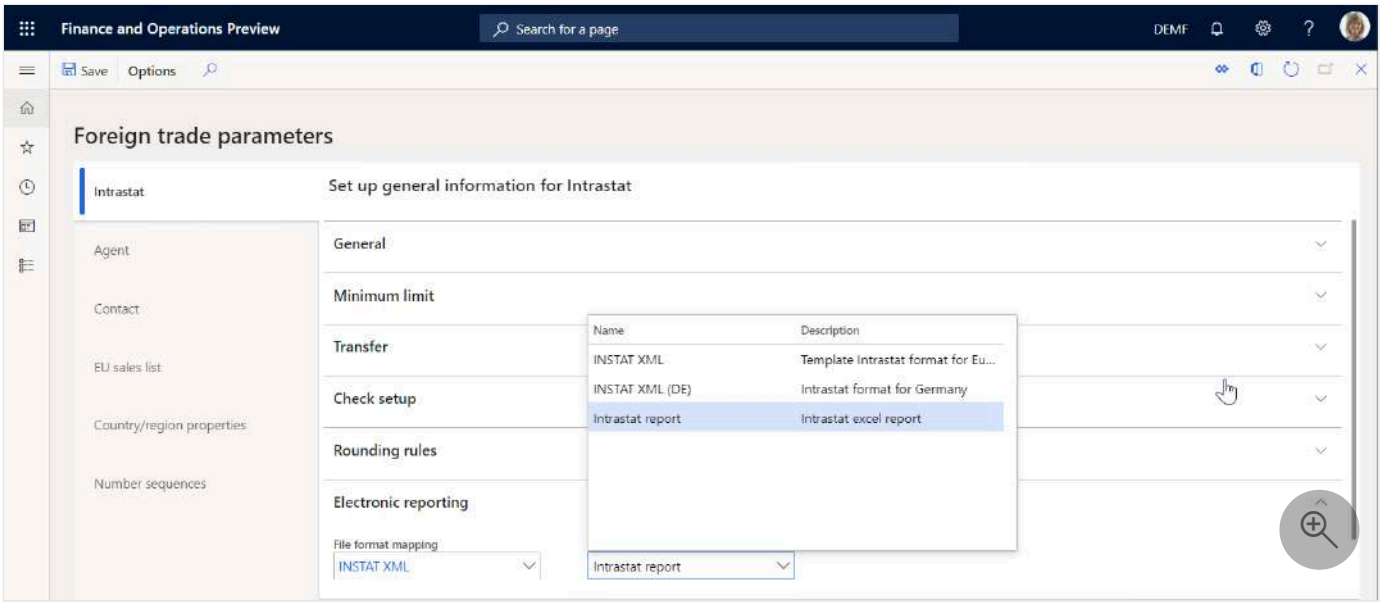
Usually, you must specify what ER format to use in a certain business process. To do that, select a single ER format in a lookup field configured as part of business process-specific parameters. Use the appropriate API of the ER framework to implement these lookup fields. For more information, see ER framework API - code to display a format mapping lookup.

For example, when you configure foreign trade parameters, you need to set up the references to individual ER formats that generate the Intrastat declaration and the Intrastat declaration control report. The following screenshots show how the ER formats lookup field looks in the **Foreign trade parameters** page.

If the current Finance instance contains no Intrastat business process-related ER formats, this lookup field is empty.

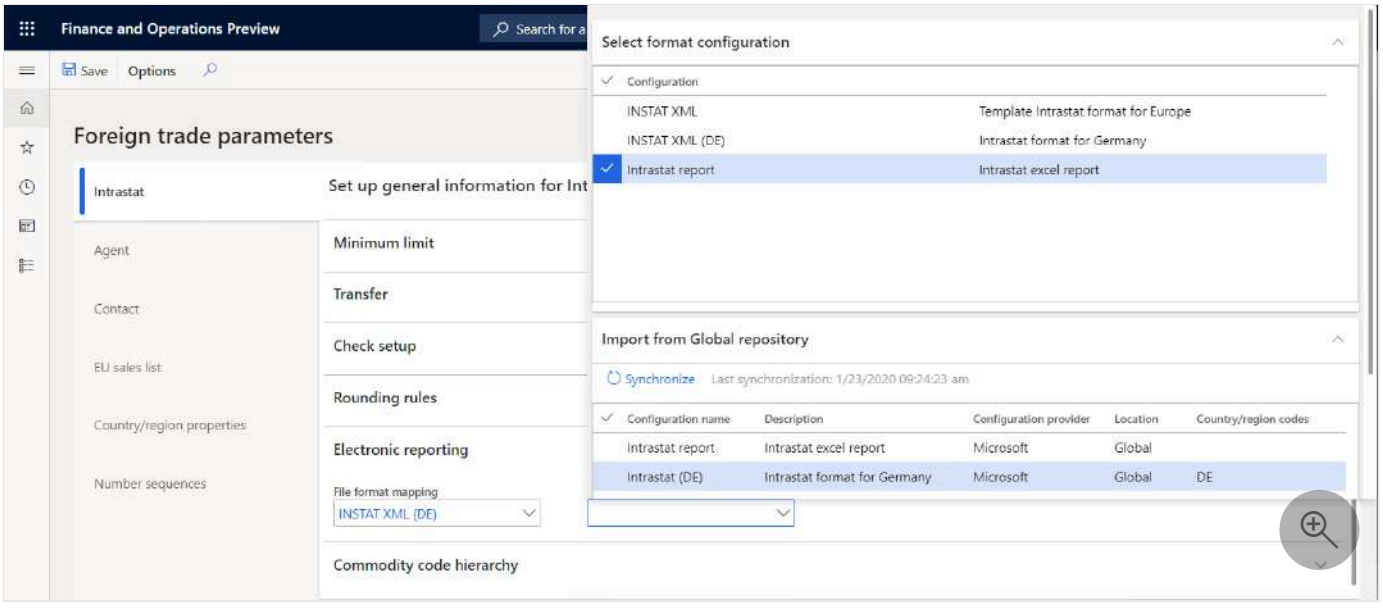


If the current Finance instance contains Intrastat business process related ER formats, this lookup field offers the ER formats.



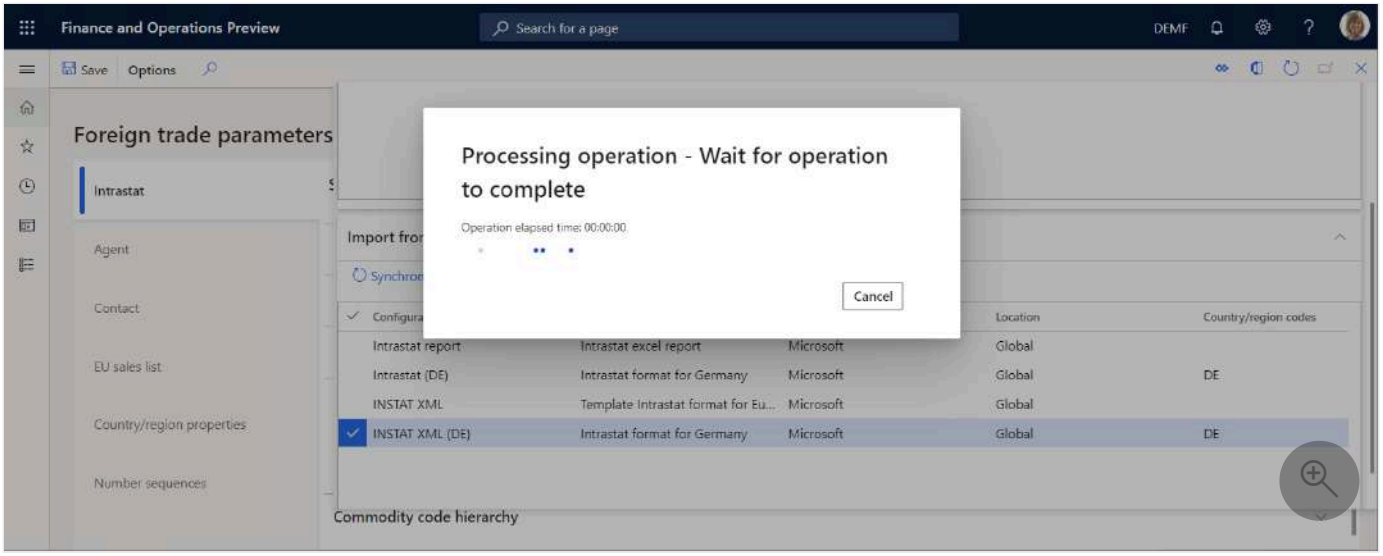
This lookup offers only the ER formats that are already imported to the current Finance instance. To import ER solutions to the current Finance instance, you need permissions to run the appropriate function of the ER framework that supports the lifecycle of ER solutions that contain ER formats.

Starting in Finance version 10.0.9 (April 2020 release), the user interface of the ER format lookup that the ER framework API implements is extended. You can still select the existing ER formats, which are on the **Select format configuration** FastTab. In addition, the extended lookup offers the new option to search the Global repository (GR) to locate specific ER formats. All ER formats of the GR are offered on the **Import from Global repository** FastTab.

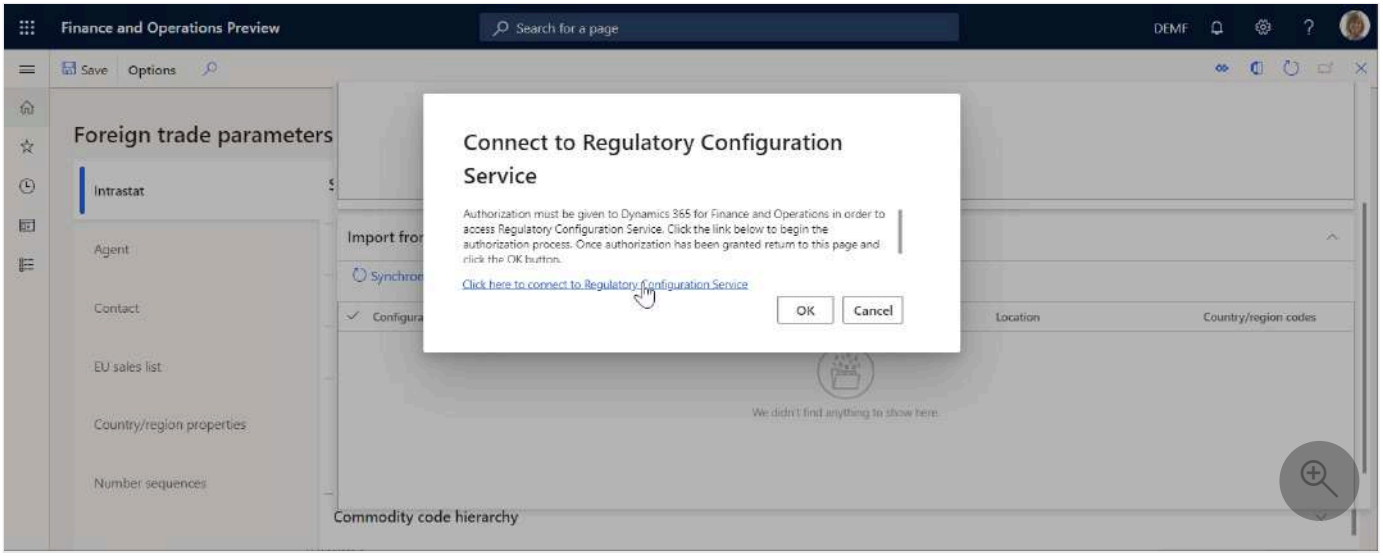


Similar to the **Select format configuration** FastTab, the **Import from Global repository** FastTab shows only the ER formats that are applicable to the business process for which an ER format is selected in this lookup field. In this example, the generation of Intrastat declaration. The ER format is applicable for the company to which the user is currently signed in, depending on the company country/region context.

When you select an ER format on the **Import from Global repository** FastTab, the selected ER format configuration is imported from the GR to the current Finance instance.



If the import completes successfully, the reference to the imported ER format is stored in this lookup field. When you access the GR for the first time, you need to follow the link provided to sign up for the Globalization studio workspace that is used to manage access to the GR storage.

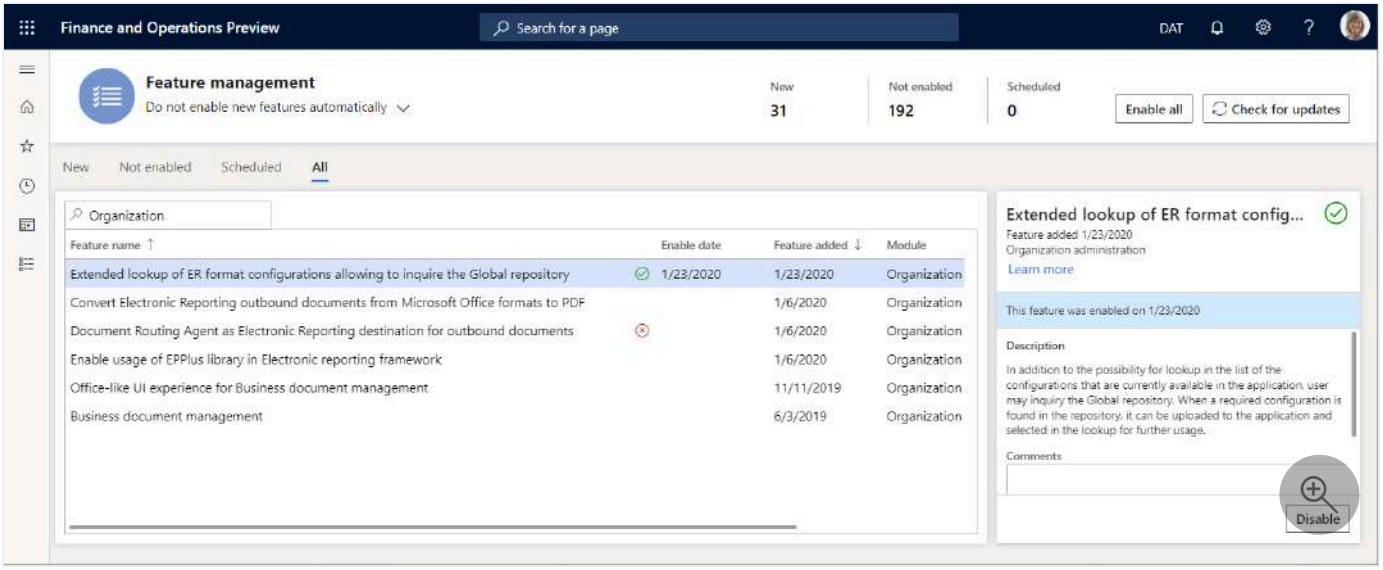


By default, the **Import from Global repository** FastTab presents the list of ER formats from the temporary storage that is automatically created based on the GR content for performance improvements. This happens when the **Import from Global repository** FastTab is opened the first time, which might take several seconds.

If you don't see the required ER format in the **Import from Global repository** FastTab, but you're sure that this ER format is stored in the GR, select the **Synchronize** option. This option updates the temporary storage and synchronizes it with the current content of the GR.

Feature activation

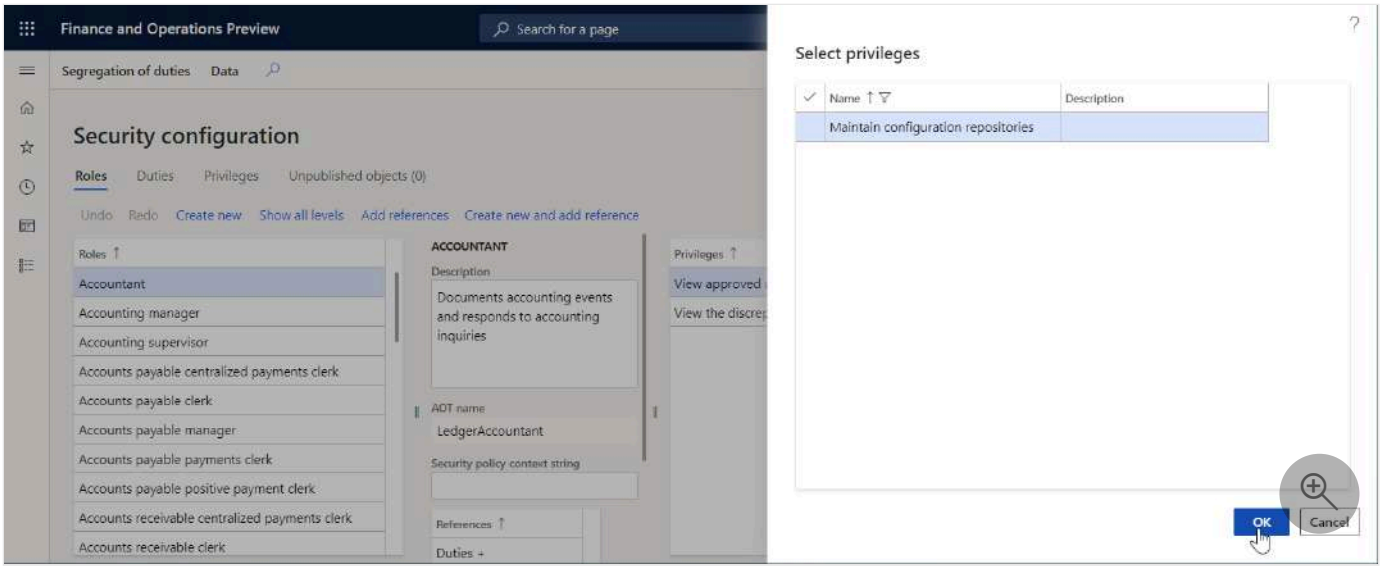
The availability of this functionality is controlled by the feature **Extended lookup of ER format configurations allowing to inquire the Global repository** in **Feature management**. This feature is enabled by default.



Security considerations

The **Maintain configuration repositories** (**ERMaintainSolutionRepositories**) privilege controls access to the GR for a user opening the ER format lookup with the enabled **Import from Global repository** FastTab. To allow users to access the GR content from the ER format lookups, change the security settings by granting the **ERMaintainSolutionRepositories** privilege to users either directly or by using already assigned roles and duties.

The following screenshot shows how to grant this privilege to users who are assigned to the **Accountant** role. This role allows users to configure foreign trade parameters and set up references to the ER formats in the **File format mapping** and **Report format mapping** fields on the **Foreign trade parameters** page.



Limitations

Access to the GR in the ER format lookup is currently only supported for the selection of ER formats that are used to generate outbound documents.

Frequently asked questions

Why can't I access the Global repository from the ER format lookup?

If you enable the **Extended lookup of ER format configurations allowing to inquire the Global repository** feature on the **Feature management** page, but users can't see ER formats on the **Import from Global repository** FastTab and the **Synchronize** option is visible but disabled, make sure that the **Maintain configuration repositories** (**ERMaintainSolutionRepositories**) privilege is granted to the user. Contact your system administrator to receive this privilege.

Trace generated report results and compare them with baseline values

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can trace the results of Electronic reporting (ER) formats that generate outgoing electronic documents. When you turn on trace generation by using the **Run in debug mode** ER user parameter, the system creates a new trace record in the ER format execution log every time it runs an ER report. Each trace record stores the following details:

- All warnings that validation rules generate
- All errors that validation rules generate
- All generated files that are stored as attachments of the trace record

You can store individual baseline application files for any ER format. Files are baseline files when they describe the expected results of reports that are run. If a baseline file exists for an ER format that you run while trace generation is turned on, the trace stores, in addition to the earlier mentioned details, the result of the comparison of the generated electronic document with the baseline file. In one click, you can also get the generated electronic document and its baseline file in a single zip file. You can then do detailed comparison by using an external tool such as WinDiff.

You can evaluate the trace to analyze whether the electronic documents that are generated include the expected content. You can do this evaluation in a user acceptance testing (UAT) environment when the code base changes (for example, when you migrated to a new instance of the application, installed hotfix packages, or deployed code modifications). In this way, you make sure that the evaluation doesn't affect the execution of ER reports that are used. For many ER reports, the evaluation can be done in unattended mode.

To learn more about this feature, watch the **ER Generate reports and compare results (Part 1)** and **ER Generate reports and compare results (Part 2)** task guides. These task guides are part

of the **7.5.4.3 Test IT services/solutions (10679)** business process and can be downloaded from the Microsoft Download Center. These task guides walk you through the process of configuring the ER framework to use baseline files to evaluate generated electronic documents.

Example: Trace generated report results and compare them with baseline values

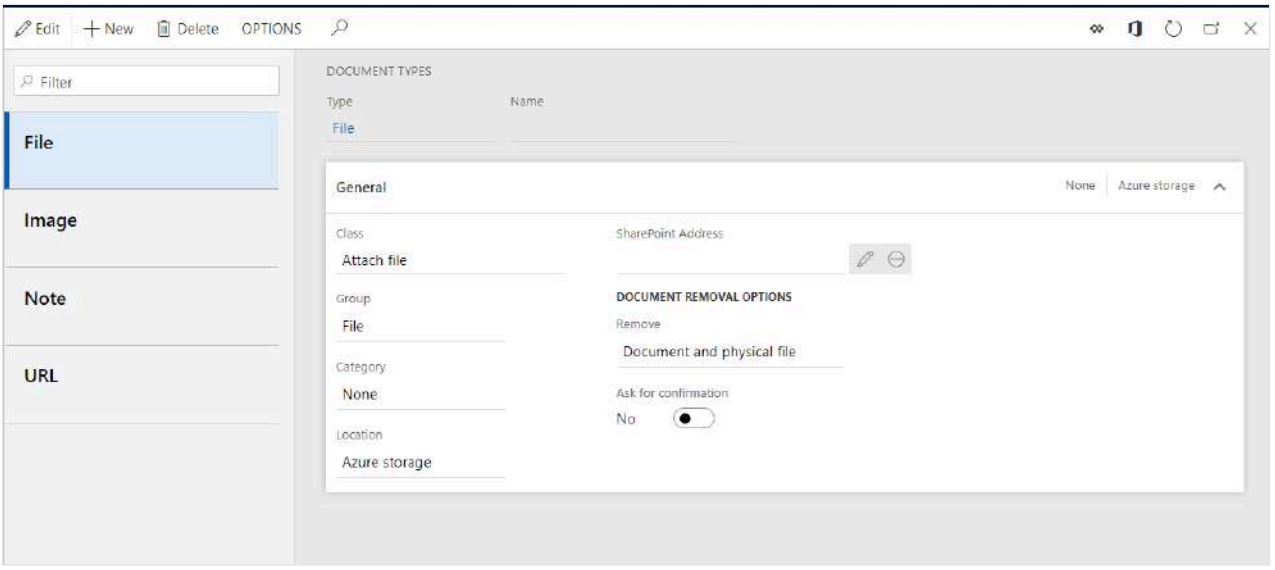
This procedure explains how to configure the ER framework to collect information about ER format executions and then evaluate the results of those executions. As part of that evaluation, generated documents are compared with their baseline files. In this example, you create the required ER configurations for the Litware, Inc. sample company. This procedure is intended for users who have the System administrator or Electronic reporting developer role assigned to them. You can complete these steps by using any data set.

To complete the steps in this example, you must first complete the steps in Create configuration providers and mark them as active.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. On **Localization configurations**, in the **Configuration providers** section, verify that the configuration provider for the Litware, Inc. sample company is listed and marked as **Active**. If you don't see this configuration provider, follow the steps in Create configuration providers and mark them as active.

Configure document management parameters

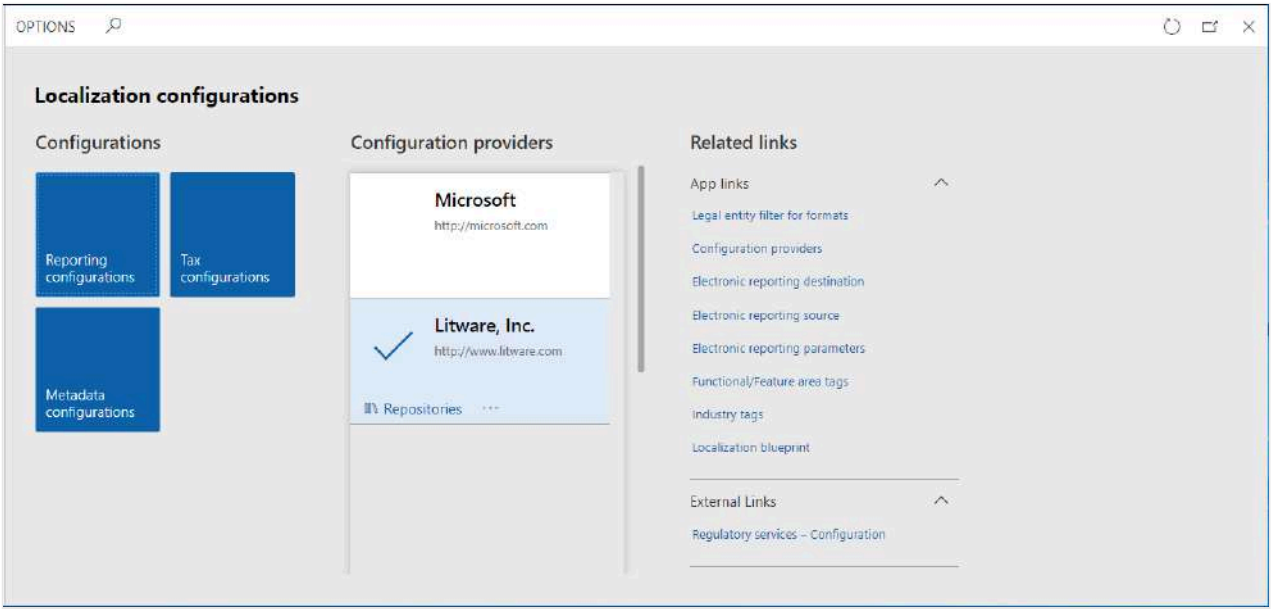
1. Go to **Organization administration** > **Document management** > **Document types**, and create a new document type to store baseline files.
2. In the **Class** field, enter **Attach file**.
3. In the **Group** field, enter **File**.



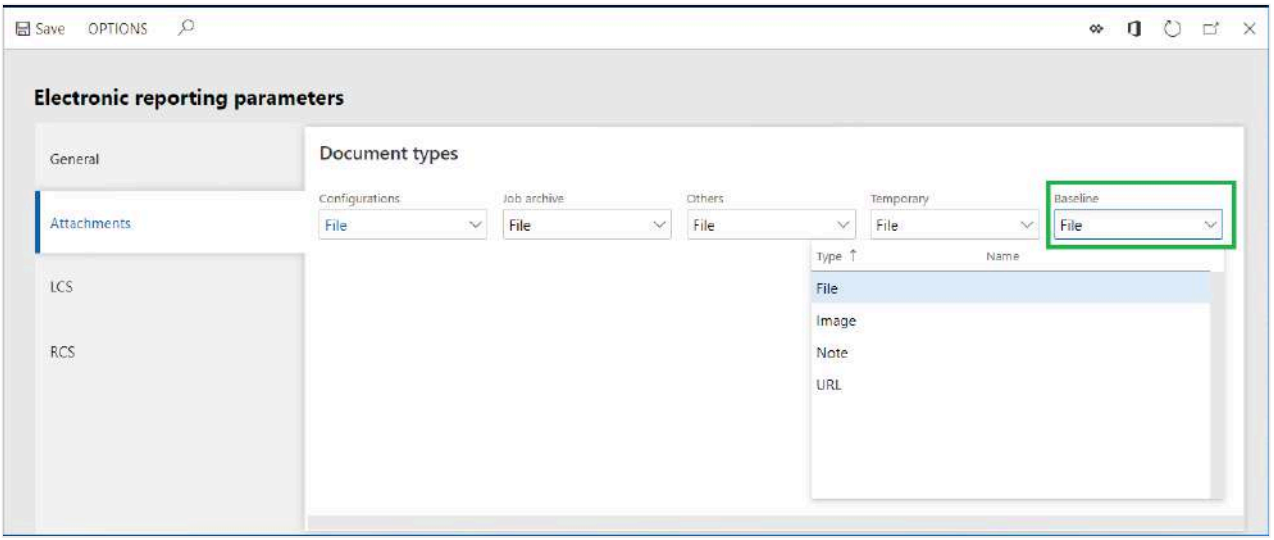
> **Note**
>
> You must configure a new document type with the same name for each data set where you plan to use the ER baseline feature.

Configure ER parameters to start using the baseline feature

1. In the **Electronic reporting** workspace, in the **Related links** section, select **Electronic reporting parameters**.



2. On the **Attachments** tab, in the **Baseline** field, enter or select the document type that you just created.



3. Select **Save**, and then close the **Electronic reporting parameters** page.

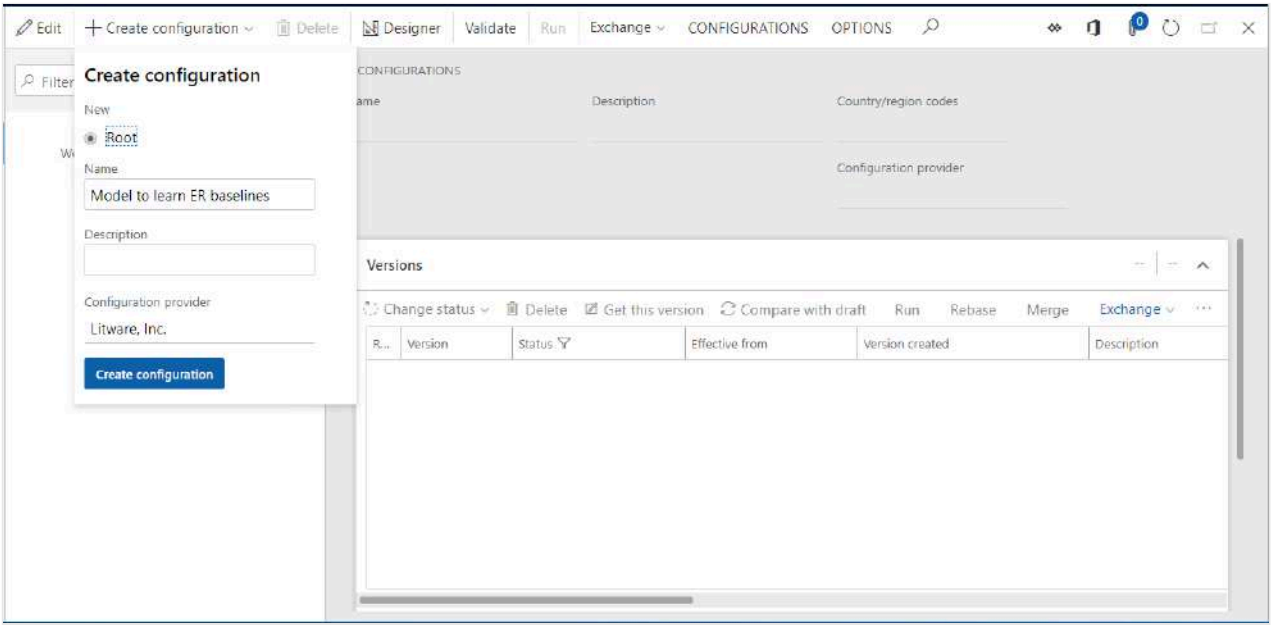
Add a new ER model configuration

1. In the **Electronic reporting** workspace, in the **Configurations** section, select the **Reporting configurations** tile.

2. On the Action Pane, select **Create configuration**.

3. In the drop-down dialog box, in the **Name** field, enter **Model to learn ER baselines**.

4. Select **Create configuration** to confirm the creation of a new ER data model entry.



Design a data model

1. On **Configurations**, on the Action Pane, select **Designer**.

2. Select **New**.

3. In the drop-down dialog box, in the **Name** field, enter **Root**.

4. Select **Add**.

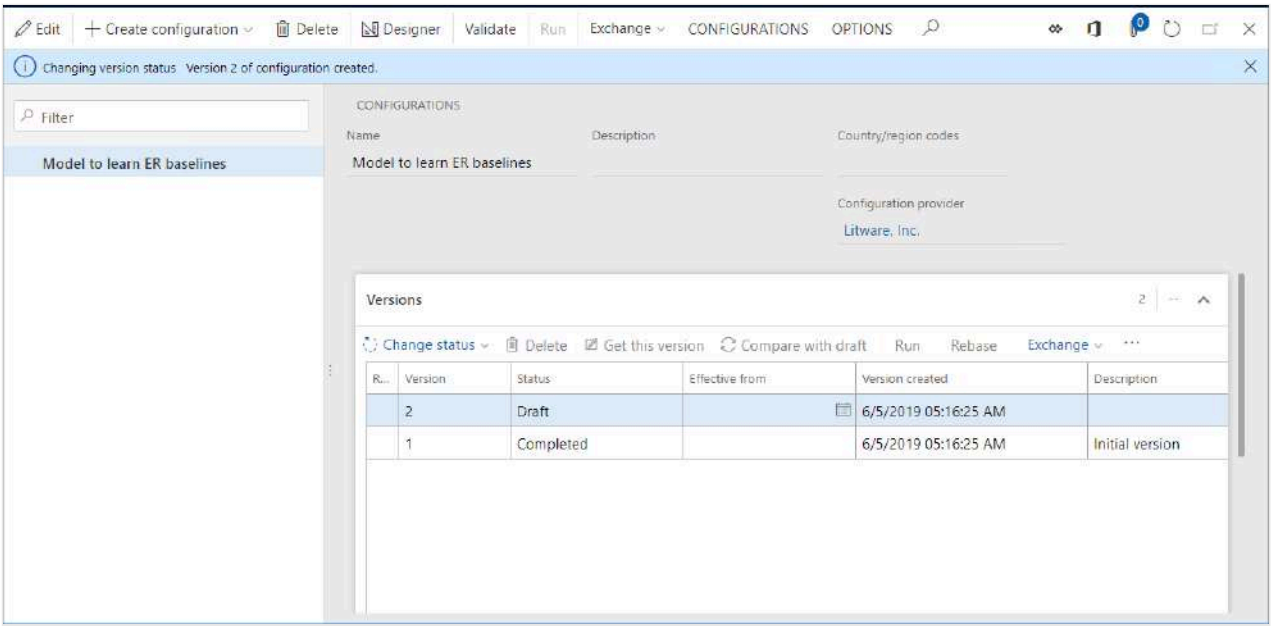
5. Select **Root reference**.

6. Select **OK**, and then select **Save**.

7. Close the **Model designer** page.

8. Select **Change status**.

9. Select **Complete**, and then select **OK**.



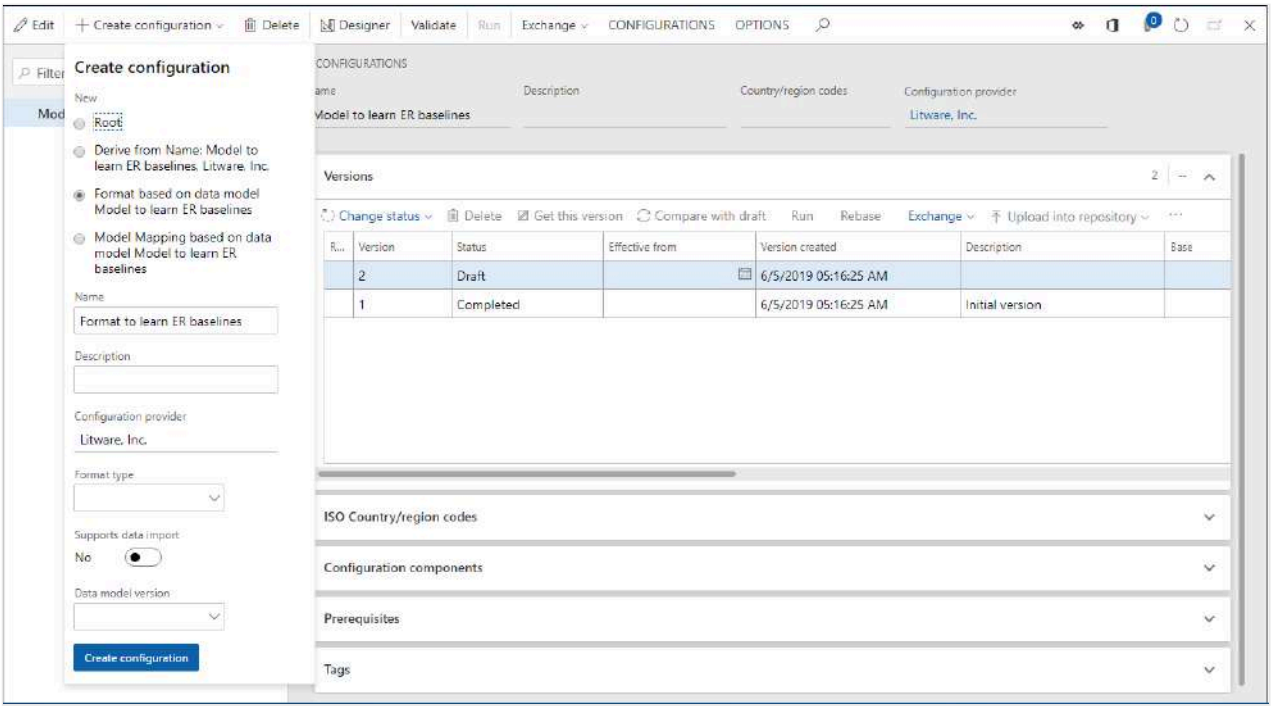
Add a new ER format configuration

1. On **Configurations**, on the action pane, select **Create configuration**.

2. In the drop-down dialog box, in the **New** field group, select **Format based on data model Model to learn ER baselines**.

3. In the **Name** field, enter **Format to learn ER baselines**.

4. Select **Create configuration** to confirm the creation of a new ER format entry.



Design a format

For this example, create a simple ER format to generate XML documents.

1. On **Configurations**, on the Action Pane, select **Designer**.

2. Select **Add root**.

3. In the drop-down dialog box, follow these steps:
   a. In the tree, select **Common\File**.
   b. In the **Name** field, enter **Output**.
   c. Select **OK**.

4. Select **Add**.

5. In the drop-down dialog box, follow these steps:
   a. In the tree, select **XML\Element**.
   b. In the **Name** field, enter **Document**.
   c. Select **OK**.

6. In the tree, select **Output\Document**.

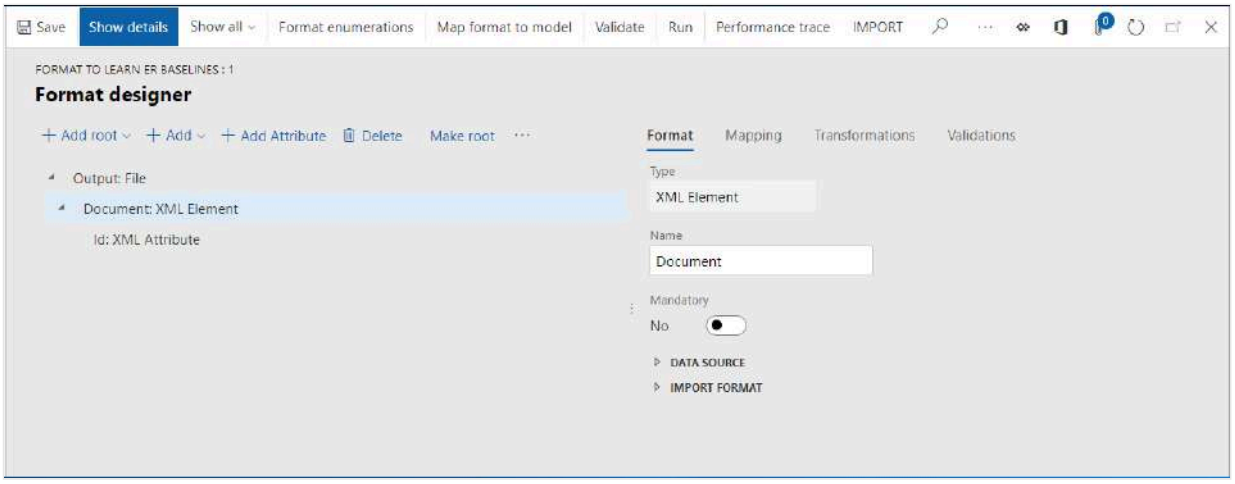
7. Select **Add**.

8. In the drop-down dialog box, follow these steps:

   a. In the tree, select **XML\Attribute**.

b. In the **Name** field, enter **ID**.

c. Select **OK**.



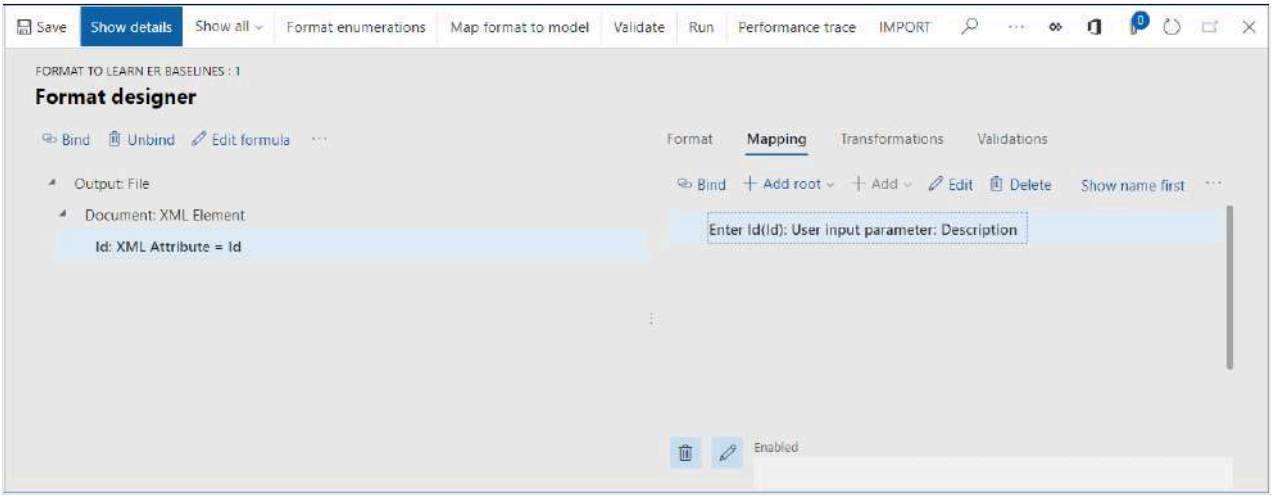
9. On the **Mapping** tab, select **Delete**.

10. Select **Add root**.

11. In the drop-down dialog box, in the tree, select **General\User input parameter**, and then follow these steps:
    a. In the **Name** field, enter **ID**.
    b. In the **Label** field, enter **Enter ID**.
    c. Select **OK**.

12. In the tree, select **Output\Document\Id**.

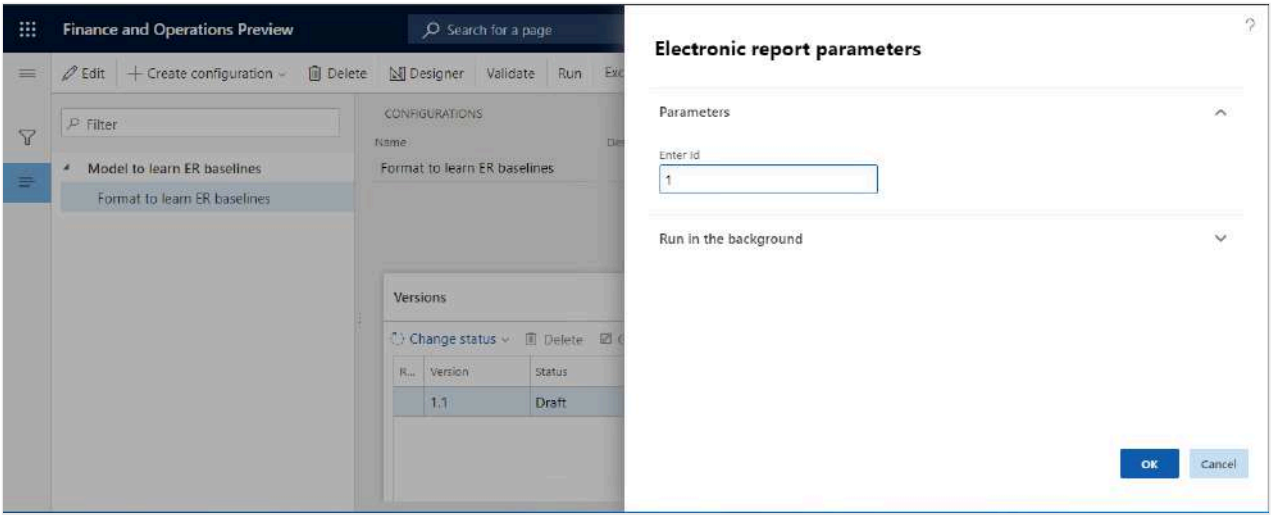
13. Select **Bind**, and then select **Save**.



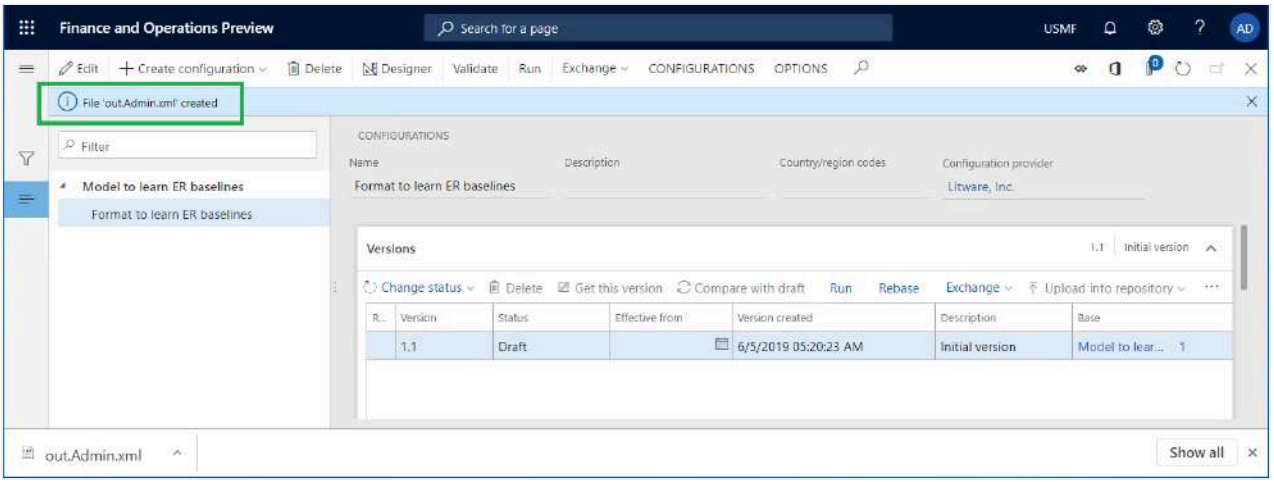
Based on the designed structure, the configured format generates an XML file. This XML contains the **Root** element that has the **ID** attribute set to the value that the user enters in the ER runtime dialog box.

Generate a new baseline file for a designed ER format

1. On **Configurations**, on the **Versions** FastTab, select **Run**.
2. In the **Enter ID** field, enter **1**.
3. Select **OK**.

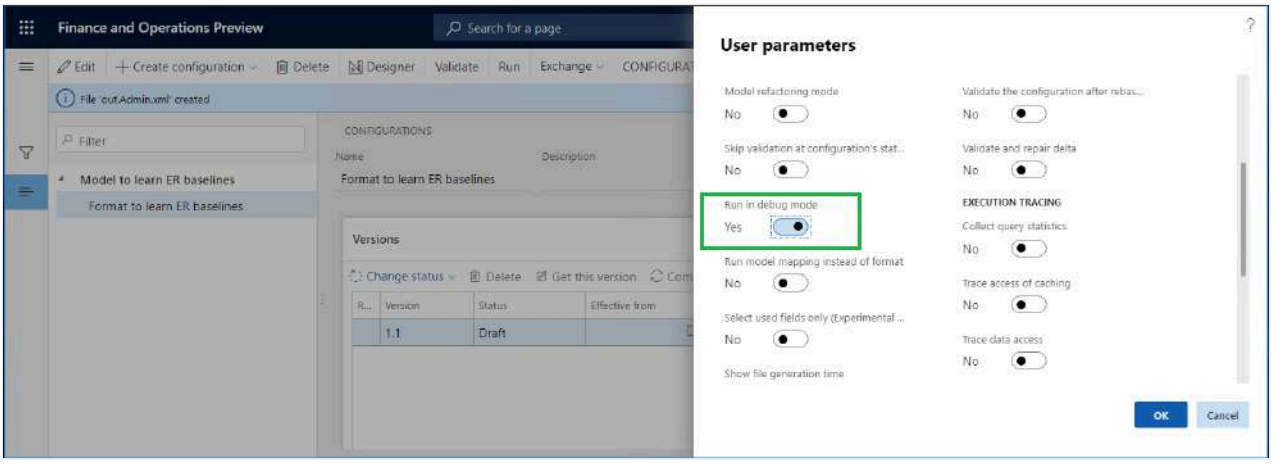


4. Save a local copy of the **out.Admin.xml** file that is generated, so you can use it later as a baseline for this ER format.



Configure ER parameters to use the baseline feature

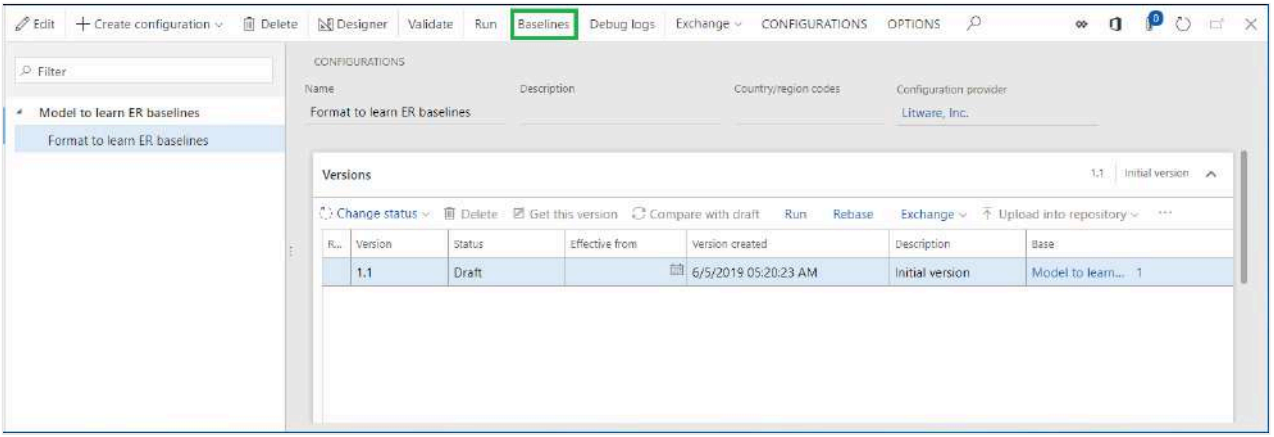
1. On **Configurations**, on the Action Pane, on the **Configurations** tab, select **User parameters**.
2. Set the **Run in debug mode** option to **Yes**.
3. Select **OK**.



Add a new baseline for designed ER format

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.

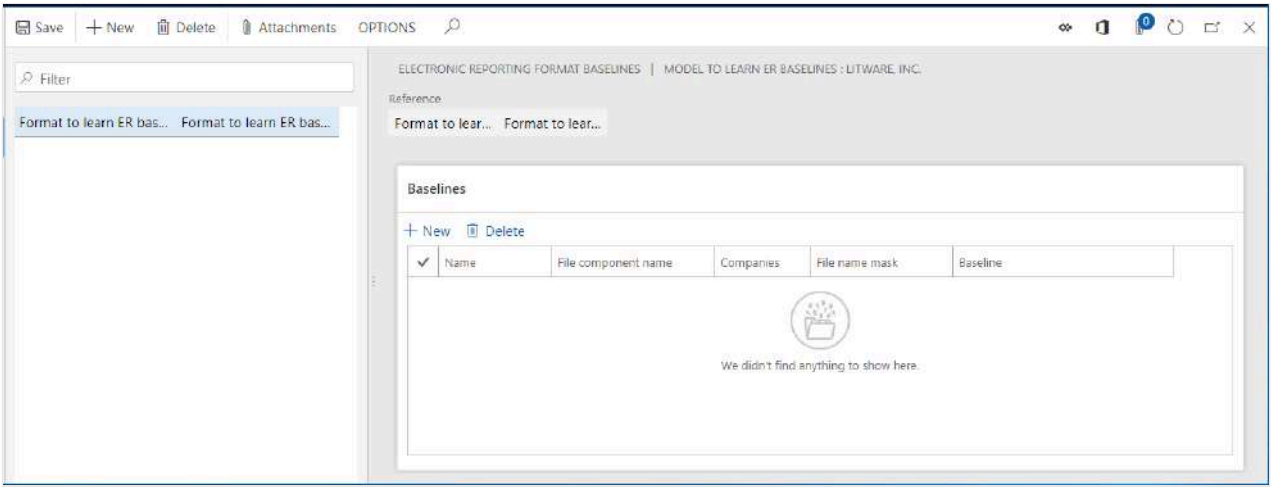
2. On the Action Pane, select **Baselines**.



3. On the Action Pane, select **New**.

4. Select the **Format to learn ER baselines** ER format that you designed earlier.

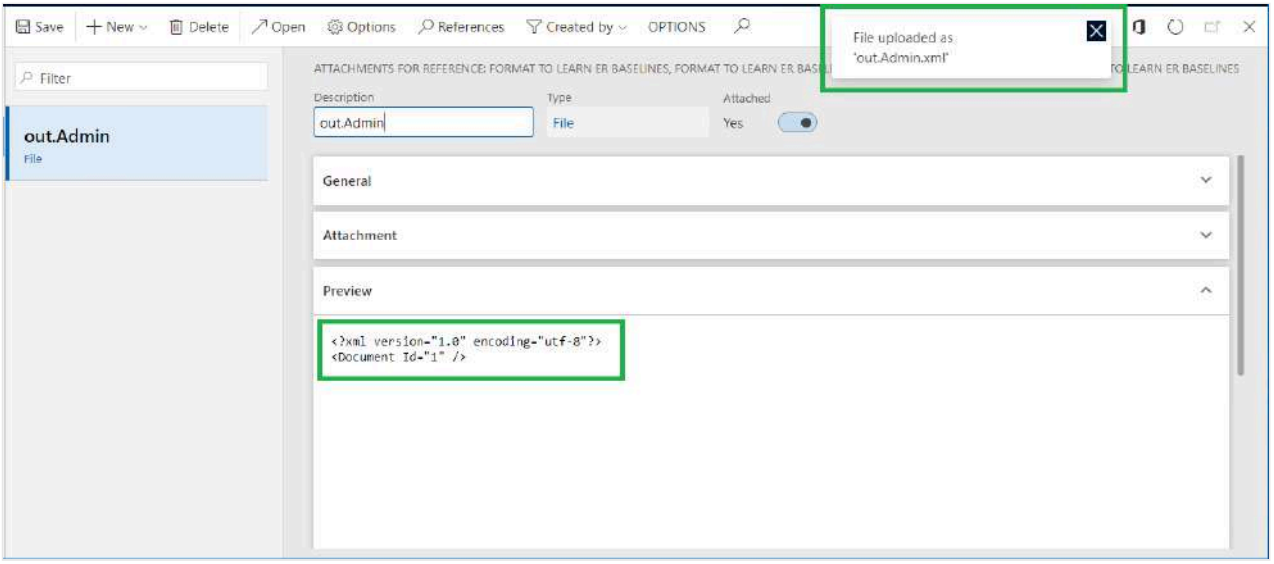
5. Select **Save**.



The baseline is added for the **Format to learn ER baselines** format.

Configure a baseline rule for the added baseline

1. On **Electronic reporting format baselines**, on the Action Pane, select the **Attachments** button (the paper clip symbol).
2. On the Action Pane, select **New** > **File**. In the ER parameters, select the **File** document type as the document type that stores baseline files.
3. Select **Browse**, and select the **out.Admin.xml** file that was generated when you ran the configured ER format earlier.



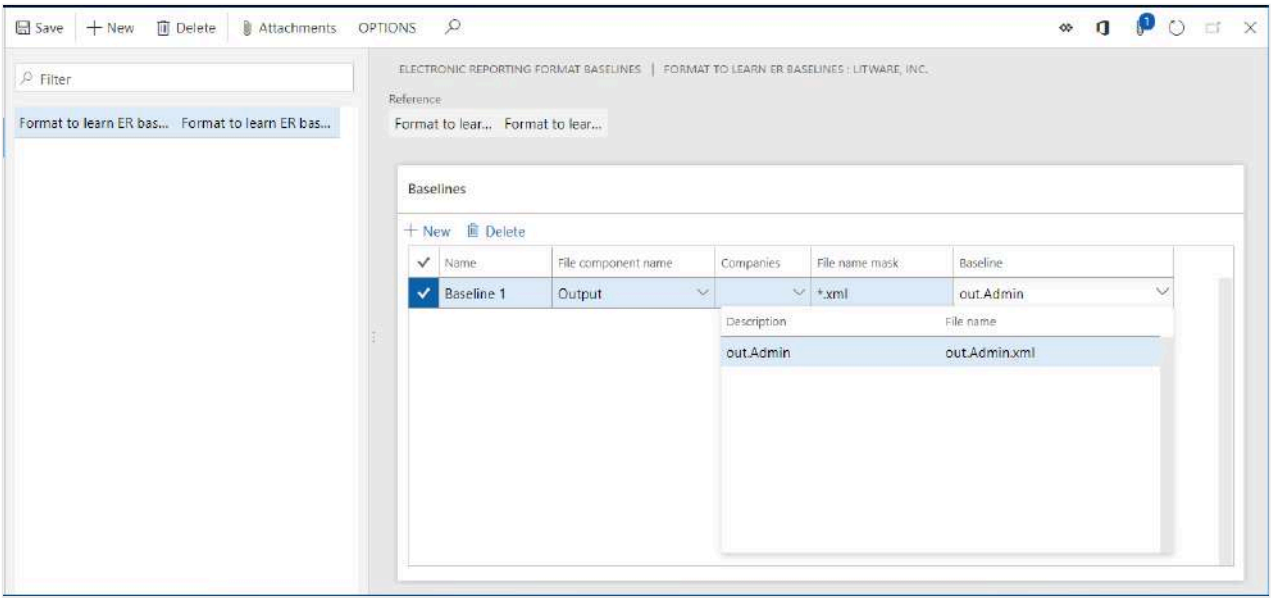
4. Close the **Attachments** page.
5. On the **Baselines** FastTab, select **New**.
6. In the **Name** field, enter **Baseline 1**.
7. In the **File component name** field, enter or select **Output**. This value indicates that the configured baseline is compared with a file that uses the **Output** format element.
8. In the **File name mask** field, enter ***.xml**.

> **Note**
>
> You can define the file name mask. When you define the file name mask, the baseline record evaluates the generated output only when the name of the output file satisfies that mask.

9. If users must run the **Format to learn ER baselines** ER format and sign in to specific companies to use the configured baseline, select those companies in the **Companies** field.

10. In the **Baseline** field, enter or select the **out.Admin** attachment.

11. Select **Save**.



Run the designed ER format and review the log to analyze the results

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.

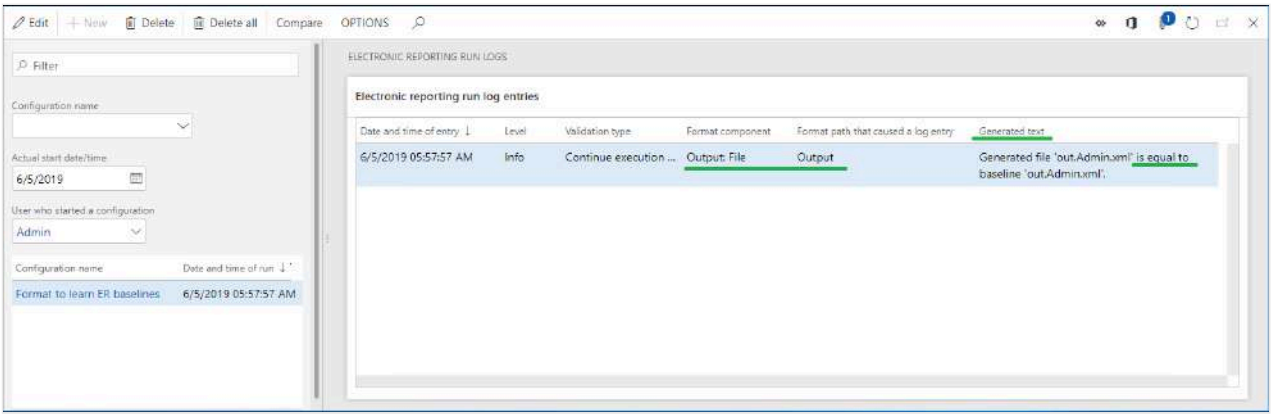
2. In the tree, expand **Model to learn ER baselines**, and then select **Model to learn ER baselines\Format to learn ER baselines**.

3. On the **Versions** FastTab, select **Run**.

4. In the **Enter ID** field, enter **1**.

5. Select **OK**.

6. Go to **Organization administration** > **Electronic reporting** > **Configuration debug logs**.

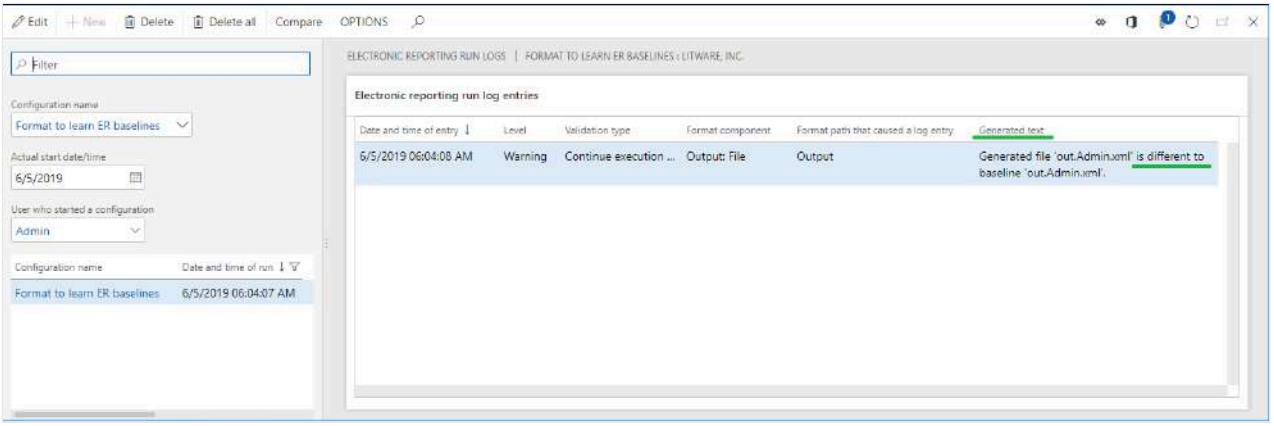


> **Note**
>
> The execution log contains information about the results of the comparison of the generated file with the configured baseline. In this example, the log indicates that the generated file and the baseline are equal.

7. Select **Delete all**.

Run the designed ER format and review the log to analyze the results

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Model to learn ER baselines**, and then select **Model to learn ER baselines\Format to learn ER baselines**.
3. On the **Versions** FastTab, select **Run**.
4. In the **Enter ID** field, enter **2**.
5. Select **OK**.
6. Go to **Organization administration** > **Electronic reporting** > **Configuration debug logs**.



> **Note**
>
> The execution log contains information about the results of the comparison of the generated file with the configured baseline. In this example, the log indicates that the generated file and the baseline differ.

7. Select **Compare**.

> **Note**
>
> The generated file and the baseline file are offered as a zip file. You can use external comparison tools such as WinDiff to compare the files and review the differences.

Additional resources

- Configure the Electronic reporting (ER) framework

Last updated on 04/13/2026

Improve tracing the results of generated ER reports to compare with baseline values

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes the first set of improvements to the baseline feature of the Electronic reporting (ER) framework. These improvements are available in Microsoft Dynamics 365 Finance version 10.0.3 (June 2019) and later.

Automate the setting of baseline rules

The Trace generated report results and compare them with baseline values article explains how to configure the ER framework to collect information about ER format executions and evaluate the results of those executions. The example in this article shows the steps that you must complete.

Here are some of the steps:

- Run an ER format to generate an outbound file, and store the file locally.
- Add the locally stored file as an attachment of the baseline that you added for an ER format.
- Configure the baseline rule for the added baseline. This configuration includes the following steps:
  - Specify an ER format element that you use to generate an outbound file.
  - Select the attachment that refers to the generated outbound file.

> **Note**

You must complete these steps manually, even though the new ER capabilities enable you to automate them. To learn more about this feature, complete the following example.

Example: Automate the setting of baseline rules

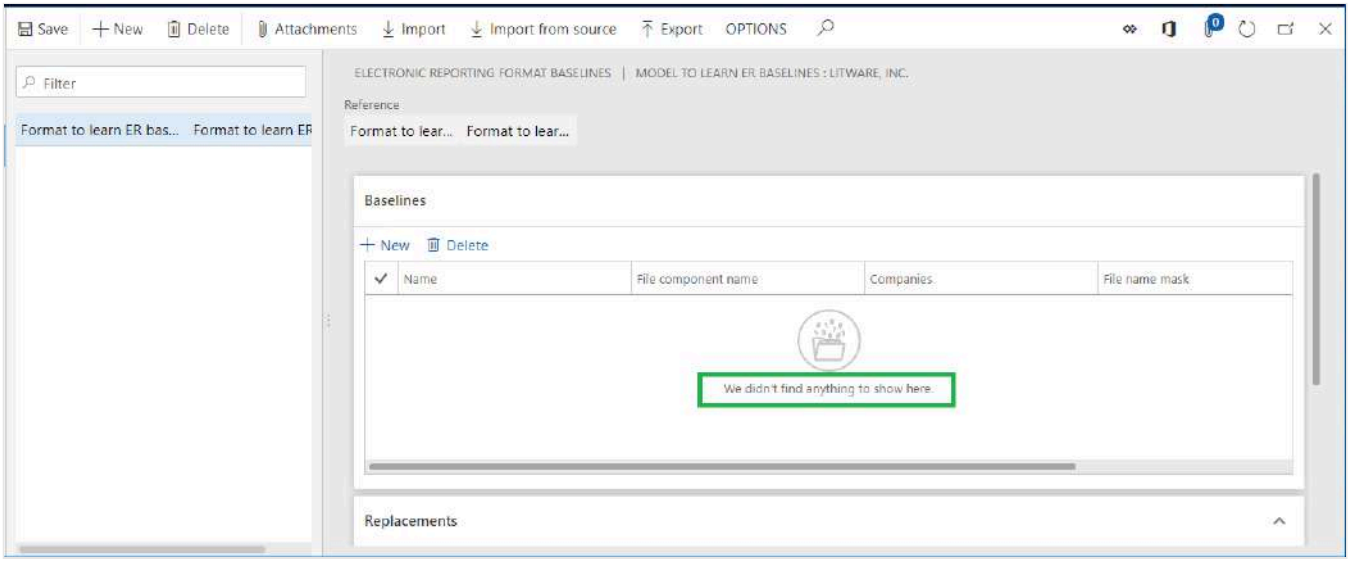
To complete the steps in this example, you must first complete the steps in the example in the Trace generated report results and compare them with baseline values article, up through the "Add a new baseline for a designed ER format" section.

Review added baseline

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. Select **Baselines**.

> **Note**
>
> The **Baselines** button on the Action Pane is available only when the **Run in debug mode** ER user parameter is turned on for the current company.

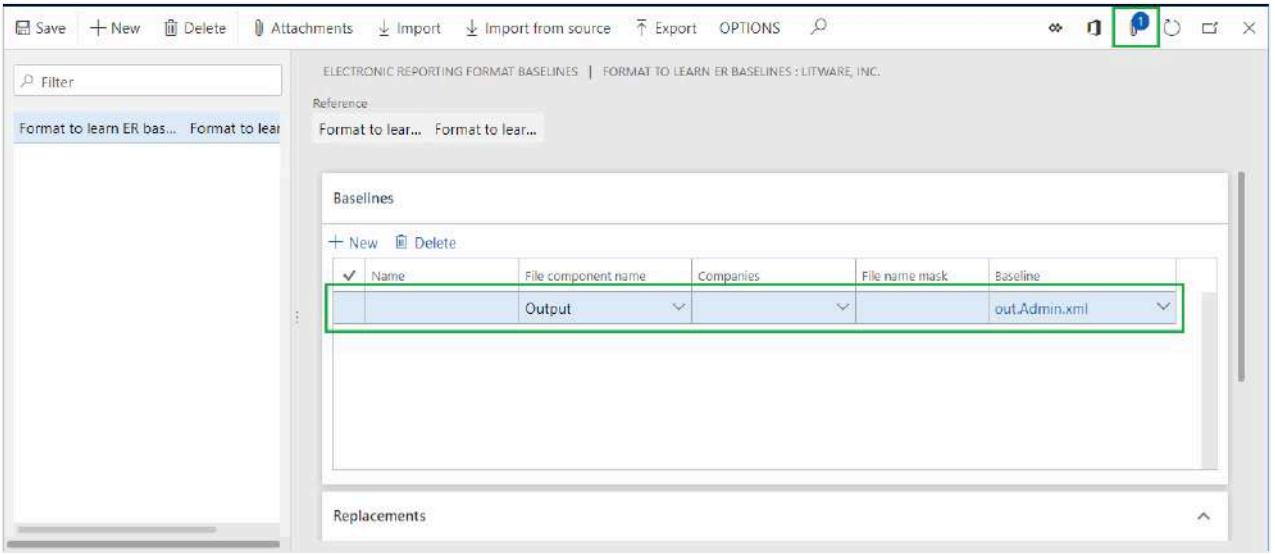
The baseline is added for the selected **Format to learn ER baselines** format, but you didn't add baseline rules for this baseline yet.



Create a new baseline rule

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Model to learn ER baselines**.

3. In the tree, select **Model to learn ER baselines\Format to learn ER baselines**.
4. On the **Versions** FastTab, select **Run**.
5. In the **Enter Id** field, enter **1**.
6. Set the **Make baseline files** option to **Yes**.
7. Select **OK**.
8. Select **Baselines**.



The generated outbound file is automatically attached to the baseline of the executed ER format. The baseline rule is automatically added to this baseline and also contains the reference to the attached file.

9. In the **Name** field, enter **Baseline 1**.
10. In the **File name mask** field, enter **.xml**.
11. Select **Save**.

Run the format

You're now ready to complete the remaining steps in the example in the Trace generated report results and compare them with baseline values article, starting from the "Run the designed ER format and review the log to analyze the results" section.

> **Note**

When you delete the automatically added baseline rule on the **Baselines** FastTab, the referenced attachment isn't automatically deleted.

Configure the baseline to ignore constantly changing parts of the ER output

When you design an ER format to contain information that changes when the format runs, you must use the ER baseline feature to compare the generated results with baseline values. For example, the information might be the processing date and time or the unique identifier of a generated document in different formats (globally unique identifier [GUID], and so on). The new ER capabilities let you configure the baseline rule to ignore changeable elements of an ER format when the format runs with the purpose of comparing baseline values with the results of the format's execution. To learn more about this feature, complete the following example.

Example: Configure the baseline to ignore constantly changing parts of the ER output

To complete the steps in this example, you must first complete the steps in the example in the Trace generated report results and compare them with baseline values article.

Modify a configured ER format

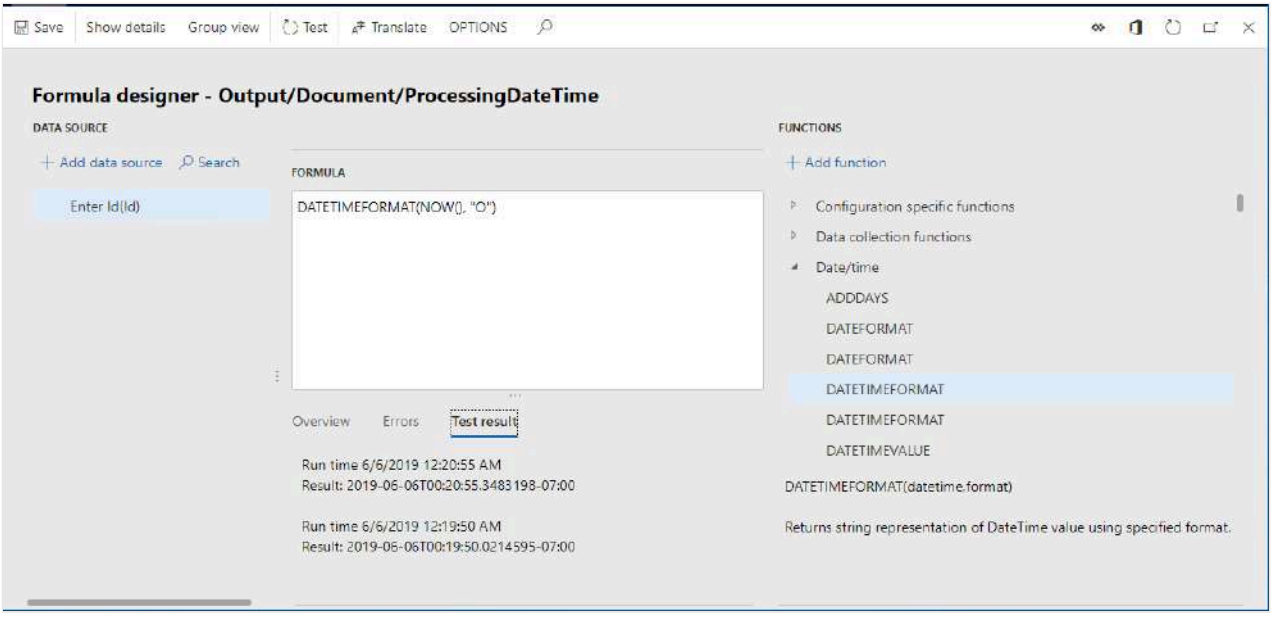
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Model to learn ER baselines**.
3. In the tree, select **Model to learn ER baselines\Format to learn ER baselines**.
4. Select **Designer**.
5. In the tree, select **Output\Document**.
6. Select **Add**.
7. In the drop-down dialog box, in the tree, select **XML\Attribute**.
8. In the **Name** field, enter **ProcessingDateTime**.
9. Select **OK**.
10. On the **Mapping** tab, in the tree, select **Output\Document\ProcessingDateTime**.

11. Select **Edit formula**.

12. In the **Formula** field, enter the following expression: **DATETIMEFORMAT(NOW(), "O")**

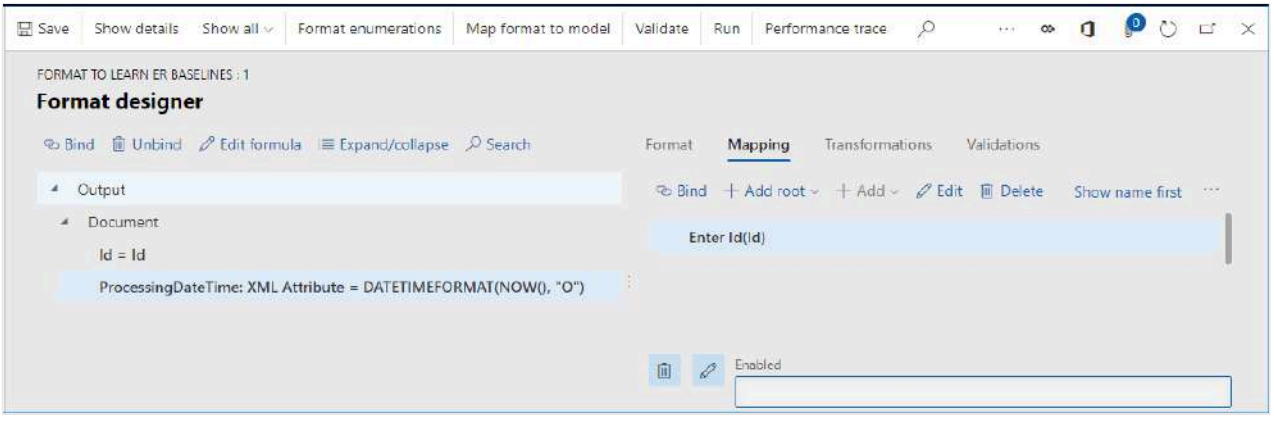
13. Select **Save**, and then select **Test**.

14. Select **Test** again to retest the configured expression.



> ⓘ Note
>
> The **Test result** tab shows that the configured expression returns a different date and time value whenever it's called.

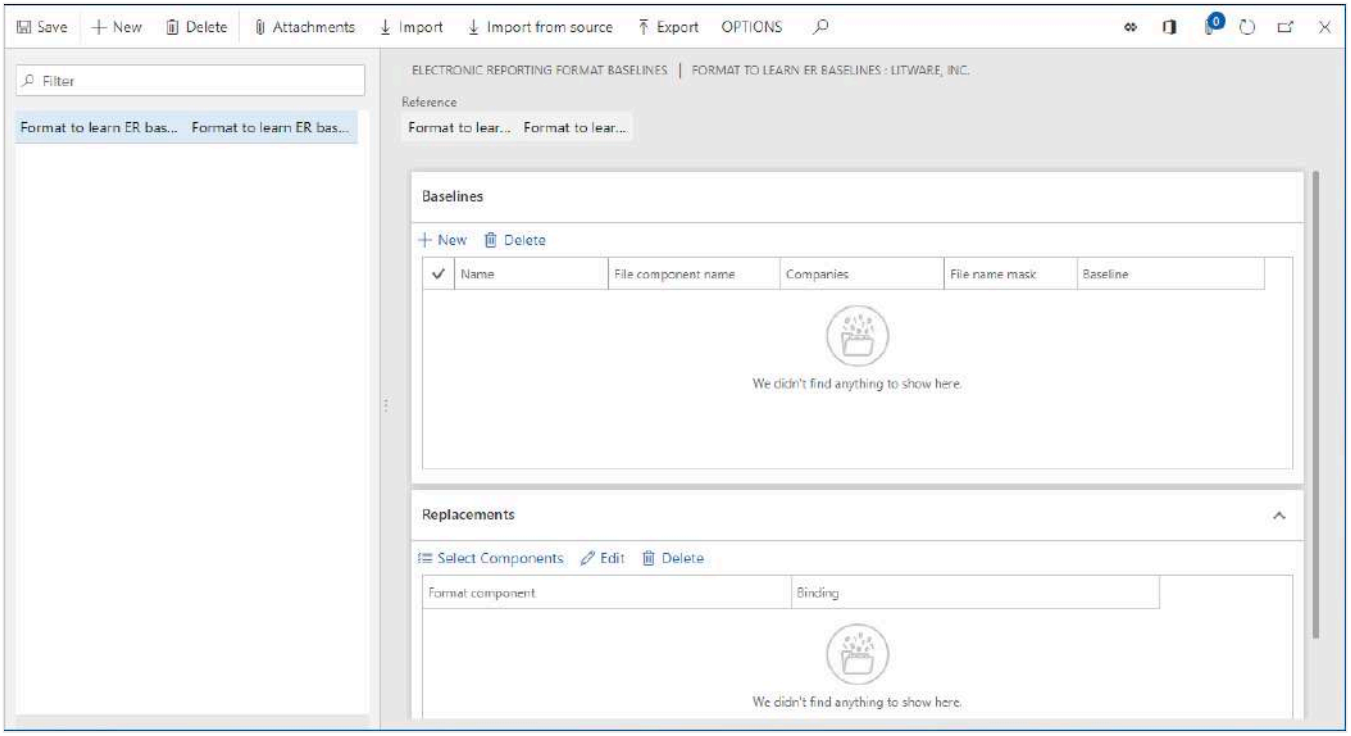
15. Close the **Formula designer** page, and then select **Save**.



16. Close the **Format designer** page.

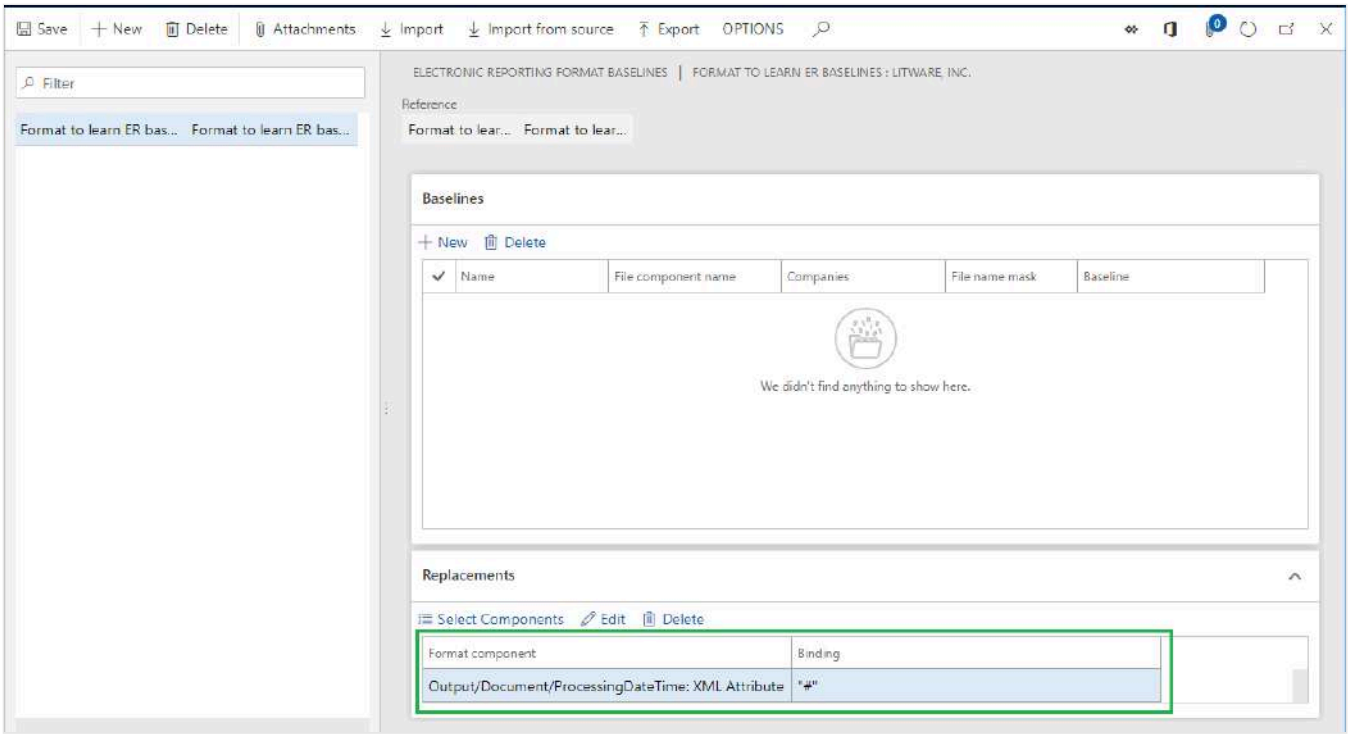
Remove an existing baseline rule

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. Select **Baselines**.
3. In the list of baselines, select the baseline that you configured for the **Format to learn ER baselines** format.
4. On the **Baselines** FastTab, select **Delete** to remove the baseline rule that you configured earlier.



Define replacements for bindings of designed ER format

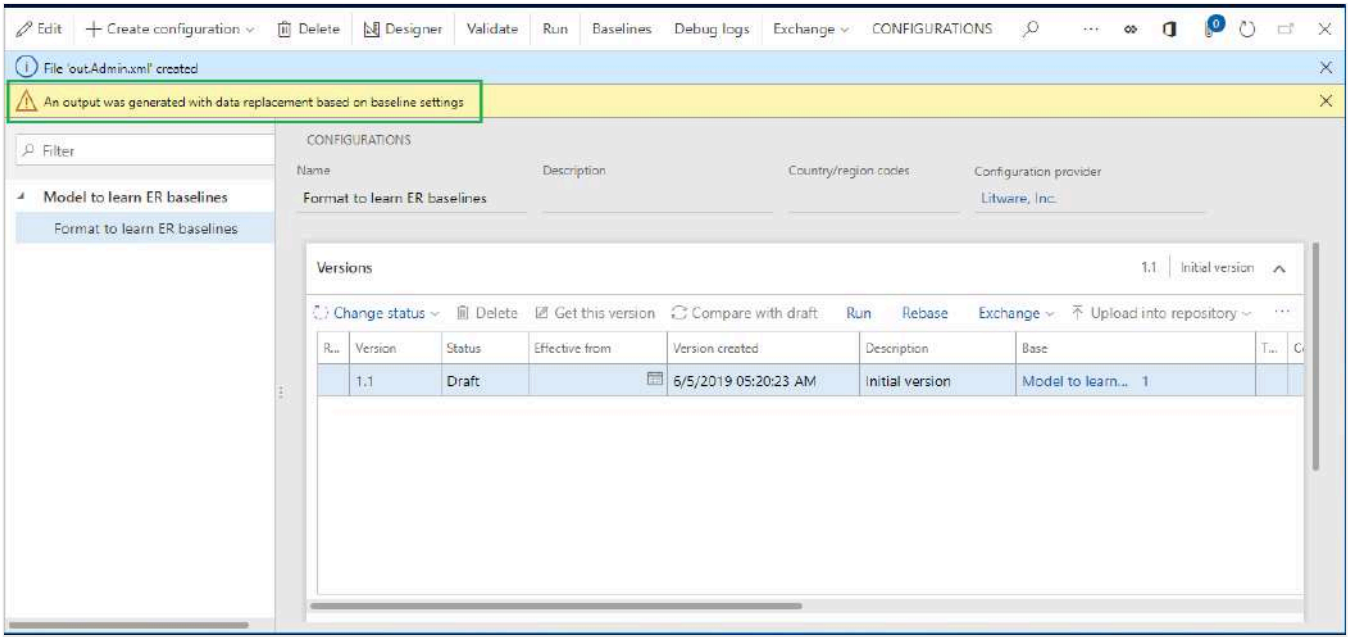
1. On the **Configurations** page, on the **Replacements** FastTab, select **Select components**.
2. In the format components tree, expand **Output**, expand **Output\Document**, and then select the check box for **Output\Document\ProcessingDateTime**.
3. Select **OK**.



The selected ER format component is added to the list of components on the **Replacements** FastTab. When you run the base ER format in debug mode, the format's binding for each component is replaced by the binding that appears in the **Binding** column. To change the default binding for a component that appears on the **Replacements** FastTab, select **Edit**.

Create a new baseline rule

Follow the steps in the "Example: Automate the setting of baseline rules" section earlier in this article. A notification warns you that the outbound file is generated by using baseline settings, and that a forced replacement of the format bindings occurs.



Suppress warnings about the replacement of format bindings

Set specific ER parameters to suppress notifications about the replacement of format bindings. This suppression is useful when the Regression Suite Automation Tool replaces format bindings in unattended mode. In this case, the warning can cause the test case to fail.

1. On **Configurations**, on the Action Pane, on the **Configurations** tab, select **User parameters**.
2. Set the **Suppress baseline warnings** option to **Yes**, and then select **OK**.

Review the generated baseline file

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. Select **Baselines**.
3. Select **Attachments**.

   > ⓘ **Note**
   >
   > The generated file contains the processing date and time text ("#") from the binding that you configured in the added baseline rule, not from the format's binding.

4. Close **Attachments**.

Run the designed ER format and review the log to analyze the results

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. In the tree, expand **Model to learn ER baselines**.
3. In the tree, select **Model to learn ER baselines\Format to learn ER baselines**.
4. On the **Versions** FastTab, select **Run**.
5. In the **Enter Id** field, type **1**.
6. Select **OK**.
7. Go to **Organization administration** > **Electronic reporting** > **Configuration debug logs**.

The execution log contains information about the results of the comparison of the generated file with the configured baseline. The log indicates that the generated file and the baseline are equal, even though the executed format contains the binding to enter a constantly changing date and time value in the outbound file.

> **Note**
>
> Although the outbound file is generated by using baseline settings that force the replacement of the format's bindings, you don't receive any warnings about the replacement.

Exchange baseline settings between environments

Export baseline settings

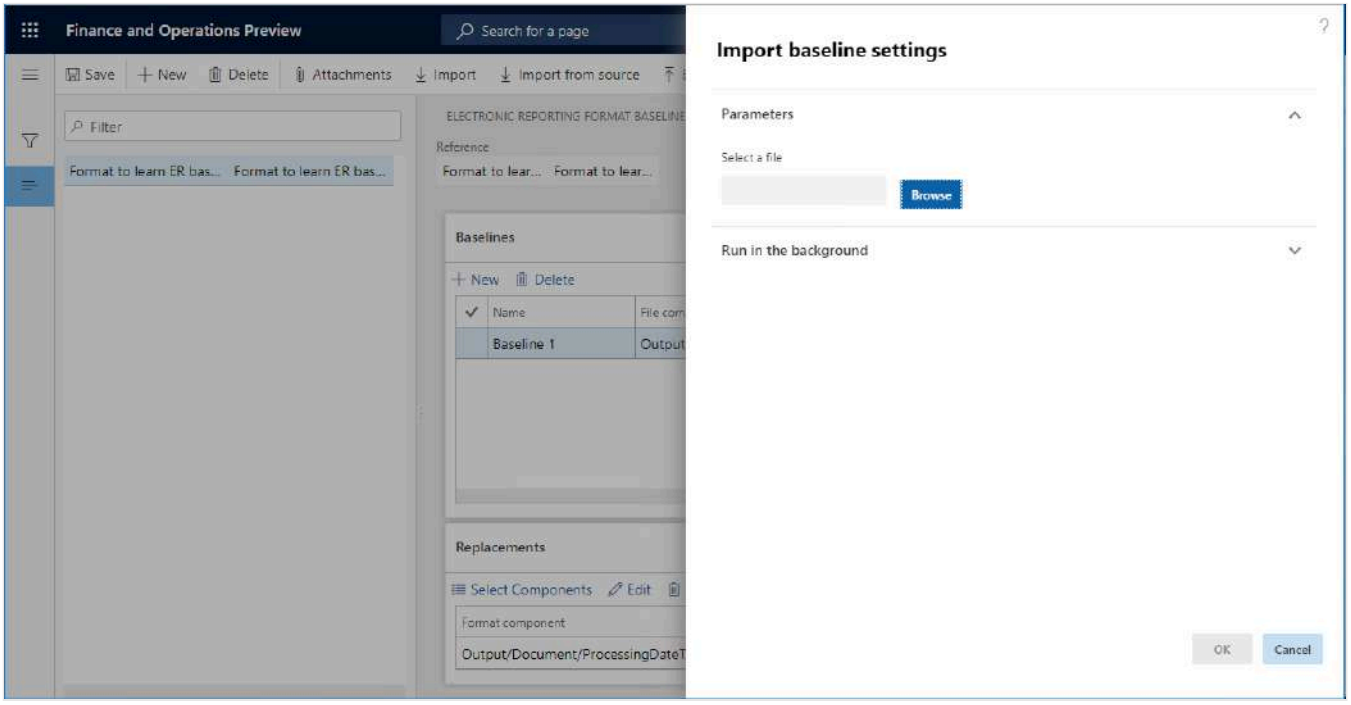
The new ER capabilities let you export baseline settings for the selected ER format from the current environment and store them as XML files.

To export baseline settings, on the **Electronic reporting format baselines** page, select **Export**.

Import baseline settings

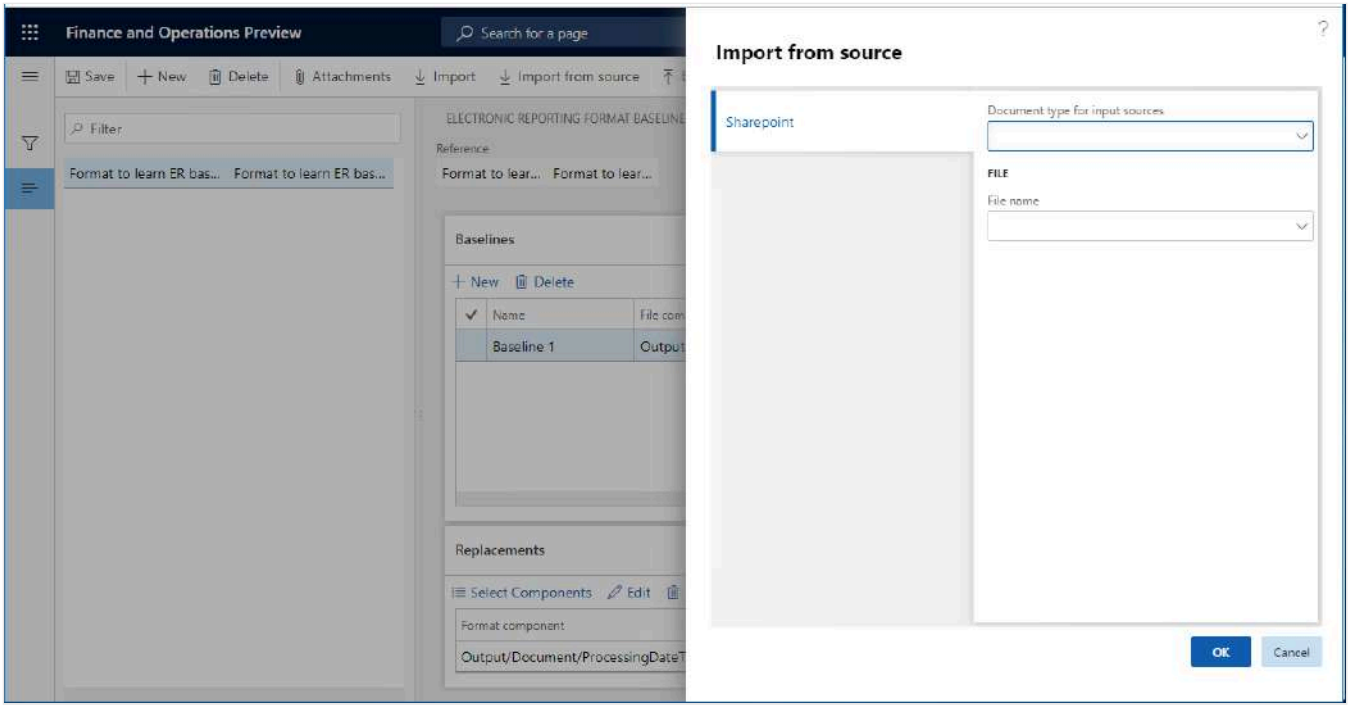
You can import exported baseline settings into a different environment. First, import the environment as an ER format. Then, import the baseline settings.

To import baseline settings from a locally stored XML file, on the **Electronic reporting format baselines** page, select **Import**, and then select **Browse** to select the XML file.



To import baseline settings from an XML file that is stored on the Microsoft SharePoint Server, based on the current Document management settings and the selected document type, on the

Electronic reporting format baselines page, select **Import from source**. Then select the document type and the XML file. You must configure the required document type to access the SharePoint folder.



> **Note**
>
> Use Task recorder to record the steps for selecting the required document type and the file name in the **Import from source** dialog box. By using this method, you can keep required baseline settings on SharePoint Server and then automatically import them by playing a task recording when you run automated tests by using the Regression Suite Automation Tool.

Additional resources

- Trace generated report results and compare them with baseline values
- Task recorder resources

Automate testing by using Electronic reporting

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how you can use the Electronic reporting (ER) framework to automate testing of some functionality. The example in this article shows how to automate the testing of vendor payment processing.

The application uses the ER framework to generate payment files and corresponding documents during vendor payment processing. The ER framework consists of a data model, model mappings, and format components that support payment processing for different payment types and the generation of documents in different formats. These components can be downloaded from Microsoft Dynamics Lifecycle Services (LCS) and imported into the instance.

You can also customize each Microsoft component and use it as the basis of your own custom component. By creating a custom version, you can make changes that support specific requirements. For example, you can adjust the ER data model and ER model mapping to access customer-specific application data, or you can change an ER format to modify the layout of a generated document.

You can use customized ER formats to process payment files that generate vendor payments and also to process control reports. ER components support versioning. Therefore, Microsoft can provide updated versions of ER solutions for vendor payment processing, and you can automatically merge the updated version with your customized component by rebasing it. However, you must test the rebased version to make sure that it works as you expect.

ER data models and ER model mappings are common for many ER formats that are used to process payments of different types and to generate country/region-specific payment documents. Therefore, it's highly desirable to automate user acceptance and integration testing so that it automatically happens in multiple companies but considers the country/region context of each target company, uses different datasets, and so on.

For more information about how to create a custom version of a format that's based on the format that you received from a configuration provider, see ER Upgrade your format by

adopting a new, base version of that format.

Key concepts

Functional power users can create user acceptance and integration testing without writing source code.

- Use the ER baseline feature to compare generated documents to master copies. For more information, see Trace generated report results and compare them with baseline values.
- Use Task recorder to record test cases, and include baseline assessment. For more information, see Task recorder resources.
- Group test cases for required test scenarios. For more information, see Create and automate user acceptance tests.
  - Use Business process modeler (BPM) in LCS to make libraries for user acceptance tests.
  - Use BPM test libraries to create a test plan and test suites in Microsoft Azure DevOps Services (Azure DevOps).

Functional power users can run user acceptance and integration tests.

- Use Regression suite automation tool (RSAT) to run test cases of the desired test suite.
- Report the results of the testing to Azure DevOps, and use this service to investigate those results.

Prerequisites

Before you can complete the tasks in this article, complete the following prerequisites:

- Deploy a topology that supports test automation. You must have access to the instance of this topology for the **System administrator** role. This topology must contain the demo data used in this example. For more information, see Deploy and use an environment that supports continuous build and test automation.
- To run user acceptance and integration tests automatically, install RSAT in the topology that you're using and configure it in the appropriate manner. For information about how to install and configure RSAT and configure it to work with finance and operations apps and Azure DevOps, see Regression Suite Automation Tool. Pay attention to the prerequisites for using the tool.
- To organize test cases in suites to help guarantee the correct execution sequence, so that you can collect logs of test executions for further reporting and investigation, you must have access to Azure DevOps from the deployed topology.

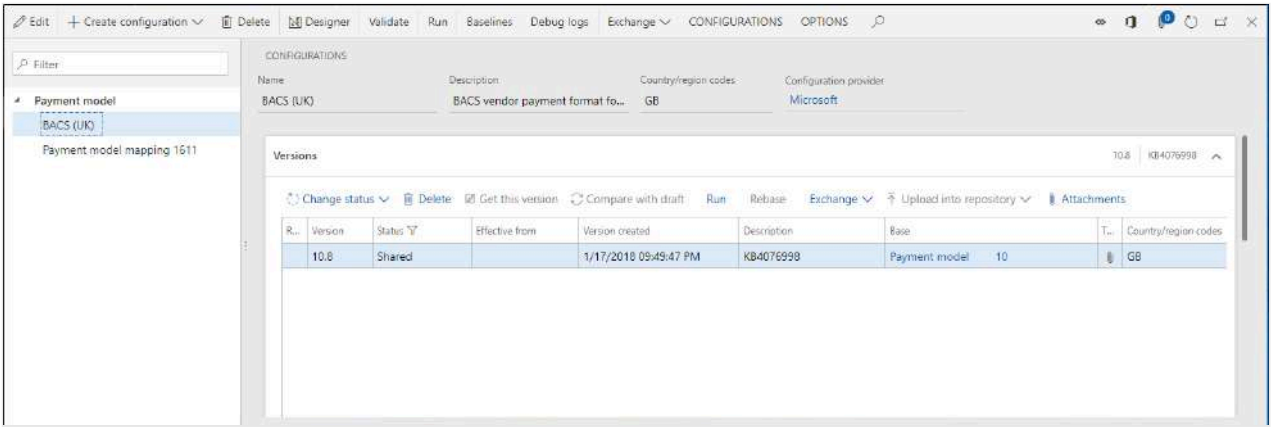
- To complete the example in this article, download ER usage for RSAT tests. This zip file contains the following task guides:

Expand table

Content	File name and location
Sample task recording to prepare data for testing	Prepare\Recording.xml
Sample task recording to process vendor payment	Process\Recording.xml

Prepare the Accounts payable module to process vendor payments

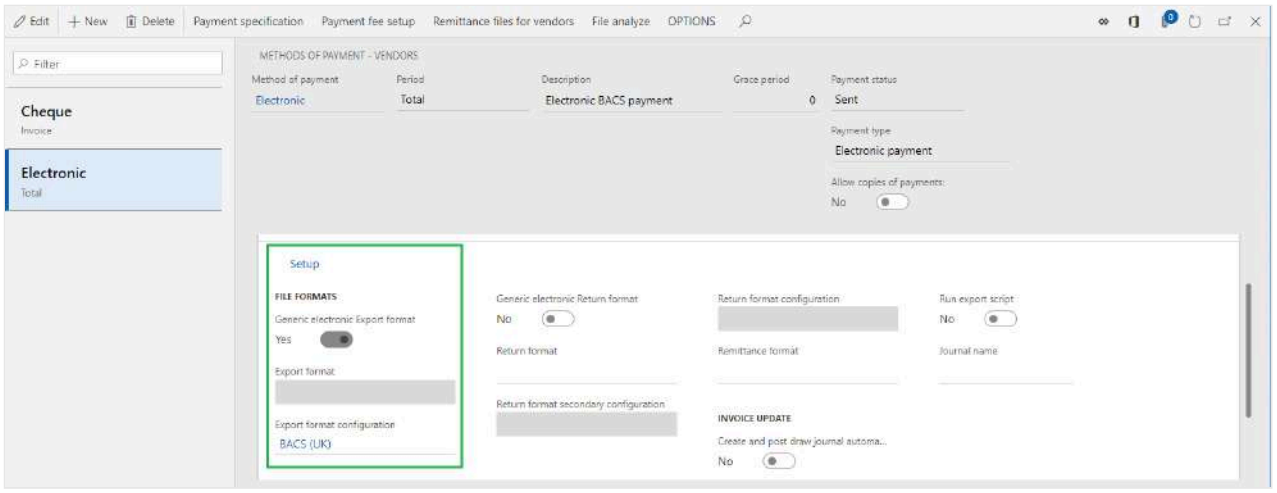
1. Sign in to your instance.
2. Download the following ER configurations from LCS. For instructions, see ER Import a configuration from Lifecycle Services.
    - **Payment model** ER model configuration
    - **Payment model mapping 1611** ER model mapping configuration
    - **BACS (UK)** ER format configuration



3. Select the **GBSI** demo data company, which has a country/region context in the United Kingdom.
4. Configure Accounts payable parameters:
    a. Go to **Accounts payable** > **Payment setup** > **Methods of payment**.
    b. Select the **Electronic** method of payment.
    c. Configure the selected method of payment so that it uses the **BACS (UK)** ER format that you downloaded earlier for vendor payment processing:

i. On the **File formats** FastTab, set the **Generic electronic Export format** option to **Yes**.

ii. In the **Export format configuration** field, select **BACS (UK)**.

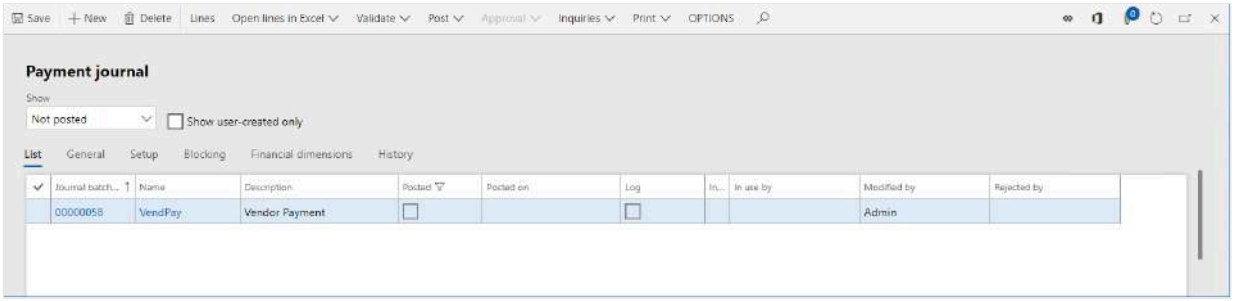


> **Note**
>
> If you have the derived version of this ER format that was created to support customizations, you can select this configuration in the **Electronic** method of payment.

5. Create an example vendor payment:

a. Go to **Accounts payable** > **Payments** > **Payment journal**.

b. Make sure that you didn't post the payment journal.

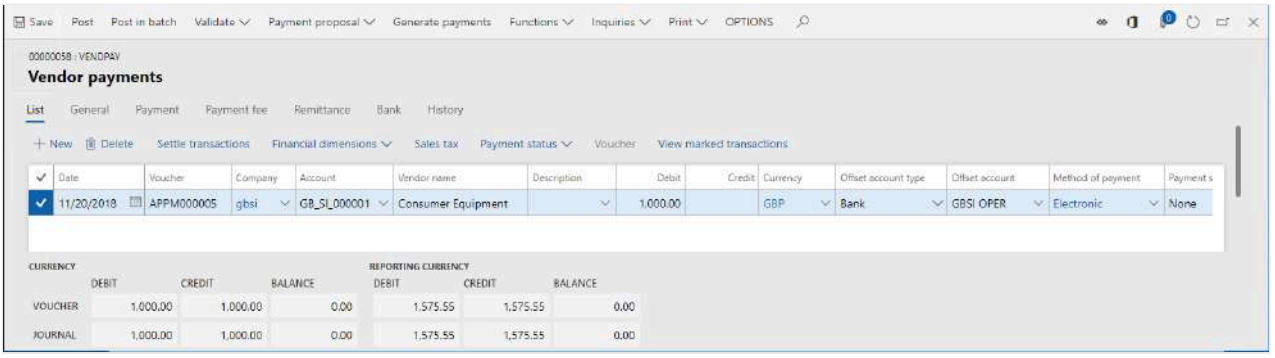


c. Select **Lines**, and enter a line that has the following information.

Expand table

Field	Example value
Vendor name	GB_SI_000001
Debit	1,000.00
Currency	GBP

Field	Example value
Offset account type	Bank
Offset account	GBSI OPER
Method of payment	Electronic

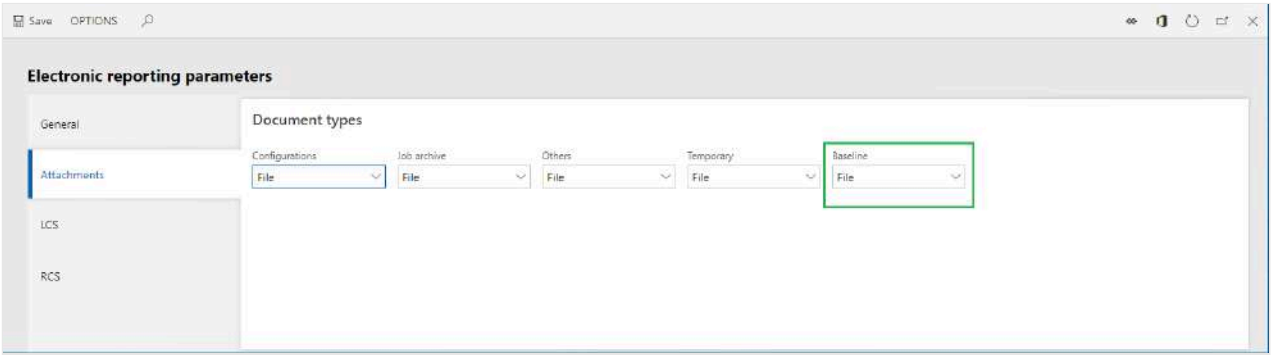


Prepare the ER framework to test vendor payment processing

Configure ER parameters

1. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting parameters**.

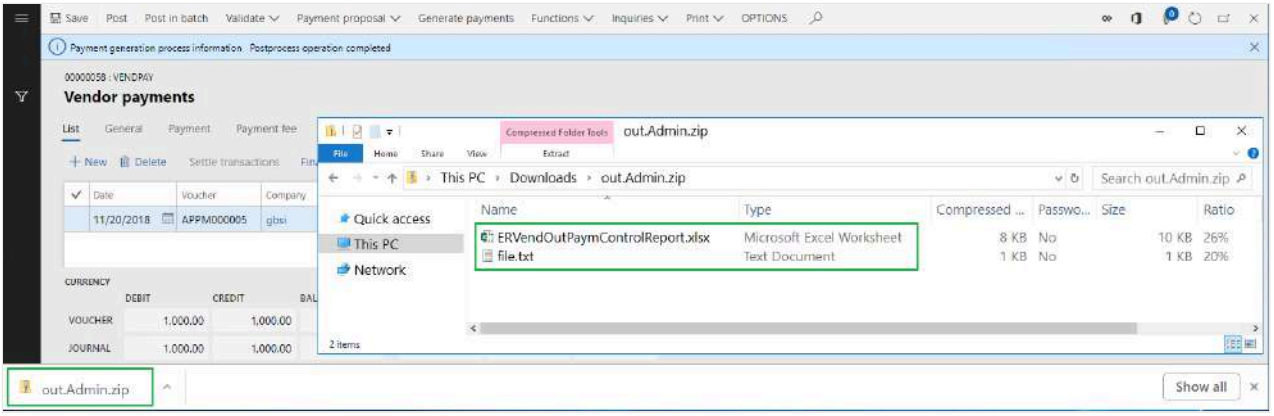
2. On the **Attachments** tab, in the **Baseline** field, select **File** as the document type. The Document management (DM) framework uses this type to keep documents that are related to the baseline feature as DM attachments.



Generate baseline copies of vendor payment–related documents

1. Go to **Accounts payable** > **Payments** > **Payment journal**.

2. Select **Lines**.
3. Select **Generate payments**.
4. Select the **Electronic** method of payment.
5. Select the **GBSI OPER** bank account.
6. Set the **Print control report** option to **Yes**.
7. Download the generated output as a ZIP file.
8. Open the downloaded file.
9. Extract the following files from the downloaded file:
    - **File** payment file in text format
    - **ERVendOutPaymControlReport** control report file in XLSX format



Turn on the ER baseline feature

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** tab, select **User parameters**.
3. Set the **Run in debug mode** option to **Yes**.

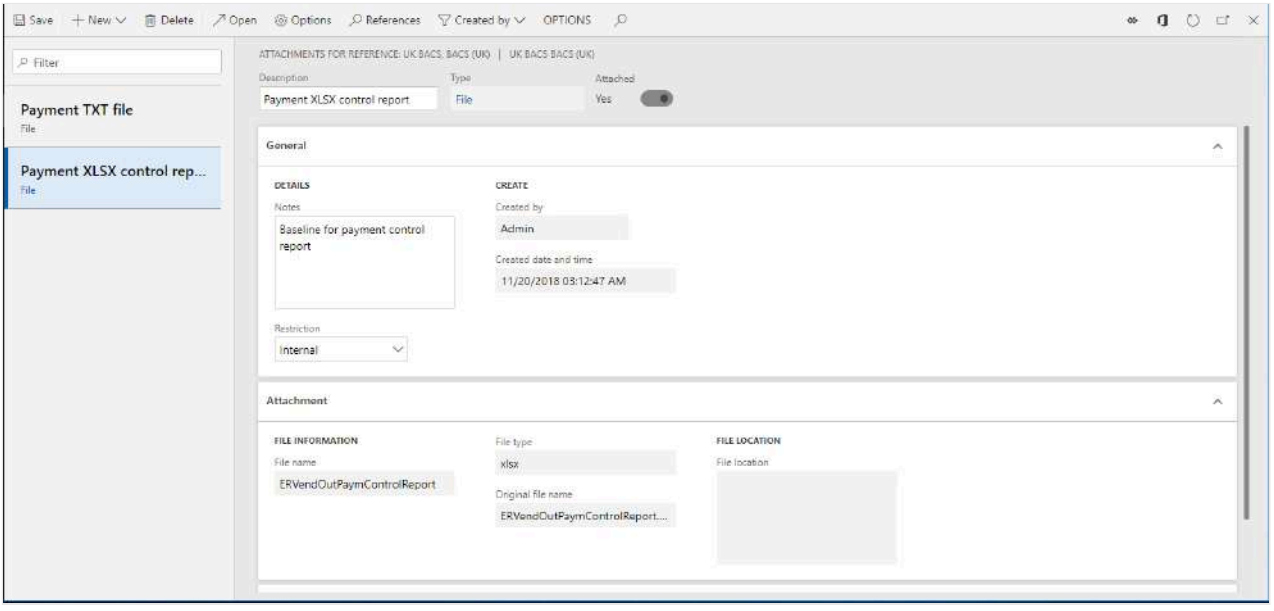
When you turn on the **Run in debug mode** parameter, the ER framework takes these actions after it runs any ER format that generates outgoing documents:

1. It checks whether a baseline is configured for any components of the ER format that ran.
2. It checks whether each configured baseline is applicable in the current conditions, like the company code of the signed-in company, the file name, and the file name extension of the generated output.
3. For each applicable baseline, it takes these steps:
    a. It compares the output that the ER format generates with the corresponding baseline.

b. It stores the results of the comparison in the ER configurations debug log.

Configure ER baselines for vendor payment processing

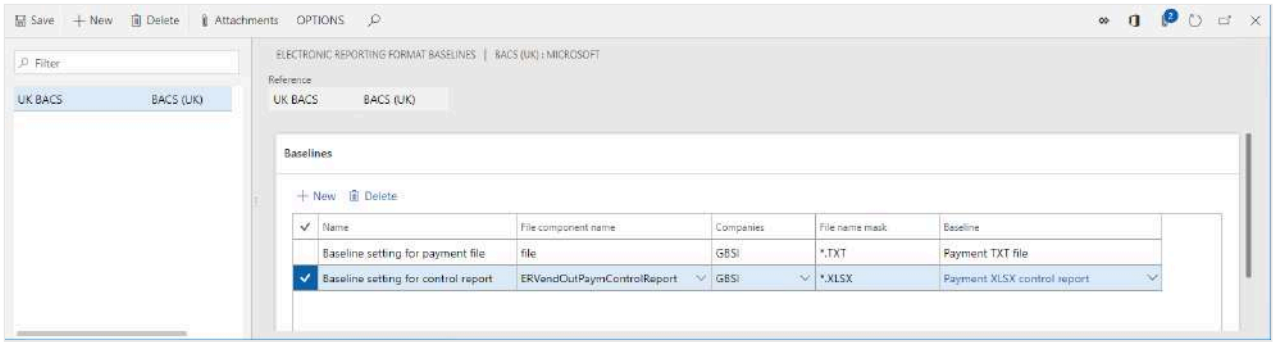
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. Select **Baselines**.
3. Select **New**.
4. In the **Reference** field, select the **BACS (UK)** format.
5. Select **Attachments**.
6. Add a new baseline for the vendor payment file:
   a. Select **New**.
   b. In the **Type** field, select the **File** DM document type that you configured in the ER parameters to store baseline artifacts.
   c. Browse to select the locally saved **File** payment file in text format.
   d. In the **Description** field, enter **Payment TXT file**.
7. Add a new baseline for the control report for the vendor payment:
   a. Select **New**.
   b. In the **Type** field, select the **File** DM document type that you configured in the ER parameters to store baseline artifacts.
   c. Browse to select the locally saved **ERVendOutPaymControlReport** control report file in XLSX format.
   d. In the **Description** field, enter **Payment XLSX control report**.



8. Close the page.

9. On the **Baselines** tab, select **New** to configure a baseline for the payment file:
    a. Name the line **Baseline setting for payment file**.
    b. In the **File component name** field, select **file** to apply this baseline to the ER format output that generates the payment file in BACS (UK) text format.
    c. In the **Companies** field, select **GBSI** to apply this baseline when the **BACS (UK)** ER format is run in the GBSI company.
    d. In **File name mask** field, enter ***.TXT** to apply this baseline only to outputs of the **file** format component that have the **.txt** file name extension.
    e. In the **Baseline** field, select **Payment TXT file** so that this baseline is used for comparison with the generated output.

10. Select **New** to configure a baseline for the control report:
    a. Name the line **Baseline setting for control report**.
    b. In the **File component name** field, select **ERVendOutPaymControlReport** to apply this baseline to the ER format output that generates the control report.
    c. In the **Companies** field, select **GBSI** to apply this baseline when the **BACS (UK)** ER format is run in the GBSI company.
    d. In **File name mask** field, enter ***.XLSX** to apply this baseline only to outputs of the **ERVendOutPaymControlReport** format component that have the **.xslx** file name extension.
    e. In the **Baseline** field, select **Payment XLSX control report** so that this baseline is used for comparison with the generated output.



Record tests to validate vendor payment processing

As a functional power user, you can record your own steps to test vendor payment processing. Play (and edit, as required) the **Prepare\Recording.xml** task recording that you downloaded earlier. Use this recording to set all testing data to the correct state. This step is required because you can run the testing many times, and every test must use data that's in the same state.

Reset user settings

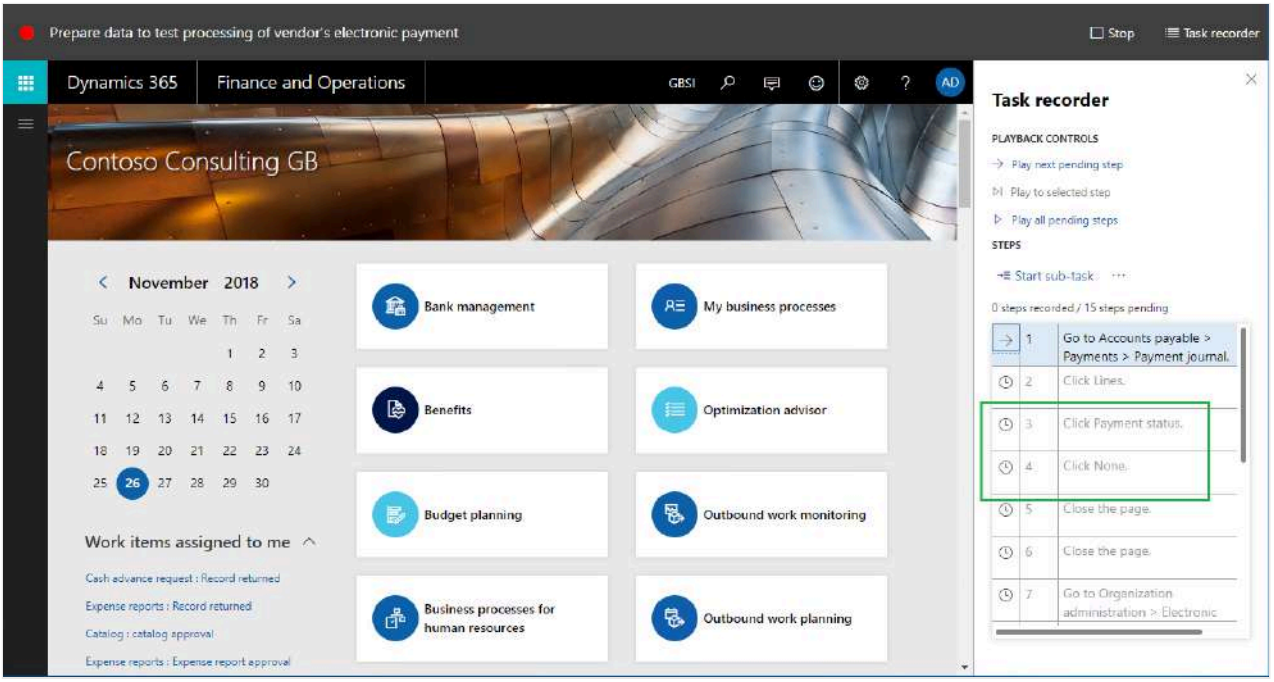
1. Open the default dashboard.
2. Select the **Settings** button (the gear symbol).
3. Select **User options**.
4. Select **Usage data**.
5. Select **Reset**.
6. Select **Yes** to confirm that you want to reset usage data.
7. Close the page.

Record the steps to prepare data for testing

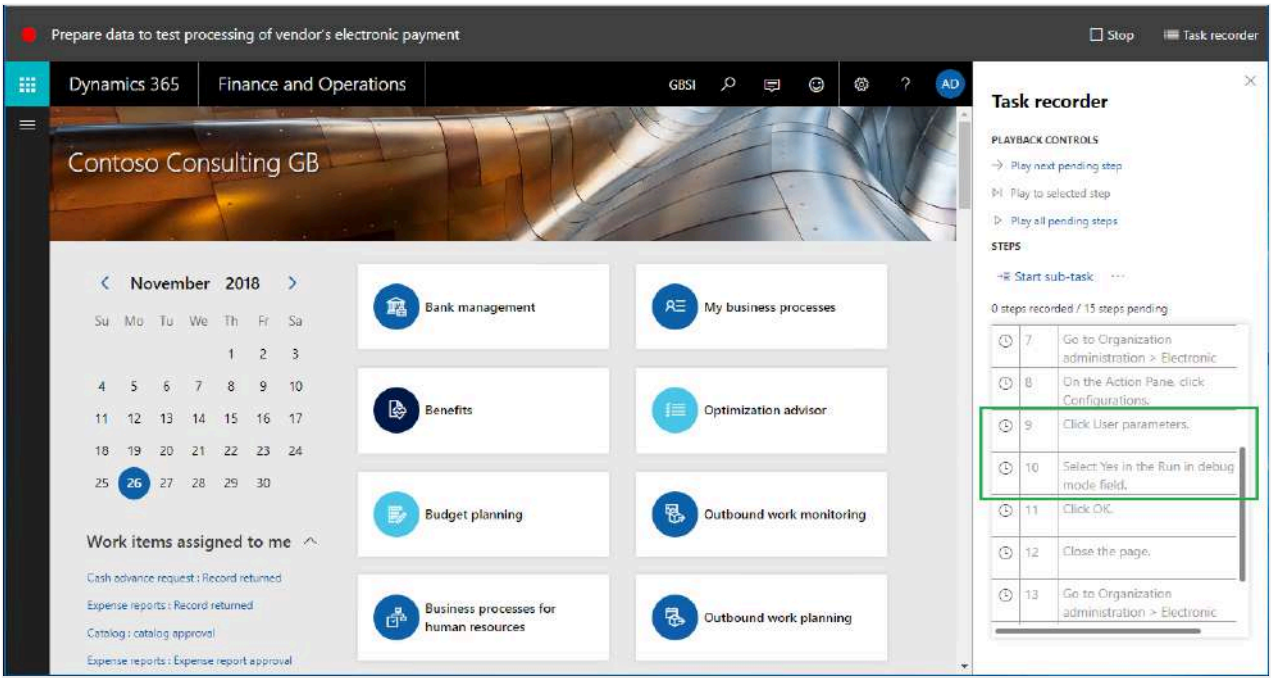
1. Select the **Settings** button (the gear symbol).
2. Select **Task recorder**.
3. Select **Playback recording**.
4. Select **Open from this PC**.
5. Select **Browse**, and select the locally saved **Prepare\Recording.xml** file.
6. Select **Start**.
7. Keep selecting **Play next pending step** until you play all the steps in the recording.

This task recording performs the following actions:

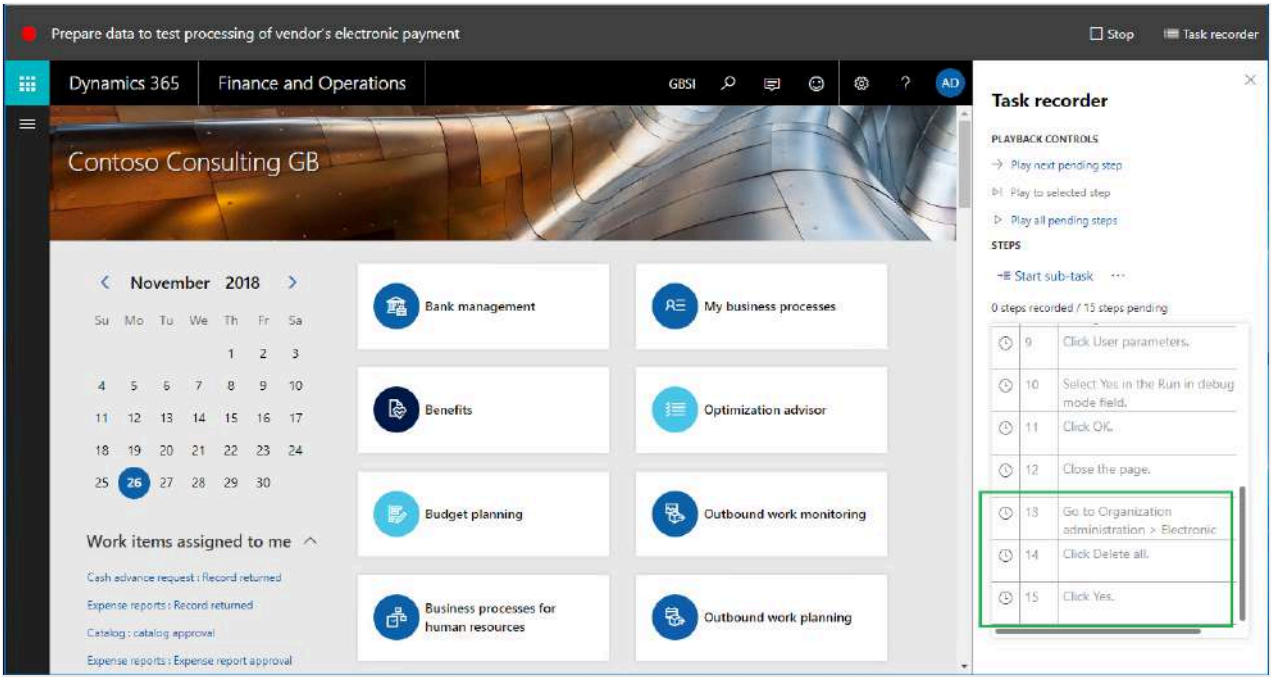
1. Set the status of the processed payment line to **None**.



2. Turn on the **Run in debug mode** ER user parameter.



3. Clean up the ER debug log that contains the results of the comparison of generated files to baselines.



Record the steps to test vendor payment processing

Play (and edit, if needed) the **Process\Recording.xml** task recording that you downloaded earlier. This recording processes vendor payments and validates the results of the comparison of generated documents to corresponding baselines.

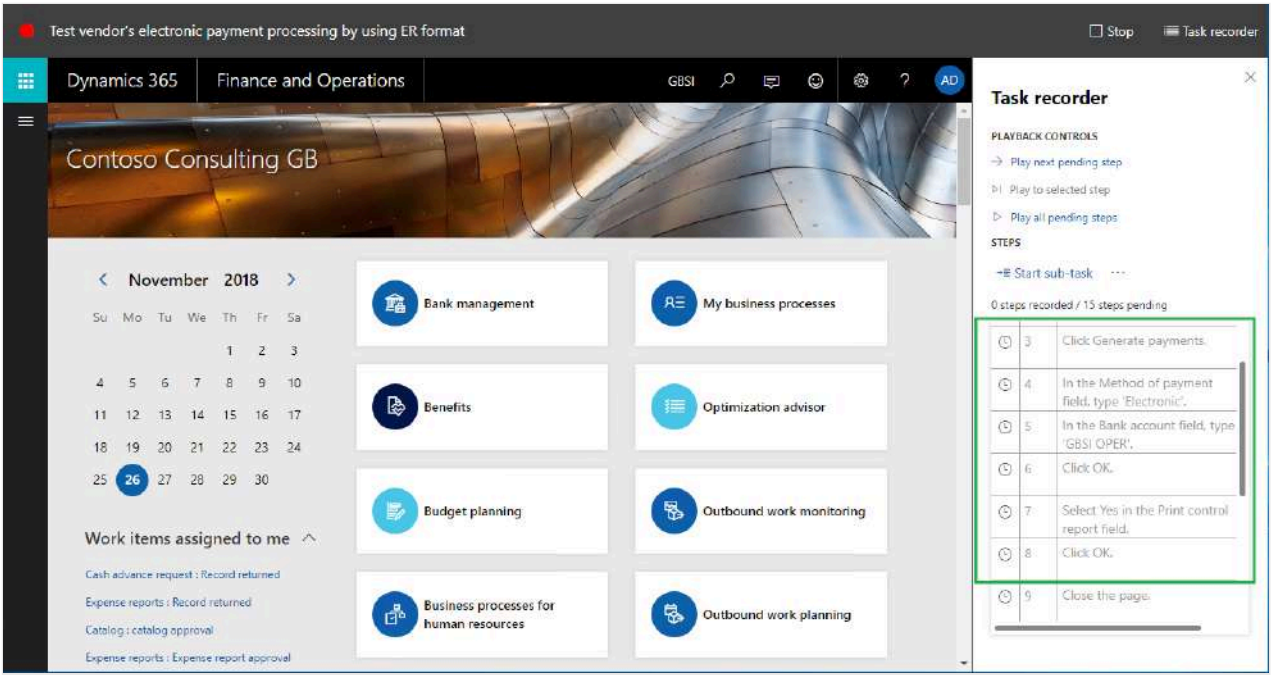
1. Select the **Settings** button (the gear symbol).
2. Select **Task recorder**.
3. Select **Playback recording**.
4. Select **Open from this PC**.

5. Select **Browse**, and select the locally saved **Process\Recording.xml** file.
6. Select **Start**.
7. Keep selecting **Play next pending step** until you play all the steps in the recording.

This task recording performs the following actions:

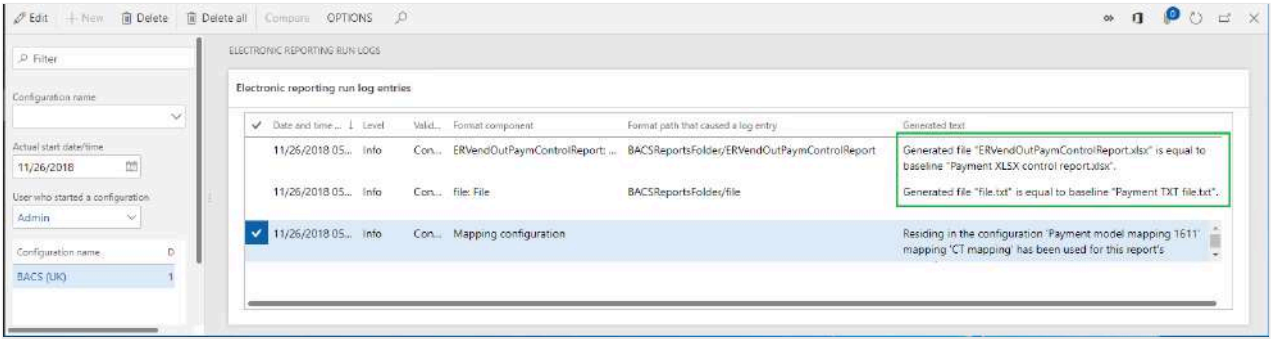
1. Starts vendor payment processing.

2. Selects the correct runtime parameters, and turns on generation of a control report.

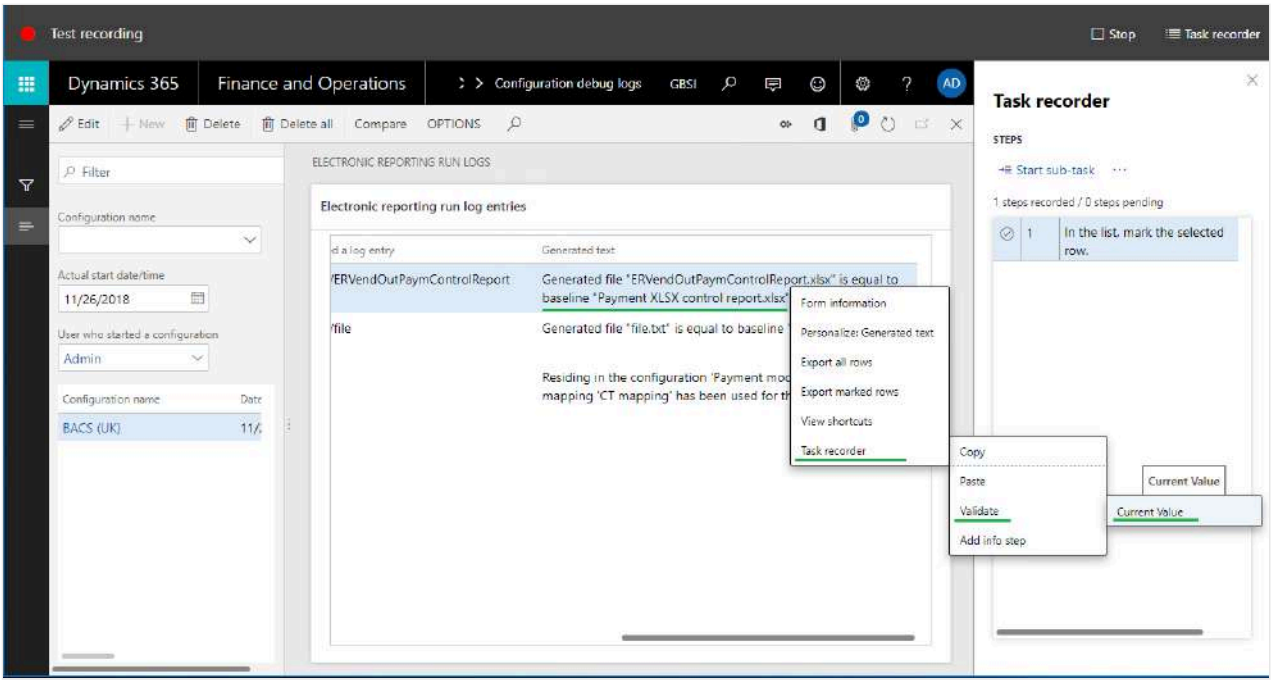


3. Accesses the ER debug log to record the results of the comparison of generated outputs to corresponding baselines.

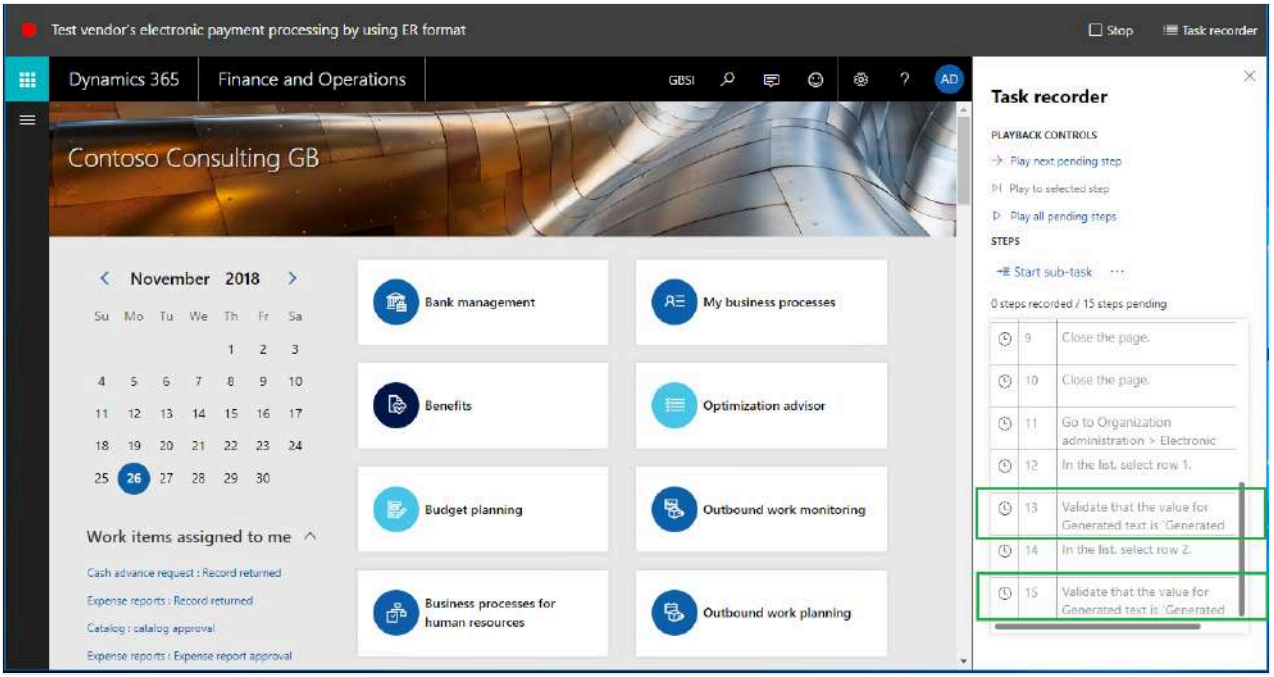
   In the ER debug log, the results of the comparison appear in the **Generated text** field. The **Format component** and **Format path that caused a log entry** fields refer to the file component for which the generated output is compared to the baseline.



4. Records the comparison of the current output to the baseline by using the **Validate** Task recorder option and selecting **Current Value**.



The following illustration shows what the recorded validation steps look like in the task recording.

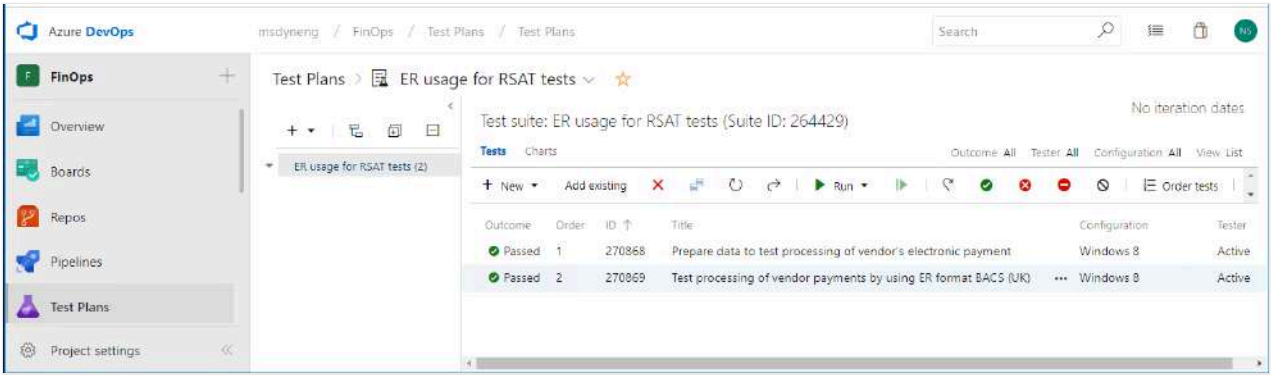


Add the recorded tests to Azure DevOps

1. Open the Azure DevOps environment.
2. Select the project that you defined in the RSAT parameters when you configured the tool.
3. Select the test plan that you defined in the RSAT parameters when you configured the tool.
4. Create a new test case for the selected test plan:

a. Name the test case **Prepare data to test processing of vendor's electronic payment**.
b. Attach the **Recording.xml** file from the **Prepare** folder that you downloaded earlier.

5. Create a new test case for the selected test plan:
   a. Name the test case **Test processing of vendor payments by using ER format BACS (UK)**.
   b. Attach the **Recording.xml** file from the **Process** folder that you downloaded earlier.



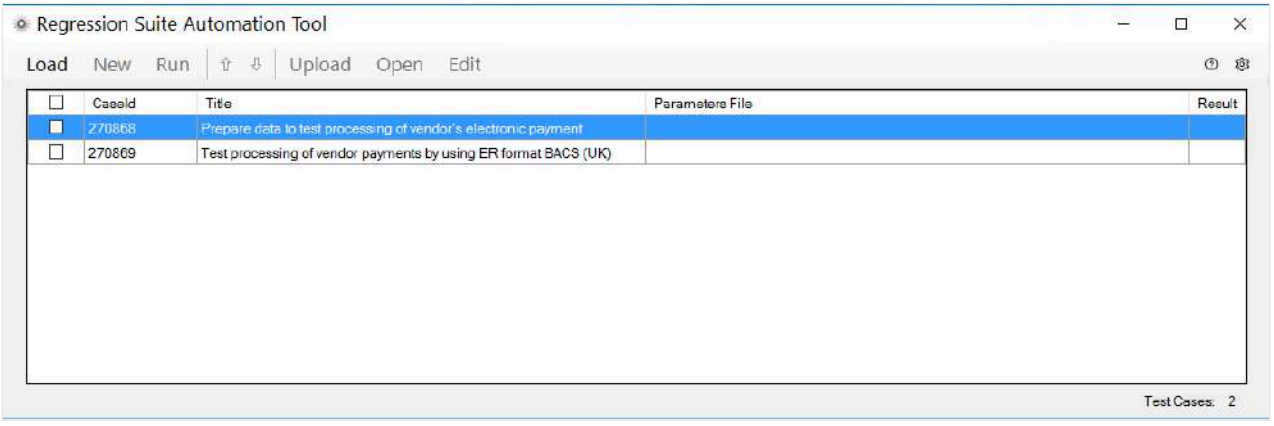
> ⓘ **Note**
>
> Pay attention to the correct execution order of the tests that are added.

Prepare RSAT to run the recorded tests

Load the tests from Azure DevOps to RSAT

1. Open the local RSAT application in the current topology.

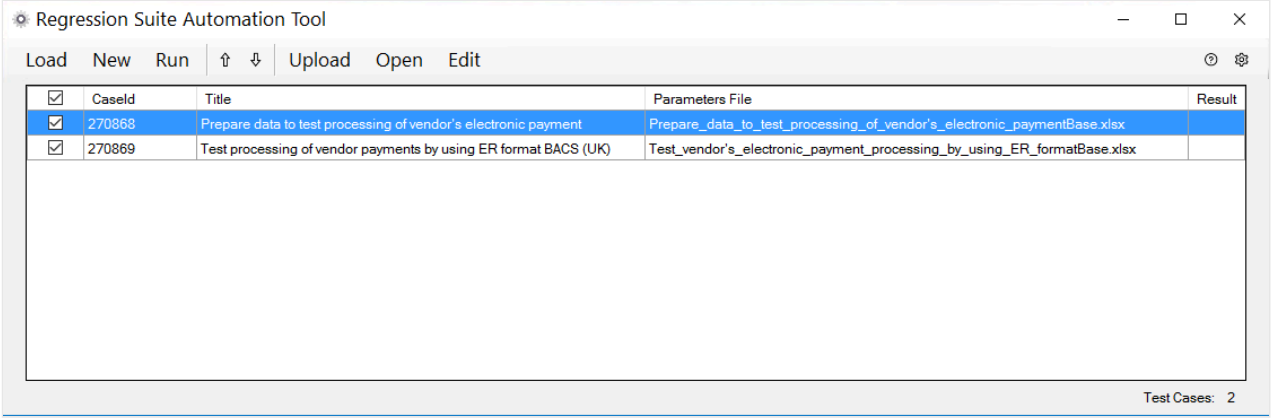
2. Select **Load** to load the tests that currently reside in Azure DevOps into RSAT.



Create automation and parameters files

1. In RSAT, select the tests that you loaded from Azure DevOps.

2. Select **New** to create RSAT automation and parameters files.



Modify the parameters files

1. In RSAT, select the **Prepare data to test processing of vendor's electronic payment** test case.

2. Select **Edit**.

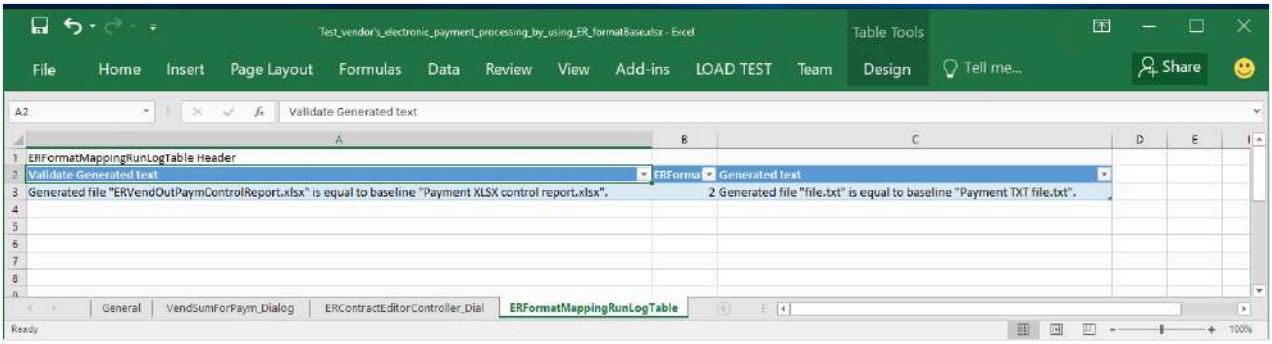
3. In the Microsoft Excel workbook that is opened, on the **General** worksheet, change the company code to **GBSI**, because this company will be used for test execution.

4. In RSAT, select the **Test processing of vendor payments by using ER format BACS (UK)** test case.

5. Select **Edit**.

6. In the Excel workbook that is opened, on the **General** worksheet, change the company code to **GBSI**.

7. On the **ERFormatMappingRunLogTable** worksheet, notice that cells A:3 and C:3 contain the text of the fields in the ER debug log table that are used to validate the results of the comparison of the output to the baseline. These texts will be used to evaluate ER debug log records that are created during test execution.



Run the tests and analyze the results

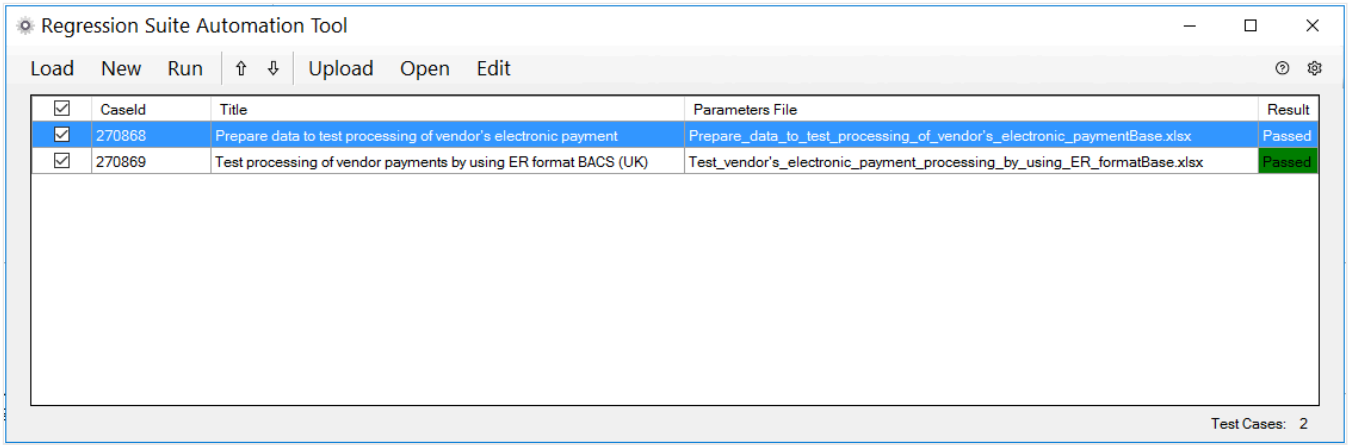
Run the tests in RSAT

1. In RSAT, select the loaded tests.
2. Select **Run**.

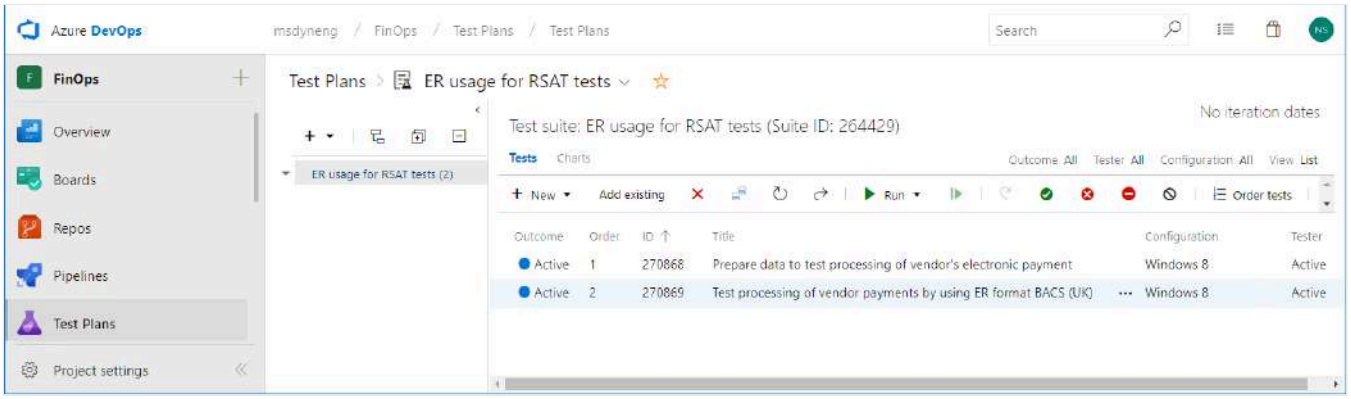
Test cases automatically run in the application by using a web browser.

Analyze the results of test execution

The results of the test execution are stored in RSAT. Notice that both tests were passed.



The test execution results are also sent to Azure DevOps so that you can do further analysis.



Simulate a situation where tests fail

This test suite fails when at least one of the generated outputs doesn't match the corresponding baseline. To create this condition, use your derived version of the **BACS (UK)** format that generates a payment file with different content than the corresponding baseline. To simulate this condition, use the same **BACS (UK)** format but change the payment amount on the processed payment line.

1. Open the application and go to **Accounts payable** > **Payments** > **Payment journal**.
2. Select **Lines**.
3. Select the payment line, and then select **Payment status** > **None**.
4. In the **Debit** field, change the value from **1,000.00** to **2,000.00**.
5. Select **Save** to save your changes.

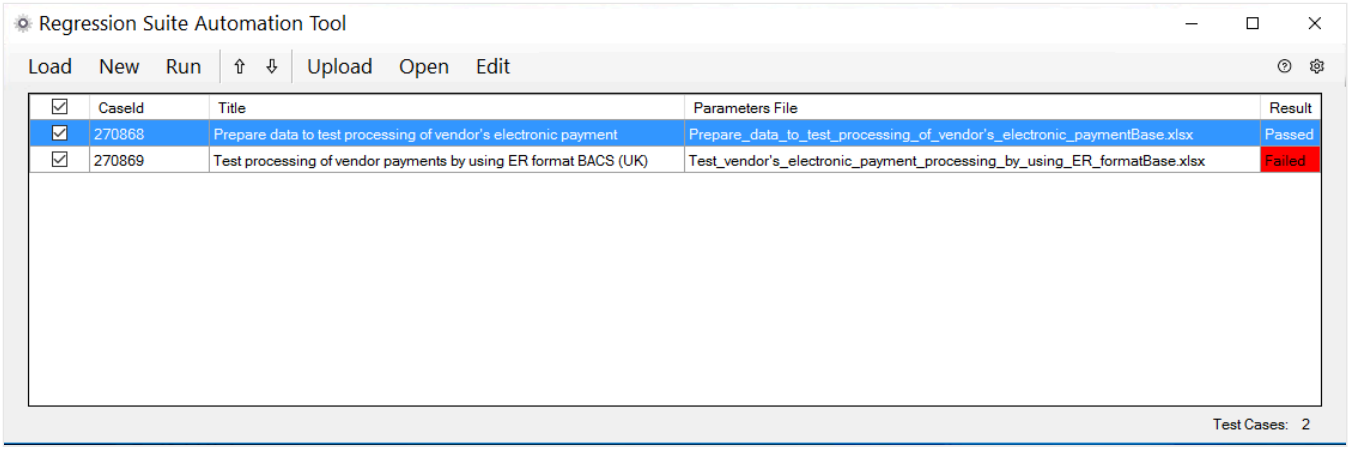
Run the tests in RSAT

1. In RSAT, select the loaded tests.
2. Select **Run**.

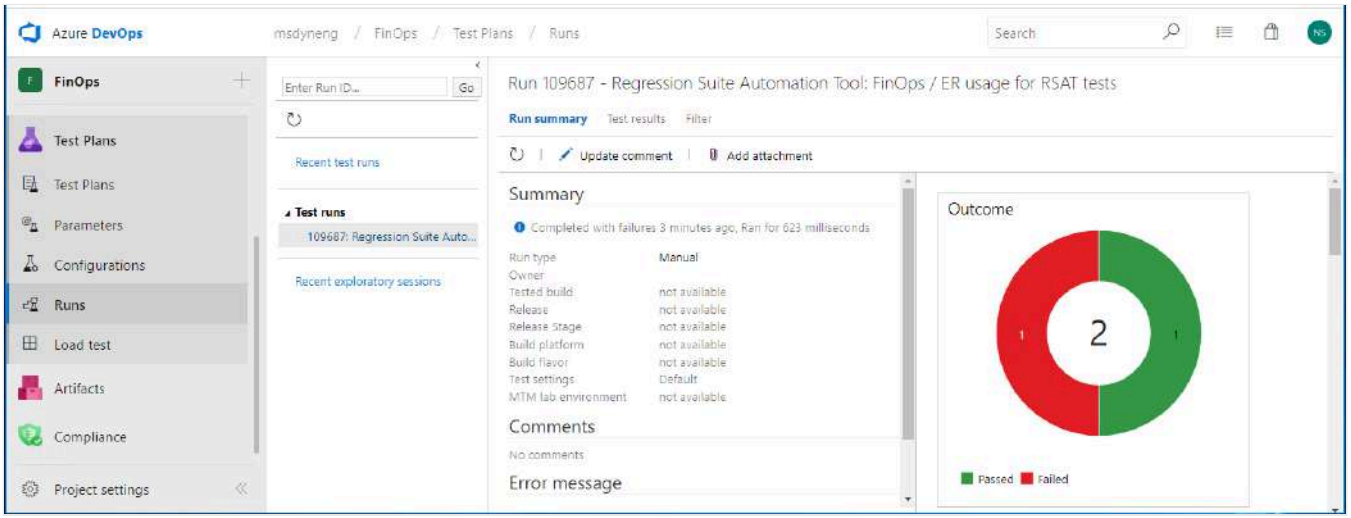
Test cases automatically run in the application by using a web browser.

Analyze the results of test execution

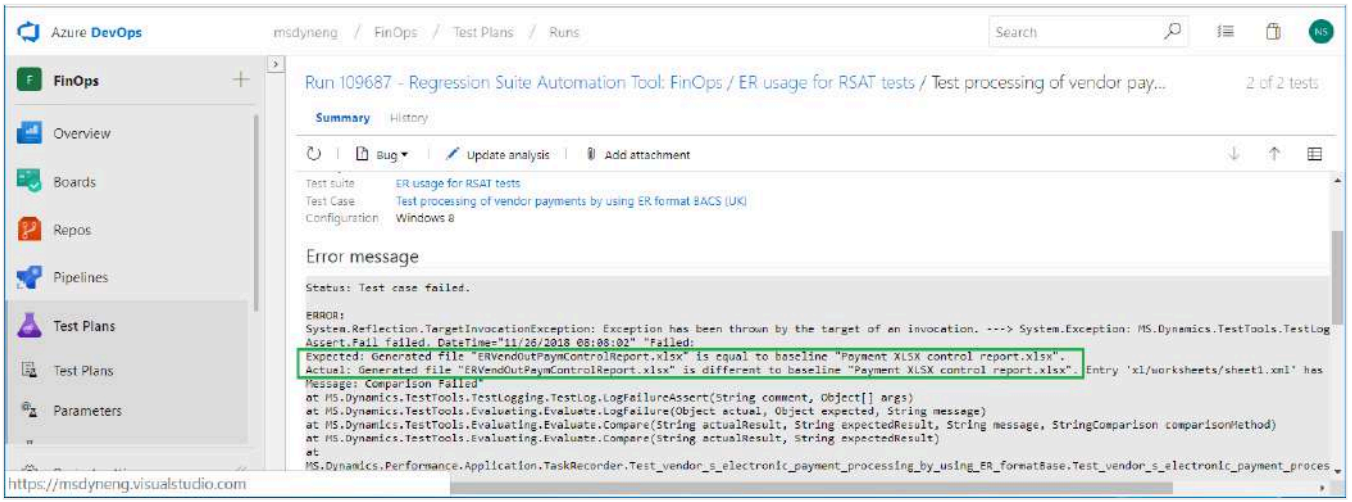
RSAT stores the results of the test execution. Notice that the second test failed during the second execution.



The test execution results are also sent to Azure DevOps so that you can do further analysis.



You can access the status of each test. You can also access the execution log so that you can analyze the reasons for any failure. In the following illustration, the execution log shows that the failure occurred because of the difference in content between the generated payment file and its baseline.



Therefore, as you saw, you can automatically evaluate the functioning of any ER format by using RSAT as the testing platform and by using Task recorder-based test cases that use the ER baseline feature.

Additional resources

- Task recorder resources
- Regression suite automation tool
- Create and automate user acceptance tests
- Deploy and use an environment that supports continuous build and test automation
- Trace generated report results and compare them with baseline values
- ER Upgrade your format by adopting a new, base version of that format

Configure Electronic reporting (ER) to pull data into Power BI

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to use your Electronic reporting (ER) configuration to arrange the transfer of data from your instance to Power BI services. As an example, this article uses Intrastat transactions as business data that you must transfer. The Power BI map visualization uses this Intrastat transaction data to present a view for analysis of company import and export activities on the Power BI report.

Overview

Microsoft Power BI is a collection of software services, apps, and connectors that work together to turn external sources of data into coherent, visually immersive, and interactive insights. Electronic reporting (ER) lets users easily configure data sources and arrange the transfer of data from the application to Power BI. The data is transferred as files in the OpenXML worksheet (Microsoft Excel workbook file) format. You store the transferred files on a Microsoft SharePoint Server that you configure for this purpose. Use the stored files in Power BI to make reports that include visualizations (tables, charts, maps, and so on). Share Power BI reports with Power BI users, and access them in Power BI dashboards and on the application pages. This article explains the following tasks:

- Configure Microsoft Dynamics 365 Finance.
- Prepare your ER format configuration to get data from the Finance application.
- Configure the ER environment to transfer data to Power BI.
- Use transferred data to create a Power BI report.
- Make the Power BI report accessible in Finance.

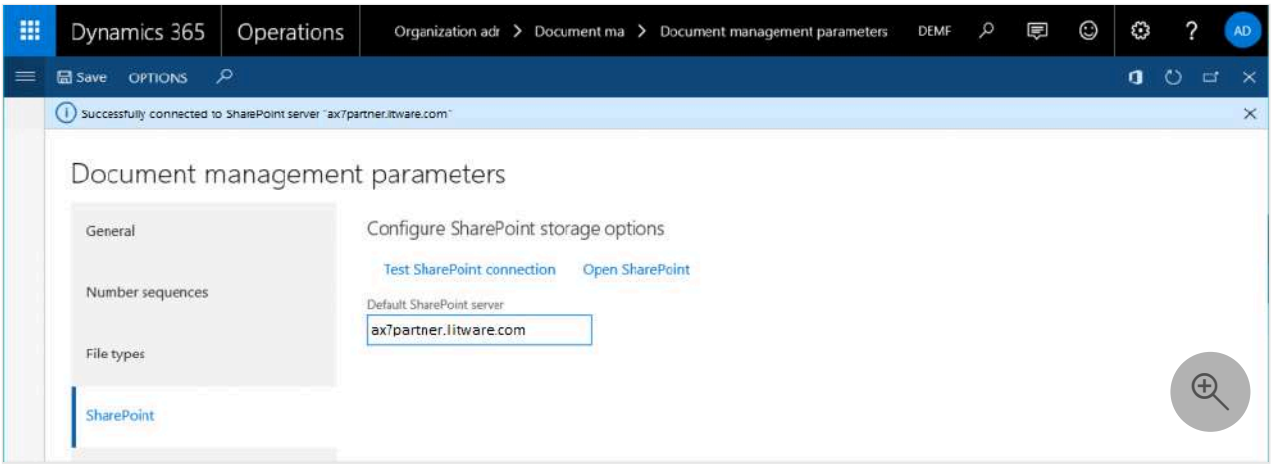
Prerequisites

To complete the example in this article, you must have the following access:

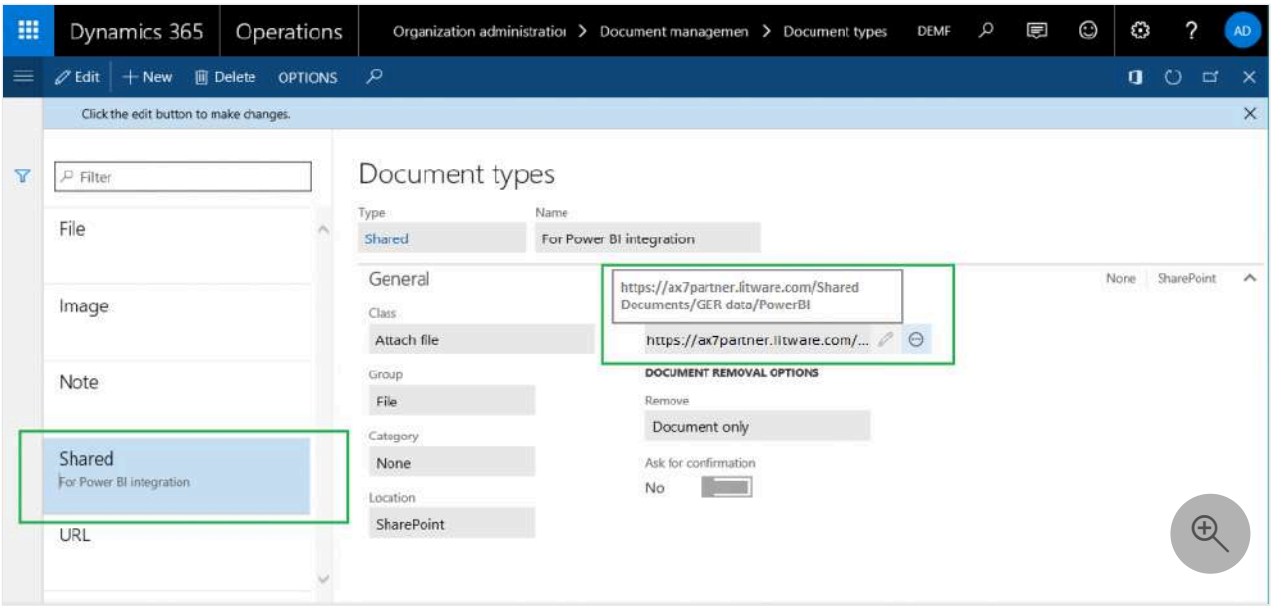
- Access for one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator
- Access to the SharePoint Server that you configure for use with the application
- Access to the Power BI framework

Configure document management parameters

1. On **Document management parameters**, configure access to the SharePoint Server that the company uses and that you sign in to (the DEMF company in this example).
2. Test the connection to the SharePoint Server to make sure that you have access.



3. Open the configured SharePoint site. Create a new folder where ER stores Excel files that have the business data that the Power BI reports require as a source of Power BI datasets.
4. On **Document types**, create a new document type that you use to access the SharePoint folder that you just created. Enter **File** in the **Group** field and **SharePoint** in the **Location** field, and then enter the address of the SharePoint folder.

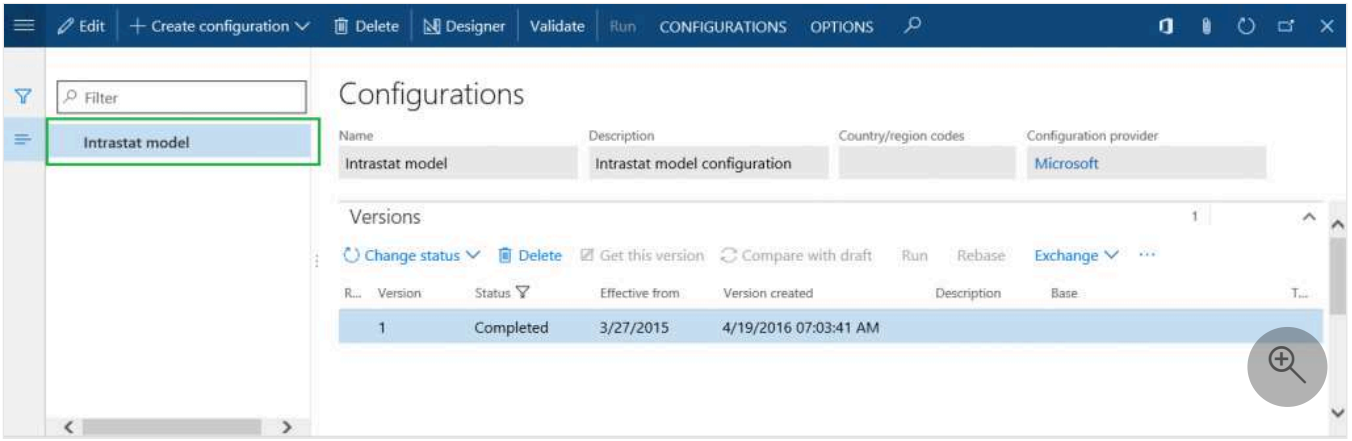


Configure ER parameters

1. In the **Electronic reporting** workspace, select the **Electronic reporting parameters** link.
2. On the **Attachments** tab, select the **File** document type for all the fields.
3. In the **Electronic reporting** workspace, make the required provider active by selecting **Set active**. For more information, see the **ER Select service provider** task guide.

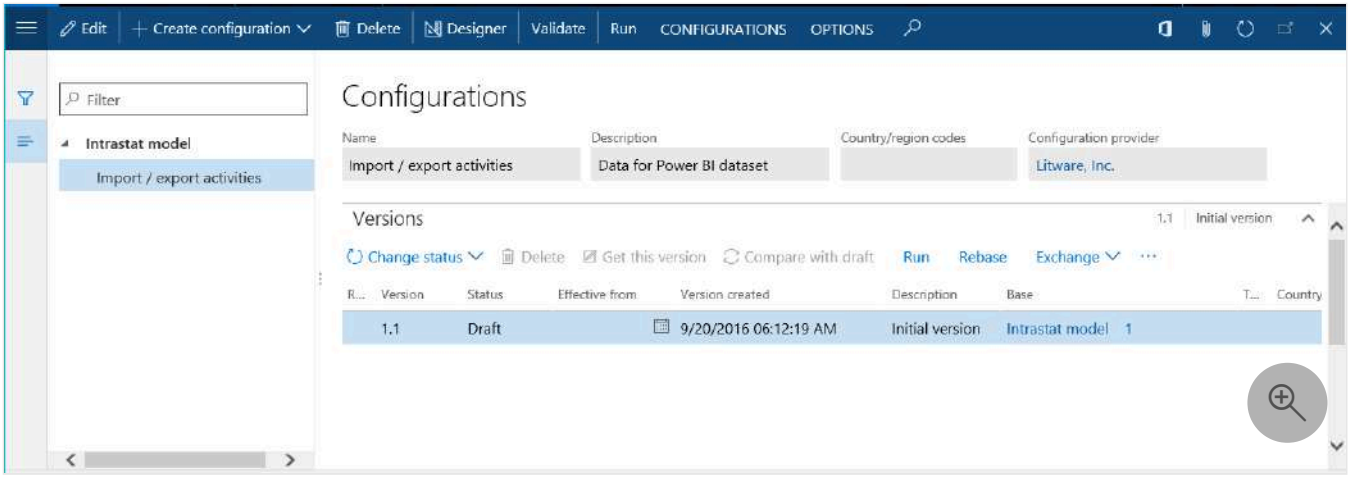
Use an ER data model as the source of data

You must have an ER data model as the source of business data that Power BI reports use. You upload this data model from the ER configurations repository. For more information, see Download Electronic reporting configurations from Lifecycle Services or see the **ER Import a configuration from Lifecycle Services** task guide. Select **Intrastat** as the data model that you upload from the selected ER configurations repository. (In this example, version 1 of the model is used.) You can then access the **Intrastat** ER model configuration on the **Configurations** page.



Design an ER format configuration

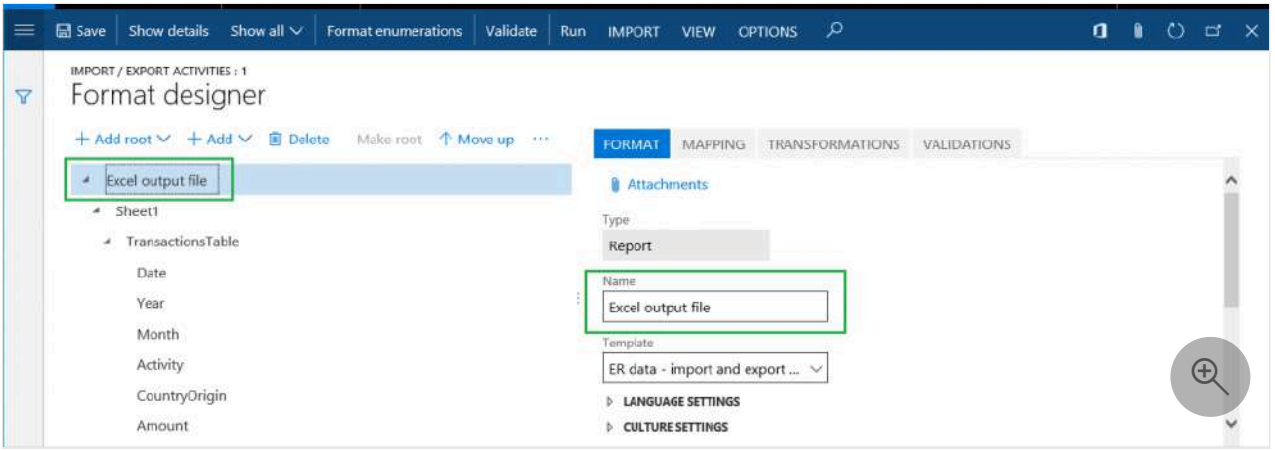
Create a new ER format configuration that uses the **Intrastat** data model as the source of business data. This format configuration generates output results as electronic documents in OpenXML (Excel file) format. For more information, see the **ER Create a configuration for reports in OPENXML format** task guide. Name the new configuration **Import / export activities**, as shown in the following illustration. Use the ER data - import and export details Excel file as a template when you design the ER format. For information about how to import a format template, see the task guide.



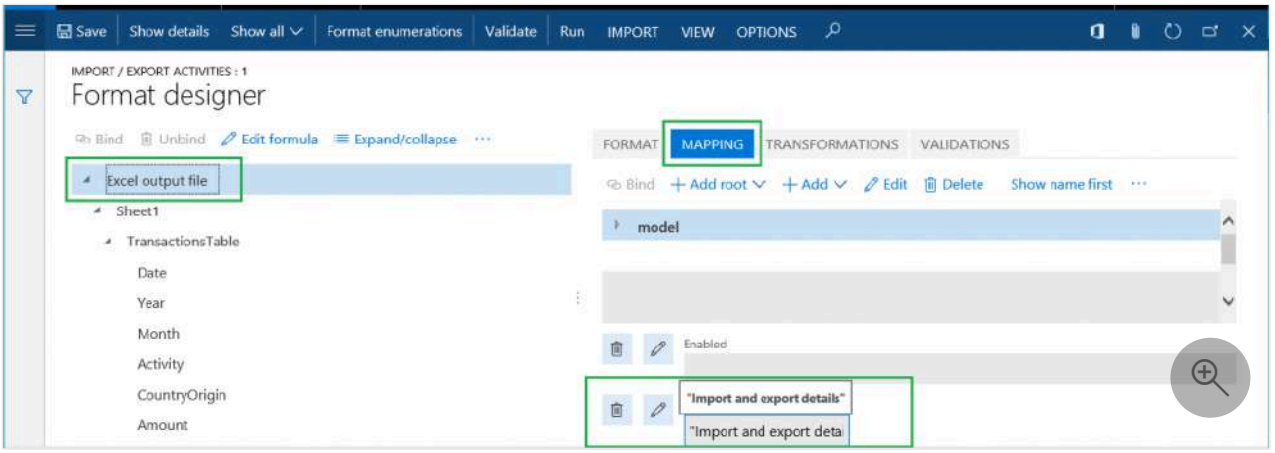
To modify the **Import / export activities** format configuration, follow these steps:

1. Select **Designer**.

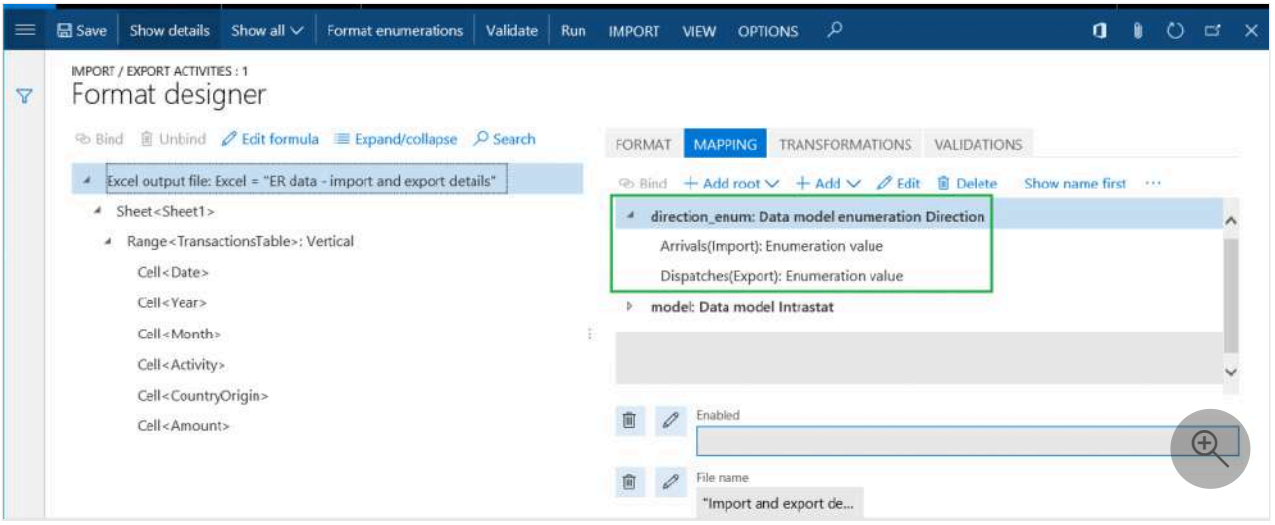
2. On the **Format** tab, name the file element for this format **Excel output file**.



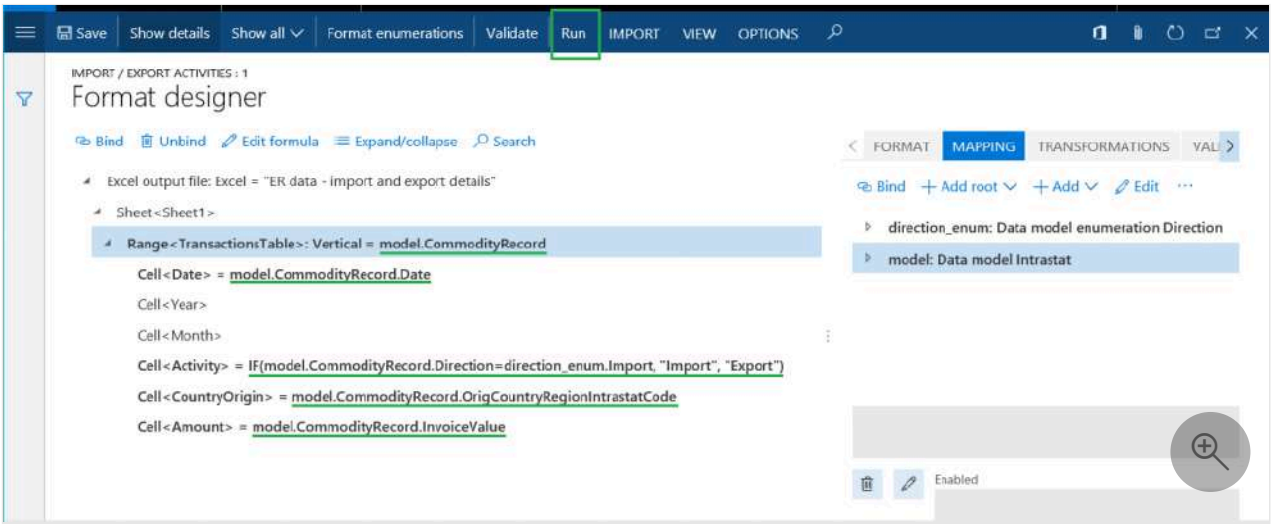
3. On the **Mapping** tab, specify the name of the Excel file that this format generates whenever it runs. Configure the related expression to return the value **Import and export details**. The .xlsx file name extension is added automatically.



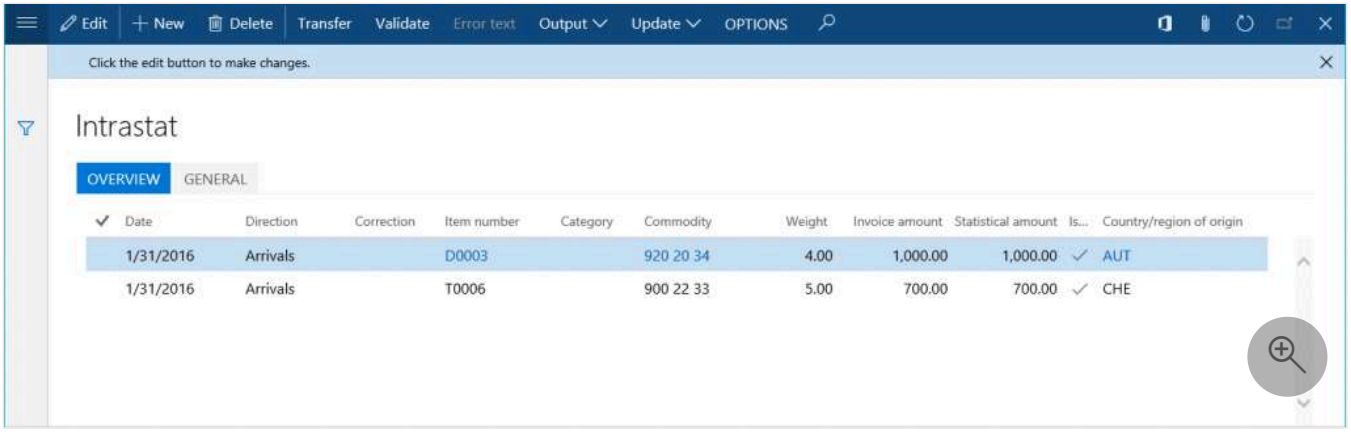
4. Add a new data source item for this format. This enumeration is required for further data binding.
   a. Name the data source **direction_enum**.
   b. Select **Data model enumeration** as the data source type.
   c. Refer to the **Direction** data model enumeration.



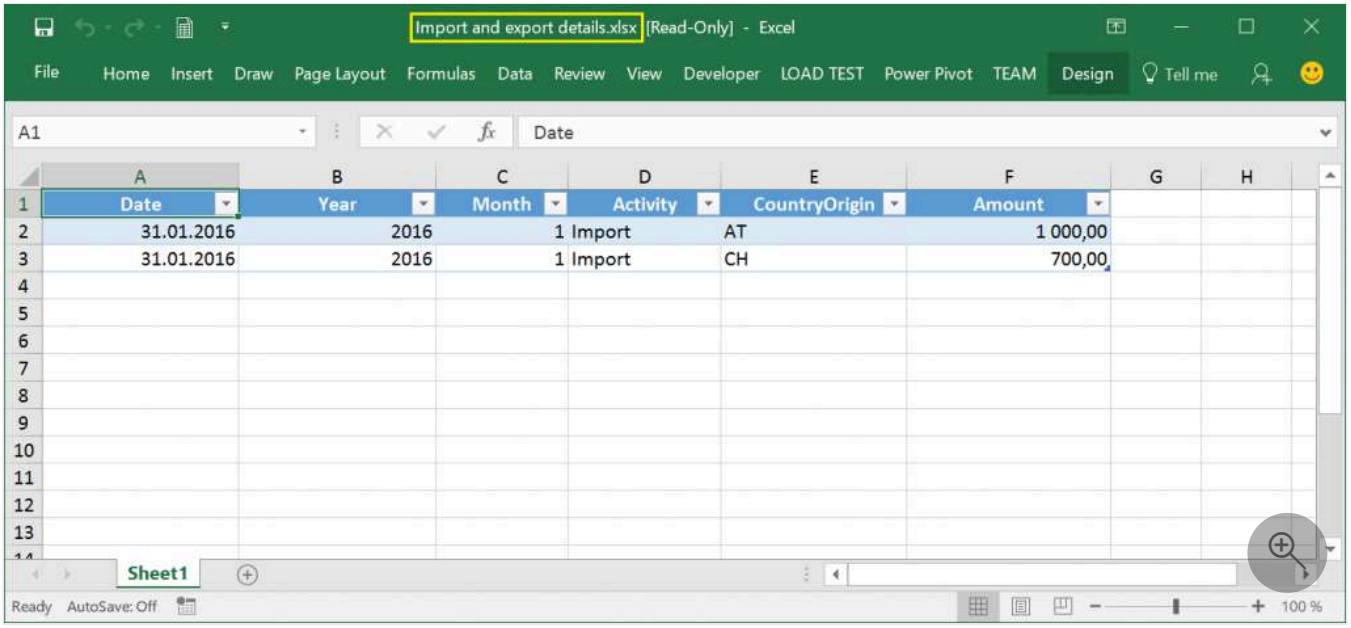
5. Bind elements of the **Intrastat** data model to elements of the designed format, as shown in the following illustration.



After you run it, the ER format generates the output result in Excel format. It sends the details of the Intrastat transactions to the output result, and separates them as transactions that describe either import activities or export activities. Select **Run** to test the new ER format for the list of Intrastat transactions on the **Intrastat** page (**Tax** > **Declarations** > **Foreign trade** > **Intrastat**).



The following output result is generated. The file is named **Import and export details.xlsx**, as you specified in the format settings.



Configure the ER destination

You must configure the ER framework to send the output result of the new ER format configuration in a special way.

- The output result must go to the folder of the selected SharePoint Server.
- Each execution of the format configuration must create a new version of the same Excel file.

On **Electronic reporting** (**Organization administration** > **Electronic reporting**), select **Electronic reporting destination**, and add a new destination. In the **Reference** field, select the **Import / export activities** format configuration that you created earlier. Follow these steps to add a new file destination record for the reference.

1. In the **Name** field, enter the title of the file destination.
2. In the **File name** field, select the name **Excel output file** for the Excel file format component.

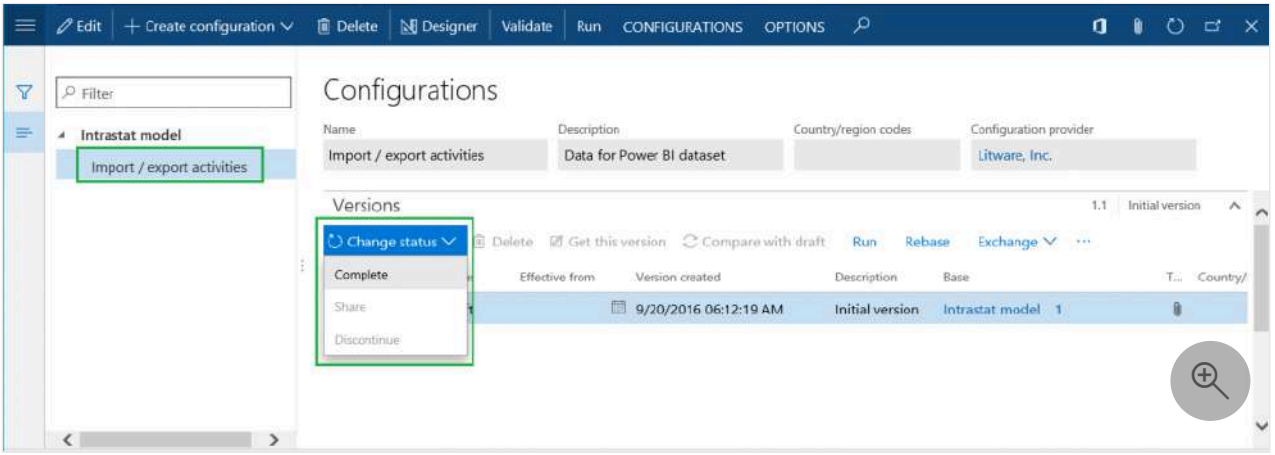
Select the **Settings** button for the new destination record. Then, in the **Destination settings** dialog box, follow these steps:

1. On the **Power BI** tab, set the **Enabled** option to **Yes**.
2. In the **SharePoint** field, select the **Shared** document type that you created earlier.

Schedule execution of the configured ER format

1. On **Configurations** (**Organization administration** > **Electronic reporting** > **Configurations**), in the configurations tree, select the **Import / export activities** configuration that you created earlier.

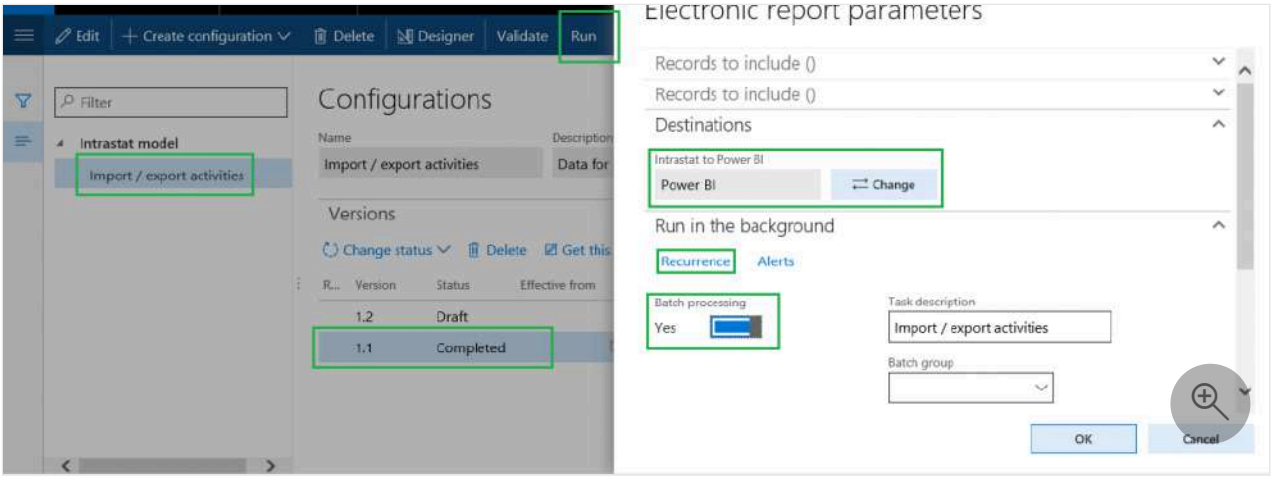
2. Change the status of version 1.1 from **Draft** to **Complete** to make this format available for use.



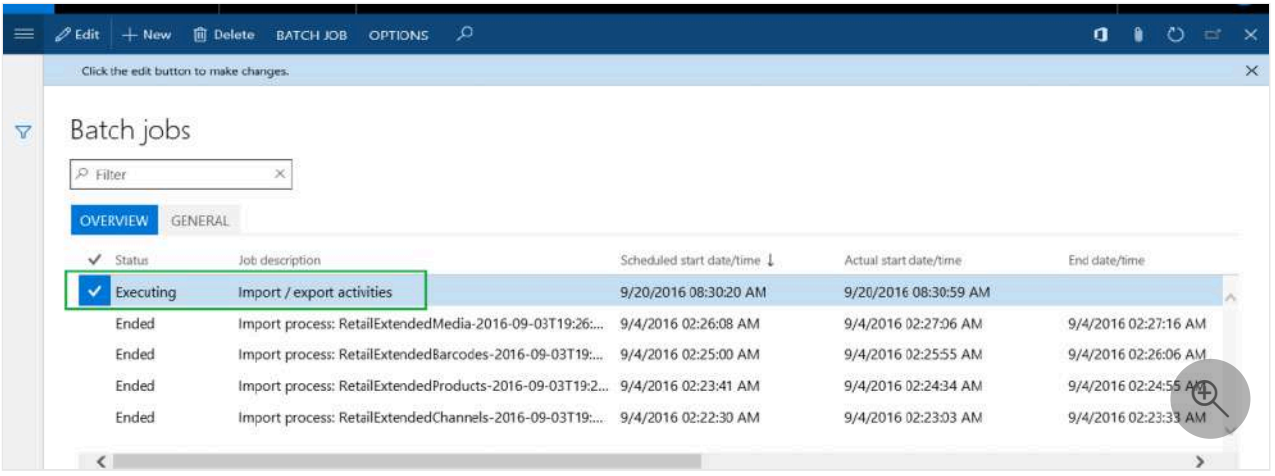
3. Select the completed version of the **Import / export activities** configuration, and then select **Run**. The configured destination is applied to the output result that is generated in Excel format.

4. Set the **Batch processing** option to **Yes** to run this report in unattended mode.

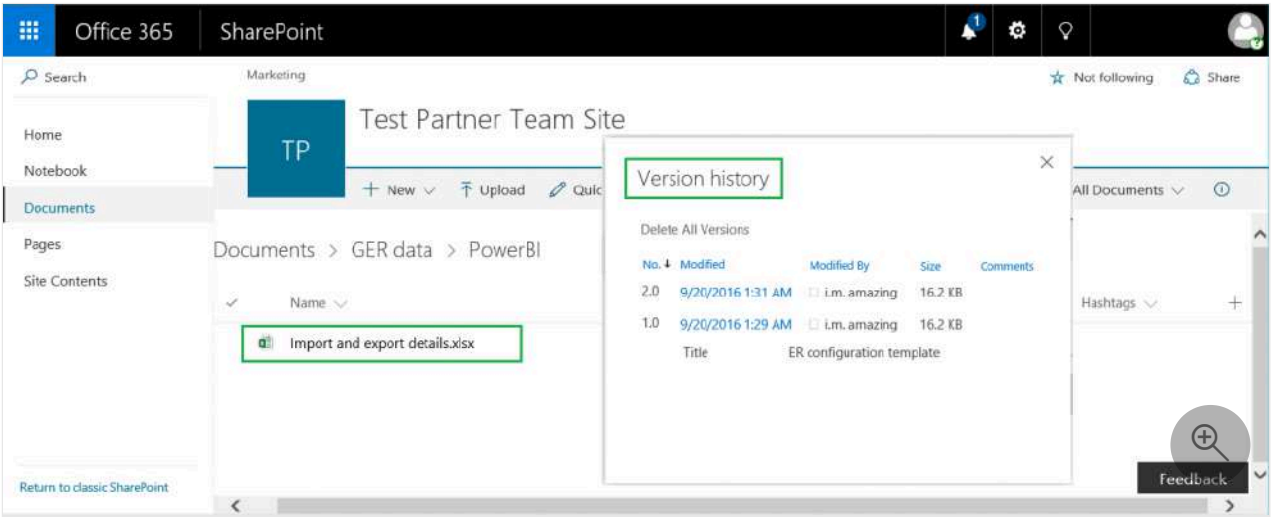
5. Select **Recurrence** to schedule the required recurrence of this batch execution. The recurrence defines how often the updated data is transferred to Power BI.



6. After you configure it, you can find the ER report execution job on the **Batch jobs** page (**System administration** > **Inquiries** > **Batch jobs**).

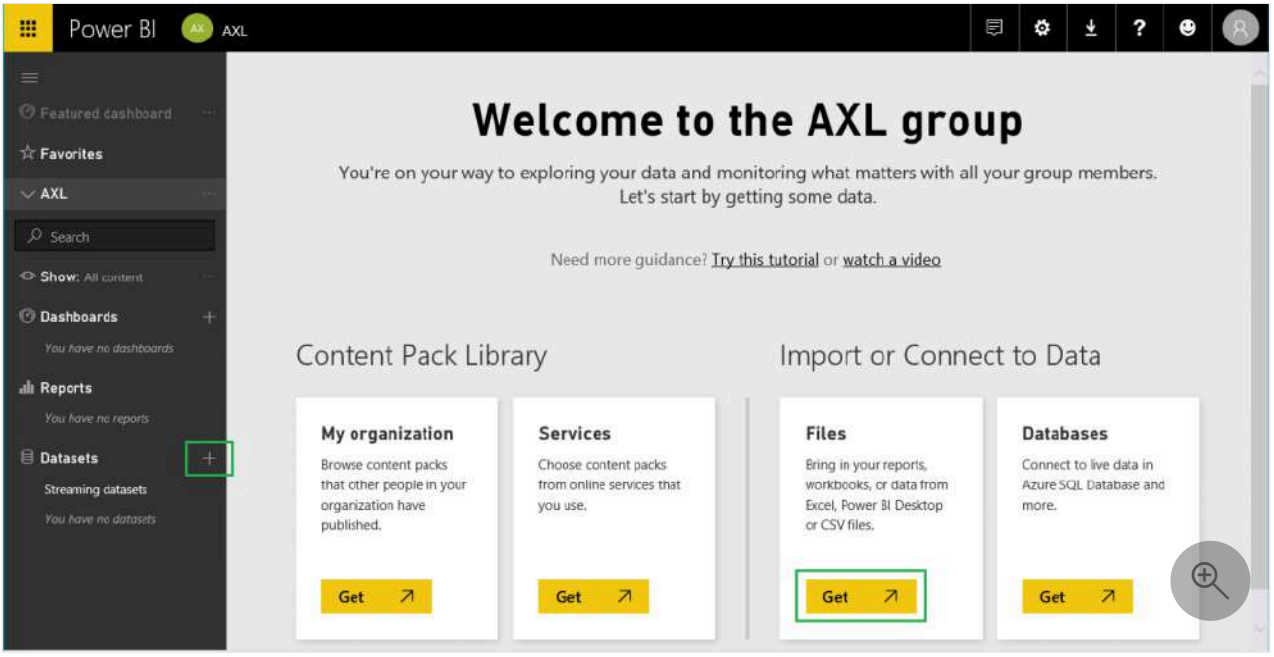


7. When you run this job for the first time, the destination creates a new Excel file that has the configured name in the selected SharePoint folder. Every subsequent time that you run the job, the destination creates a new version of this Excel file.



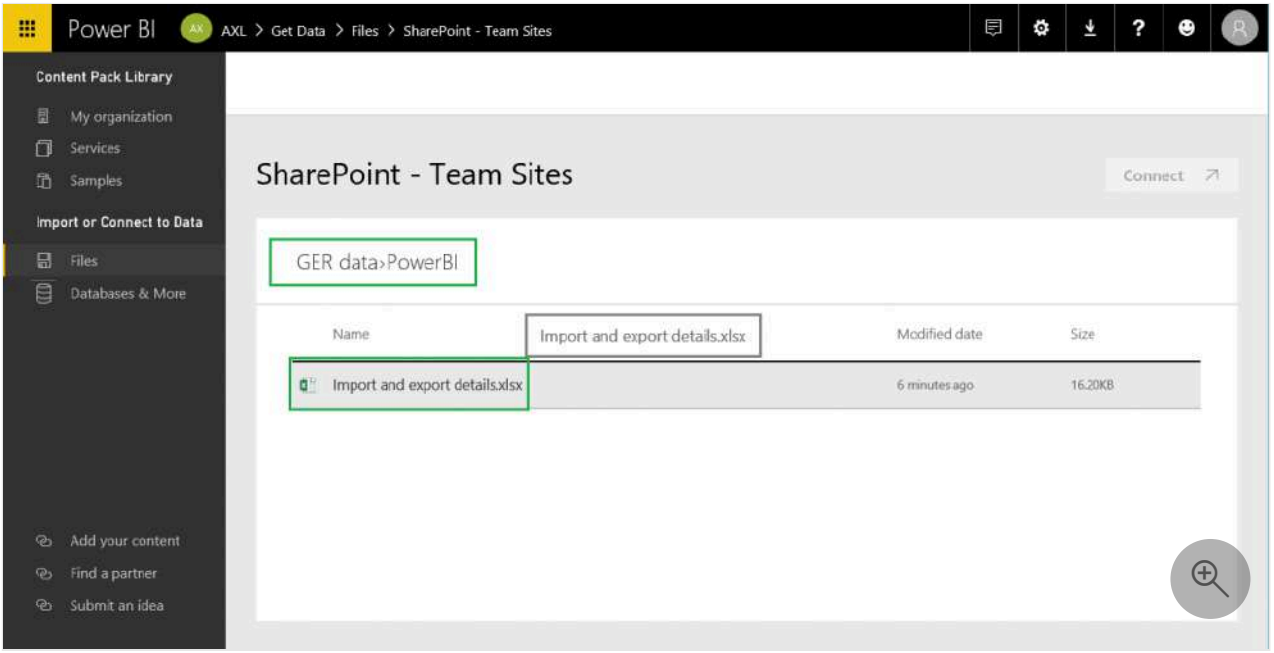
Create a Power BI dataset by using the output result of the ER format

1. Sign in to Power BI, and either open an existing Power BI group (workspace) or create a new group. Either click **Add** under **Files** in the **Import or Connect to Data** section, or click the plus sign (+) next to **Datasets** in the left pane.

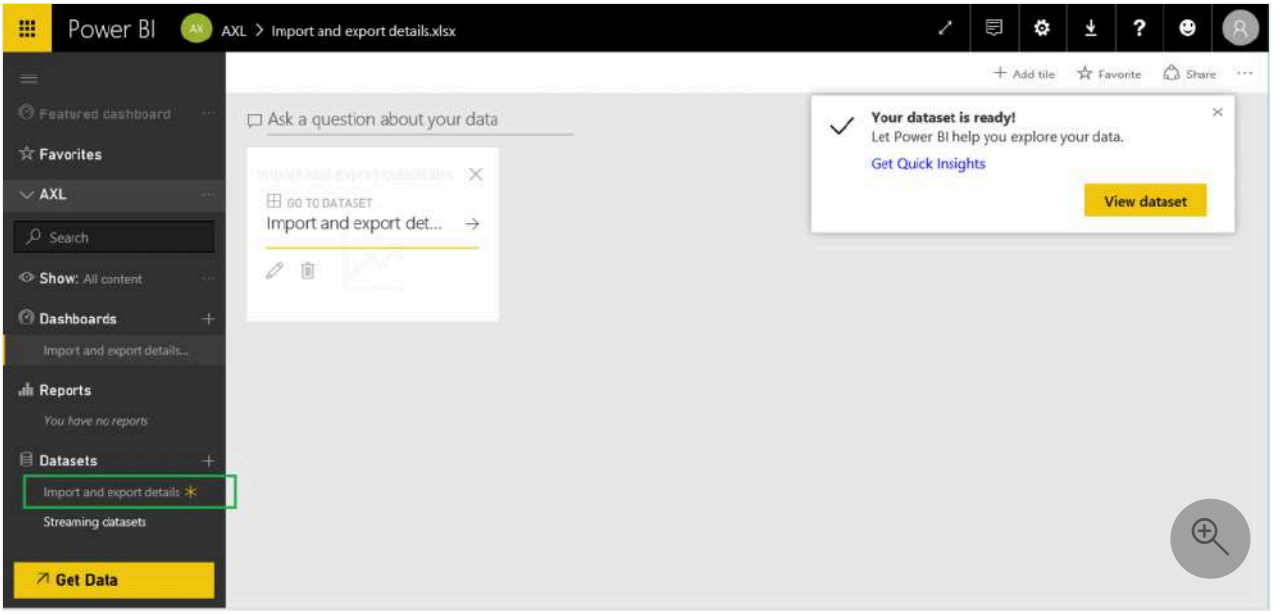


2. Select the **SharePoint – Team sites** option, and then enter the path of SharePoint Server that you're using (`https://ax7partner.litware.com` in our example).

3. Browse to the **/Shared Documents/GER data/PowerBI** folder, and select the Excel file that you created as the source of data for the new Power BI dataset.



4. Click **Connect**, and then click **Import**. A new dataset is created that is based on the selected Excel file. The dataset can also be added automatically to the newly created dashboard.



5. Configure the refresh schedule for this dataset to force a periodic update. Periodic updates enable the consumption of new business data that comes via periodic execution of the ER report through new versions of the Excel file that are created on the SharePoint Server.

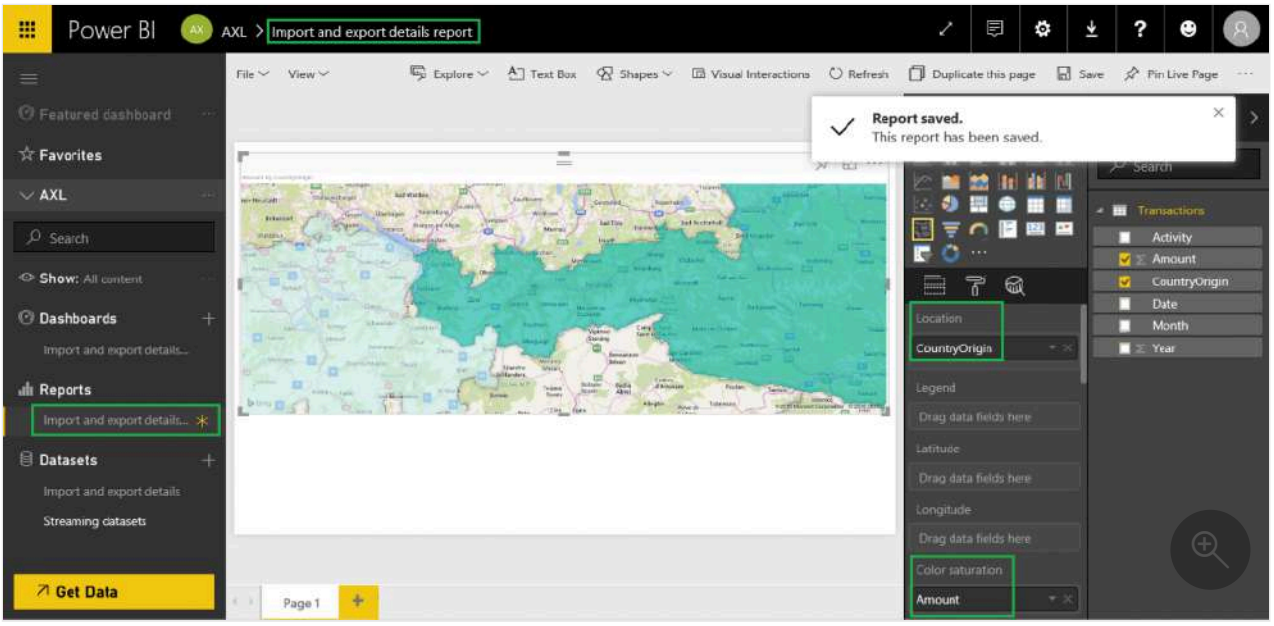
Create a Power BI report by using the new dataset

1. Select the **Import and export details** Power BI dataset that you created.

2. Configure the visualization. For example, select the **Filled map** visualization, and configure it as follows:

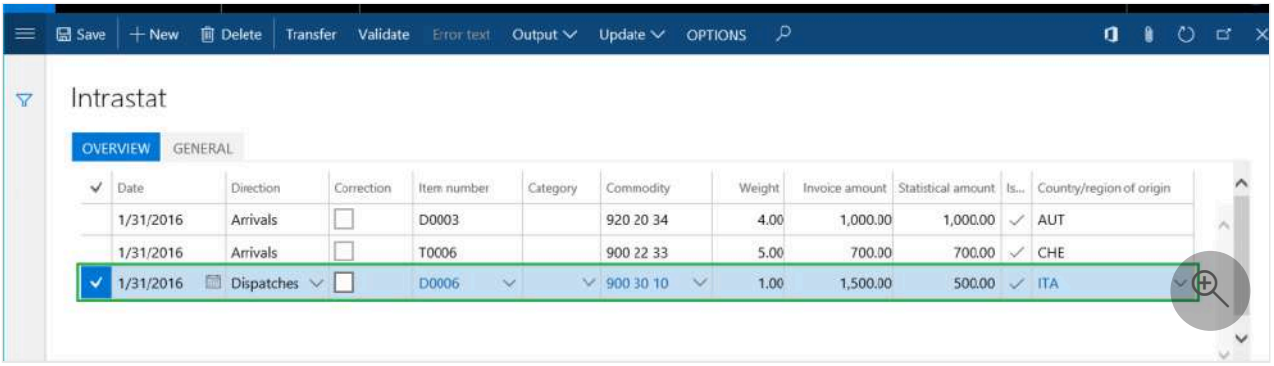
    - Assign the **CountryOrigin** dataset field to the **Location** field of the map visualization.
    - Assign the **Amount** dataset field to the **Color saturation** field of the map visualization.
    - Add the **Activity** and **Year** dataset fields to the **Filters** fields collection of the map visualization.

3. Save the Power BI report as **Import and export details report**.

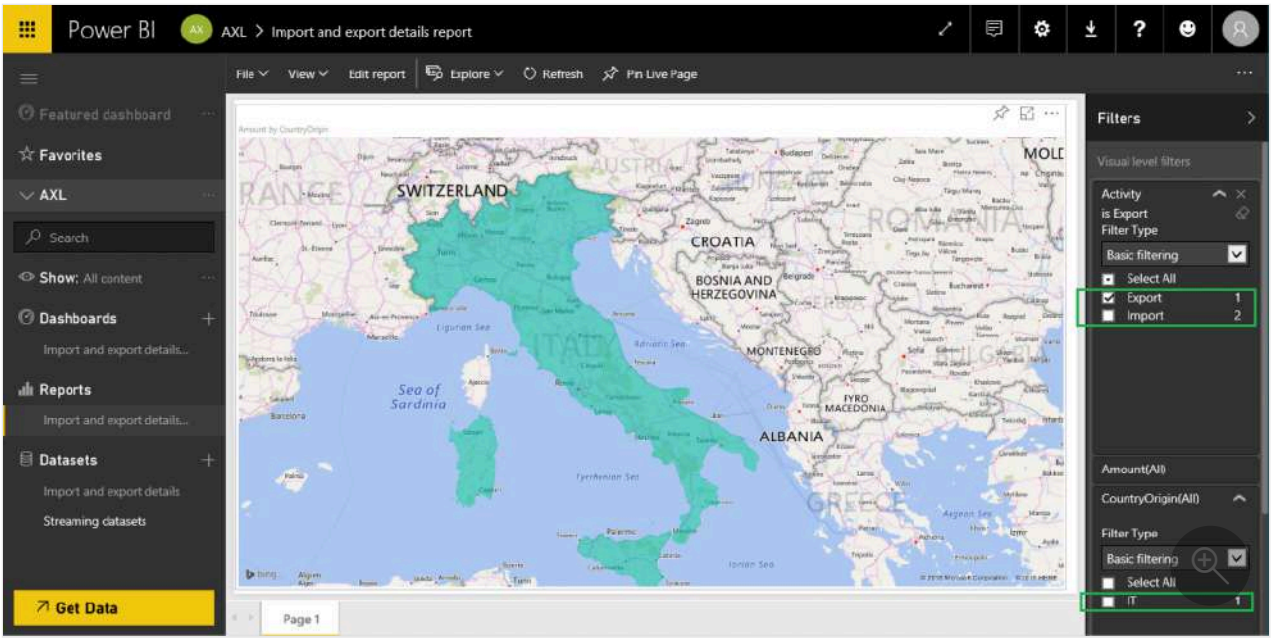


The map shows the countries and regions that are mentioned in the Excel file (Austria and Switzerland in this example). These countries and regions are colored to show the proportion of invoiced amounts for each.

4. Update the list of Intrastat transactions. The export transaction that originated from Italy is added.



5. Wait for the next scheduled execution of the ER report and the next scheduled update of the Power BI dataset. Then review the Power BI report (select to show import transactions only). The updated map now shows Italy.



Access Power BI report in Finance

Set up the integration with Power BI. For more information, see Configure Power BI integration for workspaces.

1. On the **Electronic reporting** workspace page that supports Power BI integration (**Organization administration** > **Workspaces** > **Electronic reporting workspace**), select **Options** > **Open report catalog**.

2. Select the **Import and export details** Power BI report that you created, to show that report as an action item on the selected page.

3. Select the action item to open the page that shows the report that you designed in Power BI.

Electronic reporting (ER) overview

Last updated on 04/13/2026

Generate printable FTI forms

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The Electronic reporting (ER) framework lets you generate printable free text invoice (FTI) forms as Microsoft Office documents. This article provides information about how to build your own configurations as well as details of available configuration templates.

Overview

In addition to the existing capability of generating printable FTI forms by using Microsoft SQL Server Reporting Services (SSRS), you can now use the ER framework. You can manage printable FTI forms in Microsoft Office Excel and Word. You can also modify the layout, data flow, and formatting to meet specific requirements without making code changes.

> **Note**
>
> If you want to start with an overview of existing ER configurations for this sample of the printable FTI forms solution, you can go directly to section **Download sample ER configurations to generate printable FTI forms** later in this article.

Create customized configurations for FTI printable forms

As part of your customized solution for printable FTI forms, you must create a set of ER configurations.

Configure the ER data model

Your application must include the ER data model configuration that contains a data model that describes the customer invoicing business domain. As a requirement, the name of the data

model must be **CustomersInvoicing**. For information about how to design ER data models, see ER Design domain specific data model.

Configure the ER model mapping

Your application must include the ER model mapping for the CustomersInvoicing data model. You can add the model mapping to either the ER data model configuration or the ER model mapping configuration. However, the name of the root descriptor of the model mapping must be **FreeTextInvoice**.

The mapping must contain the following data sources:

- Data source type: **Table records**
  - This data source must be named **CustInvoiceJour**.
  - It must refer to the CustInvoiceJour application table.
  - At runtime, it passes from the application to the ER model mapping the list of invoices that you select for printing.
- Data source type: **Object**
  - This data source must be named **PrintMgmtPrintSettingDetail**.
  - It must refer to the **PrintMgmtPrintSettingDetail** application class.
  - At runtime, it passes from the application to the ER model mapping details of the print management settings for the ER format that is running.

You can find the details of the application integration with the ER framework in the **ERPrintMgmtReportFormatSubscriber** class (ER Application Suite integration model) in the source code of the application.

For more information about the design of ER model mappings, see Define ER model mappings and select data sources for them.

Configure the ER format

In your application instance, you must have the ER format configuration that you use to generate FTI forms.

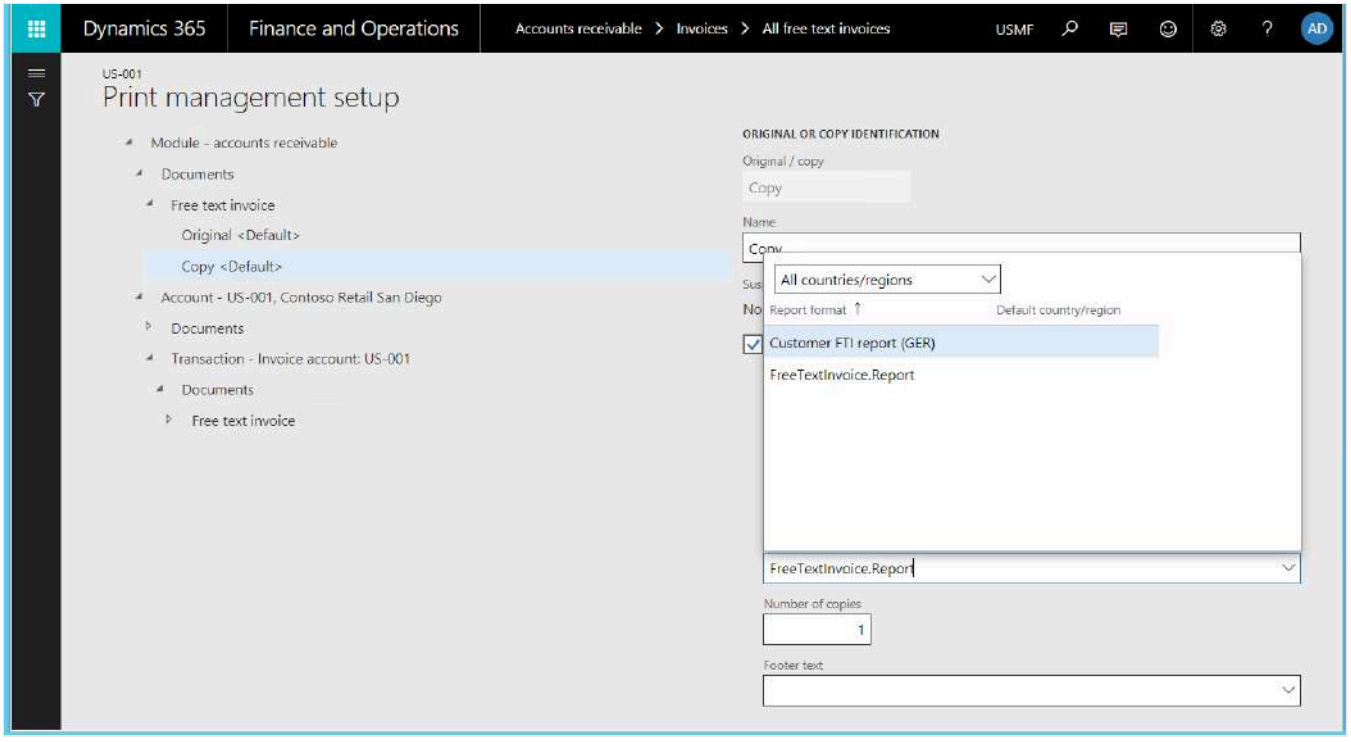
> **Note**
>
> Create this format configuration for the **CustomersInvoicing** data model. Use the model mapping that has the **FreeTextInvoice** root descriptor.

For information about how to configure ER formats, see ER Create a format configuration (November 2016). For information about how to design ER formats to generate reports in OpenXML format, see ER Design a configuration for generating reports in OPENXML format (November 2016).

Configure print management

To generate FTI forms by using the ER framework, assign ER formats in the same way that you assign SSRS reports. To associate the ER format with all Accounts receivable FTIs, go to **Accounts receivable** > **Setup** > **Forms** > **Form setup** > **General** > **Print management** > **Free text invoice** > **Original**. To associate the ER format with a specific customer or invoice, follow these steps:

1. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.
2. Select the FTI to associate the ER format with, and open the **Print management setup** page.
3. Select the document level to specify the scope of invoices for processing.
4. Select the ER format for the specified document level.

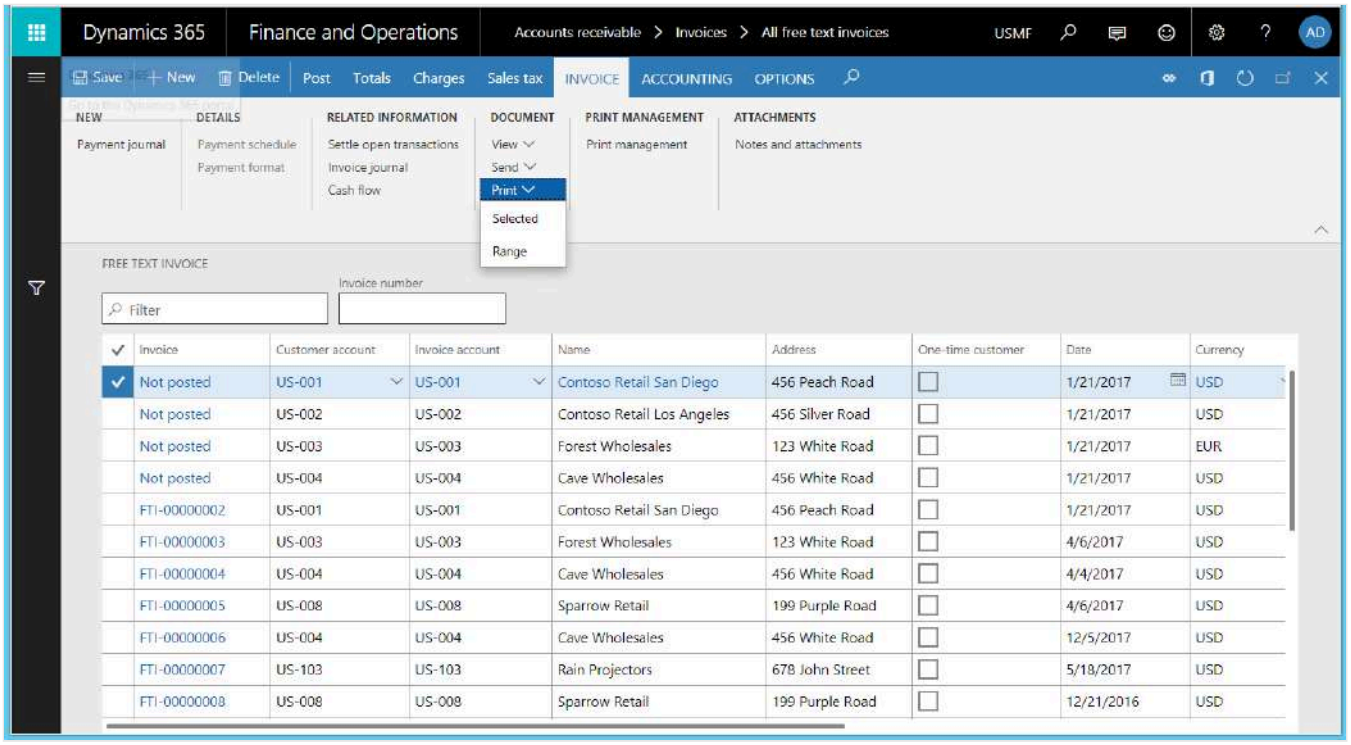


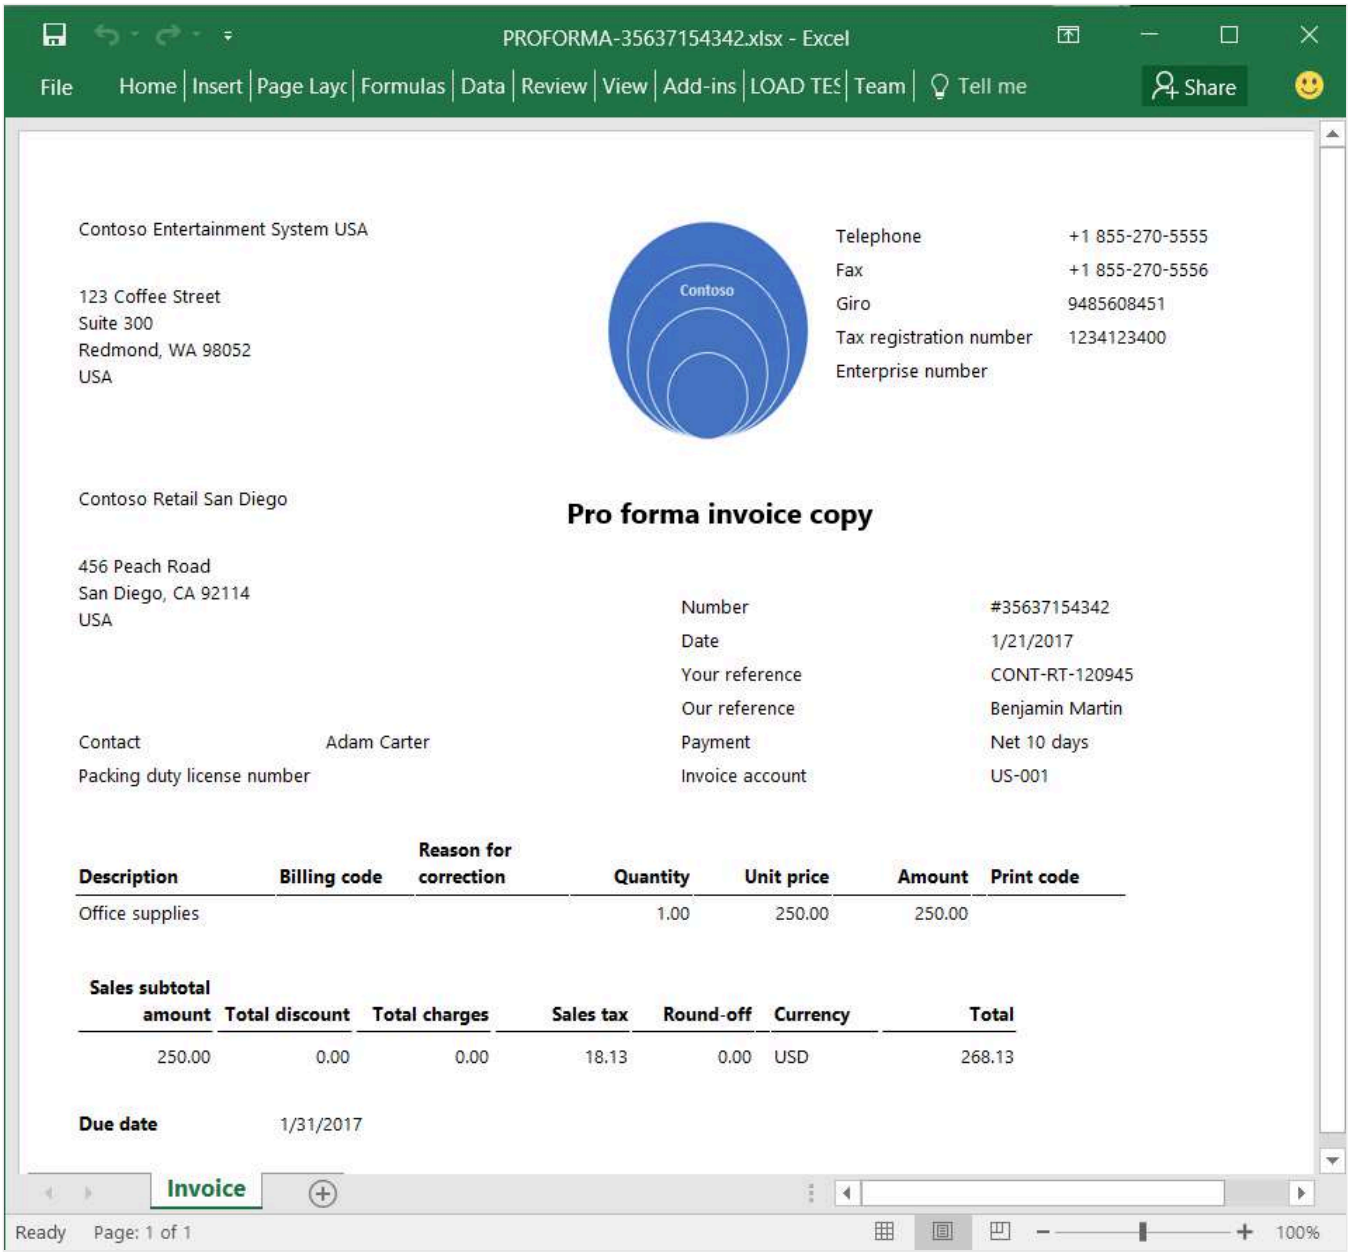
> **Note**
>
> Only ER formats that use the **FreeTextInvoice** root descriptor of the **CustomersInvoicing** data model appear in the **Report format lookup** field for the selected format.

Generate FTI forms

The ER framework generates FTI forms the same way it generates SSRS reports.

To generate FTI forms, select invoices by range or by selection.



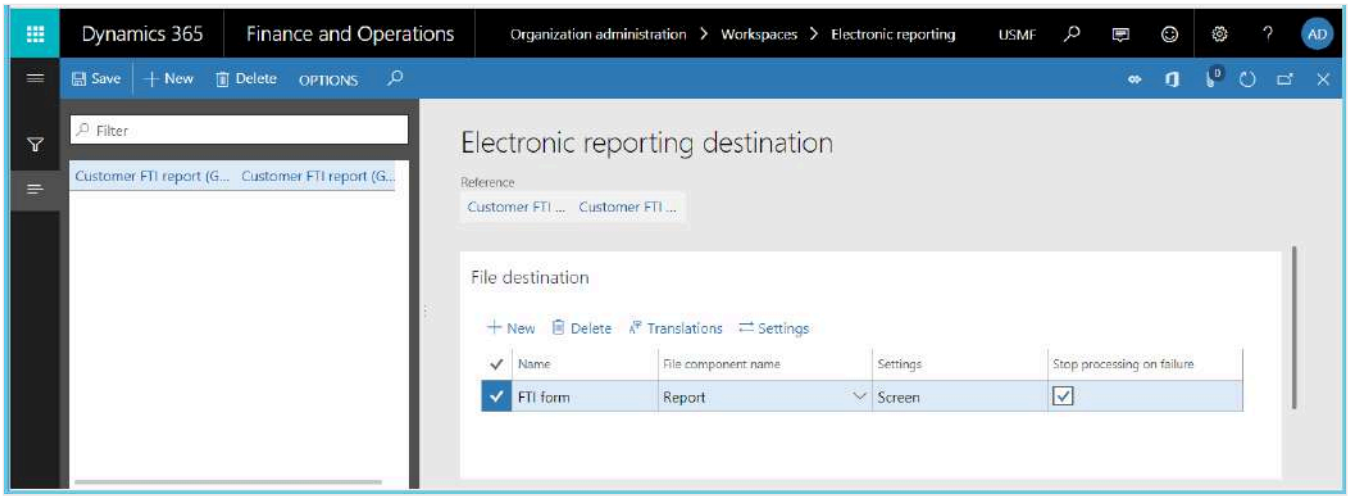


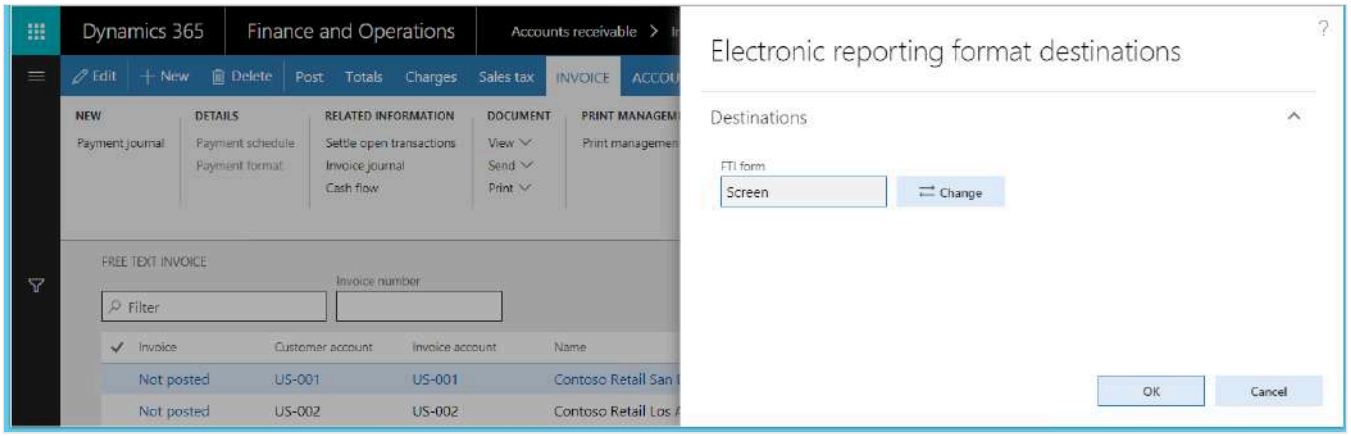
When you use ER formats to print FTI forms, the default ER file destinations are used. You can't change the destination. For more information about how to configure the ER destinations for ER formats, see Electronic reporting (ER) destinations.

You can also generate FTI forms when you post an FTI, by turning **Print invoice** on and turning **Use print management destinations** off.

> ⓘ Note
>
> When you use ER formats to print FTI forms, the default ER file destinations are used. You can change the default destination at runtime if the destination is already configured. To change the destination, you must have the following security privilege:
>
> - **Name:** ERFormatDestinationRuntimeMaintain

- **Label:** Maintain electronic reporting format destination during runtime





The ER framework currently supports the following destinations for generated documents:

- **Downloaded file** – You can save generated forms by downloading them through the browser.
- **Screen** – Microsoft 365 Excel previews generated FTI forms in Excel format.
- **SharePoint folder** – The Document management framework settings store generated forms.
- **Application archive** – Microsoft Azure Storage stores generated forms as attachments of execution log records.
- **Email** – Generated forms are sent as email attachments.

> ⓘ **Note**
>
> You can't send the generated FTI forms directly to the printer, because direct printing that uses the Dynamics Printer Routing Agent isn't currently supported.

Download sample ER configurations to generate printable FTI forms

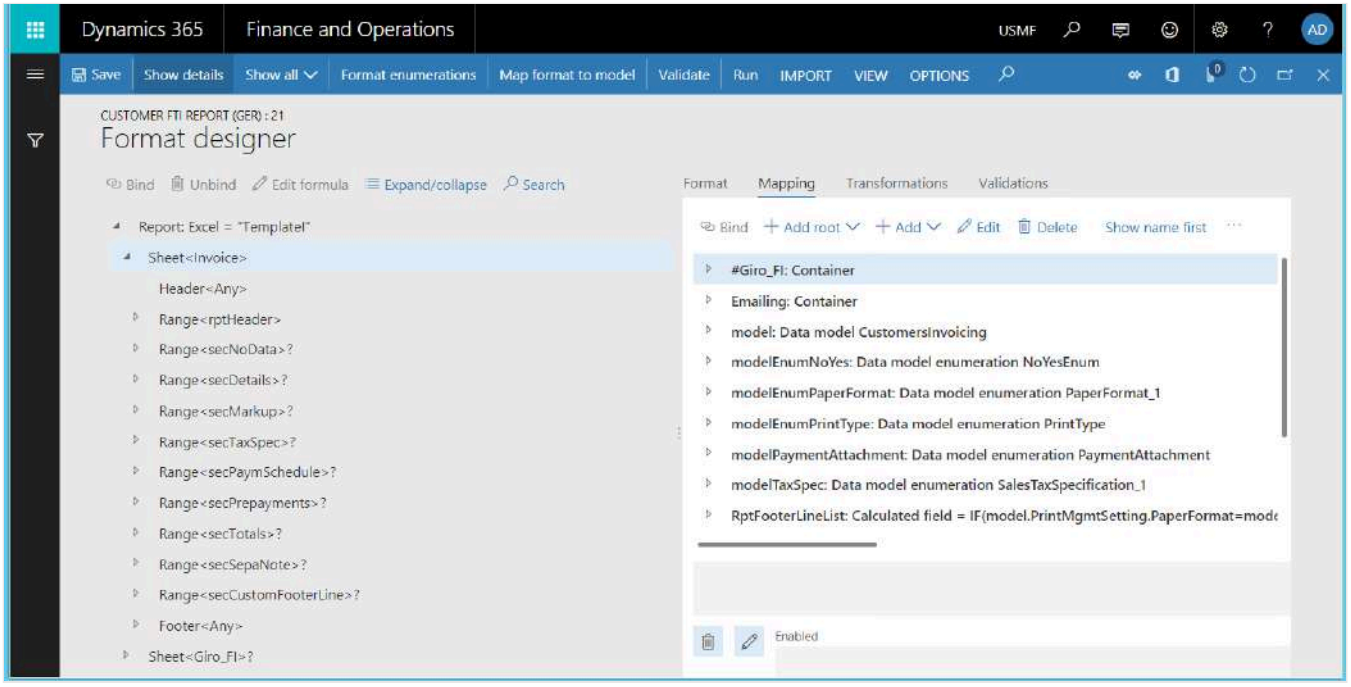
You can download sample ER configurations to use as a template for your FTI solution. Microsoft Dynamics Lifecycle Services stores these configurations in the Shared asset library. The configurations include:

- The **Customer invoicing model** configuration contains the required data model and model mapping.
- The **Customer FTI report (GER)** configuration contains the sample format.

> **Note**
>
> These configurations are samples to help clarify possible scenarios. The future of these configurations depends on the results of this evaluation and any feedback that you provide.

Features implemented in the sample ER format

In the sample ER format configuration, an Excel file is used as a template to generate FTI forms.



Currently, this sample ER format supports the following features to generate FTI forms:

- The system generates FTI forms for both original invoices that you posted and original invoices that you didn't post yet. Corrected invoices and credit notes aren't supported.

- The system generates FTI forms in the invoice language. The format of values and dates in the generated forms is based on the settings of the user's client locale.
- Generated invoices show data unavailability notifications if there are no lines in the invoices that are processed.
- Generated invoice headers are based on the paper format that you select for the FTI form on the **Accounts receivable parameters** page. Company details appear in the header of the generated invoice form only if the paper format is blank.
- Generated invoice forms show company and customer tax exempt numbers when you select the appropriate option for the FTI form on the **Accounts receivable parameters** page.
- The generated invoice lines and invoice totals sections show the default invoice's monetary details in the invoice registration currency.
- The generated invoice totals section can show monetary details in the euro currency and the invoice registration currency when you enable the **Print amount in currency representing the euro** option on the **Accounts receivable parameters** page.
- Generated invoice forms show any process invoice notes that are available, based on settings on the **Accounts receivable parameters** page. Notes are included for both the whole invoice and each invoice line.
- Generated invoice forms include notes for the customer FTI form and the processing invoice language when you configure them in the AR form notes list.
- Depending on the Print management settings, generated invoices include custom footer text when you configure it for the invoice language, the ER format, and the FTI document scope.
- The totals section of generated invoice forms includes any cash discount information that is available.
- The payment schedule section of generated invoice forms includes any payment schedule details that are available.
- The markup section of generated invoice forms includes any charges transactions that are available.
- Generated invoice forms include sales tax details, based on the **Sales tax specification** setting on the **Accounts receivable parameters** page. This section can show tax details either in the invoice registration currency only, or in the invoice registration currency and the company accounting currency at the same time.
- Generated invoice forms show direct debit notification details. For example, they show when the method of payment that has the mandatory direct debit mandate ID was selected for the invoice, when the processing invoice was registered in the euro currency, and when the direct debit mandate ID was defined for the invoice.

- Generated invoices show any prepayment details that are available for posted invoices.
- Generated invoice forms can be sent to an invoice customer as an email attachment. You should configure the appropriate ER file destination for the ER format that you're using.

Country/region-specific features

The sample ER format includes the following country/region-specific features to show how you can handle specific requirements in ER configurations.

Norway

The generated invoice form header includes the Enterprise register term when you process the invoice for a legal entity that you configure as follows:

- Use the country/region context for Norway.
- Activate the **Print Foretaksregisteret** parameter on sales documents.

Spain

The generated invoice form header includes the **Special regime for cash accounting method** term when you process the invoice for a legal entity that you configure as follows:

- Use the country/region context for Spain.
- Enable the special regime for the cash accounting method on the invoice processing date.

When cash discount details, such as the cash discount amount and invoice line net amount, are available, present them in the invoice totals section of the generated invoice form when you process the invoice for a legal entity that you configure as follows:

- Use the country/region context for Spain.
- Turn on **Cash discount is applied in the invoice** in the invoice option (**General ledger parameters** > **Sales tax section**).

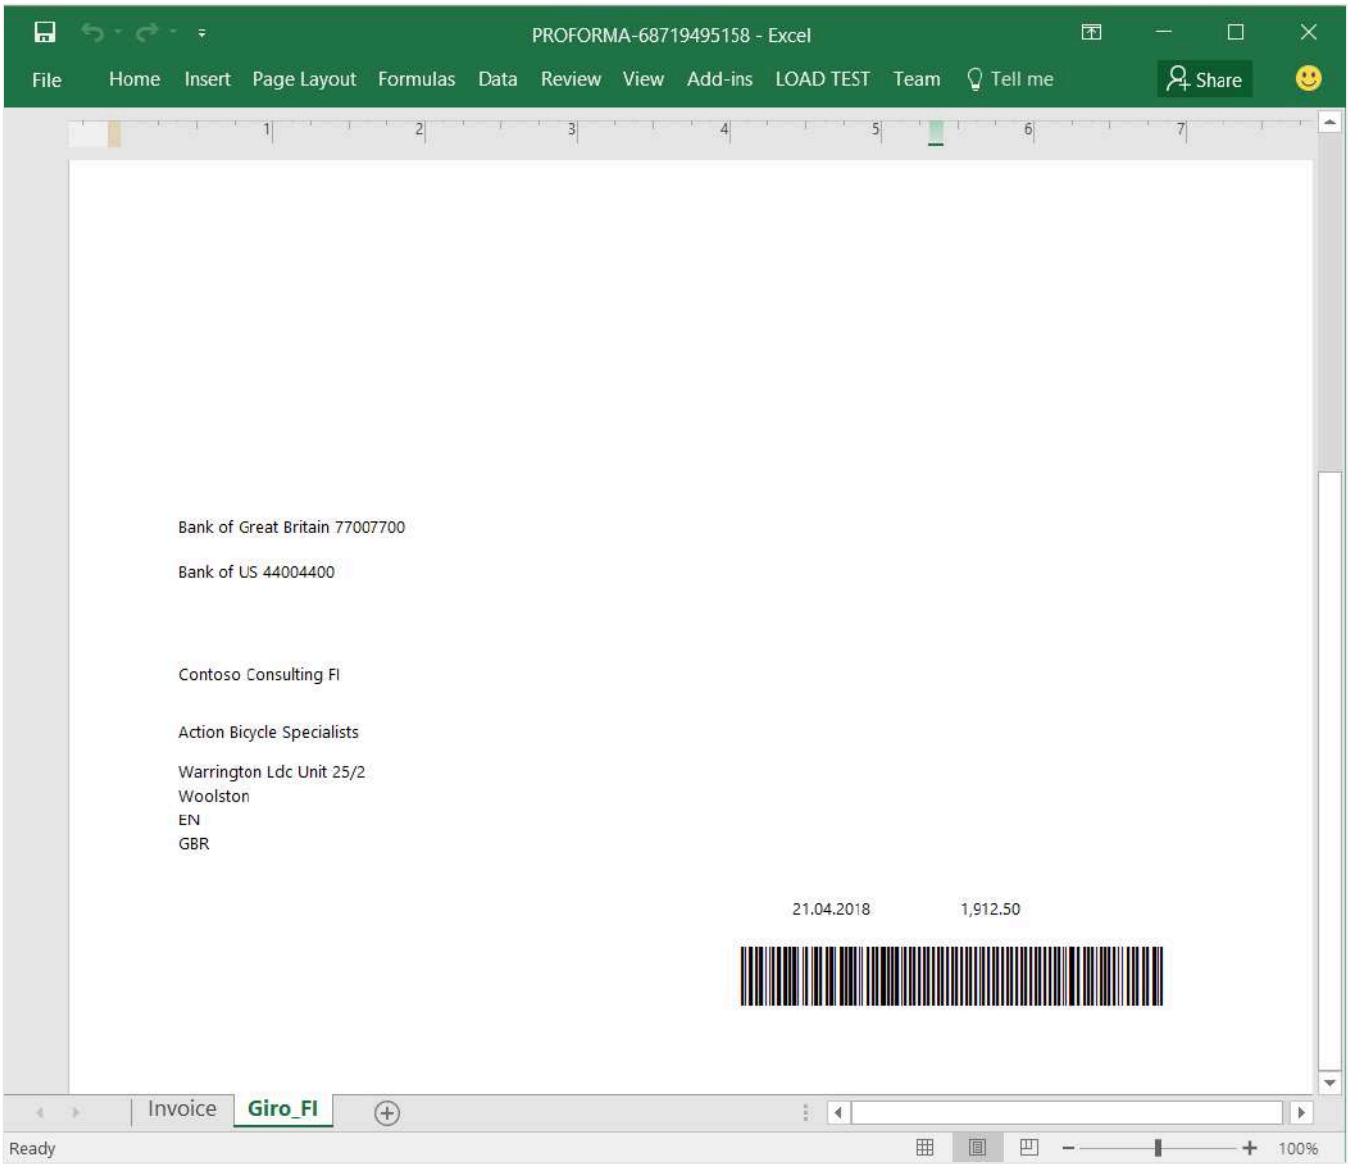
Italy

Include the goods discount mark on the invoice lines of the generated invoice when you process the invoice for a legal entity that you configure by using the country/region context for Italy.

Finland

In addition to the generated invoice form, you can generate Giro money transfer slips as follows:

- For the legal entity that uses the country/region context for Finland, and that has at least one bank account that is marked as **Giro account** and **Bank bar code**.
- For an invoice that is marked as required for the **Finnish** associated payment attachment.



> ⓘ **Note**
>
> The sample ER format is configured to optionally generate the Giro money transfer slips in the separate worksheet.

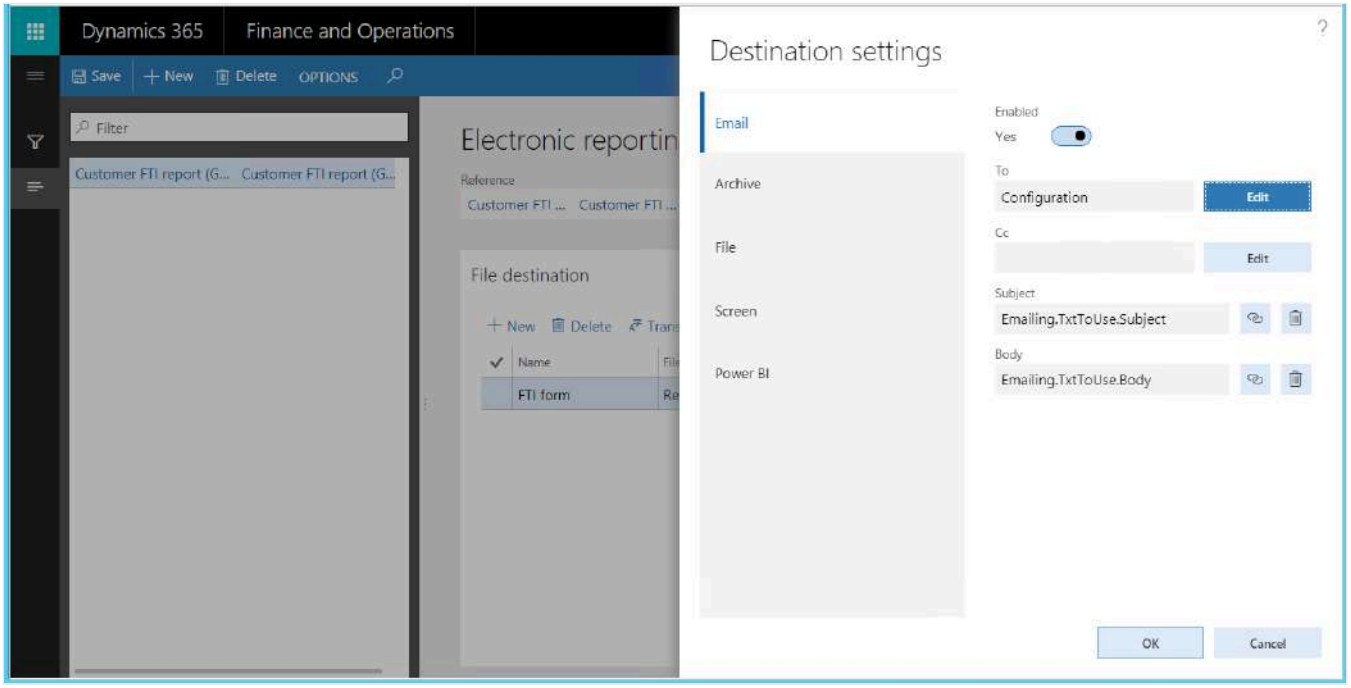
> ⓘ **Note**

You must first install the font that is used to generate the bar code on the local machine where you preview the generated invoice form in Excel format.

Use the sample ER format to configure email destinations

Use the following elements of the sample ER format to configure email destinations:

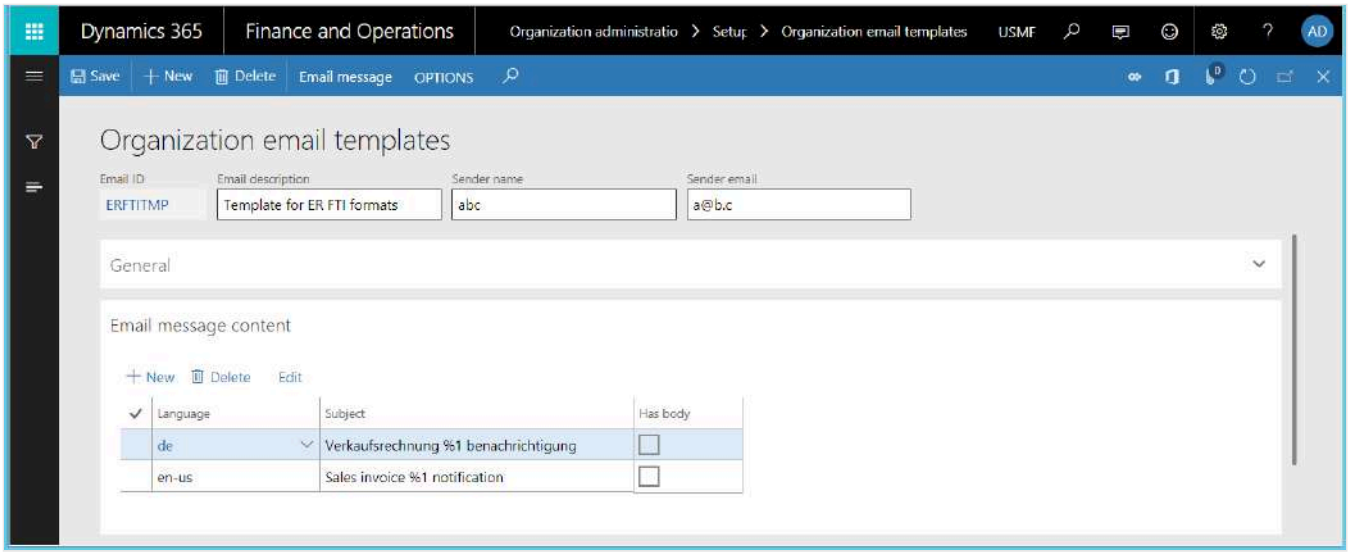
- Access the email address of a customer contact through the following ER expression: **model.InvoiceBase.Contact.ElectronicMail**.
- Access the email subject text through the following ER expression: **Emailing.TxtToUse.Subject**.
- Access the email body text through the following ER expression: **Emailing.TxtToUse.Body**.

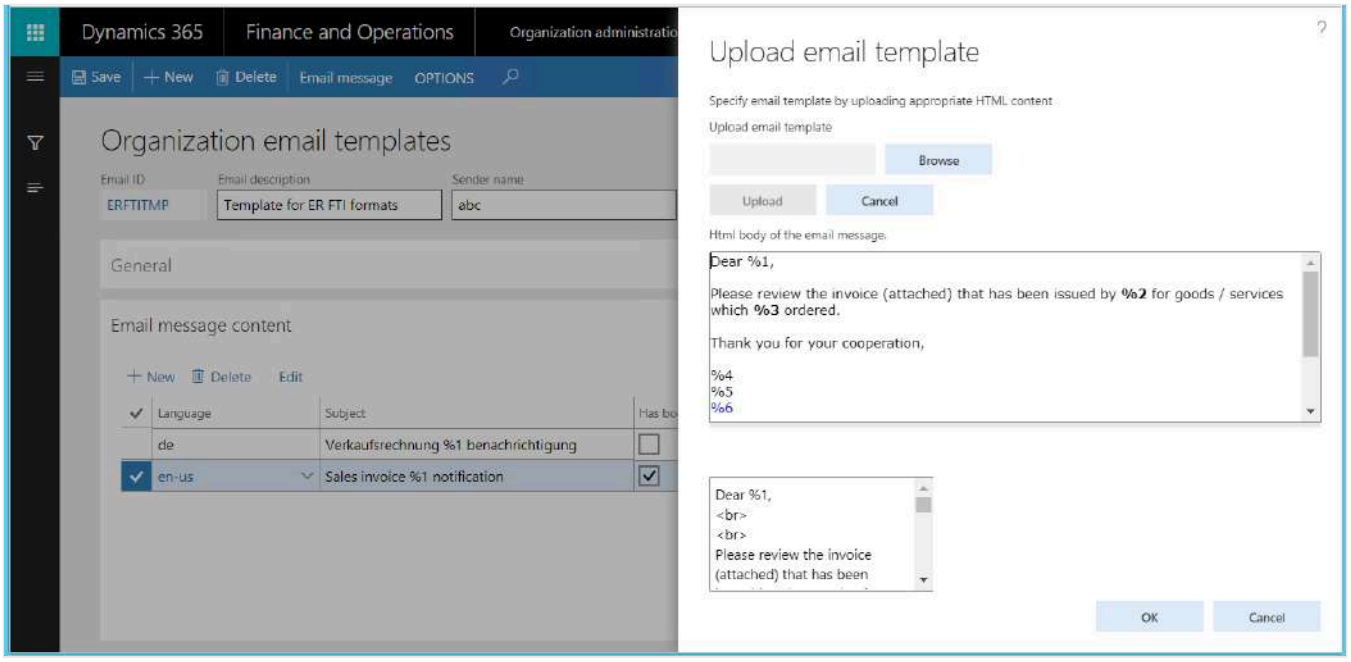


The sample ER format defines the default text of the email's subject and body. The language depends on the format's labels. If you don't add a custom organization email template that uses the predefined **ERFTITMP** ID, this default text is used for emails.

> **Note**
>
> The sample ER format defines the **ERFTITMP** email template ID. You can change this ID as needed in a new ER format that you create from this sample format.

If you add the organization email template that uses the predefined **ERFTITMP** ID for the legal entity that you're processing the invoice for, the template for the email subject and body text is used to generate the email.





The **Emailing.TxtToUse.Subject** ER expression of the sample ER format is configured to replace any occurrences of the placeholder %1 with the processing invoice ID.

The **Emailing.TxtToUse.Body** expression of the sample format is configured for the following substitutions for placeholders:

- "%1" is replaced with the name of the customer's contact person.
- "%2" is replaced with the company name.
- "%3" is replaced with the customer name.
- "%4" is replaced with the name of the company's contact person.
- "%5" is replaced with the job title of the company's contact person.
- "%6" is replaced with the email address of the company's contact person.

Electronic reporting (ER) overview

Last updated on 04/13/2026

Trace the execution of ER formats to troubleshoot performance issues

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

As part of the process of designing Electronic reporting (ER) configurations to generate electronic documents, you define the method that gets data out of the application and puts it in the generated output. The ER performance trace feature helps you significantly reduce the time and cost involved in collecting the details of ER format execution and using them to troubleshoot performance problems. This tutorial provides guidelines about how to take performance traces for executed ER formats, and how to use the information from these traces to help improve performance.

Prerequisites

To complete the examples in this tutorial, you need the following access:

- Access to one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator
- Access to the instance of Regulatory Configuration Services (RCS) that's provisioned for the same tenant as the application, for one of the following roles:
  - Electronic reporting developer
  - Electronic reporting functional consultant
  - System administrator

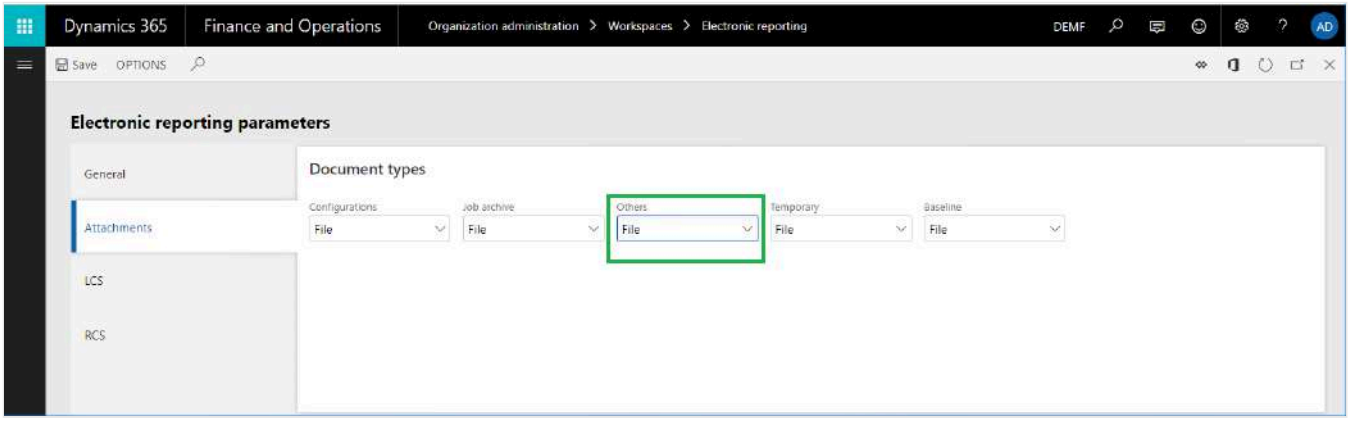
Also, download and store the following files locally.

Expand table

File	Content
Performance trace model.version.1	Sample ER data model configuration
Performance trace metadata.version.1	Sample ER metadata configuration
Performance trace mapping.version.1.1	Sample ER model mapping configuration
Performance trace format.version.1.1	Sample ER format configuration

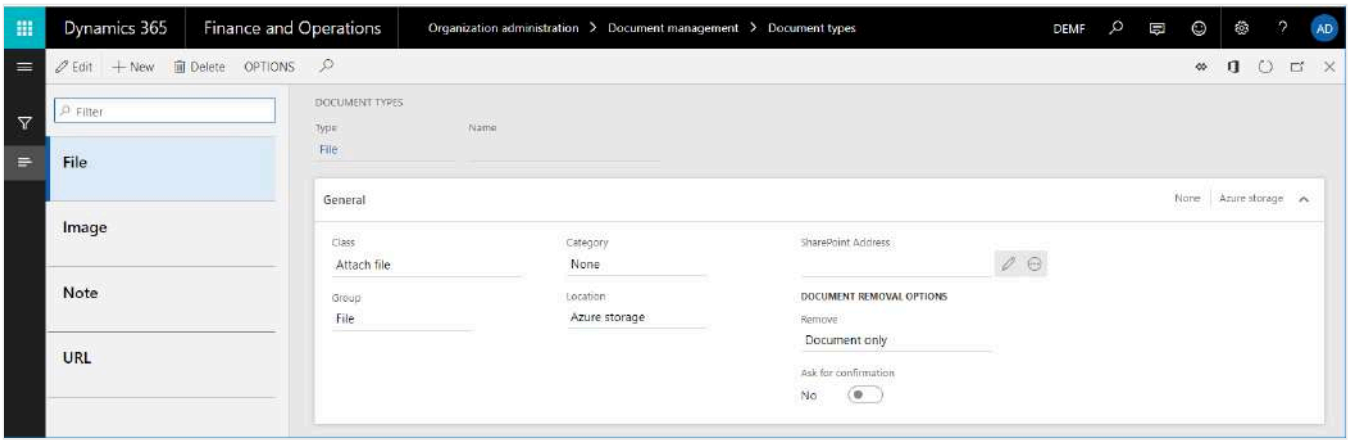
Configure ER parameters

Each ER performance trace that the application generates is stored as an attachment of the execution log record. The Document management (DM) framework manages these attachments. You must configure ER parameters in advance to specify the DM document type that should be used to attach performance traces. In the **Electronic reporting** workspace, select **Electronic reporting parameters**. Then, on the **Electronic reporting parameters** page, on the **Attachments** tab, in the **Others** field, select the DM document type to use for performance traces.



To be available in the **Others** lookup field, a DM document type must be configured in the following manner on the **Document types** page (**Organization administration** > **Document management** > **Document types**):

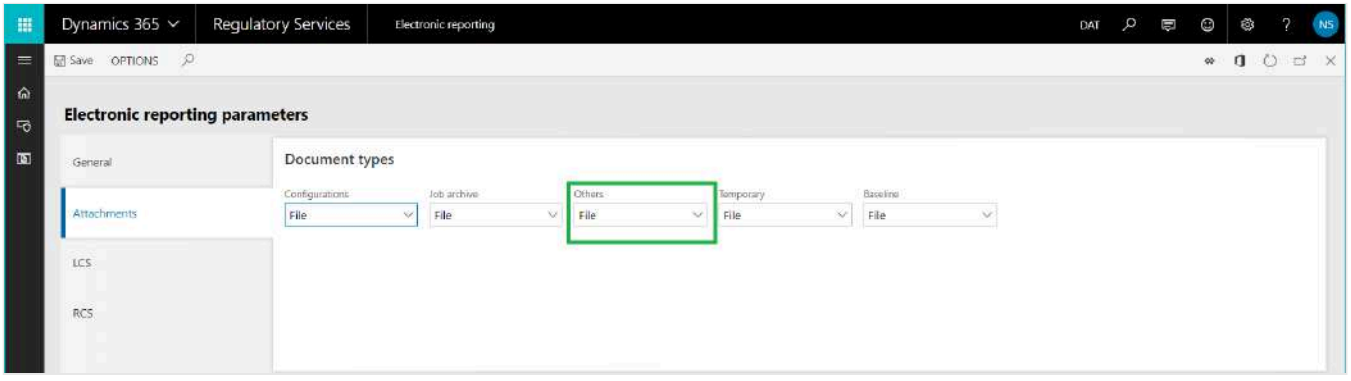
- **Class:** Attach file
- **Group:** File



> **Note**
>
> The selected document type must be available in every company of the current instance, because DM attachments are company-specific.

Configure RCS parameters

You import ER performance traces into RCS for analysis by using the ER format designer and the ER mapping designer. Because ER performance traces are stored as attachments of the execution log record that relates to the ER format, you must configure RCS parameters in advance to specify the DM document type that should be used to attach performance traces. In the instance of RCS that you provisioned for your company, in the **Electronic reporting** workspace, select **Electronic reporting parameters**. Then, on the **Electronic reporting parameters** page, on the **Attachments** tab, in the **Others** field, select the DM document type to use for performance traces.



To be available in the **Others** lookup field, a DM document type must be configured in the following manner on the **Document types** page (**Organization administration** > **Document management** > **Document types**):

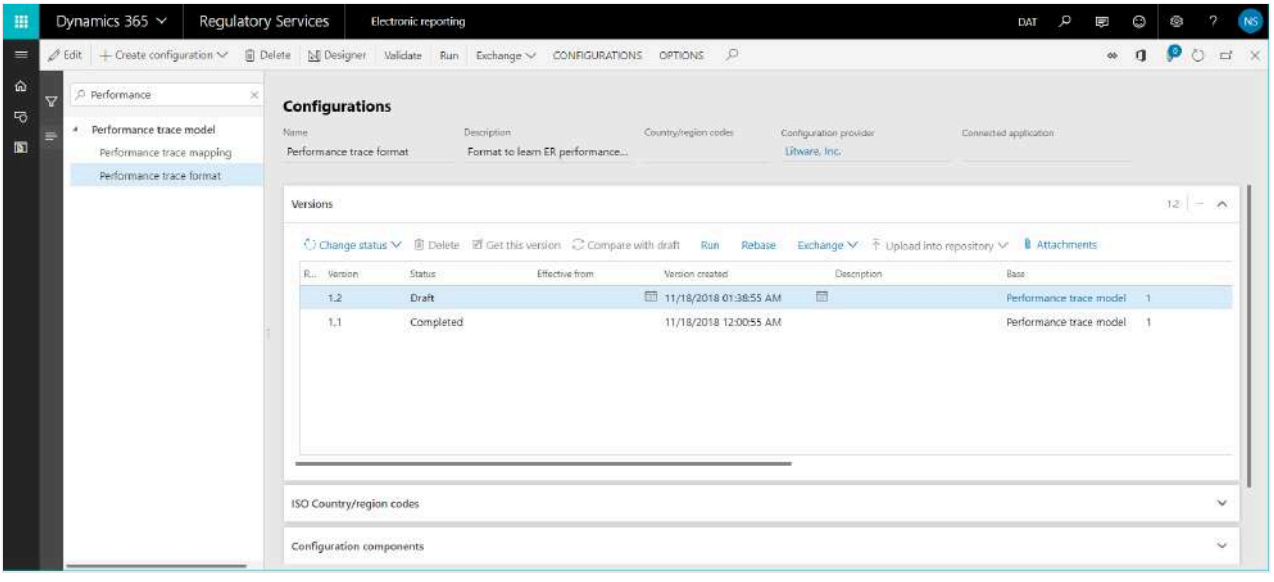
- **Class:** Attach file

- **Group:** File

Design an ER solution

Assume that you start designing a new ER solution to generate a new report that presents vendor transactions. Currently, you can find the transactions for a selected vendor on the **Vendor transactions** page (go to **Account payable** > **Vendors** > **All vendors**, select a vendor, and then, on the Action Pane, on the **Vendor** tab, in the **Transactions** group, select **Transactions**). However, you want to have all vendor transactions at the same time in one electronic document in XML format. This solution consists of several ER configurations that contain the required data model, metadata, model mapping, and format components.

1. Sign in to the instance of RCS that is provisioned for your company.
2. In this tutorial, you create and modify configurations for the **Litware, Inc.** sample company. Therefore, make sure that you add this configuration provider to RCS and select it as active. For instructions, see the Create configuration providers and mark them as active procedure.
3. In the **Electronic reporting** workspace, select the **Reporting configurations** tile.
4. On the **Configurations** page, import the ER configurations that you downloaded as a prerequisite into RCS, in the following order: data model, metadata, model mapping, format. For each configuration, follow these steps:
   a. On the Action Pane, select **Exchange** > **Load from XML file**.
   b. Select **Browse** to select the appropriate file for the required ER configuration in XML format.
   c. Select **OK**.



Run the ER solution to trace execution

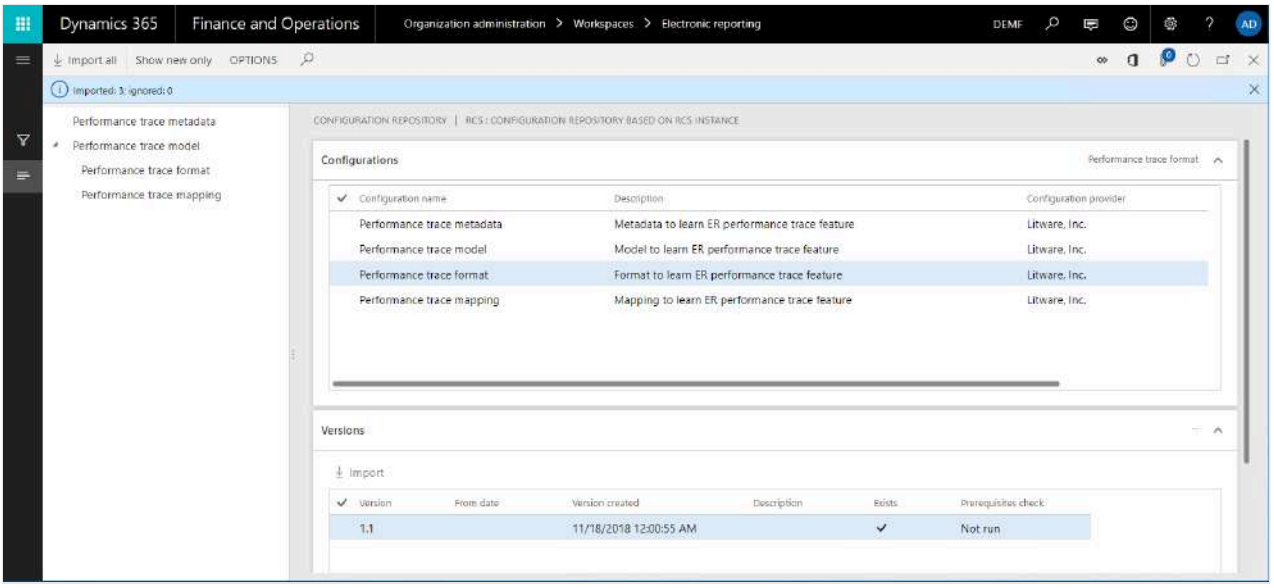
Assume that you finish designing the first version of the ER solution. You now want to test it in your instance and analyze execution performance.

Import an ER configuration from RCS into finance and operations

1. Sign in to your application instance.

2. For this tutorial, import configurations from your RCS instance (where you design your ER components) into your instance (where you test and finally use them). Therefore, make sure that you prepare all the required artifacts. For instructions, see the Import Electronic reporting (ER) configurations from Regulatory Configuration Services (RCS) procedure.

3. Follow these steps to import the configurations from RCS into the application:
   a. In the **Electronic reporting** workspace, on the tile for the **Litware, Inc.** configuration provider, select **Repositories**.
   b. On the **Configuration repository** page, select the repository of the **RCS** type, and then select **Open**.
   c. On the **Configurations** FastTab, select the **Performance trace format** configuration.
   d. On the **Versions** FastTab, select version **1.1** of the selected configuration, and then select **Import**.



The corresponding versions of the data model and model mapping configurations are automatically imported as prerequisites for the imported ER format configuration.

Turn on the ER performance trace

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.

2. On **Configurations**, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.

3. In **User parameters**, in the **Execution tracing** section, follow these steps:

    a. In the **Execution trace format** field, specify the format of the generated performance trace that stores execution details for ER format and mapping elements:

    - **Debug trace format** – Select this value if you plan to interactively run an ER format that has a short execution time. The collection of details about ER format execution starts. When you select this value, the performance trace collects information about the time spent on the following actions:
        - Running each data source in the model mapping that the process calls to get data
        - Processing each format item to enter data in the output that is generated

      If you select the **Debug trace format** value, you can analyze the content of the trace in the ER Operation designer. There, you can view the ER format or mapping elements that are mentioned in the trace.

    - **Aggregated trace format** – Select this value if you plan to run an ER format that has a long execution time in batch mode. The collection of the aggregated details about ER format execution starts. When you select this value, the performance trace collects information about the time spent on the following actions:
        - Running each data source in the model mapping that the process calls to get data
        - Running each data source in the format mapping that the process calls to get data
        - Processing each format item to enter data in the output that is generated

      The **Aggregated trace format** value is available in Microsoft Dynamics 365 Finance version 10.0.20 and later.

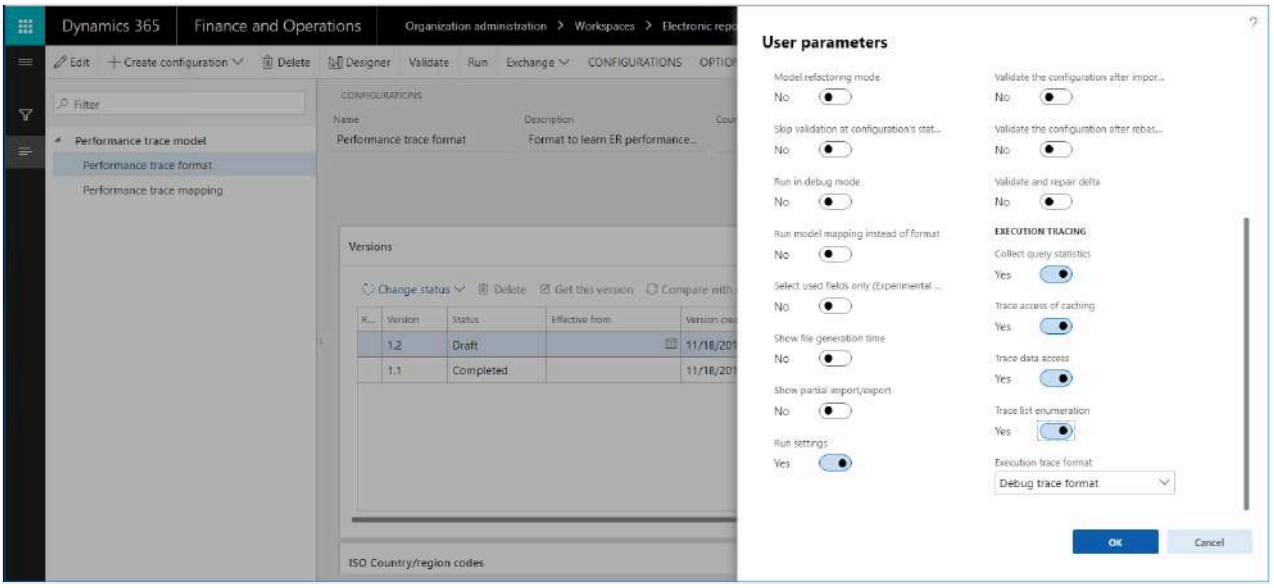
      In the ER format designer and ER model mapping designer, you can view the total execution time for a single component. Additionally, the trace contains details about the execution, such as the number of executions, and the minimum and maximum time of a single execution.

> **Note**
>
> This trace is collected based on the traced components path. Therefore, the statistics might be incorrect when a single parent component contains several unnamed child components, or when several child components have the same name.

b. Set the following options to **Yes** to collect specific details of the execution of the ER model mapping and ER format components:

- **Collect query statistics** – When you turn on this option, the performance trace collects the following information:
  - The number of database calls that data sources make
  - The number of duplicate calls to the database
  - Details of the SQL statements that were used to make database calls
- **Trace access of caching** – When you turn on this option, the performance trace collects information about the ER model mapping's cache usage.
- **Trace data access** – When you turn on this option, the performance trace collects information about the number of calls to the database for executed data sources of the record list type.
- **Trace list enumeration** – When you turn on this option, the performance trace collects information about the number of records that are requested from data sources of the record list type.

> **Note**
>
> The parameters in the **User parameters** dialog box are specific to the user and the current company.



Run the ER format

1. Select the **DEMF** company.
2. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
3. On **Configurations**, in the configuration tree, select the **Performance trace format** item.
4. On the Action Pane, select **Run**.

The generated file presents information about 265 transactions for six vendors.

Review the execution trace

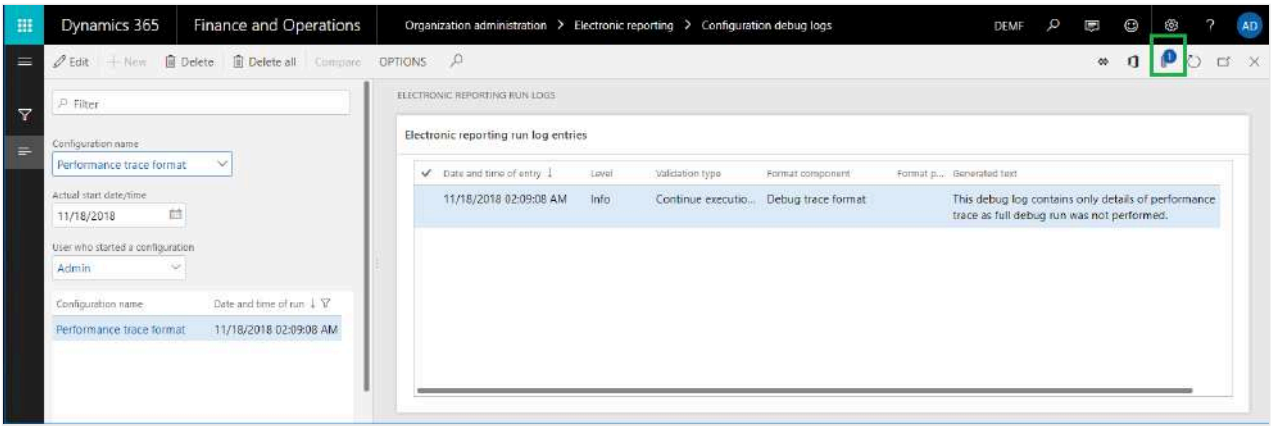
Export the generated trace from the application

Performance traces are decoupled from the source ER format and can be serialized to an external zip file.

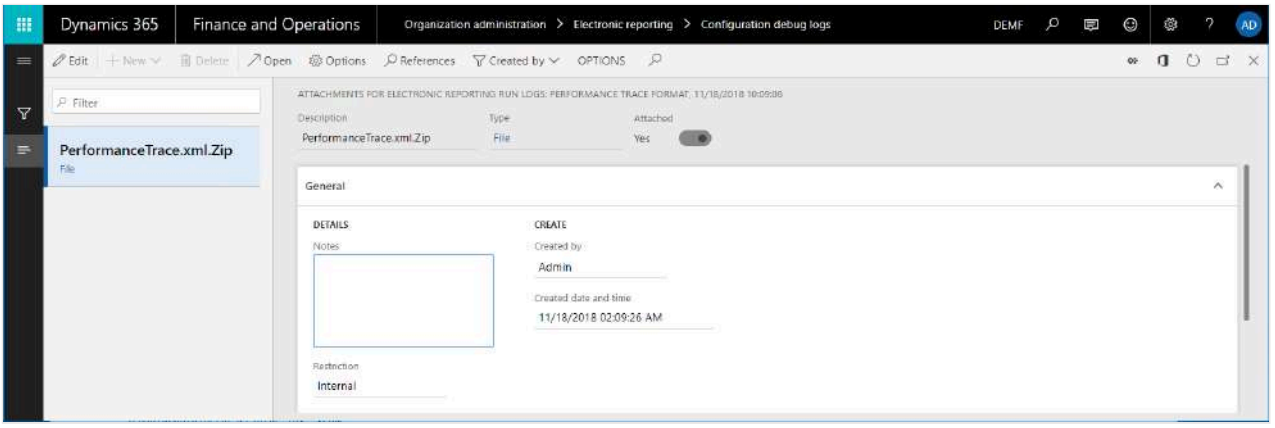
1. Go to **Organization administration** > **Electronic reporting** > **Configuration debug logs**.

2. On **Electronic reporting run logs**, in the left pane, in the **Configuration name** field, select **Performance trace format** to find the log records that the execution of the **Performance trace format** configuration generates.

3. Select the **Attachments** button (the paper clip symbol) in the upper-right corner of the page, or press **Ctrl+Shift+A**.



4. On **Attachments for Electronic reporting run logs**, on the Action Pane, select **Open** to get the performance trace as a zip file and store it locally.



> ⓘ **Note**
>
> The generated trace has a reference to the source ER report via a unique report identifier in **GUID** format only. The version numbering of the format isn't considered.

The association between the performance trace that the application generates for the executed ER format and the ER model mapping is based on the root descriptor that the application uses and the common data model. The version numbering of the format and model mapping isn't considered. The setting of the **Default for model mapping** flag for the model mapping also isn't considered.

Import the generated trace into RCS

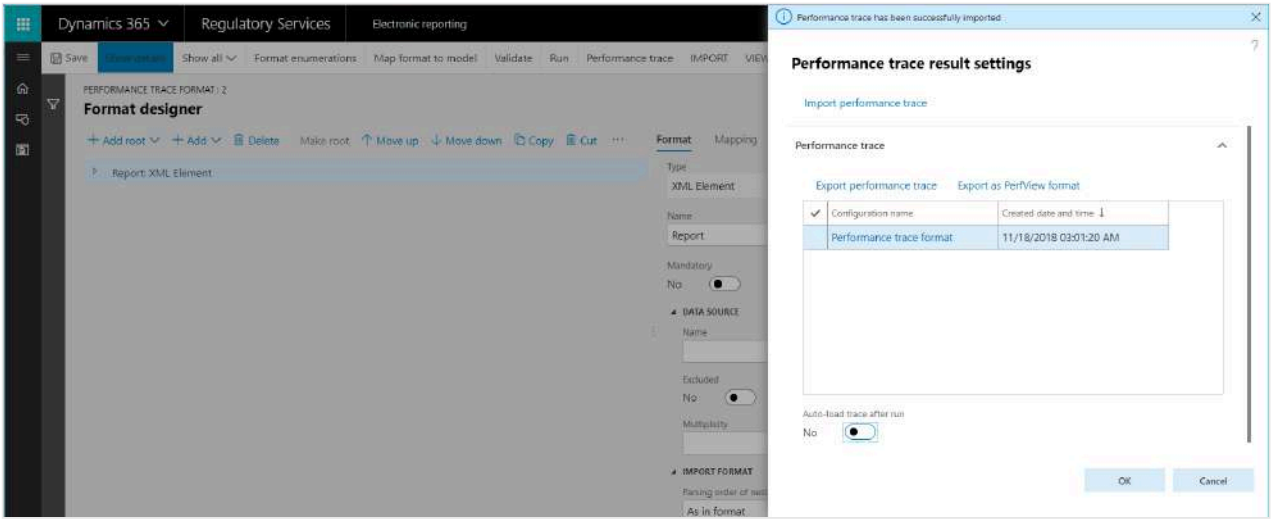
1. In RCS, in the **Electronic reporting** workspace, select the **Reporting configurations** tile.
2. On the **Configurations** page, in the configuration tree, expand the **Performance trace model** item, and select the **Performance trace format** item.
3. On the Action Pane, select **Designer**.

4. On the **Format designer** page, on the Action Pane, select **Performance trace**.

5. In the **Performance trace result settings** dialog box, select **Import performance trace**.

6. Select **Browse** to select the zip file that you exported earlier.

7. Select **OK**.

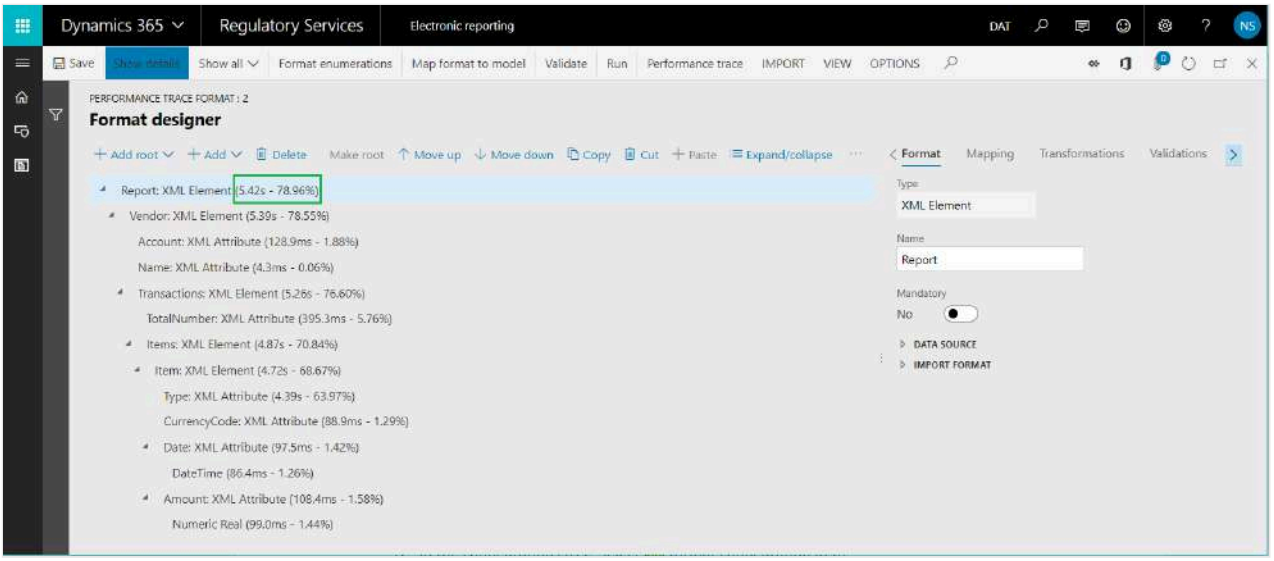


Use the performance trace for analysis in RCS – Format execution

1. In RCS, on the **Format designer** page, select **Expand/collapse** to expand the content of all format items.

   Notice that the trace shows extra information for some items of the current format:

   - The actual time that was spent entering data in the generated output by using the format item
   - The same time expressed as a percentage of the total time that was spent generating the whole output



2. Close **Format designer** page.

Use the performance trace for analysis in RCS – Model mapping

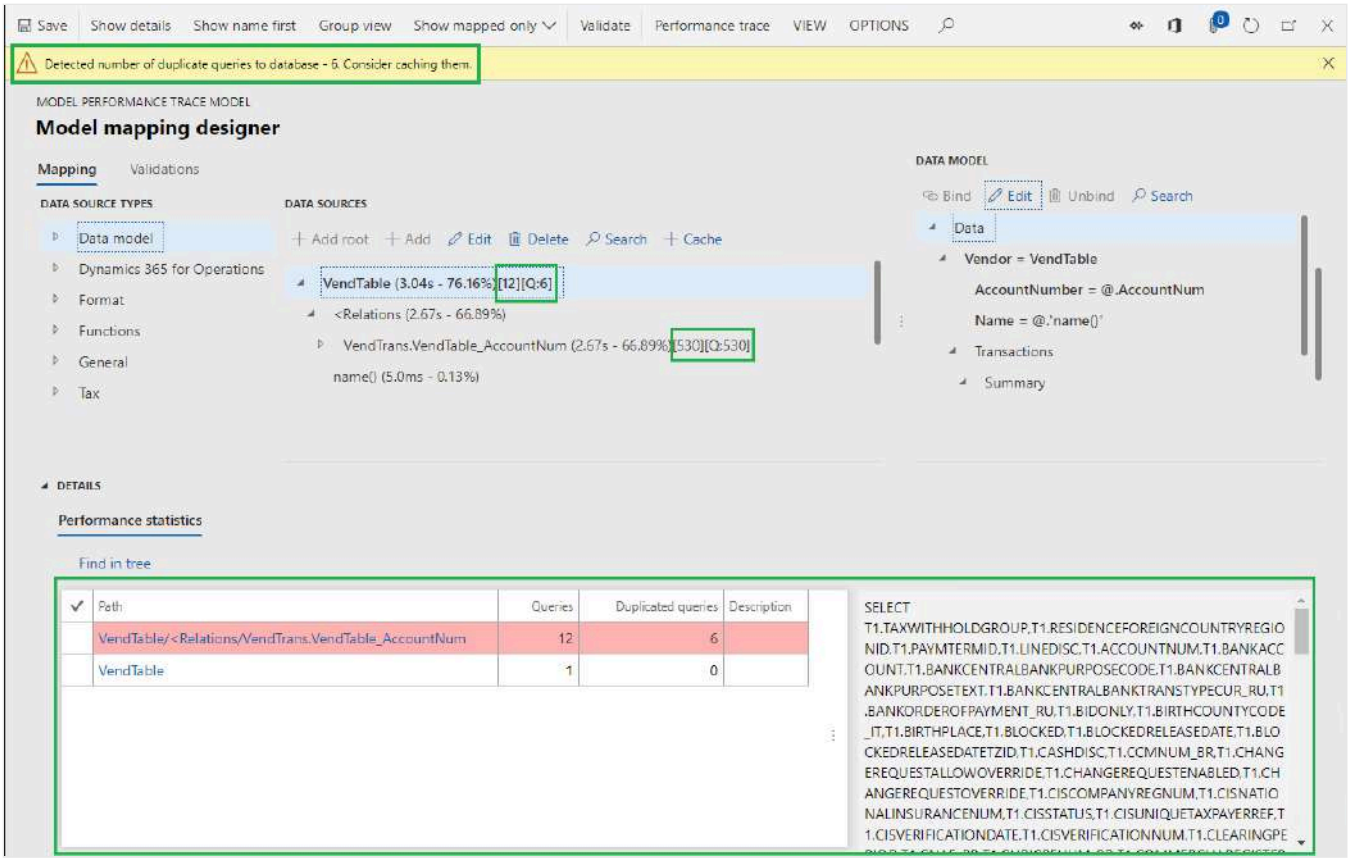
1. In RCS, on the **Configurations** page, in the configuration tree, select the **Performance trace mapping** item.
2. On the Action Pane, select **Designer**.
3. Select **Designer**.
4. On the **Model mapping designer** page, on the Action Pane, select **Performance trace**.
5. Select the trace that you imported earlier.
6. Select **OK**.

You see new information for some data source items of the current model mapping:

- The actual time that the data source spends getting data
- The same time expressed as a percentage of the total time that was spent running the whole model mapping

ER informs you that the current model mapping duplicates database requests while the VendTable/<Relations/VendTrans.VendTable_AccountNum data source runs. This duplication occurs because the list of vendor transactions is called two times for each iterated vendor record:

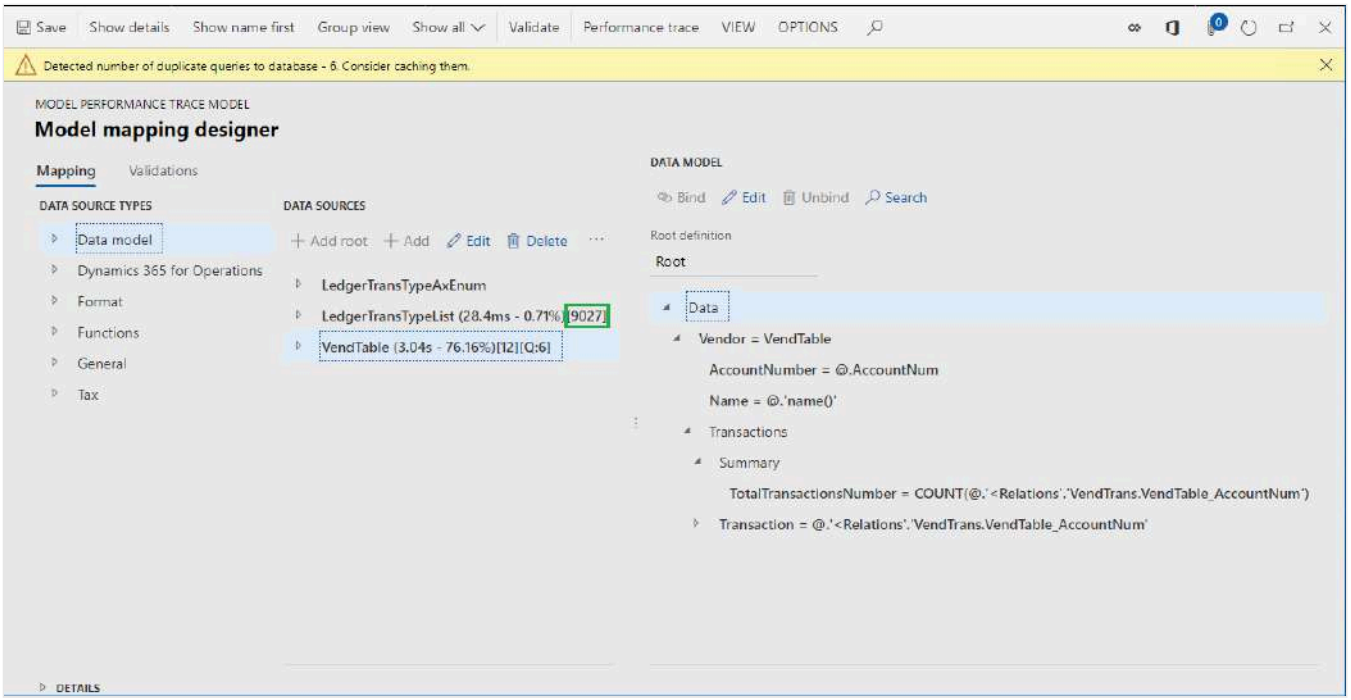
- One call enters details of each transaction in the data model, based on configured bindings.
- One call enters the calculated number of transactions per vendor in the data model.



The value **[Q:530]** indicates that the VendTrans table was called 530 times to return a record from that table to the VendTable/<Relations/VendTrans.VendTable_AccountNum data source. The value **[530]** indicates that the VendTable/<Relations/VendTrans.VendTable_AccountNum data source was called 530 times to return a record from that data source and enter the details from it in the data model.

Use caching for the VendTable/<Relations/VendTrans.VendTable_AccountNum data source to reduce the number of calls that are made to get the details for 265 transactions and help improve the performance of the model mapping.

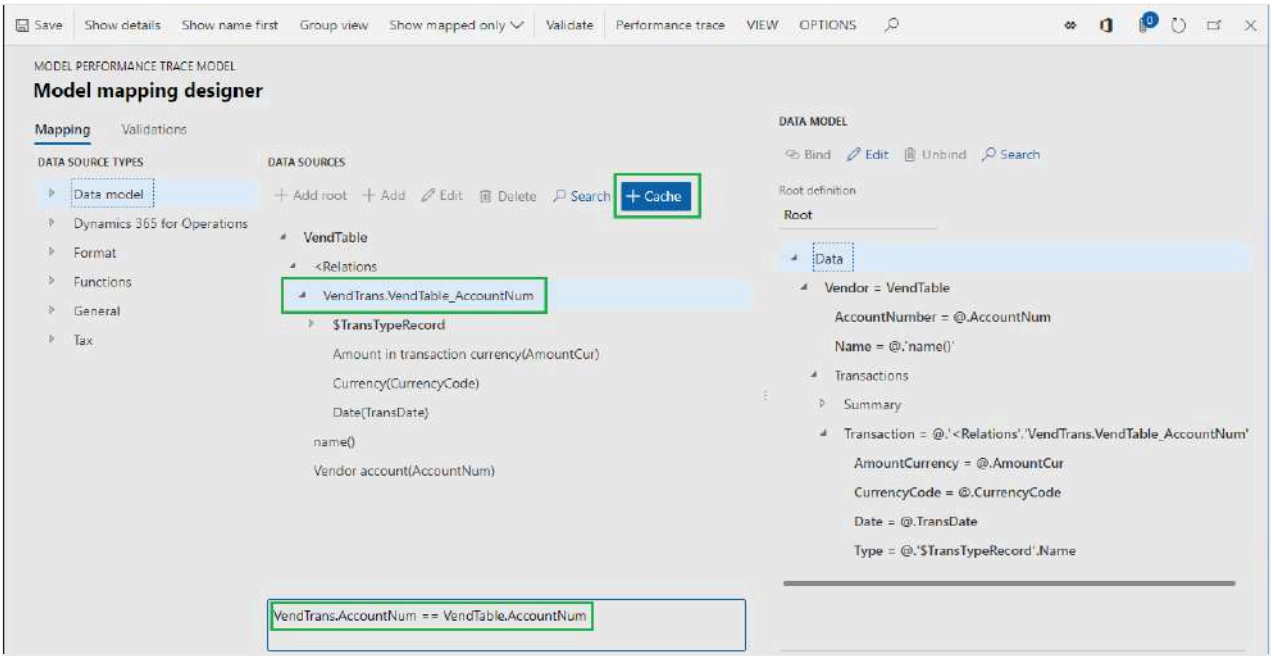
It can also be useful to reduce the number of calls that are made to the LedgerTransTypeList data source. This data source associates each value of the **LedgerTransType** enumeration with its label. By using this data source, you can find an appropriate label and enter it in the data model for each vendor transaction. The current number of calls to this data source (9,027) is quite high for 265 transactions.



Improve the model mapping based on information from the execution trace

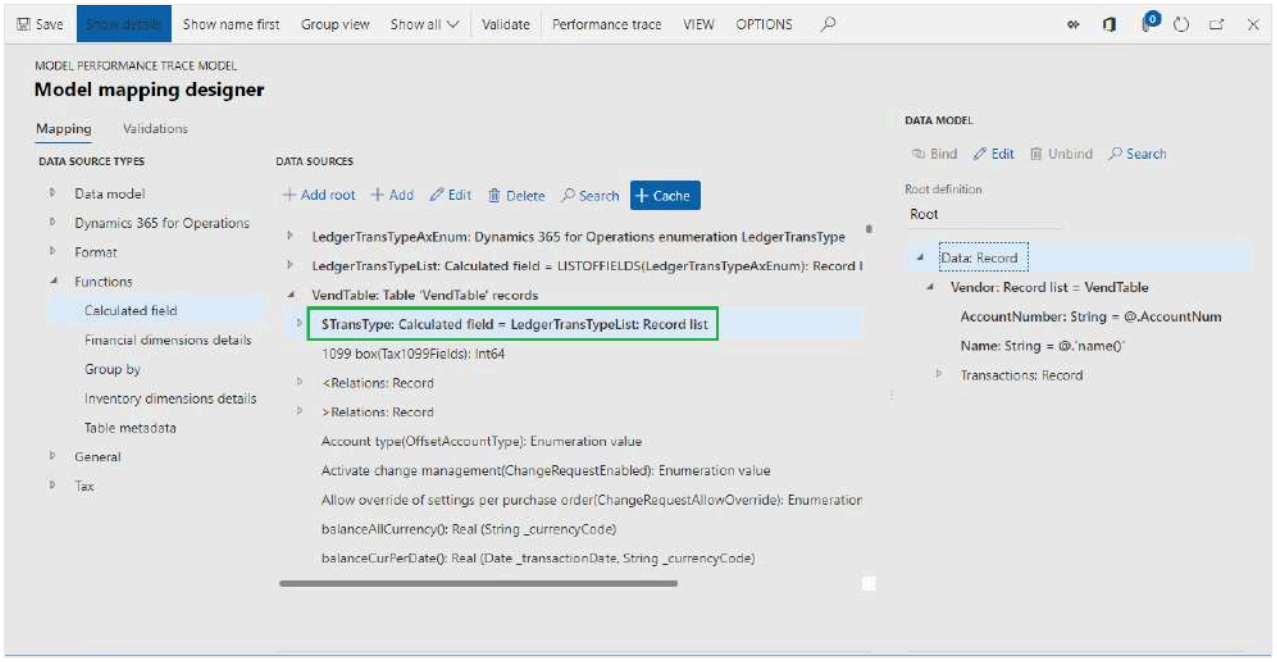
Modify the logic of the model mapping

1. To use caching and help prevent duplicate calls to the database, follow these steps:
   a. In RCS, on the **Model mapping designer** page, in the **Data sources** pane, select the **VendTable** item.
   b. Select **Cache**.
   c. Expand the **VendTable** item, expand the list of one-to-many relations for the VendTable data source (the **<Relations** item), and select the **VendTrans.VendTable_AccountNum** item.
   d. Select **Cache**.



2. To bring the LedgerTransTypeList data source into the scope of the VendTable data source, follow these steps:
   a. In the **Data source types** pane, expand the **Functions** item, and select the **Calculated field** item.
   b. In the **Data sources** pane, select the **VendTable** item.
   c. Select **Add**.
   d. In the **Name** field, enter **$TransType**.
   e. Select **Edit formula**.
   f. In the **Formula** field, enter **LedgerTransTypeList**.
   g. Select **Save**.
   h. Close the **Formula editor** page.
   i. Select **OK**.

3. To cache the **$TransType** field, follow these steps:
   a. Select the **LedgerTransTypeList** item.
   b. Select **Cache**.
   c. Select the **VendTable.$TransType** item.
   d. Select **Cache**.



4. To change the **$TransTypeRecord** field so that it starts to use the cached **$TransType** field, follow these steps:

   a. In the **Data sources** pane, expand the **VendTable** item, expand the **<Relations** item, expand the **VendTrans.VendTable_AccountNum** item, and select the **VendTable.VendTrans.VendTable_AccountNum.$TransTypeRecord** item.

   b. Select **Edit**.

   c. Select **Edit formula**.

   d. In the **Formula** field, find the following expression:

      FIRSTORNULL (WHERE (LedgerTransTypeList, LedgerTransTypeList.Enum = @.TransType))

   e. In the **Formula** field, enter the following expression:

      FIRSTORNULL (WHERE (VendTable.'$TransType', VendTable.'$TransType'.Enum = @.TransType)).

   f. Select **Save**.

   g. Close the **Formula editor** page.

   h. Select **OK**.

5. Select **Save**.

6. Close the **Model mapping designer** page.

7. Close the **Model mappings** page.

Complete the modified version of the ER model mapping

1. In RCS, on the **Configurations** page, on the **Versions** FastTab, select version **1.2** of the **Performance trace mapping** configuration.
2. Select **Change status**.
3. Select **Complete**.

Import the modified ER model mapping configuration from RCS into the application

To import version 1.2 of the **Performance trace mapping** configuration, see Import an ER configuration from RCS into finance and operations.

Run the modified ER solution to trace execution

Run the ER format

To generate a new performance trace, see Run the ER format.

Work with the execution trace

Export the generated trace from the application

To save a new performance trace locally, see Export the generated trace from the application.

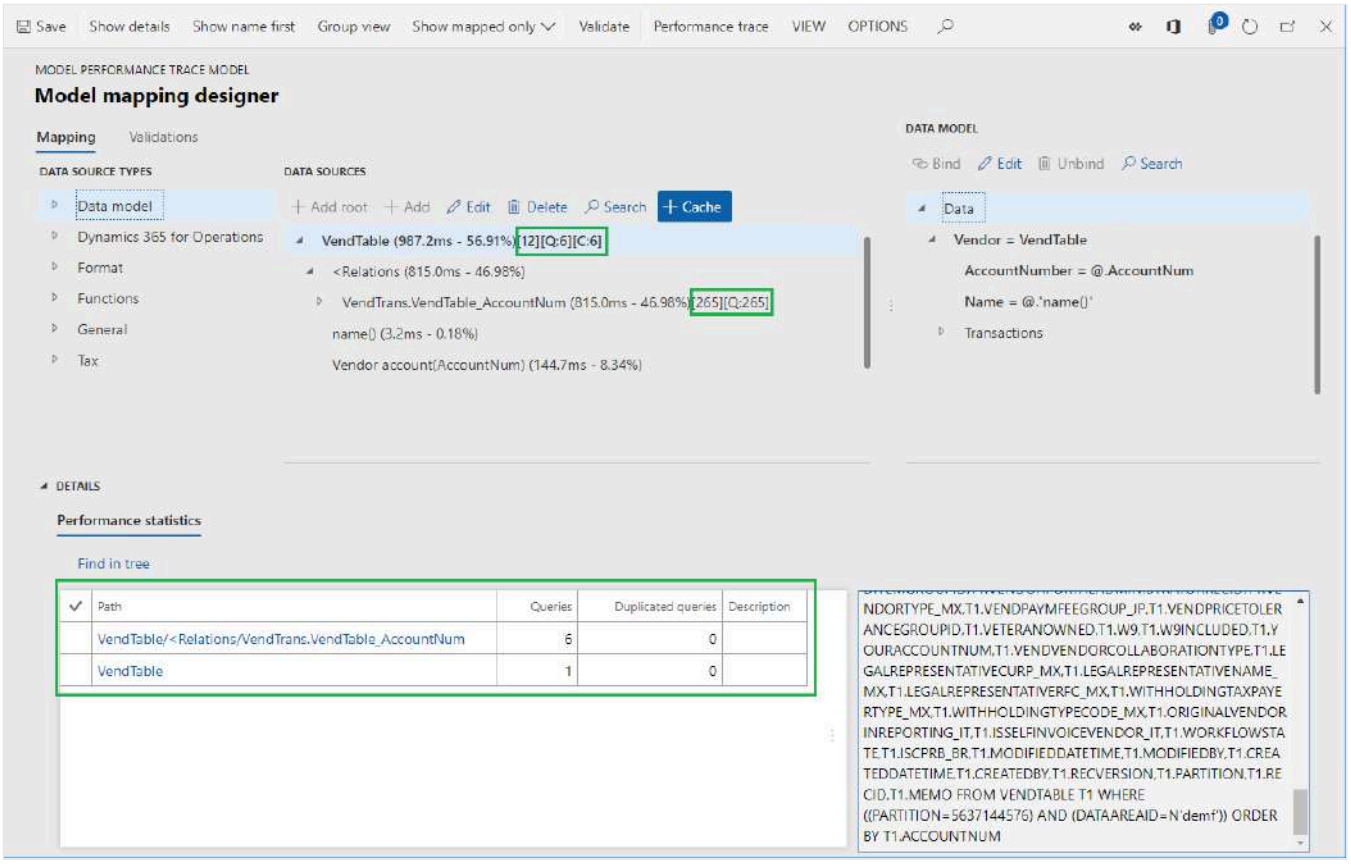
Import the generated trace into RCS

To import the new performance trace into RCS, see Import the generated trace into RCS.

Use the performance trace for analysis in RCS – Model mapping

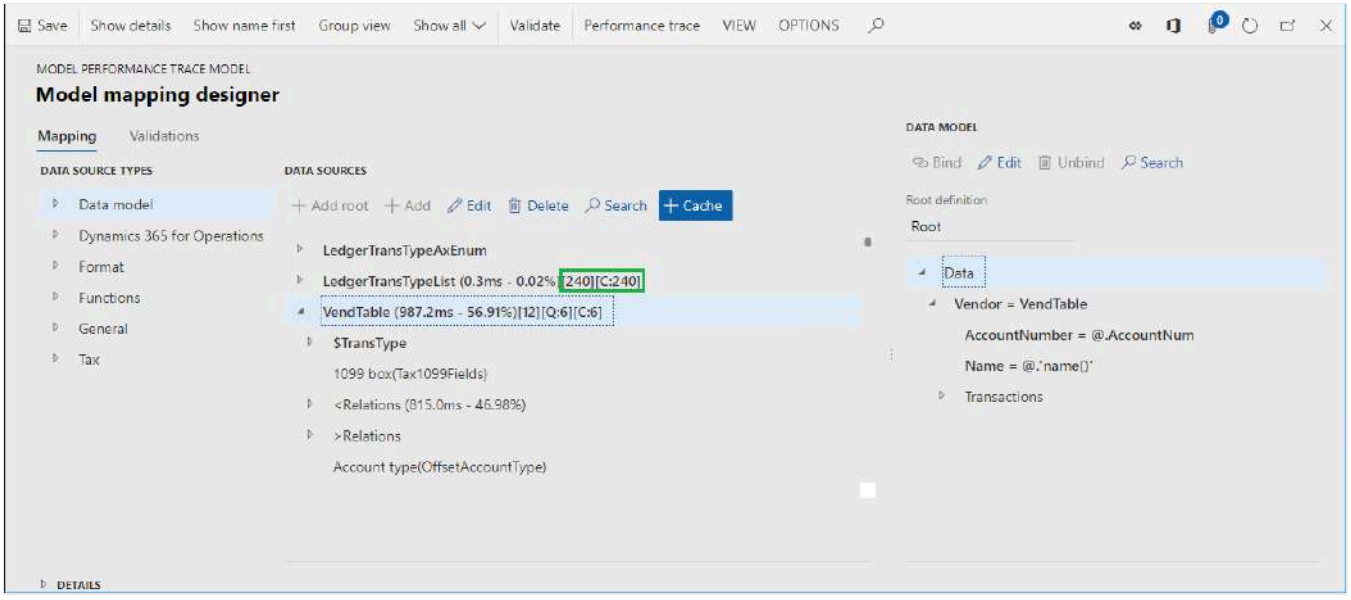
To analyze the latest performance trace, repeat the steps in the Use the performance trace for analysis in RCS – Model mapping section earlier in this article.

The adjustments you made to the model mapping eliminate duplicate queries to the database. The number of calls to database tables and data sources for this model mapping is also reduced. Therefore, the performance of the whole ER solution improves.



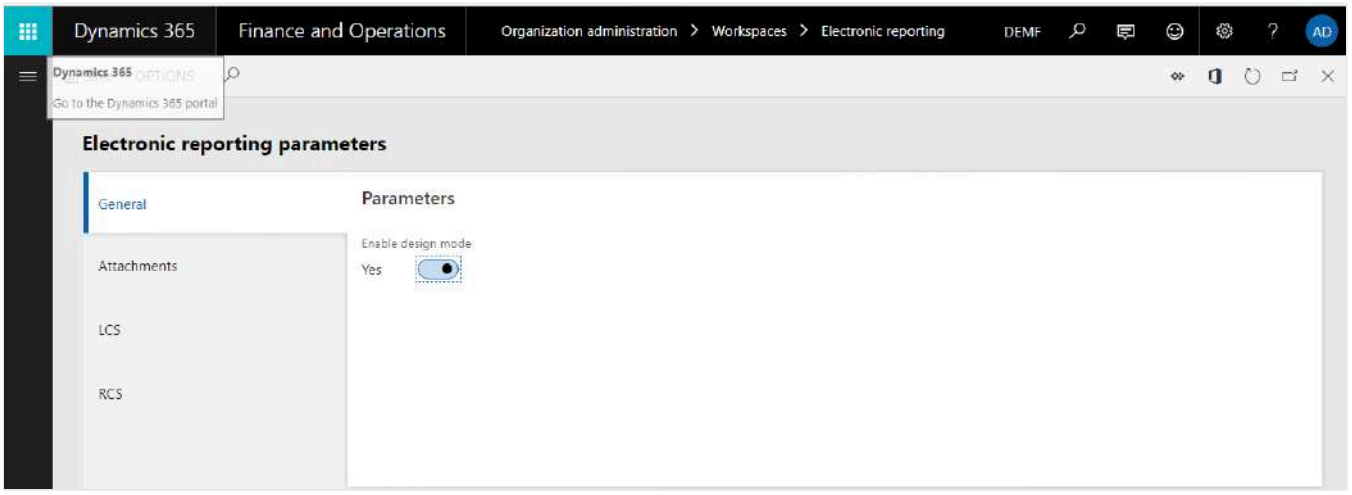
In the trace information, the value **[12]** for the VendTable data source indicates that this data source was called 12 times. The value **[Q:6]** indicates that six calls were translated to database calls to the VendTable table. The value **[C:6]** indicates that the records fetched from the database were cached, and six other calls were processed by using the cache.

The number of calls to the LedgerTransTypeList data source is reduced from 9,027 to 240.



Review the execution trace in the application

In addition to RCS, some versions might offer capabilities for an ER framework designer experience. These versions have an **Enable design mode** option that you can turn on. You can find this option on the **General** tab of the **Electronic reporting parameters** page, which you can open from the **Electronic reporting** workspace.



If you use one of these versions, you can analyze the details of generated performance traces directly in the application. You don't have to export them from the application and import them into RCS.

Review the execution trace by using external tools

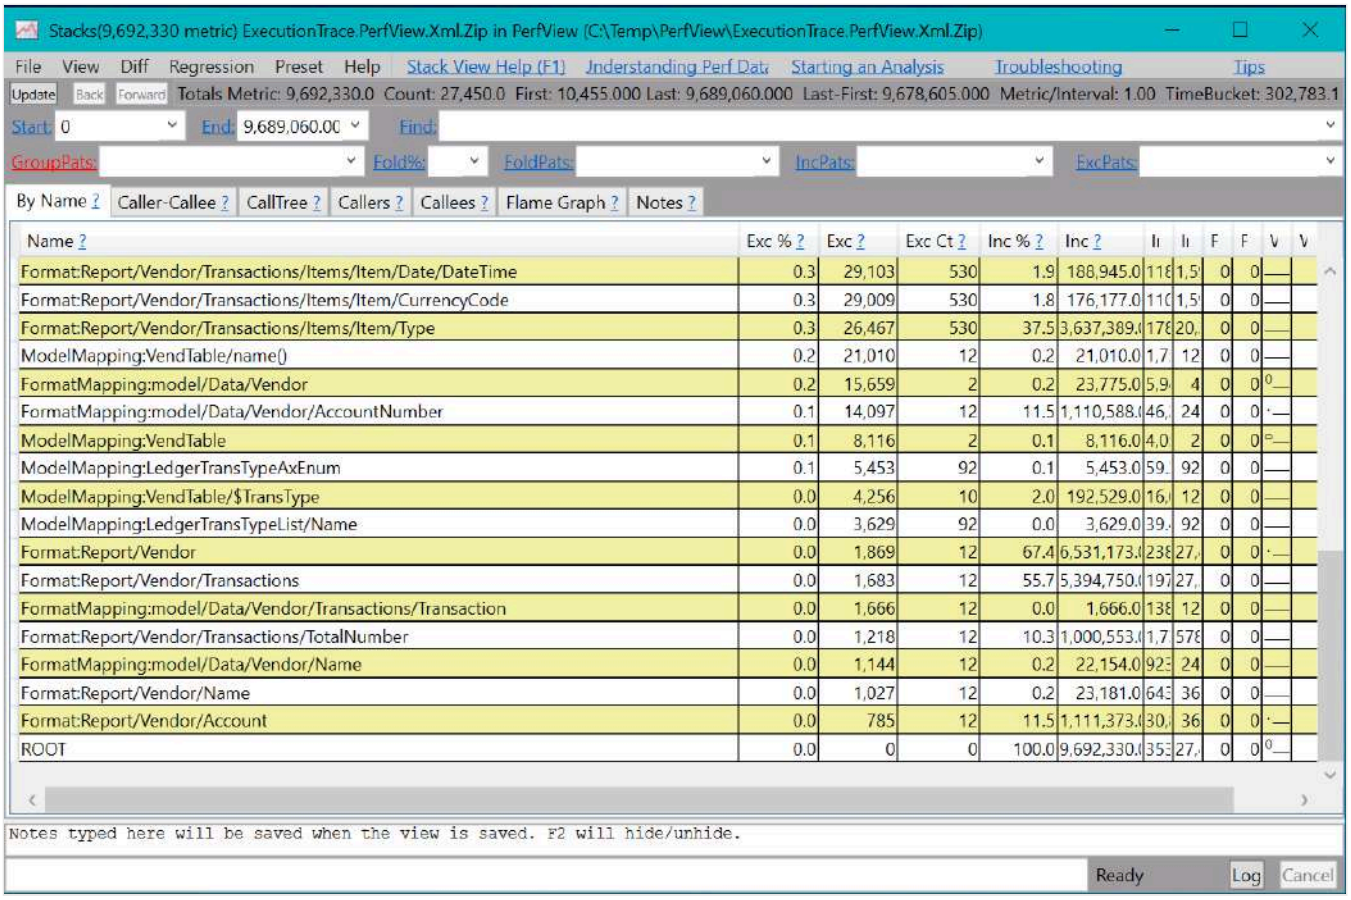
Configure user parameters

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, in the **Execution tracing** section, in the **Execution trace format** field, select **PerfView XML**.

Run the ER format

To generate a new performance trace, see Run the ER format.

The web browser offers a zip file for download. This file contains the performance trace in PerfView format. You can use the PerfView performance analysis tool to analyze the details of ER format execution.

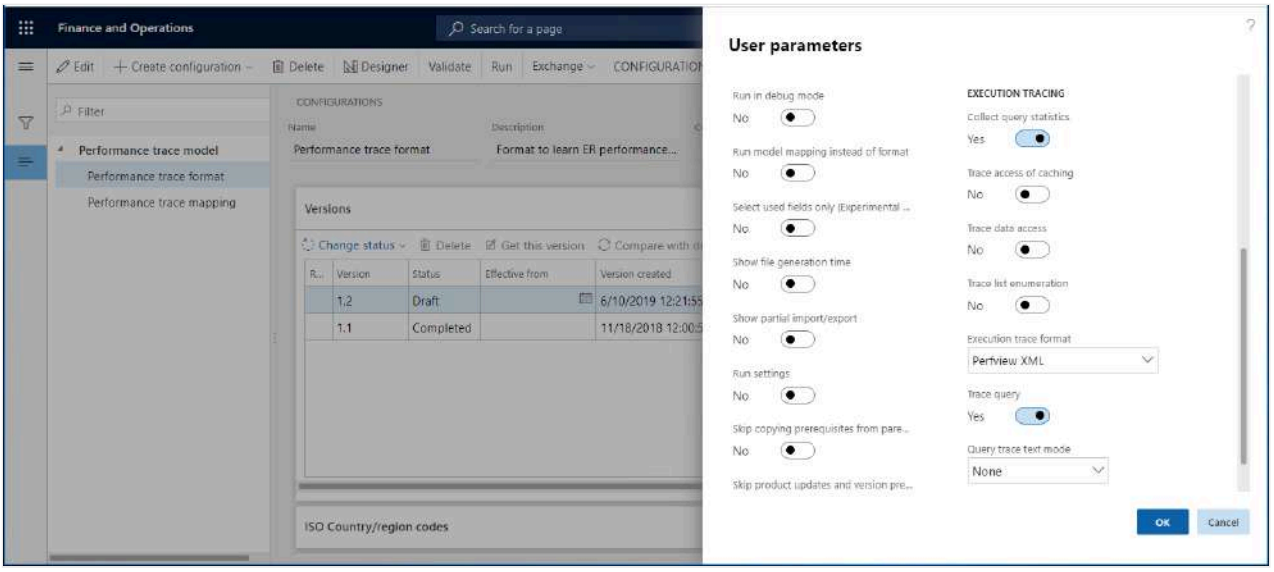


Use external tools to review an execution trace that includes database queries

Improvements to the ER framework mean that the performance trace generated in PerfView format now offers more details about ER format execution. In Microsoft Dynamics 365 Finance version 10.0.4 (July 2019), this trace can also include details of executed SQL queries to the application database.

Configure user parameters

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, in the **Execution tracing** section, set the following parameters:
    - In the **Execution trace format** field, select **PerfView XML**.
    - Set the **Collect query statistics** option to **Yes**.
    - Set the **Trace query** option to **Yes**.



Run the ER format

To generate a new performance trace, see Run the ER format.

When you finish, the web browser offers a ZIP file for download. This file contains the performance trace in PerfView format. You can use the PerfView performance analysis tool to analyze the details of ER format execution. This trace now includes the details of SQL database access during the execution of the ER format.

Performance and memory considerations for ER

This article describes how the Electronic reporting (ER) engine manages memory during report execution, and how that management affects reports that process large volumes of data.

Overview

When you run an ER format, the ER engine loads data from the configured data sources, transforms it according to the format mapping, and produces the output document. For reports that process large volumes of data such as statutory declarations or high-volume transaction extracts, the amount of memory used during execution can become a limiting factor. High peak memory consumption can slow down execution and, in extreme cases, cause a report run to fail.

Optimized memory consumption during ER execution

Starting in version 10.0.49, the ER reporting engine includes targeted optimizations that improve memory efficiency during execution. These optimizations reduce peak memory consumption by:

- **Minimizing unnecessary object creation** during data processing and document generation.
- **Avoiding redundant duplication of data in memory** so that the same data isn't held in multiple places at the same time.
- **Reusing existing data structures more effectively** instead of allocating new ones.

These improvements are broadly applicable across ER scenarios and are beneficial for reports that process large volumes of data.

> ⓘ **Note**
>
> These optimizations are built into the ER engine. You automatically benefit from them after you update to the applicable version. No configuration changes, parameter settings, or report redesign are required.

What to expect

- **Reduced peak memory usage** during execution, which lowers the risk of out-of-memory failures for high-volume runs.
- **More consistent completion** of large reports, because the engine holds less data in memory at any one time.
- **No change to report output.** The optimizations affect only how the engine uses memory internally. The generated documents are identical to those produced by earlier versions.

Recommendations for large reports

To get the most benefit when you run reports that process large volumes of data, consider the following practices:

- **Run high-volume reports in batch mode.** Batch execution offloads processing from interactive sessions. For more information, see Electronic reporting (ER) destinations.
- **Filter the source data** to the records that the report actually requires, so that the engine processes only the data that you need.
- **Keep your ER configurations up to date** so that you receive the latest engine optimizations and fixes.

Troubleshooting performance issues in ER configurations

This article explains how to find and solve performance issues in Electronic reporting (ER) configurations.

Typically, performance investigation consists of several steps.

1. Collect data.
2. Analyze the collected data.
3. Based on the results of the analysis, use ER configurations to make changes, or decide to collect more data.

Troubleshooting

Analyze execution time

Execution time can depend on unpredictable factors, such as other tasks that run in the same environment and caching that uses data when it's called for the first time. Therefore, you should repeat the execution and measurement several times.

Sometimes, performance issues aren't caused by an ER format configuration that you use for reporting. Instead, X++ code that you use to open that ER format configuration causes the issues.

1. In either the Action center or the event log, look at the execution time of the report.
2. Compare the execution time of the report with the total execution time in the scenario.
3. If the execution time of the report is much less than the total execution time, consider the amount of data that the report processes:

    - If the report processes a small amount of data, the issue might involve the loading time of the configuration.
    - If the report processes a large amount of data, the issue might involve preprocessing X++. Use Trace parser to analyze this case.

    For other cases, see the next sections.
4. Run multiple tests that involve different amounts of data to determine how the execution time depends on the amount of data.

Analyze Trace parser traces

Prepare a small example, or collect several traces during random parts of the report generation.

Then, in Trace parser, perform a standard bottom-up analysis and answer the following questions:

- What methods consume the most time?
- What part of the overall time do those methods use?

Answer the same questions for queries.

If you see that methods are prefixed with "ER," move on to the next section.

If you see that methods or queries originated in the application suite, consider generic optimizations (for example, create indexes).

Analyze the number of calls. If the number is higher than expected, consider caching the corresponding nodes of the configuration.

Analyze database calls

Prepare an example that has a small amount of data, so that you can collect an ER trace.

Then open the trace in the ER model mapping designer, and look at the bottom of the page. Answer the following questions:

- Is there any query duplication? If there is, consider one of the following fixes:
  - Use caching if you think that there are several calls inside one parent record.
  - Use a cached, parameterized calculated field if you think that there are calls to the same record inside different records.
  - Use a **JOIN** data source if you have to read to a substantial number of different records from a database.

- Does the number of queries and fetched records correspond to the overall amount of data? For example, if a document has 10 lines, do the statistics show that the report extracts 10 lines or 1,000 lines? If you have a substantial number of fetched records, consider one of the following fixes:
  - Use the **FILTER** function instead of the **WHERE** function to process data on the Microsoft SQL Server side.
  - Use caching to avoid fetching the same data.
  - Use collected data functions to avoid fetching the same data for summarization.

Analyze PerfView traces

PerfView is a tool for experienced developers. For more detailed information about the following steps, see Wall Clock Time Investigation Basics.

1. Collect a trace by using thread time.
2. Include only stacks that use **runUnattended**, to filter only the thread that has configuration execution. (Add **runUnattended** to the **IncPats** input box.)
3. Fold all CPU, network, and blocked time.
4. Load ER presets for PerfView.
5. Select **ER** > **Other preset**.
6. Look at the names:
    - You probably see the platform code that consumes the most time.
    - You can double-tap (or double-click) and go up through **callees**.

      If you find classes that have the prefix "ERExpression," and if they're functions related to formulas, you can guess the function name based on the class name, and you can look at the ER repo to view the attributes.

Fixes

- If queries consume most of the CPU time, try to reduce the number of queries:
    - Review the ER trace for duplicated queries.
    - Check how many records are fetched, and evaluate how much data should theoretically be fetched.
- If functions consume most of the CPU time, try to find the place in the configuration that consumes the most resources.
- If data collection functions consume most of the CPU time, consider replacing them with *SQL group by* on the model mapping side.

Collecting data

Depending on your environment, you can collect available data in several ways:

- Get the total running time:
    - From the Action center

    - From the event log

- Profile the execution:
    - By using ER tools
    - By using Trace parser
    - By using PerfView

Collecting data in a production environment

Sometimes, you can reproduce issues only in a production environment. Collect data in the following ways:

- By using Trace parser traces
- By using ER execution traces
- By using the total execution time

Collecting data in a development environment

In addition to the tools that you can use in a production environment, use several tools in a development environment:

- Event log (Microsoft-Dynamics-ElectronicReporting). This log can give you the total execution time.
- Common .NET tools, such as PerfView.

Additionally, a development environment gives you more flexibility to experiment. For example, you can turn off parts of reports to see how the execution time is affected.

Tools

Execution time in the Action center

ER can show the execution time of the configuration in the Action center. This option works only for a specific user and a specific company, and only for interactive sessions. To make this feature available, follow these steps.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In the **User parameters** dialog box, set the **Show file generation time** option to **Yes**.

Execution time in the event log

1. Open Windows Event Viewer.
2. Under **Applications and Services logs**, open **Microsoft-Dynamics-ElectronicReporting/Operational**.
3. Look for **FormatMapingRun** events where **EventID=2**, because these events contain the information about elapsed time.

Trace parser traces

Because ER is implemented in X++, you can use common X++ tools to analyze performance. For more information, see Take traces by using Trace parser.

There are a few limitations to this approach. Because part of ER is implemented in C#, not all the details are available. However, you can view the data usage details. Additionally, long report runs can exceed trace storage limitations.

ER traces

ER can collect its own traces, and it has visualization and analysis tools for those traces. For more information, see Trace the execution of ER formats to troubleshoot performance issues.

PerfView

Because both X++ and ER are implemented on top of the .NET platform, you can use common .NET tools. For example, you can use the free PerfView tool.

You can also collect data from the command line. For example, the following Windows PowerShell script collects the execution time until any format execution is stopped on the machine.

PowerShell

```
c:\programs\PerfView collect "e:\traces\$(date -format "ddMMyyyy_hhmm").etl" `
    -CircularMB:20000 -ThreadTime `
    -NoNGenRundown `
    -StopOnEtwEvent:Microsoft-Dynamics-ElectronicReporting/FormatMappingRun/Stop
```

There are a few limitations to this approach. You must have administrative access to the machine. Additionally, you must be an experienced developer, because there's a steep learning curve.

Making changes

Use caching

Although caching reduces the amount of time that it takes to fetch data again, it costs memory. Use caching in cases where the amount of fetched data isn't large. For more information and an example that shows how to use caching, see Improve the model mapping based on information from the execution trace.

Reduce volume of data fetched

You can reduce memory consumption for caching by limiting the number of fields in the records of an application table that you fetch at runtime. In this case, you fetch only those field values of an application table that you need in your ER model mapping. You don't fetch other fields in that table. Therefore, the volume of memory that is required to cache fetched records is reduced. For more information, see Improve performance of ER solutions by reducing the number of table fields that are fetched at runtime.

Use a cached, parameterized calculated field

Sometimes, you need to look up values repeatedly. Examples include account names and account numbers. To help save time, you can create a calculated field that has parameters on the top level, and then add the field to the cache.

Use this approach only when the size of the cached data is small. For more information, see Improve the performance of ER solutions by adding parameterized CALCULATED FIELD data sources.

Use a JOIN data source

A **JOIN** data source enables one query to fetch several connected records. You don't need a separate query to fetch each connected record. For example, if you have 1,000 lines, and you fetch item data for each line by relation, you have 1,001 queries (= 1,000 + 1). If you use a **JOIN** data source, you use only one query to fetch the same data. For more information, see Use JOIN data sources in ER model mappings to get data from multiple application tables.

Use the FILTER function instead of the WHERE function

The **FILTER** function runs conditions on SQL Server, whereas the **WHERE** function fetches all data from the list, one record at a time, and applies the condition for each record. For example,

you want to select one record out of 1,000 records. If you use **WHERE**, you fetch all 1,000 records. However, if you use **FILTER**, you fetch exactly one record. **FILTER** can also use indexes on the database side.

Use collected data functions or an accumulated data source

If your configuration has a *group by* component that summarizes previously fetched data by report, the component fetches all the data again. By using collected data functions, you enable ER to accumulate data during the first fetch. For more information, see ER Configure format to do counting and summing.

Rewrite parts of the configuration in X++

ER supports calling methods of tables and classes, including extensions. Consider rewriting parts of the model mapping in X++ to help improve performance.

ER can consume data from the following sources:

- Classes (**object** and **class** data sources)
- Tables (**table** and **table records** data sources)

The ER application programming interface (API) also provides a way to send precalculated data from the calling code. The application suite contains numerous examples of this approach.

Improve performance of ER solutions by reducing the number of table fields that are fetched at runtime

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can design Electronic reporting (ER) formats that generate outgoing documents in various formats. When a document is generated, an ER format calls data sources that were configured in a corresponding ER model mapping. To configure access to application tables, queries, or entities for record retrieval, you can use ER data sources of the *Table records* type. By default, a data source of the *Table records* type retrieves the values of all fields in the requested records. However, you can configure this type of data source so that it fetches only the field values that are required for the running ER format. This configuration helps reduce memory consumption of the application server that performs data retrieval and further record caching.

To learn more about how to limit the list of fetched fields of data sources of the *Table records* type, complete the example in this article.

Example: Reduce the number of table fields that are fetched at runtime

The following procedures show how a user in the System administrator or Electronic reporting developer role can configure an ER model mapping so that it fetches only the fields that are required to run the ER format, to help reduce the consumption of application server memory.

These procedures can be completed in the **USMF** company in Microsoft Dynamics 365 Finance. No coding is required.

To complete this example, you must have access to the **USMF** company for one of the following roles:

- Electronic reporting functional consultant
- System administrator

In this example, you will use the ER configurations that are provided for the **Litware, Inc.** sample company. Make sure that the configuration provider for the **Litware, Inc.** (`http://www.litware.com`) sample company is listed for the ER framework, and that it's marked as **Active**. If this configuration provider isn't listed, or if it isn't marked as **Active**, follow the steps in Create a configuration provider and mark it as active.

Configure the ER framework

Follow the steps in Configure the ER framework to set up the minimal set of ER parameters. You must complete this setup before you start to use the ER framework to modify data sources of the provided ER solution.

Import the sample ER configurations

If you haven't yet completed the example in the Design a new ER solution to print a custom report article, download and locally store the XML files for the following configurations of the provided ER solution.

Expand table

Content description	File name
ER data model configuration	Questionnaires model.version.1.xml
ER model mapping configuration	Questionnaires mapping.version.1.1.xml
ER format configuration	Questionnaires format.version.1.1.xml

Then follow these steps to upload the configurations of the provided ER solution to your Finance instance.

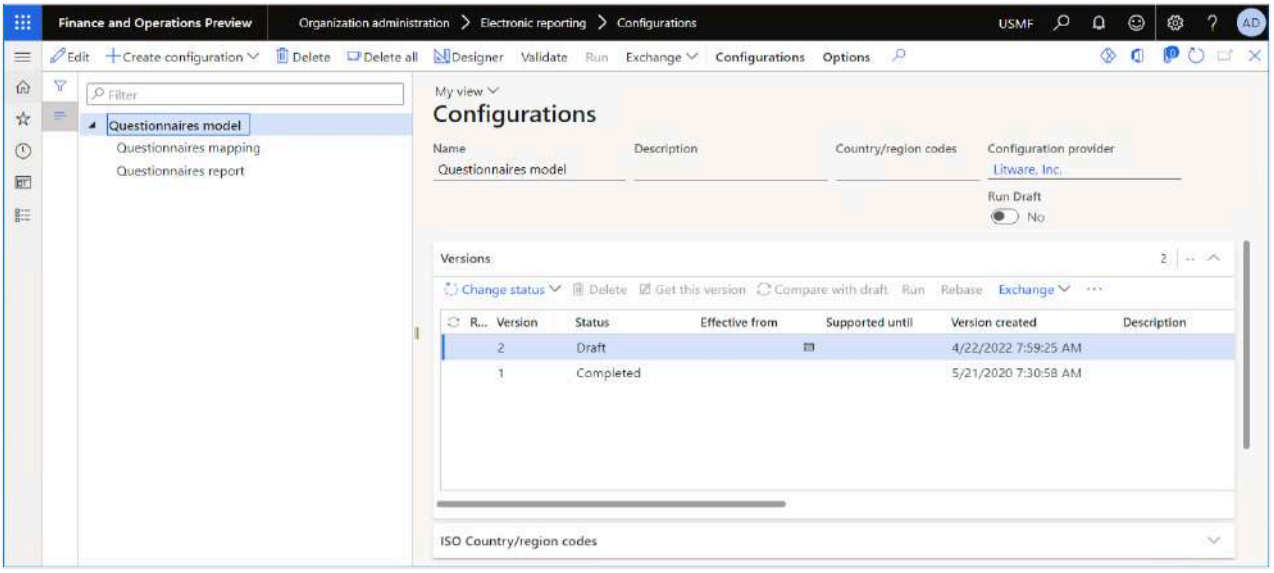
1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. On the **Configurations** page, import the ER data model configuration.
   a. Select **Exchange**, and then select **Load from XML file**.
   b. Select **Browse**, find and select the **Questionnaires model.version.1.xml** file, and then select **OK**.

4. Import the ER model mapping configuration.
    a. Select **Exchange**, and then select **Load from XML file**.
    b. Select **Browse**, find and select the **Questionnaires mapping.1.1.xml** file, and then select **OK**.

5. Import the ER format configuration.
    a. Select **Exchange**, and then select **Load from XML file**.
    b. Select **Browse**, find and select the **Questionnaires format.1.1.xml** file, and then select **OK**.

6. In the configuration tree, expand **Questionnaires model**.

7. Review the list of imported ER configurations in the configuration tree.



Review the provided ER model mapping

1. On the **Configurations** page, select **Questionnaires mapping**.

2. On the Action Pane, select **Designer**.

3. On the **Model to datasource mapping** page, select **Designer**.

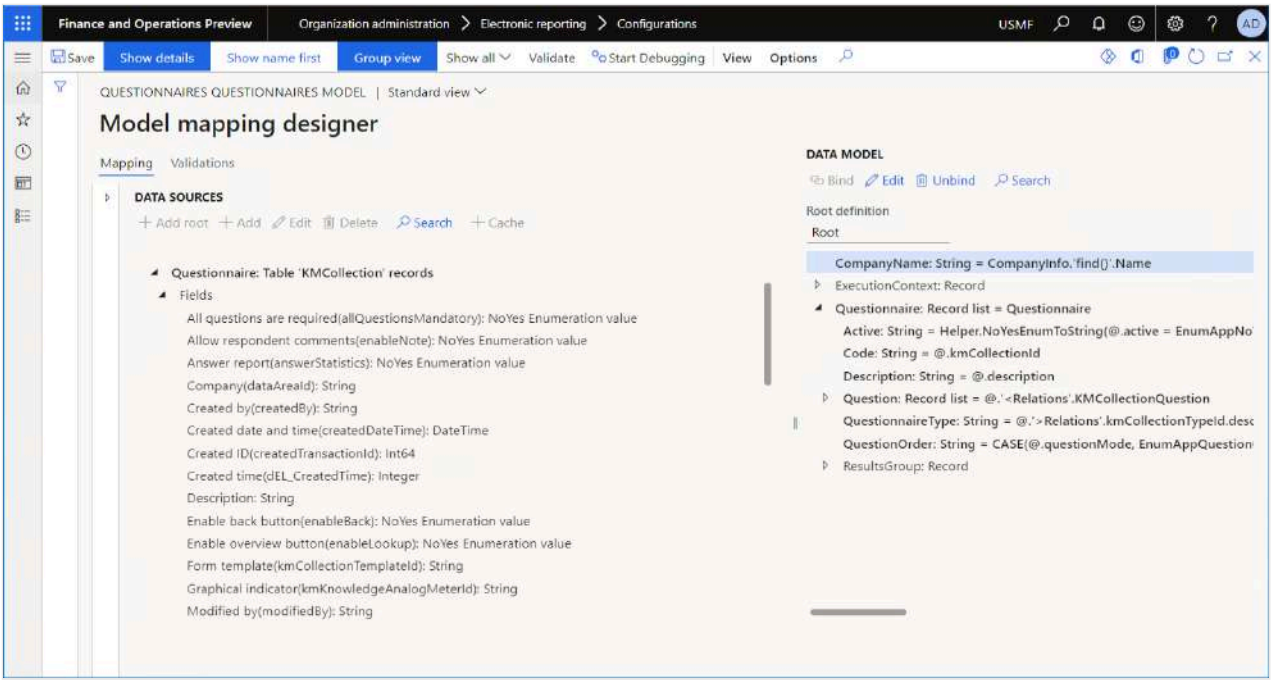
4. On the **Model mapping designer** page, on the Action Pane, select **Group view** to turn on **Group** view.

5. In the **Data model** pane, expand **Questionnaire**.

    Notice that the **Questionnaire** data source has been configured to access the `KMCollection` application table.

6. In the **Data sources** pane, expand **Table records** > **Questionnaire** > **Fields**.

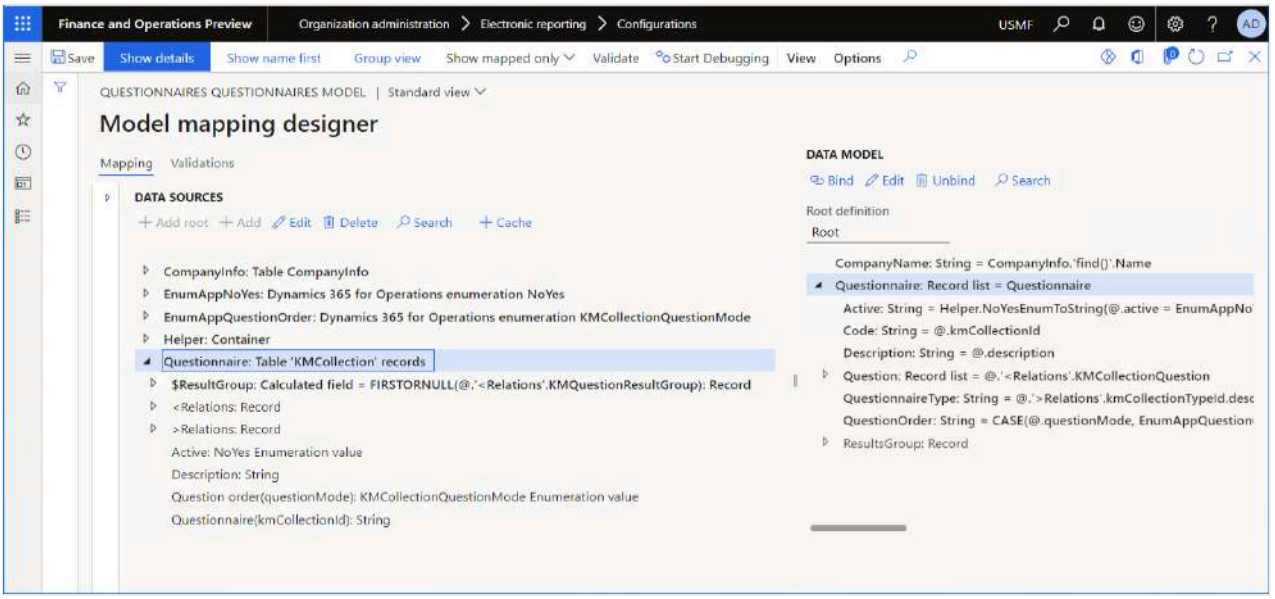
   Notice how many fields from the `KMCollection` application table are exposed by the **Questionnaire** data source of the *Table records* type.



7. On the Action Pane, select **Group view** again to turn off **Group** view, and then select **Show all** > **Show mapped only**.

   Notice that a few fields of the `KMCollection` application table are used to fill in the **Questionnaire** record list in the ER data model:

   - `Active`
   - `Description`
   - `questionMode`
   - `kmCollectionId`



Turn on the ER performance trace

Follow the steps in Turn on the ER performance trace to set the ER user parameters that enable the execution of ER components to be traced.

Run the provided ER format by using the provided model mapping

Follow the steps in Run a designed format from ER to run the provided ER format for a single questionnaire from the **Configurations** page.

Review the execution trace of the first run

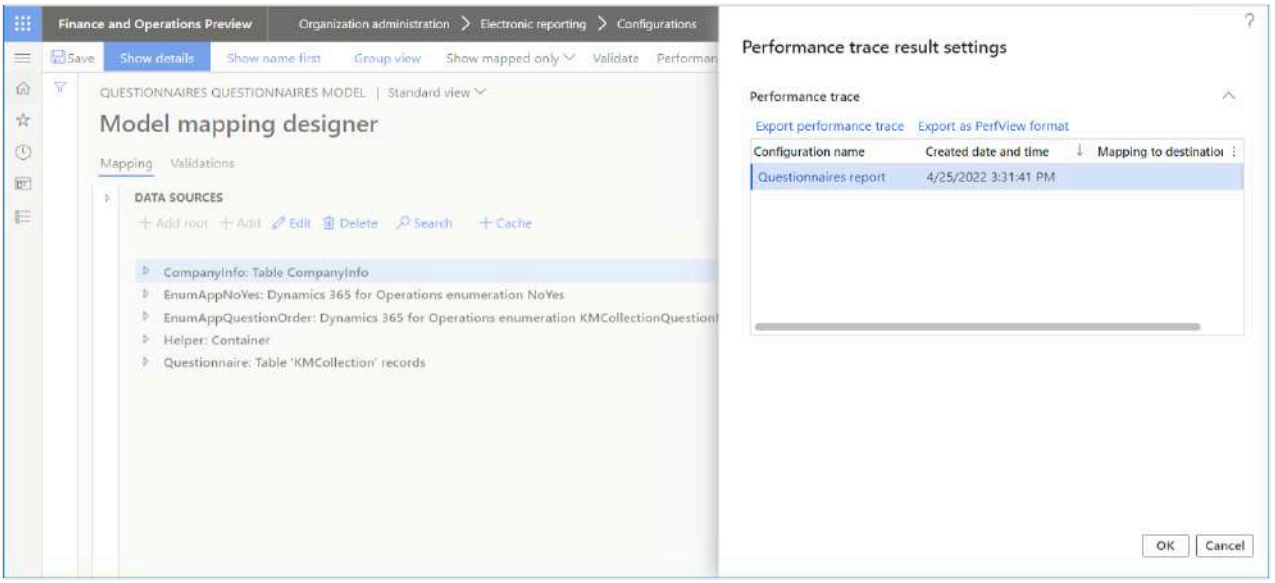
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, expand **Questionnaires model**, and select **Questionnaires mapping**.

   > **Note**
   >
   > The details on the **Versions** FastTab indicate that you selected the draft version of the **Questionnaires mapping** configuration. Therefore, you can modify the content of this model mapping.

3. On the Action Pane, select **Designer**.
4. On the **Model to datasource mapping** page, select **Designer**.

5. On the **Model mapping designer** page, on the Action Pane, select **Performance trace**.

6. In the **Performance trace result settings** dialog box, select the trace that was generated during the last format run.

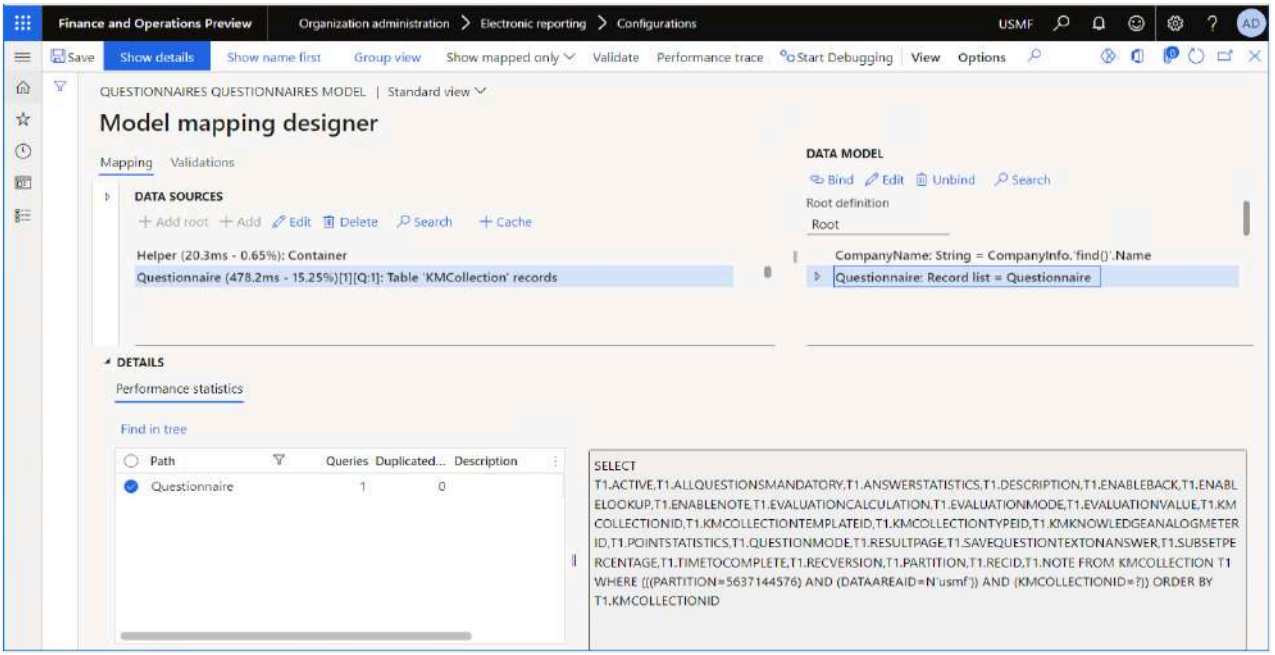


7. Select **OK**.

8. On the **Details** FastTab, filter the **Questionnaire** path that points to the **Questionnaire** data source.

9. Review the details of the database query that was generated when the **Questionnaire** data source was called.

   Notice that all fields of the `KMCollection` application table were fetched at runtime when the **Questionnaire** data source was called.

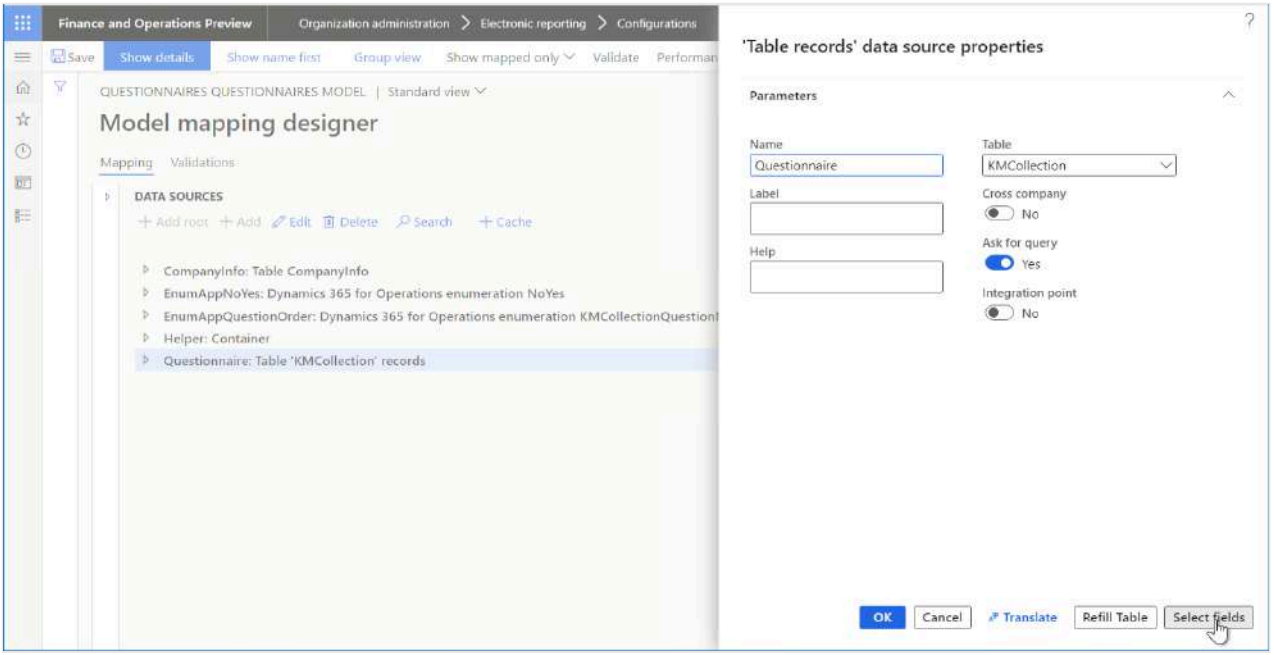


Modify the provided ER model mapping

1. On the **Model mapping designer** page, in the **Data sources** pane, select the **Questionnaire** data source.

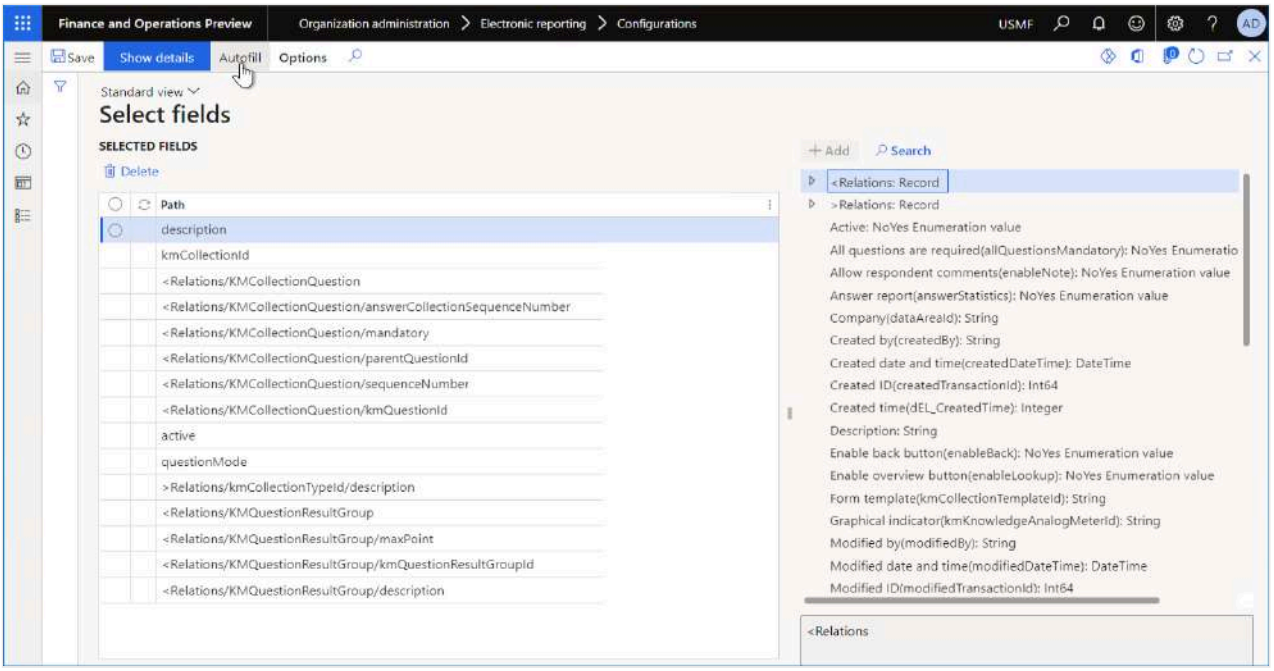
2. In the **Data sources** pane, select **Edit**.

3. In the **Data source properties** dialog box, select **Select fields** to specify the list of fields of the referenced `KMCollection` application table that will be fetched at runtime when the editable **Questionnaire** data source is called.



4. On the **Select fields** page, select **Autofill**.

   The **Selected fields** list is automatically filled in, based on preconfigured artefacts of the model mapping. All fields and relations of the referenced table that are mentioned in any binding, formula, or data source of the model mapping are added to the list.

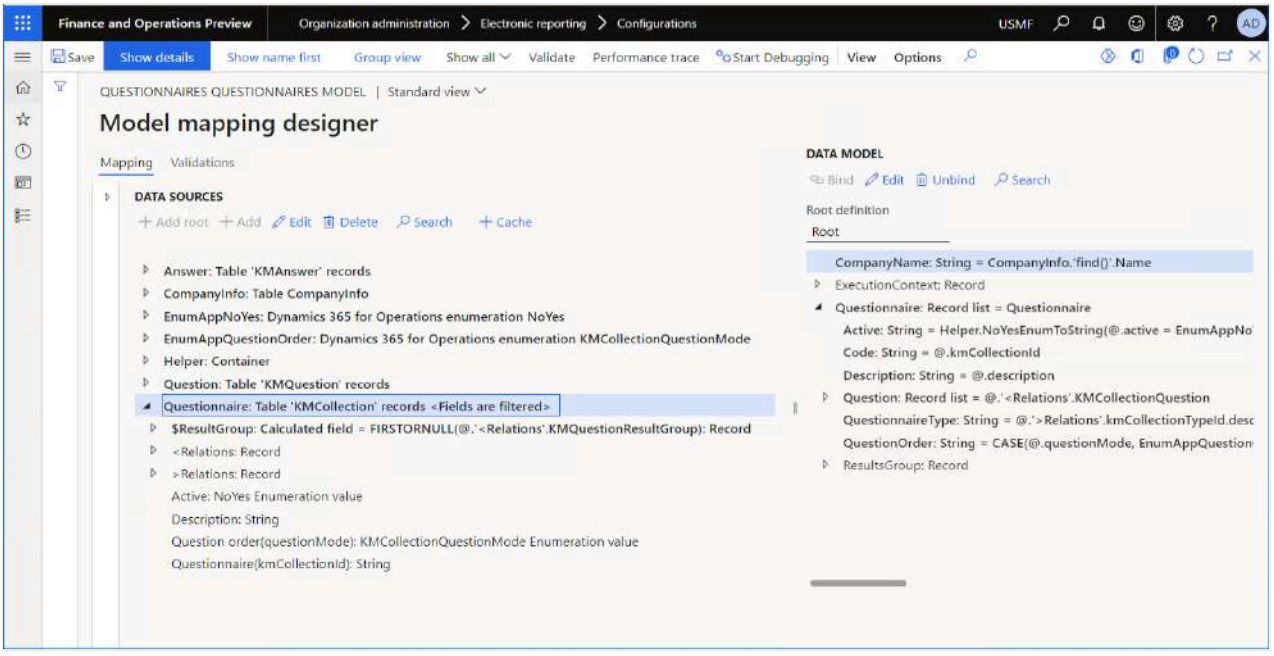


5. Select **Save**, and close the **Select fields** page.

6. Select **OK** to store the changes that you've made to the data source settings.

7. On the Action Pane, select **Show all**.

   Notice that the **Questionnaire** data source now shows the text **<Fields are filtered>**. This text indicates that the data source has been configured to fetch a limited number of fields from the referenced application table.



8. Select **Save** to store the changes that you've made to the editable model mapping.

> **Note**

At runtime, ER analyzes the added relations and adds all fields that are used in them to the database query, even if those fields weren't explicitly added to the list of fetched fields at design time.

Run the provided ER format by using the updated model mapping

Follow the steps in Run a designed format from ER to run the provided ER format for a single questionnaire from the **Configurations** page.

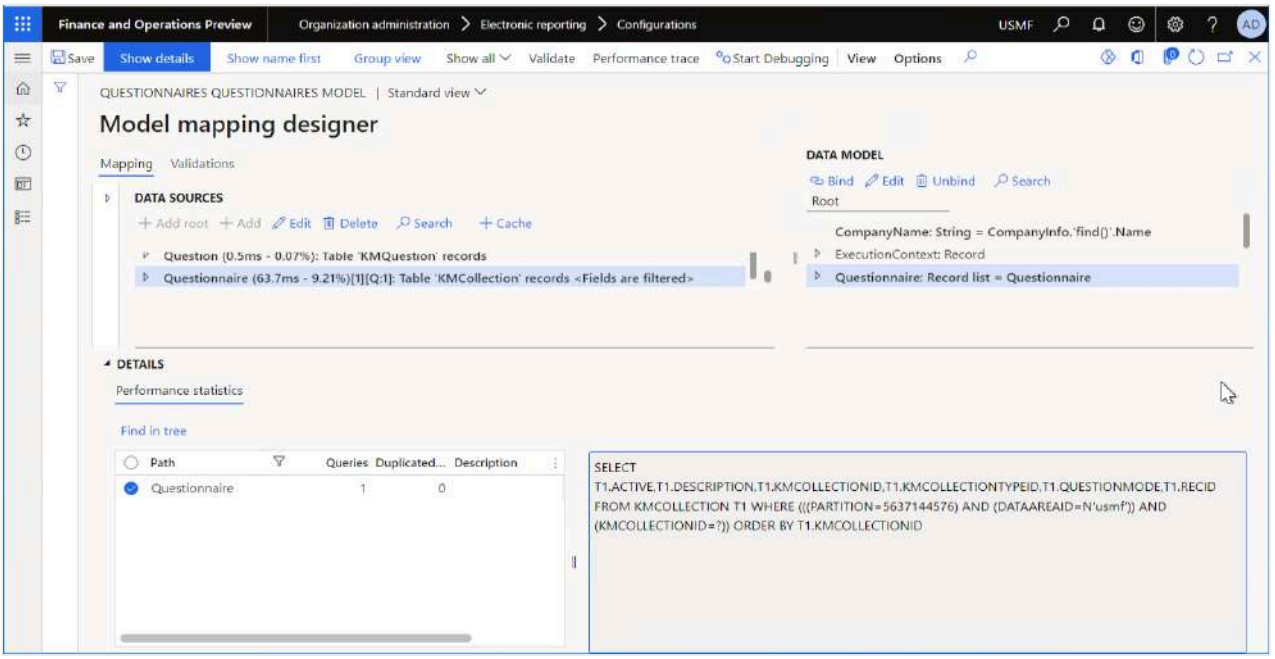
Review the execution trace of the second run

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On the **Configurations** page, expand **Questionnaires model**, and select **Questionnaires mapping**.
3. On the Action Pane, select **Designer**.
4. On the **Model to datasource mapping** page, select **Designer**.
5. On the **Model mapping designer** page, on the Action Pane, select **Performance trace**.
6. In the **Performance trace result settings** dialog box, select the trace that was generated during the last format run.
7. Select **OK**.
8. On the **Details** FastTab, filter the **Questionnaire** path that points to the **Questionnaire** data source.
9. Review the details of the database query that was generated when the **Questionnaire** data source was called.

   Notice that only the fields that are required to fill in the data source were fetched at runtime from the `KMCollection` application table when the **Questionnaire** data source was called.

   Note

Some fields, such as the fields for the partition ID, data area ID, and record ID, are automatically added by the Data Management framework of the Finance app.



You can use this technique to reduce the number of fetched records when you must reduce memory consumption by the running ER model mapping and ER format.

Limitations

When you limit the number of fetched fields for a data source of the *Table records* type, you can't use the methods of an application table that the data source refers to, because the application metadata doesn't provide information about table fields that are required to call those methods.

Usage notes

Although the **Autofill** command automatically adds fields, it doesn't automatically delete previously added fields, even if they are no longer used in bindings, formulas, and data sources of the editable model mapping.

When you select **Autofill**, ER analyzes bindings, formulas, and the data sources that the editable model mapping had when you opened it for editing. If you change bindings, formulas, and data sources of the editable model mapping, and you want to use the **Autofill** command, close the model mapping designer, and then re-open it to edit your model mapping.

Business document management overview

Business users use the **Business document management** (BDM) workspace to configure formats for outbound documents in accordance with the legal requirements of various countries or regions or company-specific needs. **Business document management** is built on top of the Electronic reporting (ER) framework and enables business users to edit business document templates by using Microsoft 365 Apps for business or an appropriate Microsoft 365 desktop applications. Edits to the documents might include changing business document designs and adding placeholders for extra data without source code changes and new deployments. Updating business document templates doesn't require any prior knowledge of the ER framework.

The ER framework generates outbound documents in Excel and Word formats by using predefined templates. The templates are populated with required data according to the configured dataflow while required documents are generated. Each configured format can be published as part of an ER solution to generate specific outbound documents. This process is represented by an ER format configuration that can contain templates you can use to generate different outbound documents.

> **Note**
>
> **Business document management** enables you to modify templates that are used to produce business documents such as orders, invoices, and more. When you modify a template and publish a new version, the system uses this version to generate required business documents. You can't use Business document management to modify already generated business documents.

Supported deployments

Currently, the **Business document management** workspace is implemented only for cloud deployments. If this feature is critical to your on-premises deployment, provide feedback on the Ideas site.

Supported Microsoft 365 and Office applications

To use **Business document management** for editing templates in Excel or Word formats by using Microsoft Office desktop applications, you must have Microsoft Office 2010 or later installed and

a configured **SharePoint** integration to host the files during editing. This support is available in cloud and on-premises deployments.

To use **Business document management** for editing templates in Excel or Word formats to edit templates online in Microsoft 365 (Word or Excel for the web), you must have a Microsoft 365 Office for the web subscription and a configured **SharePoint** integration to host the files during editing.

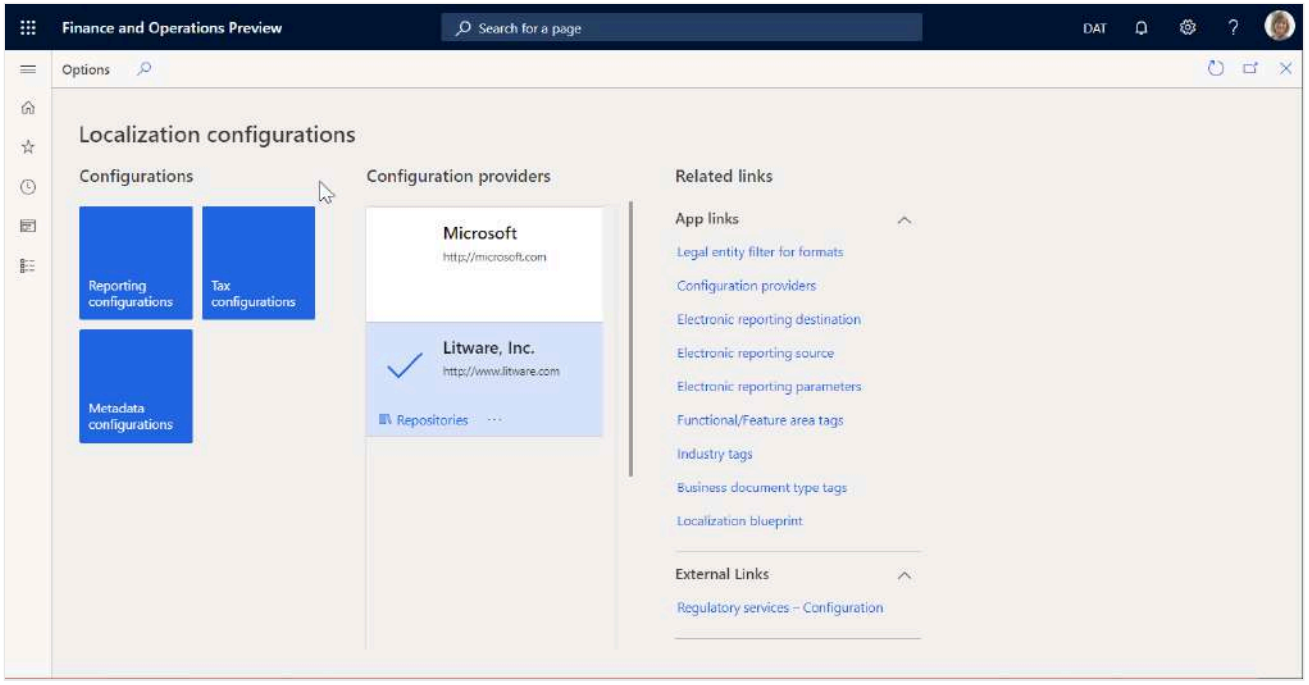
Configure Electronic reporting parameters for business documents

Business document management is built on top of the ER framework. Complete configuring the ER parameters to start working with **Business document management**.

- Set up the ER parameters as described in Configure the Electronic reporting (ER) framework.
- Add a new configuration provider as described in Create configuration providers and mark them as active.



Import ER solutions

This procedure uses sample ER configurations. You must import into your current instance of Dynamics 365 Finance the ER configurations that contain the business document templates you can edit by using Business document management. To complete this procedure, download and locally store the following files.

Sample ER customer invoicing solution

Expand table

File	Content
Customer invoicing model.version.2.xml	ER data model configuration
Customer FTI report (GER).version.2.3.xml	Free text invoice ER format configuration

Sample ER payment checks solution

Expand table

File	Content
Model for cheques.version.10.xml	ER data model configuration
Cheques printing format.version.10.9.xml	Payment cheque ER format configuration

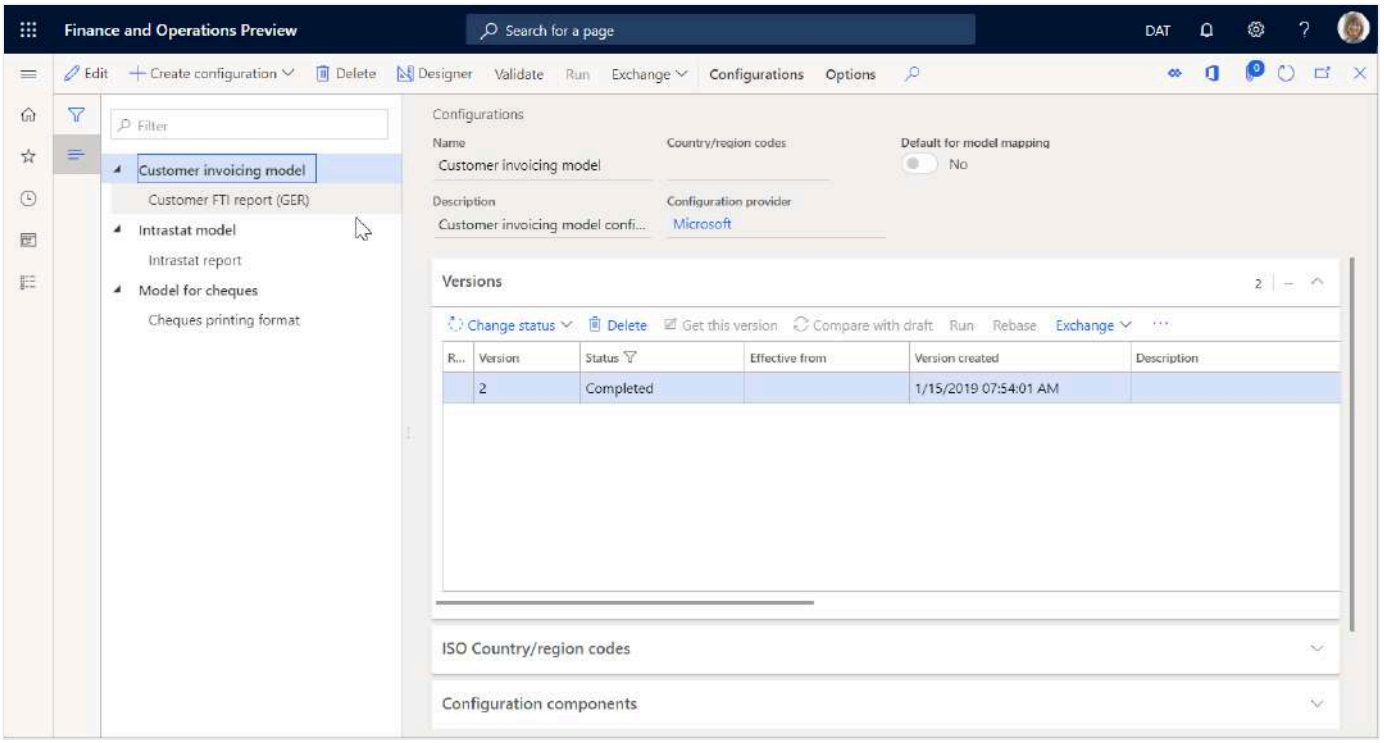
Sample ER foreign trade solution

Expand table

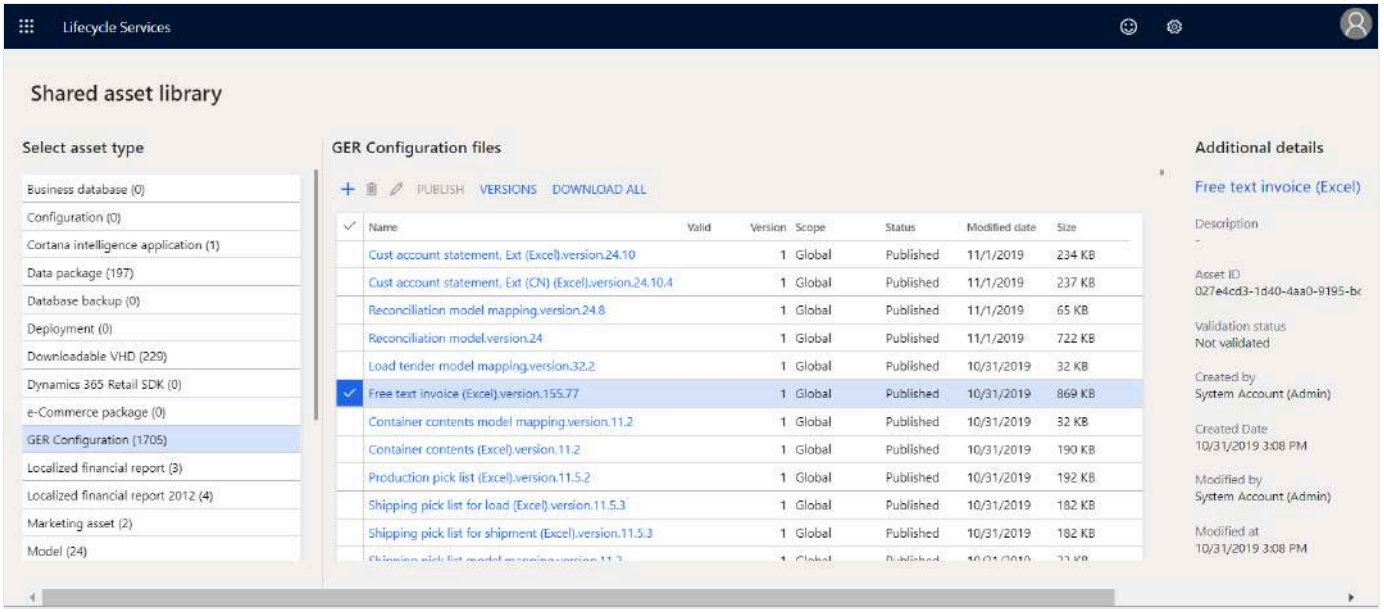
File	Content
Intrastat model.version.1.xml	ER data model configuration
Intrastat report.version.1.9.xml	Intrastat control report ER format configuration

Use the following procedure to import each file. Import the ER *data model* configuration of each ER solution in the preceding tables before you import the corresponding ER *format* configuration.

1. Open **Organization administration** > **Electronic reporting** > **Configurations**.
2. At the top of the page, select **Exchange**.
3. Select **Load from XML file**.
4. Select **Browse** to load the required XML file.
5. Select **OK** to confirm the configuration import.



Alternatively, you can import the officially published ER format configurations from Microsoft Dynamics Lifecycle Services. For example, to complete this procedure, you can import the latest version of the **Free text invoice (Excel)** ER format configuration. The corresponding ER data model and ER model mapping configurations are imported automatically.



For more information about importing ER configurations, see Manage the ER configuration lifecycle.

Configure parameters

Use the information in the following sections to set up the basic parameters for **Business document management**.

Prerequisites for parameter setup

Before you set up **Business document management**, configure **SharePoint** storage in the **Document management** framework. This configuration is required so you can host templates in SharePoint for online editing in Word or Excel for the web (and for desktop editing). To edit templates online in Microsoft 365 (Word or Excel for the web), you must have a Microsoft 365 Office for the web subscription and a configured **SharePoint** integration to host the files during editing.

Configure SharePoint storage

On the **Document management parameters** page, on the **SharePoint** tab, enter the Microsoft SharePoint address in the **SharePoint server** field and select **Test interactive SharePoint connection** to verify valid connection with SharePoint.

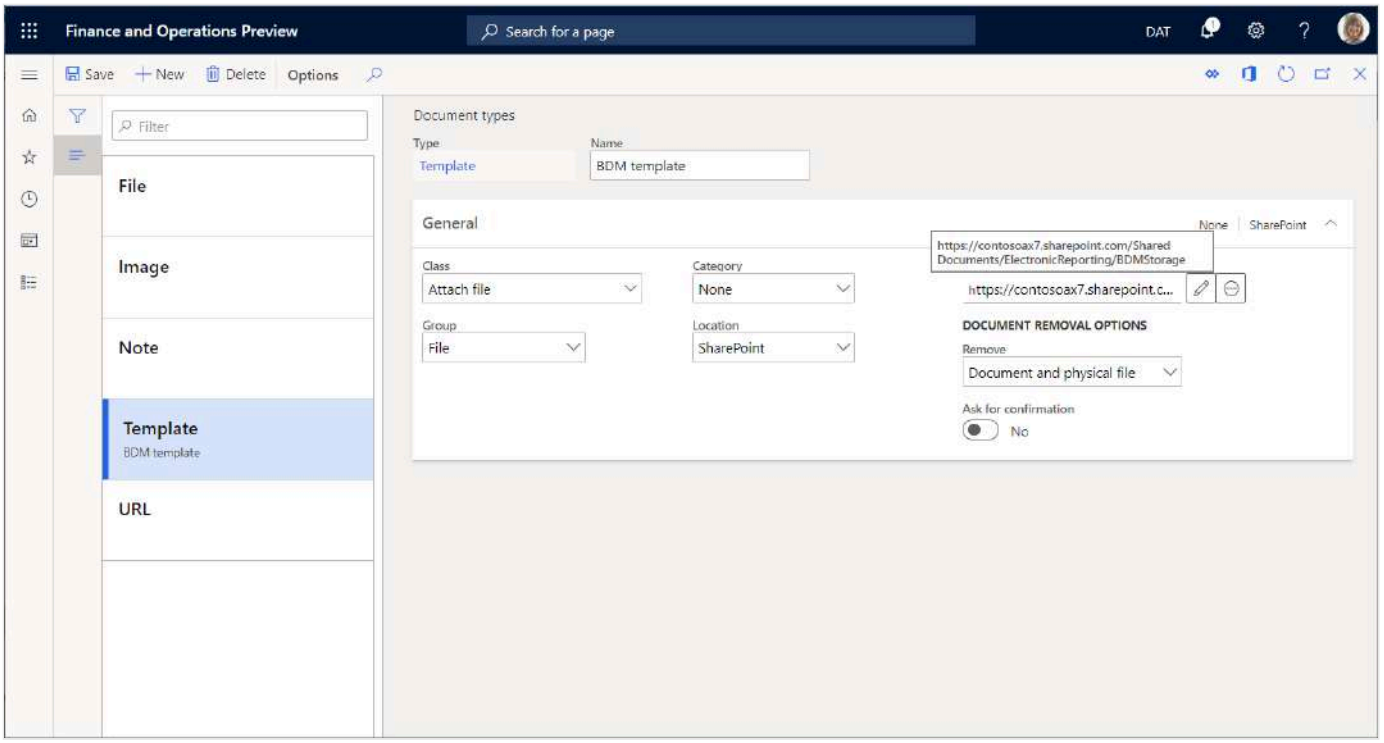
Set up document type in the Document management framework

Create a document type that **Business document management** can use for template editing. This document type specifies a temporary storage of documents in Office formats (Excel and Word) that are used as templates for ER reports. For this document type, go to the **Document types** page, select the following attribute values.

Expand table

Attribute name	Attribute value
Class	Attach file
Group	File
Location	SharePoint

For information about how to set up the required document management parameters and document types, see Configure document management.



Set up parameters

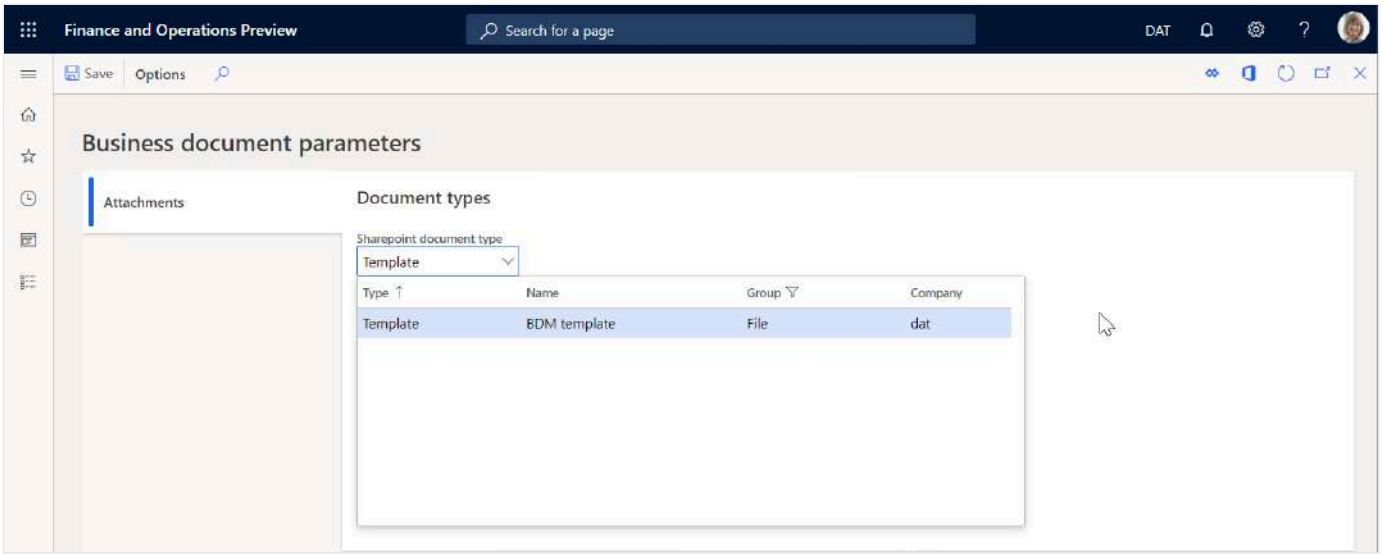
Set up basic **Business document management** parameters on the **Business document parameters** page. Only specific users can access the page. This access includes:

- Users assigned to the **System administrator** role.
- Users assigned to any role that is configured to perform the duty, **Maintain Business document management parameters** (AOT name **ERBDMaintainParameters**).

Use the following procedure to set up the basic parameters for all legal entities.

1. Sign in as a user with access to the **Business document parameters** page.
2. Go to **Organization administration** > **Electronic reporting** > **Business document management** > **Business document parameters**.
3. On the **Business document parameters** page, on the **Attachments** tab, in the **SharePoint document type** field, define the document type that you want to use to temporarily store templates in Office formats while you edit them online in Microsoft 365 (Word/Excel for the web) or in the Office desktop applications.

> ⓘ **Note**
>
> Only document types that are configured by using a SharePoint location are available for this parameter.



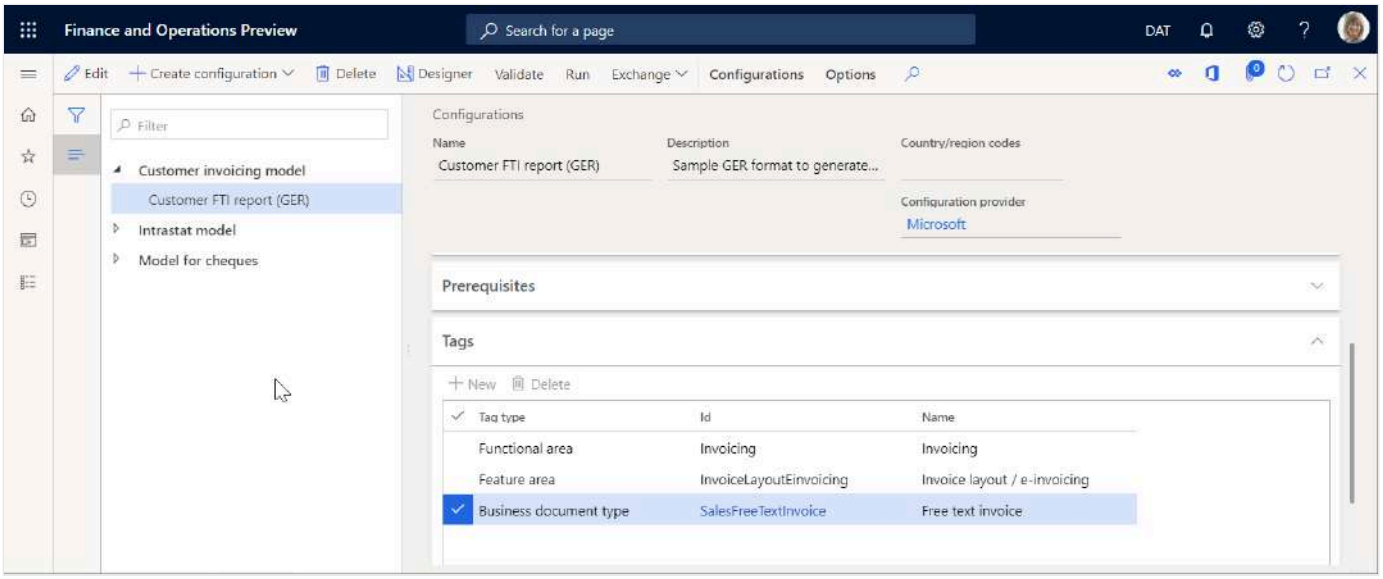
The selected document type is company-specific and is used when the user works with **Business document management** in the company for which the selected document type is configured. When the user works with **Business document management** in another company, the same selected document type is used if one isn't configured for this company. When you configure a document type, it replaces the one selected in the **SharePoint document type** field.

> **Note**
>
> The **SharePoint document type** parameter defines a SharePoint folder as temporary storage for templates that are editable by using either Microsoft Excel or Word. Set up this parameter if you plan to use these Office desktop applications for editing templates. For more information, see Edit a Business document template.

Last updated on 08/07/2026

Manage access permissions to edit templates for configurable business documents

By default, when you don't enable access to **Business document management** permissions, every user with access to the **Business document management** workspace sees all of the ER solution templates that are available. The **Business document management** workspace shows only those templates that reside in ER format configurations and that are marked by a **Business document type** tag.



You can restrict the list of templates available in the **Business document management** workspace by configuring access permissions. This restriction is important when different templates produce business documents for different business domains (functional areas), and you want to allow specific users access to different templates for editing in the **Business document management** workspace.

Set **Business document management** access permissions on the **Configurator of access permissions**. Only the following users can access the page:

- Users assigned to the **System administrator** role.
- Users assigned to any other role that is configured to perform the duty, **Configure permissions to access Business document templates for editing** (AOT name **ERBDTemplatesSecurity**).

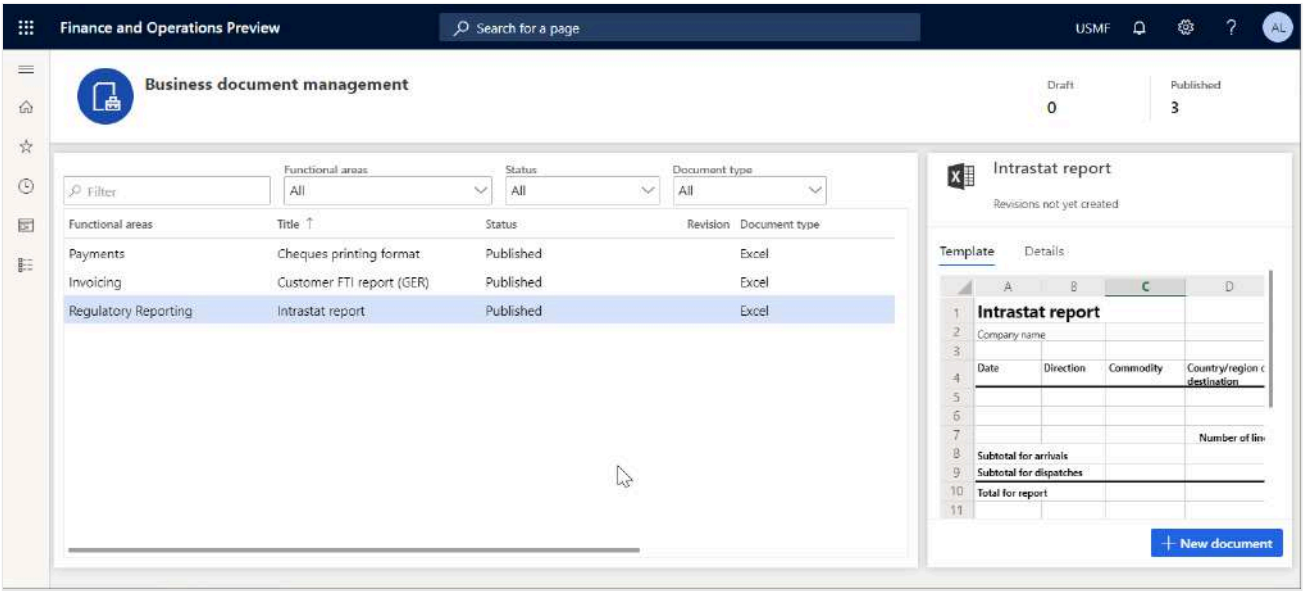
Use the following procedure to set up the access **Business document management** permissions for all legal entities.

1. Sign in as a user with access to the **Configurator of access permissions** page.
2. Go to **Organization administration** > **Electronic reporting** > **Business document management** > **Manage access permissions**.

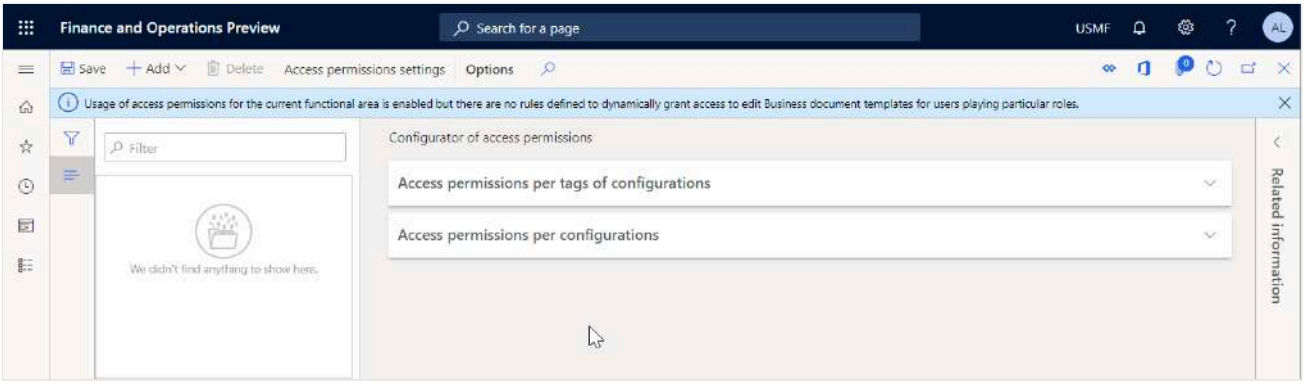
   Pay attention to the notification that informs you that the usage of access permissions for **Business document management** isn't currently enabled.

   With this setting, every user assigned to any security role that is configured to perform the **Manage Business document templates** (AOT name **ERBDManageTemplates**) duty can open the Business document management workspace and can edit any template that is available.

   The following graphic shows what is available in the **Business document management** workspace for users assigned to the **Accounts receivable clerk** role. With the current access permissions setting, the user can edit business document templates from different functional areas including invoicing, regulatory reporting, and payments.

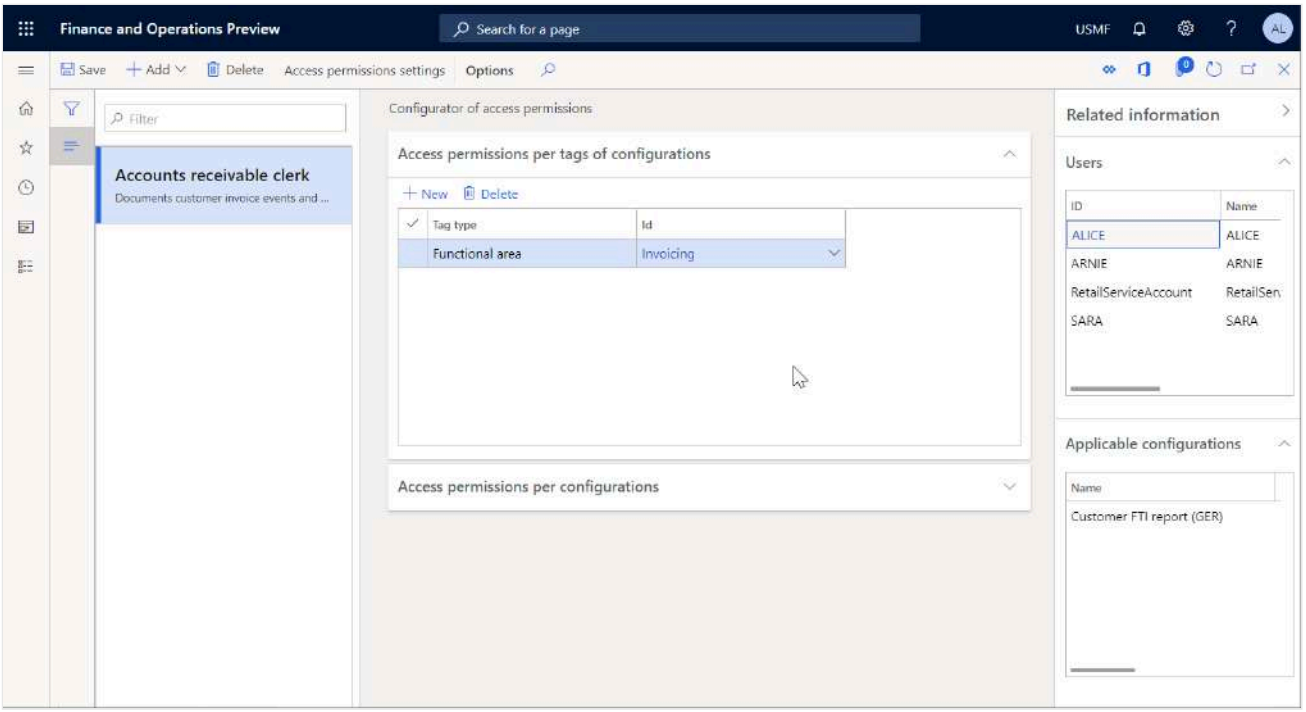


3. On the **Configurator of access permissions** page, select **Access permissions setting**.
4. In the **Settings of access permissions to edit templates** dialog box, enable the **Apply configured access permissions** option.
5. Select **OK** to confirm that Business document management access permissions are enabled.



6. Select **Add** to enter a new business role for which permissions to access Business document management templates must be configured.
7. In the **Security roles** dialog box, select the **Accounts receivable clerk** role and then select **OK** to confirm the role selection.
8. On the **Access permissions per tags of configurations** tab, select **New**.
9. In the **Tag type** field, select **Functional area**, and in the **ID** field, select **Invoicing**.
10. Select **Save** to store configured access permissions for the selected role.

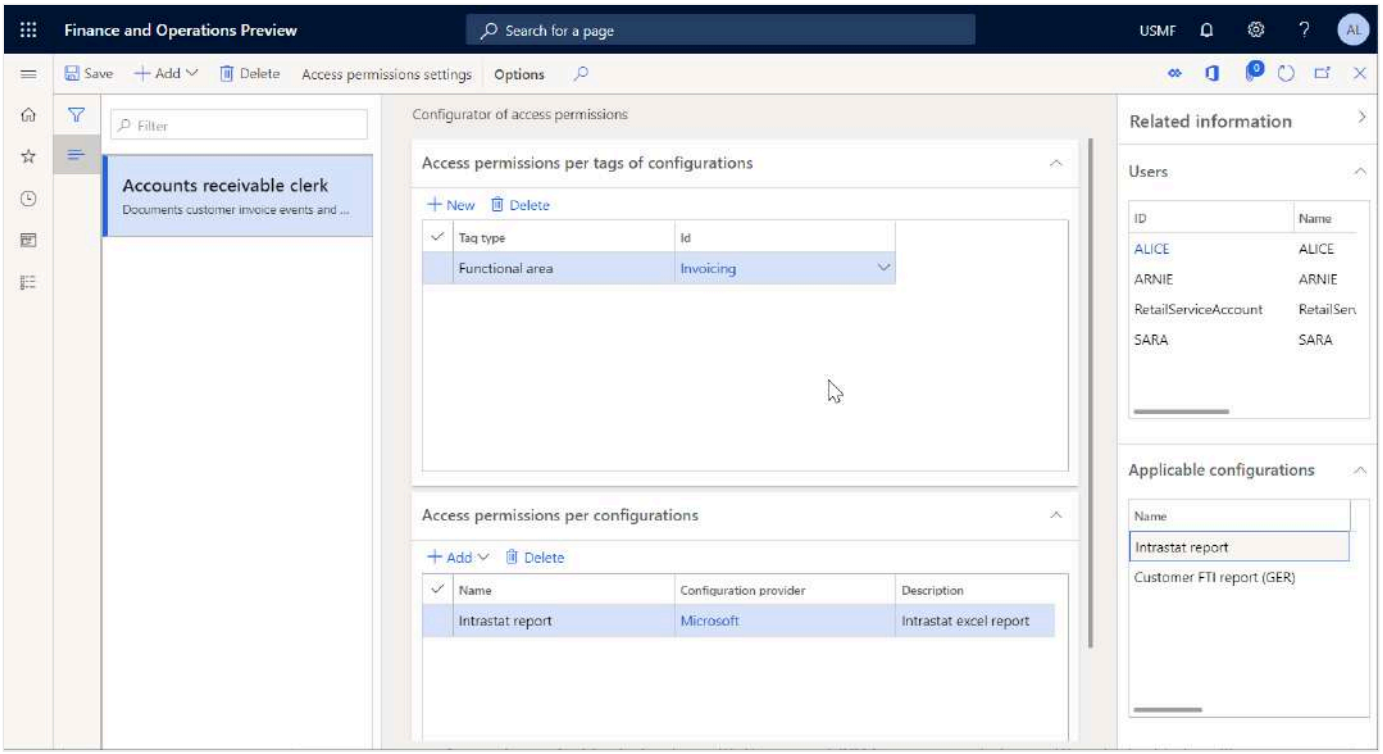
    The current setting means that for any user who is assigned to the **Accounts receivable clerk** role and performing the duty, **Manage Business document templates** (AOT name **ERBDManageTemplates**), ER format configuration templates that have the **Invoicing** value for the **Functional area** tag are available to edit in the Business document management workspace.
11. Switch the **Related information** pane from the right side of the current page. The **Related information** pane shows how the configured access permissions are applied, including what ER configuration templates are available for users that are assigned to the **Accounts receivable clerk** role.



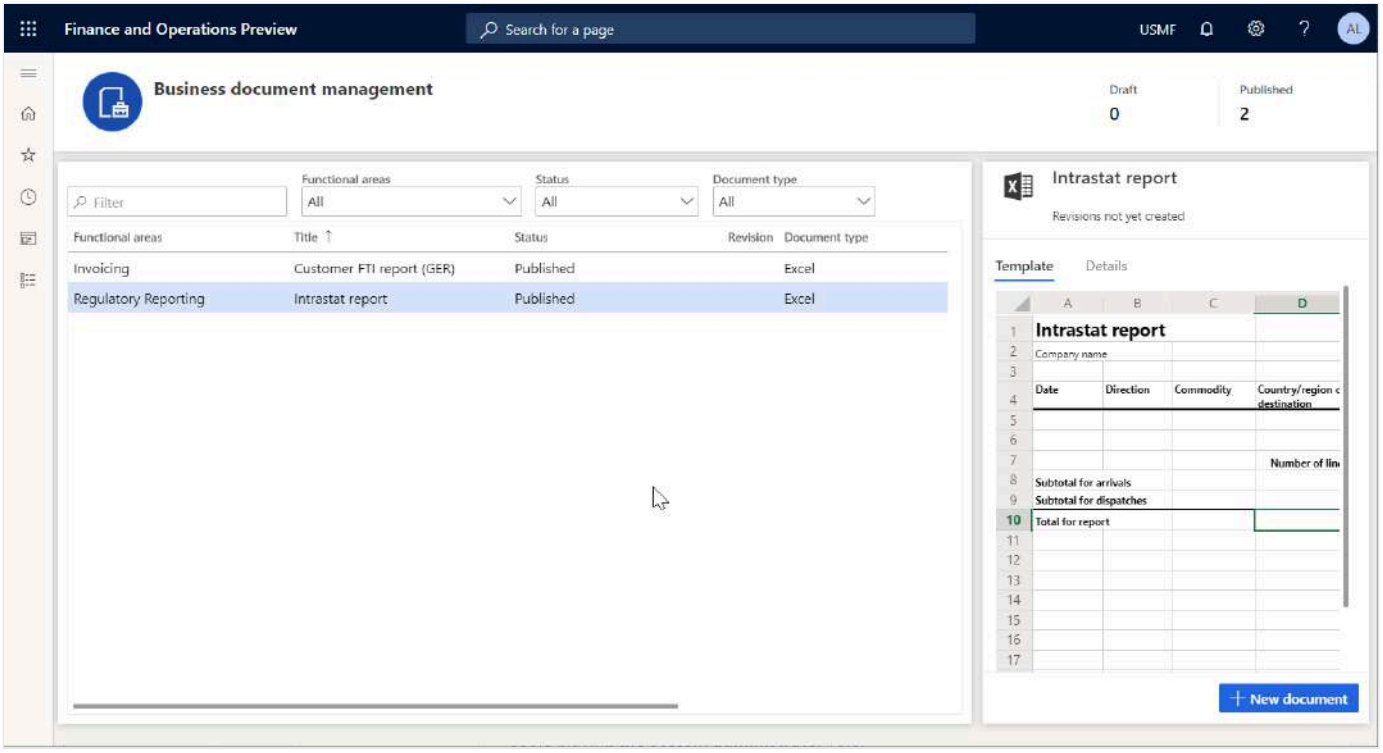
12. On the **Access permissions per configurations** tab, select the **Add** option.
13. In the **Select configuration** dialog box, mark the **Intrastat report** ER format configuration.
14. Select **OK** to confirm the entry of the selected configurations and then select **Save** to store the configured access permissions for the selected role.

The current setting means that for any user assigned to the **Accounts receivable clerk** role and performing the duty, **Manage Business document templates** (AOT name **ERBDManageTemplates**), the following templates are available to edit in the Business document management workspace:

- Templates that have the value, **Invoicing** for the **Functional area** tag.
- Templates from ER format configurations that are listed on the **Access permissions per configurations** tab (templates from the **Intrastat report** format configuration of the **Statutory reporting** domain in this example).



The following graphic shows what the **Business document management** workspace provides to a user assigned to the **Accounts receivable clerk** role. With the current Business document management access permissions setting, the user can edit business document templates from the **Invoicing** domain and the **Intrastat report** ER format configuration. Templates from the **Payments** domain aren't accessible for the **Accounts receivable clerk** role.



> **Note**

The **Access permissions per configurations** rules use the unique identification ID of an ER format configuration. These rules stay even if you delete an ER configuration that refers to them. When you import deleted configurations back to this instance, these rules refer to them again. You don't need to set up the rules again after you import the deleted configurations.

Last updated on 08/07/2026

Use Business document management to edit templates

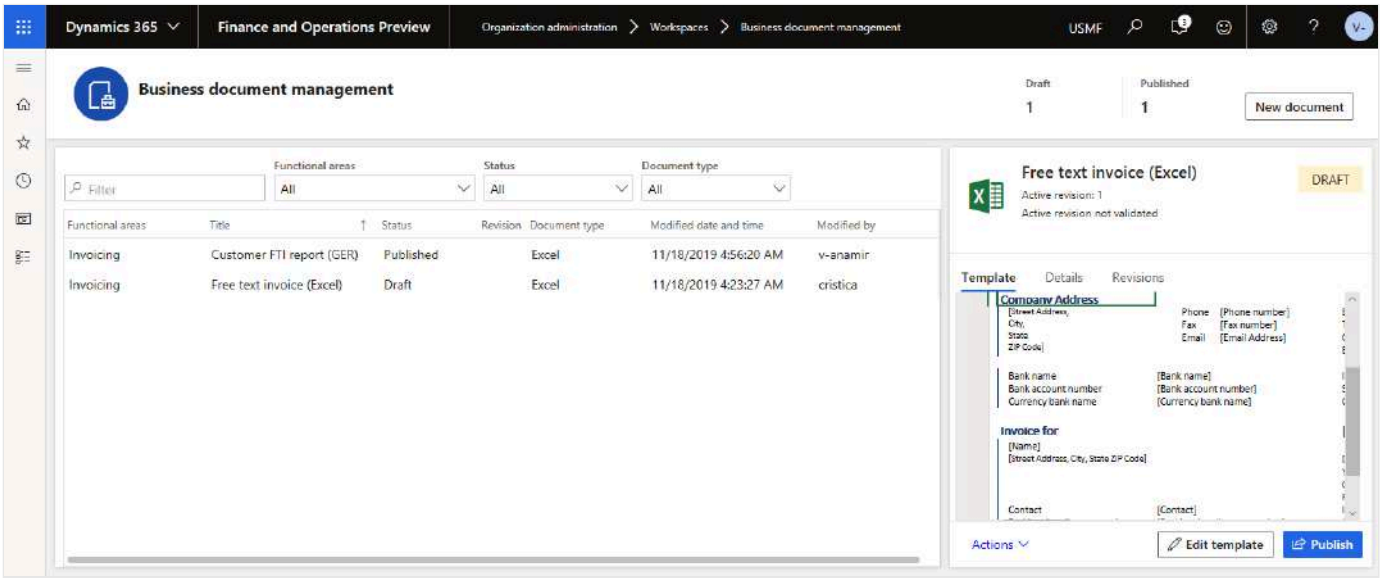
Business users can access business document templates for editing in the **Business document management** workspace. Only the following users can access the **Business document management** workspace:

- Users assigned to the role, **System administrator**.
- Users assigned to any role that is configured to perform the duty, **Manage Business document templates** (AOT name **ERBDManageTemplates**).

Use the following procedure to edit free text invoice templates in the **Business document management** workspace. Before you complete this procedure, you must complete all of the preceding procedures described in Configure Electronic reporting parameters for business documents.

1. Sign in as a user with access to the **Business document management** workspace.
2. Open the **Organization administration** > **Business document management** workspace.

The **Business document management** workspace shows only the templates that the current active provider owns and that are located in the current instance of Dynamics 365 Finance.



On the **Template** tab, you can preview the content of the selected template. Select the **Details** tab to review details of the selected template as well as details of an ER format configuration this template resides in.

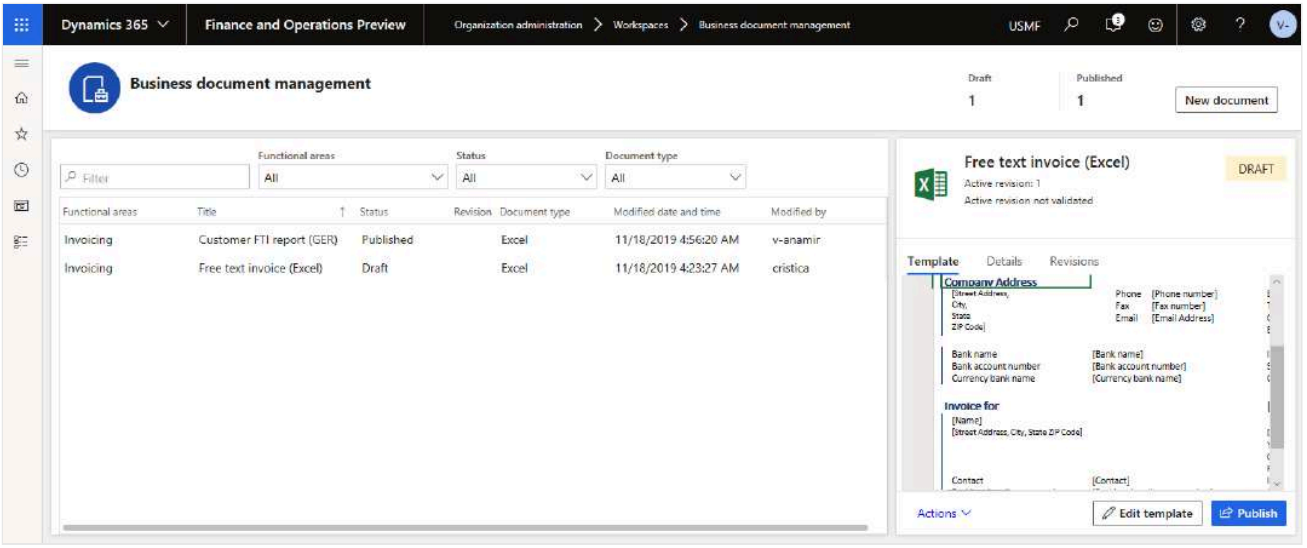
You can use the **New document** button in the **Business document management** workspace to create and edit a template in an Electronic reporting (ER) format configuration that another provider provides and that is located in the current Finance instance. You can also use the **New document** button to upload a new template from an Excel workbook. Additionally, you can use the **New document** button to create and edit a template in an ER format configuration that is stored in the Global repository.

Edit a template that another provider owns

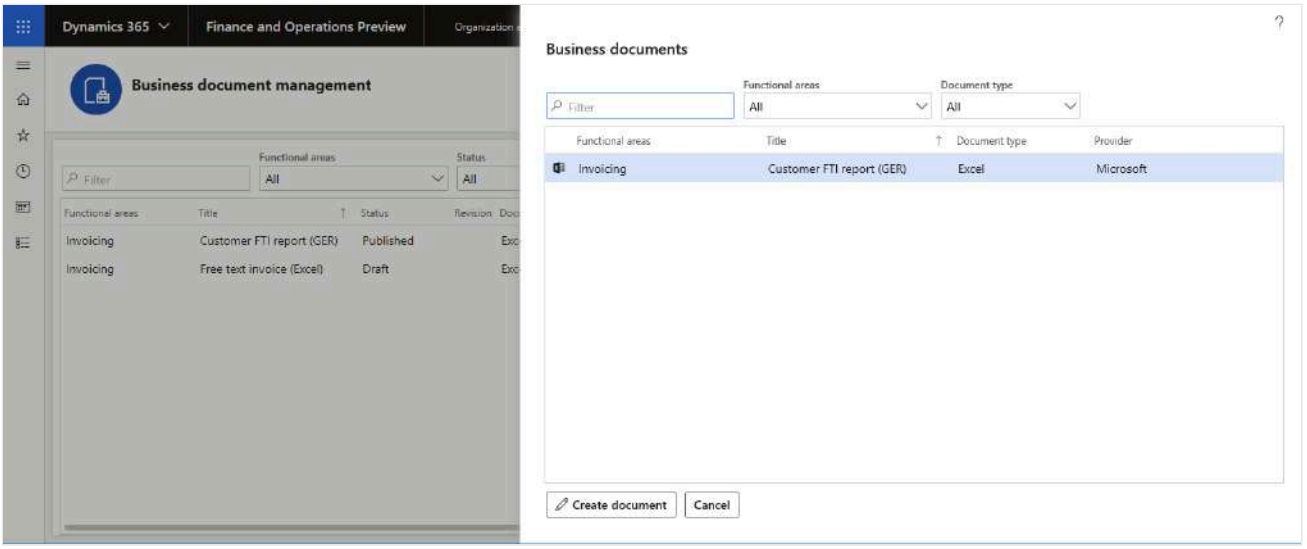
This example shows how to use the **New document** button in the **Business document management** workspace to create and edit a template in an ER format configuration that another provider supplies and that is located in the current Finance instance. In this example, the active provider is Contoso, which uses the ER format configuration that Microsoft provides. After you select **New document**, the **Select** tab on the **Create a new template** page shows all the templates of the current Finance instance that the current provider and other providers own. Select a template to open it. You can then create a new editable copy of the template. The edited template is stored in a new ER format configuration that is automatically generated.

To edit a template that another provider owns, follow these steps:

1. In the **Business document management** workspace, select **New document**.



2. On the **Create a new template** page, on the **Select** tab, select the document to use as a template, and then select **Create document**.

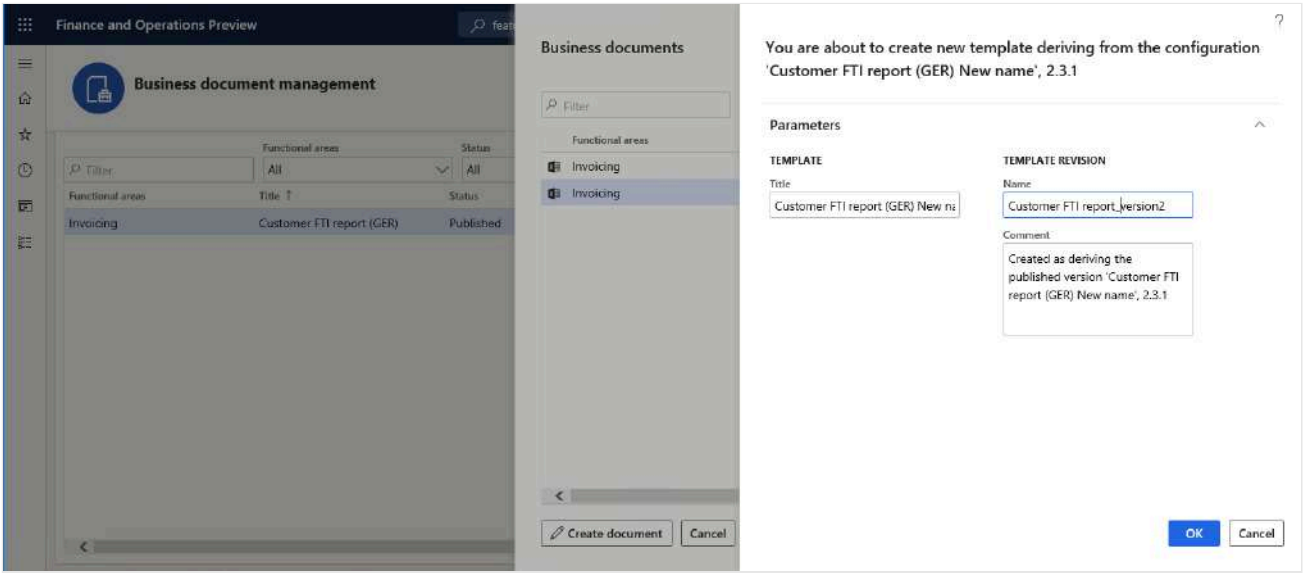


3. In the new dialog box, in the **Title** field, change the title as you require. The title text names the new ER format configuration that is automatically created. The draft version of this configuration (**Customer FTI report (GER) Copy**) contains the edited template and is used to run this ER format for the current user. The original template from the base ER format configuration is used to run this ER format for every other user.

4. In the **Name** field, change the name of the first revision of the editable template that is automatically created.

5. In the **Comment** field, update the remarks for the revision of the editable template that is automatically created.

6. Select **OK** to confirm the start of the editing process.



Upload a template that uses an existing Excel workbook

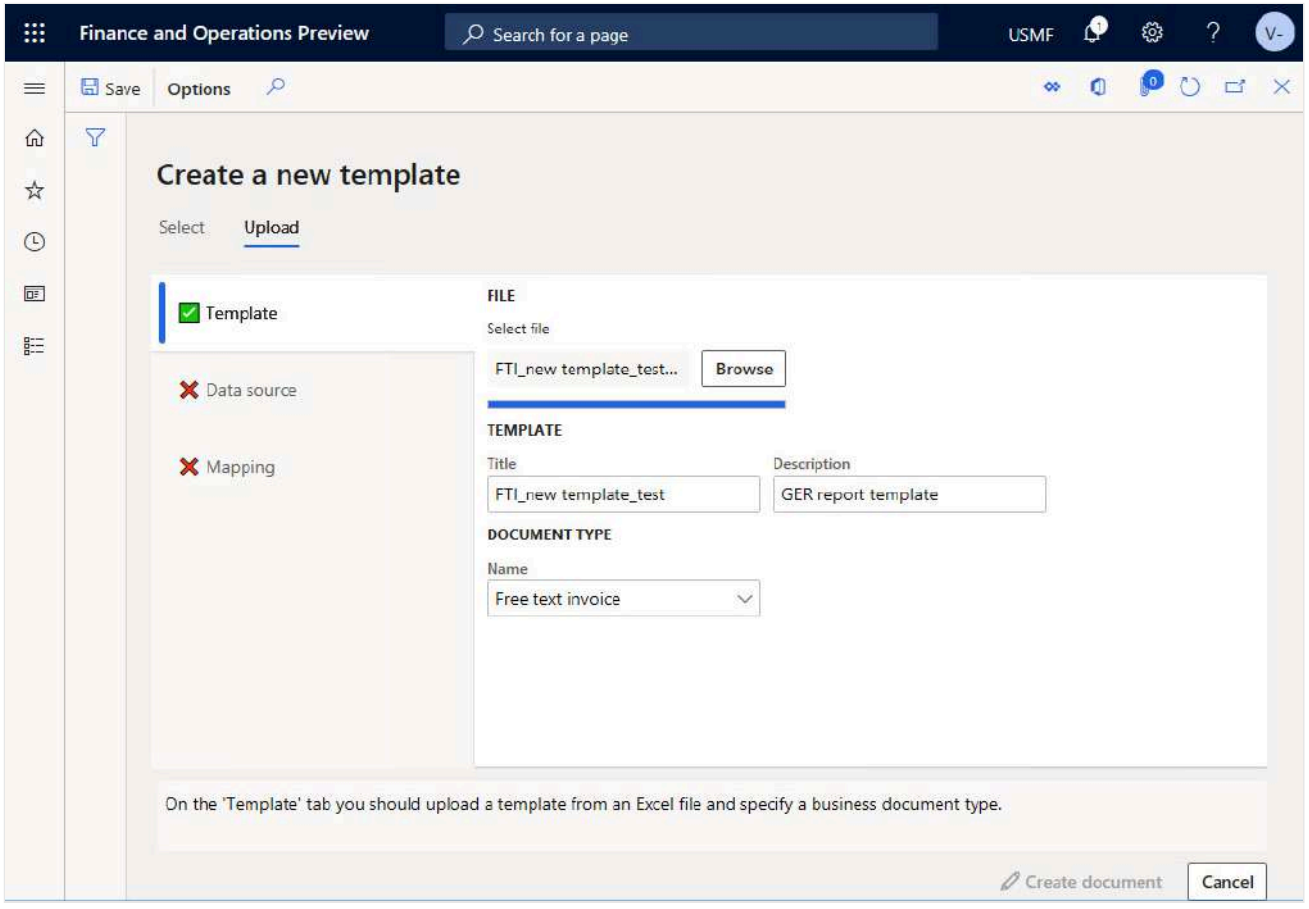
This example shows how to use the **New document** button in the **Business document management** workspace to create and edit a template in an ER format configuration, based on the available Excel workbook. In this example, the active provider is Contoso, and you use the ER data model and ER model mapping configurations that Microsoft provides. After you select **New document**, select the **Upload** tab on the **Create a new template** page. You can specify the details of an Excel workbook upload. When you upload the Excel workbook, the system transforms it into a business document template and opens it for editing. The edited template is stored in a new ER format configuration that the system automatically generates.

To provide the required information before you upload a template, follow these steps:

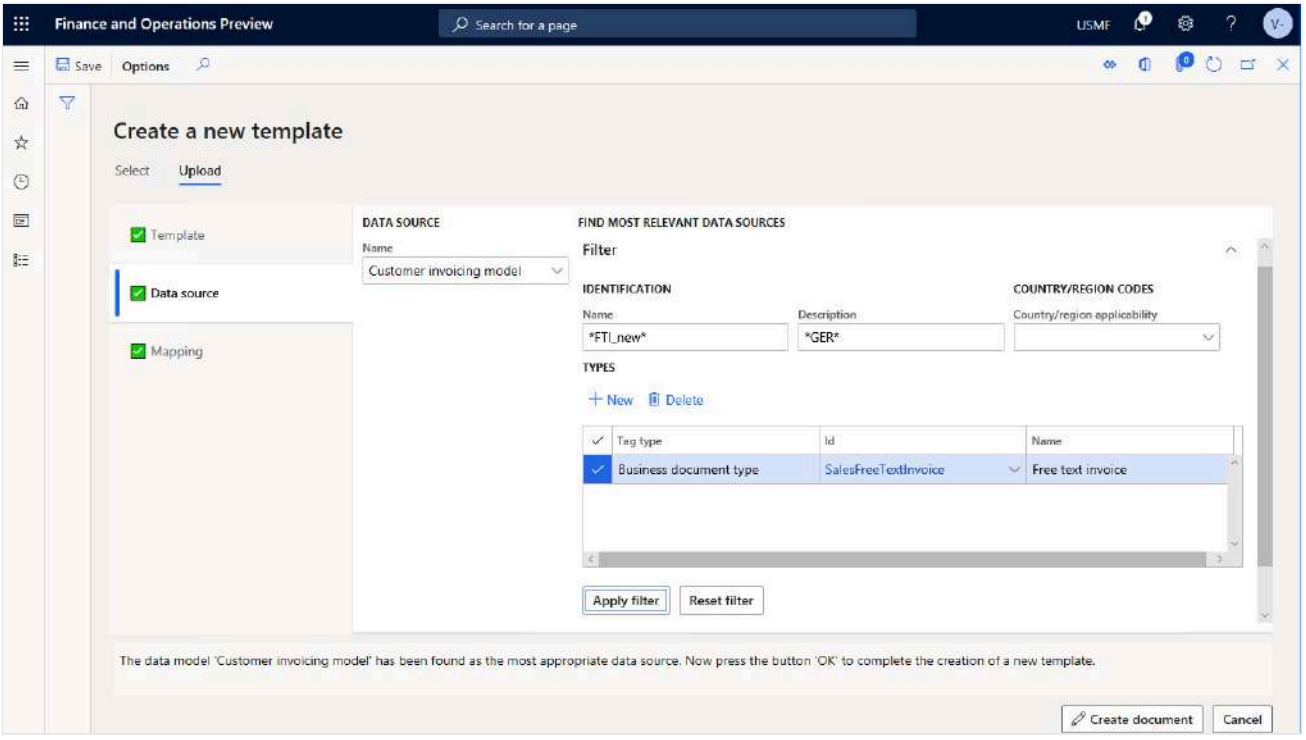
1. In the **Business document management** workspace, select **New document**.

2. On the **Create a new template** page, on the **Upload** tab, on the **Template** tab, select **Browse** to find and select the Excel file that you want to use as a template. In the **Template** section, the **Title** and **Description** fields are automatically filled in. They specify the name and description of the new ER format configuration that the system automatically creates. You can edit these fields as needed.

3. In the **Document Type** section, in the **Name** field, specify the type of business document. This value is used to search the correct data source (that is, the ER model configuration).

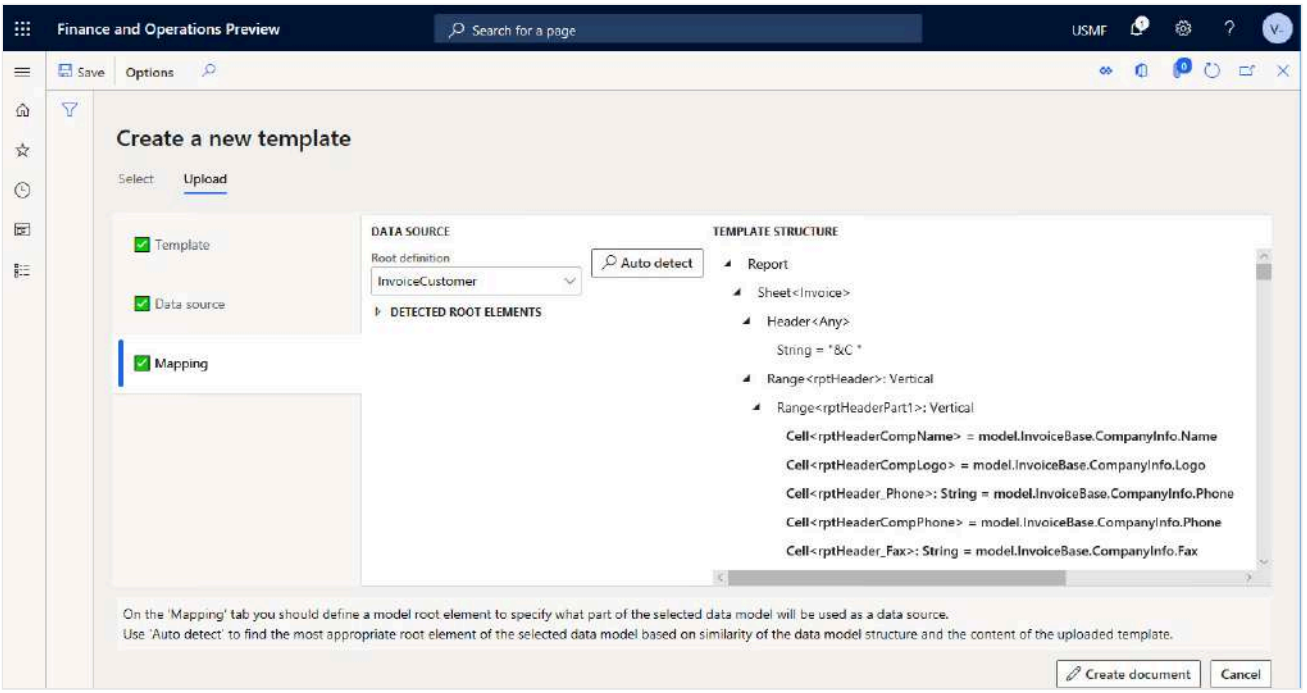


4. On the **Data source** tab, on the **Filter** FastTab, select **Apply filter**. In the **Data source** section, the **Name** field is automatically filled in, or you can manually select a value. You can use the filter to search for the appropriate data source name by name, description, country/region code, and business document type.



> **Note**
>
> Use the **Filter** FastTab to search the correct data source (that is, the ER model configuration). You can edit all filter fields to find the most appropriate data source for the document that you're uploading.
>
> The conditions on the **Filter** FastTab are used as **OR** conditions.

5. On the **Mapping** tab, select **Auto detect**. The **Root definition** field is automatically filled in, or you can manually select a value. This tab shows the end mapping for the elements from the template and the model.



> **Note**
>
> The mapping in the **Template structure** section uses the full match of the labels or descriptions in the data source in the user's language, and in the cell name in the template.

6. Select **Create document** to confirm that you want to create a template and start the editing process.

Learn more in Business document management overview.

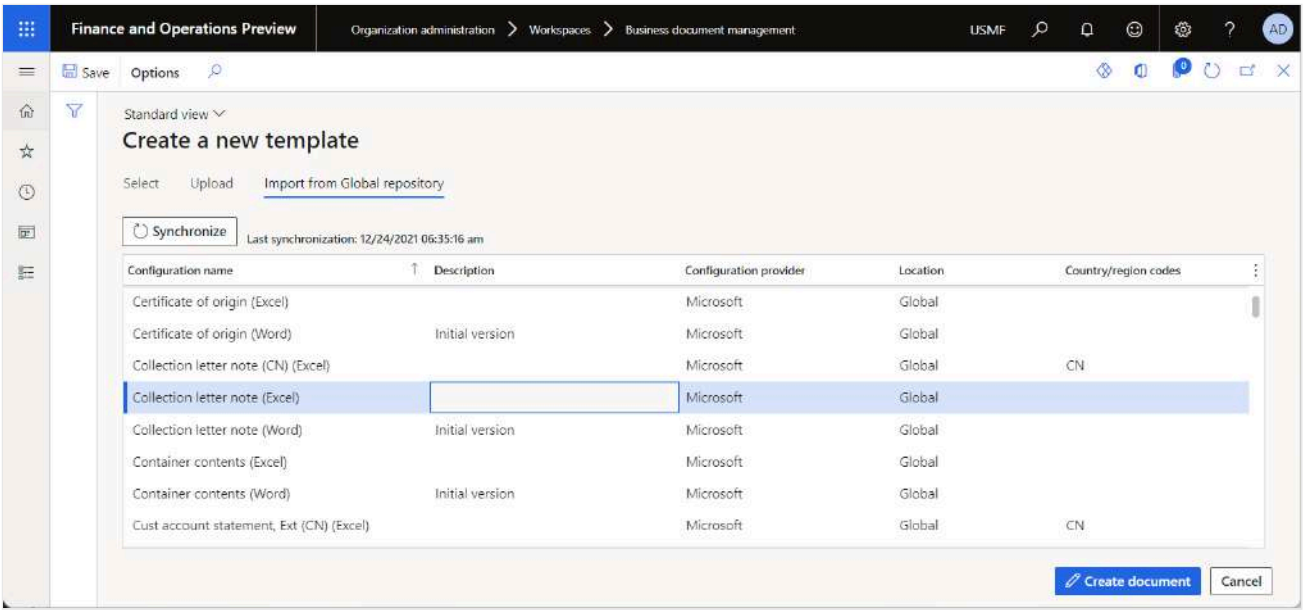
Upload a template from the Dataverse repository

This example shows how to use the **New document** button in the **Business document management** workspace to create and edit a template in an ER format configuration that Microsoft provides and stores in the Microsoft Dataverse repository. In this example, the active provider is Contoso, which uses the ER format configuration that Microsoft provides. After you select **New document**, the **Import from Dataverse repository** tab on the **Create a new template** page shows all the business document templates that are stored in the Dataverse repository but missing in the current Finance instance. After you select a template, you import it from the Dataverse repository into the current Finance instance to create a new editable copy. The edited template is stored in a new ER format configuration that is automatically generated.

To upload a template from the Dataverse repository, follow these steps:

1. In the **Business document management** workspace, select **New document**.

2. On the **Create a new template** page, on the **Import from Dataverse repository** tab, select the document to use as a template, and then select **Create document**.



3. In the message box, select **Yes** to confirm that you want to import the selected document from the Dataverse repository into the current Finance instance. If you're prompted for authorization, follow the on-screen instructions.

4. In the new dialog box, in the **Title** field, change the title as you require. The title text is used to name the new ER format configuration that is automatically created. The draft version of this configuration (**Collection letter note (Excel) Copy**) contains the edited template and is used to run this ER format for the current user. The original template from the base ER format configuration is used to run this ER format for every other user.

5. In the **Name** field, change the name of the first revision of the editable template that is automatically created.

6. In the **Comment** field, update the remarks for the revision of the editable template that is automatically created.

Initiate editing templates owned by your configuration provider

To initiate editing templates owned by your configuration provider, follow these steps:

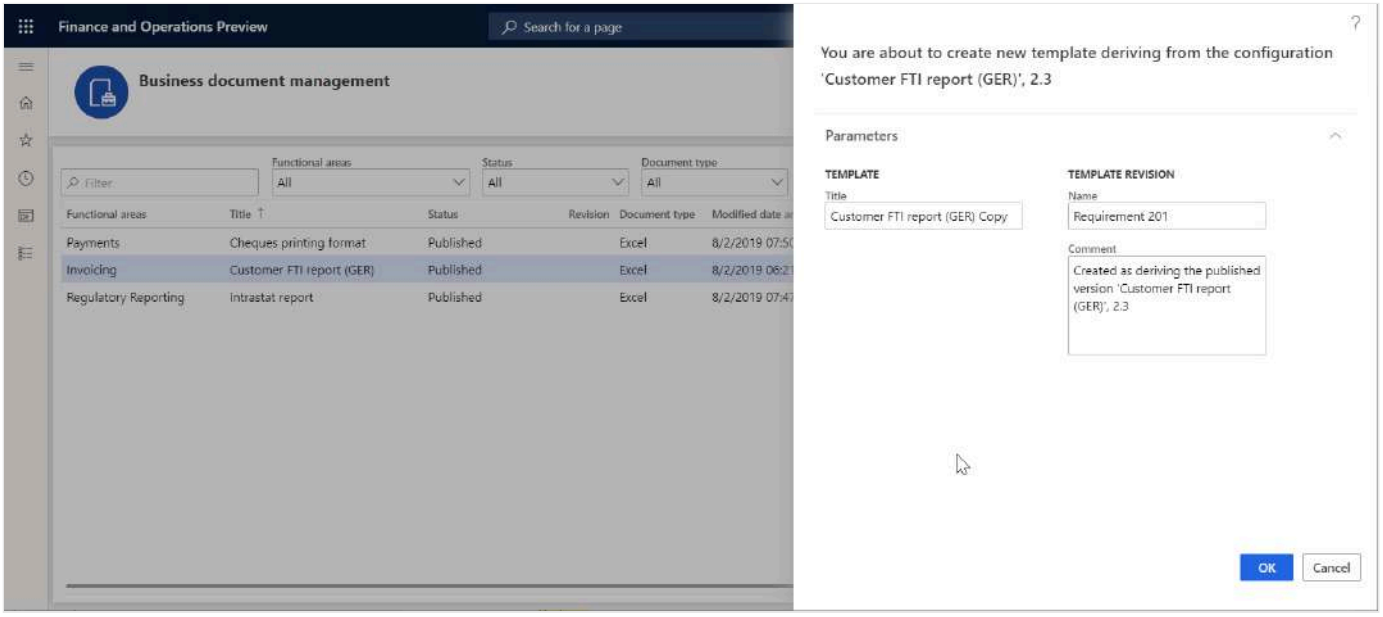
1. In the **Business document management** workspace, select the **Cheques printing format** template in the list.

2. Select the **Details** tab. The **Edit** option is available for the selected template. This option is always available for a template in an ER format configuration that the active ER configuration provider owns. When you select **Edit** for the template, the existing template from the draft version of the underlying ER format configuration is available to edit.

Initiate editing templates owned by other providers

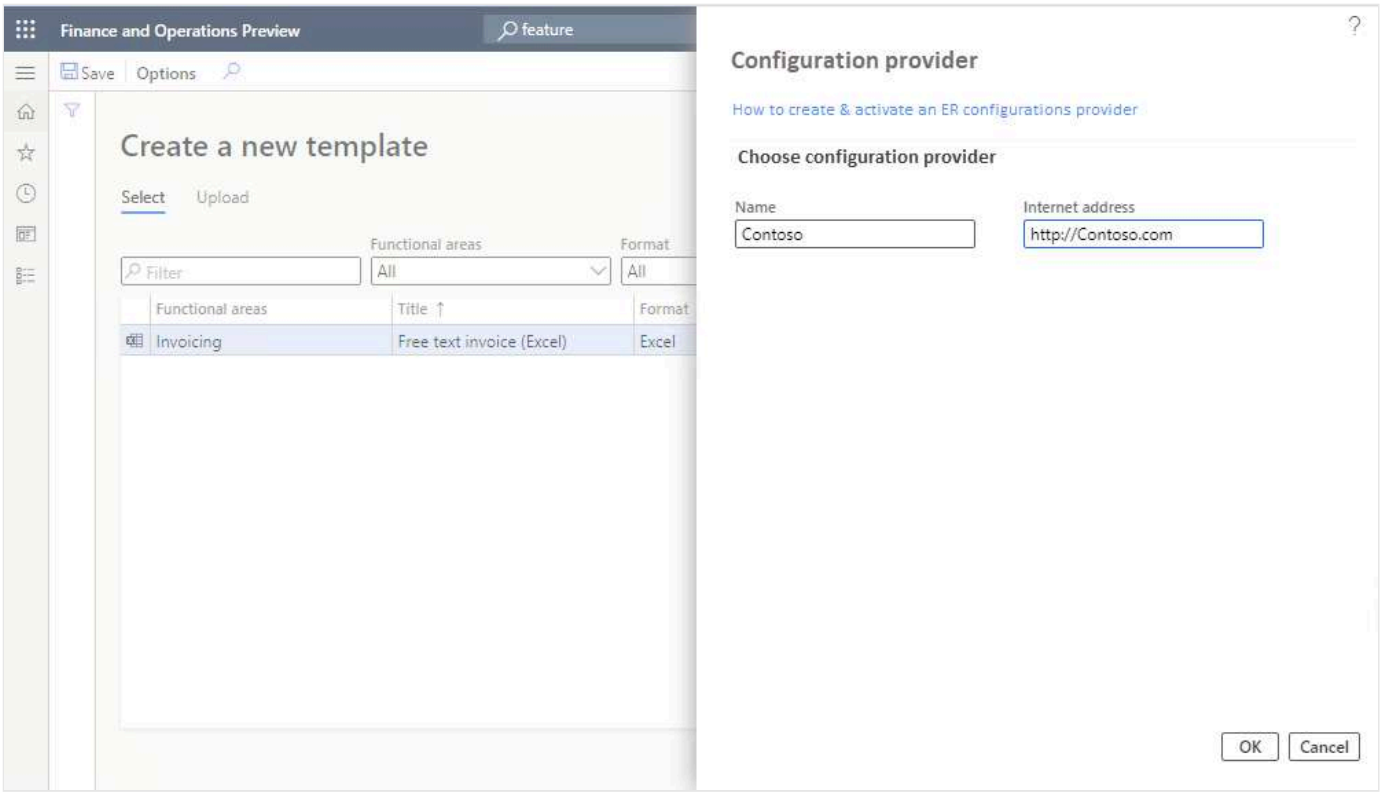
To initiate editing templates owned by other providers, follow these steps:

1. In the **Business document management** workspace, select the document that you want to use as a template.
2. Select **New document**, and in the **Title** field, change the title of the editable template if needed. The text names the ER format configuration that is automatically created. The draft version of this configuration (**Customer FTI report (GER) Copy**) automatically runs this ER format for the current user. At the same time, the non-modified original template from the base ER format configuration runs this ER format for any other user.
3. In the **Name** field, change the name of the first revision of the editable template that you create automatically.
4. In the **Comment** field, change the comment for the automatically created revision of the editable template.
5. Select **OK** to confirm the start of the editing process.

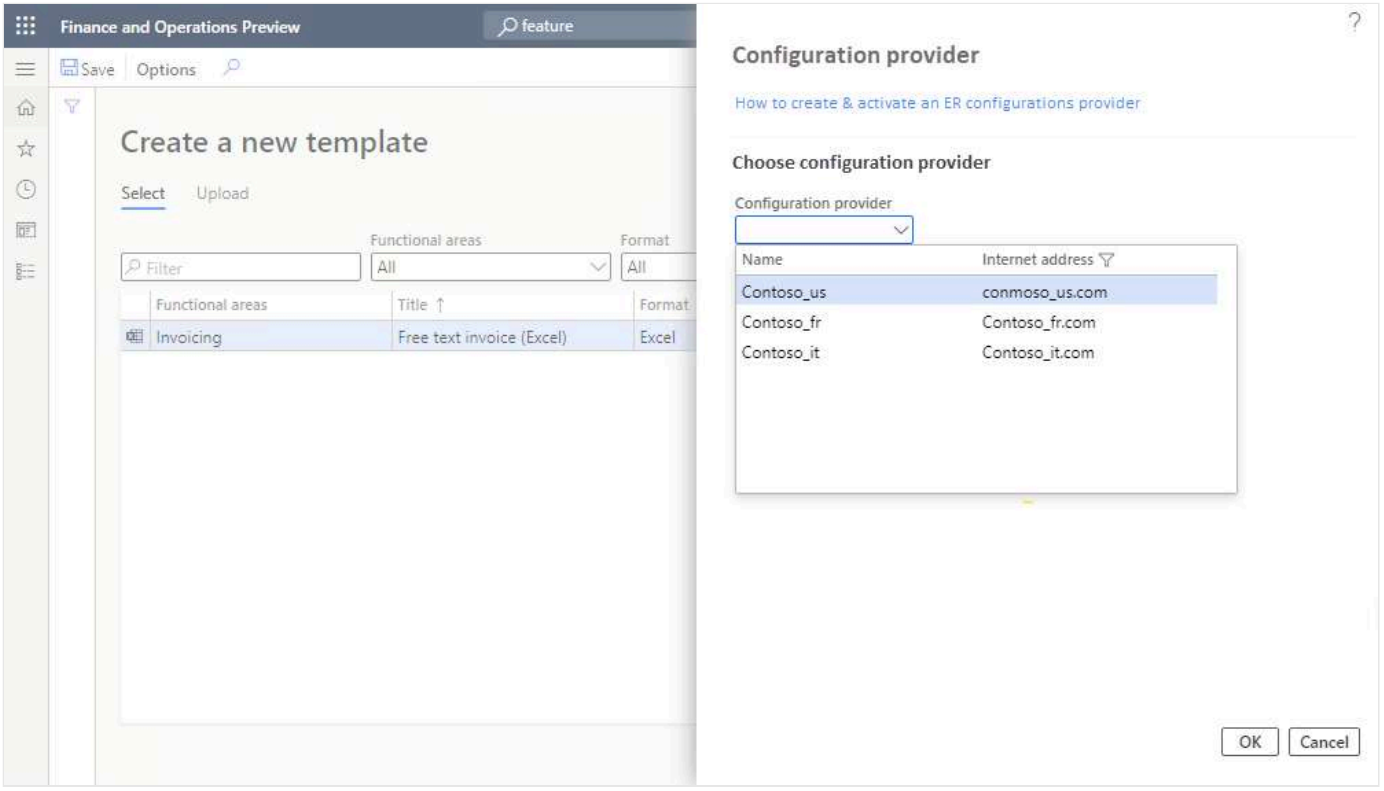


If there's no provider, the system offers to create one. If there's no active provider, the system offers to choose one for activation.

To create a provider, change the name of the provider in the **Name** field, update the internet address of the new provider in the **Internet address** field, and select **OK** to confirm.



To activate an existing provider, choose the name of the provider in the **Configuration provider** field, and select **OK** to set the provider as active.



> **Note**
>
> Each BDM template refers to the provider as the author of the configuration. This is why an active provider is required for the template.

The **New document** option is always available for a template in an ER format configuration provided by current and another provider (Microsoft in this example) that doesn't have any revision. The edited template is stored in a new ER format configuration that is automatically generated.

Start editing a template

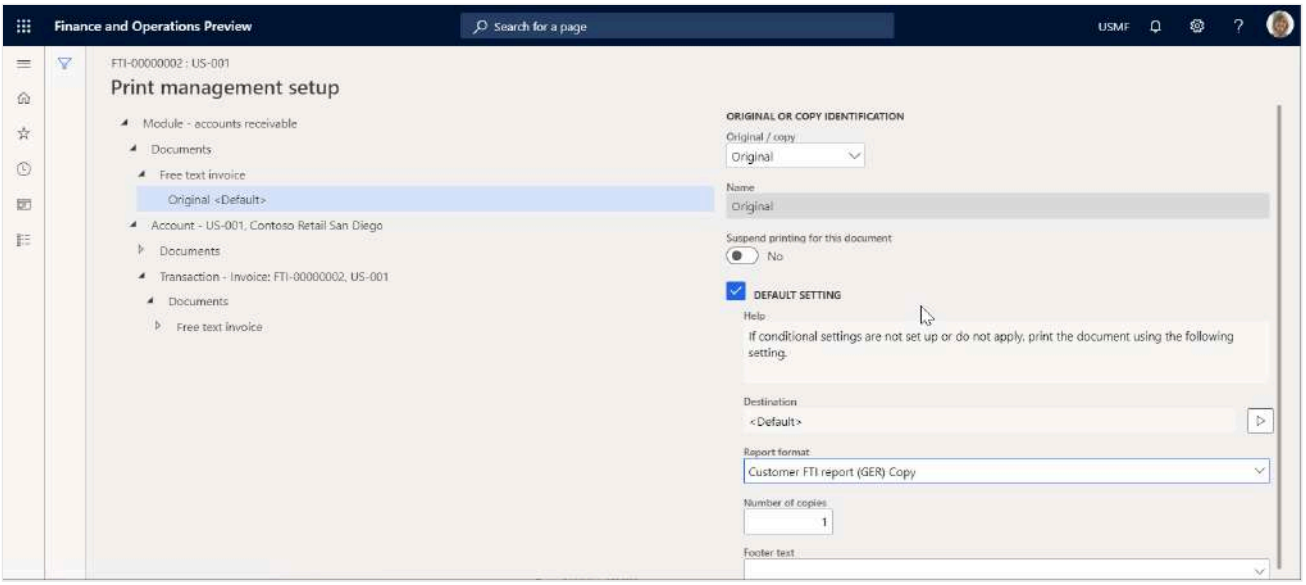
To start editing a template, follow these steps:

1. Select **Edit** from the selected template.
2. In the **Name** field, change the name of the first revision of the editable template that you create automatically.
3. In the **Comment** field, enter a remark for the automatically created revision of the editable template.
4. Select **OK** to confirm the start of the editing process. The selected template is available for online editing by using Microsoft 365. You can modify the template, for example, change the font of the field prompts in the template header from **Regular** to **Bold**.

Test the modified template

To test the modified template, follow these steps:

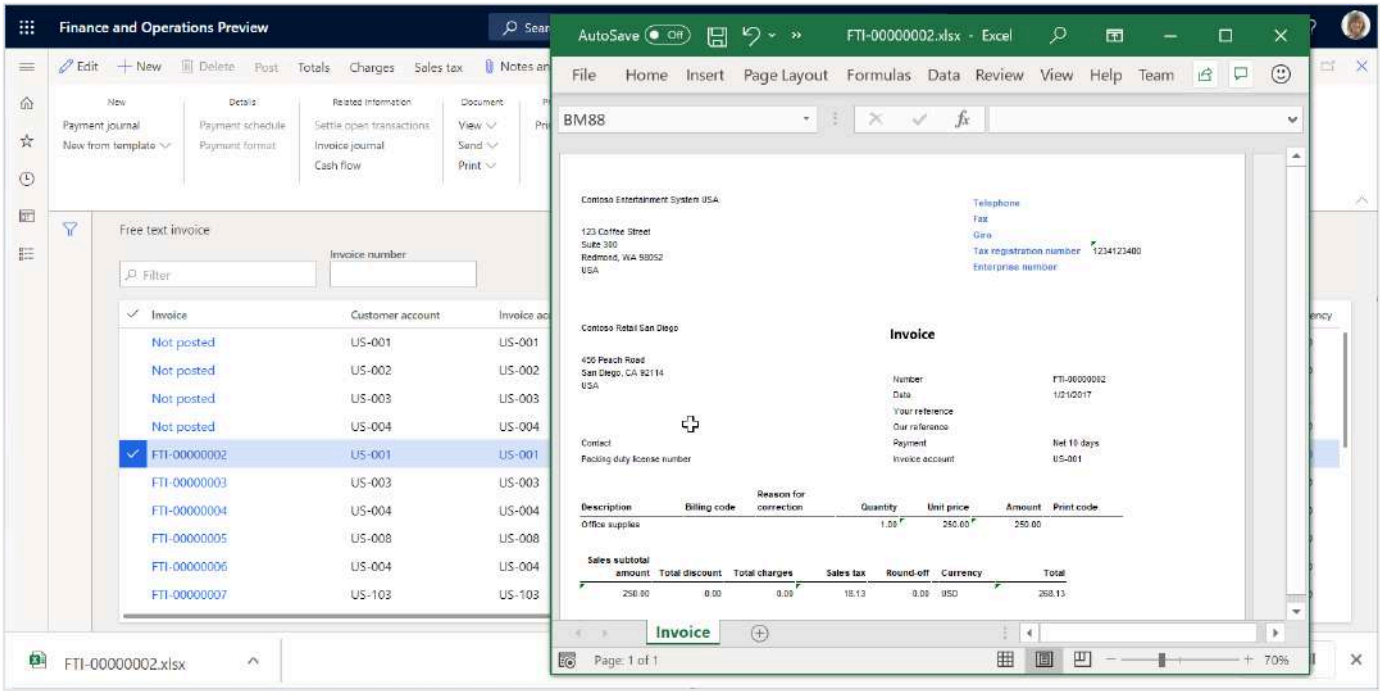
1. In the application, change to the company, **USMF**.
2. Go to **Accounts receivable** > **Invoices** > **All free text invoices**.
3. Select the **FTI-00000002** invoice, and then select **Print management**.
4. Select the **Module - accounts receivable** > **Documents** > **Free text invoice** > **Original document** level to specify the scope of invoices for processing.
5. In the **Report format** field, select the **Customer FTI report (GER) Copy** ER format for the specified document level.



6. Press **Escape** to close the current page.

7. Select **Print**, and then select **Selected**.

8. Download the document and open it by using the Excel desktop application.



The modified template is used to generate the free text invoice report for the selected item. To analyze how this report is affected by the changes that you introduced to the template, you can run this report in one application session right after you modified the template in another application session.

Create an alternative template revision

To create an alternative template revision, follow these steps:

1. Open the **Business document management** workspace and select the **Customer FTI report (GER) Copy** template.
2. On the **Revisions** tab, select **New**.
3. If needed, change the name of the second revision in the **Name** field. Base it on the currently active first revision.
4. If needed, change the remark in the **Comment** field for the automatically created revision of the editable template. You created a new revision of your template that is stored in the permanent template's storage. Now you can continue editing the template of the second revision that is currently selected as active.
5. Select the first revision and then select **Set active**. You can select another revision as active if you want to return to that revision of the template.
6. Select the second revision, and then select **Delete**.
7. Select **OK** to confirm that you want to delete the selected revision. You can delete any of the non-active revisions when they're no longer needed.

Delete a modified template

To delete a modified template, follow these steps:

1. In the **Business document management** workspace, select the **Template** tab.
2. Select **Delete**.
3. If you select **OK** to confirm deletion, the **Customer FTI report (GER) Copy** ER format with the modified template is deleted. Select **Cancel** to explore other options.

Revoke changes of template

To revoke changes of template, follow these steps:

When you edit the template from an ER format that the current active provider owns, the option to revoke changes introduced for the template appears.

1. In the **Business document management** workspace, select the **Template** tab.
2. Select **Undo**.
3. If you select **OK** to revoke the changes introduced for the template, the modified template is replaced by the original template and all changes are removed. When you revoke changes to the template, you can delete the template. Select **Cancel** to explore other options.

Publish a modified template

To publish a modified template, follow these steps:

1. In the **Business document management** workspace, on the **Template** tab, select **Publish**.
2. Select **OK** to confirm publishing. The draft version of the derived **Customer FTI report (GER) Copy** ER format that contains the modified template is marked as completed. The modified template becomes available for other users. The completed versions of this ER format keep only the last active revision of your template. Other revisions are deleted. Select **Cancel** to explore other options.

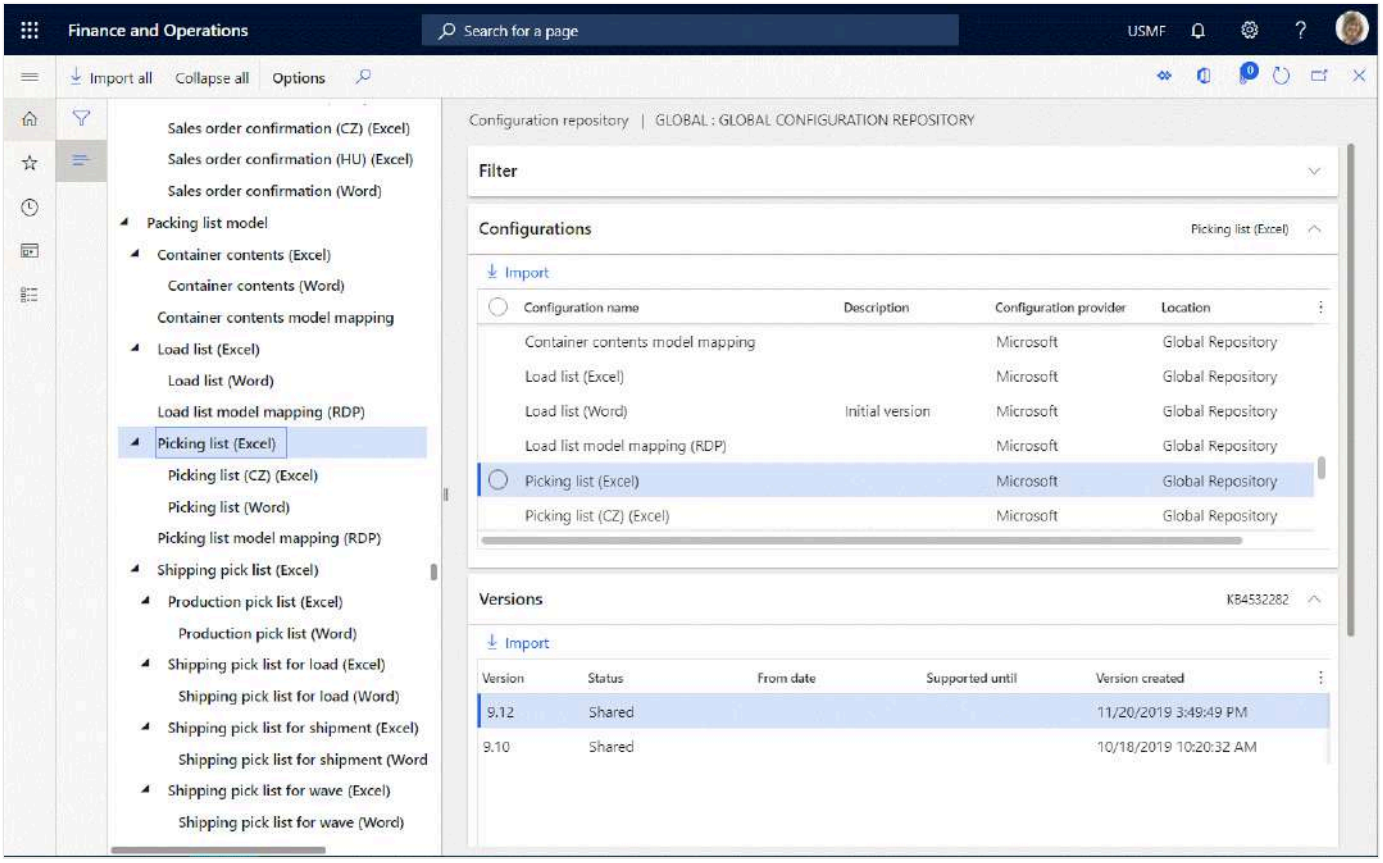
List of configurable business documents

This article provides the list of Electronic reporting (ER) configurations that are released in Dynamics 365 Finance to support configurable business documents.

The list of ER configurations for Finance is updated regularly. Open the configuration repository of Microsoft configuration provider to review the list of ER configurations that are currently supported. You can filter the repository to review the list of ER configurations that support configurable business documents.



The following table shows the list of ER configurations that support configurable business documents and that are released in Finance up until December 2020.

Expand table

Data model configuration	Format configurations
Bill of lading model	Bill of lading (Excel)
	Bill of lading (Word)
Certificate of origin model	Certificate of origin (Excel)

Data model configuration	Format configurations
	Certificate of origin (Word)
Invoice model	Customer Debit and Credit Note (Excel)
	Customer Debit and Credit Note (Word)
	Free text invoice (Excel)
	Free text invoice (Excel) (BH)
	Free text invoice (FR) (Excel)
	Free text invoice (LT) (Excel)
	Free text invoice (LV) (Excel)
	Free text invoice (PL) (Excel)
	Free text invoice (CZ) (Excel)

Extend the list of Electronic reporting (ER) functions

Electronic reporting (ER) expressions support various types of functions for data transformation, including text, date and time, mathematical, logical, information, data type conversion, and other business domain–specific functions. In addition to built-in functions, you can extend the list of available functions in ER. This article provides an overview of key tasks that you must complete to introduce a new function.

> **Important**
>
> In Microsoft Dynamics 365 Finance, Enterprise edition 7.3, extensions of the **ERExpression** class are deprecated. Instead of using extensions of the **ERExpression** class to add custom built-in ER functions, implement your custom logic as public methods of your custom classes. Then, call those methods from ER formats and ER model mappings that configure the required ER data sources of either the ***Class*** type or the ***Object*** type. For more information, see Design ER expressions to call application class methods.

All ER functions in application code are represented as classes that extend the **ERExpression** class. Two types of functions exist:

- **Fixed number of arguments** – These functions are represented by classes that include methods with the prefix **parm** (see **parmInput**, **parmStartNum** in the sample code that follows). The **SysOperationDisplayOrderAttribute** attribute sets the order of arguments.
- **Variable number of arguments** – These functions (see the **ERExpressionGenericCase** class) are represented by classes that implement the **ERIObjectContainer** interface. An additional **Add** method declares the types that a function accepts.

To introduce a new function for ER expressions, follow these steps:

- Select a base class for your function, based on the return value type (see **ERExpressionString** in the sample code that follows).
    - Create a new class that extends the selected class (see **ERExpressionStringMid** in the sample code that follows).
        - Add the required attributes:

        - **SysOperationLabelAttribute** – Defines the function's name.
        - **SysOperationHelpTextAttribute** – Defines the function's Help text.
        - **ERComponentGroupAttribute** – Defines the group that the function belongs to. For more information, see Formula designer in Electronic reporting (ER).

    - Add arguments:
        - For a fixed number of arguments function, add methods with the prefix **parm**, and use the **SysOperationDisplayOrderAttribute** attribute to set the order of the arguments.
        - For a variable number of arguments function, implement the **ERIObjectContainer** interface.

    - Add an evaluation method.

Here's an example.

X++

```
/// <summary>
/// Returns the characters from the middle of a text string, given a starting position
and length.
/// </summary>
[
    SysOperationLabelAttribute ('MID'),
    SysOperationHelpTextAttribute
("@ElectronicReporting:ExpressionStringMidHelpText"),
    ERComponentGroupAttribute ("@ElectronicReporting:String")
]
class ERExpressionStringMid extends ERExpressionString
{
    ERExpressionString input;
    ERExpressionInt startNum;
    ERExpressionInt numChars;
    public str evaluateString(ERIDataContext _dataContext)
    {
        return subStr(
            this.parmInput().evaluateString(_dataContext),
            this.parmStartNum().evaluateInt(_dataContext),
            this.parmNumChars().evaluateInt(_dataContext));
    }
    [DataMemberAttribute, SysOperationLabelAttribute ("@ElectronicReporting:Input"),
SysOperationDisplayOrderAttribute ("1")]
    public ERExpressionString parmInput(ERExpressionString _input = input)
    {
        input = _input;
        return input;
    }
    [DataMemberAttribute, SysOperationLabelAttribute
("@ElectronicReporting:NumChars"), SysOperationDisplayOrderAttribute ("3")]
```

```
    public ERExpressionInt parmNumChars(ERExpressionInt _numChars = numChars)
    {
        numChars = _numChars;
        return numChars;
    }
    [DataMemberAttribute, SysOperationLabelAttribute
("@ElectronicReporting:StartNum"), SysOperationDisplayOrderAttribute ("2")]
    public ERExpressionInt parmStartNum(ERExpressionInt _startNum = startNum)
    {
        startNum = _startNum;
        return startNum;
    }
    public str toString()
    {
        return ERExpressionStringPresenter::namedFunctionToStr(this);
    }
}
```

Suggested guidance

The following guidance helps you design your custom ER functions:

- Reuse the names of Microsoft Excel functions whenever you can, so that ER formulas remain Excel-like. In this way, you keep ER formulas intelligible for end users.
- ER doesn't support list types for primitive data types. Therefore, use a data container list that has a single **Value** item in it.
- Release a new function's list extension as a new application hotfix. ER designers refer to the hotfix number in ER configurations that use that new custom function. Whenever you import a configuration of this type into a new instance, ER evaluates whether the required hotfix is installed, to maintain compliance between the ER configuration and the version that configuration is imported into.

ER framework API changes for Application update 7.3

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how the API of the Electronic reporting (ER) framework is changed in Dynamics 365 Finance, Enterprise edition Application update 7.3.

Two types of changes affect the ER APIs:

- Several X++ classes moved from X++ to an external assembly.
- The rest of X++ classes are internal.

How to access classes that moved from X++ to an external assembly

To access external classes, add the **using** directive to the beginning of your file.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
```

You can then access an external class without any additional changes.

X++

```
var destination = new ERFileDestinationMemory();
```

You can also create an alias for your namespace.

X++

```
using LF = Microsoft.Dynamics365.LocalizationFramework;
```

You can then refer to an external class by using the namespace alias that you created.

X++

```
var destination = new LF.ERFileDestinationMemory();
```

How to access internal X++ objects by using ERObjectsFactory

In Application update 7.3 and later updates, the calling code must access the ER objects by using the methods of the **ERObjectsFactory** class. Several examples of these changes are shown.

Code to display a format mapping lookup

Before application update 7.3

X++

```
// pattern
ERFormatMappingTableLookup::lookupFormatMapping(<form control>, <model name>[,
<data container name>]);
// sample code
ERFormatMappingTableLookup::lookupFormatMapping(_referenceGroupControl,
bankLCMiscChargeReportERModelName);
```

Application update 7.3 and later

X++

```
// pattern
ERObjectsFactory::createFormatMappingTableLookupForControlAndModel(<form control>,
<model name>[, <data container name>]).performFormLookup();
// sample code
ERObjectsFactory::createFormatMappingTableLookupForControlAndModel(_referenceGroupC
ontrol, bankLCMiscChargeReportERModelName).performFormLookup();
```

Code to run a format mapping for data export

Before application update 7.3

X++

```
// pattern
ERFormatMappingRun::constructByFormatMappingId(<format mapping id>, <file name>,
<show prompt dialog>).run();
```

```
// sample code
ERFormatMappingRun::constructByFormatMappingId(erBinding, '', true).run();
```

Application update 7.3 and later

X++

```
// pattern
ERObjectsFactory::createFormatMappingRunByFormatMappingId(<format mapping id>,
<file name>, <show prompt dialog>).run();
// sample code
ERObjectsFactory::createFormatMappingRunByFormatMappingId(erBinding, '',
true).run();
```

Code to run a format mapping for data import

Before application update 7.3

X++

```
// pattern
ERModelMappingDestinationRun::constructByImportFormatMappingId(<mapping id>,
<integration point>).run();
// sample code
ERModelMappingDestinationRun::constructByImportFormatMappingId(custPaymModeTable.ER
ModelMappingTable, CustVendOutPaymConstants::IntegrationPoint).run();
```

Application update 7.3 and later

X++

```
// pattern
ERObjectsFactory::createMappingDestinationRunByImportFormatMappingId(<mapping id>,
<integration point>).run();
// sample code
ERObjectsFactory::createMappingDestinationRunByImportFormatMappingId(custPaymModeTa
ble.ERModelMappingTable, CustVendOutPaymConstants::IntegrationPoint).run();
```

Code to create a browser file destination

Before application update 7.3

X++

```
// sample code
new ERFileDestinationBrowser();
```

Application update 7.3 and later

```
X++
```

```
// sample code
ERObjectsFactory::createFileDestinationBrowser();
```

Code to create an attachment file destination

Before application update 7.3

```
X++
```

```
// pattern
ERFileDestinationAttachment::construct(<record>,
ERDocuManagement::instance().otherDocuType());
// sample code
ERFileDestinationAttachment::construct(_cashRegisterFiscalTrans_W,
ERDocuManagement::instance().otherDocuType());
```

Application update 7.3 and later

```
X++
```

```
// pattern
ERObjectsFactory::createFileDestinationAttachmentWithOtherDocuType(<record>);
// sample code
ERObjectsFactory::createFileDestinationAttachmentWithOtherDocuType(_cashRegisterFis
calTrans_W);
```

Electronic reporting framework API changes for application update 10.0.11

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how the application programming interfaces (APIs) of the Electronic reporting (ER) framework are changed in Microsoft Dynamics 365 Finance version 10.0.11.

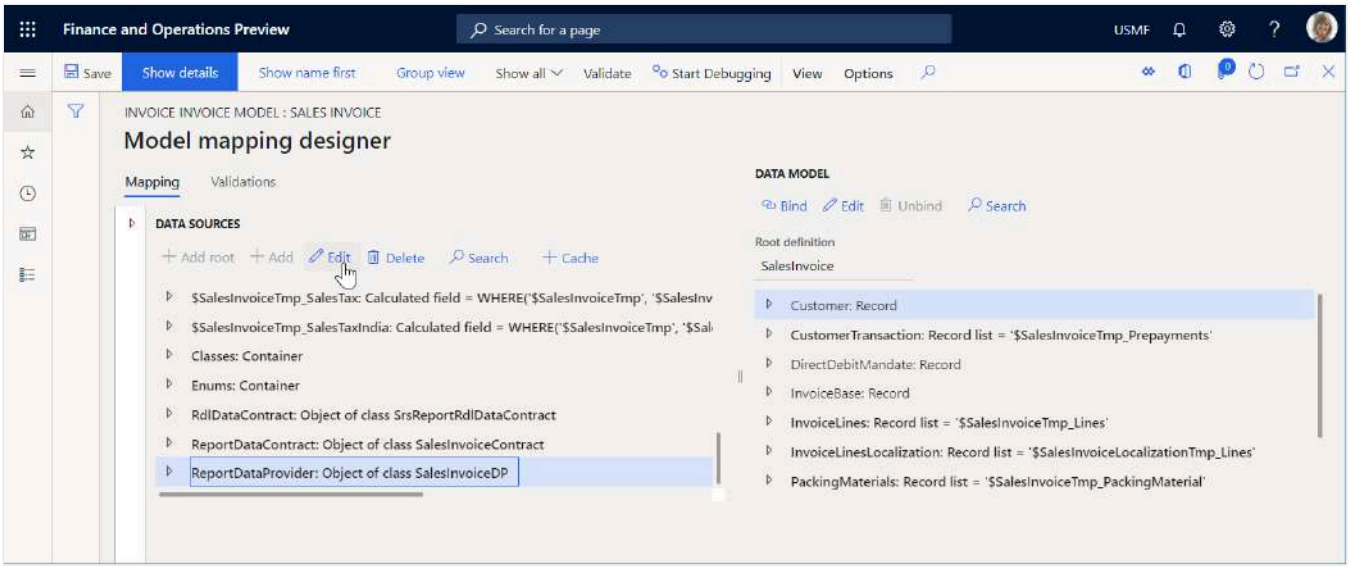
API to run a format mapping for the generation of outbound documents

To generate an outbound document, run an ER format mapping. Most ER format mappings contain a data source of the **Data model** type. At runtime, a specific model mapping must be identified as the implementation of the data model for which the data source is configured.

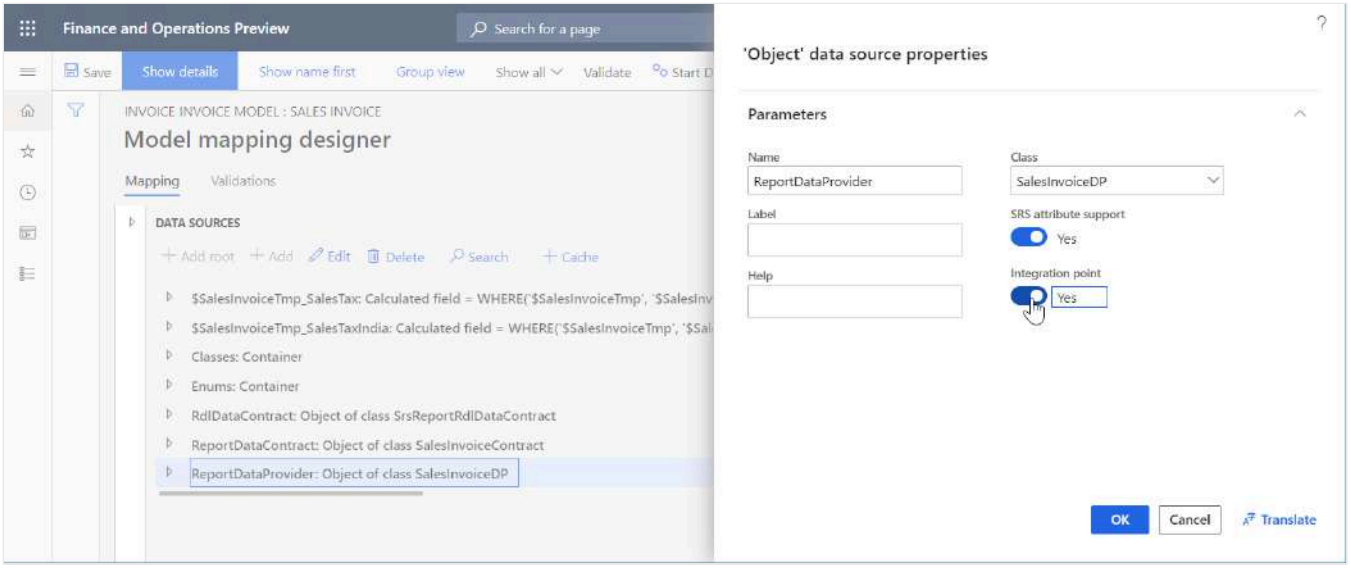
When you use the initial API of the ER framework to call an ER format mapping from an execution point in the source code, the API finds a model mapping by using the settings (the default model mapping flag and country/region codes) of the corresponding ER configurations that contain a model mapping component. For more information, see Configure country/region context dependent ER model mappings.

In some cases, when an ER format mapping is called from a specific place in the X++ code, you must specify additional criteria to find the most appropriate model mapping. For example, you configure an ER format mapping by using a data model that has two model mappings. The first model mapping is marked as a default model mapping, because it ensures the smooth execution of this ER format mapping whenever it's called, from every execution point that's currently available. In X++, you implement a new execution point from which to call this ER format mapping. By using this new execution point, you force the data model to use the second model mapping, because that model mapping performs better given the other conditions of this call (for example, the arguments that are provided and the available resources of the current application instance).

To complete this setup, configure your model mapping with an integration point. In the **Data sources** pane, select a single data source of your model mapping as the component of this integration point. Then select **Edit** to change the properties of this data source.



In the **Data source properties** dialog box, set the **Integration point** option to **Yes** to mark the data source as the component of the integration point.



You can then use the new API of the ER framework to call an ER format mapping and force it to use a model mapping that has a specific integration point. The following example shows how to use this new API.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
using Microsoft.Dynamics365.LocalizationFramework.XppSupportLayer;

class ERIntegrationPointCodeSamples extends RunBaseBatch
{
    private ERFormatMappingId formatMappingId;

    public void run()
    {
        var runner =
ERObjectsFactory::createFormatMappingRunByFormatMappingId(this.formatMappingId,
'OutboundFileName', true);
```

```
        var integration_point = new
ERIntegrationPointFactory().WithObjectIntegrationPoint('SalesInvoiceDP').ToIntegrat
ionPoint();
        /// new
ERIntegrationPointFactory().WithTableRecordsIntegrationPoint(tableName)
        /// new ERIntegrationPointFactory().WithTableIntegrationPoint(tableName)
        /// new ERIntegrationPointFactory().WithObjectIntegrationPoint(className)
        /// new ERIntegrationPointFactory().WithClassIntegrationPoint(className)
        runner.withIntegrationPoint(integration_point).run();
    }
}
```

> ⓘ **Note**
>
> - Only a data source of the **Table record**, **Table**, **Class**, or **Object** type can be the component of the model mapping integration point.
> - Currently, only a single data source can be the component of the model mapping integration point.
> - In addition to other existing criteria, the integration point is considered during the selection of the most appropriate model mapping.
> - At runtime, an error occurs if more than one model mapping that has the requested integration point is found among the model mappings that are applicable to the ER format mapping that is running.

API to show a format mapping lookup

Use the initial API of the ER framework to look up the ER format mappings. It uses the data model name and container name as text constants. This lookup offers only the ER format mappings of the one data model that meets both these conditions:

- It has the specified names.
- Its criteria are met first in the ER configurations list.

The new API of the ER framework lets you use the configured integration point to implement the same lookup. This lookup offers all the ER format mappings that contain a data source of the **Data model** type that a model mapping that has the specified integration point is available for. The ER format mappings that are offered in this lookup can use different model mappings as data sources.

The following example shows how you can use this new API.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
using Microsoft.Dynamics365.LocalizationFramework.XppSupportLayer;

class ERIntegrationPointCodeSamples extends RunBaseBatch
{
    private ERFormatMappingId formatMappingId;

    public void formatMappingLookup(FormReferenceControl _referenceGroupControl)
    {
        var integration_point = new
ERIntegrationPointFactory().WithIntegrationPointKey('SalesInvoiceDP').ToIntegration
Point();
        ERObjectsFactory::createFormatMappingTableLookupForIntegrationPoint(
            integration_point,
            _referenceGroupControl
            ).performFormLookup();
    }
}
```

Electronic reporting framework API changes for Application update 10.0.17

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how the application programming interfaces (APIs) of the Electronic reporting (ER) framework changed in Microsoft Dynamics 365 Finance version 10.0.17.

API to run a format mapping that provides a user action code to run action-dependent destinations

To generate an outbound document, you must run an ER format mapping. When you use the initial API of the ER framework to call an ER format mapping, all destinations configured for components of the format are always run. To review the sample code for a call of this type, see Add a report service class.

X++

```
// Call ER to generate the report.
ERIFormatMappingRun formatMappingRun =
ERObjectsFactory::createFormatMappingRunByFormatMappingId(formatMappingId,
DefaultExportedFileName);
if(formatMappingRun.parmShowPromptDialog(true))
{
    formatMappingRun.withParameter(parameters);
    formatMappingRun.withFileDestination(_contract.getFileDestination());
    formatMappingRun.run();
}
```

In some cases, when an ER format mapping is called from a specific place in the X++ code, you need to specify an action that the user performs by running an ER format so that only action-dependent destinations are run instead of all the ER destinations configured for that format.

For example, you have an ER format that is based on Print management settings. When you call this ER format to preview a generated document, you expect that only the Screen destination is run. However, when you call the same ER format to send a generated document

as the attachment of an outbound email message, you expect that only the Email destination is run.

To achieve these results, you must configure action-dependent ER destinations for the ER format. For more information, see Configure action-dependent ER destinations.

After you complete the configuration, you can use the new API of the ER framework to call an ER format mapping that provides a user action code, which runs only destinations configured for the provided action. The following example shows how you can change the previously mentioned sample code to use this new API to run an ER format that provides the **View** action.

X++

```
// Call ER to generate the report.
ERIFormatMappingRun formatMappingRun =
ERObjectsFactory::createFormatMappingRunByFormatMappingId(formatMappingId,
DefaultExportedFileName);
if(formatMappingRun.parmShowPromptDialog(true))
{
    formatMappingRun.withParameter(parameters);
    formatMappingRun.withFileDestination(_contract.getFileDestination());

    var formatMappingRunWithAction = formatMappingRun as
ERIFormatMappingRunWithDestinationAction;
    formatMappingRunWithAction.withDestinationAction(ERDestinationAction::View);
    formatMappingRun.run();
}
```

> **ⓘ Important**
>
> To set up action-dependent destinations and force the ER framework to use the provided action code, you must first turn on the **Configure specific ER destinations to be used for different PM actions** feature in the Feature management workspace.

Electronic reporting framework API changes for Application update 10.0.19

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how the application programming interfaces (APIs) of the Electronic reporting (ER) framework is changed in Microsoft Dynamics 365 Finance version 10.0.19.

API to extend the list of ER destinations

To implement a custom ER destination, use the `ERIFormatFileDestinationSettings` public interface.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
using Microsoft.Dynamics365.LocalizationFramework.Format.FileGeneration;

using SL = Microsoft.Dynamics365.LocalizationFramework.XppSupportLayer;

/// <summary>
/// Destination settings are required to store settings of a FILE destination type
for the format file component.
/// </summary>
/// <remarks>
/// The implementation object should have static create(container) method for a
proper packing.
/// </remarks>
public interface ERIFormatFileDestinationSettings extends SysPackable
{
    /// <summary>
    /// Determines if current settings are enabled.
    /// </summary>
    /// <returns>True if enabled; otherwise - false.</returns>
    boolean isEnabled()
    {
    }

    /// <summary>
    /// Sets settings enabling state.
    /// </summary>
```

```
    /// <param name = "_value">An enabling state.</param>
    void setEnabled(boolean _value)
    {
    }

    /// <summary>
    /// Gets a name of the destination.
    /// </summary>
    /// <returns>The name.</returns>
    str getName()
    {
    }

    /// <summary>
    /// Creates a file destination for current settings.
    /// </summary>
    /// <param name = "_destinationContext">A destination context.</param>
    /// <param name = "_isGrouped">Determines whether the current file destination
is grouped with others.</param>
    /// <returns>A new instance of a file destination.</returns>
    ERIFileDestination createDestination(ERDestinationExecutionContext
_destinationContext, boolean _isGrouped)
    {
    }

    /// <summary>
    /// Gets a settings key. This key should start with or be an implementation
class name. It should also be persistent and should not be changed over time.
    /// This key will be used to retrieve this type of settings from a settings
storage.
    /// </summary>
    /// <remarks>Examples of good keys: MyCustomDestinationSettings,
MyCustomDestinationSettings#UniqueKey.</remarks>
    /// <returns>The settings key.</returns>
    str getKey()
    {
    }

    /// <summary>
    /// Validates the settings.
    /// </summary>
    void validate()
    {
    }
}
```

This interface lets you offer parameters of a custom destination in the ER destinations dialog box, so that they can be set at design time. The configured destination can then be used at runtime to store generated outbound documents.

To learn more about this interface, see the example in Implement a custom destination for generated documents.

Electronic reporting framework API changes for Application update 10.0.21

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how the application programming interfaces (APIs) of the Electronic reporting (ER) framework changed in Microsoft Dynamics 365 Finance version 10.0.21.

API to enable users to configure ER destinations that are print management record specific

This new API lets you configure ER destinations for a specific type of business document and assign a configured named destination to a print management record. Therefore, you can make ER destinations print management record specific.

X++

```
/// <summary>Class for enabling NamedDestinationFeature for current document type.
</summary>
/// <remarks>To enable the document type you should wrap a
<c>isNamedDestinationEnabledByDocumentType</c> method.</remarks>
public class ERNamedDestinationReportEnabler
{
    /// <summary>Checks that feature enabled for current document type. Make
extension for this method.</summary>
    /// <param name = "_typeId">Print mgmt document type</param>
    /// <returns>True if feature enabled.</returns>
    [Wrappable(true), SuppressBPWarning('BPParameterNotUsed', 'Required by
signature')]
    public static boolean
isNamedDestinationEnabledByDocumentType(PrintMgmtDocumentType _typeId)
    {
        return false;
    }
}
```

API to run a format mapping where the destination that is provided is print management record specific

Use this new API to force ER to deliver generated documents by using a named ER destination.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;

/// <summary>
/// Format mapping run interface to provide an ability to specify destination
preset.
/// </summary>
public interface ERIFormatMappingRunWithNamedDestination
{
    /// <summary>
    /// Sets the named destination to the format mapping run object.
    /// </summary>
    /// <param name = "_destinationNamedId">A rec id of named destination.</param>
    /// <returns>The format mapping run object.</returns>
    ERIFormatMappingRun withDestinationNamed(RefRecId _destinationNamedId)
    {
    }
}
```

Applicability

To set up named destinations and force the ER framework to use the named destination, turn on the **Allow to set up ER destinations per print management item** feature in the Feature management workspace.

Electronic reporting framework API changes for Application update 10.0.23

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how the application programming interfaces (APIs) of the Electronic reporting (ER) framework are changed in Microsoft Dynamics 365 Finance version 10.0.23.

API to extend the list of ER sources of inbound documents

To implement a custom ER source of inbound documents, use the following public interfaces:

- `ERIImportFile`
- `ERIImportFileSourceSettings`
- `ERIImportFileSourceSettingsStorage`

cs

```cs
using Microsoft.Dynamics365.LocalizationFramework.XppSupportLayer;

namespace Microsoft.Dynamics365.LocalizationFramework
{
    /// <summary>
    /// The import file object.
    /// </summary>
    public interface ERIImportFile : ERIFile
    {
        /// <summary>
        /// Gets or sets a file source settings key.
        /// </summary>
        string SourceSettingsKey { get; set; }

        /// <summary>
        /// Sets a file id. File ID should be unique string with max length 300.
        /// </summary>
        string FileId { set; }

        /// <summary>
```

```
        /// Gets or sets a file name. File name with max length 259.
        /// </summary>
        string Name { get; set; }

        /// <summary>
        /// Gets or sets a file created date time.
        /// </summary>
        utcdatetime CreatedDateTime { get; set; }

        /// <summary>
        /// Sets a file modified date time.
        /// </summary>
        utcdatetime ModifiedDateTime { set; }
    }
}
```

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
using System.IO;

/// <summary>
/// Format source settings required to store settings for a specific sources for
the import format.
/// </summary>
/// <remarks>
/// The implementation object should have static create(container) method for a
proper packing.
/// </remarks>
public interface ERIImportFileSourceSettings extends SysPackable
{
    /// <summary>
    /// Gets a name of the source.
    /// </summary>
    /// <returns>The name.</returns>
    str getName()
    {
    }

    /// <summary>
    /// Validates the settings.
    /// </summary>
    /// <returns>True, if validated successful; otherwise - false.</returns>
    boolean validate()
    {
    }

    /// <summary>
    /// Determines if current settings are enabled.
    /// </summary>
    /// <returns>True if enabled; otherwise - false.</returns>
    boolean isEnabled()
    {
    }
```

```
    /// <summary>
    /// Sets settings enabling state.
    /// </summary>
    /// <param name = "_value">An enabling state.</param>
    void setEnabled(boolean _value)
    {
    }

    /// <summary>
    /// Gets a settings key, this key should start with or be an implementation
class name. This key should also be persistent and shouldn't be changed over time.
    /// This key will be used to retrieve this type of settings from a settings
storage.
    /// </summary>
    /// <remarks>Examples of good keys: MyCustomFileSourceSettings,
MyCustomFileSourceSettings#UniqueKey.</remarks>
    /// <returns>The settings key.</returns>
    str getKey()
    {
    }

    /// <summary>
    /// Creates a file source for current settings.
    /// </summary>
    /// <param name = "_fileMask">A file mask.</param>
    /// <returns>A new instance of a file source.</returns>
    ERIFileSource createFileSource(str _fileMask)
    {
    }

    /// <summary>
    /// Post processing for resulted file. An action after file importing.
    /// </summary>
    /// <param name = "_args">Arguments for file post import process.</param>
    void fileImported(ERFileImportedArgs _args)
    {
    }

}
```

X++

```
/// <summary>
/// Provides access to the source settings storage.
/// </summary>
public interface ERIImportFileSourceSettingsStorage
{
    /// <summary>
    /// Adds settings to the format source settings storage.
    /// </summary>
    /// <param name = "_settings">A given settings to add.</param>
    public void addSettings(ERIImportFileSourceSettings _settings)
    {
```

```
    }

    /// <summary>
    /// Gets source settings by the key.
    /// </summary>
    /// <param name = "_key">A given key.</param>
    /// <returns>The source settings.</returns>
    public ERIImportFileSourceSettings getSettingsByKey(str _key)
    {
    }

}
```

These interfaces let you offer custom source parameters in the **ER source settings** dialog box, so that they can be set at design time. The configured source can be used to access, in a configured custom source, inbound documents that must be imported at runtime.

To learn more about this interface, see the example in Implement a custom source of inbound documents.

Electronic reporting framework API changes for Application update 10.0.25

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how the application programming interfaces (APIs) of the Electronic reporting (ER) framework are changed in Microsoft Dynamics 365 Finance version 10.0.25.

API to enable a model mapping to run in batch mode

The initial API of the ER framework lets you run an ER model mapping for data import in interactive mode. To specify an ER format for inbound file parsing and an ER model mapping for application data update, this API uses the format name and the integration point.

The new `ERIModelMappingDestinationWithVirtualSourceRun` public interface of the ER framework lets you run an ER model mapping in batch mode for data import of an inbound file. To provide the file, you can either manually select it in the ER user interface (UI) or provide it programmatically.

The code of the `ERModelMappingDestinationRun` class shows how you can use the new API to include the **Run in the background** tab in the dialog box so that data import can run in batch mode.

X++

```
private ERModelMappingDestinationRunController getControllerInternal()
    {
        if (!controller)
        {
            controller = ERModelMappingDestinationRunController::construct();
            controller.parmShowDialog(showPromptDialog);
            controller.showBatchTab(showPromptDialog && showBatchTab &&
this.isBatchEnabledForFileSource());
            controller.parmDialogCaption(this.getBatchJobCaption());
            controller.parmModelMappingRun(this);
            controller.parmModelDefinitionParameters(parameters);
```

```
            controller.parmHiddenParameters(hiddenParameters);

controller.parmIsImportLoadingFilesFromSource(this.getImportFormatFileSourceContrac
t() != null);
        }
        return controller;
    }

    private boolean isBatchEnabledForFileSource()
    {
        var fileSource = this.getImportFormatFileSourceContract();
        if (ERCast::asAny(fileSource) is
ERImportFormatDatasourceByVirtualFileSourceContract)
        {
            return useVirtualImportFormatSource;
        }
        else
        {
            return ERCast::asAny(fileSource) is
ERImportFormatDatasourceByFileSourceContract;
        }
    }
```

To learn more about this interface, see the examples in Import data from manually selected files in batch mode.

Last updated on 03/17/2026

Specify a custom storage location for generated documents

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The application programming interface (API) of the Electronic reporting (ER) framework lets you extend the list of storage locations for documents that ER formats generate. This article provides an overview of the main tasks you must complete to add a custom storage location.

Prerequisites

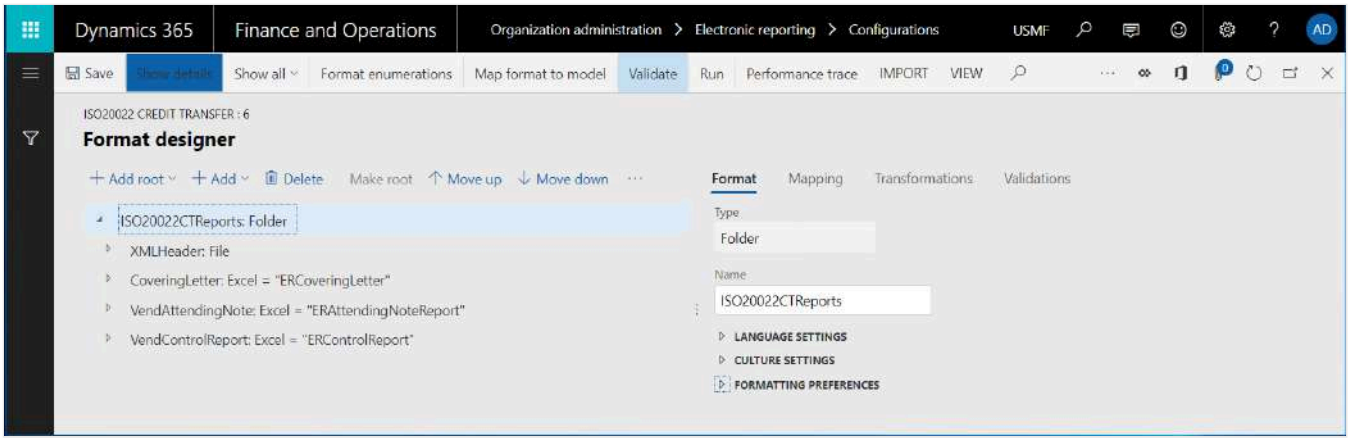
You must deploy a topology that supports continuous build. For more information, see Deploy topologies that support continuous build and test automation. You must have access to this topology for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

You must also have access to the development environment for this topology.

Create or import an ER format configuration

In the current topology, create a new ER format to generate documents that you plan to add a custom storage location for. Alternatively, import an existing ER format into this topology.

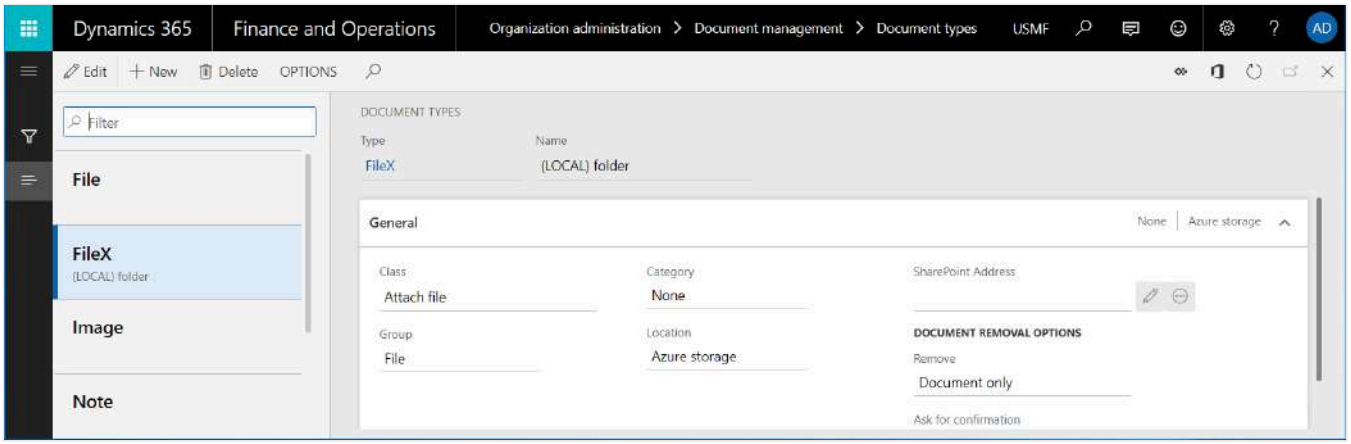


> **Important**
>
> The ER format that you create or import must contain at least one of the following format elements:
>
> - File
> - Folder
> - Merger
> - Attachment

Create a new document type

To specify how to route documents that an ER format generates, configure Electronic reporting (ER) destinations. In each ER destination that you configure to store generated documents as files, specify a document type of the Document management framework. Use different document types to route documents that different ER formats generate.

1. Add a new document type for the ER format that you created or imported earlier. In the following illustration, the document type is **FileX**.
2. To differentiate this document type from other document types, include a specific keyword in its name. For example, in the following illustration, the name is **(LOCAL) folder**.
3. In the **Class** field, specify **Attach file**.
4. In the **Group** field, specify **File**.



> **Note**
>
> Document types are company-specific. To use an ER format with a configured destination in multiple companies, you must configure a separate document type in each company.

Review source code

Review the code of the **insertFile()** method of the **ERDocuManagement** class. Notice that the **AttachingFile()** event is raised while the generated file is attached to a record.

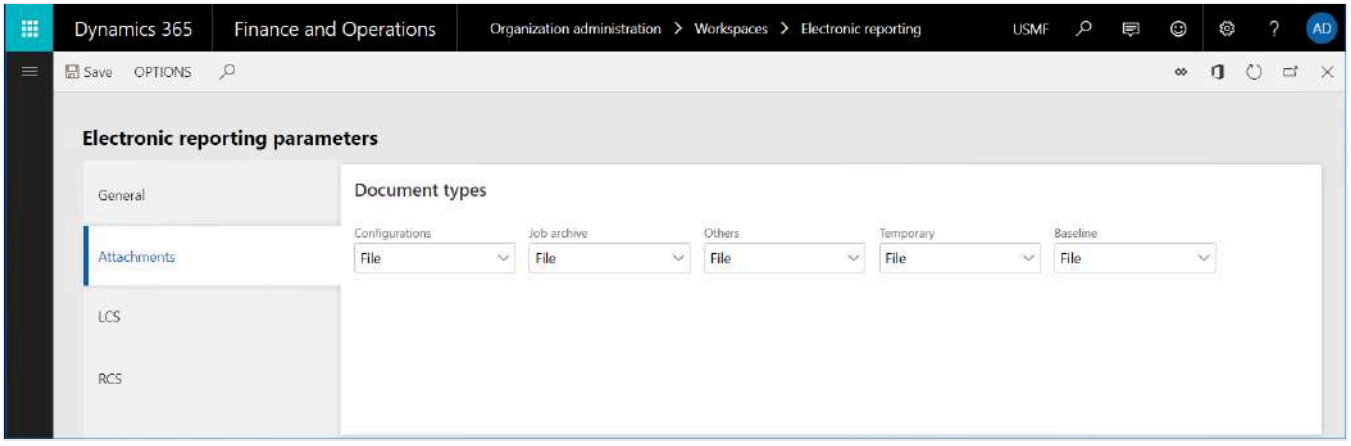
X++

```
/// <summary>
/// Inserts file as attachment in Document Management.
/// </summary>
/// <param name = "_owner">A record as the attachment owner.</param>
/// <param name = "_stream">The file stream.</param>
/// <param name = "_filePath">The file path with name.</param>
/// <param name = "_attachmentName">The name of file attachment.</param>
/// <returns>The reference to inserted file.</returns>
[Hookable(false)]
public DocuRef insertFile(
    Common _owner,
    System.IO.Stream _stream,
    str _filePath,
    str _attachmentName,
    DocuTypeId _docuTypeId)
{
    DocuRef docuRef;
    if (_stream)
    {
        DocuType::createDefaults();
        if (!this.isDocuTypeValid(_docuTypeId))
        {
            throw error(strFmt("@ElectronicReporting:DocuTypeIsNotValid",
_docuTypeId));
```

```
        }
        var args = ERDocuManagementAttachingFileEventArgs::construct(_owner,
_stream, _filePath, _attachmentName, _docuTypeId);
        ERDocuManagementEvents::onAttachingFile(args);
        if (args.isHandled())
        {
            docuRef = args.getDocuRef();
        }
        else
        {
            docuRef = this.attachFile(_owner, _stream, _filePath, _attachmentName,
_docuTypeId);
        }
    }
    return docuRef;
}
```

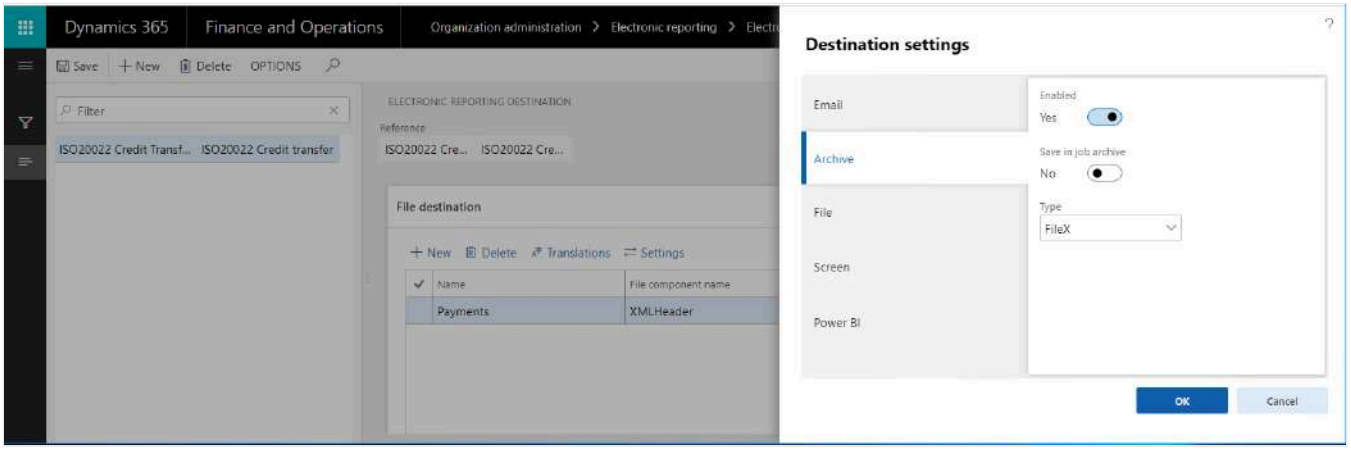
The **AttachingFile()** event is raised when the following ER destinations are processed:

- **Archive** – When you use this destination, a new record for the ER format that runs is created in the ERFormatMappingRunJobTable table. The **Archived** field in this record is set to **False**. If the ER format successfully runs, the generated document is attached to this record, and the **AttachingFile()** event is raised. The document type that is selected in this ER destination determines the storage location for the attached file (Microsoft Azure Storage or a Microsoft SharePoint folder).
- **Job archive** – When you use this destination, a new record for the ER form that runs is created in the ERFormatMappingRunJobTable table. The **Archived** field in this record is set to **True**. If the ER format successfully runs, the generated document is attached to this record, and the **AttachingFile()** event is raised. The document type that is configured in the ER parameters determines the storage location for the attached file (Azure Storage or a SharePoint folder).



Configure an ER destination

1. Configure the archived destination for one of the previously mentioned elements (file, folder, merger, or attachment) of the ER format that you created or imported. For guidance, see ER Configure destinations.
2. Use the document type that you added earlier for the configured destination. (For the example in this article, the document type is **FileX**.)



Modify source code

1. Add a new class to your Microsoft Visual Studio project, and write code to subscribe to the **AttachingFile()** event that was mentioned earlier. (For more information about the extensibility pattern that is used, see Respond by using EventHandlerResult.) For example, in the new class, write code that performs the following actions:
   a. Store generated files in a folder of the local file system of the server that runs the Application Object Server (AOS) service.
   b. Store these generated files only when the new document type (for example, the **FileX** type that has the "(LOCAL)" keyword in its name) is used while a file is attached to the record in the ER execution job log.

X++

```
class ERDocuSubscriptionSample
{
    void new()
    {
    }
    [SubscribesTo(classStr(ERDocuManagementEvents),
    staticDelegateStr(ERDocuManagementEvents,
    attachingFile))]
    public static void
ERDocuManagementEvents_attachingFile(ERDocuManagementAttachingFileEventArgs
_args)
    {
        if (!_args.isHandled())
        {
```

```
            DocuType docuType = DocuType::find(_args.getDocuTypeId());
            if (strContains(docuType.Name, '(LOCAL)'))
            {
                _args.markAsHandled();
                var stream = _args.getStream();
                if (stream.CanSeek)
                {
                    stream.Seek(0, System.IO.SeekOrigin::Begin);
                }
                using (var localStream = System.IO.File::OpenWrite(@'c:\0\' +
_args.getAttachmentName()))
                {
                    stream.CopyTo(localStream);
                }
            }
        }
    }
}
```

2. Rebuild your project.

Run the ER format that you created or imported

1. Execute the ER format that you created or imported.
2. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting jobs**. Find the record that was created for this execution job, and that has the generated file attached to it.
3. Explore the local **C:\0** folder to find same generated file.

> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The application programming interface (API) of the Electronic reporting (ER) framework lets you extend the list of storage locations for documents that ER formats generate. This article explains how to add a custom storage location for generated documents by delegating the task of creating ER destinations to the default destination factory and then implementing a custom class that has its own destination logic.

Prerequisites

Deploy a topology that supports continuous build. For more information, see Deploy topologies that support continuous build and test automation. You must have access to this topology for one of the following roles:

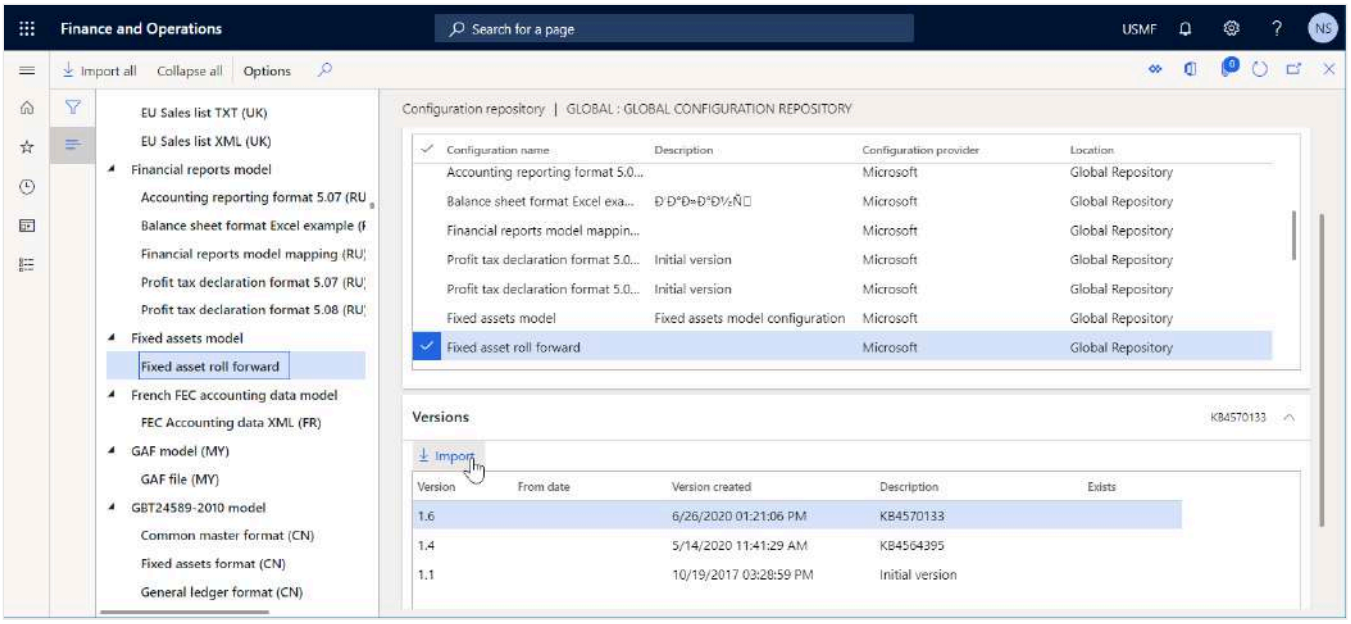
- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

You must also have access to the development environment for this topology.

You can complete all the tasks in this article in the **USMF** company.

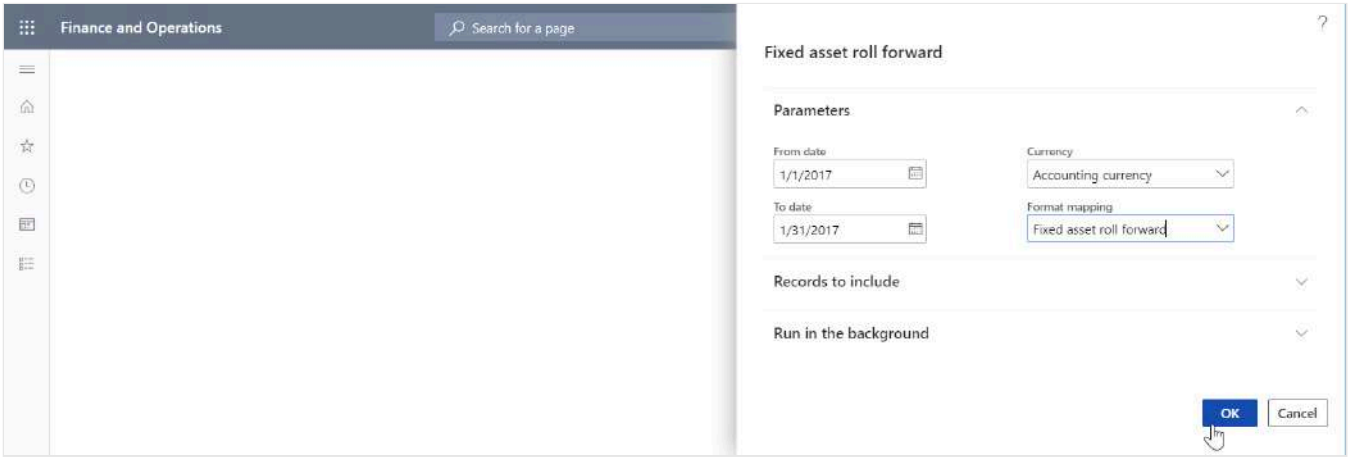
Import the Fixed asset roll forward ER format

To generate the documents that you plan to add a custom storage location for, import the **Fixed asset roll forward** ER format configuration into the current topology.



Run the Fixed asset roll forward report

1. Go to **Fixed assets** > **Inquiries and reports** > **Transaction reports** > **Fixed asset roll forward**.
2. In the **From date** field, enter **1/1/2017** (January 1, 2017).
3. In the **To date** field, enter **1/31/2017** (January 31, 2017).
4. In the **Currency** field, select **Accounting currency**.
5. In the **Format mapping** field, select **Fixed asset roll forward**.
6. Select **OK**.



In Microsoft Excel, review the outbound document that is generated and available for download. This behavior is the default behavior for an ER format that no destinations are configured for, and that is running in interactive mode.

Review the source code

Review the code of the `generateReportByGER()` method of the `AssetRollForwardService` class. Notice that the `Run()` method is used to call the ER framework and generate the **Fixed asset roll forward** report.

X++

```
class AssetRollForwardService extends SysOperationServiceBase
{
    public const str ERFormatModelName = 'Fixed assets';
    public const str ERModelDataSourceName = 'model';
    public const str DefaultExportedFileName = 'AssetRollForward';

    /// <summary>
    /// Generates report by general electronic reporting
    /// </summary>
    /// <param name = "_contract">The Asset Period Statement contract</param>
    public void generateReportByGER(AssetRollForwardContract _contract)
    {
        ERFormatMappingId   formatMappingId;
        AssetRollForwardDP  dataProvider;
        AssetRollForwardTmp assetRollForwardTmp;
        Query               query;

        query = new Query(SysOperationHelper::base64Decode(_contract.parmQuery()));
        dataProvider = AssetRollForwardDP::construct();
        formatMappingId = _contract.parmFormatMapping();
        assetRollForwardTmp = dataProvider.getAssetRollForwardTmp(_contract,
query);

        if (assetRollForwardTmp)
        {
            try
            {
                ERIModelDefinitionParamsAction parameters = new
ERModelDefinitionParamsUIActionComposite()
                    .add(new
ERModelDefinitionDatabaseContext().addTemporaryTable(assetRollForwardTmp))
                    .add(new
ERModelDefinitionObjectParameterAction(ERModelDataSourceName, 'MyParameters',
_contract, true));

                // Call ER to generate the report.

EREObjectsFactory::createFormatMappingRunByFormatMappingId(formatMappingId,
DefaultExportedFileName)
                    .withParameter(parameters)
                    .withFileDestination(_contract.getFileDestination())
                    .run();
            }
            catch
            {
                // An error occurred while exporting data.
                error("@SYP4861341");
```

```
            }
        }
        else
        {
            // There is no data available.
            info("@SYS300117");
        }
    }
}
```

Modify the source code

1. In your Visual Studio project, add a new class (`AssetRollForwardDestination` in this example), and write code to implement your custom destination for **Fixed asset roll forward** reports that are generated.

    - The `new()` method gets the original ER destination object and the application logic–driven parameter that specifies the custom location where generated reports should be stored. In this example, the custom location is the name of a folder on the local file system of the server that runs the Application Object Server (AOS) service.
    - The `saveFile()` method saves a generated document to a folder on the local file system of the server that runs the AOS service.

    X++

```
using Microsoft.Dynamics365.LocalizationFramework;

/// <summary>
/// Destination class for <c>AssetRollForwardDestinationFactory</c> that
stores a generated report.
/// </summary>
public class AssetRollForwardDestination implements ERIFileDestination
{
    private ERIFileDestination originDestination;
    private str TargetFolder;

    /// <summary>
    /// Creates a stream for new file.
    /// </summary>
    /// <param name = "_fileName">Name of a new file.</param>
    /// <returns>Stream for new file.</returns>
    public System.IO.Stream newFileStream(System.String _fileName)
    {
        return originDestination.newFileStream(_fileName);
    }

    /// <summary>
    /// Saves file in destination.
```

```
    /// </summary>
    /// <param name = "_stream">A stream to save.</param>
    /// <param name = "_fileName">A file name.</param>
    /// <returns>Saved stream.</returns>
    public System.IO.Stream saveFile(System.IO.Stream _stream, System.String
_fileName)
    {
        _stream.Seek(0, System.IO.SeekOrigin::Begin);
        using (var localStream = System.IO.File::OpenWrite(TargetFolder +
_fileName))
        {
            _stream.CopyTo(localStream);
        }
        return _stream;
    }

    /// <summary>
    /// Constructs destination for fixed asset roll forward report.
    /// </summary>
    /// <param name = "_originDestination">The original destination.</param>
    /// <param name = "_TargetFoder">The folder to store a report that's being
created.</param>
    /// <returns>The fixed asset roll forward destination.</returns>
    public static AssetRollForwardDestination construct(ERIFileDestination
_originDestination, str _TargetFoder)
    {
        return new AssetRollForwardDestination(_originDestination,
_TargetFoder);
    }

    protected void new(ERIFileDestination _originDestination, str
_TargetFoder)
    {
        originDestination = _originDestination;
        TargetFolder = _TargetFoder;
    }
}
```

2. In your Visual Studio project, add a new class (`AssetRollForwardDestinationFactory` in this example), and write code to set up a custom destination factory that delegates the creation of a destination to the default destination factory, and to wrap a file destination with your own destination.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
using Microsoft.Dynamics365.LocalizationFramework.Format.FileGeneration;

/// <summary>
/// Destination factory for using <c>AssetRollForwardDestinationFactory</c>.
/// </summary>
public class AssetRollForwardDestinationFactory implements
```

```
ERIFileDestinationFactory, ERIFileDestinationFactoryPostProcessor
{
    private ERIFileDestinationFactory originDestinationFactory;
    private str TargetFolder;

    /// <summary>
    /// Creates file destination for print management.
    /// </summary>
    /// <param name = "_fileDestination">A default file destination.</param>
    /// <param name = "_identification">An identification strategy.</param>
    /// <param name = "_rootContext">A root context.</param>
    /// <param name = "_root">A root element.</param>
    /// <returns>A file destination.</returns>
    public ERIDataDrivenFileDestination createPrintMgmtDestination(
        ERIFileDestination _fileDestination,
        ERIObjectIdentificationStrategy _identification,
        ERTextFormatDataContext _rootContext,
        ERTextFormatIFileComponent _root)
    {
        ERIDataDrivenFileDestination dataDrivenDestination =
originDestinationFactory.createPrintMgmtDestination(
            _fileDestination,
            _identification,
            _rootContext,
            _root);

        IFileDestinationHost fileDestinationHost = dataDrivenDestination as
IFileDestinationHost;
        if (fileDestinationHost)
        {
            fileDestinationHost.FileDestination =
AssetRollForwardDestination::construct(
                fileDestinationHost.get_FileDestination(),
                TargetFolder);
        }

        return dataDrivenDestination;
    }

    /// <summary>
    /// Constructs the fixed asset roll forward destination factory.
    /// </summary>
    /// <param name = "_originDestinationFactory">The original destination.
</param>
    /// <param name = "_TargetFolder">The string containing a folder name that
corresponds to the report, that's being created.</param>
    /// <returns>The destination factory for the fixed asset roll forward
report.</returns>
    public static AssetRollForwardDestinationFactory
construct(ERIFileDestinationFactory _originDestinationFactory, str
_TargetFolder)
    {
        AssetRollForwardDestinationFactory destinationFactory = new
AssetRollForwardDestinationFactory(_originDestinationFactory, _TargetFolder);
```

```
        ERIFileDestinationFactoryPostProcessorsHost factoryPostProcessing =
ERCast::asObject(destinationFactory.originDestinationFactory) as
ERIFileDestinationFactoryPostProcessorsHost;

        if (factoryPostProcessing)
        {

factoryPostProcessing.addDestinationPostProcessor(destinationFactory);
        }
        return destinationFactory;
    }

    public ERIFileDestination
processDestinationAfterCreation(ERIFileDestination _sourceDestination)
    {
        return AssetRollForwardDestination::construct(_sourceDestination,
TargetFolder);
    }

    protected void new(ERIFileDestinationFactory _originDestinationFactory,
str _TargetFolder)
    {
        originDestinationFactory = _originDestinationFactory;
        TargetFolder = _TargetFolder;
    }
}
```

3. Modify the existing `AssetRollForwardService` class, and write code to set up a custom destination factory for the report runner. When a custom destination factory is constructed, the application-driven parameter that specifies a target folder is passed. In this way, the target folder stores generated files.

> **Note**
>
> Make sure that the specified folder (**c:\0** in this example) is present in the local file system of the server that runs the AOS service. Otherwise, a DirectoryNotFoundException exception is thrown at runtime.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
/// <summary>
/// The electronic reporting service class for fixed asset roll forward report
/// </summary>
class AssetRollForwardService extends SysOperationServiceBase
{
    public const str ERFormatModelName = 'Fixed assets';
    public const str ERModelDataSourceName = 'model';
```

```
    public const str DefaultExportedFileName = 'AssetRollForward';

    /// <summary>
    /// Generates report by general electronic reporting
    /// </summary>
    /// <param name = "_contract">The Asset Period Statement contract</param>
    public void generateReportByGER(AssetRollForwardContract _contract)
    {
        ERFormatMappingId   formatMappingId;
        AssetRollForwardDP  dataProvider;
        AssetRollForwardTmp assetRollForwardTmp;
        Query               query;

        query = new
Query(SysOperationHelper::base64Decode(_contract.parmQuery()));
        dataProvider = AssetRollForwardDP::construct();
        formatMappingId = _contract.parmFormatMapping();
        assetRollForwardTmp = dataProvider.getAssetRollForwardTmp(_contract,
query);

        if (assetRollForwardTmp)
        {
            try
            {
                ERIModelDefinitionParamsAction parameters = new
ERModelDefinitionParamsUIActionComposite()
                    .add(new
ERModelDefinitionDatabaseContext().addTemporaryTable(assetRollForwardTmp))
                    .add(new
ERModelDefinitionObjectParameterAction(ERModelDataSourceName, 'MyParameters',
_contract, true));

                // Call ER to generate the report.
                ERIFormatMappingRun formatMappingRun =
ERObjectsFactory::createFormatMappingRunByFormatMappingId(formatMappingId,
DefaultExportedFileName);
                formatMappingRun.withParameter(parameters);

formatMappingRun.withFileDestination(_contract.getFileDestination());

                ERIFileDestinationFactoryHost factoryHost =
ERCast::asObject(formatMappingRun) as ERIFileDestinationFactoryHost;
                if (factoryHost)
                {
                    ERIFileDestinationFactory fileDestinationFactory =
factoryHost.getFileDestinationFactory();

factoryHost.setFileDestinationFactory(AssetRollForwardDestinationFactory::cons
truct(fileDestinationFactory, @'c:\0\'));
                    formatMappingRun.run();
                }
            }
            catch
            {
                // An error occurred while exporting data.
```

```
                error("@SYP4861341");
            }
        }
        else
        {
            // There is no data available.
            info("@SYS300117");
        }
    }
}
```

4. Rebuild your project.

Re-run the Fixed asset roll forward report

1. Go to **Fixed assets** > **Inquiries and reports** > **Transaction reports** > **Fixed asset roll forward**.
2. In the **From date** field, enter **1/1/2017**.
3. In the **To date** field, enter **1/31/2017**.
4. In the **Currency** field, select **Accounting currency**.
5. In the **Format mapping** field, select **Fixed asset roll forward**.
6. Select **OK**.
7. Browse the local **C:\0** folder to find the generated file.

> **Note**
>
> Because the `originDestination` object isn't used in the `AssetRollForwardDestination` object in this example, the configurations for the ER format destinations is ignored at runtime.

Implement a custom destination for generated documents

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The application programming interface (API) of the Electronic reporting (ER) framework lets you extend the list of ER destinations that you can use to store documents that ER formats generate. This article provides an overview of the main tasks that you must complete to implement a custom ER destination.

Prerequisites

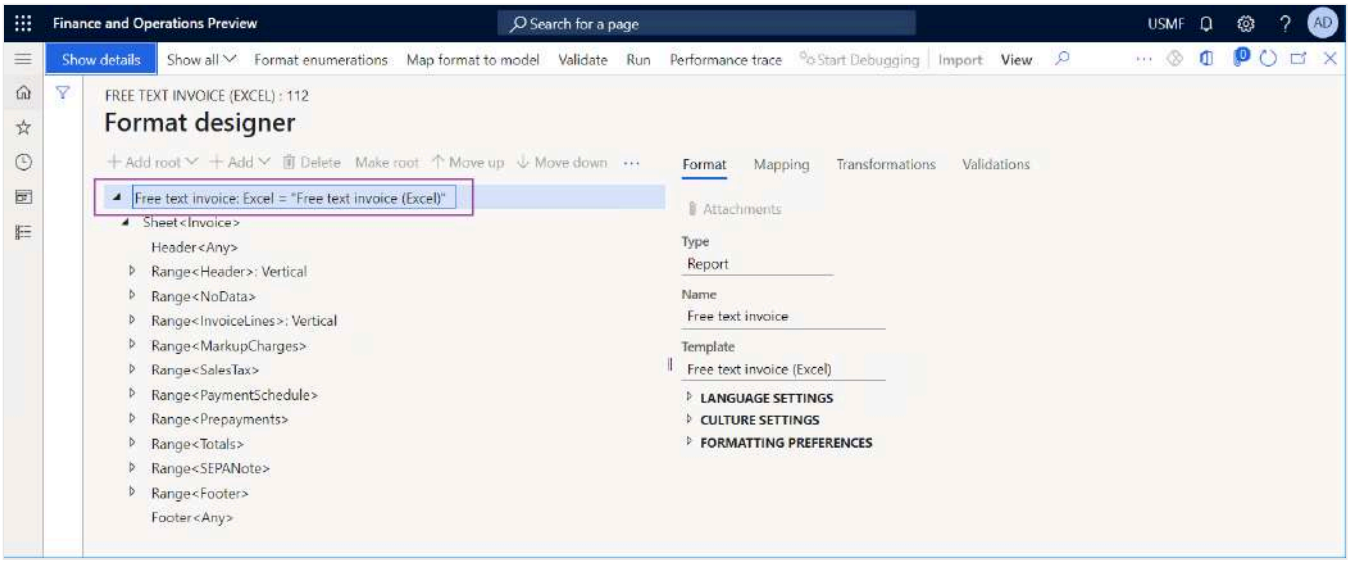
You must deploy a topology that supports continuous build. For more information, see Deploy topologies that support continuous build and test automation. You must have access to this topology for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

You must also have access to the development environment for this topology.

Create or import an ER format configuration

In the current topology, create a new ER format to generate the documents that you plan to store by using a custom ER destination. Alternatively, you can import an existing ER format into this topology.



> **ⓘ Important**
>
> The ER format that you create or import must contain at least one of the following format elements:
>
> - Common\File
> - Common\File attachment
> - Common\Folder
> - Excel\File
> - PDF\Merger
> - PDF\File

Extend the source code

1. Append your Microsoft Visual Studio project with a new class (`ERFileDestinationFolder` in this example), and write code that uses the `ERIFileDestination` public interface to implement your custom destination. In the following example, the class is designed to store generated documents as files in a folder of the local file system.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;

public class ERFileDestinationFolder implements ERIFileDestination
{
    private str folderPath;
    private boolean overwrite;

    public str parmFolderPath(str _value = folderPath)
```

```
    {
        folderPath = _value;
        return folderPath;
    }

    public boolean parmOverwrite(boolean _value = overwrite)
    {
        overwrite = _value;
        return overwrite;
    }

    [Hookable(false)]
    public System.IO.Stream saveFile(System.IO.Stream _stream, str _filePath)
    {
        this.sendFileToFolder(_stream,
System.IO.Path::GetFileName(_filePath));
        return _stream;
    }

    [Hookable(false)]
    public System.IO.Stream newFileStream(str _filePath)
    {
        return new System.IO.MemoryStream();
    }

    private str getFileName(str _fileName)
    {
        if (overwrite)
        {
            return _fileName;
        }
        System.DateTime now = DateTimeUtil::utcNow();
        return strFmt('%1_%2%3',
System.IO.Path::GetFileNameWithoutExtension(_fileName), now.ToString('yyyy-M-
d_HH_mm_ss'), System.IO.Path::GetExtension(_fileName));
    }

    private void sendFileToFolder(System.IO.Stream _stream, str _fileName)
    {
        var resultPath = System.IO.Path::Combine(this.folderPath,
this.getFileName(_fileName));
        using(var fileStream = System.IO.File::Create(resultPath))
        {
            if( _stream.CanSeek)
            {
                _stream.Seek(0, System.IO.SeekOrigin::Begin);
            }
            _stream.CopyTo(fileStream);
        }
    }

    /// <summary>
    /// Finalizes files processing.
    /// </summary>
    [Hookable(false)]
```

```
    public void finalize()
    {
    }
}
```

2. Add a new class to your Visual Studio project (`ERFormatDestinationSaveInFolderSettings` in this example) to use the `ERIFormatFileDestinationSettings` public interface to write code that specifies how a custom destination is created, how its parameters are packed for storage, and how its parameters are unpacked for presentation in the user interface (UI).

X++

```
using Microsoft.Dynamics365.LocalizationFramework;

public class ERFormatDestinationSaveInFolderSettings implements
ERIFormatFileDestinationSettings
{
    internal const str SettingsKey =
classStr(ERFormatDestinationSaveInFolderSettings);
    public const int CurrentVersion = 1;

    private boolean isEnabled;
    private boolean overwrite;
    private str folderPath;

    [Hookable(false)]
    public str parmFolderPath(str _value = folderPath)
    {
        folderPath = _value;
        return folderPath;
    }

    [Hookable(false)]
    public boolean parmIsEnabled(boolean _value = isEnabled)
    {
        isEnabled = _value;
        return isEnabled;
    }

    [Hookable(false)]
    public boolean parmOverwrite(boolean _value = overwrite)
    {
        overwrite = _value;
        return overwrite;
    }

    [Hookable(false)]
    public void setEnabled(boolean _value)
    {
        isEnabled = _value;
```

```
    }

    [Hookable(false)]
    public boolean isEnabled()
    {
        return isEnabled;
    }

    [Hookable(false)]
    public str getName()
    {
        return 'Save in folder';
    }

    [Hookable(false)]
    public void validate()
    {
    }

    [Hookable(false)]
    public ERIFileDestination createDestination(ERDestinationExecutionContext
_destinationContext, boolean _isGrouped)
    {
        ERFileDestinationFolder ret = new ERFileDestinationFolder();
        ret.parmFolderPath(this.parmFolderPath());
        ret.parmOverwrite(this.parmOverwrite());
        return ret;
    }

    [Hookable(false)]
    public str getKey()
    {
        return SettingsKey;
    }

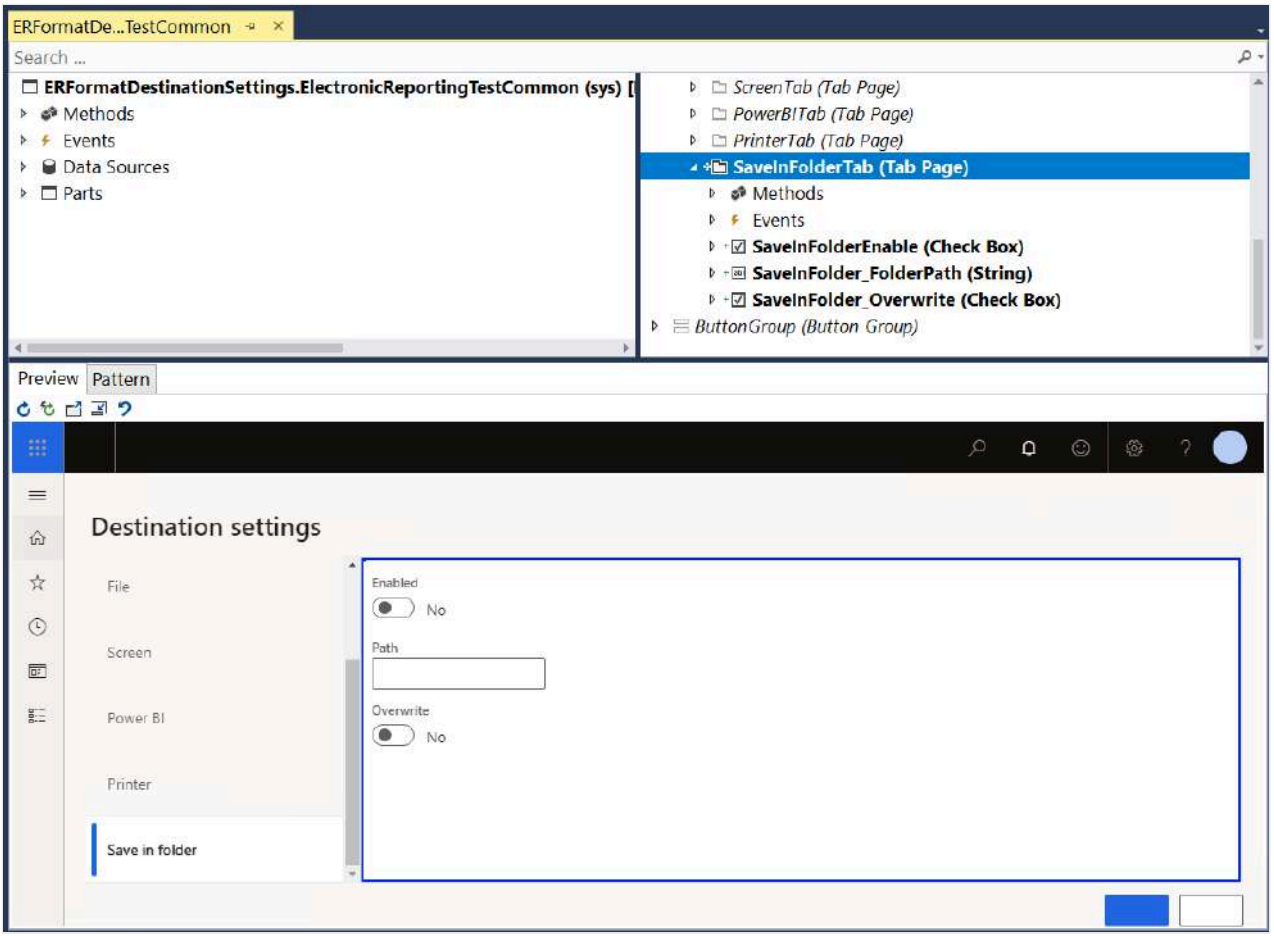
    [Hookable(false)]
    public container pack()
    {
        return [CurrentVersion, isEnabled, folderPath];
    }

    [Hookable(false)]
    public boolean unpack(container packedClass)
    {
        int version = RunBase::getVersion(packedClass);
        switch (version)
        {
            case CurrentVersion:
                [version, isEnabled, folderPath] = packedClass;
                return true;
            default:
                return false;
        }
    }
```

```
    /// <summary>
    /// Creates a new instance of an objected from a packed class container.
    /// </summary>
    /// <param name = "_packedClass">A packed class container.</param>
    /// <returns>The new instance of an object.</returns>
    public static ERFormatDestinationSaveInFolderSettings create(container
_packedClass)
    {
        var ret = new ERFormatDestinationSaveInFolderSettings();
        ret.unpack(_packedClass);
        return ret;
    }
}
```

> **Note**
>
> In the preceding code, the `ERFormatDestinationSaveInFolderSettings` class is introduced as the `static` class. The implementation object should have a `static create(container)` method that creates an object and unpacks the container that the object requires for a correct pack-unpack process. For more information, see Pack-Unpack Design Pattern.

3. In your Visual Studio project, add a new extension for the `ERFormatDestinationSettings` form, and write code that implements a custom UI for your custom destination. The following illustration shows what this UI looks like in the Visual Studio designer.



4. Add another new class (`ERFormatDestinationSettingsEventHandlers` in this example) to your Visual Studio project, and write the event handler code for an extended destination form. This step requires that the public `ERIFormatFileDestinationSettingsStorage` interface be implemented.

X++

```
public class ERFormatDestinationSettingsEventHandlers
{
    [PostHandlerFor(formStr(ERFormatDestinationSettings),
formMethodStr(ERFormatDestinationSettings, init))]
    public static void ERFormatDestinationSettings_Post_init(XppPrePostArgs
args)
    {
        FormRun formRun = args.getThis();
        ERIFormatFileDestinationSettingsStorage settingsStorage =
args.getThis();
        var settings =
ERFormatDestinationSettingsEventHandlers::getSaveInFolderSettings(settingsStor
age);

        FormStringControl folderPathControl =
formRun.design().controlName(formControlStr(ERFormatDestinationSettings,
SaveInFolder_FolderPath));
        folderPathControl.text(settings.parmFolderPath());

        FormCheckBoxControl enabledControl =
```

```
formRun.design().controlName(formControlStr(ERFormatDestinationSettings,
SaveInFolderEnable));
        enabledControl.checked(settings.isEnabled());

        FormCheckBoxControl overwriteControl =
formRun.design().controlName(formControlStr(ERFormatDestinationSettings,
SaveInFolder_Overwrite));
        overwriteControl.checked(settings.parmOverwrite());
    }

    [PreHandlerFor(formStr(ERFormatDestinationSettings),
formMethodStr(ERFormatDestinationSettings, closeOk))]
    public static void ERFormatDestinationSettings_Pre_closeOk(XppPrePostArgs
args)
    {
        FormRun formRun = args.getThis();
        ERIFormatFileDestinationSettingsStorage settingsStorage =
args.getThis();
        var settings =
ERFormatDestinationSettingsEventHandlers::getSaveInFolderSettings(settingsStor
age);

        FormStringControl folderPathControl =
formRun.design().controlName(formControlStr(ERFormatDestinationSettings,
SaveInFolder_FolderPath));
        settings.parmFolderPath(folderPathControl.text());

        FormCheckBoxControl enabledControl =
formRun.design().controlName(formControlStr(ERFormatDestinationSettings,
SaveInFolderEnable));
        settings.setEnabled(enabledControl.checked());

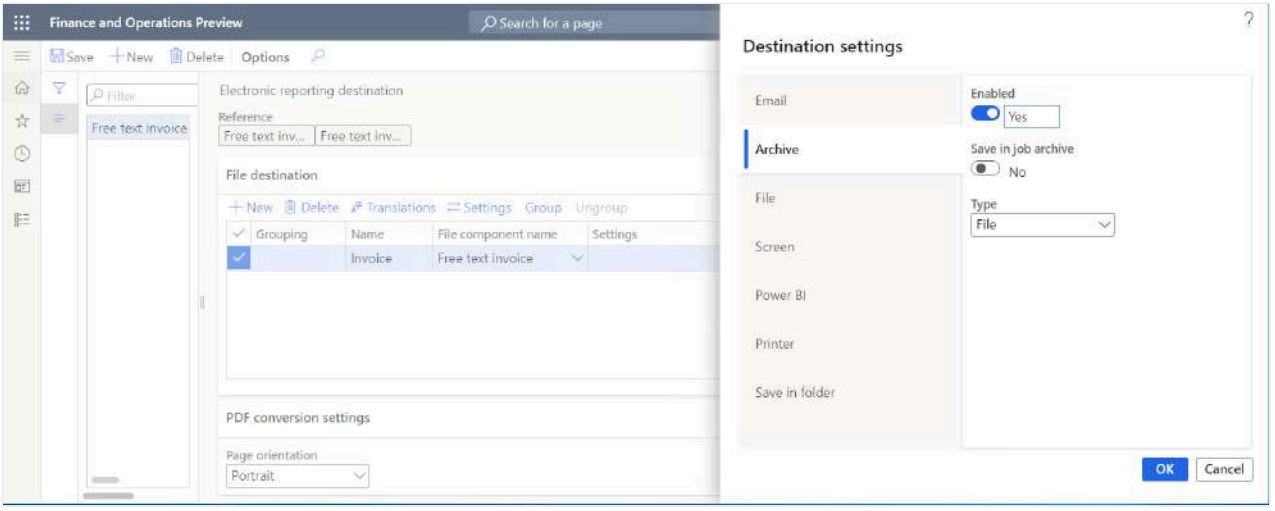
        FormCheckBoxControl overwriteControl =
formRun.design().controlName(formControlStr(ERFormatDestinationSettings,
SaveInFolder_Overwrite));
        settings.parmOverwrite(overwriteControl.checked());
    }

    private static ERFormatDestinationSaveInFolderSettings
getSaveInFolderSettings(ERIFormatFileDestinationSettingsStorage
_settingsStorage)
    {
        ERFormatDestinationSaveInFolderSettings ret =
_settingsStorage.getSettingsByKey(ERFormatDestinationSaveInFolderSettings::Set
tingsKey);
        if (ret == null)
        {
            ret = new ERFormatDestinationSaveInFolderSettings();
            _settingsStorage.addSettings(ret);
        }
        return ret;
    }
}
```

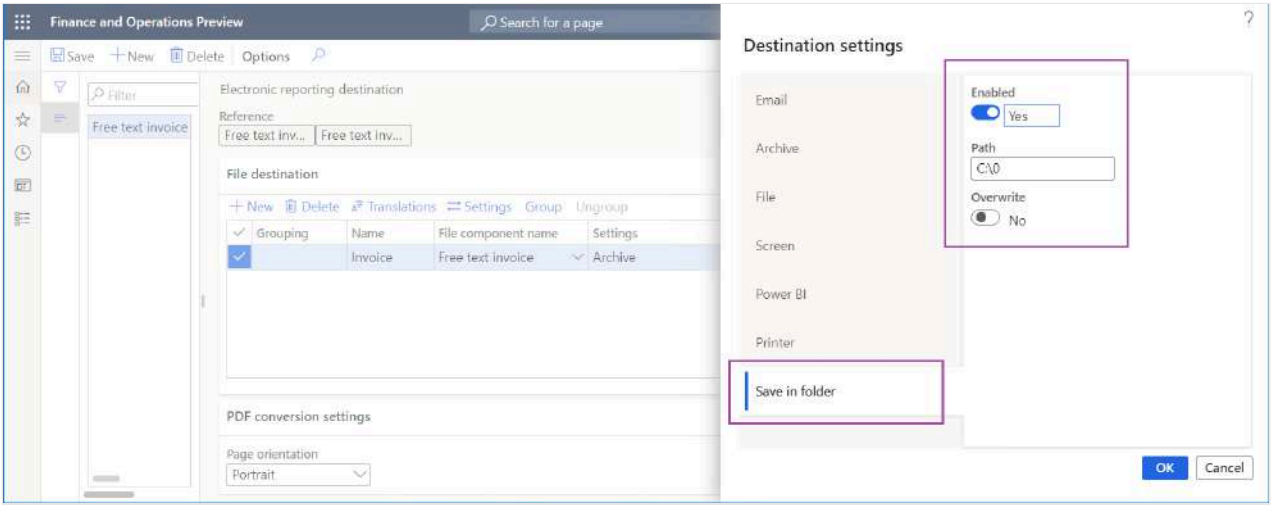
5. Rebuild your Visual Studio project.

Configure ER destinations for the ER format that you created or imported

1. Configure the Archive destination for one of the previously mentioned components (file, folder, merger, or attachment) of the ER format that you created or imported. For more information, see ER Configure destinations.



2. For the same component of the selected ER format, enable and configure the custom **Save in folder** destination.



> **Note**
>
> Make sure that the specified custom destination folder (**c:\0** in this example) is present in the local file system of the server that runs the AOS service. Otherwise, a DirectoryNotFoundException exception is thrown at runtime.

Run the ER format that you created or imported

1. Run the ER format that you created or imported.
2. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting jobs**, and find the record that was created for this execution job and that has the generated file attached to it.
3. Browse to the local **C:\0** folder to find the generated file.

Electronic reporting (ER) destinations

Electronic reporting framework API changes for Application update 10.0.19

Last updated on 04/09/2026

Initialize data source values of the USER INPUT PARAMETER type from source code

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you design ER model mapping and ER format components, use the data sources of the *User input parameter* type to get the necessary values at runtime before the execution of an ER format begins. You can programmatically turn off this dialog box when another page provides the required parameters or when an ER format runs in unattended (batch) mode. When the ER dialog box is turned off, you must initialize the data source values of the *User input parameter* type from source code.

Format components for outgoing electronic documents

You can configure an ER format to generate an outbound document. When you configure the format, select an ER data model as the data source to fill the outbound document. Configure an ER model mapping to specify how the selected data model is filled by application data at runtime. When you design your model mapping, specify data sources to collect the desired values from different sources and populate them to your data model. Among other data sources, you might use data sources of the *User input parameter* type to fill your data model with values that users enter on the ER user dialog box that appears when you first run an ER format.

For an ER format that you configure to generate an outbound document, you can programmatically turn off the ER dialog box by using the `_showPromptDialog` parameter of the `createFormatMappingRunByFormatMappingId()` method of the `ERObjectsFactory` class. When you turn off the ER dialog box, you need to initialize values of data sources of the *User input parameter* type from the source code. To do this, use the following pattern.

X++

```
ERModelDefinitionInputParametersAction Obj = new
ERModelDefinitionInputParametersAction();
Obj.addParameter(<path to an ER data source>, <data source value>);
ERObjectsFactory::createFormatMappingRunByFormatMappingId(formatMappingID,
fileName, false)
            .withParameter(Obj)
            .run();
```

For ER formats that you configure to generate an outbound document, the path to an ER data source is constructed from the prefix and the suffix that are separated by a slash (**/**) character. The prefix represents the name of a data source of the *Model* type that resides in the running ER format. The suffix represents the path to a data source of the *User input parameter* type that resides in a model mapping that the running ER format uses as the implementation of the relevant data model.

> **Tip**
>
> The nodes of a data source path are separated by a slash (**/**) character. Use the `ERPath::Combine()` method to construct a path.

For more information, review the source code of the `BankPaymBalanceXML` application class that you can use as an example. From the Global repository, import the **BLWI format (BE)** ER format configuration that this application class calls to your Finance instance. The base **BLWI model** configuration is imported automatically with the imported ER format configuration.

x++

```
    /// <summary>
    /// Runs export via ER solution.
    /// </summary>
    [Microsoft.Dynamics.BusinessPlatform.SharedTypes.InternalUseOnlyAttribute]
    protected void runER()
    {
        const str erParmEmail = 'model/parameters.Email';
        const str erParmFromDate = 'model/parameters.FromDate';
        const str erParmToDate = 'model/parameters.ToDate';
        const str erParmSurveyCode = 'model/parameters.SurveyCode';

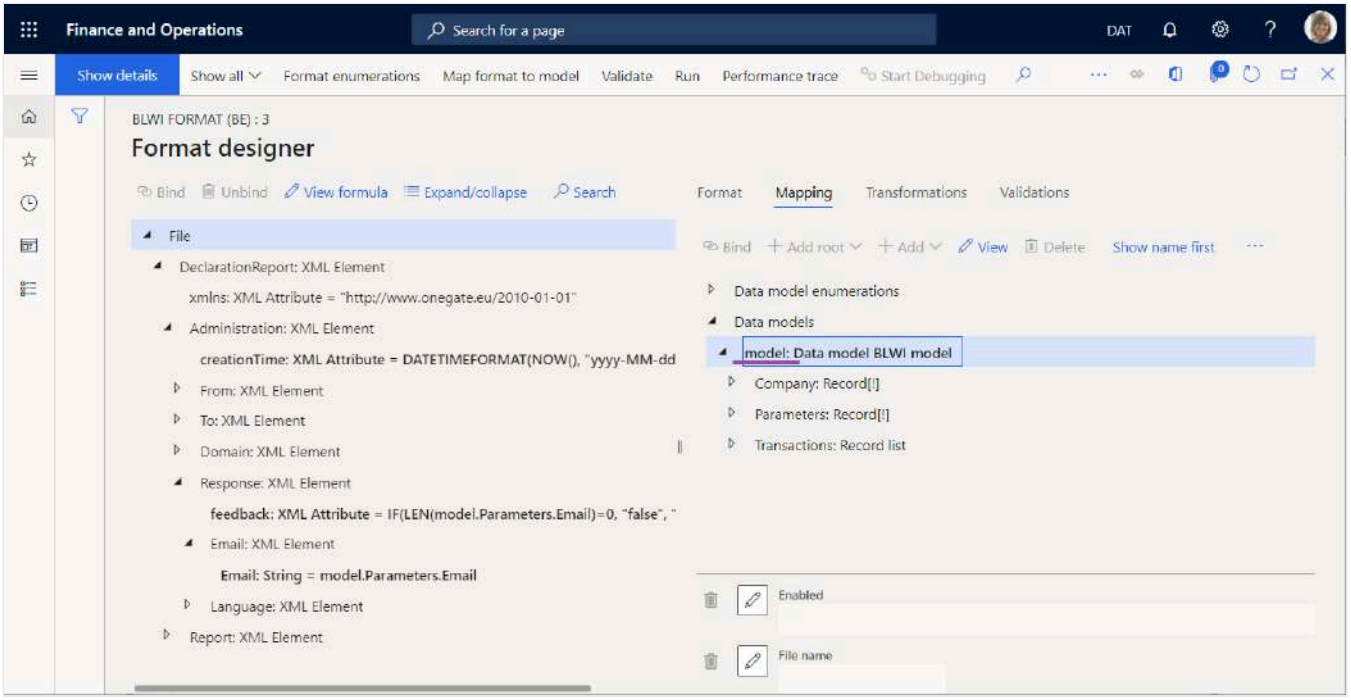
        ERModelDefinitionInputParametersAction modelDefinitionInputParametersAction
= new ERModelDefinitionInputParametersAction();

        modelDefinitionInputParametersAction.addParameter(erParmEmail, email)
            .addParameter(erParmFromDate, fromDate)
            .addParameter(erParmToDate, toDate)
```

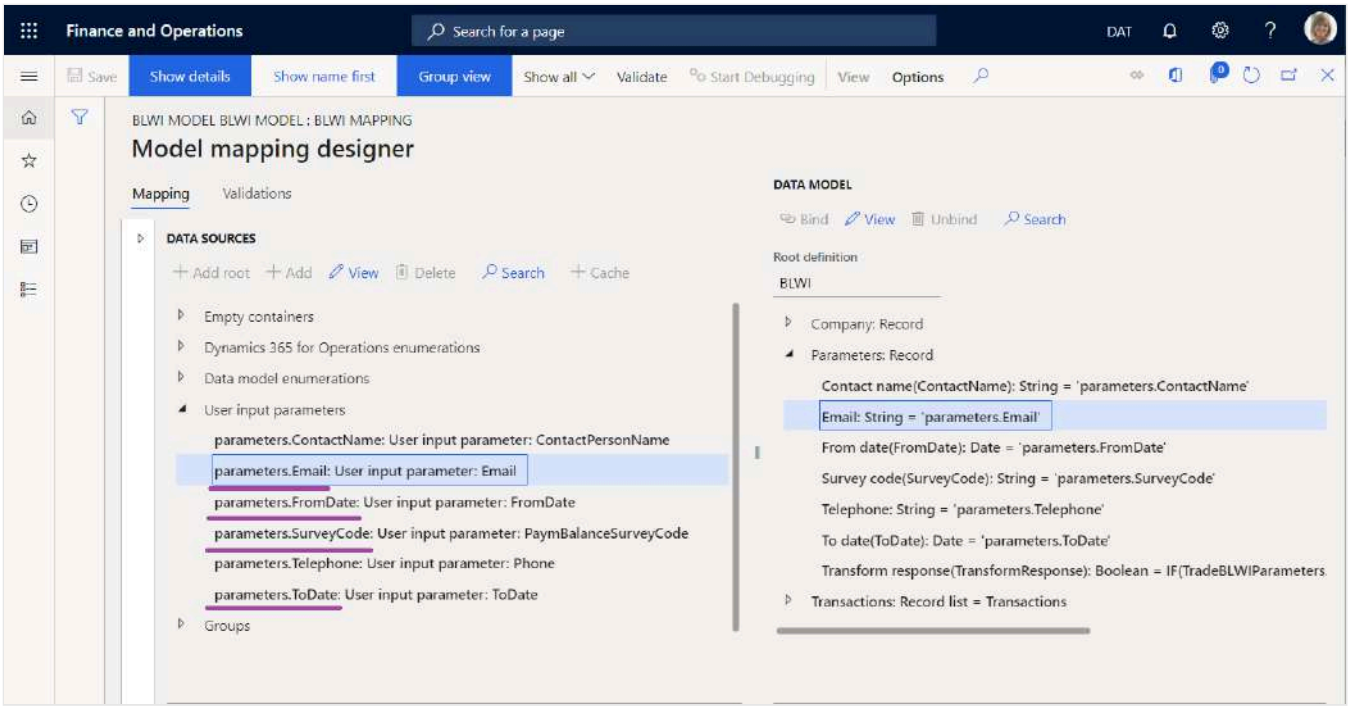
```
            .addParameter(erParmSurveyCode,
BankPaymBalanceSurvey::find(surveyCodeRecId).SurveyCode);

EROjectsFactory::createFormatMappingRunByFormatMappingId(tradeBLWIParameters.ERFor
matMappingID, fileName)
            .withFileDestination(fileDestination)
            .withParameter(modelDefinitionInputParametersAction)
            .run();
    }
```

The `email`, `fromDate`, and `toDate` variables store values that users enter on other pages before an ER format is called. The `runER()` method of this class runs an ER format mapping that uses these variables to initialize values of several data sources. The prefix of every path of such a data source (such as `erParmEmail`, `erParmFromDate`, or `erParmToDate` constants in the sample code) is defined as the name of a format data source of the *Model* type (**model** value).



The suffix of every path of such a data source is defined as the path to the relevant data source of a model mapping that is used at runtime. In the sample code, this path can include `parameters.Email`, `parameters.FromDate`, or `parameters.ToDate`.



Format components for inbound electronic documents

You can also configure an ER format that can be run to parse an inbound document and update application data. This format must contain a format mapping that refers to a model mapping of the *To destination* type that is used to update application data based on the content of an inbound document. In this type of model mapping, you can also use data sources of the *User input parameter* type to get values at runtime from the ER user dialog box and then use them for application data update.

When an ER format is executed to parse an inbound document, you can turn off the ER dialog box programmatically by using the `_showPromptDialog` parameter of the `createMappingDestinationRunByImportFormatMappingId()` method of the `ERObjectsFactory` class.

For ER formats that are configured to parse an inbound document, the path to an ER data source is constructed as the path to a data source of the *User input parameter* type that resides in a model mapping of the *To destination* type that the running ER format calls to update application data.

For more information, review the source code of the `BankStatementImportBatch` application class that you can use as an example.

X++

```
        var integrationPoint = classStr(ERTableDestination) + '#' +
tableStr(BankStatementDocumentEntity);
```

```
        ERmodelDefinitionInputParametersAction inputParameters = new
ERmodelDefinitionInputParametersAction();
        inputParameters.addParameter('$ExecutionID', _executionID)
            .addParameter('$gerConfigName', _gerConfigName)
            .addParameter('$AccountId', bankAccount);

        var runner =
ERObjectsFactory::createMappingDestinationRunByImportFormatMappingId(_erModelMappin
gId, integrationPoint);
        runner.withParameter(inputParameters);
        runner.init();

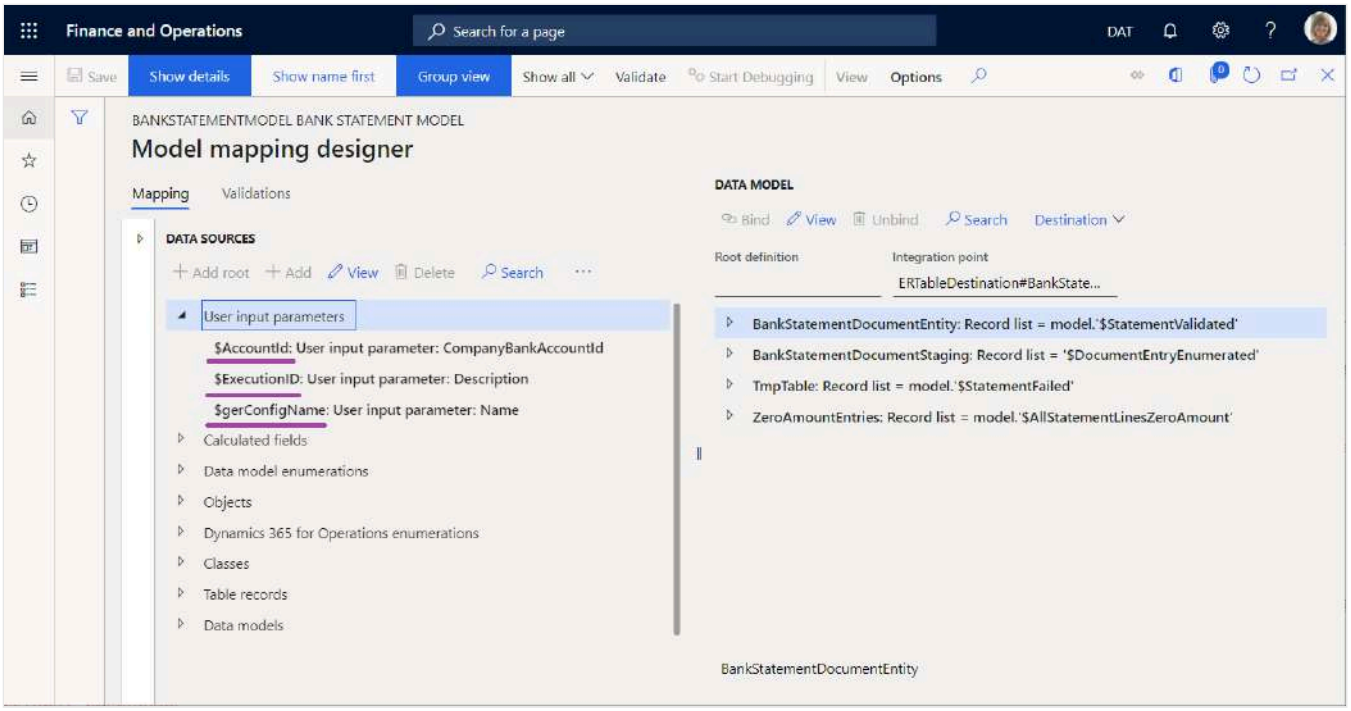
        if (runner.promptsContractedModelMapping())
        {
            var parameters = runner.getParameters();
            var traverser = new ERModelDefinitionParametersTraverser(parameters);
            while (traverser.moveNext())
            {
                ERIImportFormatDataSourceContract current =
ERCast::asObject(traverser.current()) as ERIImportFormatDataSourceContract;
                if (current)
                {

current.parmInputDataStream(File::UseFileFromURL(DMFStagingWriter::getDownloadURLFr
omFileId(_uploadedStatement)));
                }
            }
        }

        runner.runUnattended();
```

Pay attention to the `_executionID`, `_gerConfigName`, and `bankAccount` variables that are used to initiate the values of the `$ExecutionID`, `$gerConfigName`, and `$AccountId` data sources.

From the Global repository, import the **Camt.053 Format** ER format configuration that this application class calls to your Finance instance. The **Bank statement model** configuration is imported automatically with the imported ER format configuration. Additionally, import the **Bank statement mapping to destination** ER configuration that contains a model mapping used to update application data.



Limitations

You can only initiate data source values of the *User input parameter* type that you configure in an ER model mapping that is used at runtime. You can't initiate data source values of the *User input parameter* type that you configure in an ER format from the source code.

Electronic reporting (ER) overview

Parse incoming documents

Last updated on 04/13/2026

Change code so users can configure and use named ER destinations

To generate an outbound document, run an ER format mapping. When you use the initial API of the ER framework to call an ER format mapping, it runs all destinations configured for components of the format. To review the sample code for a call of this type, see Add a report service class.

You can also configure action-dependent ER destinations for the ER format. You can then use the extended API of the ER framework to call an ER format mapping that provides a user action code. The action code runs only the destinations configured for the action provided.

In some cases, you must configure print management and select the same ER format for different print management records, so that you can apply different ER destinations for generated documents when you run that format. For example, you might configure print management so that it runs the same ER format to email original documents and to print document copies to a network printer. Use the new API of the ER framework in Microsoft Dynamics 365 Finance version 10.0.21 for this purpose.

API to enable users to configure ER destinations that are print management record specific

Currently, you can open the **Print management setup** page for every type of business document, to specify how the business document is generated and delivered. For every available record of the print management tree, you can perform the following actions:

- Use the **Report format** field to select either a SQL Server Reporting Services (SSRS) report or an ER format that runs.
- Use the **Destination** button to open the **Print destination settings** dialog box, so that you can change the destination of the generated report.
- Review the **Destination** field, which shows the defined destination.

> **Important**
>
> If you select an ER format in the **Report format** field, the configured SSRS destination isn't applied for a generated report.

You can change this behavior and configure ER destinations that are specific to a print management record. Unlike general ER destinations, these destinations are named. You can select a single named destination for several print management records. For more information, see Configure print management record-specific ER destinations.

First, turn on the **Allow to set up ER destinations per print management item** feature in the Feature management workspace.

Next, enable users to configure print management record–specific ER destinations for a specific type of business document, if this functionality isn't enabled by default. In Finance version 10.0.21, the functionality isn't enabled for every type of business document, because the `isNamedDestinationEnabledByDocumentType` method of the `ERNamedDestinationReportEnabler` class returns *false* for any `PrintMgmtDocumentType` document type that is provided.

X++

```
/// <summary>Class for enabling NamedDestinationFeature for current document type.
</summary>
/// <remarks>To enable the document type you should wrap a
<c>isNamedDestinationEnabledByDocumentType</c> method.</remarks>
public class ERNamedDestinationReportEnabler
{
    /// <summary>Checks that feature enabled for current document type. Make extension
for this method.</summary>
    /// <param name = "_typeId">Print mgmt document type</param>
    /// <returns>True if feature enabled.</returns>
    [Wrappable(true), SuppressBPWarning('BPParameterNotUsed', 'Required by
signature')]
    public static boolean
isNamedDestinationEnabledByDocumentType(PrintMgmtDocumentType _typeId)
    {
        return false;
    }
}
```

You must wrap the `isNamedDestinationEnabledByDocumentType` method for a specific document type to enable users to configure print management record–specific ER destinations for documents of that type. The following example shows how to enable the functionality for free text invoices.

X++

```
[ExtensionOf(classStr(ERNamedDestinationReportEnabler))]
final class ERNamedDestinationReportEnablerContoso_Extension
{
    public static boolean
```

```
isNamedDestinationEnabledByDocumentType(PrintMgmtDocumentType _typeId)
    {
        var ret = next isNamedDestinationEnabledByDocumentType(_typeid);
        if(_typeId == PrintMgmtDocumentType::SalesFreeTextInvoice)
        {
            return true;
        }
        else
        {
            return ret;
        }
    }
}
```

API to run a format mapping where the destination that is provided is print management record specific

When you enable users to configure print management record–specific destinations, they expect a named destination configured for a print management record. When you use the print management record to run an ER format and generate an outbound document, you must pass that named destination to the ER framework to force ER to run only that destination, not any other destinations that might be configured for the ER format that is running.

The following code for the `ERPrintMgmtReportFormatSubscriber` class shows how the ER framework currently gets called to generate a free text invoice.

X++

```
/// <summary>
/// Runs a format mapping based on incoming arguments.
/// </summary>
/// <param name = "_args">Event arguments object.</param>
public static void
runFreeTextInvoiceReport(NonSSRSPrintMgmtAdapterReportExecutedEventArgs _args)
{
    ERIFormatMappingRun formatMappingRun =
ERPrintMgmtReportFormatSubscriber::buildFreeTextInvoiceReportMappingRun(_args);

    if (_args.parmArgs() && _args.parmArgs().parmEnumType() ==
enumNum(PrintCopyOriginal))
    {
        Args args = _args.parmArgs();
        boolean doUsePrintManagement = true;

        if (args.caller() is SalesFormLetter)
        {
            SalesFormLetter caller = args.caller();
            doUsePrintManagement = caller.usePrintManagement();
        }
```

```
        ERDestinationAction action;
        if (doUsePrintManagement ||
!isFlightEnabled(LocalizationFlights::ForcePrintJobSettings))
        {
            action =
ReportDestinationContract::getPrintDestinationAction(args.parmEnum());
        }
        else
        {
            action = ERDestinationAction::View;
        }

        ERIFormatMappingRunWithDestinationAction mappingRunWithAction =
formatMappingRun as ERIFormatMappingRunWithDestinationAction;

        if (mappingRunWithAction && action != ERDestinationAction::NoAction)
        {
            mappingRunWithAction.withDestinationAction(action);
        }
    }

    formatMappingRun.withCreatingObjectParameter(
        CustomersInvoicingModelName,
        classStr(PrintMgmtPrintSettingDetail),
        _args.parmSettingDetail());
    formatMappingRun.run();
}
```

The following example shows how you can change the sample code to use the new API to run an ER format and provide an ER named destination that is print management record specific.

X++

```
/// <summary>
/// Runs a format mapping based on incoming arguments.
/// </summary>
/// <param name = "_args">Event arguments object.</param>
public static void
runFreeTextInvoiceReport(NonSSRSPrintMgmtAdapterReportExecutedEventArgs _args)
{
    ERIFormatMappingRun formatMappingRun =
ERPrintMgmtReportFormatSubscriber::buildFreeTextInvoiceReportMappingRun(_args);

    if (_args.parmArgs() && _args.parmArgs().parmEnumType() ==
enumNum(PrintCopyOriginal))
    {
        Args args = _args.parmArgs();
        boolean doUsePrintManagement = true;

        if (args.caller() is SalesFormLetter)
        {
            SalesFormLetter caller = args.caller();
```

```
            doUsePrintManagement = caller.usePrintManagement();
        }

        ERDestinationAction action;
        if (doUsePrintManagement ||
!isFlightEnabled(LocalizationFlights::ForcePrintJobSettings))
        {
            action =
ReportDestinationContract::getPrintDestinationAction(args.parmEnum());
        }
        else
        {
            action = ERDestinationAction::View;
        }

        ERIFormatMappingRunWithDestinationAction mappingRunWithAction =
formatMappingRun as ERIFormatMappingRunWithDestinationAction;

        if (mappingRunWithAction && action != ERDestinationAction::NoAction)
        {
            mappingRunWithAction.withDestinationAction(action);
        }

        // Check whether a named destination is provided.
        // If so, pass it to ER to specify a single destination for a generated
document

        RefRecId NamedDestination;
        if (doUsePrintManagement ||
!isFlightEnabled(LocalizationFlights::ForcePrintJobSettings))
        {
            NamedDestination =
ReportDestinationContract::getNamedDestination(args.parmEnum());
        }
        else
        {
            NamedDestination = 0;
        }

        ERIFormatMappingRunWithNamedDestination RunWithNamedDestination =
formatMappingRun as ERIFormatMappingRunWithNamedDestination;

        if (RunWithNamedDestination && NamedDestination)
        {
            RunWithNamedDestination.withDestinationNamed(NamedDestination);
        }
    }

    formatMappingRun.withCreatingObjectParameter(
        CustomersInvoicingModelName,
        classStr(PrintMgmtPrintSettingDetail),
         _args.parmSettingDetail());
    formatMappingRun.run();
}
```

The `NamedDestination` field of the `PrintMgmtSettings` table includes the reference to a named destination. You must pass this reference to the `runFreeTextInvoiceReport` method from the processed print management record that extends `ReportDestinationContract`.

Applicability

To set up named destinations and force the ER framework to use the named destination, first turn on the **Allow to set up ER destinations per print management item** feature in the Feature management workspace.

The feature enables named ER destinations for all types of business documents that can be generated in Finance by using the ER framework. For more information, see the **Configurable business documents – specific destinations via printer management settings in the reports** feature in the "Globalization" section for the "Dynamics 365 Finance" application in the Dynamics 365 and industry clouds release plan for the 2021 release wave 2.

Electronic reporting (ER) destinations

Configure action-dependent ER destinations

Configure print management record-specific ER destinations

Electronic reporting framework API changes for Application update 10.0.21

Last updated on 03/17/2026

Implement a custom ER source of inbound documents

To import data from an inbound document by using the Electronic reporting (ER) framework, configure an ER format that supports the import, and then run a model mapping of the **To destination** type that uses that format as a data source. To import data, go to the document that you want to import, and use a SharePoint folder as the standard ER source of inbound documents that you can import in unattended mode. For more information about this process, see Configure data import from SharePoint.

The application programming interface (API) of the ER framework now lets you extend the list of ER sources that you can use to access inbound documents that ER formats parse for data import. Therefore, you can use ER configurations to perform data import from documents that are stored in your custom source.

This article provides an overview of the main tasks that you must complete to implement and start to use a custom ER source of inbound documents. To complete these tasks, use the same example for importing vendor transactions that is described in Configure data import from SharePoint. You can complete the steps of these tasks in the **USMF** company in Microsoft Dynamics 365 Finance.

Prerequisites

Deploy a topology

You must deploy a topology that supports continuous build. For more information, see Deploy topologies that support continuous build and test automation. You must have access to this topology for one of the following roles:

- Electronic reporting developer
- Electronic reporting functional consultant
- System administrator

You must also have access to the development environment for this topology.

Configure the ER framework

Follow the steps in Configure the ER framework to set up the minimal set of ER parameters. Complete this setup before you start to use the ER framework to import inbound documents from a custom source.

Import an ER format configuration

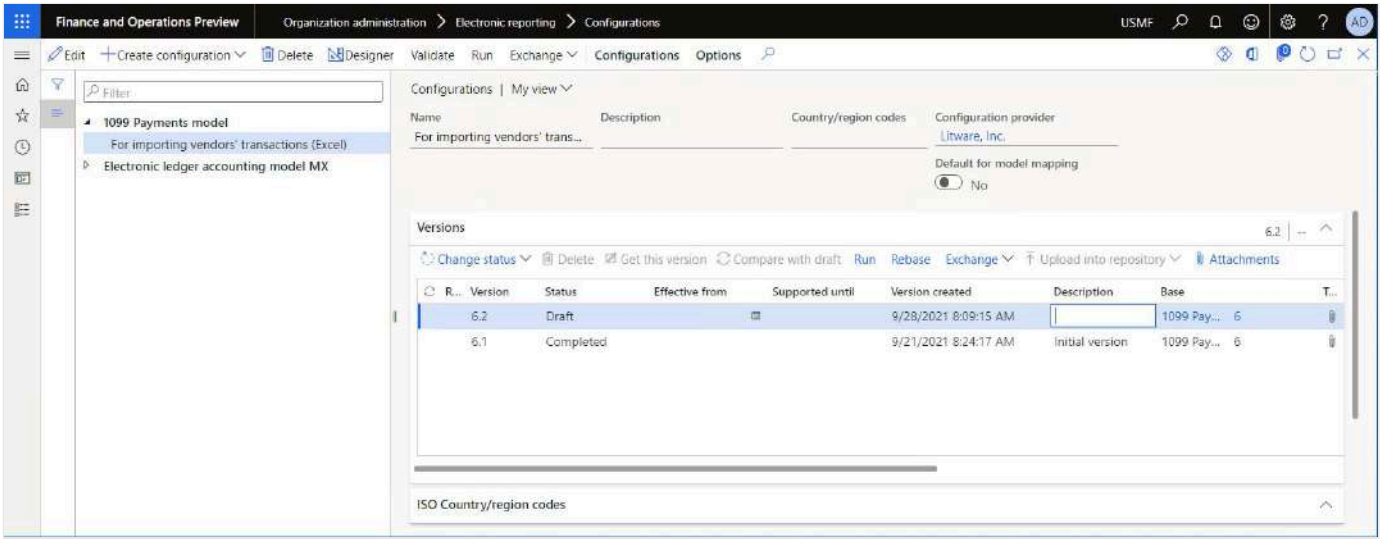
Additional tasks use the ER configurations that are mentioned in Configure data import from SharePoint. If you didn't follow the task guide in that article, download the following files.

Expand table

Content description	File
ER data model configuration	1099model.xml
ER format configuration	1099format-import-from-excel.xml
Inbound file in .XLSX format containing sample data for import	1099import-data.xlsx

Use the Load from XML file ER option to import the downloaded ER configurations into your Finance instance in the following order:

1. ER data model configuration
2. ER format configuration



> **Important**
>
> The ER format that you create or import must contain at least one of the following format elements:
>
> - Common\File

- Excel\File

Extend the source code

1. Append a new class to your Visual Studio project. In this example, use `ContosoInboundFile`.

2. Write code that uses the `ERIImportFile` public interface to describe a custom inbound file. To comply with the ER framework's requirements for handling inbound files, specify the following information:

   - A key to uniquely identify a custom source at runtime (the `sourceSettingsKey` variable in this example), and the methods to get and set this key. The key is important because there might be many sources.
   - *DateTime* values to specify the date and time of inbound file creation and modification (the `createdDateTime` and `modifiedDateTime` variables in this example), and the methods to get and set these dates. The values are used at runtime to sort and filter inbound documents that are recognized in a custom source.
   - A method to load an inbound file from a custom source (the `Load()` method in this example).
   - A method to delete an imported file in custom storage (the `Delete()` method in this example).
   - A method to expose additional information about an inbound file (the `parmAdditionalInfo()` method in this example), so that this information can be stored and then extracted upon request.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
using SL = Microsoft.Dynamics365.LocalizationFramework.XppSupportLayer;
using System.IO;

/// <summary>
/// Import file
/// </summary>
public class ContosoInboundFile implements ERIImportFile
{
    private str folderPath;
    private System.IO.Stream fileContent;
    private str additionalInfo;
    private str fileId;
    private str name;
    private SL.utcdatetime createdDateTime;
    private SL.utcdatetime modifiedDateTime;
    private str sourceSettingsKey;
```

```
    protected void new(
        str _fileId,
        str _name,
        utcdatetime _dateTime,
        str _folderPath,
        Stream _fileContent
        )
    {
        fileId = _fileId;
        name = _name;
        createdDateTime = ERLFConvert::fromUtcdatetime(_dateTime);
        modifiedDateTime =  ERLFConvert::fromUtcdatetime(_dateTime);
        folderPath = _folderPath;
        fileContent = _fileContent;

this.set_SourceSettingsKey(ContosoInboundFileSourceSettings::SettingsKey);

    }

    [Hookable(false)]
    public str get_SourceSettingsKey()
    {
        return sourceSettingsKey;
    }

    [Hookable(false)]
    public void set_SourceSettingsKey(str _sourceSettingsKey = sourceSettingsKey)
    {
        sourceSettingsKey = _sourceSettingsKey;
    }

    [Hookable(false)]
    public str parmAdditionalInfo(str _additionalInfo = additionalInfo)
    {
        additionalInfo = _additionalInfo;
        return additionalInfo;
    }

    /// <summary>
    /// Construct new object.
    /// </summary>
    /// <param name = "_fileId">File id.</param>
    /// <param name = "_name">Name.</param>
    /// <param name = "_dateTime">Date time.</param>
    /// <param name = "_folderPath">Folder path.</param>
    /// <param name = "_fileContent">File content as stream.</param>
    /// <returns>Import file.</returns>
    public static ContosoInboundFile construct(str _fileId,
        str _name,
        utcdatetime _dateTime,
        str _folderPath,
        Stream _fileContent
        )
    {
```

```
        return new ContosoInboundFile(_fileId, _name, _dateTime, _folderPath,
_fileContent);
    }

    [Hookable(false)]
    public void set_FileId(str _fileId = fileId)
    {
        fileId = _fileId;
    }

    [Hookable(false)]
    public void set_Name(str _name = name)
    {
        name = _name;
    }

    [Hookable(false)]
    public str get_Name()
    {
        return name;
    }

    [Hookable(false)]
    public SL.utcdatetime get_CreatedDateTime()
    {
        return createdDateTime;
    }

    [Hookable(false)]
    public void set_CreatedDateTime(SL.utcdatetime _createdDateTime =
createdDateTime)
    {
        createdDateTime = _createdDateTime;
    }

    [Hookable(false)]
    public void set_ModifiedDateTime(SL.utcdatetime _modifiedDateTime =
modifiedDateTime)
    {
        modifiedDateTime = _modifiedDateTime;
    }

    /// <summary>
    /// Loads the file from the source.
    /// </summary>
    /// <returns>A file operation result.</returns>
    public ERFileLoadResult Load()
    {
        return ERFileLoadResult::Success(fileContent);
    }

    public ERFileDeleteResult Delete()
    {
        if (System.IO.File::Exists(Path::Combine(folderPath, name)))
        {
```

```
            System.IO.File::Delete(Path::Combine(folderPath, name));
            return ERFileDeleteResult::Success();
        }
        return ERFileDeleteResult::Fail();
    }

    [Hookable(false)]
    public str GetFileId()
    {
        return fileId;
    }

    [Hookable(false)]
    public SL.utcdatetime GetModifiedDateTime()
    {
        return modifiedDateTime;
    }

}
```

3. Append a new class to your Visual Studio project. In this example, use `ContosoInboundFileSource`.

4. Write code that uses the `ERIFileSource` public interface to describe a custom source of inbound files. To comply with the ER framework's requirements for handling inbound files, specify the following information:

    - A file mask (the `fileMask` variable in this example), so that users can specify the file name pattern to filter only specific files from a custom source, based on a file name and extension.
    - A method to load inbound files from a custom source (the `GetFiles()` method in this example). This method refers to the `ContosoInboundFile()` method for specifying an inbound file.

    X++

```
using Microsoft.Dynamics365.LocalizationFramework;
using System.IO;

/// <summary>
/// File source as a folder
/// </summary>
public class ContosoInboundFileSource implements ERIFileSource
{
    private str folderPath;
    private str fileMask;

    /// <summary>
    /// Creates a new instance of <C>ERFileSourceFolder</C>.
```

```
    /// </summary>
    /// <param name = "_folderPath">A folder path.</param>
    /// <param name = "_fileMask">A file mask to filter; optional.</param>
    protected void new(str _folderPath, str _fileMask)
    {
        folderPath = _folderPath;
        fileMask = _fileMask;
    }

    /// <summary>
    /// Construct new instance of <c>ERFileSourceFolder</c>.
    /// </summary>
    /// <param name = "_folderPath">A folder path.</param>
    /// <param name = "_fileMask">A file mask to filter; optional.</param>
    /// <returns>New instance of class.</returns>
    internal static ContosoInboundFileSource construct(str _folderPath, str
_fileMask)
    {
        return new ContosoInboundFileSource(_folderPath, _fileMask);
    }

    public str parmFolderPath(str _value = folderPath)
    {
        folderPath = _value;
        return folderPath;
    }

    [Hookable(false)]
    public ERIFiles GetFiles()
    {
        if (fileMask == '')
        {
            fileMask = '*.*';
        }
        var ret = new ERFiles();
        var directoryInfo = new System.IO.DirectoryInfo(folderPath);
        var files = directoryInfo.GetFiles(fileMask);
        var i = files.GetEnumerator();

        while (i.MoveNext())
        {
            System.IO.FileInfo fileInfo = i.get_Current();
            if (fileInfo)
            {
                using (StreamReader sr = fileInfo.OpenText())
                {
                    var localStream = new System.IO.MemoryStream();

                    System.IO.Stream base = sr.BaseStream;
                    base.CopyTo(localStream);
                    if (localStream.CanSeek)
                    {
                        localStream.Seek(0, System.IO.SeekOrigin::Begin);
                    }
                    ERIFile file = ContosoInboundFile::construct(fileInfo.Name,
```

```
fileInfo.Name, DateTimeUtil::getSystemDateTime(), folderPath, localStream);
                    ret.Add(file);

                }
            }
        }
        return ret;
    }

}
```

> **Note**
>
> The file name is the unique file identifier in the configured custom source when the file object is constructed while the `GetFiles()` method is called. If you use something other than a folder of the local file system source to store inbound files, you can implement another way to uniquely identify inbound files.

5. Append a new class to your Visual Studio project. In this example, use `ContosoERFileDestinationFolder`.

6. Write code that uses the `ERIFileDestination` public interface to describe a custom source of inbound files as a folder. You can reuse the code sample from step 1 of the "Extend the source code" procedure in Implement a custom destination for generated documents. In the example, the class is designed to look for inbound documents as files in a folder of the local file system.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;

/// <summary>
/// File destination as a folder
/// </summary>
public class ContosoERFileDestinationFolder implements ERIFileDestination
{
    private str folderPath;
    private boolean overwrite;

    public str parmFolderPath(str _value = folderPath)
    {
        folderPath = _value;
        return folderPath;
    }

    public boolean parmOverwrite(boolean _value = overwrite)
    {
```

```
        overwrite = _value;
        return overwrite;
    }

    [Hookable(false)]
    public System.IO.Stream saveFile(System.IO.Stream _stream, str _filePath)
    {
        this.sendFileToFolder(_stream, _filePath);
        return _stream;
    }

    [Hookable(false)]
    public System.IO.Stream newFileStream(str _filePath)
    {
        return new System.IO.MemoryStream();
    }

    private str getFileName(str _fileName)
    {
        if (overwrite)
        {
            return _fileName;
        }
        System.DateTime now = DateTimeUtil::utcNow();
        return strFmt('%1_%2%3',
System.IO.Path::GetFileNameWithoutExtension(_fileName), now.ToString('yyyy-M-
d_HH_mm_ss'), System.IO.Path::GetExtension(_fileName));
    }

    private void sendFileToFolder(System.IO.Stream _stream, str _filePath)
    {
        using(var fileStream = System.IO.File::Create(_filePath))
        {
            if( _stream.CanSeek)
            {
                _stream.Seek(0, System.IO.SeekOrigin::Begin);
            }
            _stream.CopyTo(fileStream);
        }
    }

    /// <summary>
    /// Finalizes files processing.
    /// </summary>
    [Hookable(false)]
    public void finalize()
    {
    }

}
```

7. Append a new class to your Visual Studio project. For this example, use `ContosoInboundFileSourceSettings`.

8. Write code that uses the `ERIImportFileSourceSettings` public interface to specify how a custom source is created, how its parameters are packed for storage, and how its parameters are unpacked for presentation in the user interface (UI). To comply with the ER framework's requirements for handling inbound files, specify the following information:

    - A key (the `SettingsKey` text constant in this example) to uniquely identify settings of a custom source at runtime. Use a class name to guarantee the uniqueness of keys of this type.
    - The name of a custom source (the `Folder` text constant in this example) to present a custom source in the appropriate UI dialog box at design time.
    - A parameter (the `isEnabled` variable in this example) to indicate whether a custom source is enabled at design time for use at runtime.
    - Because all these parameters must be stored as parts of a single binary object in the application database, they must be packed for this purpose at design time and then unpacked when they are requested at runtime. The appropriate methods must be implemented to support this process.
    - Pay attention to the `fileImported()` method that is used to implement the logic of any required post-processing that must be applied to the imported file. The argument of this method represents an imported file itself and information about the import that is performed. A state manager is included. This state manager includes a logger that collects information about whether an imported file was deleted or moved to another location. In this example, the code moves successfully imported files to another folder (**C:\InboundFiles\Archive**) of the local file system and keeps the original file names.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;
using System.IO;

/// <summary>
/// Folder file source settings
/// </summary>
public class ContosoInboundFileSourceSettings implements SysPackable,
ERIImportFileSourceSettings
{
    internal const str SettingsKey = classStr(ContosoInboundFileSourceSettings);
    public const int CurrentVersion = 1;

    private boolean isEnabled;
    private str folderPath;

    [Hookable(false)]
    public str parmFolderPath(str _value = folderPath)
    {
```

```
        folderPath = _value;
        return folderPath;
    }

    [Hookable(false)]
    public boolean parmIsEnabled(boolean _value = isEnabled)
    {
        isEnabled = _value;
        return isEnabled;
    }

    [Hookable(false)]
    public void setEnabled(boolean _value)
    {
        isEnabled = _value;
    }

    [Hookable(false)]
    public boolean isEnabled()
    {
        return isEnabled;
    }

    [Hookable(false)]
    public str getName()
    {
        /// Name of settings of a custom source.
        /// This name will be presented in the dialog box that is offered at
runtime for user to adjust configured settings.
        return 'Folder';
    }

    [Hookable(false)]
    public boolean validate()
    {
        return true;
    }

    [Hookable(false)]
    public str getKey()
    {
        return SettingsKey;
    }

    [Hookable(false)]
    public container pack()
    {
        return [CurrentVersion, isEnabled, folderPath];
    }

    [Hookable(false)]
    public boolean unpack(container packedClass)
    {
        int version = RunBase::getVersion(packedClass);
        switch (version)
```

```
        {
            case CurrentVersion:
                [version, isEnabled, folderPath] = packedClass;
                return true;
            default:
                return false;
        }
    }

    /// <summary>
    /// Creates a file source for current settings.
    /// </summary>
    /// <param name = "_fileMask">File mask.</param>
    /// <returns>A new instance of a file source.</returns>
    public ERIFileSource createFileSource(str _fileMask)
    {

    }

    /// <summary>
    /// Creates a file destination for current settings.
    /// </summary>
    /// <param name = "_destination">A destination folder to move the file.
</param>
    /// <returns>A new instance of a file destination.</returns>
    private ERIFileDestination
createPostProcessingDestination(ERFormatFileDestinationAfterImport _destination)
    {
        ContosoERFileDestinationFolder ret = new
ContosoERFileDestinationFolder();
        var path = folderPath;
        switch (_destination)
        {
            case ERFormatFileDestinationAfterImport::None :
                break;
            default:
                path = System.IO.Path::Combine(path, enum2Str(_destination));
                break;
        }
        ret.parmFolderPath(path);
        return ret;
    }

    public void fileImported(ERFileImportedArgs _args)
    {
        if (_args.IsImportOperationSuccessful())
        {
            /// copy an outbound file to the alternative location
            var destination = this.createPostProcessingDestination(
_args.IsImportOperationSuccessful() ? ERFormatFileDestinationAfterImport::Archive
: ERFormatFileDestinationAfterImport::None);
            ERIImportFile file = _args.getFile();
            destination.saveFile(_args.getFileStream(),
@'C:\InboundFiles\Archive\'+file.Name);
```

```
            /// do logging
            ttsbegin;
            _args.getState().markAsMoved();

_args.getState().getLogger().logMoved(!_args.IsImportOperationSuccessful(),
'Custom error message', 'Custom description');
            ttscommit;

            /// delete file
            ttsbegin;
            _args.getFile().Delete();
            _args.getState().markAsDeleted();
            ttscommit;
        }
    }

    /// <summary>
    /// Create new instance of <c>ERImportFormatSourceFolderSettings</c> from
packed presentation.
    /// </summary>
    /// <param name = "_packedClass">A container with packed presentation.
</param>
    /// <returns>New instance.</returns>
    internal static ContosoInboundFileSourceSettings create(container
_packedClass)
    {
        var settings = new ContosoInboundFileSourceSettings();
        settings.unpack(_packedClass);
        return settings;
    }

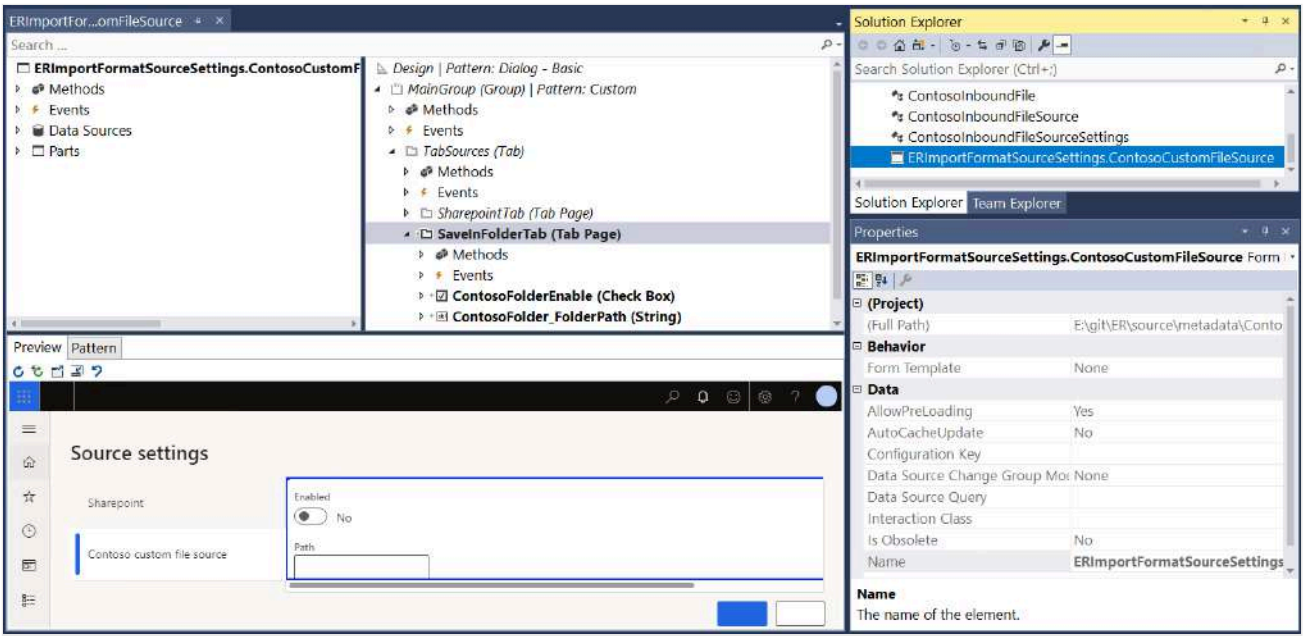
    /// <summary>
    /// Event.
    /// </summary>
    /// <param name="_record">Record.</param>
    /// <param name="_file">File.</param>
    ///
    /// This code and code below presents the sample how you can memorize
additional info about an imported file
    /// in the extended field of the ERImportFormatFileSourceStateTable table.
    ///
    [SubscribesTo(tableStr(ERImportFormatFileSourceStateTable),
delegateStr(ERImportFormatFileSourceStateTable, objectInitialized))]
    public static void
ERImportFormatFileSourceStateTable_objectInitialized(ERImportFormatFileSourceStat
eTable _record, ERIImportFile _file)
    {
        anytype file =_file;
        var folderFile = file as ContosoInboundFile;
        if (folderFile != null)
        {
///             folderFile.parmAdditionalInfo(_record.additionalInfo);
        }
    }
```

```
    /// <summary>
    /// Event.
    /// </summary>
    /// <param name="_record">Record.</param>
    /// <param name="_file">File</param>
    [SubscribesTo(tableStr(ERImportFormatFileSourceStateTable),
delegateStr(ERImportFormatFileSourceStateTable, tableRecordInitialized))]
    public static void
ERImportFormatFileSourceStateTable_tableRecordInitialized(ERImportFormatFileSourc
eStateTable _record, ERIImportFile _file)
    {
        anytype file =_file;
        var folderFile = file as ContosoInboundFile;
        if (folderFile != null)
        {
///             _record.AdditionalInfo = folderFile.parmAdditionalInfo();
        }
    }

}
```

9. In your Visual Studio project, add a new extension for the `ERImportFormatSourceSettings` form. In this example, use `ERImportFormatSourceSettings.ContosoCustomFileSource`.

10. Write code that implements a custom UI for your custom source of inbound files. The following illustration shows what this UI looks like in the Visual Studio designer.



11. Append a new class to your Visual Studio project. For this example, use `ContosoImportFormatSourceSettingsEventHandlers`.

12. Write the event handler code for an extended form of settings of a custom source. This step requires implementation of the public `ERIImportFileSourceSettingsStorage` interface.

X++

```
using Microsoft.Dynamics365.LocalizationFramework;

/// <summary>
/// Handler for <c>ERImportFormatSourceSettings</c> form
/// </summary>
public class ContosoImportFormatSourceSettingsEventHandlers
{
    /// <summary>
    /// Post init method event handler.
    /// </summary>
    /// <param name = "args">Args.</param>
    [PostHandlerFor(formStr(ERImportFormatSourceSettings),
formMethodStr(ERImportFormatSourceSettings, init))]
    public static void ERImportFormatSourceSettings_Post_init(XppPrePostArgs
args)
    {
        FormRun formRun = args.getThis();
        ERIImportFileSourceSettingsStorage settingsStorage = args.getThis();
        var settings =
ContosoImportFormatSourceSettingsEventHandlers::getSaveInFolderSettings(settingsS
torage);

        FormStringControl folderPathControl =
formRun.design().controlName(formControlStr(ERImportFormatSourceSettings,
ContosoFolder_FolderPath));
        folderPathControl.text(settings.parmFolderPath());

        FormCheckBoxControl enabledControl =
formRun.design().controlName(formControlStr(ERImportFormatSourceSettings,
ContosoFolderEnable));
        enabledControl.checked(settings.isEnabled());

    }

    /// <summary>
    /// CloseOk method event handler.
    /// </summary>
    /// <param name = "args">Args.</param>
    [PreHandlerFor(formStr(ERImportFormatSourceSettings),
formMethodStr(ERImportFormatSourceSettings, closeOk))]
    public static void ERFormatDestinationSettings_Pre_closeOk(XppPrePostArgs
args)
    {
        FormRun formRun = args.getThis();
        ERIImportFileSourceSettingsStorage settingsStorage = args.getThis();
        var settings =
ContosoImportFormatSourceSettingsEventHandlers::getSaveInFolderSettings(settingsS
torage);

        FormStringControl folderPathControl =
formRun.design().controlName(formControlStr(ERImportFormatSourceSettings,
ContosoFolder_FolderPath));
        settings.parmFolderPath(folderPathControl.text());
```

```
        FormCheckBoxControl enabledControl =
formRun.design().controlName(formControlStr(ERImportFormatSourceSettings,
ContosoFolderEnable));
        settings.setEnabled(enabledControl.checked());

    }

    private static ContosoInboundFileSourceSettings
getSaveInFolderSettings(ERIImportFileSourceSettingsStorage _settingsStorage)
    {
        ContosoInboundFileSourceSettings ret =
_settingsStorage.getSettingsByKey(ContosoInboundFileSourceSettings::SettingsKey);
        if (ret == null)
        {
            ret = new ContosoInboundFileSourceSettings();
            _settingsStorage.addSettings(ret);
        }
        return ret;
    }

}
```

13. Rebuild your Visual Studio project.

Configure ER sources for the imported ER format

1. Configure the custom source of inbound files for one of the previously mentioned components (Common\File or Excel\File) of the ER format that you imported.

    a. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting source**.

    b. On **Electronic reporting source**, select **New**.

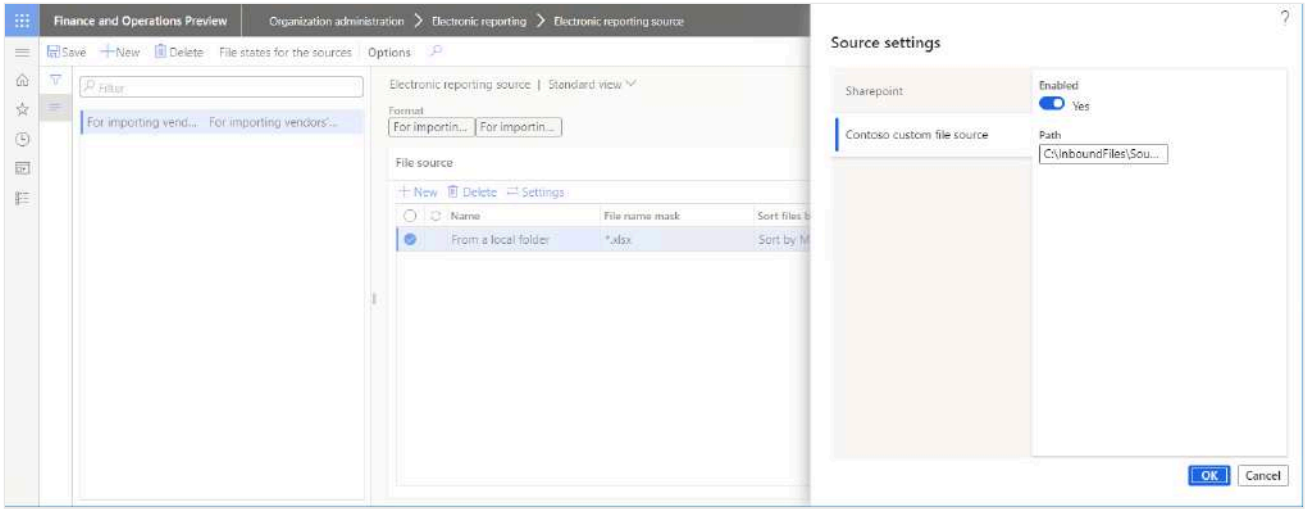
    c. In the **Format** field, select the imported ER format.

    d. On the **File source** FastTab, select **New**, and then follow these steps:
        i. In the **Name** field, enter **From a local folder** as the name of a custom source.
        ii. In the **File name mask** field, enter the ***.xlsx** mask to filter only files that have the .xlsx extension in a custom source.
        iii. In the **Sort files before import** field, select **Sort by Modified date/time**.

    e. For the source record that you entered, select the **Settings** option, and then follow these steps:
        i. In the **Source settings** dialog box, on the **Contoso custom file source** tab, set the **Enabled** option to **Yes**.

ii. In the **Path** field, enter **C:\InboundFiles\Source** to specify the local folder that contains inbound files.

iii. Select **OK**, and then select **Save**.



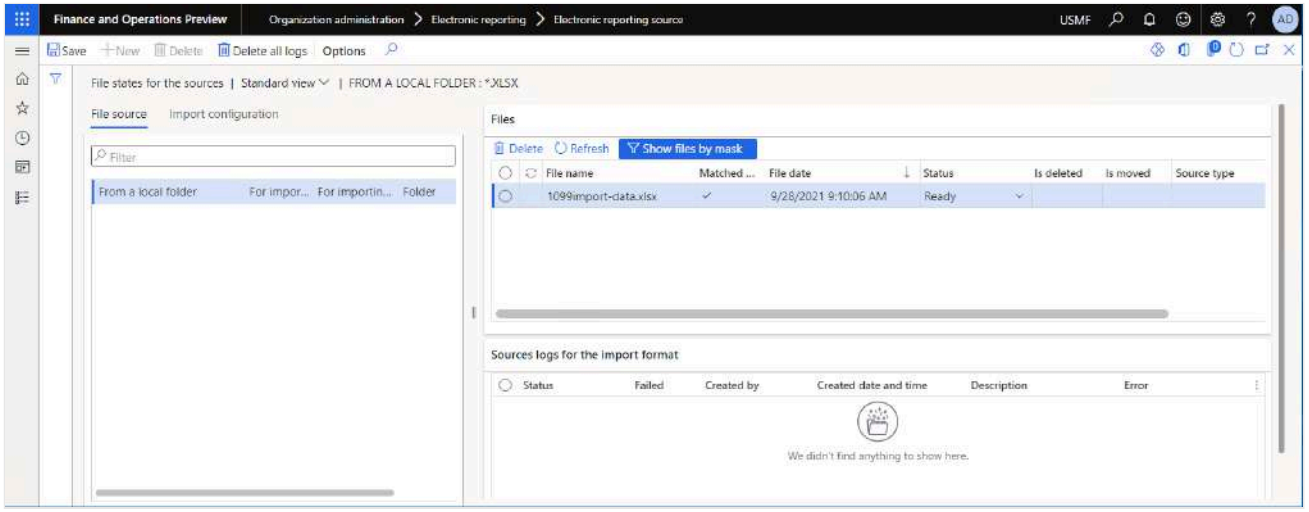
2. Copy the imported file, **1099import-data.xlsx**, to the **C:\InboundFiles\Source** folder of the file system of the server that runs the first instance of Application Object Server (AOS).

3. Make sure that the **C:\InboundFiles\Archive** folder exists in the file system of the server that runs the first AOS instance.

4. On **Electronic reporting source**, select **File states for the sources**, and then follow these steps to review the content of the configured custom file source for the current ER format:

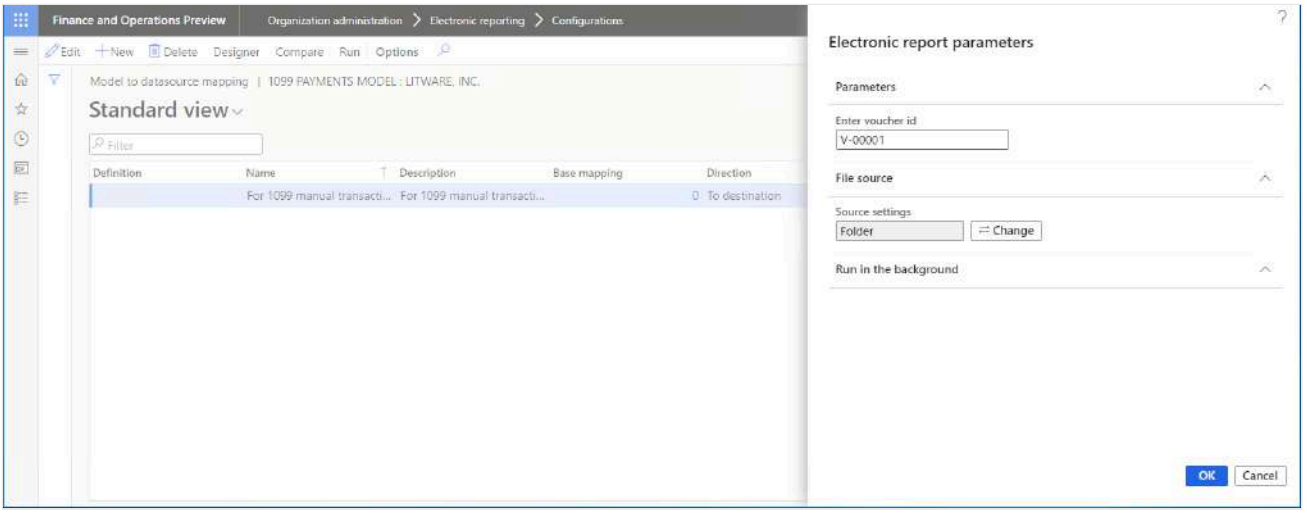
   a. On **File states for the sources**, in the **File source** list, select the **From a local folder** source.

   b. On the **Files** tab, select **Refresh** to see the **1099import-data.xlsx** file that is ready for import from a custom source.



Run the ER mapping that you imported

1. To import vendor transactions from an inbound file that is located in a custom source, follow these steps to run the ER model mapping that you imported:
    a. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
    b. In the **Configurations** tree, select **1099 Payments model**.
    c. On the **Configuration components** FastTab, select the name of the **Model mapping** component to open the list of model mappings for the selected ER model configuration.
    d. Select **Run** to run the selected model mapping. Because you configured file sources for the ER format, you can change the setting of the **File source** option as you require. If you keep the setting of this option, the .xslx files are imported from the configured custom sources (the **1099import-data.xlsx** file from the **C:\InboundFiles\Source** local folder in this example).
    e. Enter the voucher ID, such as **V-00001**, and then select **OK**.



2. Browse to the local **C:\InboundFiles\Archive** folder to find the imported **1099import-data.xlsx** file that is moved from the **C:\InboundFiles\Source** local folder, based on the post-processing logic that is defined in the source code.

3. Follow these steps to review the current status of the configured custom source of inbound files.
    a. Go to **Organization administration** > **Electronic reporting** > **Electronic reporting source**.
    b. On the **Electronic reporting source** page, select **File states for the sources** to review the content of the configured custom file source for the current ER format.
    c. On **File states for the sources**, in the **File source** list, select the **From a local folder** source.
        i. On the **Files** tab, select **Refresh** to see the previously imported **1099import-data.xlsx** file that is moved from the **C:\InboundFiles\Source** folder to the **C:\InboundFiles\Archive** folder.

Inventory management overview

08/29/2025

With Inventory management, you can perform the following tasks:

- Inbound operations
- Quality assurance
- Inventory activities
- Outbound operations
- Inventory control

Learning map

The following learning map shows the major concepts and tasks that make up the framework of the Inventory management module.

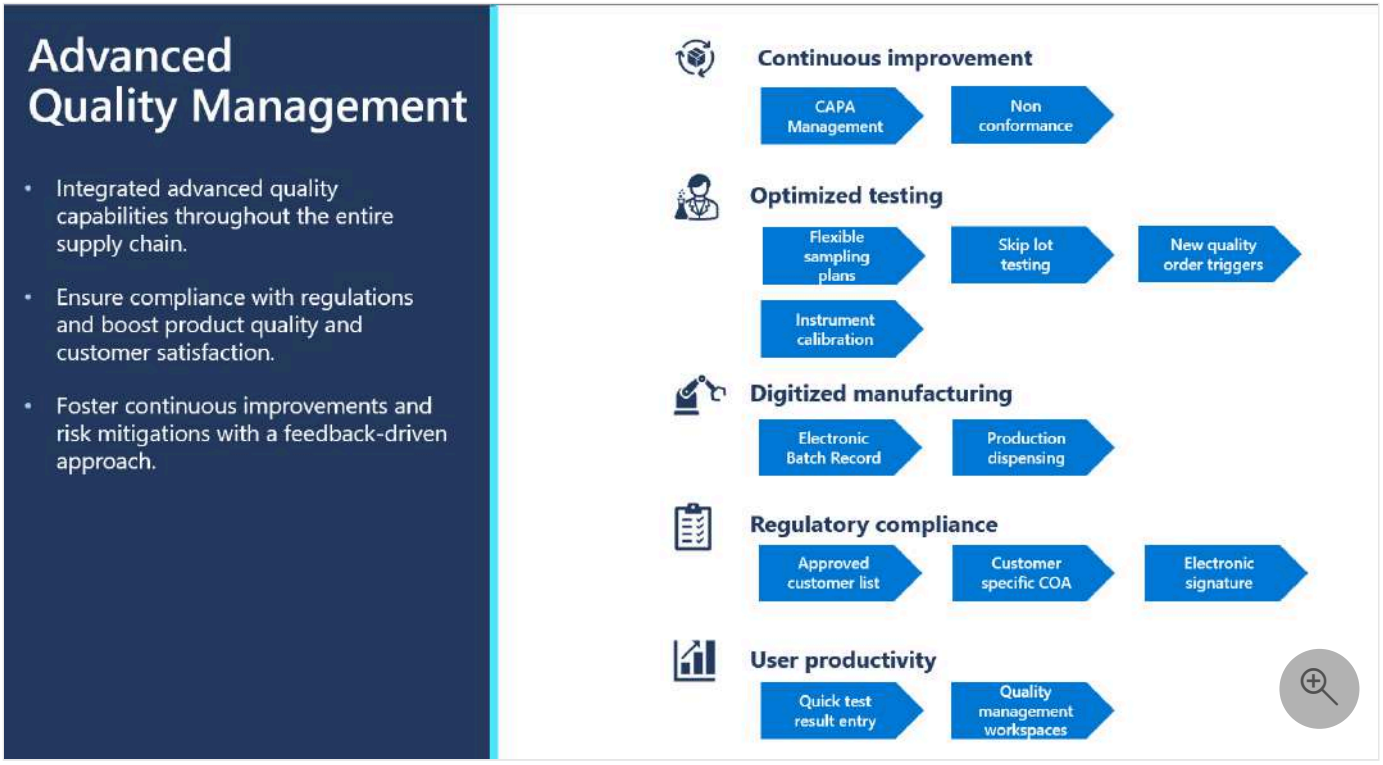
Advanced quality management overview

Advanced quality management is a suite of quality management features introduced in Microsoft Dynamics 365 Supply Chain Management version 10.0.44. It enhances the existing quality management features by adding many new tools. These tools address core issues that manufacturers face as they try to meet the United States Food and Drug Administration's (FDA's) Quality System Regulation (QSR), part 11 of Title 21 of the Code of Federal Regulations (21 CFR Part 11), current Good Manufacturing Practice (cGMP), and other regulatory and international standards, such as the International Organization for Standardization (ISO) and Six Sigma.



Prerequisites

Before you can use the features that this article describes, ensure that your system meets the following requirements:

- You're running Supply Chain Management version 10.0.44 or later.
- The following features are turned on in Feature management. As of Supply Chain Management version 10.0.47, all of these features are turned on by default.
  - *Approved customer list* – This feature lets administrators set up rules that limit the sale of specific products to specific customers. The feature applies to sales orders, sales quotations, and sales agreements.

- *Dispense management* – This feature lets users separate dispensing activities from picking activities. In this way, it ensures effective management of controlled and regulated products. The feature supports over-picking where residual products are returned to inventory, identifies items that require dispensing control, and requires authorized personnel for dispensing. Additionally, it captures electronic signatures for dispensing postings, establishes dispensing tolerance parameters, generates pick lists and dispensing tickets at production release, and enables the quantity that is issued to exceed the proposed quantity. As of Supply Chain Management version 10.0.49, this feature is mandatory and can't be turned off.
- *Electronic signature improvements* – This feature introduces new electronic signature requirements for various management tasks, including dispense management, corrective and preventive actions (CAPA) management, instrument calibration, and validation of quality orders. The feature also defines passkey expiration and passphrase constraints for electronic signatures.
- *Advanced quality management* – This feature integrates advanced quality capabilities throughout the Supply Chain Management solution. Key capabilities include optimized testing strategies (flexible sampling plans, skip lot testing, new quality order triggers, and instrument calibration), regulatory compliance (customer-specific certificates of analysis [COAs] and enhancements to electronic signatures), digitized manufacturing for precision and compliance (electronic batch records), continuous improvement, risk mitigation (CAPA management and enhancements to nonconformance), and an enhanced user experience (simplified entry of quality test results and new workspaces for quality management). As of Supply Chain Management version 10.0.49, this feature is mandatory and can't be turned off.

Key features of advanced quality management

This section describes some of the key industry-specific capabilities of the solution.

- **Corrective and preventive actions (CAPA)** – Users can automate processes for managing, tracking, and correcting root causes of issues. They can also implement action plans to prevent the same issues and similar issues from occurring in the future. For more information, see Corrective and preventive action (CAPA) management overview.
- **Electronic signature requirement for CAPA case closure** – Users can establish CAPA case closure and cancellation as a trigger for electronic signature sign-off. For more information, see CAPA management administration.
- **Flexible sampling plans** – Companies can inspect a fraction of a lot, or skip lots completely, to reduce quality and material handling costs, accelerate material throughput, and make

testing less redundant and destructive. For more information, see Flexible sampling plans.

- **Approved customer lists (ACLs)** – This feature provides more control over what products specific customers can buy and when they can buy those products. This capability is especially important for a product line that involves controlled substances and branded products. For more information, see Approved customer lists.
- **Electronic signature** – This feature enhancement improves the security of digital signatures to meet the latest government requirements and regulations. For more information, see CAPA management administration and Electronic batch records (EBRs).
- **Electronic batch records (EBRs)** – Users can view all the versions, methods, and characteristics for consumed bill of materials (BOM) and formula items. This view is referred to as a *master manufacturing record* (MMR). It maintains all the methods that can be used to produce an item. Users can also view and print reports of the actual versions, test values, attribute values, and quality order results of all the items that are produced and the ingredients that are consumed. This view is referred to as a *batch production record* (BPR). It captures the actual version and methods that are used to produce an item. For more information, see Electronic batch records (EBRs).
- **Instrument calibration** – This new feature adds a capability for tracking individual test instrument tags. It also supports an ongoing calibration process for instrument tags and tracks the use of tags against quality order tests. For more information, see Test instrument calibration.
- **Quality associations for return and transfer orders** – This feature enhances the capability of quality associations by enabling automatic creation of quality orders that are triggered from a sales return or a transfer order. For more information, see Quality associations.
- **Customer-specific certificates of analysis (COAs)** – This feature supports the setup and application of customer-specific COA requirements. Each customer drives details such as whether a specific test should be included, whether minimum and maximum values should be suppressed, whether customer-specific batch attribute ranges should be used instead of the standard range, and whether pass and fail results should be replaced with standard text. In addition, customer-specific COAs can be automatically generated from the sales order packing slip posting process. For more information, see Customer specific certificate of analysis (COA).
- **Production dispensing** – Users can segregate the dispensing area and activities from the picking activities. For more information, see Production dispensing.
- **Quick test results entry** – Users can quickly and easily enter test results on a quality order from a consolidated view that provides visibility into minimum, maximum, and target values for a test. For more information, see Enter quality test results quickly.

Quality order usability improvements

Advanced quality management adds several usability improvements to the quality order process. Quality order tests can now be skipped. A user who decides not to perform a test on a given quality order can make a note of that decision on the quality order without losing visibility into the original test. When a test is skipped, all validations on the test are bypassed, and the test is excluded from the results. Acceptable quality level (AQL) calculations are then performed on the remaining tests.

The priority level of the quality order and the tester that the quality order is assigned to are new data elements on the quality order. Use them to sort and filter the quality work that must be completed. Additionally, you can now record result notes for a given test result line. Finally, a parameter now controls the validation that determines whether a selected test instrument tag is already used on an open quality order. Previously, this validation always ran. However, it can now be skipped if it isn't important to a business.

Skip tests as required

A common business process is to create a test group that has several tests, but intentionally skip some tests when the test group runs within a quality order. Previously, you had to delete tests that you didn't want to enter results for. However, some businesses prefer to mark the test as *Skipped* instead of deleting it, so that the decision to skip it can be logged in an audit trail.

When you skip a test, all result data is cleared and can no longer be edited. In addition, no validation is done on associated test result data, such as tag numbers and test result values. The skipped test is also excluded from AQL calculations.

You can reverse the decision to skip a test. In this case, the test returns to its original state, and you can enter test results as usual.

Skip tests from a quality order test line

To mark a test as *Skipped*, select the desired test lines, and then, on the Action Pane, select **Skip**. The test result symbol, order line result, and batch attribute values are cleared. The **Update inventory batch attribute** and **Include results** checkboxes are cleared, and the **Skip test** checkbox is selected. You can't edit the test while it is in the *Skipped* state.

If test results were already entered, you receive a warning message when you try to skip the test.

If you no longer want to skip a test that was previously skipped, select the line, and then select **Skip** again. The line returns to its original state.

Skip tests during quick results entry

When you use the **Skip** option from quick results entry, you can't select multiple test lines at a time. If there are multiple rows of result data for the same test, the **Skip** option collapses them to their original quantities before it updates the data and makes the line uneditable.

Quality order priority and tester assignment

Quality orders now include **Quality order priority** and **Worker** fields on the **General** tab. Both fields are optional.

- **Quality order priority** – This free-form field can be user-defined based on business requirements. For example, a business might express priority as a number between 0 (zero) and 100, where 100 represents the highest priority.
- **Worker** – This field must be set to a valid worker.

Additionally, quality orders now include fields for entering a test outcome description and result notes for each test line.

Skip test instrument tags validation

Previously, the system always ran a validation to check whether the test instrument tags that were selected for use on a new quality order are already used on an existing open quality order. If the system found a selected test instrument tag on an open quality order, it showed a warning message.

This validation is now optional, and a parameter lets you control whether it's run or skipped. You can configure this parameter for each tag individually. You can also set a default value that applies to all new tags.

To set the validation option for individual tags, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality Control** > **Test instrument tags**.
2. For each tag, set the **Skip check for test instrument on open quality order** option to one of the following values:
    - *Yes* – Skip the validation that determines whether the tag is already assigned to an open quality order. If the tag is already assigned to an open quality order, no warning

message is shown.

- *No* – The system runs the validation and shows a warning message if the tag is already assigned to an open quality order.

To set the default validation setting for all new tags, follow these steps:

1. Go to **Inventory management** > **Setup** > **Inventory and Warehouse Management parameters**.
2. On the **Quality management** tab, in the **Skip check for test instrument on open quality order** field, specify whether the validation should be skipped for all new test instrument tags by default. You can change the setting for individual tags.

Learn more in Test instrument calibration.

Arrival overview

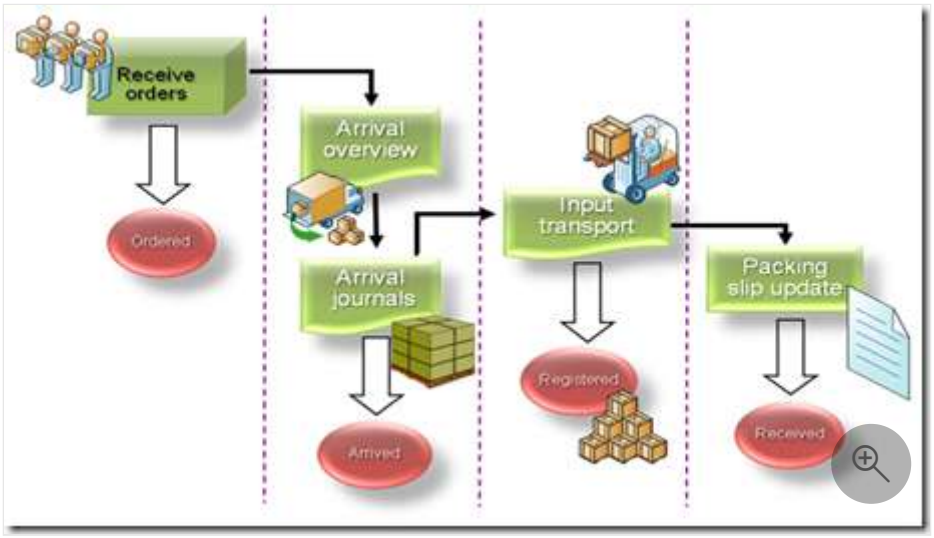
08/29/2025

This article provides information about the Arrival overview feature. The Arrival overview page is part of this feature and provides an overview of all items that are expected to arrive as incoming items.

The **Arrival overview** page provides an overview of all expected incoming items. It also shows arrivals that you can initialize based on the overview. This article focuses on the receiving process.

Business scenario

Consider the following scenario in the inbound processes.



Sammy, a receiving clerk, wants to know what is expected to be received on the current day. On the **Arrival overview** page, Sammy can get an overview of the current tasks, and a rough estimate of quantities, volume, weight, different order types, and so on. Later, a delivery arrives at one of the inbound docks, and Sammy receives a list of the delivery. On the **Arrival overview** page, Sammy can perform the following tasks:

- Identify the matching receipt order, and register the receipt as *In progress*. The lines that are required for a registration are automatically generated, and the receipt can be monitored, even though the transactions aren't yet posted as *Registered*.
- Access the appropriate arrival journal reference (that is, the **Item arrival** journal or the **Production input** journal), and identify journals that are ready for a product receipt update.

Arrival overview page

To open the **Arrival overview** page, select **Inventory management** > **Inbound orders** > **Arrival overview**. You can view a list of orders that are expected to be received. The overview is divided into a header and lines. The header information is grouped by the order type, expected receipt date, and delivery destination. When you select a header line for arrival, all the detail lines that are related to the receipt reference are selected for arrival in the line details part of the page. When you post all related journal lines, this information isn't shown.

Arrival overview profiles

The **Arrival overview** page provides an overview of items that are expected to arrive and the date when they're expected to arrive. As part of the arrival process, you can use multiple sets of personal settings. Individual users can define their personal settings on the **Arrival overview profiles** page.

Set up item arrival

In this example, Sammy sets up a new computer at a location that receives finished goods from production at Site 1. On the **Arrival overview profiles** page, Sammy creates a new setup named **Site 1 production** and specifies the following settings.

1. On the **Arrival options** FastTab, in the **Range** field group, enter information about a day interval and the warehouses to include in the overview.
2. On the **Arrival options** FastTab, in the **Journal** field group, enter a receiving warehouse, a location, and a journal name (item arrival/production input).
3. On the **Arrival query details** FastTab, in the **Site** field group, in the **Restrict to site** field, enter a site to limit the view in the overview area.
4. On the **Arrival query details** FastTab, in the **Transaction types shown** field group, set the **Production orders** option to *Yes*.
5. On the **Arrival query details** FastTab, in the **Miscellaneous** group, set the **Update on startup** option to *Yes* if the view should be automatically updated at startup. Set the **Update on range change** option to **Yes** if the view should be automatically updated when range values are changed.

For this example, the **Arrival overview profile name** field on the **Arrival options** FastTab of the **Arrival overview** page is set to *Site 1 production*.

Prerequisites for arrival journals

To automatically create arrival journals from the **Arrival overview** page, define appropriate information in the **Journal** field group on the **Arrival options** FastTab.

- You must specify a journal name to create a journal.
- If you specify values in the **Warehouse** and **Location** fields, those values apply on the journal lines. If you don't specify values, the system uses the values from the dimension that is specified on the inventory transactions.

Items that you receive from one expected receipt order

On the **Receipts** FastTab, Sammy selects a line and then selects **Start arrival**. All related lines that are in the specified range and that have a quantity to register are automatically selected. An item arrival journal is generated that matches the expected receipt order and the journal. The quantity is automatically initialized on all lines that are created.

Items that you receive from more than one expected receipt order

On the **Receipts** FastTab, Sammy selects multiple lines and then selects **Start arrival**. An item arrival journal is generated that matches all the expected receipt orders and the journal. All lines are created on one item arrival journal header, and the quantity is automatically initialized.

Receive items from one or more expected receipt orders

View information

To get an overview of expected receipts in a date interval, Sammy enters the following information in the fields on the **Arrival options** FastTab on the **Arrival overview** page and then selects **Update** to update the view:

- Arrival overview profile name: *Inquiry*
- Show lines: *All*
- Days back: (Blank)
- Days forward: *0*
- Warehouses: *GW, MW*

Sammy can view the following information:

- All related receipt orders for the system date and an infinite number of days back from it (the **InventTrans.StatusDate** interval), and receipts to warehouses GW and MW, regardless of status.
- Detailed line information for more than one order. Sammy can select multiple header lines in the overview and then select **Show all selected** to view all the corresponding line detail information for all selected orders.

- Information about a specific purchase order. To show only information that is related to a specific reference number in the overview, Sammy can enter an account number in the **Account number** field and an order number in the **Reference number** field.
- An overview of the registration tasks that are due for all the order lines that an item arrival journal has been created for but hasn't yet been posted. To view this information, Sammy can select **In progress** in the **Show lines** field.

Update journals

To register one or more order lines that are due to be processed, Sammy can select the lines in the overview grid or in the line grid, and then select **Journals** > **Show arrivals from receipts**. The item arrival headers that match the lines are shown. To update the purchase order product receipt for the registered items, Sammy can access the item arrival journal headers that are ready for update. To access these item arrival journal headers, Sammy selects **Journals** > **Product receipt ready journals**. All the header lines that are ready for product receipt update in the specified warehouse range are shown. (The header lines that are shown aren't related to the day interval).

Start an arrival registration

By selecting multiple lines on the **Arrival overview** page, Sammy can start an arrival of more than one receipt reference. When Sammy selects a line from the receipts overview, the corresponding line details are selected. If a quantity for registration exists, the **Start arrival** button is available. Sammy can use two methods to start the arrival registration:

- To filter the page so that it shows only records that meet specific criteria, in the **Vendor reference** field, scan a reference number from a vendor, such as the bar code for a delivery note.
- In the overview part or the details part of the **Arrival overview** page, manually select or cancel the selection of records for arrival registration. Then, when Sammy selects **Start arrival**, the selected records are automatically created in an item arrival journal. The records include line information, and all unique field information is assigned.

Update arrival information and process a product receipt

When all goods have been registered, the warehouse manager or purchasing manager can update the received items with a product receipt to add the physical cost. To update arrival information and post a product receipt, follow these steps.

1. Select **Inventory management** > **Inbound orders** > **Arrival overview**.
2. On the **Arrival overview** page, select **Journals** > **Product receipt ready journals** to show a list of the journals that are ready for product receipt update.
3. Select the journals that you want to update, then select **Functions** > **Product receipt**.
4. On the **Posting** page, enter the product receipt number, if it isn't already available on the journal, then select **OK** to process the product receipt.

Summary

The **Arrival overview** page helps the warehouse manager and warehouse workers get an overview of expected work that must be done as part of an inbound process. You can also use the page to start the item arrival process, to help guarantee that items are tracked at the first entry into the warehouse.

Set up an item arrival overview profile

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article focuses on the setup of an arrival overview profile. The arrival overview profile is a collection of rules that will be applied when the Arrival overview page is opened by a user. You can use this procedure in demo data company USMF. This procedure would typically be carried out by a receiving clerk.

1. Go to **Inventory management** > **Setup** > **Distribution** > **Arrival overview profiles**.
2. Select **New**. Because you'll almost always work in the same warehouse offloading full truck loads, you should create an arrival overview profile to simplify the process of registering received items.
3. In the **Arrival overview profile name** field, type a value.
4. In the **Show lines** field, select an option. Select which lines to show for the receipts:
    - *All* – Show all lines, regardless of status.
    - *In progress* – Show lines for receipts in which the progress is *Complete* or *Partly*. This means that for each line, either the full quantity or part of the quantity has been registered in an arrival journal.
    - *Not complete* – Show lines for receipts in which the progress is *None* or *Partly*. This means that for each line, nothing or only part of the quantity has been registered in an arrival journal.
5. Expand or collapse the **Arrival options** section.
6. In the **Days forward** field, type a value. This sets a filter to show the receipt lines expected to be received within the next few days (depending on the number you set).
7. In the **Days back** field, type a value. This sets a filter to show the receipt lines expected to be received within the specified number of days before today.
8. In the **Warehouses** field, type a value. Filter on one or more warehouses.
9. In the **Mode of delivery** field, select a value. This sets a filter to show only the receipt lines with this Mode of delivery.

10. In the **Name** field, select *WHS*.
11. In the **Warehouse** field, select warehouse *24*. This is the default warehouse used for registered receipt lines that use this profile.
12. In the **Location** field, select *Baydoor*. This is the default location used for registered receipt lines that use this profile.
13. Expand or collapse the **Arrival query details** section.
14. In the **Restrict to site** field, select site *2*. This sets a filter to show only the receipt lines with this site.
15. Set the **Purchase orders** option to *Yes*. Select receipt lines from purchase orders.
16. Set the **Transfer** orders option to *Yes*. Select receipt lines from transfer orders.
17. Select **Save**.
18. Close the page.

Last updated on 04/10/2025

Quality and nonconformance management overview

08/13/2025

This article introduces the quality and nonconformance management features in Microsoft Dynamics 365 Supply Chain Management and explains how they can help improve product quality in your supply chain.

Quality assurance involves product testing and the management of nonconforming material. Quality management processes help guarantee a high level of product quality in your supply chain. These processes also help optimize supply chain processes and increase customer satisfaction. Quality management can help you manage turnaround times when you're dealing with nonconforming products, regardless of point of origin of those products. You can link diagnostic results to correction tasks. The system can schedule tasks to correct problems and therefore help prevent recurrences of those problems in the future. Quality management also lets you track issues (including internal problems) by problem type, and lets you identify solutions as either short-term or long-term. Statistics about key performance indicators (KPIs) provide insight into nonconformance problems that have previously occurred and the solutions that were applied to correct them. You can use historical data to help review the effectiveness of quality measures that have previously been taken and to determine appropriate measures in the future.

Quality management can help you manage turnaround times when you handle nonconforming products, regardless of their point of origin. Because diagnostic types are linked to correction reporting, Supply Chain Management can schedule tasks to correct problems and prevent them from recurring.

In addition to functionality for managing nonconformance, quality management includes functionality for tracking issues by problem type (even when the issues are internal problems), and for identifying solutions as short-term or long-term. Statistics about key performance indicators (KPIs) provide insight into the history of previous nonconformance issues and the solutions that were used to correct them. You can use historical data to review the effectiveness of previous quality measures and determine appropriate measures to use in the future.

When you set up a quality association, Supply Chain Management can generate quality orders for various business processes, events, and conditions. The quality association can cover a specific item, a specific group of items, or all items.

Examples of the use of quality management

Quality management is flexible and can be implemented in various ways to meet the requirements of specific levels of supply chain operations. The following examples illustrate possible uses of these features:

- Automatically start a quality control process, based on predefined criteria (for example, when warehouse registration of a purchase order from a specific vendor occurs).
- Block inventory during inspection to prevent non-approved inventory from being used (full blocking of purchase order quantities).
- Use item sampling as part of a quality association to define the amount of current physical inventory that must be inspected. Sampling can be based on fixed quantities, a percentage, or a full license plate.
- Create quality orders for partial receipts. To create a quality order that is based on the quantity that is physically received with an order, you must select the **Per updated quantity** check box on the **Item sampling** page.
- Create test types that include minimum, maximum, and target test values, and perform qualitative-versus-quantitative testing that has predefined validation results.
- Specify an acceptable quality level (AQL) to control quality measure tolerances.
- Specify the resources that an inspection operation requires, such as a test area and test instruments.

> ⓘ **Note**
>
> The *Quality management for warehouse processes* feature extends the capabilities of quality management. If you're using this feature, see **Quality management for warehouse processes** for examples that show how quality management works when it's enabled.

Controlling the quality management process

Here are some of the ways that you can control the quality management process:

- Create quality orders that are based on trigger points, such as "at product receipt" for inbound operations or "at product pick-up" for outbound operations.
- Document test results, and determine whether the results meet the established test criteria and AQLs.
- Use document management for detailed product specifications and user-specific notes as part of reporting during the inspection process.
- Maintain nonconforming products, and correlate those products with additional nonconformance information to track down the original cause of a problem.
- Document the cost of managing a nonconformance. This cost can include the items (such as spare parts), miscellaneous charges, and the timesheet hours that are required to

correct the nonconformance.

- Schedule error correction processes by using correction handling that is linked to quality orders.

Product testing and quality orders

Product testing is typically referred to as quality control and uses quality orders. By using the quality control functionality, you can do the following:

- Define the tests that must be performed for material. These tests include the quality specifications, the applicable test instrument, documents that describe the test, a sampling plan, and the AQLs.
- Create a quality order that identifies the tests that must be performed for a specific order, such as a purchase or production order, or for a specific inventory quantity. You can manually create a quality order, or a quality order can be automatically generated based on quality guidelines.
- Define the quality guidelines that are related to purchase, quarantine, production, or sales orders in each business process, so that a quality order that identifies the testing requirements for incoming or outgoing material can be automatically generated.

- Record the test results in a quality order, validate the test results against the AQL, and print a certificate of analysis that shows the test results.

Nonconformance

A nonconformance describes an item that has a quality problem. The nonconformance process lets you create a nonconformance order that describes a quantity of nonconforming material, the problem source, the problem type, and explanatory notes. You can define a classification of problem types to make analysis of nonconforming material easier. You can also print a nonconformance tag and a nonconformance report to guide the disposition of nonconforming material. For example, the tag and report might indicate a condition of **Unusable** or **Restricted usage**.

The following table lists the six default nonconformance types and describes the information that must be recorded for each type.

Expand table

Nonconformance type	Source information
Customer	The customer account number, the sales order number, or a lot number of a sales order transaction. For example, the nonconformance might be related to a specific sales order shipment or to customer feedback about product quality.
Service request	The customer account number, the sales order number, or a lot number of a sales order transaction. For example, the nonconformance might be related to a specific sales order shipment or to a customer's complaint about item quality.
Vendor	The vendor account number, the purchase order number, or a lot number of a purchase order transaction. For example, the nonconformance might be related to a purchase order receipt or to a vendor's concern about a part that it supplies.
Production	The production order number or a lot number of a production order transaction. For example, the nonconformance might be related to a specific batch that was produced.
Internal	The quality order number or a lot number of a quality order transaction. For example, the nonconformance might be related to the tests that are performed as part of a quality order or to an employee's concern about product quality.
Co-product production	A co-product production order nonconformance that is related to batch production orders.

Nonconformances are associated with a problem type. Problem types are defined on the **Problem types** page, where you specify which problem types can be associated with each

nonconformance type. For example, the problem types for nonconformances of the **Service request** type might reflect a classification of customer complaints, whereas the problem types for nonconformances of the **Internal** type might represent a classification of defect codes.

When you create a new nonconformance, you select the nonconformance type and the problem type. The initial approval status is **New**, which represents a request for action. The next step is to change the approval status to **Approved** or **Refused**, to indicate that you will or won't take action on the nonconformance. You can also close a nonconformance (by selecting a separate check box) to indicate that you're finished with it, or you can reopen a nonconformance to indicate that additional consideration is required.

You can enter comments for a nonconformance by attaching a document. It's a good idea to define a unique document type for nonconformances by using the **Document type** page. You can then use the **Report setup** page to define whether comments for this document type should be printed on the nonconformance report and nonconformance tag. The conformance report and nonconformance tag can help with material disposition. You can selectively generate reports and tags, based on selection criteria that are associated with a nonconformance. These criteria include the nonconformance number, item, customer, vendor, and status.

The nonconformance report displays the nonconformance number, item, and problem type. Depending on your report setup policy, the report might also display related notes about the nonconformance. The nonconformance tag displays similar information, and also includes the quarantine zone and type (such as **Restricted usage** or **Unusable**) that you assigned to the nonconformance to help guide disposition of the defective material.

Approved nonconformance

You can optionally define one or more related operations for an approved nonconformance. A related operation describes the work that should be performed, and contains a list of the quality operations that you've defined and descriptive text about the reason for the work. After you define an operation, you can optionally define the miscellaneous charges, items, and timesheet labor hours that are required in order to perform the work. The calculated costs are shown for the related operation, and the total calculated costs are shown for the nonconformance. The calculated costs and the underlying details (about items, labor hours, and miscellaneous charges) represent reference information, and they're used only in the quality management function.

You can optionally create a quality order from a nonconformance by first performing an inquiry for quality orders and then creating the new quality order. For example, a quality order might identify the need to test (or retest) the defective material. The newly created quality order displays the link to the originating nonconformance.

You can optionally link one nonconformance to another and create a new nonconformance from an existing one. For example, the link can reflect the interconnection between quality problems.

Correction handling

The **Corrections** page lets you create a list of nonconformances that must be corrected. Each correction item is associated with the diagnostic type that caused the problem to be discovered. The **Corrections** page also contains information about who must perform a corrective action, and when. You can describe the details of the problem and the corrective action that is required by attaching a document to the correction. After the nonconformance has been addressed or corrected, you "close" the correction item by selecting the **Completed** option. You can also indicate that the solution was a short-term solution.

It's a good idea to define a unique document type for corrections by using the **Document type** page. You can then use the **Report setup** page to define whether comments for this document type are printed on the correction report. A printed correction report displays information about the nonconformance and the related nonconformance notes. The report also includes correction information, such as the diagnostic type, and the related correction notes.

Next steps

- Enable quality and nonconformance management
- Inventory blocking
- Quarantine orders
- Inspect the quality of goods

Enable quality and nonconformance management

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides an overview of the process for setting up and configuring quality and nonconformance management features in Microsoft Dynamics 365 Supply Chain Management.

Enable the feature

Follow these steps to enable quality management on your system.

1. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**.
2. On the **Quality management** tab, set the **Use quality management** option to *Yes*.
3. In the **Hourly rate** field, enter an hourly labor rate in the local currency. The hourly rate is used to calculate costs for operations that are related to a nonconformance. The hourly rate and calculated costs provide reference information for a nonconformance. They don't interact with other functionality.
4. Select **Report setup**.
5. Add new lines for the various report types, and select the type of document to use for each report.
6. Close the page.
7. Close the page.

Configure quality management

Before you can use the quality management features and generate quality orders, you must configure the system and prerequisites. Here's a list of the steps required to configure quality management.

1. Enable quality and nonconformance management.
2. Optional: Configure test instruments.
3. Configure tests.
4. Configure test variables and outcomes.
5. Configure test groups.
6. Optional: Configure quality groups, and link to products.
7. Optional: Configure quality associations.

After you complete the configuration, you can start to create and process quality orders. For more information about how to create and work with quality orders, see Quality orders.

Configure nonconformance management

Before you can use the nonconformance management features and generate nonconformances, you must configure the system and prerequisites. Here's a list of the steps required to configure nonconformance management.

1. Enable quality and nonconformance management.
2. Configure workers who are responsible for approving nonconformances.
3. Configure problem types.
4. Configure quarantine zones.
5. Configure diagnostic types.
6. Configure operations.
7. Optional: Configure quality charges.

After you complete the configuration, you can start to create and process nonconformances. For more information about how to create and work with nonconformances, see Create and process nonconformances.

Last updated on 05/27/2026

Quality management test instruments

This article describes how to create test instruments or instrument types that you can use for tests on quality orders in Microsoft Dynamics 365 Supply Chain Management.

Use the **Test instruments** page to define and view details about the instruments or instrument types that you use to perform tests on quality orders. Test instruments are optional. However, they can help quality workers determine which device or tool they should use to perform a specific test.

Test instrument example

You're performing various tests on electrical components. Some tests are for the voltage output of the components, one test is for their temperature, and one test is for their weight. Different tools, devices, or equipment are used to perform each test. For example, a voltage meter is used to measure voltage, a thermometer is used to measure temperature, and a scale is used to measure weight. You can configure each of these device types as a test instrument and indicate the unit of measure that the test results should be recorded in. For example, you record results from a voltage meter in volts, results from a thermometer in degrees Fahrenheit or degrees Celsius, and results from a scale in pounds or kilograms.

Prerequisites for calibration-related settings

Most of the features that are described in this article are available as a standard part of all current versions of Supply Chain Management. However, the calibration-related settings (the **Tag number required**, **Used for calibration**, and **Calibration label layout** fields) add the following requirements:

- You must be running Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Learn more in Test instrument calibration.

Create a test instrument

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test instruments**.

2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:

    - **Test instrument** – Enter a unique ID or name for the test instrument.
    - **Description** – Enter a detailed description of the test instrument.
    - **Unit** – Select the unit that the instrument measures results in. The **Precision** field is automatically set based on the unit that you select.
    - **Tag number required** – Select this checkbox if a test instrument tag number (in addition to an instrument type) must be specified for the test instrument on quantity orders. The test instrument tag identifies the specific physical instrument that is used in the test. Selection of this checkbox triggers other functionality that is related to tracking and calibration of test instruments. To view, create, and edit the available test instrument tags, select **Test instrument tags** on the Action Pane.
    - **Used for calibration** – Select this checkbox for test instrument types that are used to calibrate other instruments and equipment.
    - **Calibration label layout** – For test instrument types where the **Tag number required** checkbox is selected, select the layout that is used to print calibration labels.

3. If you're using Asset Management to manage test instruments, then make the following additional settings. Skip this step for test instrument types that you aren't managing with Asset Management. These settings are only available when the **Tag number required** checkbox is selected.

    - **Asset type** – If you want to manage test instruments of this type using Asset Management, then select the related asset type here.
    - **Test quantity counter type** – Select the counter to increment each time a quality order for a test instrument of this type is validated. The system increments the counter by the quantity that was tested on the quality order. If you select a counter type in this field, you can't select a value in the **Fixed increment counter type** field. Learn more about counters in Counters.
    - **Fixed increment counter type** – Select the counter to increment each time a quality order for a test instrument of this type is validated. The system increments the counter by the value specified in the **Usage increment** field, regardless of the quantity that was tested on the quality order. If you select a counter type in this field, you can't select a value in the **Test quantity counter type** field. Learn more about counters in Counters.
    - **Usage increment** – If you chose a fixed-increment counter, then enter the value by which to increment the asset counter when a quality order is validated.

- **Calibration state** – Select the asset lifecycle state that indicates that the asset is being calibrated. When an asset of the type specified in the **Asset type** column changes status to the value set in this field, the system automatically updates the related test instrument tag to *Calibration*. Learn more about asset stages in Asset lifecycle states.
- **Out of service state** – Select the asset lifecycle state that indicates that the asset is out of service. When an asset of the type specified in the **Asset type** column changes status to the value set in this field, the system automatically updates the related test instrument tag to *Out of service*. Learn more about asset stages in Asset lifecycle states.
- **Auto-create test instrument tag from asset** – Select this checkbox to automatically create a test instrument tag when you create a new asset of the linked **Asset type** (existing assets aren't affected).

4. Close the page.

Quality management tests

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to create tests that you can use for quality orders in Microsoft Dynamics 365 Supply Chain Management.

You use the **Tests** page to define and view the individual tests that determine whether your products meet quality specifications. You can assign one or more individual tests to a test group. In this case, you also specify test-specific information, such as the acceptable measurement values. Measurement values are used for quantitative tests. For qualitative tests, test variables are used.

- For quantitative tests, the **Type** field is set to *Integer* or *Fraction*. A unit of measure is also specified. Quality specifications and test results are expressed as numbers.
- For qualitative tests, the **Type** field is set to *Option*. Qualitative tests require additional information about the test variable that is being measured and its enumerated options. Quality specifications and test results are expressed according to an outcome.

You can optionally assign a test instrument to a test. However, test instruments aren't required to create and use tests with quality orders. Learn more in Quality management test instruments.

You can also optionally specify a unit for a test, to indicate the unit of measure that test results are recorded in. For example, a test for temperature might include a unit of either degrees Fahrenheit or degrees Celsius.

Example of a test

A manufacturing company performs two tests on purchased material: a quantitative test for material quality and a qualitative test for packaging damage. The company specifies additional information about the qualitative test to define the test variable (for example, damaged packaging) and its outcomes. The company uses the **Test groups** page to assign the two tests to

a test group and to specify the test-specific information. The test group is assigned to a quality order so that the company can report test results for the two tests.

Create a test

Follow these steps to create a test.

1. Go to **Inventory management** > **Setup** > **Quality control** > **Tests**.
2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Test** – Enter a unique ID or name for the test.
    - **Description** – Enter a detailed description of the test.
    - **Type** – Select the type of results that the test produces. For quantitative tests, select *Fraction* or *Integer*. For qualitative tests, select *Option*.
    - **Test instrument** – Select a test instrument that should be used for the test.
    - **Unit** – If you selected *Fraction* or *Integer* in the **Type** field (that is, if the test is a quantitative test), select the unit of measure that test results should be recorded in.
    - **Defect type** – If you're using acceptance sampling, then choose a defect type that applies for this test. Learn more about defect types, how to set them up, and how to use them in Acceptance sampling.
3. Close the page.

> **Note**
>
> After you save a test, you can no longer edit the **Type** field in the grid. If you must change the type of test results that will be recorded for a test, select **Change quality test type** on the Action Pane. In the **Change quality test type** dialog box, set the **New type** field to the desired type, and then select **OK** to close the dialog box.

Quality management test variables

Article • 06/03/2022

This article describes how to create test variables that can be used for qualitative tests on quality orders in Microsoft Dynamics 365 Supply Chain Management.

For every qualitative test that is defined on the **Tests** page, you must define a test variable and its possible outcomes (results). (For qualitative tests, the **Type** field on the **Tests** page is set to *Option*.)

You use the **Test variables** page to set up, edit, and view the possible outcomes for a test variable that is associated with a qualitative test. For each outcome, you assign an outcome status of either *Pass* or *Fail* to indicate whether the test is passed or failed when that outcome is selected as a test result. You use the **Test groups** page to assign a test variable and a default outcome for it to an individual qualitative test.

For every test variable, we recommend that you define at least two outcomes: one that has an outcome status of *Pass* and one that has an outcome status of *Fail*. There is no limit on the total number of variables or outcomes that can be defined. Additionally, multiple tests can use the same test variables to record results.

Examples of test variables

Example 1

A manufacturing company performs two tests on manufactured materials. In one test, the pH level is associated with a color strip. Acceptable pH levels are in lighter colors, and unacceptable pH levels are in darker colors. In another test, multiple visual inspections are performed, and quality workers use their judgement to determine whether the item passes or fails the visual inspection.

Example 2

A manufacturing company that produces cookies uses an inspection test for the finished product. This inspection test has several variables. One variable is taste, and the possible outcomes for it are good and bad. A second variable is color, and the possible outcomes for it are too dark, too light, and correct.

Create a test variable

Follow these steps to create a test variable.

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test variables**.
2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Variable** – Enter a unique ID or name for the variable.
    - **Description** – Enter a detailed description of the variable.
3. While the new row is still selected, select **Outcomes** on the Action Pane.
4. On the **Test variable outcomes** page, on the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Outcome** – Enter a unique ID or name for the outcome.
    - **Description** – Enter a detailed description of the outcome.
    - **Outcome status** – Select either *Pass* or *Fail* to indicate whether the test is passed or failed when the outcome is selected as a test result.
5. Repeat the previous step for each additional outcome. Make sure that at least one outcome has an outcome status of *Pass* and at least one has an outcome status of *Fail*.
6. Close the pages.

Quality management test groups

09/19/2025

This article describes how to create test groups so you can use multiple tests with quality orders in Microsoft Dynamics 365 Supply Chain Management.

Use the **Test groups** page to set up, edit, and view test groups and the individual tests that you assign to them. The upper part of the page shows the test groups, and the lower part shows the tests that are assigned to a selected test group.

Assign several policies to a test group, such as a sampling plan, an acceptable quality level (AQL), and the requirement for destructive testing. When you assign an individual test to a test group, define additional information, such as the sequence, documents, and validity dates. For a quantitative test, the information that you define also includes the acceptable measurement values. For a qualitative test, the information includes the test variable and default outcome.

The test group that you assign to a quality order defines the default set of tests that you must perform on the specified item. However, you can add, delete, or change tests for the quality order. The system reports test results for each test on a quality order.

When you define a test group, you can optionally specify an item sampling. Use item samplings to define the amount of the product that must be tested. Learn more in Quality management item sampling. You can also indicate whether the tests in a test group are destructive. In a destructive test, the item sampling is destroyed, and the quantity is removed from the on-hand inventory.

Example of a test group

A manufacturing company defines a test group for each variation of its quality guidelines. The various test groups reflect differences in the sampling plans, the sets of tests that must be performed together, the AQL, and other factors. For quantitative tests, there are also differences in the acceptable measurement values. To enforce its quality guidelines, the company assigns a test group to each rule that is used to automatically generate quality orders on the **Quality associations** page. It also assigns a test group to quality orders that are manually created.

Create a test group

To create a test group, follow these steps.

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test groups**.

2. On the Action Pane, select **New** to add a row to the grid in the upper part of the page. Then set the following fields for the new row:

    - **Test group** – Enter a unique ID or name for the test group.
    - **Description** – Enter a detailed description of the test group.
    - **Acceptable quality level** – Enter the total percentage of test results that must pass for the group of tests to be considered passed.
    - **Item sampling** – Select an item sampling. Learn more in Quality management item sampling.
    - **Destructive** – Select this check box to indicate that the test group destroys the items that are tested.

3. While the new row is still selected, select the **General** tab in the upper part of the page. Some of the settings for the test group that you select on the **Overview** tab are repeated here. In addition, you can set the following fields for the group:

    - **Update inventory batch attribute** – When you set this option to *Yes* here, it automatically sets to *Yes* for every new test that you add to the test group in the lower part of the page.
    - **Update batch disposition** – When you set this option to *Yes*, if the item that you're testing is batch controlled, the batch disposition automatically updates with the value selected in the **Failed quality order batch disposition** or **Passed quality order batch disposition** field.
    - **Failed quality order batch disposition** – Select the batch disposition code that should be assigned when a quality order that includes this test group fails because it doesn't meet the AQL.
    - **Passed quality order batch disposition** – Select the batch disposition code that should be assigned when a quality order that includes this test group passes because it meets the AQL.
    - **Update inventory status** – When you set this option to *Yes*, if **Inventory status** is enabled on the storage dimension group for the item that you're testing, the status automatically updates with the status selected in the **Failed quality order status** or **Passed quality order status** field.
    - **Failed quality order status** – Select the inventory status that should be assigned to the item when a quality order that includes this test group fails because it doesn't meet the AQL.
    - **Passed quality order status** – Select the inventory status that should be assigned to the item when a quality order that includes this test group passes because it meets the AQL.

Add a qualitative test to a test group

To add a qualitative test to a test group, follow these steps.

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test groups**.
2. On the **Overview** tab in the upper part of the page, select the test group that you want to add a test to.
3. In the lower part of the page, on the **Overview** tab, select **Add** on the toolbar to add a row to the grid. Then set the following fields for the new row:
    - **Sequence number** – Enter an integer to specify the order that the tests should be performed in. Tests that have smaller sequence numbers run before tests that have larger sequence numbers.

      > ⓘ **Note**
      >
      > Leave a gap between sequence numbers. For example, set the **Sequence number** field to *10* for your first test, and then increment the value by 10 for each additional test. In this way, you can add new tests later without having to delete and re-create the lines to put them in the desired order.

    - **Test** – Select the test that you want to perform. For a qualitative test, select a test where the **Type** field is set to *Option*.
    - **Effective** – Select the first date when the test is valid. If you leave this field blank, there's no limit.
    - **Expiration** – Select the last date when the test is valid. If you leave this field blank or set it to *Never*, there's no limit.
    - **Test value determination** – Select how an AQL should be determined when multiple results are recorded for the same test. For a qualitative test, only *Manual* can be selected. If you select one of the other values (*Average*, *Minimum*, or *Maximum*), you receive an error message when you save the test group.
    - **Attribute** – If you want to record test results on a batch attribute, select the attribute here, and select the **Update inventory batch attribute** check box.
    - **Update inventory batch attribute** – Select this check box to record test results for the batch attribute that is selected in the **Attribute** field.
4. In the lower part of the page, select the **General** tab. Some of the settings for the test selected on the **Overview** tab are repeated here. In addition, you can set the following fields for the test:

- **Certificate of analysis report** – Set this option to *Yes* to indicate that the test results should be printed on the certificate of analysis (CoA). This report can be generated from the quality order.
- **Action on failure** – Select either *Accept* or *Fail* to indicate whether the test should pass or fail if the AQL for it isn't met.
- **Acceptable quality level** – Enter the total percentage of test results that must pass for the test to be considered passed.

5. In the lower part of the page, on the **Test** tab, set the following fields:

    - **Variable** – Select the test variable to record the qualitative test results for.
    - **Default outcome** – Select the default outcome that should be recorded for the test results.
    - **Test instrument** – Select the device that should be used for the test. If a test instrument is defined, it's automatically entered for the test in the test group.

6. Close the page.

Add a quantitative test to a test group

To add a quantitative test to a test group, follow these steps.

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test groups**.

2. On the **Overview** tab in the upper part of the page, select the test group that you want to add a test to.

3. In the lower part of the page, on the **Overview** tab, select **Add** on the toolbar to add a row to the grid. Then set the following fields for the new row:

    - **Sequence number** – Enter an integer to specify the order that the tests should be performed in. Tests that have smaller sequence numbers run before tests that have larger sequence numbers.

        > **Tip**
        >
        > You should leave a gap between sequence numbers. For example, set the **Sequence number** field to *10* for your first test, and then increment the value by 10 for each additional test. In this way, you can add new tests later without having to delete and re-create the lines to put them in the desired order.

    - **Test** – Select the test that you want to perform. For a quantitative test, select a test where the **Type** field is set to *Fraction* or *Integer*.

- **Effective** – Select the first date when the test is valid. If you leave this field blank, there's no limit.
- **Expiration** – Select the last date when the test is valid. If you leave this field blank or set it to *Never*, there's no limit.
- **Test value determination** – Select how an AQL should be determined when multiple results are recorded for the same test. The available options are *Average*, *Minimum*, *Maximum*, and *Manual*.
- **Attribute** – If you want to record test results on a batch attribute, select the attribute here, and select the **Update inventory batch attribute** check box.
- **Update inventory batch attribute** – Select this check box to record test results for the batch attribute that is selected in the **Attribute** field.

4. In the lower part of the page, select the **General** tab. Some of the settings for the test selected on the **Overview** tab are repeated here. In addition, you can set the following fields for the test:
    - **Certificate of analysis report** – Set this option to *Yes* to indicate that the test results should be printed on the CoA. This report can be generated from the quality order.
    - **Action on failure** – Select either *Accept* or *Fail* to indicate whether the test should pass or fail if the AQL for it isn't met.
    - **Acceptable quality level** – Enter the total percentage of test results that must pass for the test to be considered passed.
5. In the lower part of the page, on the **Test** tab, set the following fields:
    - **Standard** – Enter the amount (integer or fraction) that is expected for the test results. The value that you enter is entered by default in the test results. Additionally, it automatically enters as a default value in the **Min** and **Max** fields.
    - **Min** – Enter the minimum allowed value for the test results. The value that you enter must be less than the amount that is set in the **Standard** field. When you update the **Min** field, the **Min tolerance (%)** field is automatically updated. Likewise, when you update the **Min tolerance (%)** field, the **Min** field is automatically updated.
    - **Max** – Enter the maximum allowed value for the test results. The value that you enter must be more than the amount that is set in the **Standard** field. When you update the **Max** field, the **Max tolerance (%)** field is automatically updated. Likewise, when you update the **Max tolerance (%)** field, the **Max** field is automatically updated.
    - **Test instrument** – Select the device that should be used for the test. If a test instrument is defined, it's automatically entered for the test in the test group.

6. Close the page.

Item quality groups

A quality group represents common testing requirements for items. This article describes how to use and create item quality groups to logically group products so that they can be assigned to quality associations for the automatic generation of quality orders.

To set up, edit, and view the items that are assigned to a quality group, or the quality groups that are assigned to an item, go to **Inventory management** > **Setup** > **Quality groups**. After you define the test requirements on the **Test groups** page, you can define the rules for automatically generating quality orders. To simplify the process, you don't define rules for individual items. Instead, you can define the rules for a quality group on the **Quality associations** page.

Example of an item quality group

A manufacturing company purchases various raw materials that have the same testing requirements for incoming inspection. Therefore, the company defines a quality group and then assigns the item numbers that are associated with the raw materials to that group. Later, the company purchases a new type of raw material that has the same testing requirements. Instead of setting up new testing requirements for the new material, the company adds the item number for the new material to the existing quality group.

The same company also produces items that have the same production testing requirements and ships items that have the same requirement for pre-shipment testing. Therefore, the company defines two additional quality groups and then assigns the relevant item numbers to each group.

Create a quality group

To create a quality group, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Quality groups**.
2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Quality group** – Enter a unique ID or name for the quality group.
    - **Description** – Enter a detailed description of the quality group.
3. Close the page.

Manually add items to a quality group

To manually add items to a quality group, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Quality groups**.
2. Select the quality group that you want to add items to.
3. On the Action Pane, select **Items**.
4. On the **Items in quality groups** page, on the Action Pane, select **New** to add a row to the grid. Then, for the new row, set the **Item number** field to the item number that you want to add.
5. Repeat the previous step for each additional item that must be added.
6. Close the pages.

Add multiple items to a quality group

To add multiple items to a quality group, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Quality groups**.
2. Create or select the quality group that you want to add items to.
3. On the Action Pane, select **Add items**.
4. In the **Inquiry** dialog box, enter the filter criteria for the items that you want to add. For example, you might filter for all items in a specific item group.
5. Select **OK**.
6. In the **Add items** dialog box, a grid shows all the items that match your query. Review the results.

   If any changes are required, select **Select** to return to the **Inquiry** dialog box, and adjust your query.
7. When the results include all the items that you want to add, select **OK**.
8. Close the page.

Manually associate an item with a quality group

To manually associate an item with a quality group, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Item quality groups**.
2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Item number** – Select the item number to add.
    - **Quality group** – Select the quality group to assign to the item.
3. Repeat the previous step for each additional combination of an item and a quality group that must be added.
4. Close the pages.

Manually add a quality group from the Released products page

To manually add a quality group from the **Released products** page, follow these steps:

1. Go to **Product information management** > **Products** > **Released products**.
2. Select the product that you want to assign a quality group to.
3. On the Action Pane, on the **Manage inventory** tab, in the **Quality** group, select **Item quality groups**.
4. On the **Items in quality groups** page, on the Action Pane, select **New** to add a row to the grid. Then, for the new row, set the **Quality group** field to the quality group that you want to assign to the product.
5. Repeat the previous step for each additional quality group that you want to assign to the product.
6. Close the pages.

Quality management item sampling

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Item sampling is used as part of a quality association. It defines the amount of current physical inventory that must be inspected. Sampling can be based on fixed quantities, a percentage, or a full license plate.

Set up item sampling

Follow these steps to set up item sampling.

1. Go to **Inventory management** > **Setup** > **Quality control** > **Item sampling**.
2. Select **New**.
3. Make the following settings in the header of your new record:

    - **Item sampling** – Enter a name for the record.
    - **Description** – Enter a short description of the record.
    - **Sampling scope** – Select the scope to use when evaluating if quality work should be created. When set to *Shipment* or *Load*, those entities are used if available. If not, the *Order* is used.
    - **Use acceptance sampling charts** – Choose whether to use acceptance sampling with this record. Learn more in Acceptance sampling.

4. If you're using acceptance sampling, then fill out the settings provided on the **Acceptance sampling** FastTab. Learn more about how to use these settings in Acceptance sampling.
5. If you're using sample management, then fill out the settings provided on the **Sample management** FastTab to set up inline or continuous sampling. Learn more about how to use these settings in Enable and configure sample management.
6. On the **Sampling quantity** FastTab, in the **Value** field, enter a number. This value is related to the quantity specification value that is selected in the adjacent field.
7. On the **Process** FastTab, make the following settings:

- **Full blocking** – Set to *Yes* if the entire lot or order line quantity should be blocked when a test fails. Set this option to *No* if only the items in the quality order should be blocked when a test fails.
- For each dimension (such as **License plate** or **Batch number**) that should be automatically populated on the **Inventory dimensions** tab of a quality order, set it's option to *Yes*.

8. Select **Save**.
9. Close the page.

> ⓘ **Note**
>
> The *Quality management for warehouse processes* feature provides additional item sampling capabilities. It adds the concept of *item sampling scope* and lets you define a full license plate as the quantity specification. If you've turned on this feature, go to **Quality management for warehouse processes**.

Last updated on 03/11/2026

Quality associations

This article describes how you can use quality associations in Microsoft Dynamics 365 Supply Chain Management to automatically generate quality orders that are related to your sales, purchase, inbound shipment order, and production processes.

A quality association defines all the following information for a quality order that is generated:

- The transaction event
- The set of tests that must be performed on the items
- The acceptable quality level (AQL)
- The sampling plan

You must define a quality association for each variation in a business process that requires automatic generation of quality orders. For example, a quality order can be generated in the business processes for purchase orders, quarantine orders, sales orders, and production orders.

Prerequisites for sales returns and transfer orders (preview)

[This section is prerelease documentation and is subject to change.]

Most of the features that are described in this article are available as a standard part of all current versions of Supply Chain Management. However, if you want to set up quality associations for sales returns and transfer orders, your system must meet the following requirements:

- You must be running Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Important

- This is a preview feature.
- Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are

available before an official release so that customers can get early access and provide feedback.

Working with quality associations

The business process that uses a quality association can be related to various source documents, such as purchase orders, sales orders, or production orders.

Each quality association record defines the set of tests, the AQL, and the sampling plan that applies to the quality orders that are generated. You must define a quality association record for each variation in a business process. For example, you can set up a quality association that generates a quality order when a purchase order product receipt is updated. Depending on the setup of the execution plan, the triggering process itself can be blocked while there's an open quality order. Alternatively, subsequent processes, such as purchase order invoicing, can be blocked.

> **Note**
>
> While there are open quality orders, inventory quantities are automatically blocked from being issued. Depending on the setting of the **Full blocking** field on the **Item samplings** page, the quantity is either the quantity on the quality order or the quantity on the source document line. Learn more in Quality management item sampling.

For a given business process, the quality association record identifies the event and conditions that a quality order is generated for. The conditions can be specific to either a site or a legal entity. A quality order that involves destructive tests can be generated only when on-hand inventory exists for the event.

To work with quality associations, go to **Inventory management** > **Setup** > **Quality control** > **Quality associations**. The following examples show how a quality association record is defined for the variations in each business process. For each example, the following table summarizes the events and conditions that are defined by a quality association record.

> **Note**
>
> The *Quality management for warehouse processes* feature adds capabilities for quality order processing for production where the **Event type** field is set to *Report as finished* and the

Execution field is set to *After*, and for purchases where the **Event type** field is set to *Registration*. Learn more in Quality management for warehouse processes.

The following table provides more information about how quality orders can be generated for specific types of processes.

Expand table

Type of process	When quality orders can be automatically generated	When quality orders can be generated if destructive testing is required	Condition information	Manual generation information
Purchase order	Before or after a receipts list or product receipt is posted for the material that is received	After the product receipt is posted for the material that is received, because the material must be available for destructive testing	The requirement for a quality order can reflect a specific site, item, or vendor, or a combination of these conditions.	A manually generated quality order that refers to a purchase order can use information in a quality association record, such as the test sampling plan.
Inbound shipment order	As part of the registration process (warehouse receiving)	As part of the registration process (warehouse receiving)	The requirement for a quality order can reflect a specific site, item, or consigner, or a combination of these conditions.	A manually generated quality order that refers to an inbound shipment order can use information in a quality association record, such as the test sampling plan.
Quarantine order	Before or after the quarantine order is reported as finished or ended	Quality orders that require destructive tests can't be generated. The assumption is that the quarantine order functionality	The requirement for a quality order can reflect a specific site, item, or vendor, or a combination of these conditions.	A manually generated quality order that refers to a quarantine order can use information in a quality association

Type of process	When quality orders can be automatically generated	When quality orders can be generated if destructive testing is required	Condition information	Manual generation information
		handles the disposition of the material that is destroyed.		record, such as the test sampling plan.
Sales order	Before a scheduled picking process or packing slip update for the items that are being shipped	At any step	The requirement for a quality order can reflect a specific site, item, or customer, or a combination of these conditions.	A manually generated quality order that refers to a sales order can use information in a quality association record, such as the test sampling plan.
Production order	Before or after the finished quantity is reported for the production order	After the finished quantity is reported for the production order	The requirement for a quality order can reflect a specific site or item, or a combination of these conditions.	A manually generated quality order that refers to a production order can use information in a quality association record, such as the test sampling plan.
Production order that has a route operation	Before or after the report is finished for an operation	After the reporting production is finished for the last operation	The requirement for a quality order can reflect a specific site, item, or operations resource, or a combination of these conditions.	A manually generated quality order that refers to a route operation can use information in a quality association record, such as the test sampling plan.
Inventory	A quality order can't be			A quality order must be manually

Type of process	When quality orders can be automatically generated	When quality orders can be generated if destructive testing is required	Condition information	Manual generation information
	automatically generated for a transaction in an inventory journal or for transfer order transactions.			created for an item's inventory quantity. Physical on-hand inventory is required.
Sales return	A quality order is generated when the packing slip on the sales return order is posted.	After the product receipt is posted for the material that is received, because the material must be available for destructive testing.	Before the packing slip is posted on the return order, the quantity on the return line must be registered. To register the quantity, on the **Update line** menu, select **Registration**. Then, on the **Assign disposition code** dropdown menu, select one of the applicable disposition codes. The selected disposition code must be set up to search for an applicable quality association. To complete this setup, select the **Check for quality association** checkbox in the definition of the disposition code.	
Transfer order	A quality order can be generated when you do the picking, when you ship the product, or when you receive it.	After registration of the receipt of the material, because the material must be available for destructive testing.		

Note

When you filter quality associations for the *Inbound shipment order* reference type, and the **Account code** value is *Table* or *Group*, you must create consigners (for *Table*) or consigner groups (for *Group*) beforehand.

Set up a quality association

Follow these steps to create a quality association:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Quality associations**.
2. On the Action Pane, select **New**.
3. On the header, make the following settings:
    - **Reference type** – Select the business process for which quality orders are generated by the system, such as *Purchase* or *Production*.
    - **Item code** – Select which products should be included in the rule. Choose one of the following values:
        - *Table* – A specific product.
        - *Group* – A group of products.
        - *All* – All products.
    - **Item** – Depending on what you selected for **Item code**, choose the specific product or product group for which this rule should apply. Leave blank if **Item code** is set to *All*.
4. On the **Conditions** FastTab, make the following settings:
    - **Site** – Select the site where the rule applies.
    - **Applicable warehouse type** – Select the type of warehouse for which the quality association is used for. Choose one of the following values:
        - *All* – Includes all warehouses. Quality order functionality for warehouse processes isn't available for the quality association when **Applicable warehouse type** is set to *All*.
        - *Quality order for warehouse processes only* – Includes only warehouses where **Enable quality order for warehouse processes** is set to *Yes*.
    - **Account code** – Select the vendor or customer account to whom this rule applies. Available options depend on the selected **Reference type**.
    - **Account selection** – Depending on which **Account code** is selected, choose a specific account or account group. Leave this blank if **Account code** is set to *All*.

- **Resource code** – Select the scope of resources to which the rule applies. This option only applies if the **Reference type** is *Route operation*. Choose one of the following values:
  - *All* – Applies to all resources.
  - *Group* – Applies to a group of resources.
  - *Table* – Applies to a single, selected resource.
- **Resource** – Depending on what you selected for **Resource code**, choose the specific resource or resource group to which this rule should apply. Leave this blank if **Resource code** is set to *All*.

5. On the **Process** FastTab, make the following settings:

- **Event type** – Depending on the **Reference type**, select the business event that should generate the quality order. For example, if the **Reference type** is *Production* you can choose between *Report as finished* and *Registration*.
- **Execution** – Choose one of the following values:
  - *Before* – Automatically create the quality order before the business event occurs.
  - *After* – Automatically create the quality order after the business event occurs.
- **Show info** – Select whether an info-log should be shown after the quality order is automatically created based on the business event.

6. On the **Quality order process** FastTab, make the following settings:

- **Event blocking** – Choose whether the document should be set on hold until the associated quality order is validated and closed. Choose one of the following values:
  - *End* – Blocks processing of the document until the associated quality order is validated and closed.
  - *None* – Don't block the document from being processed.
- **Quarantine upon validation failure** – Set to *Yes* to automatically create a quarantine order if the associated quality order fails validation.
- **Use for certificate of analysis** – Choose one of the following values:
  - *No* – Don't make it possible to generate a certificate of analysis for this quality association.
  - *Yes* – Make it possible to generate a certificate of analysis for this quality association.
- **Quality processing policy** – Choose one of the following values:
  - *Create quality order* – Uses the full quality process and create quality orders.
  - *Create item sampling work only* – Uses a minimal quality process that creates quality item sampling work but doesn't create quality orders or inventory blocking. This

option only applies when the **Applicable warehouse type** is set to *Quality order for warehouse processes only*.

7. On the **Specifications** FastTab, make the following settings:

- **Test group** – Select a test group with tests defined for acceptance sampling or sample management. Learn more in Acceptance sampling and Enable and configure sample management.
- **Item sampling** – Select an item sampling defined for acceptance sampling or sample management. Learn more in Acceptance sampling and Enable and configure sample management.
- **Acceptable quality level** – Choose the acceptable quality level (AQL) to be used for the quality association. The AQL determines whether the quality order passes or fails validation.
- **Flexible sampling** – Choose whether to use the flexible sampling plans as part of this quality association.
- **Flexible sampling plan code** – If **Flexible sampling** is set to *Yes*, then select a flexible sampling plan code.
- **Effective** – Select the date on which this quality association becomes effective.
- **Expiration** – Select the date on which the quality association expires.
- **Worker** – Select the default worker to be assigned to quality orders generated by this quality association.
- **Quality order priority** – Select the default priority that should be assigned by default to the quality order generated for this quality association.
- **Description** – Displays the description of the selected quality order priority.

Quality associations and flexible sampling plans

Instead of selecting a fixed test group and item sampling, you can set up a *flexible sampling plan*. A flexible sampling plan is a test strategy where you can change both the test and sample sizes over time, based on successful test validation. To use flexible sampling, on the **Specification** FastTab, select **Flexible sampling**. Then, in the **Flexible sampling plan code** field, select the code for a flexible sampling plan. Learn more in Flexible sampling plans.

Examples of automatic generation of quality orders

Purchasing

In purchasing, if you set the **Event type** field to *Product receipt* and the **Execution** field to *After* on the **Quality associations** page, you get the following results:

- If the **Per updated quantity** option is set to *Yes*, a quality order is generated for every receipt against the purchase order, based on the received quantity and settings in the item sampling. Every time that a quantity is received against the purchase order, new quality orders are generated based on the newly received quantity.
- If the **Per updated quantity** option is set to *No*, a quality order is generated for the first receipt against the purchase order, based on the received quantity. Additionally, one or more quality orders are created based on the remaining quantity, depending on the tracking dimensions. Quality orders aren't generated for subsequent receipts against the purchase order.

Production

In production, if you set the **Event type** field to *Report as finished* and the **Execution** field to *After* on the **Quality associations** page, you get the following results:

- If the **Per updated quantity** option is set to *Yes*, a quality order is generated based on every finished quantity and settings in the item sampling. Every time that a quantity is reported as finished against the production order, new quality orders are generated based on the newly finished quantity. This generation logic is consistent with purchasing.
- If the **Per updated quantity** option is set to *No*, a quality order is generated the first time that a quantity is reported as finished, based on the finished quantity. Additionally, one or more quality orders are created based on the remaining quantity, depending on the tracking dimensions of the item sampling. Quality orders aren't generated for subsequent finished quantities.

Expand table

Quality specification	Per updated quantity	Per tracking dimension	Result
Percentage: 10%	Yes	Batch number: No Serial number: No	Order quantity: 100 1. Report as finished for 30 • Quality order 1 for 3 (10% of 30) 2. Report as finished for 70

Quality specification	Per updated quantity	Per tracking dimension	Result
			• Quality order 2 for 7 (10% of the remaining order quantity, which is 70 in this case)
Fixed quantity: 1	No	Batch number: No Serial number: No	Order quantity: 100 1. Report as finished for 30 • Quality order 1 for 1 (for the first reported-as-finished quantity, which has a fixed value of 1) • Quality order 2 for 1 (for the remaining quantity, which still has a fixed value of 1) 2. Report as finished for 10 • No quality orders are created. 3. Report as finished for 60 • No quality orders are created.
Fixed quantity: 1	Yes	Batch number: Yes Serial number: Yes	Order quantity: 10 1. Report as finished for 3: 1 for batch number b1, serial number s1; 1 for batch number b2, serial number s2; and 1 for batch number b3, serial number s3 • Quality order 1 for 1 of batch number b1, serial number s1 • Quality order 2 for 1 of batch number b2, serial number s2 • Quality order 3 for 1 of batch number b3, serial number s3 2. Report as finished for 2: 1 for batch number b4, serial number s4; and 1 for batch number b5, serial number s5 • Quality order 4 for 1 of batch number b4, serial number s4 • Quality order 5 for 1 of batch number b5, serial number s5 **Note:** The batch can be reused.
Fixed quantity: 2	No	Batch number: Yes	Order quantity: 10 1. Report as finished for 4: 1 for batch number b1, serial number s1; 1 for batch number b2, serial number s2; 1

Quality specification	Per updated quantity	Per tracking dimension	Result
		Serial number: Yes	for batch number b3, serial number s3; and 1 for batch number b4, serial number s4 • Quality order 1 for 1 of batch number b1, serial number s1 • Quality order 2 for 1 of batch number b2, serial number s2 • Quality order 3 for 1 of batch number b3, serial number s3 • Quality order 4 for 1 of batch number b4, serial number s4 • Quality order 5 for 2, without a reference to a batch number and a serial number 2. Report as finished for 6: 1 for batch number b5, serial number s5; 1 for batch number b6, serial number s6; 1 for batch number b7, serial number s7; 1 for batch number b8, serial number s8; 1 for batch number b9, serial number s9; and 1 for batch number b10, serial number s10 • No quality orders are created.

Workers responsible for approving nonconformances

Article • 06/03/2022

This article describes how to configure workers that are responsible for approving nonconformances.

Nonconformances must be approved before users can start to enter details such as corrections or operations. Before users can approve or reject nonconformances, their user ID (user record) must be linked to a worker record. You can optionally configure workers that are responsible for quality and then allow one worker to approve work on behalf of another worker.

Enable a user for nonconformance processing

Before a user can approve or reject nonconformances, you must link their user record to a worker record. The approval fields can then be automatically set, and the current user can be automatically filled in for the timesheet. Before the user can use the document notes, you must activate document handling in their user options.

1. Go to **System administration** > **Users** > **Users**.
2. Find and open the user who should be able to approve or reject nonconformances.
3. Set the **Person** field to the name of the worker that is related to the current user record.
4. On the Action Pane, select **User options**.
5. On the **Options** page for the current user record, on the **Preferences** tab, set the **Enable document handling** option to *Yes*.
6. Close the pages.

Define workers that are responsible for quality

1. Go to **Inventory management** > **Setup** > **Quality control** > **Workers responsible for quality**.
2. On the Action Pane, select **New**.
3. In the **Worker** field, select the worker that enters quality data.
4. In the **Worker responsible** field, select the worker that the selected worker enters work on behalf of. When nonconformances are created and updated, this worker will be entered by default in **Worker** fields.

Problem types for nonconformances

Article • 06/03/2022

This article describes how to create and use problem types for nonconformances.

You use the **Problem types** page to define a classification of the quality problems that might occur for the various nonconformance types. For each problem type that you create, you must specify the types of nonconformances that the problem type can be used with. You can set up the following nonconformance types:

- **Internal** – Nonconformances of this type are related to on-hand inventory (for example, quality orders or quarantine orders).
- **Customer** – Nonconformances of this type are related to sales orders.
- **Vendor** – Nonconformances of this type are related to purchase orders.
- **Service request** – Nonconformances of this type are related to service orders.
- **Production** – Nonconformances of this type are related to batch orders or production orders.
- **Co-product production** – Nonconformances of this type are related to batch orders for co-products.

When you create a new problem type, select **Non conformance types** on the Action Pane to create a list of one or more nonconformance types that are authorized for the problem type. For example, a problem type that is related to a defect code might apply to all nonconformance types. However, a problem type that is related to customer complaints might apply only to the **Customer** and **Service request** nonconformance types.

Examples of problem types

Here are some examples of scenarios for problem types that can be used with the different nonconformance types:

- **Customer:** A customer filed a complaint, a customer made a return, or quality specifications weren't met.
- **Vendor:** The product was damaged, quality specifications weren't met, or the wrong product was received.
- **Service request:** Quality specifications weren't met, a customer filed a complaint, or machine maintenance is required.
- **Production:** Quality specifications weren't met, machine maintenance is required, or the product was damaged.

- **Co-product production:** Quality specifications weren't met, machine maintenance is required, or the product was damaged.

Create a problem type and assign it to nonconformance types

1. Go to **Inventory management** > **Setup** > **Quality management** > **Problem types**.
2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Problem type** – Enter a unique ID or name for the problem type.
    - **Description** – Enter a detailed description of the problem type.
3. While the new row is still selected, select **Non conformance types** on the Action Pane.
4. On the Action Pane, select **New** to add a row to the grid. Then, for the new row, set the **Non conformance type** field to the nonconformance type that you want to allow for the problem type.
5. Repeat the previous step for each additional nonconformance type that you want to authorize for the problem type.
6. Close the pages.

Quarantine zones for nonconformances

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to create and use quarantine zones for nonconformances.

You use the **Quarantine zones** page to define zones that can be assigned to nonconformances. When you create a nonconformance, you can set the **Quarantine zone** and **Quarantine type** fields on the **General** tab of the **Non conformances** page. The **Quarantine zone** field typically indicates the area or location where the item is located. The **Quarantine type** field defines the item as either *Restricted usage* or *Unusable*.

When you print a nonconformance or corrections report for a nonconformance, you can view the quarantine zone where the item is located.

You can also print a nonconformance tag for a nonconformance. This report shows the assigned quarantine zone and information about usage to provide guidance about how defective material should be handled. The quarantine zones might correspond to inventory locations or operations resources.

Examples of quarantine zones

Example 1

You work at an electronics manufacturing company that produces and distributes televisions, speakers, and media players. In this case, you can configure a quarantine zone to represent each type of product.

Example 2

Three bins and two racks are used to store items that are nonconforming. In this case, you can configure five quarantine zones, one for each bin and each rack.

Create a quarantine zone

1. Go to **Inventory management** > **Setup** > **Quality management** > **Quarantine zones**.
2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Quarantine zone** – Enter a unique ID or name for the quarantine zone.
    - **Description** – Enter a detailed description of the quarantine zone.
3. Close the page.

Diagnostic types for nonconformances

This article describes how to use and create diagnostic types that can be used with nonconformances.

Diagnostic types define classifications of diagnostic actions. When you create a *correction* for a nonconformance, you select a diagnostic. A correction specifies what type of diagnostic action should be taken for an approved nonconformance and who should take that action. It also specifies the requested completion date and the planned completion date.

Examples of diagnostic types

You work for a manufacturing company, and several items have failed quality tests. Those items are moved into a quarantine area and marked as nonconforming products. A nonconformance record is created in Microsoft Dynamics 365 Supply Chain Management to track the details through issue resolution.

In this case, the quality issues are occurring because bearings in the machine that packages the items have gone bad and are overheating. The correction for this problem is to replace the parts in the machine.

When you configure the diagnostic types, you can create multiple records, each of which represents a different type of problem that the machine might have. Alternatively, you can create one generic diagnostic type that represents machine repair.

Create a diagnostic type

1. Go to **Inventory management** > **Setup** > **Quality management** > **Diagnostic types**.
2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Diagnostic** – Enter a unique ID or name for the diagnostic type.
    - **Description** – Enter a detailed description of the diagnostic type.
3. Close the page.

Diagnostic groups

Use *diagnostic groups* to collect related diagnostic types so that you can quickly apply them all at once as corrections to a nonconformance. For example, you might create a group of diagnostic types that together describe how to diagnose an issue with raw material quality (such as repair and retest).

Prerequisites

Before you can use diagnostic groups, your system must meet the following requirements:

- You must be running Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Manage diagnostic groups

1. Go to **Inventory management** > **Setup** > **Quality management** > **Diagnostic groups**.
2. Use the buttons on the Action Pane to create a new diagnostic group in the list pane or edit an existing one. (You can also delete existing groups.)
3. On the heading of the new or selected group, enter a name and description for the group.
4. On the **Diagnostic** FastTab, use the buttons on the toolbar to add and remove diagnostics that belong to the current group. For each row, select the diagnostic that should be performed and the worker who should perform it.

Nonconformance root cause codes

Use *nonconformance root cause codes* to establish standard codes for root causes that are associated with corrections for nonconformance issues that are often encountered at your company. For example, you might create codes for wind damage, water damage, training issues, or other common issues that you encounter. Root cause code give you a consistent way to identify causes that you can apply to the relevant corrective actions.

Prerequisites

Before you can use the features that are described in this article, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Manage root cause codes

1. Go to **Inventory management** > **Setup** > **Quality management** > **Correction root cause codes**.

2. Use the buttons on the Action Pane to add new root cause codes or edit existing ones. (You can also delete existing codes.)

3. Set the following fields for each row:

    - **Root cause code** – Enter a unique ID or name for the root cause code.
    - **Description** – Enter a short description of the root cause code.

Assign a root cause code to a nonconformance correction

You can assign a root cause code to each correction that you create for a nonconformance. Learn more in Create and process nonconformances.

Last updated on 07/23/2026

Nonconformance work groups

Use *nonconformance work groups* to define group names that you can assign to nonconformance records to make your nonconformances easier to classify. For example, you might create a group for inspecting receipts and another one for inspecting production output.

Prerequisites

Before you can use the features that are described in this article, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Manage nonconformance work groups

1. Go to **Inventory management** > **Setup** > **Quality management** > **Non conformance work groups**.

2. Use the buttons on the Action Pane to create new nonconformance work groups in the grid or edit existing ones. (You can also delete existing work groups.)

3. Set the following fields for each row:

    - **Work group** – Enter a unique ID or name for the work group.
    - **Description** – Enter a short description of the work group.

Assign a work group to a nonconformance

To assign a work group to a nonconformance, edit the **Work group** field when you create or edit a nonconformance.

Last updated on 07/23/2026

Operations for nonconformances

This article describes how to create and use operations for nonconformances.

Operations are classifications of work that can be performed for an approved nonconformance. When you assign operations to a nonconformance, you can provide details such as the associated material, labor hours, and charges that are required to do the operation. The system uses this information to calculate an estimated cost for the operation. The detailed information and estimated costs are for reference. The related operations for quality differ from the operations that can be defined for a production route.

> **Note**
>
> Although you can track costs, time, and the items that are used in an operation that is related to a nonconformance, the data that you enter is only informational. It isn't automatically integrated with the general ledger, inventory subledger, or the **Time and attendance** module.

Examples of operations

You work for a manufacturing company. A nonconformance was created and approved for items that failed a quality test. A correction was created to indicate that the problem was related to a bad bearing on a machine. Several steps are required to replace the bearing, and the responsibility for each operation is tracked. For example, the following steps might be required:

1. The production line is stopped, and the clean-out routine is performed.
2. Maintenance personnel replace the bearing.
3. Quality assurance personnel inspect the machine before it's turned back on.

For this example, the following operations can be created to represent the work that must be done:

- Stop the production line.
- Clean out the production line.
- Perform machine maintenance.
- Inspect the machine.

Create an operation

1. Go to **Inventory management** > **Setup** > **Quality management** > **Operations**.
2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Operation** – Enter a unique ID or name for the operation.
    - **Description** – Enter a detailed description of the operation.
    - **Type** – If the operation can be used only with nonconformances that are related to a specific type of order, select the order type (*Purchase order* or *Sales order*).
3. Close the page.

Nonconformance operation groups

Use *nonconformance operation groups* to collect related operations that you can apply quickly to a nonconformance all at once. For example, you might create a group of operations that together describe the steps that your company takes to fix issues with purchased raw materials (research, repair, and retest).

Prerequisites

Before you can use nonconformance operation groups, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Manage nonconformance operation groups

1. Go to **Inventory management** > **Setup** > *Quality management* > *Non conformance operation groups*.
2. Use the buttons on the Action Pane to create new nonconformance operation groups in the list pane or edit existing ones. (You can also delete existing groups.)
3. On the heading of a new or selected group, enter a name and description for the group.

4. On the **Operations** FastTab, use the buttons on the toolbar to add and remove operations that belong to the current group.

Charges for nonconformance operations

Article • 06/03/2022

This article describes how to create quality charges that can be used with operations for a nonconformance.

You use the **Quality charges** page to define the types of charges that can be added to operations for a nonconformance. Charges let you track details about fees or charges that you owe to a customer for nonconforming products, or that a vendor owes to you for nonconforming products that you received. You might also use charges to track costs that are required for external vendors or services to perform an operation.

Examples of quality charges

You work for a manufacturing company. Your company has contracts with several vendors. Those contracts outline standards for on-time shipment, damages, and product quality for items. Likewise, several of your customers have agreements with your company about returns, damages, and product quality.

A fee structure is defined for each circumstance and specified in the contract. You can configure quality charges to outline the various types of charges, such as *Damages*, *Late shipment*, and *Quality*. Then, when you create a nonconformance, you add one or more operations. For each operation, you select **Charges** to define the details about the fees.

Create a quality charge

1. Go to **Inventory management** > **Setup** > **Quality management** > **Quality charges**.
2. On the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:
    - **Charges code** – Enter a unique ID or name for the quality charge.
    - **Description** – Enter a detailed description of the quality charge.
3. Close the page.

Add a quality charge to an operation for a nonconformance

For details about how to add operations to a nonconformance and apply charges to them, see Operations for nonconformances.

Sample management overview

Summarize this article for me

Sample management enables manufacturers to systematically handle, track, and test product samples throughout their lifecycle. This functionality supports industries such as pharmaceuticals, food and beverage, chemicals, and life sciences, where quality assurance and regulatory compliance are critical.

Sample management provides tools to:

- Define and register samples.
- Execute sampling and testing plans.
- Track sample lifecycle states.
- Analyze test results.
- Control inventory disposition based on quality outcomes.

The following video provides a high-level overview of sample management capabilities and a demo of how to work with them.

https://learn-video.azurefd.net/vod/player?id=36124ac5-86c0-44f6-a57e-3beb10c753ca&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Finventory%2Fquality-sample-management-overview

Why sample management matters

In regulated and quality-sensitive industries, manufacturers must ensure that products meet strict specifications before release. Sampling is a key part of this process. It allows organizations to test small quantities of product at various stages of production to detect issues early and ensure consistency.

Sample management helps organizations:

- Maintain traceability and auditability of samples.
- Automate sample registration and testing.
- Integrate quality control with production workflows.
- Comply with standards like GMP, GLP, ISO, FDA, and EMA.

Sample inspection methods

Sample management supports two primary sample inspection methods:

- **Inline process** – Manually collect samples during production, before the item is reported as finished. This method detects quality issues early and ensures stable quality before the finished product. Here are the main characteristics for inline sampling:
  - *When used* – During production, before inventory is reported as finished.
  - *Purpose* – Detect and correct quality issues early (such as pH imbalance or viscosity).
  - *How it works* – Manually register samples on a production or batch order. Each sample generates a quality order. Track quality test results over time to monitor trends.
  - *Inventory impact* – No inventory transactions are associated with inline samples.

- **Continuous process** – Automatically take samples at regular intervals throughout batch production to monitor quality trends and maintain consistency in product quality during a production run. Here are the main characteristics for continuous sampling:
  - *When used* – During batch production, triggered automatically when items are reported as finished.
  - *Purpose* – Monitor quality trends and control inventory release.
  - *How it works* – Register samples at defined intervals, such as every two license plates. Test a subset of samples. Based on the test results, release or block the inventory by using batch disposition codes.
  - *Inventory impact* – Inventory transactions are associated with continuous samples.

Each sample type is configured with its own lifecycle states, label layouts, and procedures. These configurations ensure that you handle samples consistently and according to business rules.

Related quality management tools

Sample management both leverages and enhances existing quality management entities and capabilities within Supply Chain Management, while also introducing new tools and features to support advanced quality processes.

Existing entities and capabilities

Sample management builds on the following existing quality management entities and capabilities:

- **Quality orders** – Automatically or manually created for each sample to record test results.
- **Item sampling** – Enhanced to support sample registration and testing plans.
- **Test groups** – Define which tests are performed during quality orders and control how inventory is updated for samples, based on whether tests pass or fail.
- **Quality associations** – Link sampling logic to the report-as-finished production event.

- **Batch disposition codes** – Used to block or release produced inventory batches based on test outcomes.
- **Inventory status** – Used to block or release produced license plates based on test outcomes.

New entities and capabilities

Sample management introduces the following new entities and capabilities:

- **Sample label layouts** – Enable flexible design of sample label content to accommodate specific business requirements.
- **Sample procedures** – Define the specific steps or actions required for handling samples.
- **Sample life cycle states** – Represent the various stages a sample goes through during its lifecycle.
- **Sample types** – Define the classification and processing methods for samples.
- **Sample associations** – Define how and when quality samples are taken for a specific item.
- **Sample procedures** – Define the specific steps or actions required for handling samples.
- **Sample procedure types** – Define categories and groups for organizing sample procedures.
- **Sample management workbench** – A centralized interface for managing samples, viewing audit trails, and performing lifecycle actions.
- **Audit trail** – Tracks all sample-related events including registration, testing, and inventory updates.

Last updated on 03/11/2026

Enable and configure sample management

This article provides step-by-step instructions for enabling and configuring sample management. It covers key aspects such as designing sample label layouts, setting up parameters and number sequences, defining lifecycle states, and configuring quality associations. By following these instructions, manufacturing managers and system administrators can ensure that they manage samples efficiently, accurately, and in compliance with industry standards.

Prerequisites

To use sample management, your system must meet the following requirements:

- To run the preview version of this feature, you must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.46 or later.
- To run the general availability version of this feature, you must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.47 or later.
- The following features must be turned on in feature management:
  - *Advanced quality management* (As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.)
  - *Sample management* (As of Supply Chain Management version 10.0.49, this feature is turned on by default.)

Set up the sample ID number sequence

The sample ID number sequence ensures that each sample has a unique identifier for traceability and compliance. As with other number sequences in Supply Chain Management, you can define the format and scope of the sample ID number sequence to meet your organization's requirements.

Follow these steps to create and assign a number sequence for sample IDs:

1. Go to **Organization administration** > **Number sequences** > **Number sequences**.
2. Create and configure a number sequence for generating sample IDs, as described in Set up number sequences on an individual basis. The number sequence must be defined to use a non-shared scope.
3. Note the **Number sequence code** that you assign to this number sequence.

4. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**.
5. Open the **Number sequences** tab.
6. Find the row with a **Reference** of *Sample ID* and set the **Number sequence code** field for that row to the number sequence that you created previously in this procedure.
7. On the Action Pane, select **Save**.

Set up sample labels

Sample labels play an important role in the sample management process. They make sure that each sample is properly identified and traceable throughout its lifecycle. A well-designed label layout includes essential information such as the sample ID, type, and other relevant details. This information helps with efficient handling and reduces the risk of errors.

Sample labels are designed and printed in Zebra Programming Language (ZPL) format, which is a standard format for printing labels on Zebra printers. Sample labels can include information such as the sample ID, sample type, lot ID, and more.

Design sample label layouts

To design and configure sample label layouts, follow these steps:

1. Go to **Inventory management** > **Setup** > **Sample management** > **Sample label layouts**.

2. Use the buttons on the Action Pane to create a new calibration label layout or edit an existing one as required. You can also delete existing layouts.

3. On the header of the new or selected layout, enter details such as the name, description, and dimensions.

4. On the **Label layout** FastTab, use the large field to design your label layout. For help, consult a ZPL reference.

5. The page helps you find the codes that you need to insert field values. To add a field value to your layout, follow these steps:
   a. Set the **Use fields from** field to the type of database record that you want to use a field from (such as *Samples*).
   b. In the **Labels** list, select a field name.
   c. Select **Insert at end of text** to add the reference code to the end of the label layout text.

d. Use a cut-and-paste operation to move the reference code to the desired location in the label layout text.

Assign which labels to use when printing

Make one or both of the following assignments to specify which label layout to use for printing sample labels:

- Assign the default label layout, which applies to all samples that don't have a more specific layout assigned to them.

  To do this, go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**. Open the **Quality management** tab, and then set the **Default sample label layout** field to the desired label layout.

- Assign a custom label layout to each specific sample type as needed (overrides the default).

  To do this, go to **Inventory management** > **Setup** > **Sample management** > **Sample types**. Select a sample type, and then set the **Label layout** field to the desired label layout.

Configure lifecycle states

Lifecycle states represent the various stages a sample goes through during its lifecycle. Lifecycle states ensure that you track samples accurately and update their status consistently as they progress through the management process.

Follow these steps to manage your lifecycle states:

1. Go to **Inventory management** > **Setup** > **Sample management** > **Sample lifecycle states**.
2. Use the buttons on the Action Pane to create a new lifecycle state or edit an existing one as required. You can also delete existing lifecycle states.
3. Enter the following details for your new or selected lifecycle state:
   - **Sample lifecycle state** – Enter a unique name for the lifecycle state, such as *Registered*, *Tested*, *Archived*, or *Scrapped*.
   - **Sample lifecycle state description** – Add a brief description of the lifecycle state.
   - **Quality order created** – Select this checkbox for the lifecycle state that a sample should be updated to when you create a quality order for it.

- **Quality order validated** – Select this checkbox for the lifecycle state that a sample should be updated to when you validate a quality order against it.
- **Sample scrapped** – Select this checkbox for the lifecycle state that, when you assign it manually, triggers an audit trail logging for *Scrapped by* and *Scrapped date/time*.

  Only samples with this property selected can be deleted from the **Sample management workbench**.

4. On the Action Pane, select **Save**.

Configure sample procedure types

Sample procedure types define categories and groups for organizing procedures. These configurations ensure that you process samples consistently and in compliance with organizational and regulatory requirements.

Follow these steps to manage your procedure types:

1. Go to **Inventory management** > **Setup** > **Sample management** > **Sample procedure types**.
2. Use the buttons on the Action Pane to create a new procedure type or edit an existing one as required. You can also delete existing procedure types.
3. Enter the following details for your new or selected procedure type:
   - **Sample procedure type** – Provide a unique name for the procedure type.
   - **Description** – Add a brief description of the procedure type.
4. On the Action Pane, select **Save**.

Define sample procedures

Sample procedures define the specific steps or actions required for handling samples. These configurations ensure that you process samples consistently and in compliance with organizational and regulatory requirements.

Follow these steps to manage your sample procedures:

1. Go to **Inventory management** > **Setup** > **Sample management** > **Sample procedures**.
2. Use the buttons on the Action Pane to create a new procedure or edit an existing one as required. You can also delete existing procedures.

3. Enter the following details in the header of your new or selected procedure:

    - **Sample procedure ID** – Provide a unique name for the procedure.
    - **Description** – Add a brief description of the procedure.
    - **Sample procedure type** – Select the relevant procedure type for the procedure.
    - **Sample inspections method** – Choose which inspection methods the procedure is intended for (*Inline process*, *Continuous process*, or *Both*).

4. On the **Procedure** FastTab, enter or paste detailed instructions for the procedure.

5. On the Action Pane, select **Save**.

Define sample types

Sample types define the classification and processing methods for samples. When you configure sample types, you ensure that samples are managed according to their specific requirements and that appropriate workflows are applied.

To manage your sample types, follow these steps:

1. Go to **Inventory management** > **Setup** > **Sample management** > **Sample types**.

2. Use the buttons on the Action Pane to create a new sample type or edit an existing one as required. You can also delete existing sample types.

3. Enter the following details in the header of your new or selected sample type:

    - **Sample type** – Enter a unique name for the sample type, such as *Inline* or *Continuous*.
    - **Description** – Add a brief description of the sample type.
    - **Sample inspections method** – Choose which inspection methods the sample type applies to (*Inline process*, *Continuous process*, or *Both*).
    - **Label layout** – Select the label layout to use for this sample type.
    - **Description** – Shows the description configured for your selected label layout (read only).

4. On the Action Pane, select **Save**.

5. Use the **Sample lifecycle states** FastTab to select the lifecycle states that are relevant to this sample type. Use the buttons between the columns to move the relevant states between the **Available** and **Selected** lists as needed. Selecting lifecycle states ensures that the sample type follows a defined progression through its lifecycle, from creation to completion or disposal. These states trigger specific system behaviors, such as updating the sample when

a quality order is created or validated, or logging audit trail details when a sample is scrapped. By configuring the relevant states, you enable consistent handling, tracking, and automation of sample-related processes.

6. On the Action Pane, select **Save**.

Set up sample associations

A sample association defines how and when quality samples are taken for a specific item. It supports both inline and continuous sampling methods, using designated sample types with configurable retention periods and automated expiration tracking. Linking sampling procedures to items and test groups ensures consistent quality control, supports regulatory compliance, and enables efficient inspection workflows tailored to operational needs.

Follow these steps to define and configure sample associations:

1. Go to **Inventory management** > **Setup** > **Sample management** > **Sample associations**.

2. Use the buttons on the Action Pane to create a new sample association or edit an existing one as required. You can also delete existing sample associations.

3. Enter the following details in the top section to set up your new or selected sample association:

    - **Item code** – Select the scope of products to include in the rule. Choose one of the following values:
        - *Table* – A specific product.
        - *Group* – A group of products.
        - *All* – All products.
    - **Item** – Depending on what you selected for **Item code**, choose the specific product or product group for which this rule should apply. Leave blank if **Item code** is set to *All*.
    - **Inline sample type** – Select the sample type that defines how inline samples for this item should be inspected, including their applicable lifecycle states. This sample type governs the inspection method used for inline sampling and ensures that the correct procedures and validations are applied throughout the sample's lifecycle.
    - **Inline sample scrap in days** – Specify how many days inline samples should be retained before being automatically scrapped. This setting helps manage sample lifecycle and storage by defining the retention period for inline samples associated with the item.

- **Default item sampling for inline** – Specifies the default item sampling policy applied to inline samples during production. Item sampling policies define the criteria for selecting samples. When initiating inline sampling from the production orders list or details page, this value is prefilled in the create dialog but can be adjusted as needed.
- **Default inline test group** – Specify the default test group used for inline samples from production. When initiating inline sampling from the production orders list or details page, this value is prefilled in the create dialog but can be adjusted as needed.
- **Continuous sample type** – Select the sample type that defines how continuous samples for this item should be inspected, including their applicable lifecycle states. This sample type governs the inspection method used for continuous sampling and ensures that the correct procedures and validations are applied throughout the sample's lifecycle.
- **Continuous sample scrap in days** – Select the number of days that continuous samples for this item should be saved before being scrapped.

4. In the bottom section, with the relevant row still selected in the top section, add each of the sample procedures that workers should follow when handling samples for this association. Use the toolbar buttons to add or remove procedures as needed.

5. On the Action Pane, select **Save**.

Configure item sampling policies

Item sampling policies define the criteria for selecting samples. Configuring these settings ensures that you select samples consistently and in compliance with quality standards.

Follow these steps to define an item sampling policy:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Item sampling**.

2. Use the buttons on the Action Pane to create a new item sampling policy or edit an existing one as required. You can also delete existing policies.

3. Set up the item sampling policy as described in Quality management item sampling.

4. On the **Sample management** FastTab, set up the settings that are specific for sample management. Make the following settings here.

    - To set up inline sampling, make the following settings on the **Sample management** FastTab:
        - **Sample inspections method** – Select *Inline process*.

    - **Sample size** – Enter the desired sample size.
    - **Unit** – Select the unit of measurement for the sample size (such as *Pieces* or *Milliliters*).

- To set up continuous sampling, make the following settings on the **Sample management** FastTab:
    - **Sample inspections method** – Select *Continuous process*.
    - **Sample size** – Enter the desired sample size.
    - **Unit** – Select the unit of measurement for the sample size (such as *Pieces* or *Milliliters*).
    - **One sample every** – Specify how often samples should be taken and then choose whether to count batches or license plates (for example, enter *10* and select *Batch* to take a sample from every tenth batch that's reported as finished).
    - **Number of samples per quality order generated** – Specify how often samples should be tested (for example, enter *4* to test every fourth sample).

5. On the Action Pane, select **Save**.

Configure related quality management records

The following subsections describe other important settings for sample management. These records and settings are shared by other kinds of quality management processes supported by Supply Chain Management, but they are also essential for sample management.

Quality associations

Configure quality associations to trigger sample management when production orders are reported as finished for specific items. This setup references test groups and item sampling policies to ensure consistency and automation in quality control. For inline samples, you don't need a quality association because you collect these samples on demand directly from the production order. Learn more in Quality associations. The following settings for quality associations are particularly relevant for sample management:

- **Reference type** – Select *Production*, which is the only supported type for sample management.
- **Event type** – Select *Report as finished*.
- **Execution** – Select *After*.
- **Test group** – Select the test group that should be used for quality orders generated for samples.

- **Item sampling** – Select the item sampling configuration used for sample management. This configuration determines whether the *Inline* or *Continuous* sampling method is applied, along with related details for how each method is used.

Configure default item status

The default item status establishes the initial inventory status assigned to new items in inventory. This is relevant when samples are configured to be generated for each license plate produced. Typically, you should define the default inventory status as *On-hold*, which indicates that the license plate is awaiting inspection. You can configure the default item status to apply for an individual item or for all transactions at a specific warehouse.

To configure the default item status for a specific item, follow these steps:

1. Go to **Warehouse management** > **Setup** > **Inventory** > **Default item status**.
2. On the Action Pane, select **New** to create a new record.
3. Enter the following details for your new record:

    - **Item number** – Select the product you want to configure for sample management.
    - **Module** – Select *Inventory*, which is the only applicable value for sample management.
    - **Default inventory status ID** – From the list, select the inventory status that should be used as default when a sample with an associated license plate is created in sample management.

To configure the default item status that is applicable for all item transactions at a specific warehouse, follow these steps:

1. Go to **Warehouse management** > **Setup** > **Inventory breakdown** > **Warehouses**.
2. Find and select the warehouse where you want to configure the default item status.
3. On the **Warehouse** FastTab, set the default inventory status in the **Default inventory status ID** field.

Test groups

Test groups define the set of tests applied while processing quality orders. On each test group, you also define the status the system should apply to license plates or product batches based on the outcome of the quality order test results.

If you configured sample management to generate samples per license plate, then the **Inventory status** is used to control the status of the license plate. To control the initial status of the license

plates generated during production report as finished, set the following fields on the relevant test group:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test groups**.
2. Select an existing test group or create a new one.
3. Select the **General** tab and make the following settings:

    - **Update inventory status** – Set to *Yes* to enable inventory status updates based on test results.
    - **Failed quality order status** – Specify the inventory status to apply to the license plate when a quality order fails. This setting only applies when **Update inventory status** is set to *Yes*.
    - **Passed quality order status** – Specify the inventory status to apply to the license plate when a quality order passes. This setting only applies when **Update inventory status** is set to *Yes*.

If you configured sample management to generate samples per product batch number, then the batch disposition master is used to control the status of the individual batch number. To control the initial status on batch numbers generated during report as finished, set the following fields on each test group:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test groups**.
2. Select an existing test group or create a new one.
3. Select the **General** tab and make the following settings:

    - **Update batch disposition** – Set to *Yes* to enable update of the tested batch number based on whether the quality order is failing or passing.
    - **Failed quality order batch disposition** – Specify the batch disposition master to apply to the tested batch number when a quality order fails. This setting only applies when **Update batch disposition** is set to *Yes*.
    - **Passed quality order batch disposition** – Specify the batch disposition master to apply to the tested batch number when a quality order passes. This setting only applies when **Update batch disposition** is set to *Yes*.

Learn more in Batch disposition codes.

Set up continuous sampling (preview)

10/24/2025

[This article is prerelease documentation and is subject to change.]

Prerequisites

To prepare your environment for inline sampling, set up the following elements as described in Enable and configure sample management (preview):

- A number sequence for generating sample IDs.
- Sample life cycle states.
- Sample type used for continuous sampling.
- Sample procedures and sample procedure types.
- An item sampling policy set up for continuous sampling. It must have the following settings on the **Sample management** FastTab:
  - **Sample inspection method** – Select *Continuous process*.
  - **Sample size** – Set to the amount of material you want to sample.
  - **Unit** – Set the unit that applies to the selected sample size.
  - **One sample every** – Specify how often samples should be taken and then choose whether to count batches or license plates.
  - **Number of samples per quality order generated** – Specify how often samples should be tested.
- Sample associations configured to link the continuous sample type, continuous item sampling, and continuous sample procedures to the relevant products. Each sample association also defines how long samples can be kept before being scrapped.

Continuous sampling example scenario

This section illustrates how to configure and use continuous sampling. The example assumes the following setup for generating samples and quality orders: - A sample is created for every second license plate that is reported as finished. - A quality order is created for every second sample that is generated.

To work through a scenario that shows how to set up and use continuous sampling, follow these steps:

1. Create a batch-controlled product with the following characteristics:

   - **Enabled for advanced warehouse processes** – Associate the product with a **Storage dimension group** that has **Use warehouse management processes** set to *Yes*.

- **Batch enabled** – Associate the product with a **Tracking dimension group** that has the **Batch number** dimension enabled.
- **Automatic batch numbering** – Associate the product with a **Batch number group** that automatically generates a batch number from a number sequence when quantities are reported as finished from a production or batch order.

2. Set up a sample association for a batch-controlled product as described in Enable and configure sample management.

3. Create a production or batch order for the product with the following information:

    - Choose a warehouse that is enabled for the advanced warehouse processes. Make sure that **Use warehouse management processes** is set to *Yes* for the selected warehouse.
    - Set the quantity for the order to *2,000 pieces*.

4. Go to **Inventory management** > **Setup** > **Quality control** > **Item sampling**. Set up an item sampling policy as described in Quality management item sampling. On the **Sample management** FastTab, make the following settings to set up continuous sampling:

    - **Sample inspection method** – Set to *Continuous process*.
    - **Sample size** – Set to *1*.
    - **Unit** – Set to *Sp* (spoonful).
    - **One sample per every** – Set to *2* and *License plate*.
    - **Number of samples per quality order generated** – Set to *2*.

5. Go to **Inventory management** > **Setup** > **Quality control** > **Test groups**. Set up a test group as described in Quality management test groups. Make sure at least one test is assigned in the bottom section. On the **General** tab in the top section, make the following settings to set up the test group for continuous sampling:

    - **Update inventory status** – Set to *Yes* to enable inventory status updates based on test results.
    - **Failed quality order status** – Specify the inventory status to apply to the license plate when a quality order fails.
    - **Passed quality order status** – Specify the inventory status to apply to the license plate when a quality order passes.

6. Go to **Inventory management** > **Setup** > **Quality control** > **Quality associations**. Set up a quality association as described in Quality associations. Make the following settings:

    - **Reference type** – Select **Production*.
    - **Item code** – Select *Table*.

- **Item** – Select the item from the production or batch order you created for this scenario.
- **Event type** – Select *Report as finished*
- **Execution** – Select *After*.
- **Item sampling** – Select the item sampling policy that you created for this exercise.
- **Test group** – Select the test group that you created for this exercise.

7. Return to the production or batch order that you created for this scenario.

8. Bring the order into status *Started*.

9. Report four license plates as finish by following these steps:
   a. On the Action Pane, open the **Production order** tab and, from the **Process** group, select **Report as finished**.
   b. The **Report as finished** dialog opens. Check that the **License plate** dimension is visible in the grid. If it's not visible, select **Inventory** > **Display dimensions** from the toolbar and then select the **License plate** check box in the **Display dimensions** dialog.
   c. Create four new license plates by following these steps:

      - Right-click on the right side of the **License plate** field. Then select **View details** from the context menu to open the **License plates** page.
      - On the Action Pane, select **New** to create a new license plate.
      - In the **License plate** field, enter a unique and recognizable ID for the license plate.
      - Repeat the last two steps until you have created four license plates.
      - On the Action Pane, select the **Back** button to return to the **Report as finished** dialog.

   d. Complete the report-as-finished operation by providing the following information in the **Report as finished** dialog:

      - In the **Good quantity** field, set the value to *20*.
      - In the **License plate** field, select the first license plate you created in the previous step.
      - Make sure that the **End job** checkbox isn't selected.
      - Select **OK** to confirm report as finished of the first license plate.

   e. Complete three more report-as-finished operations for this production order—one for each of the remaining three license plates. Make sure to set the **Good quantity** field to *20* for each license plate.
   f. Verify that two samples and one quality order were created by following these steps:

      - On the Action Pane, open the **View** tab and, from the **Manage quality** group, select **Sample management workbench**.

- Verify that two samples were created for separate license plates, and that these license plates are blocked according their default inventory status. Learn more about configuring the default item status in Enable and configure sample management.
- Select the last sample and open the **References** tab in the bottom section to confirm that the sample has an associated **Quality order**.

Initiate an inline sample

Summarize this article for me

Prerequisites

To prepare your environment for inline sampling, be sure to set up the following elements as described in Enable and configure sample management

- A number sequence for generating sample IDs.
- Sample lifecycle states.
- Sample type used for inline sampling.
- Sample procedures and sample procedure types.
- An item sampling policy set up for inline sampling. It must have the following settings on the **Sample management** FastTab:
  - **Sample inspection method** – Select *Inline process*.
  - **Sample size** – Set to the amount of material you want to sample.
  - **Unit** – Set the unit that applies to the selected sample size.
- Sample associations configured to link the inline sample type, inline item sampling, and inline sample procedures to the relevant products.

Initiate the sample

To initiate an inline sample, follow these steps:

1. Go to **Production control** > **Production orders** > **All production orders**.
2. Open or create a production or batch order for a batch-controlled product that is configured for inline sampling.
3. Bring the production or batch order into status *Started*.
4. On the Action Pane, open the **View** tab and, from the **Manage quality** group, select **Initiate inline sample management**.
5. The **Initiate inline sample management** dialog opens. Review and adjust the following settings:

   - **Item number** – The product for which you want to take a sample. This field is defaulted based on the production or batch order that you had open.
   - **Product name** – The name of the product for which you want to take a sample. This field is read-only and comes from the selected **Item number**.

- **Sample type** – Set to *Inline*.
- **Item sampling** – Item samplings define the criteria for selecting samples. This field is defaulted based on the product that you selected, but you choose a new one if necessary.
- **Test group** – Test groups define the set of tests applied while processing quality orders. Select the test group that defines the tests that need to be performed on this sample. This field is defaulted based on the selected item sampling.
- **Sample size** – The amount of material that you want to sample. This field is read-only and comes from the selected item sampling.
- **Unit** – The unit that applies to the selected sample size. This field is read-only and comes from the selected item sampling.

6. Select **OK**.

Work with samples in the sample management workbench

To manage the inline samples related to a production or batch order, follow these steps:

1. Go to **Production control** > **Production orders** > **All production orders**.
2. Open or create a production or batch order for a batch-controlled product that is configured for inline sampling.
3. Initiate an inline sample as described in the previous section.
4. On the production order details page, go to the Action Pane, open the **View** tab and, from the **Manage quality** group, select **Sample management workbench**.
5. On the sample management workbench, go to the Action Pane and open the **Sample** tab. Select the various actions here to update the sample and view related information. Learn more in Manage and process samples.

Manage and process samples (preview)

10/24/2025

[This article is prerelease documentation and is subject to change.]

Sample management is a component of quality control in manufacturing. It ensures that products meet regulatory and quality standards. The processes described in this article serve as an example of how you can implement sample management. However, the specific details might vary depending on your company's branch, industry, and practices. By tailoring the sample management process to your organization's needs, you can maintain compliance, improve operational efficiency, and ensure product integrity. Use this guide as a framework to understand the key steps involved, and adapt them to align with your unique requirements and workflows. Proper implementation of sample management can significantly enhance traceability, accountability, and overall quality assurance.

The following video provides a high-level overview of sample management capabilities and a demo of how to work with them.
https://learn-video.azurefd.net/vod/player?id=36124ac5-86c0-44f6-a57e-3beb10c753ca&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Finventory%2Fquality-sample-management-use

Understanding the lifecycle of a sample in sample management

In modern manufacturing and quality control environments, the ability to systematically manage product samples is essential for ensuring compliance, traceability, and consistent product quality. Sample management provides a structured framework for handling samples from their creation through to disposal. It integrates seamlessly with production workflows and quality assurance protocols. The lifecycle of a sample begins with its registration. You can trigger registration either manually or automatically based on predefined sampling plans. Tailor these plans to the production context, whether *inline sampling*, which occurs during active production before inventory is finalized, or *continuous sampling*, which monitors quality at regular intervals throughout batch production.

Once registered, the system assigns each sample a unique identifier and categorizes it by sample type. The sample type determines its handling procedure, retention policy, and applicable lifecycle states. These lifecycle states, such as *Quality order created*, *Quality order validated*, and *Sample scrapped*, are system-defined and visually tracked to ensure clarity and accountability throughout the sample's journey.

Samples undergo testing through *quality orders*. You can automatically generate or manually initiate these quality orders. The outcome of these tests directly influences inventory control decisions. Passing results might release blocked inventory, while failed tests can trigger automatic blocking of related batches or license plates. This dynamic interaction between sample status and inventory disposition ensures that only quality-approved goods proceed through the supply chain.

Throughout the lifecycle, you manage samples by using tools like the *Sample management workbench*. It offers capabilities such as label printing, audit trail review, lifecycle state changes, and manual overrides. These features empower quality teams to maintain control and visibility over sample data, enabling informed decision-making and regulatory compliance.

In essence, sample management transforms quality control from a reactive process into a proactive, data-driven discipline. By embedding sample lifecycle tracking into production and inventory systems, organizations can uphold high standards of product integrity while streamlining operations across departments.

The remaining sections of this article provide an overview of the activities connected to what could be typical lifecycle states of a sample.

Sample registration

Sample registration is the first step in the sample management process. It serves as the foundation for ensuring quality control in manufacturing. This step involves creating a database record that uniquely identifies each sample, which you can use for accurate tracking and management throughout its lifecycle. By registering samples, manufacturing managers can ensure that the system records all quality-related data and makes it easily accessible. You can register samples in multiple ways, but usually production personnel register them manually as inline samples, or periodically based on a continuous sampling setup.

Register new samples automatically with continuous sampling

Use the continuous sampling method to register new samples automatically based on predefined sampling plans.

Register new samples manually with inline sampling

The inline sampling method lets you register new samples directly during the production or inspection process.

Register new samples manually from the sample management workbench

You can also use the sample management workbench to manually register new samples, providing flexibility for ad-hoc or planned sampling activities. You can only create manual samples from the workbench for existing license plates or batch numbers for products that are set up for continuous sampling.

Follow these steps to use the sample management workbench to manually register a new sample for a license plate or batch number for a product set up for the continuous sampling process:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Sample Management Workbench**.
2. On the Action Pane, open the **Sample** tab, and select **Create sample**.
3. The **Create manual sample** page opens, showing a list of license plates or batch numbers that are available for sampling. Select the license plate or batch number from which you want to register a new sample.
4. From the Action Pane, select **Create sample**.
5. You return to the sample management workbench, which should now list the newly created sample.
6. Usually, you should also create a quality order for the newly created sample. To do so, go to the Action Pane, open the **Sample** tab, and select **Create manual quality order**. The **Create manual quality order** dialog opens. Review the information, edit it as needed, and select **OK** to create the quality order.

Collect, label, and test a sample

Accurate sample collection and labeling are foundational to reliable testing and traceability. Proper collection ensures that the sample truly represents the intended material, while clear and consistent labeling safeguards identification throughout analysis and storage, preventing costly mix-ups. Learn more in Enable and configure sample management.

Collect samples

Collecting samples is the physical process of extracting a small fraction of the produced material to represent the entire batch or license plate. This step is essential for quality control and traceability, ensuring that subsequent testing reflects the actual production output.

Workers typically use the sample management workbench to find sample registrations that require collection and labeling. It provides visibility and filtering options for finding sample

registrations generated through either inline or continuous sampling methods. The sample registration includes details such as the sample type, size, license plate, associated production order, and sampling procedures, guiding workers on how to collect the sample correctly.

Print labels

Printed labels ensure proper identification and traceability of a sample throughout the testing process. The label includes the sample ID and other information, such as batch or license plate ID, preventing mix-ups and supporting compliance. After you register a sample in the system, you can generate and print a label for it directly from the sample management workbench. First collect the sample, and then attach the label before storage or analysis. Use the following procedure to print labels for one or more samples.

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Sample Management Workbench**.
2. Find the sample registrations that you want to print a label for by using the **Filter** field or column filters.
3. Select one or more samples you want to print labels for.
4. Usually, use the default label layout, but if you want to choose an alternative layout, open the **Samples** tab on the Action Pane, and select **Change label layout**. Choose the desired layout in the drop-down dialog and select **OK**.
5. On the Action Pane, open the **Samples** tab and select **Print sample label**.
6. The **Print sample label** dialog opens. Make the following settings:

    - **Print destination** – Select *File* to save the label or *Print* to print it now.
    - **Name** – If you chose *Print* as the destination, select the printer you want to use.

7. Select **OK** to print (or save) the labels.

Test your samples

The purpose of collecting samples is to test them to ensure your production run meets its defined specifications. Sample management uses your recorded test results to influence which produced items can be used or shipped by updating the status of associated license plates or batch numbers based on the outcome.

Test inline samples

When you create an inline sample from a production order, the system automatically links it to a new quality order. This link ensures that every inline sample has a defined testing process from the start.

Workers can identify inline samples that are ready for testing by using the sample management workbench and applying filters to find samples according to their inspection method or lifecycle state. For example, you might have a sample lifecycle state named *Quality order generated*, which indicates a sample that has an untested quality order, and your system could be configured so that any inline sample automatically moves to this state when a quality order is created for it. Learn more about configuring lifecycle states in Configure lifecycle states.

Here's an example of how to test an inline sample:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Sample Management Workbench**.
2. Use the **Filter** field or column filters to find and select the sample registration that you want to test.
3. On the Action Pane, open the **Sample** tab and select **Quality orders**.
4. On the Action Pane, select **Quick result entry**.
5. In the **Result value** field, enter the result of your test. The test passes or fails based on whether your measure value is within the acceptable limits defined by the test.
6. On the Action Pane, select the **Back** button to return to the quality order. Then select **Validate** from the Action Pane.
7. Select **OK** to confirm the dialog and verify that the quality order shows the expected **Status** (either *Pass* or *Fail*).

Test continuous samples

As with inline samples, workers can identify continuous samples that are ready for testing by using the sample management workbench and applying filters to find samples according to their inspection method or lifecycle state.

When you use continuous sampling, the system automatically generates samples according to a predefined sampling plan set up on the item sampling configuration. Learn more about item sampling in Configure item sampling policies. For example, if the item sampling plan specifies that a sample should be created for every second license plate produced and a quality order should be produced for every second sample, then for every four license plates manufactured, the system creates two sample registrations and one quality order. The one quality order covers all four license plates. This means that the validation of that single quality order determines the inventory status for all four plates. If the quality order fails, the system updates the status of all four plates to *Blocked*, ensuring that none of them can be used or shipped. If a worker wants to perform more detailed testing, they can manually create a quality order from the sample management workbench for a sample that doesn't yet have one associated. When this manual test passes, the system automatically updates the inventory status of the related plates, such as the first two, to indicate availability. This method reduces the number of quality orders required for routine checks while still allowing targeted testing when necessary, and it

ensures that inventory status always reflects the outcome of quality validations across the linked items.

Here's an example of how to test a continuous sample:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Sample Management Workbench**.
2. Select a row that shows the **Item number** you want to test.
3. On the Action Pane, open the **Sample** tab and select **Sample relationships**. The **Sample relationships** page shows information about samples and license plates related to the selected sample. You can find the following information here:

    - There is record for each license plate that has been reported as finished and is waiting for quality testing.
    - Some license plates have samples registered for them (for example, every second license plate), as configured in the item sampling setup.
    - Some of the sampled license plates also have quality orders created for them (for example, every second sample), as configured in the item sampling setup.

4. Go back to the sample management workbench and select the specific sample that you want to test. The sample should be for the item you selected that has a quality order associated with it.
5. On the Action Pane, open the **Sample** tab and select **Quality orders**.
6. On the Action Pane, select **Quick result entry**.
7. In the **Result value** field, enter the result of your test. The test passes or fails based on whether your measure value is within the acceptable limits defined by the test.
8. On the Action Pane, select the **Back** button to return to the quality order. Then select **Validate** from the Action Pane.
9. The **Validate the quality order** dialog opens. The **Sample management** section of the dialog shows the following information:

    - If the test passes, then the **Update inventory status to** field is set to *Available*. If the test fails, then the **Update inventory status to** field is set to *Blocked*. The statuses for each type of result are configured on the relevant test group.
    - All the license plates listed in the grid will be assigned the **Update inventory status to** status, which is based on the test result.
    - A failed status typically prevents the license plate from being used in any warehouse or inventory transactions.

10. Select **OK** to confirm the dialog and assign the inventory status to each of the listed license plates.
11. Go back to the sample management workbench and confirm that the license plates for each sample has the updated inventory status that you expect to see. If you don't see the

inventory status in the grid, select **Dimensions display** on the Action Pane to add it.

Sample archiving

After you collect, label, and successfully test a sample, you can archive it for a defined period until it reaches its expiration date. The system sets the expiration date when you create the sample and calculates it based on the rules specified in the sample association. The system uses the sample lifecycle state to show when a sample is archived, marking its transition from active testing to storage. For details on how expiration periods are determined through sample associations, go to Set up sample associations.

To support archiving, make sure you define a lifecycle state that represents the archived state and select this state on the sample type configured for the product. Learn more in Configure lifecycle states and Define sample types.

Use the following procedure to change the lifecycle state:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Sample Management Workbench**.
2. Use the **Filter** field or column filters to find and select the sample registration that you want to archive.
3. On the Action Pane, open the **Sample** tab and select **Change lifecycle state**. Choose the desired lifecycle state in the drop-down dialog and select **OK**.

Sample disposal

Disposal involves safely and compliantly disposing of samples that reached the end of their retention period or are no longer needed for testing or quality assurance. Proper disposal minimizes environmental impact, prevents contamination, and ensures compliance with regulatory requirements.

The system uses the sample lifecycle state to show when a sample is disposed, marking its transition from active testing to disposal. To identify samples that have expired in the sample management workbench, you can filter for those whose expiration date has passed.

To support sample disposal, make sure you define a lifecycle state that represents the disposed state and select this state on the sample type configured for the product. Learn more in Configure lifecycle states and Define sample types.

To dispose of a sample, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Sample Management Workbench**.
2. Use the **Filter** field or column filters to find and select the sample registration that you want to archive.
3. On the Action Pane, open the **Sample** tab and select **Change lifecycle state**. Choose the desired lifecycle state in the drop-down dialog and select **OK**.

The *Disposed* state is typically the final stage in a sample's lifecycle. You can only delete samples from the sample management workbench after they reach a state that is configured with the property **Sample scrapped**. Learn more about how to define the lifecycle state in Configure lifecycle states.

Sample management reports and auditing (preview)

10/24/2025

[This article is prerelease documentation and is subject to change.]

This article describes tools that support quality management through reporting, auditing, and procedural guidance. Reports provide insights into trends in test results for specific tests, helping you monitor quality performance over time. Audit trails track changes and actions for compliance and traceability. Sample procedures are step-by-step instructions that workers can access while processing samples through different life cycle states, ensuring consistency in activities such as collection and testing.

Analyze sample test results for a production order

Sample reports provide visibility into how the results of a specific test evolve over time across multiple quality orders and samples for a given production or batch order. By analyzing these trends, you can identify patterns, monitor process stability, and detect potential quality issues early. You can perform this type of analysis for both inline sampling and continuous sampling, giving you flexibility to evaluate quality performance across different sampling strategies. These reports typically aggregate historical data for the selected test, allowing you to compare performance across different periods and make informed decisions for continuous improvement.

To analyze sample test results for a production order, follow these steps:

1. Go to **Production control** > **Production orders** > **All production orders**.
2. Find and select the order you want to analyze.
3. From the Action Pane, open the **View** tab and, from the **Manage quality** group, select **Analyze inline sample results** or **Analyze continuous sample results**, depending on which type of sample you want to analyze.
4. In the dialog, set the following fields

    - **Test** – Select the test you want to analyze.
    - **Item number** – For production orders, this value is read-only (the order you selected). For batch orders, select a formula item or co-product.

5. Select **OK** to see the report.
6. The report provides a graph that shows the upper and lower limits required to pass the test, along with the actual test results for each sample taken over time. You can hover over each data point to see more details about the specific sample and test result.

Sample procedures

Supply Chain Management stores detailed procedures for working with each type of sample. Each procedure provides step-by-step guidance for different stages of sample handling, such as collecting samples and performing tests. By following these instructions, workers ensure that sampling and testing activities are consistent and comply with defined quality standards.

To see the procedures defined for any sample, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Sample management workbench**.
2. Find and select the sample for which you want to view the procedures.
3. From the Action Pane, open the **Sample** tab and select **Sample procedures**.

Audit trail

Supply Chain Management maintains a full audit trail of all changes made to samples and sample testing records. It provides a detailed log of all actions performed on a selected sample, including the date and time of each change. For updates, the audit trail shows both the previous value and the new value, so you can track the full history of modifications. Each record in the audit trail corresponds to an insert or update event, providing a complete picture of the sample's lifecycle changes.

To view the audit trail for a sample, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Sample management workbench**.
2. Find and select the sample for which you want to view the audit trail.
3. From the Action Pane, open the **Sample** tab and select **Audit trail**.

Test instrument calibration

Calibration is the process of evaluating and adjusting the precision and accuracy of measurement equipment. It's usually defined as a performance comparison against a standard of known accuracy. Proper calibration of test instruments helps ensure a safe working environment. It also helps ensure that valid data is produced for future reference. Test instruments that aren't regularly calibrated can lead to false-positive and/or false-negative quality control tests.

The instrument calibration feature in Microsoft Dynamics 365 Supply Chain Management supports an ongoing calibration process. You can use it to track the calibration schedule and history of individual test instruments. You can also track the use of each test instrument based on the completion of quality order tests.

Instrument calibration is managed primarily through *test instrument tags*. Each test instrument tag is a digital record that represents a specific physical test instrument. This record holds settings for the test instrument and information about it.

Each test instrument tag includes a calibration history for the test instrument, indicates whether the instrument requires calibration. Each tag also provides a calibration procedure (which might include attached documents) and manages other calibration details.

Test instrument tags are assigned to a *calibration group*, which defines the calibration schedule. There are two ways to define the calibration schedule for the test instrument tags in a calibration group:

- **Based on usage** – The system tracks the numbers of times that the test instrument tag is used (that is, assigned to a quality order). It automatically creates calibration records when the usage count reaches a specified threshold. For example, calibration records might be created after every 1,000 uses.
- **Based on a periodic schedule** – The system tracks the date of the last calibration. It automatically creates a calibration record when the next scheduled calibration date is reached. For example, calibration records might be created monthly.

The feature also lets you generate and print calibration reports, such as calibration certificates and calibration schedule reports. In addition, you can design calibration label layouts that you print and attach to individual test instruments as required.

Prerequisites

Before you can use test instrument calibration features in Supply Chain Management, your system must meet the following requirements:

- You must be running Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Set up instrument calibration parameters

The settings on the **Inventory and warehouse management parameters** page affect the way that instrument calibration works across the system. Follow these steps to set up the instrument calibration parameters.

1. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**.

2. On the **Quality management** tab, in the **Test instrument calibration** section, set the following fields:

    - **Automatically assign test instrument tag number on quality order line** – Set this option to *Yes* if the system should try to automatically assign the best available test instrument tag to new quality order test lines. If you set this option to *No*, test instrument tags must be manually assigned when they are needed.

    - **Check if test instrument is being calibrated** – Select one of the following values to specify what action the system takes if the test instrument tag that is assigned to a quality order line has a usage status of *Calibration*. (This status indicates that the instrument is being calibrated and therefore can't be used.) The value that you select is used as the default setting for new test instrument tags.
        - *No check* – Skip this check.
        - *Warning only* – If the instrument is being calibrated, show a warning message, but allow the instrument to be used.
        - *Not allowed* – If the instrument is being calibrated, show an error message that states that the instrument can't be used.

    - **Check for maximum usage before calibration when assigning tag numbers** – Select one of the following values to specify what action the system takes if the maximum usage count for a test instrument tag is exceeded. (When the maximum usage count is exceeded, the instrument is due for calibration.)

    - *No check* – Skip this check.
    - *Warning only* – If the instrument is due for calibration, show a warning message, but allow the instrument to be used.
    - *Not allowed* – If the instrument is due for calibration, show an error message that states that the instrument can't be used.

- **Check for lifetime usage maximum when assigning tag numbers** – Select one of the following values to specify what action the system takes if the lifetime usage maximum for a test instrument tag is exceeded.
    - *No check* – Skip this check.
    - *Warning only* – If the instrument exceeds its lifetime usage maximum, show a warning message, but allow the instrument to be used.
    - *Not allowed* – If the instrument exceeds its lifetime usage maximum, show an error message that states that the instrument can't be used.

- **Skip check for test instrument on open quality order** – Set this option to *No* to prevent test instrument tags that are already assigned to open quality orders from being assigned to new quality orders. Set it to *Yes* to skip this check. In this case, a test instrument tag might be assigned to more than one open quality order at a time.

- **Label layout** – Select the default calibration label layout to assign to new test instrument type records. Learn more in the Design and print calibration labels section.

- **Print destination** – Select one of the following values to specify the default destination for calibration labels that are printed:
    - *Printer* – Print physical labels to a printer.
    - *File* – Download and save labels as a ZPL file.

- **Printer name** – If you set the **Print destination** field to *Printer*, select the name of the default printer to use to print calibration labels.

Set up test instrument types

Use the **Test instruments** page to define and view details about the types of devices that are used to perform tests on quality orders and calibrate other test instruments. *Test instrument types* help quality workers determine which type of device or tool they should use to run tests for a quality order and calibrate test instruments. For each test instrument type, you can specify the following details:

- Whether the instrument is used for calibration

- Whether a test instrument tag is required to identify the specific physical instrument that must be used
- What layout should be used when calibration labels are printed

Learn more in Quality management test instruments.

Set up test locations

Use the **Test locations** page to establish a list of locations where test instruments can be kept. In this way, workers who perform tests on quality orders can find the test instruments that they need. Later, you can assign locations to each test instrument tag as required.

To set up test locations, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test locations**.
2. Use the buttons on the Action Pane to create new test locations or edit existing ones as required. (You can also delete existing test locations.)
3. For each test location, set the following fields:
    - **Test location** – Enter a unique name or number that identifies the test location.
    - **Description** – Enter a short description of the test location.

Set up test departments

Use the **Test departments** page to establish a list of departments that use test instruments. In this way, users can find a test instrument and/or the people who work with it. Later, you can assign departments to each test instrument tag as required.

To set up test departments, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test departments**.
2. Use the buttons on the Action Pane to create new test departments or edit existing ones as required. (You can also delete existing test departments.)
3. For each test department, set the following fields:
    - **Test departments** – Enter a unique name or number that identifies the test department.
    - **Description** – Enter a short description of the test department.

Set up calibration procedures

For each type of instrument calibration that you perform, you can define a *calibration procedure* in Supply Chain Management. Calibration procedures help you track the steps that are required to calibrate a specific type of instrument. You can also use them to track the external vendors that you use to calibrate instruments. Later, when you set up a test instrument tag, you can assign a calibration procedure to it.

To set up a calibration procedure, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Calibration procedures**.
2. Create a new calibration procedure, or select an existing one that you want to edit.
3. On the header of the new or selected procedure, set the following fields:
    - **Calibration procedure name** – Enter a name for the calibration procedure.
    - **Description** – Enter a short description of the calibration procedure.
    - **External calibrating vendor** – Enter or select the account number of the external vendor that you use to calibrate instruments. Leave this field blank for calibration procedures that you perform in-house. After you select a value in this field, the read-only **External vendor name** field shows the name of the selected external vendor.
4. On the **Procedure** FastTab, enter details about the steps that are required to calibrate instruments where this procedure must be used.
5. Optional: If you want to attach a document that provides even more details about the calibration procedure, select the **Attachments** button (paperclip symbol) on the right side of the Action Pane. The **Attachments for Calibration procedures** page shows all the documents that are attached to the calibration procedure. Use the **New** menu on the Action Pane to upload a file as a new attachment. Attachments can be viewed from instrument and calibration records that use this procedure.

Set up calibration groups

Use calibration groups to group test instrument tags and assign calibration schedules to them. All test instrument tags that are assigned to a given calibration group share the same calibration method, calibration schedule, and other settings.

To set up a calibration group, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Calibration groups**.

2. Create a new calibration group, or select an existing one that you want to edit.

3. On the header of the new or selected group, set the following fields:

    - **Calibration group** – Enter the name of the group.
    - **Description** – Enter a short description of the group.

4. On the **General** FastTab, set the following fields:

    - **Calibration method** – Select one of the following values to specify the method that determines when the instrument is calibrated:
        - *Manual* – Manually calibrate the instrument as it's required.
        - *Usage* – Calibrate the instrument based on the number of times that it's used.
        - *Periodic* – Calibrate the instrument on a regular schedule, based on calendar days, months, or years.

    - **Calibration period** – This field is available only when the **Calibration method** field is set to *Periodic*. Select one of the following values to specify the unit for the amount of time between calibrations:
        - *Day* – Specify the period in days.
        - *Month* – Specify the period in months.
        - *Year* – Specify the period in years.

    - **Calibration period frequency** – This field is available only when the **Calibration method** field is set to *Periodic*. Enter the amount of time between calibrations, in the unit that is selected in the **Calibration period** field. For example, if test instrument tags for this group are assigned to instruments that should be calibrated every three months, set the **Calibration period** field to *Month* and the **Calibration period frequency** field to *3*.

    - **Calibration usage update method** – This field is available only when the **Calibration method** field is set to *Usage*. Select one of the following values to specify the method that is used to update the current usage of the test instrument:
        - *Fixed increment* – Each time a quality order that has a test instrument tag in this group is validated, update the test instrument tag's usage count by the value that is specified in the **Usage increment** field.
        - *Test quantity* – Each time a quality order that has a test instrument tag in this group is validated, update the test instrument tag's usage count by the test quantity that

is specified on the quality order.

- **Usage increment** – This field is available only when the **Calibration method** field is set to *Usage* and the **Calibration usage update method** field is set to *Fixed increment*. Specify the increment by which to increase the usage count of a test instrument tag each time an instrument is used. For example, if the **Usage increment** field is set to *2*, the usage count for a test instrument tag in this group is increased by two for every validated quality order that includes the test instrument tag, regardless of the number of units that are tested.

- **Usage count trigger for calibration** – This field is available only when the **Calibration method** field is set to *Usage*. Enter the usage value that triggers a calibration for test instrument tags in this group. The instrument can still be used until the usage count that is specified in the **Maximum usage before calibration** field is reached. For example, if the **Usage count trigger for calibration** field is set to *100*, and a test instrument tag in this group reaches 100 uses, the periodic job that creates calibration records creates a record for that test instrument tag the next time the job runs.

- **Maximum usage before calibration** – This field is available only when the **Calibration method** field is set to *Usage*. Enter the maximum number of times that a test instrument tag in this group can be used before it must be calibrated. For example, the **Usage count trigger for calibration** field might be set to *100*, whereas the **Maximum usage before calibration** field might be set to *125*. In this case, calibration is triggered after 100 uses, but the instrument can continue to be used until it reaches 125 uses.

- **Lifetime usage maximum** – This field is available only when the **Calibration method** field is set to *Usage*. Enter the maximum number of times that an instrument can be used before it's taken out of service. For example, if the **Lifetime usage maximum** field is set to *10,000*, test instrument tags in this group that reach 10,000 uses are marked as out of service and can no longer be calibrated.

> ⓘ **Note**
>
> Use the **Inventory and warehouse management parameters** page to configure how the system reacts when the **Maximum usage before calibration** and **Lifetime usage maximum** values are reached. You can choose to have the system do nothing, show a warning but still allow the instrument to be used, or show an error and block the instrument from being used. Learn more in the Set up instrument calibration parameters section.

Set up test instrument tags

Each physical test instrument is represented in Supply Chain Management by a test instrument tag record. This record specifies data such as the manufacturer, warranty number, acquisition date, and specifications. The test instrument tag is used to track the calibration schedule and history of the test instrument, and it can be assigned to quality order tests.

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test instrument tags**.
2. Create a new test instrument tag, or select an existing one that you want to edit.
3. On the header of the new or selected test instrument tag, review or set the following fields:
    - **Tag number** – Enter a unique name, number, or code for the instrument.
    - **Test instrument type** – Select the type or category of test instrument that the test instrument tag is associated with. Examples include *Scale*, *Thermometer*, and *Oximeter*. The test instrument type defines options such as whether the instrument is used for calibration, whether a test instrument tag is required to identify the specific physical instrument that must be used, and what layout should be used when calibration labels are printed. Learn more in the Set up test instrument types section.
    - **Instrument usage status** – The current usage status of the test instrument. Although the field is read-only, you can manually change the status to *Out of service* or *Available* by using the buttons on the **Update usage status** tab of the Action Pane. The following status values are used:
        - *Available* – The test instrument is ready to be assigned to a new quality order.
        - *Calibration* – The test instrument is currently being calibrated. This status is automatically set when an open (in-progress) calibration record exists for this test instrument tag.
        - *Out of service* – The test instrument is out of service and can't be used for quality order tests. This status is automatically set when the lifetime usage maximum is reached.
4. On the **General** FastTab, review or set the following fields. These fields provide general information about the test instrument tag of the test instrument.
    - **Description** – Enter a brief description of the test instrument.
    - **Instrument description** – A description of the test instrument type that is selected in the **Test instrument type** field on the header.

- **Used for calibration** – A value that indicates whether the test instrument is used to calibrate other instruments. The value is inherited from the selected test instrument type.
- **Skip check for test instrument on open quality order** – Set this option to *No* to prevent test instrument tags that are already assigned to open quality orders from being assigned to new quality orders. Set it to *Yes* to skip this check. In this case, a test instrument tag might be assigned to more than one open quality order at a time.
- **Restricted use** – Set this option to *Yes* if this test instrument is restricted. This option is for information only.
- **Check if test instrument is being calibrated** – Select the action that is taken on a quality order when the **Instrument usage status** value of the instrument is *Calibration*. The default value for new tags is defined in Inventory and warehouse management parameters, but you can change it for individual test instrument tags. The following values are available:
  - *Not allowed* – If the **Instrument usage status** value is *Calibration*, don't allow the instrument to be used for new or existing quality orders.
  - *Warning only* – If the **Instrument usage status** value is *Calibration*, show a warning, but still allow the instrument to be used for new or existing quality orders.
  - *No check* – Always allow the instrument to be used for new or existing quality orders, regardless of its calibration status.
- **Serial number** – Enter the serial number of the test instrument.
- **Owner** – Enter the owner of the test instrument.
- **Acquisition date** – Enter the date when the test instrument was acquired.
- **Fixed asset number** – If the test instrument is linked to a fixed asset number, select that number. This field is for information only.
- **Customer account** – Select the customer account that the test instrument is related to. For example, the test instrument might belong to and/or be assigned to a specific customer.
- **Vendor account** – Select the vendor account that the test instrument is related to. For example, the test instrument might belong to and/or be assigned to a specific vendor.

- **Test area** – Select the test area that the test instrument is associated with. This field is a standard Supply Chain Management field. It's reused on this page based on standard logic.

- **Test department** – Select the department that is responsible for the test instrument. Learn more in the Set up test departments section.

- **Test location** – Select the location where the test instrument can be found. Learn more in the Set up test locations section.

- **Unit** – The unit that the test instrument measures in (such as grams or milliliters). The value is inherited from the selected test instrument type.

- **Precision** – The precision of measurement that can be used when results from the test instrument are recorded. Precision refers to the number of digits that are used to express a value. The value of this field is inherited from the selected test instrument type.

5. On the **Calibration details** FastTab, review or set the following fields. These fields provide information that is specific to the calibration of the test instrument.

    - **Calibration required** – Specify whether calibration is required for the test instrument. The other fields on this FastTab can be edited only when this option is set to *Yes*.

    - **Calibration procedure name** – Select the name of the procedure that is used to calibrate the test instrument. The procedure provides instructions for calibrating the instrument. To read the procedure, select the link. If the selected procedure includes attached documents, select the **Attachments** button (paperclip symbol) on the right side of the Action Pane to view them. Learn more in the Set up calibration procedures section.

    - **External calibrating vendor** – If an external vendor is used to calibrate the test instrument, the account number of the vendor. The value of this read-only field is inherited from the calibration procedure that is selected in the **Calibration procedure name** field.

    - **External vendor name** – If an external vendor is used to calibrate the test instrument, the name of the vendor. The value of this read-only field is inherited from the selected calibration procedure.

- **Calibration start date** – The date of the first calibration. Other calibration dates are calculated relative to this date.
- **Usage count since last calibration** – The number of times that the test instrument has been used since its last calibration. This field applies only when the **Calibration method** field is set to *Usage*. It's used to determine when the next calibration is due. Each time the instrument is calibrated and approved, the value of this field is reset to *0* (zero). Although this field is usually read-only, you can make it editable by selecting **Override usage data** on the **Functions** tab of the Action Pane.
- **Lifetime usage count** – The number of times that the test instrument has been used during its lifetime. Although this field is usually read-only, you can make it editable by selecting **Override usage data** on the **Functions** tab of the Action Pane.
- **Calibration group** – Select the calibration group that the test instrument belongs to. The calibration group establishes the calibration method (manual, periodic, or usage) and related settings that define the calibration schedule. Settings from the selected group are shown nearby in read-only form. They depend on the calibration method that the group uses. Learn more in the Set up calibration groups section.
- **Completion assignee** – Select the user who is usually assigned to complete the calibration of the test instrument.
- **Approval assignee** – Select the user who is usually assigned to approve the calibration of the test instrument.
- **Started date** – The date when the most recent calibration of the test instrument was started.
- **Completion date** – The date when the most recent calibration of the test instrument was completed.
- **Calibration result** – The result of the most recent calibration of the test instrument.
- **Approval date** – The date when the most recent calibration of the test instrument was approved.
- **Next calibration date** – The date when the next calibration of the test instrument is scheduled. This field applies only when the **Calibration method** field is set to *Periodic* or *Manual*. If you're using the *Manual* calibration method, this field is editable. If you're using the *Periodic* calibration method, the value is automatically calculated by using

the approval date of the most recent calibration and the settings of the calibration group schedule. If you must reschedule the date that is automatically calculated for the next calibration, select **Reschedule calculations** on the **Functions** tab of the Action Pane.

Here are some examples that show how dates are calculated:

- The **Approval date** value of the last closed calibration is *January 1, 2025*, the **Calibration period** value is *Day*, and the **Calibration period frequency** value is *10*. In this case, the **Next calibration date** value is calculated as *January 11, 2025*.
- The **Approval date** value of the last closed calibration is *January 1, 2025*, the **Calibration period** value is *Month*, and the **Calibration period frequency** value is *3*. In this case, the **Next calibration date** value is calculated as *April 1, 2025*.
- The **Approval date** value of the last closed calibration is *January 1, 2025*, the **Calibration period** value is *Year*, and the **Calibration period frequency** value is *1*. In this case, the **Next calibration date** value is calculated as *January 1, 2026*.

- **Date calibration certificate printed** – The date when the instrument calibration certificate was last printed.

6. Enter information on the following FastTabs as required. The fields on these FastTabs are for information only. They aren't used in any calculations or processes.

    - **Manufacturer data** – Enter information that is specific to the test instrument and its manufacturer.
    - **Test procedures** – Add more test procedures to support the calibration procedures.
    - **Specifications** – Add more specifications.
    - **Notes** – Add notes and other comments.

Create calibration records

When a test instrument requires calibration, a *calibration record* must be created. The calibration record is used to track the details of the calibration process, including the date and time when the calibration was started, completed, and approved, the person who performed each step, and the results of the calibration. To review the full calibration history, open the calibration record list. You can filter the list so that it shows the calibration history of a specific physical instrument, for example.

While a calibration record is open, its related test instrument tag shows an **Instrument usage status** value of *Calibration*. This status usually indicates that the instrument isn't available for use.

Manually create a calibration record

You can manually create a calibration record for a test instrument tag at any time by following these steps.

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test instrument tags**.
2. Select the test instrument tag that you want to create a calibration record for.
3. On the Action Pane, on the **Functions** tab, select **Calibrate instrument**.
4. On the **Test instrument calibration record detail** page, most of the fields are preset so that the values match the settings of the selected test instrument tag. However, you can adjust the values as you require.
5. On the Action Pane, select **Save**.

Schedule a batch job to automatically create calibration records as required

The *Create calibration records* batch job automatically creates calibration records for test instrument tags that are due for calibration. The batch job can be scheduled to run regularly (for example, daily or weekly), or it can be manually run as required. Each time the batch job runs, it checks every test instrument tag and uses the following method to determine whether it should create an open calibration record:

- If the **Calibration method** value is *Usage*, the job checks the **Usage count since last calibration** and **Maximum usage before calibration** fields to determine whether a calibration record should be created.
- If the **Calibration method** value is *Periodic*, the job checks the **Next calibration date** field to determine whether a calibration record should be created.

To run or schedule the batch job, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Create calibration records**.
2. On the **Records to include** FastTab, set up filters and constraints to define which test instrument tags are checked. Select **Filter** to open a standard query editor dialog, where you can define selection criteria, sorting criteria, and joins. The fields work just as they do for other types of queries in Supply Chain Management.
3. On the **Run in the background** FastTab, specify how, when, and how often the job runs. The fields work just as they do for other types of background jobs in Supply Chain Management.
4. Select **OK** to apply your settings and close the dialog.

Calibrate an instrument

Calibration work is created and traced by using calibration records. Each calibration record is associated with a specific test instrument tag. It contains information about the calibration process, including the date and time when the calibration was started, completed, and approved, the person who performed each step, and the results of the calibration.

Calibration records are listed on the **Calibrate test instruments** page. There, you can view, start, take notes about, complete, and approve the calibration of a test instrument.

The three possible calibration results are *Pass*, *Limited pass*, and *Fail*. For failed calibrations, you can mark the instrument as out of service or have it continue to show up as being calibrated. Calibrations that pass must also be approved. Electronic signatures can optionally be required for approval of a completed calibration record.

A completed or approved calibration can be reopened at any time. You can view a history of all reopened calibrations.

To perform a calibration, follow these steps:

1. Go to **Inventory management** > **Periodic** > **Quality management** > **Calibrate test instruments**.

2. All the open records that are listed on the page represent calibrations that are due. Either select one of these records or select **New** on the Action Pane to create a new one.

3. Review and set the following fields as required:

    - **Test instrument type** – The test instrument that is being calibrated.
    - **Description** – A description of the test instrument.
    - **Tag number** – The test instrument tag number of the test instrument that is being calibrated.
    - **Description** – A description of the test instrument tag.
    - **Instrument usage status** – The current status of the test instrument tag (*Available*, *Calibration*, or *Out of Service*).
    - **Calibration procedure name** – The calibration procedure to use. By default, this field is set to the procedure that is selected for test instrument tag. However, you can select a different procedure. Learn more in the Set up calibration procedures section.
    - **Description** – A description of the calibration procedure.

- **External calibrating vendor** – If an external vendor is used to calibrate the test instrument, the account number of the vendor. This value of this read-only field is inherited from the calibration procedure that is selected in the **Calibration procedure name** field.
- **External vendor name** – If an external vendor is used to calibrate the test instrument, the name of the vendor. This value of this read-only field is inherited from the selected calibration procedure.
- **Calibration procedure** – The procedures as they are specified on the **Calibration procedure** page. The value of this read-only field is inherited from the selected calibration procedure.
- **Started by** – The user who started the calibration. This field is updated by the **Start calibration** action.
- **Started date** – The date when the calibration was started. This field is updated by the **Start calibration** action.
- **Completion assignee** – The user who is responsible for assigning the user who will perform the calibration. The default value comes from the test instrument tag, but you can modify it.
- **Completion by** – The user who completed the calibration. This field is updated by the **Complete calibration** action.
- **Completion date** – The date when the calibration was completed. This field is updated by the **Complete calibration** action.
- **Calibration result** – The result of the calibration of the test instrument. This field is updated by the **Complete calibration** action.
- **Approval assignee** – The user who is responsible for assigning the user who will approve the calibration. The default value comes from the test instrument tag, but you can modify it.
- **Approval by** – The user who approved the calibration. This field is updated by the **Approve calibration** action.
- **Approval date** – The date when the calibration was approved. This field is updated by the **Approve calibration** action.
- **Test procedures** – More information about how to calibrate the test instrument that must be calibrated. The default information comes from the test instrument tag, but it can be updated during calibration.
- **Specifications** – Further specifications for the test instrument that must be calibrated. The default information comes from the test instrument tag, but it can be updated during calibration.

- **Calibration notes** – Further notes about the calibration. The default information comes from the test instrument tag, but it can be updated during calibration.

> **Tip**
>
> If more calibration instructions are available as attached documents, the **Attachments** button (paperclip symbol) on the right side of the Action Pane includes a badge that shows the number of attachments. Select the **Attachments** button to open the **Attachments for Calibration procedures** page, where you can view, add, and describe documents that are attached to the calibration record.

4. If you want to record details about the specific instruments that are required or used to calibrate the test instrument, on the Action Pane, on the **Calibrate instruments** tab, select **Assign calibration tools**. Then use the **Calibration tools used** page to record each instrument. For each instrument that you add, set the following fields:

   - **Calibration tool** – Select the test instrument type for the instrument that is used. This field lists only test instrument types where the **Use for calibration** option is set to *Yes*. Learn more in Quality management test instruments.
   - **Calibration tool tag number** – To identify a specific physical test instrument, select its test instrument tag number. This field is required if the **Requires test instrument tag** option is set to *Yes* for test instrument type that is selected in the **Calibration tool** field.

5. To start the calibration, on the Action Pane, on the **Calibrate instruments** tab, select **Start calibration**. Then select **OK** in the dialog. The **Started by** and **Started date** fields on the calibration record are updated.

6. Do your calibration tests as required. When you're finished, on the Action Pane, on the **Calibrate instruments** tab, select **Complete calibration**. Then, in the **Calibration action** dialog, set the following fields:

   - **Calibration result** – Select one of the following values to specify the result of the calibration:
     - *Pass* – The instrument passed the calibration.
     - *Limited pass* – The instrument can still be used, but within a limited scope.
     - *Fail* – The instrument failed the calibration.

- **Update associated test instrument tag status to 'Out of service'** – Set this option to *Yes* if the instrument failed the calibration, and you want to mark it as out of service. This option is available only when the **Calibration result** field is set to *Fail*.

7. The calibration must now be approved, either by you or by somebody else (such as a supervisor), depending on the setup of your system. The approver must open the calibration record, and then, on the Action Pane, on the **Calibrate instruments** tab, select **Approve calibration**. The instrument is now approved, and the **Approved by** and **Approved date** fields are updated. The related test instrument tag is updated with the test result, approval date, and next calibration date.

8. If you must print a calibration label and/or calibration certificate, on the Action Pane, on the **Calibration instruments** tab, in the **Print** group, select the appropriate button.

Reopen an approved calibration record

If you must edit an approved calibration record, follow these steps:

1. Go to **Inventory management** > **Periodic** > **Quality management** > **Calibrate test instruments**.
2. Find and select the relevant calibration record. The record must be in the *Fail* or *Approved* state.
3. On the Action Pane, on the **Calibrate instruments** tab, select **Reopen calibration**. The completed and approved fields are cleared, a *reopen calibration history* record is created, and the calibration record returns to the *Open* state. You can now edit and complete the calibration record in the usual way.

To view a history of reopened calibration records, follow these steps:

- Go to **Inventory management** > **Inquiries and reports** > **Quality management** > **Calibration reopen history log**.
- Go to **Inventory management** > **Periodic** > **Quality management** > **Calibrate test instruments**. On the Action Pane, on the **Calibrate instruments** tab, select **Calibration reopen history log**.

Apply test instrument types and tags to a quality order

You set up and manage quality tests by using quality orders. A quality order defines what must be tested and how. A test group is assigned to each quality order. The test group defines which tests must be done, and which test instrument type should be used for each test.

When you assign a test group to a quality order, each line from the selected test group becomes a line on the new quality order. The quality order also inherits the test instrument type from the test group. When you create a quality order, you can (and in some cases must) assign a specific test instrument tag to each line. In this way, you specify the physical instrument that must be used for the test.

To view and assign test instrument types for a test group, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test groups**.
2. Create a new test group, or select an existing one.
3. At the bottom of the page, on the **Overview** tab, create or select a test group line.
4. On the **Test** tab, in the **Test instrument** field, select the test instrument type.

To view and assign test instrument tags to a quality order, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Quality orders**.
2. Create a new quality order, or select an existing one.
3. At the bottom of the page, the **Overview** tab has a line for each test that the quality order requires. It includes lines that are inherited from the test group that is assigned to the quality order. You can manually add more lines as you require.
4. On the **Overview** tab, select a quality order line.
5. On the **Test** tab, in the **Tag number** field, review or set the test instrument tag for the selected quality order line.

Here are some guidelines for using test instrument types and tags on quality orders:

- If the **Automatically assign test instrument tag number on quality order line** option is set to *Yes* in Inventory and warehouse management parameters, when a quality order is created, the system sorts through the test instrument tags for each selected instrument type and selects the best available test instrument tag for the quality test. If the option is set to *No*, you must manually assign test instrument tags as required.
- If a test instrument type that is selected for use on a quality order line is set up to require a test instrument tag, the quality order can't be validated until a test instrument tag is selected on the quality order line.
- Test instrument tags that have an **Instrument usage status** value of *Out of service* aren't available for selection on the quality test.
- Test instrument tags that have an **Instrument usage status** value of *Calibration* might be available for selection on the quality test, depending on the setup of the test instrument tag.

- Depending on how you set up the system to validate test instrument tags, you might receive a warning or error if you select a test instrument tag that is already assigned to another open quality order, or if the selected tag has exceeded its maximum usage and/or its lifetime usage.
- When a quality order is validated, if a selected test instrument tag is calibrated based on usage, the usage counts on the tag are updated based on the quality order. The current usage count and the lifetime usage count are incremented by either the test quantity or the usage increment, depending on the details of the calibration group on the test instrument tag.

Design and print calibration labels

Use calibration labels to attach calibration information directly to physical test instruments.

Set up calibration label layouts

Calibration label layouts are designed and printed in Zebra Programming Language (ZPL) format, a standard format for printing labels on Zebra printers. Calibration labels can include information such as the test instrument tag number, the test instrument type, the calibration procedure name, and the next calibration date.

To get started quickly, you can generate a predesigned ZPL layout for a calibration label. This layout is designed to be used with Zebra printers and can be modified as required. To add the predesigned ZPL layout to your system, go to **Inventory management** > **Setup** > **Quality control** > **Create sample calibration labels**. The system then generates a label layout that is named *SampleLabel_2X1*.

To customize the standard layout or create new ones, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Calibration label layout**.
2. Use the buttons on the Action Pane to create a new calibration label layout or edit an existing one as required. (You can also delete existing layouts.)
3. On the header of the new or selected layout, enter details such as the name, description, and dimensions.
4. On the **Label layout** FastTab, use the large field to design your label layout. For help, use a ZPL reference.

5. The page helps you find the codes that you need to insert field values. To add a field value to your layout, follow these steps:
    a. Set the **Use fields from** field to the type of database record that you want to use a field from (*Test instrument tags* or *Test instrument calibration records*).
    b. In the **Labels** list, select a field name.
    c. Select **Insert at end of text** to add the reference code to the end of the label layout text.
    d. Use a copy-and-paste operation to move the reference code to the desired location in the label layout text.

Assign layouts to test instrument types

When you print a calibration label, the system uses the layout that is assigned to the test instrument type of the test instrument tag. Learn how to assign a layout to a test instrument type in Quality management test instruments.

Print calibration labels

To print calibration labels for a physical test instrument, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test instrument tags**.
2. Select the test instrument tag that you want to print a calibration label for.
3. On the Action Pane, on the **Print** tab, select **Calibration label**.
4. In the **Print calibration label** dialog, set the following fields:
    - **Print destination** – Select *Printer* to print the label directly to a printer. Select *File* to download and save the label locally as a ZPL file.
    - **Name** – If you selected *Printer* in the **Print destination** field, select the printer to use.

Print calibration certificates

Calibration certificates can be printed for each calibration record. They document the calibration process and results for a test instrument, and are used to verify that the test instrument was calibrated according to the specified procedures and standards. Calibration certificates include information such as the test instrument tag number, the calibration procedure name, the calibration result, the name of the person who performed the calibration, and the next calibration date.

To print a certificate for the last closed calibration for a test instrument tag, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test instrument tags**.
2. Select the test instrument tag that you want to print a calibration label for.
3. On the Action Pane, on the **Print** tab, select **Calibration certificate**.
4. The certificate is generated and shown on your screen. You can review, print, and/or export it.

To print a certificate for any selected calibration record, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Calibrate test instruments**.
2. Select the test calibration record that you want to print a calibration label for.
3. On the Action Pane, on the **Calibrate instruments** tab, in the **Print** group, select **Calibration certificate**.
4. The certificate is generated and shown on your screen. You can review, print, and/or export it.

View or print the calibration schedule report

The calibration schedule report provides a list of test instruments that must be calibrated. However, you can customize the selection criteria to support many other uses. For example, you can filter by owner or calibration method. You can use the **Show all due today** option to create a list of test instrument tags where the due date of the next calibration is before the current date.

To print a calibration schedule report, follow these steps:

1. Go to **Inventory management** > **Inquiries and reports** > **Quality management** > **Test instrument calibration schedule**.

2. In the **Test instrument calibration schedule** dialog, on the **Parameters** FastTab, set the **Show all due today** option to one of the following values:

    - *Yes* – Show only test instrument tags where the next calibration date is before the current date.
    - *No* – Show all test instruments tags, regardless of when they are due for calibration.

3. The **Destination** FastTab shows the current destination for the report. The possible destinations are *Screen*, *Printer*, *File*, and *Email*. (The default destination is *Screen*.) To change the destination, select **Change**, select a new destination, and then configure settings that are related to that destination.

4. On the **Records to include** FastTab, set up filters and constraints to define which test instrument tags are included. Select **Filter** to open a standard query editor dialog, where you can define selection criteria, sorting criteria, and joins. The fields work just as they do for other types of queries in Supply Chain Management.

5. On the **Run in the background** FastTab, specify how, when, and how often to run the job. The fields work just as they do for other types of background jobs in Supply Chain Management.

6. Select **OK** to apply your settings and close the dialog.

Flexible sampling plans

A *flexible sampling plan* defines the criteria for inspecting randomly selected units of items from a lot. The results from the inspected sample determine whether the whole lot passes or fails testing. Typically, the number of units that are selected for inspection is proportional to the total size of the lot. The quality association that is defined for a plan identifies the activity for the inspection. For example, the activity might be a quality order to inspect a product before it's released to a customer on a sales order. Alternatively, it might be a quality order to inspect a manufactured product after production is completed.

Flexible sampling plans offer other features that you can use to modify your criteria over time, based on previous testing results.

- **Sampling size variations** – Flexible sampling lets you vary your item sampling over time, based on test findings. For example, for the first five rounds of testing, you inspect 50% of the receipt. If no quality failures are found in those rounds, you might decide to reduce the inspection sampling size for subsequent rounds to 10% of the receipt. Rounds identify the number of times that a test is performed at a specific level before testing moves to the next level in the testing plan. For example, if a level requires five rounds of testing, the assigned item sampling should be used for all five rounds before the testing moves to the next level. The next level might use a different item sampling.
- **Test group flexibility** – By using a flexible sampling plan, you can change a plan's current test group based on inspection results. The test group identifies the individual tests that are performed. For example, if previous testing results show minimal issues with the quality of receipts, you might change the test group to one that has a less stringent set of tests. You can also specify different test groups for different levels in a flexible sampling plan.
- **Skip lot inspections** – Skip lot inspections are an alternative to lot-by-lot inspections. They let you skip a set number of goods during testing. For example, a long-time supplier has demonstrated that the quality of their receipts is very good. Therefore, a quality manager might set up a flexible sampling plan to inspect a quantity of 10 units from this supplier and then skip the next 10 units. Receipts that don't require inspection are put away, and no quality order is generated.

Because flexible sampling plans give you the flexibility to perform lot-by-lot inspections instead of unit-by-unit inspections, and to use features such as sampling size variations, test group flexibility, and skip lot inspections, they help your company minimize time, costs, handling damage, and inspection errors.

Prerequisites

Before you can use the features that are described in this article, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Set up flexible sampling plans

To set up flexible sampling plans, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Flexible sampling plans**.

2. On the Action Pane, use the following buttons as required:

    - **Add** – Add a new sampling plan.
    - **Delete** – Remove an existing plan. (You can't delete a plan if quality orders use it or activities are tracked against it.)
    - **Copy plan** – Copy content from another plan to the selected plan.
    - **View activities** – Open the **Flexible sampling plan activities** page, where you can view summaries and detailed information about the plan activities.

3. On the header of the new or selected sampling plan, set the following fields:

    - **Flexible sampling plan code** – Enter a name for the sampling plan.
    - **Name** – Enter a short description of the sampling plan.
    - **Alert role** – Select the security role that should be notified if a specified number of failures for a level is reached.
    - **Last level** – Select the level number for the last activity that is performed in this flexible sampling plan process.
    - **Approved** – Set the plan to the *Approved* state.

4. On the **Details** FastTab, use the grid to set up the plan. Use the buttons on the toolbar to add and remove lines in the grid. For new or selected lines, set the following fields:

    - **Level** – Select or review the level number that is assigned to the activity. The plan is processed in descending order of levels.

- **Item sampling** – Select or review the item sampling. The item sampling determines the sampling size of the quality order for the activity. Examples include a 10% sampling or a 50-unit quantity sampling.

- **Test group** – Select or review the test group. The test group determines the set of tests for the quality order for the activity.

- **Rounds** – Set or review the number of testing rounds for the specific flexible sampling plan level that must pass quality order validation before testing can move to the next level. After you select a level in the **Last level** field, any **Rounds** value that you entered for that level is removed from the plan. In this way, the last level can continue indefinitely until several failures cause the plan to revert to a previous level.

  > ⓘ **Note**
  >
  > Unless rounds are removed from the last level in the testing plan, all future tests remain at that level indefinitely, until the enough failures occurred so that the plan can revert to a previous level.

  For example, a quality association is set up to test purchase order registrations for a specific vendor. The vendor's flexible sampling plan requires that 10% of every registration is tested for five rounds. If you receive 100 units, a quality order is generated to test 10 of them. The quality order for the first registration passes. The second quality order then fails, but the next three quality orders pass. If round six passes, the first level in the plan is accomplished, because the number of passed rounds met the requirement.

- **Time span (days)** – Enter or review the number of days within which the specified number of rounds must be completed. This field is optional. It works together with the **Rounds** field. If this field is set, testing can move to the next level only if the specified number of rounds pass inspection within the defined time span. For example, if you set the time span to 60 days and specify 10 rounds, testing can move to the next level in the plan only if 10 quality orders for the quality association pass within 60 days.

- **Skip** – Select this checkbox to enable skip lot sampling, where only a fraction of the submitted lots is inspected. If you select this checkbox, you must enter the skip range in the **Test frequency** and **Out of frequency** fields.

- **Test frequency** – If the **Skip** checkbox is selected, enter the first number in the skip range.
- **Out of frequency** – If the **Skip** checkbox is selected, enter the last number in the skip range.

  For example, the quality association is set for production order registrations. The flexible sampling plan that is associated with this reference type uses skip lot sampling. The **Test frequency** field is set to *1*, and the **Out of frequency** field is set to *5*. In this case, a quality order is generated to test one out of every five registrations. The system randomly selects one of the five registrations for testing, and the other four registrations are skipped.
- **Number of fails** – Enter or review the number times that tests can fail before the flexible sampling plan reverts to a previous testing level. That level might be more or less restrictive than the current test, based on previous testing results. If the **Consecutive** checkbox is selected, the plan reverts to a previous level only if the failures are consecutive. For example, a vendor might initially define a plan to test 10 out of 40 receipts, to minimize the costs that are associated with testing. However, if recent testing results show a notable increase in failures, the current level might be replaced by a level that tests 20 out of 40 receipts. On the other hand, if the vendor's testing results show consistent quality and no failures, the current level might be replaced by a level that requires fewer failures.
- **Consecutive** – Select this checkbox if the number of failures that is specified in the **Number of fails** field must be consecutive. If this checkbox is selected, and the number of consecutive failures is reached, the appropriate action is initiated, based on the specified fail action level and fail action code. For example, if the **Number of fails** field is set to *2*, and this checkbox is selected, two consecutive failures generate a predefined fail action, such as issuing an alert notification to the quality manager.
- **Fail action level** – Enter or review the level of action that is initiated when the number that is specified in the **Number of fails** field is reached. This action indicates that more testing is required. If the **Consecutive** checkbox is also selected, the action is initiated only if the failures are consecutive. For example, if two consecutive quality orders fail at level 3, the defined action might require that testing starts over at level 1. You can assign any level that is currently defined in the flexible sampling plan, provided that it's equal to or lower than the current level.

- **Fail action code** – Select the action code that defines the action that should be taken when the failure criteria are met or exceeded for the flexible sampling plan. All the actions return the test sampling process to the fail action level.

Set up the quality association for the flexible sampling plan

Quality orders that use flexible sampling plans are set up so that they are automatically generated by using a quality association.

Learn more about how to manage quality associations in Quality associations.

View flexible sampling plan activities

To open the **Flexible sampling plan activities** page, select the **View activities** button on the Action Pane of the **Flexible sampling plan** page. The **Flexible sampling plan activities** page provides an overview of the quality associations where flexible sampling plans are used.

The following buttons are available on the **Flexible sampling plan activities** page:

- **Flexible sampling plan activity summary** – View a summary of activity for the selected flexible sampling plan.
- **Flexible sampling plan activity details** – View the specific details of the flexible sampling plan that you select. On this page, you can view how the activities in the plan are progressing through the levels of the plan. For each activity, the page indicates the quality order that is used. Color-coded related text describes the pass and fail criteria for each level. For example, a red color indicates that a quality order failed. If a quality order fails, the page also indicates whether the test reverted to a previous level that requires more testing. From this page, you can also open pages that include summaries and details about activities, and view charts that show statistics about the performance of quality order testing.
- **Flexible sampling plans** – View the specific activity details for the flexible sampling plan that you select. You can also create a new flexible sampling plan from this page.

Last updated on 07/27/2026

Acceptance sampling

Acceptance sampling is a quality control method that uses statistical analysis to evaluate a batch or lot of products. Instead of checking every item, you examine a subset of items to determine whether the entire lot meets predefined quality standards. This approach is widely used in manufacturing and supply chain operations to balance inspection effort with quality assurance.

Acceptance sampling overview

Defect types and categories

In many practical applications, you inspect sampled items for different *types* of defects. Each defect type typically falls into one of the following *categories*:

- **Critical defects** – Might cause harm or render a product unsafe or unusable. Even a single critical defect can lead to rejection of the entire lot.
- **Major defects** – Significantly reduce the usability or performance of a product but don't pose safety risks. A limited number of major defects might be acceptable depending on the sampling plan.
- **Minor defects** – Don't affect a product's function or safety but might impact appearance or user satisfaction. A higher tolerance is usually allowed for minor defects.

You define acceptance criteria in advance, often using standards like ANSI/ASQ Z1.4 or ISO 2859-1. These standards specify permissible defects count per category before rejecting a lot. This structured, statistically supported approach ensures consistent product quality while optimizing inspection resources.

Single and double sampling plans

Single and double sampling plans use two different strategies to decide if a lot meets quality standards.

- **Single sampling plan** – You inspect one sample from the lot. Based on the number of defects found, you either accept or reject the lot. Use this method when simplicity and speed are important.
- **Double sampling plan** – If the first sample gives an inconclusive result, you take a second sample. You base the final decision on the combined results of both samples. This strategy can reduce inspection effort over time while maintaining decision accuracy.

The current version of Supply Chain Management supports only the single sampling strategy, where each lot is evaluated by using one sample and a fixed acceptance threshold.

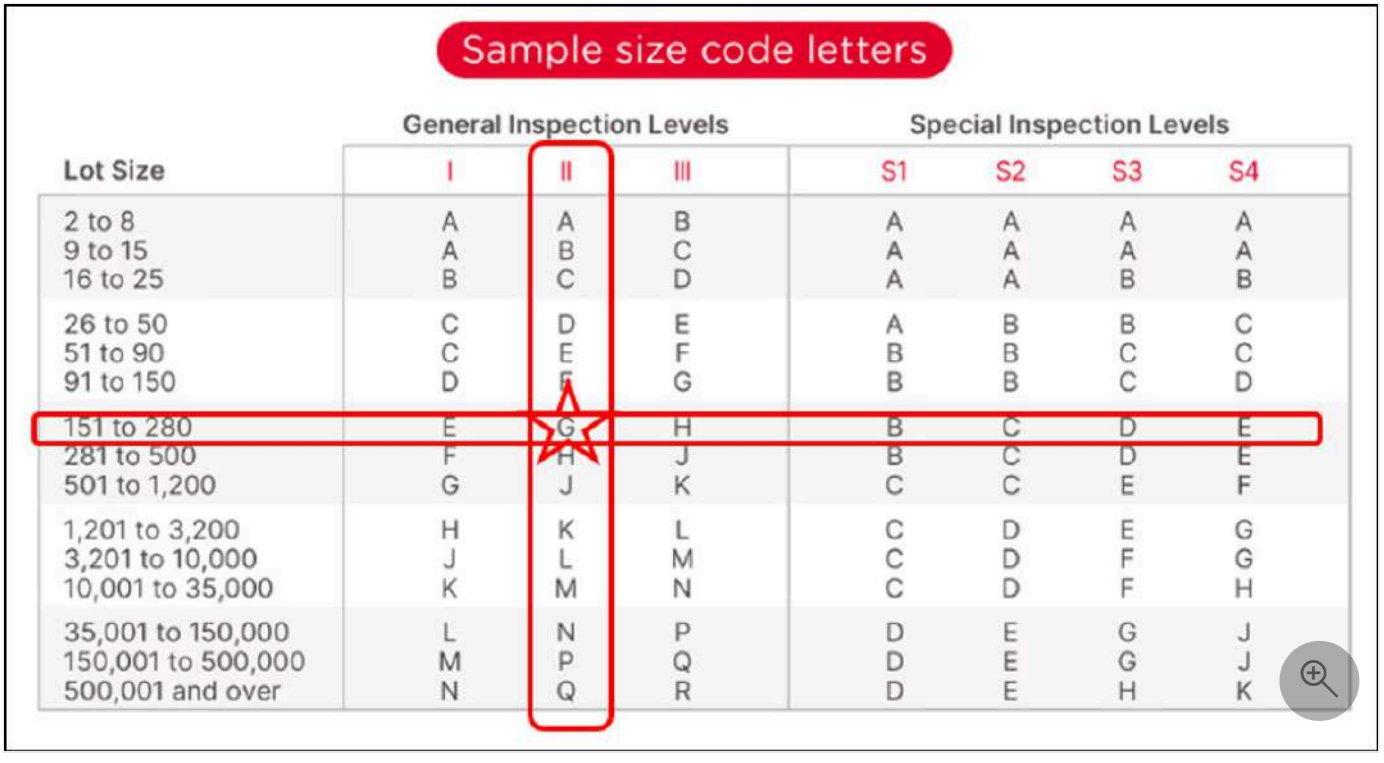
Acceptance sampling charts

Acceptance sampling uses a chart with the following two components to validate whether a lot passes or fails an inspection:

- **Sampling code letter chart** – Defines code letters for each combination of lot size and inspection level.
- **Acceptable quality limit (AQL) chart** – Uses the code letter and AQL index to determine sample size and defect thresholds.

An *inspection level* is a code or category defined by a business user. It indicates the extent of inspection based on the importance of the product, the production history, and customer requirements. There are two categories of inspection levels: - *General inspection level* – Used for routine, thorough inspections - *Special inspection level* – Apply to less critical checks with smaller sample sizes.

The following image shows an example of a code letter chart. In this example, if you have a lot size between 151 and 280 and use a general inspection level II, then use code letter G as input in the acceptable quality limit chart.



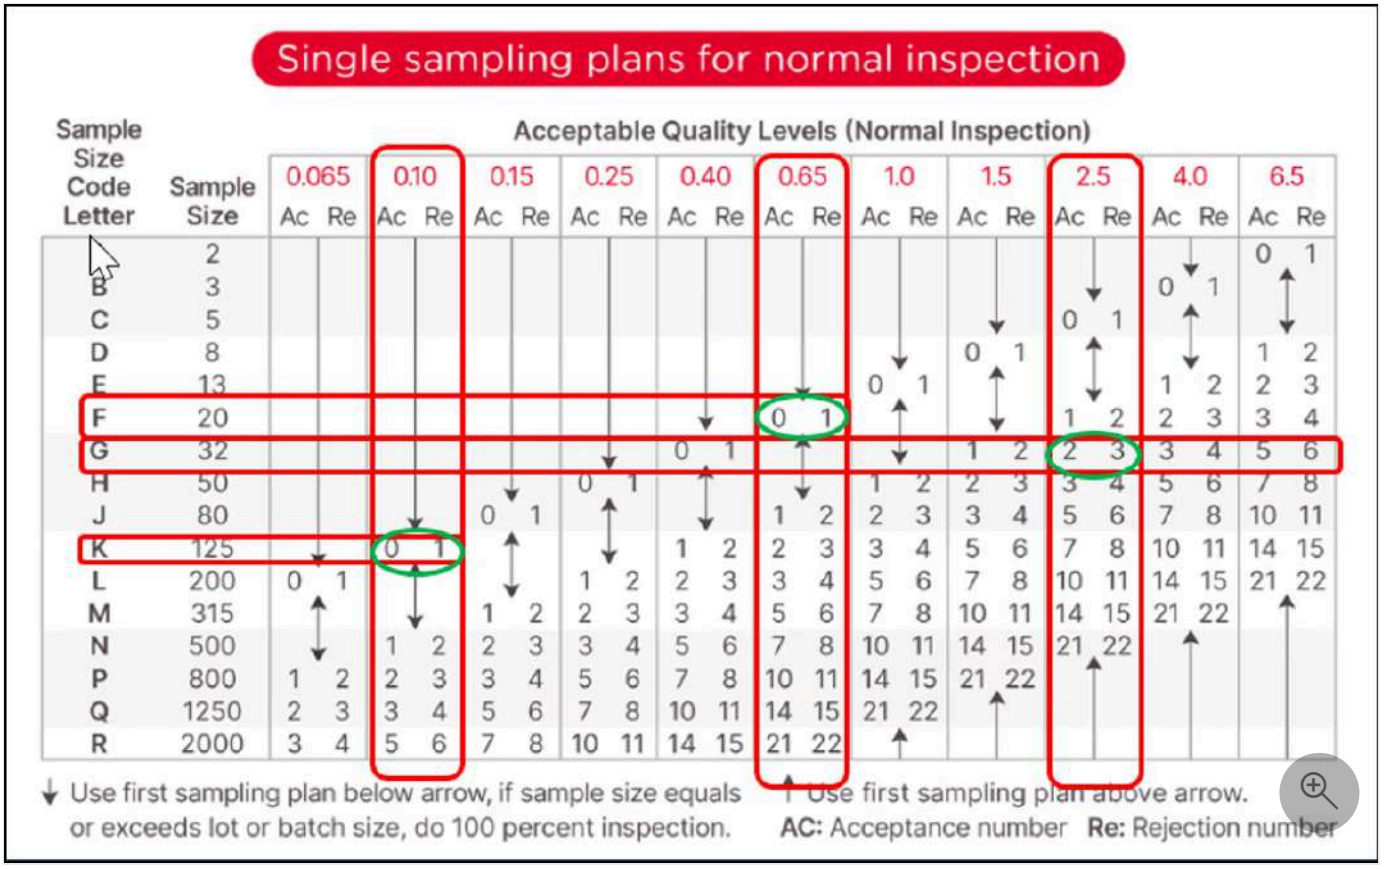
Sample size code letters

	General Inspection Levels			Special Inspection Levels			
Lot Size	I	II	III	S1	S2	S3	S4
2 to 8	A	A	B	A	A	A	A
9 to 15	A	B	C	A	A	A	A
16 to 25	B	C	D	A	A	B	B
26 to 50	C	D	E	A	B	B	C
51 to 90	C	E	F	B	B	C	C
91 to 150	D	F	G	B	B	C	D
151 to 280	E	G	H	B	C	D	E
281 to 500	F	H	J	B	C	D	E
501 to 1,200	G	J	K	C	C	E	F
1,201 to 3,200	H	K	L	C	D	E	G
3,201 to 10,000	J	L	M	C	D	F	G
10,001 to 35,000	K	M	N	C	D	F	H
35,001 to 150,000	L	N	P	D	E	G	J
150,001 to 500,000	M	P	Q	D	E	G	J
500,001 and over	N	Q	R	D	E	H	K

The AQL chart defines the acceptable quality level for each combination of sampling code letter and AQL index. Business users determine the AQL indexes based on how critical the product is,

industry standards, customer requirements, and the acceptable level of risk. Lower indexes are used for high-risk or critical items, while higher AQLs are acceptable for less critical products where some defects are tolerable. For example, businesses can use index 0.1% for testing for critical defects, 0.65% for major defects, and 2.5% for minor defects. The selected code letter and AQL index resolve to find the sample size and acceptable quality level for the test.

The following image shows an example of an acceptable quality limit chart. In this example, if you use code letter G with an AQL index of 2.5%, then the sample size should be 32 units and up to two defects are accepted for the lot to pass, but three or more defects cause the lot to fail inspection. If you use code letter G for AQL index 0.65%, then the arrow in the chart indicates that an AQL level for a different code letter should be used. In this case, the code letter with the nearest AQL values is F, which has a different sample size than code letter G (so 20 units should be tested instead of 32), and zero defects are accepted for the lot to pass.



In Supply Chain Management, you can load all the data for generating the sampling code letter chart and the acceptable quality limit chart from a template. The template generates inspection levels, AQL indexes, and lot size ranges. After you load these values from the template, you can customize the charts as needed.

You can learn more about how to use the charts in the following video:

https://learn-video.azurefd.net/vod/player?id=bb27c2c0-ffda-4768-9d06-2ca67c05d508&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Finventory%2Fquality-acceptance-sampling

Quality orders, item sampling methods, and quality associations

Supply Chain Management uses *quality orders* to schedule and manage testing based on acceptance sampling. To enable this functionality, you must define an appropriate item sampling method that supports acceptance sampling.

Item sampling methods define how much of a product you should inspect during a quality order. They specify the sample quantity or percentage to test from a lot, and are essential for enabling acceptance sampling in quality control processes. Learn more in Quality management item sampling.

Item sampling methods take effect when you assign them to *quality associations*. Supply Chain Management uses quality associations to establish and apply rules that automatically trigger a quality order based on specific events, such as product receipt, production output, or inventory movement. Each quality association links a product, process, or condition to a quality inspection requirement, ensuring consistent and automated quality control. Learn more in Quality associations.

When a quality order is triggered based on an event defined in a quality association, the system automatically creates a quality order that you can use for acceptance sampling. The quality association links the triggering event (such as a product receipt or production output) to a specific test process. If the associated item sampling record is configured for acceptance sampling, the generated quality order uses the defined sampling criteria to determine how much of the lot you should inspect.

On the quality order for acceptance sampling, the various categories of tests (critical, major, and minor), their sample sizes, and acceptable quality levels are clearly indicated. If a test falls outside a quality level, the entire quality order fails during validation.

Prerequisites

To use the features described in this article, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.45 or later.

- The feature named *Acceptance sampling* must be turned on in feature management. As of Supply Chain Management version 10.0.49, this feature is turned on by default.

Set up acceptance sampling charts

To set up your acceptance sampling charts, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Acceptance sampling** > **Acceptance sampling chart**.

2. Use the buttons on the Action Pane to add a new chart or edit an existing one.

3. On the header of the new or selected chart, set the following fields:

    - **Acceptance sampling chart name** – Enter a name for the sampling chart.
    - **Description** – Enter a short description of the sampling chart.

4. On the Action Pane, select **Save**.

5. To get started quickly, you can either copy an existing chart or load a predefined template. If you choose to do so, select one of the following options in the Action Pane. Note that all the settings for the current chart (except name and description) are replaced with the template or copied chart.

    - **Load AQL chart template** – Load all required data from a predefined JSON file. The content of the file aligns with the ANSI/ASQ Z1.4 or ISO 2859-1 standards.
    - **Copy** – Copy data from another chart. The system asks you to choose an existing chart.

6. On the **Inspection levels to include** FastTab, use the buttons in the toolbar to add and remove inspection levels for the current chart. The inspection levels are used as a criteria to find the applicable code letter in the code letter chart. Learn more about inspection levels in Acceptance sampling charts.

7. On the **AQL indexes to include** FastTab, use the buttons in the toolbar to add and remove AQL indexes. The AQL index defines the maximum acceptable defect rate in a sample that determines whether a lot passes or fails inspection. You can learn about AQL indexes in Acceptance sampling charts.

8. On the **Lot/batch size ranges** FastTab, use the buttons in the toolbar to add and remove lot size ranges for the current chart. Use the **Unlimited** button in the toolbar to set a range to have no upper limit (this sets the **To** field to *Unlimited* for the selected row). The lot size

ranges group total units in a lot and help find the applicable code letter. Learn more about lot size ranges in Acceptance sampling charts.

9. When you're done setting up the chart, select **Validate** in the Action Pane to check data integrity. If the chart is valid, it sets the **Validated** field to *Yes*. Only validated charts can be used for acceptance sampling.

   > **Tip**
   >
   > Validated charts are locked and can't be edited. If you need to edit a validated chart, select **Invalidate** from the Action Pane, make the required changes, and then validate the chart again.

Set up inspection levels and acceptance sampling indexes

If you don't use the option to load your charts from a template, you must create the inspection levels and sampling indexes manually.

Set up inspection levels

Follow these steps to create inspection levels manually:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Acceptance sampling** > **Inspection levels**.

2. Select **New** to create a new inspection level and set the following fields:

   - **Inspection level** – The identification of the inspection level.
   - **Inspection level type** – Choose between the two types *General* or *Special*, which are used as a criteria to find the code letter in the code letter chart. Learn more about level designations in Acceptance sampling charts.
   - **Description** – User defined description of the inspection level.

3. On the Action Pane, select **Save**.

Set up acceptance sampling indexes

Business users determine AQL indexes based on how critical the product is, industry standards, customer requirements, and the acceptable level of risk. If you don't want to use the option to

generate the AQL indexes by loading the AQL chart template, then you can use the following steps to create them manually:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Acceptance sampling** > **Acceptance sampling indexes**.
2. Select **New** to create a new inspection level and set the following fields:
    - **Acceptable quality limit index** – The identification of the acceptance sampling index. The AQL index defines the maximum acceptable defect rate in a sample that determines whether a lot passes or fails inspection.
    - **Description** – User defined description of the acceptance sampling index.
3. On the Action Pane, select **Save**.

View the sampling size code letter chart

After you create and validate an acceptance sampling chart, you can view the sampling size code letter chart:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Acceptance sampling** > **Acceptance sampling chart**.
2. Select the chart you want to view.
3. On the Action Pane, select **Sampling size code letter chart**. You can open the corresponding acceptable quality limit chart by selecting **Acceptable quality limit chart**.

View or edit the acceptable quality limit chart

To view or edit the acceptable quality limit chart, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Acceptance sampling** > **Acceptance sampling chart**.
2. Select the chart you want to edit.
3. On the Action Pane, select *Acceptable quality limit chart* to open the chart.
4. Use the following options to make edits:
    - **Up** – Adds an upward arrow in the selected cell, indicating the direction to find the AQL level and sample size. Learn more in Acceptance sampling charts.
    - **Down** – Adds a downward arrow in the selected cell, indicating the direction to find the AQL level and sample size. Learn more in Acceptance sampling charts.

- **Accept** – Sets the acceptance level in the selected cell, defining the maximum number of defects allowed for a given sample size and AQL index. Learn more in Acceptance sampling charts.

Set up defect types

Defect types identify the types of defects that users test for, such as *paint chipped*, *screen cracked*, *packaging damaged*, and so on. Each defect type is categorized as *Critical*, *Major*, or *Minor*.

To set up defect types, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Acceptance sampling** > **Defect types**.
2. Select **New** and set the following fields:

    - **Defect type** – Identify the type of defect to test for.
    - **Description** – Enter a detailed description of the defect type.
    - **Defect category** – Categorize the defect type with one of the three following fixed categories:
        - *Critical* – Could cause harm or render a product unsafe or unusable. Even a single critical defect might lead to rejection of the entire lot.
        - *Major* – Significantly reduces the usability or performance of a product but don't pose safety risks. A limited number of major defects might be acceptable depending on the sampling plan.
        - *Minor* – Doesn't affect function or safety but might impact appearance or user satisfaction. A higher tolerance is usually allowed for minor defects

Set up a test for acceptance sampling

You must define each of the tests that you want to use on quality orders, and each test must be associated with one of the defect types that you set up in the previous section. Learn more about tests for quality orders in Quality management tests.

Set up a test group for acceptance sampling

Each of the tests that you use for acceptance sampling must be associated with a *test group*. A test group is a collection of tests needed on a quality order. Each quality association has an assigned test group, which it uses to automatically generate quality orders. Learn more about test groups in Quality management test groups

Set up item sampling for acceptance testing

Use *item sampling* records to define how much of a product to inspect during a quality order. Each record specifies the sample quantity or percentage to test from a lot. These records are essential for enabling acceptance sampling in quality control processes. Learn more about item sampling in Quality orders, item sampling methods, and quality associations and Quality management item sampling.

To set up item sampling for acceptance sampling, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Item sampling**.

2. Select **New** to create a new item sampling and set the following fields:

    - **Item sampling** – Enter a name for the item sampling record.
    - **Description** – Enter a short description of the item sampling record.
    - **Sampling scope** – Select the scope to use when evaluating if quality work should be created. When set to *Shipment* or *Load*, those entities are used if available. If not, the *Order* is used. When you use acceptance sampling charts, the only supported sampling scope is *Order*.
    - **Use acceptance sampling charts** – Choose one of the following options:
        - *Single* – Use acceptance sampling. This value indicates that you'll use a single sampling plan. Learn more in Single and double sampling plans.
        - *None* – Don't use acceptance sampling for quality inspection.

3. On the **Acceptance sampling** FastTab, set the following required fields:

    - **Acceptance sampling chart name** – Select the sampling chart you want to use for this item sampling.
    - **Description** – Displays the name of the selected acceptance sampling chart.
    - **Inspection level** – Select the inspection level you want to use for this item sampling. Learn more about the use of inspection levels in Acceptance sampling charts.
    - **Description** – Displays the description of the selected AQL index.
    - **Minor AQL%** – Enter the AQL index for minor defects for the item sampling. Learn more about how to use AQL indexes in Acceptance sampling charts.
    - **Description** – Displays the description of the selected AQL index.
    - **Major AQL%** – Enter the AQL index for major defects for the item sampling. Learn more about AQL indexes in Acceptance sampling charts.
    - **Description** – Displays the description of the selected AQL index.

- **Critical AQL%** – Enter the AQL index for critical defects for the item sampling. Learn more about AQL indexes in Acceptance sampling charts.
- **Description** – Displays the description of the selected AQL index.

Set up a quality association for acceptance sampling

Supply Chain Management uses quality associations to define and apply rules that automatically trigger a quality order based on specific events, such as product receipt, production output, or inventory movement. Each quality association links a product, process, or condition to a quality inspection requirement, ensuring consistent and automated quality control. Learn more in Quality associations.

When an event defined in a quality association triggers a quality order, the system automatically creates a quality order that you can use for acceptance sampling. The quality association links the triggering event (such as a product receipt or production output) to a specific test process. If the associated item sampling is configured for acceptance sampling, the generated quality order uses the defined sampling criteria to determine how much of the lot you should inspect.

To set up a quality association for acceptance sampling, follow the instructions in Quality associations. When you set up your quality associations on the **Quality associations** page, pay special attention to the following settings, which are specific to acceptance sampling:

- Use the **Item sampling** field on the **Specifications** FastTab to select an item sampling record. Choose an item sampling record that's configured to use acceptance sampling charts. This setting is required to enable acceptance sampling for the quality association.
- Use the **Test group** field on the **Specifications** FastTab to select a test group that contains the tests you want to use for acceptance sampling. The test group must contain tests that are associated with defect types that you set up in Set up defect types. The test group can include at most one of each defect type.

Using acceptance sampling on quality orders

Quality orders created for acceptance sampling include an **Acceptance sampling** tab on the **Quality orders** page. This tab contains a grid with line items for each test that you need to conduct. The grid provides the following information:

- **Defect category** – Indicates one of the three fixed categories of the test: *Critical*, *Major*, or *Minor*.

- **Defect type** – Indicates the type of the test defined in the configuration. Learn more in Set up defect types.
- **Acceptable quality level index** – Indicates the AQL index for the specific test as specified in the configuration of the item sampling for the quality order.
- **Sample size** – The number of items to test.
- **Target Ac** – Maximum number of defects accepted for the test to pass.
- **Target Re** – Minimum number of defects for the test to fail.
- **Test result** – Graphical indication of whether the test passed or failed.

To record test results for a selected quality order, either enter them directly into the test lines or select **Quick results entry** from the Action Pane to use the quick-entry form.

Quality orders

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to manually or automatically create quality orders, and how to work with them to perform inspections and record test results in Microsoft Dynamics 365 Supply Chain Management.

Automatically created quality orders

Configure the system to automatically create quality orders based on item sampling rules. Learn more in Quality management item sampling.

Manually create quality orders

To manually create a quality order, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Quality orders**.
2. Select **New**.
3. In the **Quality orders** dialog box, in the **Reference type** field, select the inventory reference that your quality order is related to. For a description of the reference types that are available for selection, see the Quality order reference types section later in this article.

   > **Note**
   >
   > Inventory that is related to the selected reference must be available. If no inventory is available for the combination of the reference type, quantity, and inventory dimensions that you select, you'll receive an error message.

4. Follow one of these steps, depending on the value that you selected in the **Reference type** field:

    - If you selected **Inventory**, no additional reference information is required.
    - If you selected **Sales** or **Purchase**, specify the following information:
        - **Account selection** – Reference the customer or vendor number.
        - **Reference number** – Reference the sales order or purchase order number.
        - **Reference lot** – Reference the specific sales order line or purchase order line.
    - If you selected **Production**, **Quarantine**, or **Co-product production**, in the **Reference number** field, reference the production order, batch order, or quarantine order number.
    - If you selected **Route operation**, specify the following information:
        - **Reference number** – Reference the production order or batch order number.
        - **Oper. no.** – Reference the specific route operation number.
        - **Operation** – Reference the specific route operation.
        - **Resource** – Reference the specific resource that must be used with the route operation.

5. In the **Test group** field, select the group of tests that must be performed.
6. In the **Quantity** field, enter the quantity of items that must be tested.
7. In the **Inventory dimensions** section, enter any additional inventory dimensions that are required for the selected item.
8. Select **OK**.

After a quality order is created, you can begin to inspect the inventory and record the test results. For more information about how to record and validate test results, see Inspect the quality of goods.

Quality order reference types

Quality orders are used to track the details about inspections and test results for specific inventory in your warehouse. A quality order must include a reference that represents the source of the inventory that is being tested. Quality orders can be related to the following reference types:

- **Inventory** – This reference type indicates that you're inspecting inventory that is on hand. Inspections of this type are typically random or unplanned, and are done when a warehouse worker identifies a problem.
- **Sales** – This reference type indicates that you're inspecting inventory that is related to a specific sales order. Inspections of this type are typically related to customer specifications or the generation of a certificate of analysis (CoA) that must be provided to a customer as part of a shipment. (A CoA is sometimes also referred to as a certificate of compliance [CoC].)
- **Purchase** – This reference type indicates that you're inspecting inventory that is related to a purchase order. Inspections of this type are often used to inspect incoming goods before they're put into inventory or consumed in production processes.
- **Production** – This reference type indicates that you're inspecting inventory that is related to a production order. Inspections of this type are often used to inspect finished goods before they're put into inventory.
- **Quarantine** – This reference type indicates that you're inspecting inventory that is related to a quarantine order. Quarantine orders are a special type of order that tracks inventory in a segregated warehouse or a segregated area in your warehouse. Inspections of this type are often used to inspect goods that a customer has returned or that have been put into quarantine for further analysis. Quarantine orders can be generated from quality orders. Alternatively, they can be generated from other sources, and then quality orders can be related to the quarantine orders.
- **Route operation** – This reference type indicates that you're inspecting inventory that is related to a specific step of the route for a production order. Inspections of this type are typically used to analyze the work in process (WIP) of a product before it moves to the next step in the production process.
- **Co-product production** – This reference type indicates that you're inspecting inventory that is related to a co-product of a production order. Inspections of this type are typically used to inspect the co-product of a batch order before the co-product is added to inventory.
- **Goods in transit order** – This reference type indicates that you're inspecting inventory that is related to a goods-in-transit order from Landed Cost. Inspections of this type are often used to inspect incoming goods before they're put into inventory.

View and create quality orders from various parts of the system

Quality orders can be created manually. Alternatively, they can be automatically created based on the quality associations that you define. For more information about how to create and manage

the automatic creation of quality orders, see Quality associations.

Use the quality order page to manually create a new quality order or view the status of a quality order related to another record. There are several ways to access the quality order page.

From the Quality orders page

To manually create quality orders and view all existing quality orders, go to **Inventory management** > **Periodic tasks** > **Quality management** > **Quality orders**. The remaining sections of this article provide more information about how to work with the **Quality orders** page.

From sales orders

To work with quality orders that are related to your sales orders, go to **Sales and marketing** > **Sales orders** > **All sales orders**, and then follow any of these steps:

- Open a sales order, or select it in the grid. Then, on the Action Pane, on the **Pick and pack** tab, in the **Quality management** group, select **Quality orders** to open the **Quality orders** page. There, you can view, create, or update quality orders that are related to the sales order.
- Open a sales order, and then, on the **Header** tab, select the **General** FastTab. The **Quality order status** field shows the overall status of all quality orders that are related to the sales order.
- Open a sales order, and then, on the **Lines** tab, select the **Sales order lines** FastTab. The **Quality order status** column shows the status of each line of the sales order.

From purchase orders

To work with quality orders that are related to your purchase orders, go to **Procurement and sources** > **Purchase orders** > **All purchase orders**, and then follow any of these steps:

- Open a purchase order, or select it in the grid. Then, on the Action Pane, on the **Receive** tab, in the **Quality management** group, select **Quality orders** to open the **Quality orders** page. There, you can view, create, or update quality orders that are related to the purchase order.
- Open a purchase order, and then, on the **Header** tab, select the **General** FastTab. The **Quality order status** field shows the overall status of all quality orders that are related to the purchase order.
- Open a purchase order, and then, on the **Lines** tab, select the **Purchase order lines** FastTab. The **Quality order status** column shows the status of each line of the purchase order.

From production orders

To work with quality orders that are related to your production orders, go to **Production control** > **Production orders** > **All production orders**, and then follow any of these steps:

- Open a production order, or select it in the grid. Then, on the Action Pane, on the **View** tab, in the **Manage quality** group, select **Quality orders** to open the **Quality orders** page. There, you can view, create, or update quality orders that are related to the production order.
- Open a production order, or select it in the grid. Then, on the Action Pane, on the **Production order** tab, in the **Production details** group, select **Route** to open the **Production route** page. To view the quality orders that are related to a route operation, follow one of these steps:
  - Select the target route operation in the grid. Then, on the Action Pane, select **Inquiries** > **Quality orders**.
  - Select the value in the **Oper. No.** field for the target route operation to open its **Production route** details page. On the **General** FastTab, the **Quality order status** field shows the status for the quality orders that are related to the route operation.
- Open a production order, and select the **General** FastTab. The **Quality order status** field shows the status of the quality orders that are related to the production order.

From quarantine orders

To work with quality orders that are related to your quarantine orders, go to **Inventory management** > **Periodic tasks** > **Quality management** > **Quarantine orders**, and then follow any of these steps:

- Review the values in the **Quality order status** column. This way, you learn the overall status of all quality orders that are related to each quarantine order in the grid.
- Select a quarantine order in the grid, and then, on the Action Pane, select **Quality orders** to view, create, or update quality orders that are related to the quarantine order.

From goods-in-transit orders

If you use the **Landed cost** module, you can set up the system to automatically create quality orders when goods-in-transit orders are received. The quality control process can then be initiated for the goods-in-transit orders. This process ensures that products undergo stringent quality checks throughout transit and that high-quality goods are received at the warehouse. During quality control, inventory from goods-in-transit orders can be blocked to prevent

shipment of defective products. This function aligns with regulatory compliance and helps mitigate legal risks.

To automatically create quality orders based on goods-in-transit orders, enable the *Enable Quality Control for Goods In-Transit Order* feature. For more information, see Turn on the Landed cost module and related features for your system. In addition, configure quality associations.

To create quality orders for the received quantity only, set the **Per updated quantity** option to *Yes* on the **Item sampling** page (**Inventory management** > **Setup** > **Quality control** > **Item sampling**).

Users can view, manually create, or update quality orders directly from the **Goods-in-transit order** page. To work with quality orders that are related to your goods-in-transit orders, follow one of these steps:

- Go to **Landed cost** > **Periodic tasks** > **Goods in transit orders** and select a goods-in-transit order. Then, on the Action Pane, select **Quality orders** to open the **Quality orders** page. There, you can view, create, or update quality orders that are related to the goods-in-transit order.
- Go to **Landed cost** > **Voyages** > **All voyages** and open or select a voyage or select a voyage. On the Action pane, on the **General** tab, in the **Inquiries** group, select **Goods in transit orders** to open the **Goods in transit orders** page. Select a goods-in-transit order. Then, on the Action Pane, select **Quality orders** to open the **Quality orders** page, where you can view, create, or update quality orders that are related to the selected goods-in-transit order.

Advanced actions for quality orders

You can take several actions on quality orders to manage the status, generate documents, and inquire about additional details.

Reopen a quality order

By default, you can no longer edit or update a quality order after it has been validated and the tests have been passed. However, in some cases, you might have to reopen a quality order after it has been completed.

To reopen a quality order, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Quality orders**.

2. Open the validated quality order, or select it in the grid.
3. On the Action Pane, select **Reopen quality order**.

Create a certificate of analysis for a quality order

A certificate of analysis (CoA) is a report that an organization's quality assurance team generates. It validates that a product meets specific regulations or requirements. Your customers or regulatory establishments in your geopolitical location might require CoA reports. They might also be required based on your industry and the type of products that you handle, purchase, produce, or sell.

Supply Chain Management lets you generate a CoA from a quality order. The report includes the results of any tests on the quality order where the **Certificate of analysis report** option is set to *Yes*. You can set this option by default based on the test that you define on the **Tests** page. However, you can override the setting on specific tests for a specific quality order.

To generate a CoA for a quality order, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Quality orders**.
2. Select the quality order that you want to create a CoA for.
3. On the Action Pane, select **Inquiries** > **Certificate of analysis**.
4. On the **Certificate of analysis** page, on the Action Pane, select **New**.
5. Optional: In the **Contact** field, select the contact person that the certificate should be addressed to.
6. On the Action Pane, select **Print**.
7. In the **Certificate of analysis** dialog box, define how the report should be printed. Then select **OK** to print the report to a printer, to the screen, to a file, or to email.
8. Close the pages.

Block or unblock inventory for a quality order

When a quality order is automatically generated from a quality association, the item sampling assigned to the quality association can block the full inventory quantity of the reference that is being tested. For more information about item samplings, see Quality management item sampling.

If you aren't using full blocking, or if you're manually creating a quality order, the system automatically creates an inventory blocking record for the quantity of the item that is being tested on the quality order. In the record that is created on the **Inventory blocking** page, the **Inventory blocking type** field is set to *Quality order*.

To view and edit the inventory blocking for a quality order that is selected on the **Inventory blocking** page, select **Inquiries** > **Inventory blocking** on the Action Pane. Learn more in Inventory blocking.

Inquire about the details of a quality order

Use the following buttons on the Action Pane of the **Quality orders** page to view more information about or related to a quality order:

- **Inquiries** > **Work details** – Open a page where you can view warehouse work that is related to the quality order.
- **Inquiries** > **Non conformances** – Open a page where you can view any nonconformances that are related to the quality order.
- **Inventory** – The commands on this menu are common across all inventory transactions. Use them to view or update details such as transactions, on-hand inventory, reservations, and marking.

Create cases related to quality orders

You can create cases that are related to quality orders. This way, you can track details about issues and work toward a resolution. You can use the workflow features of case management to route a case through a predefined business process to obtain additional approvals or get more information about a specific issue. You can also use the knowledge articles feature to create a knowledge base of resolutions for common issues.

Case management examples for quality management

Example 1

You work for a manufacturing company that must follow strict regulations that are related to the production of regulated products such as food. Quality orders are used to record and track details about the quality of items throughout the production process. If a quality order fails specific tests, there might be a problem with the equipment. Cases are used to follow a business process and escalate the issue to the correct engineers so that they can determine the root cause. To make business processes easier to follow, the company keeps a knowledge base of common issues that are related to quality orders and equipment issues.

Example 2

You work for a distribution company that ships products that can be customized for various countries/regions. Some customers have strict specifications that you must follow. Otherwise, you might incur fees, returns, or chargebacks. You use quality orders to track the details about each test and results that match customer requirements. Cases are used to review and approve the details for the CoA before the document is generated and attached with other shipping paperwork.

Customer-specific certificate of analysis (COA)

Microsoft Dynamics 365 Supply Chain Management lets you create a basic certificate of analysis (COA) either from the quality order or from the menu directly after you select a quality order. Learn more about how to use the basic COA in Quality orders. This article explains how to customize the content of a COA to meet specific customer requirements and automatically print the COA when a sales order packing slip is generated.

Prerequisites

Before you can use the features that are described in this article, your system must meet the following requirements:

- You must be running Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Set up a COA customer group

To manage COAs for different customers, you can group customers into COA customer groups. To create a COA customer group and add customers to it, follow these steps:

1. Go to **Inventory management** > **Setup** > **Certificate of analysis** > **Certificate of analysis customer groups**.

2. Use the buttons on the Action Pane to add a new COA customer group or edit an existing one. (You can also delete existing groups.)

3. For the new or selected COA customer group, set the following fields:

    - **COA customer group** – Enter the identifier of the COA customer group.
    - **Description** – Enter a description for the COA customer group.

Set up and maintain customer-specific COA requirements on test groups

To set up customer-specific COA requirements on test groups, follow these steps:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test groups**.
2. In the lower section of the page, select a test.
3. On the toolbar, select **Customer COA requirements** to open the **Customer COA requirements** page.
4. Use the buttons on the Action Pane to add a new customer COA requirement or edit an existing one. (You can also delete existing requirements.)

   If you add a new customer COA requirement, the **Test** and **Test group** fields are automatically set. If the test is associated with a batch attribute, the **Attribute** field is also set.
5. For the new or selected customer COA requirement, set the following fields in the grid:

   - **Customer code** – Select *All* to make the requirement applicable to all customers, *Group* to make it applicable to a group of customers, or *Table* to make it applicable to a specific customer.
   - **Customer relation** – If you selected *Group* in the **Customer code** field, select a COA customer group. If you selected *Table*, select a specific customer account. (If you selected *All*, this field is unavailable.)
   - **Exclude** – Select whether the test should appear on the customer-specific COA. The assumption is that the customer-specific COA includes all tests except tests are explicitly marked as excluded.
   - **Use customer specific ranges** – Specify whether the customer-specific batch attribute range should be used for the customer-specific COA. If no customer -specific batch attribute range if found, the standard range is printed.
   - **Suppress Min/Max values** – Specify whether the minimum and maximum values of the test should be suppressed on the customer-specific COA. For example, the minimum value for a test is *1*, the maximum value is *10*, and the result is *1*. In this case, you might not want the range to be shown at all for some customers, to avoid drawing attention to the fact that the result barely passed the quality test.
   - **Replace pass results** – Enter text that should replace the test results on the customer-specific COA if the test is passed. In this situation, some businesses prefer to show standard text, such as "Within specification," instead of the actual test results.
   - **Replace fail results** – Enter text that should replace the test results on the customer-specific COA if the test is failed. In this situation, some businesses prefer to show

standard text, such as "Outside acceptable range," instead of the actual test results.

Set up and maintain customer-specific COA requirements from a quality order

To set up and maintain customer-specific COA requirements from a quality order, follow these steps:

1. Go to **Inventory management** > **Periodic** > **Quality management** > **Quality orders**.
2. Select a quality order.
3. Select a line on the selected quality order.
4. On the Action Pane, select **Customer COA requirements**.
5. Follow steps 4 and 5 of the previous procedure to add, edit, or delete customer-specific COA requirements.

Include product-specific and customer-specific batch attributes on a COA

You can mark product-specific and customer-specific batch attributes for inclusion on a COA, even if they aren't included in testing through a quality order.

1. Go to **Product information management** > **Products** > **Released products**.
2. On the **All released products** list page, find and select or open the batch-enabled product that you want to set up.
3. On the Action Pane, on the **Manage inventory** tab, in the **Batch attributes** group, select either **Product specific** or **Customer specific**.
4. Select an existing attribute in the list pane, or create a new one.
5. To include the new or selected attribute on a COA, set the **Include in COA independent of quality order** option to *Yes*.
6. Repeat the previous steps for every other attribute that you want to include on the COA.

After the customer-specific COA requirements are set for a test group, they automatically apply to all quality orders that use that test group. However, they can be adjusted on individual quality orders as required.

Access customer-specific COAs

The following table describes the different ways to access customer-specific COAs.

Expand table

Access method	Navigation path	Details
Directly from the menu	Go to **Inventory management** > **Inquiries** > **Quality management** > **Certificate of analysis**.	You can print either the standard COA or a customer-specific COA. (You trigger printing of a customer-specific COA by selecting a specific customer account.) In both cases, you must select a quality order.
From a quality order	Go to **Inventory management** > **Periodic** > **Quality management** > **Quality order**, and then, on the Action Pane, select **Inquiries** > **Certificate of analysis**.	You can print either the standard COA or a customer-specific COA. (You trigger printing of a customer-specific COA by selecting a specific customer account.) Because access is from a quality order, that quality order is assumed in both cases.
From an inventory batch	Go to **Inventory management** > **Inquiries** > **Dimensions** > **Batches**, and then, on the Action Pane, select **Inquiries** > **Certificate of analysis**.	You can print either the standard COA or a customer-specific COA. (You trigger printing of a customer-specific COA by selecting a specific customer account.) Because access is from an inventory batch, the COA quality order that is specified on the **General** tab of the inventory batch is used to generate the COA in both cases. If the COA quality order must be updated, you can use the **Reset COA Quality order** button on the Action Pane to change the quality order that drives the details of the COA.
As part of processing the sales order packing slip	Go to **Sales and marketing** > **Common** > **Sales orders** > **All sales orders**, and then, on the Action Pane, on the **Pick and pack** tab, select **Generate** > **Packing slip**. Alternatively, go to **Sales and marketing** > **Periodic** > **Sales update** > **Packing slip**.	Only customer-specific COAs are printed from this process. Depending on the customer who placed the order, a customer-specific COA is printed for every item/batch combination on the order that has a COA quality order specified for it in the batch. A COA is printed only for items that are batch controlled and items where the batch specifies a quality order.

> **Note**
>
> The setting of the option to print customer-specific COAs initially comes from the **Updates** tab of the **Accounts receivable parameters** page. By default, this setting is used for new customers. If you process the packing slip for a single order, the setting of the checkbox on the packing slip processing page comes from the customer. If you process packing slips for multiple orders, you must select the checkbox to print customer-specific COAs.

Inspect the quality of goods

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to process quality orders. Quality inspections are typically done by a quality clerk.

If the standard demo data is installed, you can use it to complete the procedures in this article. To use the demo data, select the *USMF* legal entity before you begin. You must then confirm purchase order *000016* and post a product receipt. A quality order is automatically generated.

Step 1: Select a quality order

To select a quality order, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Quality orders**.
2. Select the quality order that was generated before you started this procedure.

Step 2: Record test results

To record test results, follow these steps:

1. Select **Results**.
2. Select **Edit**.
3. In the **Result quantity** field, enter a number.
4. In the **Outcome** field, select the desired record. In this example, the result is based on a predefined outcome. Usually, you will record a more specific test result, such as a size or other dimension.
5. Select **Save**.
6. Close the page.

Step 3: Validate the quality order

To validate the quality order, follow these steps:

1. Select **Validate**.
2. In the **Validated by** field, select the user who is doing the inspection.
3. Select **Select**.
4. Select **OK**.
5. Close the page.

Enter quality test results quickly

The **Quick results entry** page makes the process of entering quality order test results faster and more flexible than the **Quality order line results** page. The **Quick results entry** page consolidates data from all tests into a single view to streamline the result entry process. Quantities are automatically populated based on the quality order quantities. Other details are also populated, such as minimum, maximum, and target values.

Prerequisites

Before you can use the features that are described in this article, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Enter quality test results

To enter quality test results by using the **Quick results entry** page, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Quality orders**.
2. Select a quality order, and then, on the Action Pane, select **Quick results entry**.
3. The **Quick results entry** page shows the tests that are associated with the selected quality order. Use the following buttons on the Action Pane to prepare the page for result entry:
    - **New** and **Delete** – Use these buttons to separate the test results that were entered for different quantities. For example, if the quality order quantity is *5*, you can use the **New** button to enter a total of five lines for the test. In this way, a different test result can be entered for each quantity. The sum of the quantities for each test must equal the total quantity of the quality order.
    - **Split** – Split an existing line into multiple lines. This button opens a dialog where you can set the following fields:

- **Split quantity** – Split the selected line into two lines, one of which has the quantity that you enter here, and the other of which has the remaining quantity. For example, the quantity on the selected line is *8*, and you enter *3* in this field. In this case, the quantity on one of the resulting lines is *3*, and the quantity on the other line is *5*.

- **Result quantity per line** – Split the selected line into multiple lines, each of which has the specified test quantity. For example, the quantity on the selected is *8*, and you enter *2* in this field. In this case, the line is split into four lines, each of which has a quantity of *2*.

  If the quantity can't be divided evenly, the last line has the remainder that is required to ensure that the total quantity equals the original quantity. For example, the quantity on the selected line is *8*, and you enter *3* in this field. In this case, the line is split into three lines. Each of the first two lines has a quantity of *3*, and the last line has a quantity of *2*, to produce a total quantity of *8*.

  If the item is a catch weight item, you must enter the catch weight quantity instead of the standard quantity.

- **Skip** – Skip the selected test so that it doesn't affect whether the quality order passes of fails.

- **Validate** – Validate the selected line, and evaluate whether it passes or fails. This action isn't required. Validation for all rows is automatically done when the page is closed.

- **Reset test result** – Eliminate the test result for the selected line.

4. Fill in test results for each line.

5. Select the **Back** button to return to the **Quality orders** page.

6. On the Action Pane, select **Validate** to finalize the quality order with the appropriate status, based on the line results (*Pass* or *Fail*).

Create and process nonconformances

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to perform nonconformance management based on an existing quality order. Typically, a quality clerk manages nonconformances. As a prerequisite, you must have a quality order available. For information about how to create a quality order, see Inspect the quality of goods.

Before a user can process the approval of a nonconformance, a worker must be assigned to them in the **Person** field on the **Users** page. Additionally, before the user can use the document notes, the **Enable document handling** option must be set to *Yes* in their user options.

Create a nonconformance

To create a nonconformance, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Non conformances**.
2. On the Action Pane, select **New**.
3. In the **Create non conformance** dialog, in the **Problem type** field, select the type of problem that you found during the inspection process.
4. Select **OK**.

Approve or reject a nonconformance

To approve or reject a nonconformance, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Non conformances**.

2. In the list, select the nonconformance that you want to update.

> ⓘ Note
>
> You can add a correction only to nonconformances that are approved.

3. On the Action Pane, select **Functions** > **Approve non conformance** to approve the nonconformance or **Functions** > **Refuse non conformance** to reject it. You can associate approved nonconformances with related operations. By using this association, you can record work that is done as part of the nonconformance handling and the processing of correction handling.

4. You're prompted to confirm your selection. Select **Yes** to continue.

Add operations and other details to nonconformances

After you approve a nonconformance, you can add related operations and specify additional information about them. You can only add related operations to nonconformances that are approved.

Besides the basic information, you can add the following details to an operation:

- **Items** – You can create a list of items that are consumed to perform the correction. For example, the items might be products that are required to repair equipment or ingredients that are required to rework a finished product.
- **Quality charges** – You can create a list of charges that are incurred or billed out to external sources.
- **Timesheet** – You can create a log of the time that each worker spends on the operation.

The remaining settings are optional. The cost for each item, quality charges, and the timesheet are summed and shown on the operation. You can't directly edit the **Cost** field on the operation.

Create an operation for a nonconformance

To create an operation for a nonconformance, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Non conformances**.

2. In the list, select the nonconformance that you want to update.

> ⓘ Note

> You can add or update operations only for nonconformances that are approved.

3. On the Action Pane, select **Related operations**.
4. On the **Related operations** page, add rows to the grid in one or both of the following ways:
    - To add a single row to the grid, select **New** on the Action Pane.
    - To add all the operations from a predefined operations group, select **Add operations from a group** on the Action Pane.
5. For each new row, set the following fields:
    - **Operation** – Select the code of the operation that will be performed for the nonconformance.
    - **Reason** – Enter a detailed description that explains why the operation is required.
    - **Sales order** – If the selected operation code is related to the sales order type, select the sales order that you're linking the operation to.
    - **Purchase order** – If the selected operation code is related to the purchase order type, select the purchase order that you're linking the operation to.
6. Close the pages.

Add items to an operation

To add items to an operation, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Non conformances**.
2. In the list, select the nonconformance that you want to update.

> ⓘ **Note**
>
> You can add or update operations only for nonconformances that are approved.

3. On the Action Pane, select **Related operations**.
4. On the **Related operations** page, select the operation that you want to add items to.
5. On the Action Pane, select **Items**.

6. On the **Related operations** page, on the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:

    - **Item number** – Select the product that the operation consumes.
    - **Quantity** – Enter the number of items that the operation consumes.

    > ⓘ Note
    >
    > You can view the cost for the item in the **Cost** field on the **General** tab. The cost that is shown comes from the cost that you set up on the **Released product** page. You can't update the cost directly on the **Related operation item** page. The cost of all items that you add on the **Related operation items** page automatically adds to the **Cost** field on the **Related operations** page.

7. Repeat the previous step for each additional item that you must add.

8. Close the pages.

Add quality charges to an operation

To add quality charges to an operation, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Non conformances**.

2. In the list, select the nonconformance that you want to update.

    > ⓘ Note
    >
    > You can add or update operations only for nonconformances that are approved.

3. On the Action Pane, select **Related operations**.

4. On the **Related operations** page, select the operation that you want to add quality charges to.

5. On the Action Pane, select **Quality charges**.

6. On the **Related operation charges** page, on the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:

- **Charges code** – Select the quality charge that you want to add.
- **Description** – Enter a detailed description of the charge.
- **Charges value** – Enter the amount of the charge.

7. Repeat the previous step for each additional charge that you must add.

8. Close the pages.

> ⓘ **Note**
>
> The system automatically sums the amount in the **Charges value** field for all quality charges and adds it to any other amounts in the **Cost** field on the **Related operations** page.

Create a timesheet on an operation

To add a timesheet to an operation, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Non conformances**.

2. In the list, select the nonconformance that you want to update.

   > ⓘ **Note**
   >
   > You can add or update operations only for nonconformances that are approved.

3. On the Action Pane, select **Related operations**.

4. On the **Related operations** page, select the operation that you want to add a timesheet to.

5. On the Action Pane, select **Timesheet**.

6. On the **Related operation time sheets** page, on the Action Pane, select **New** to add a row to the grid. Then set the following fields for the new row:

   - **Date** – Specify the date when work was done. By default, this field is set to the current date.
   - **Worker** – Select the worker who did the work. By default, this field is set to the worker that is assigned to the current user.
   - **Operation hours** – Enter the number of hours that were worked on the selected operation.

- **Invoiced** – Select this checkbox if the time has been charged to a customer or vendor on an invoice.

> ⓘ Note
>
> You can view the cost in the **Cost** field on the **General** tab. The system calculates the cost by using the rate that you define on the **Inventory management parameters** page.

7. Repeat the previous step for each additional timesheet line that you must add.
8. Close the pages.

> ⓘ Note
>
> The amount in the **Cost** field is summed for all timesheet lines and added to any other amounts in the **Cost** field on the **Related operations** page.

Add a correction to a nonconformance

To add a correction to a nonconformance, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Non conformances**.
2. In the list, select the nonconformance that you want to update.

   > ⓘ Note
   >
   > You can add a correction only to nonconformances that are approved.

3. On the Action Pane, select **Corrections**.
4. On the **Corrections** page, add rows to the grid in one or both of the following ways:

   - To add a single row to the grid, select **New** on the Action Pane.
   - To add a correction for each diagnostic from a predefined diagnostic group, select **Apply diagnostic group** on the Action Pane.

5. For each new row, set the following fields:

- **Diagnostic** – Select the diagnostic type that identifies the type of correction that you're creating.
- **Worker** – Select the person who is responsible for the correction.
- **Correction priority** – Select an option to indicate how the correction should be prioritized (*Low*, *Normal*, or *High*).
- **Requested date** – Enter the date when the corrective action was requested.
- **Planned date** – Enter the date when the correction is expected to be completed.
- **Short term solution** – Select this checkbox if the corrective action corrects the nonconformance only for a short time.
- **Root cause code** – Select the root cause code that identifies the root cause of the issue that required the correction.

6. Close the pages.

Mark a correction as completed

To mark a nonconformance correction as completed, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Non conformances**.

2. In the list, select the nonconformance that you want to update.

   > ⓘ **Note**
   >
   > You can add a correction only to nonconformances that are approved.

3. On the Action Pane, select **Corrections**.

4. On the **Corrections** page, in the grid, select the correction that you want to mark as completed.

5. On the Action Pane, select **Mark complete**.

6. You're prompted to confirm your selection. Select **OK** to continue. The **Completion date and time** field is set to the current date and time, and the **Completed** checkbox is selected.

7. Close the page.

Reopen a completed correction

To reopen a completed correction, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Non conformances**.
2. In the list, select the nonconformance that you want to update.
3. On the Action Pane, select **Corrections**.
4. On the **Corrections** page, in the grid, select the correction that you want to reopen.
5. On the Action Pane, select **Reopen**.
6. You're prompted to confirm your selection. Select **OK** to continue. The value is cleared from the **Completion date and time** field, and the **Completed** checkbox is cleared.
7. Close the page.

You can now make additional edits or updates to the correction. When you finish, you can mark the correction as completed again.

Close a nonconformance

To close a nonconformance, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Quality management** > **Quality orders**.
2. Select a quality order in the grid.
3. On the Action Pane, select **Inquiries** > **Non conformances**.
4. On the **Non conformances** page, select the target nonconformance in the grid.
5. On the Action Pane, select **Functions** > **Close non conformance**.
6. You're prompted to confirm your selection. Select **Yes** to continue.
7. Close the pages.

This article describes how to use quarantine orders to block inventory.

Quarantine orders block inventory. For example, you might want to quarantine items for quality control reasons. When you quarantine inventory, it gets transferred to a quarantine warehouse.

> **Note**
>
> If you're using warehouse management processes (WMS), quarantine order processing only applies to return sales orders.

Quarantine on-hand inventory items

When you quarantine items, you can either manually create the quarantine orders or set up the system to automatically create them during inbound processing.

To set up the system to automatically generate quarantine orders, follow these steps:

1. Go to **Inventory management** > **Setup** > **Inventory** > **Item model groups**.
2. Select a relevant model group in the list pane, or create a new model group.
3. On the **Inventory policies** FastTab, select the **Quarantine management** check box.
4. Close the page.
5. In the **Quarantine warehouse** field for the receiving warehouses, specify a default quarantine warehouse.

When an item that is registered as received at the warehouse belongs to a model group where the **Quarantine management** check box is selected, the system generates a quarantine order for it. The quarantine order instructs workers to move the item to the quarantine warehouse.

When you manually create quarantine orders on the **Quarantine orders** page, the item doesn't need to be set up for quarantine management in the associated item model group. For this process, you must specify the on-hand inventory that you want to quarantine and the quarantine warehouse that you want to use. You can use the quarantine order statuses to help plan the process.

Quarantine order statuses

Quarantine orders can have the following statuses:

- Created
- Started
- Reported as finished
- Ended

Created

When you manually create a quarantine order but don't yet place the item in the quarantine warehouse, the quarantine order has a status of *Created*. This status generates two inventory transactions. One transaction is an issue transaction that can have a status of *On order*, *Reserved physical*, or *Picked*. The other transaction is a receipt transaction that can have a status of *Ordered* or *Registered* at the quarantine warehouse. You can reserve, pick, and register updates to the inventory by using the usual processes.

Started

When a quarantine order has a status of *Started*, the inventory is transferred from the regular warehouse to the quarantine warehouse, and two inventory transactions are generated. One transaction has a status of *Deducted*, and the other transaction has a status of *Received*. At the same time, two inventory transactions are created to handle the return transfer. These transactions aren't dated. One transaction has a status of *Reserved physical*, and the other transaction has a status of *Ordered*.

Reported as finished

To report a started quarantine order as finished, open the order, and select **Report as finished** on the Action Pane. The item is released from quarantine, but it isn't yet moved back to the regular warehouse. You can process the movement back to the regular warehouse through an item arrival journal that you can initialize during the report as finished process.

Ended

When you end a quarantine order, move the item from the quarantine warehouse back to the regular warehouse. The status of the item transaction is set to *Sold* at the quarantine warehouse and *Purchased* at the regular warehouse.

Quarantine order scrap

As part of the quarantine order process, you can scrap inventory. When you process scrap, the status of the inventory is set to *Sold* by an issue transaction from the quarantine warehouse.

Inventory blocking

08/14/2025

This article describes how to work with inventory blocking, which is part of the quality inspection process in Supply Chain Management. You can use inventory blocking to prevent items from being processed or consumed.

You can block inventory items in the following ways:

- Manually
- By creating a quality order
- By using a process that generates a quality order
- By using inventory status blocking

Blocking items manually

You can block a quantity of an item by creating a transaction on the **Inventory blocking** page. Only items that are available as on-hand inventory can be blocked manually. For manually blocked quantities, you must decide whether planning activities include expected receipts as an expected on-hand quantity. Expected receipts are blocked items that you expect to be available as on-hand inventory after inspection is completed. You can maintain the expected date. By default, the **Expected receipts** option is selected for items that are blocked through a quality order. You can cancel a manual block on a quantity by deleting the transaction on the **Inventory blocking** page.

Blocking items by creating a quality order

You can specify items that must be inspected by creating a quality order on the **Quality orders** page. When you create a quality order, the quantity that you specify for an item is blocked. The sampling plan that is associated with a quality order controls only the quantity of items that must be inspected, not the quantity that is blocked. The quantity that is entered on the quality order is the quantity that is blocked, regardless of the quantity that the sampling plan specifies should be sent for inspection.

> **Note**
>
> Master planning doesn't support using both the batch expiry date and blocking inventory status features. This could result in double exclusion of on-hand inventory, which can occur during master planning. We recommend that you rely on batch disposition codes, instead of inventory status, for blocking expired batches.

Blocking items by using a process that generates a quality order

If a quality process specifies that an item must be inspected, a quantity of the item is blocked automatically. Therefore, when a quality order is generated automatically, the item sampling plan that is associated with the quality order controls both the quantity of items that is blocked and the quantity that must be inspected. If the **Full blocking** option on the **Item sampling** page is selected, the full quantity of, for example, a purchase order line is blocked during inspection, regardless of the item sampling quantity.

Example

In the following example, a quality order is generated when a purchase order packing slip is posted. On the **Quality associations** page, you specified that posting of a purchase order packing slip is the process that activates a quality order.

Expand table

Setup	User action	Result
A quality association specifies that a quality order must be generated when a purchase order packing slip is posted. The item sampling setup of the quality order specifies that 10 percent of the quantity on the purchase order line must be inspected. Furthermore, because the **Full blocking** option selected in the item sampling setup, the full quantity of the purchase order line must be blocked during inspection, regardless of the quantity that is sent for inspection.	The packing slip is posted.	A quality order is generated. Ten percent of the purchase order quantity for the item is sent to inspection. The full quantity of the purchase order line is blocked.

Blocking items by using inventory status blocking

You can specify which inventory statuses are blocking statuses by using the **Inventory blocking** parameter on the **Inventory statuses** page. You can't use inventory statuses as blocking statuses for production orders, sales orders, transfer orders, outbound transactions, or project integrations. For outbound work, use items that have an available inventory status. If items have a status of **Broken**, and master planning is run on those items, the items are considered missing, and inventory is automatically replenished.

Take care when blocking items that use both inventory status blocking and quality order blocking

You can create a quality order associated with inventory having an inventory status that has its **Inventory blocking** parameter enabled. In this case, the quality order generates an extra inventory blocking record in addition to the one created by the inventory status. Because the quality order inventory blocking will have the parameter **Expected receipts** enabled, this generates an extra *Ordered inventory* transaction that is also blocked by its inventory status. This combination can lead to difficulties in understanding the meaning of generated inventory transactions, because it will appear as though the total blocked quantity is in excess of the total quantity on hand. Let us examine the transactions on an example of a receipt of 10 pieces of item A0001 with a quality order generated to sample 1 piece. The behavior also depends on

whether the option **Reserve ordered items** is enabled on the **Inventory and warehouse management parameters** page.

> **Note**
>
> If you're using inventory status blocking and quality orders together, we strongly recommend having the **Reserve ordered items** option enabled.

Example with "Reserve ordered items" enabled

When **Reserve ordered items** is enabled, all inventory blocking transactions has a status of either *Reserved physical* or *Reserved ordered*.

Expand table

Inventory transaction reference	Receipt	Issue	Quantity	Site	Warehouse	Inventory status	Location	License plate	Comment
Purchase order	Purchased		10 Pcs	2	24	Blocking	RECV	receiptLp1	
Inventory blocking		Reserved physical	-9 Pcs	2	24	Blocking			Transaction generated by the inventory status blocking
Inventory blocking		Reserved physical	-1 Pcs	2	24	Blocking	RECV	receiptLp1	Transaction generated by the quality order sampling blocking
Inventory blocking	Ordered		1 Pcs	2	24	Blocking	RECV	receiptLp1	Expected receipts from the quality order sampling blocking
Inventory blocking		Reserved ordered	1 Pcs	2	24	Blocking			Transaction generated by the inventory status blocking

Example with "Reserve ordered items" disabled

When **Reserve ordered items** is disabled, the expected receipts can't be reserved because they are in status *Ordered*, so some blocking are left in status *On order*.

Expand table

Inventory transaction reference	Receipt	Issue	Quantity	Site	Warehouse	Inventory Status	Location	License Plate	Comment
Purchase order	Purchased		10 Pcs	2	24	Blocking	RECV	receiptLp1	
Inventory blocking		Reserved physical	-9 Pcs	2	24	Blocking			Transaction generated by the inventory status blocking
Inventory blocking		Reserved physical	-1 Pcs	2	24	Blocking	RECV	receiptLp1	Transaction generated by the quality order sampling blocking
Inventory blocking	Ordered		1 Pcs	2	24	Blocking	RECV	receiptLp1	Expected receipts from the quality order sampling blocking
Inventory blocking		On order	1 Pcs	2	24	Blocking	RECV	receiptLp1	Transaction generated by the inventory status blocking

Note the difference in transaction status and dimensions between the two cases. For this reason, we recommend enabling the **Reserve ordered items** option.

Expected receipts from quality orders that sample blocked inventory are disabled

To simplify the inventory transactions when quality orders that sample inventory are blocked as a consequence of inventory status, the system disables expected receipts from such quality orders. Because inventory status blocking immediately blocks the expected receipt, there's no reduction of on-hand inventory because of this.

Create and maintain an inventory blocking

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to use an inventory blocking to prevent physical on-hand inventory from being reserved by other outbound source documents. Before you start the procedures in this article, you must have an item that physical on-hand inventory is available for.

Block inventory

To create an inventory blocking record so that inventory is blocked, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Inventory blocking**.
2. On the Action Pane, select **New**.
3. On the header of the new blocking record, set the **Item number** field to the item that you want to block, and enter a description.
4. On the **General** FastTab, in the **Quantity** field, enter the number of items to block.
5. On the **Inventory dimensions** FastTab, specify the site and warehouse where the items that you want to block are currently located.
6. On the Action Pane, select **Save**.

Update the conditions of the inventory blocking

To update an inventory blocking record, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Inventory blocking**.
2. In the list pane, select the relevant blocking record.
3. Edit the record as required. For example, you might change the value of the **Expected date** field to indicate when the blocked inventory is expected to become available for reservation. If the **Expected receipts** option is selected, the date will appear on the expected transaction. (The **Expected receipts** option is selected by default when you manually create a blocking record.)
4. On the Action Pane, select **Save**.

Unblock inventory

To remove an inventory blocking record so that inventory is unblocked, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Inventory blocking**.
2. In the list pane, select the relevant blocking record.
3. On the Action Pane, select **Delete**.
4. You're prompted to confirm the operation. Select **Yes** to continue.
5. Close the page.

Corrective and preventive action (CAPA) management overview

Corrective and preventive action (CAPA) management lets you create and maintain records of the actions taken to manage and resolve nonconformities or defects. By planning, tracking, and analyzing CAPA cases, you can develop efficient processes that can also help resolve similar issues. CAPA management provides a formal and controlled process for managing various types of issues that arise from manufacturing, engineering, quality, or data quality sources.

CAPA management provides the following benefits:

- It implements a case management infrastructure for identifying, correcting, and preventing future issues.
- It leads to corrective and/or preventive actions.
- It provides a tool that drives continuous improvement.
- It provides a closed-loop system that meets current Good Manufacturing Practice (cGMP) requirements and United States Food and Drug Administration (FDA) expectations. Both cGMP and FDA mandate repeatable, systematic failure investigation and root cause analysis.

CAPA management in Microsoft Dynamics 365 Supply Chain Management lets you capture issues and investigate, evaluate, and determine the root cause or causes of each issue. In this way, you can find a solution for the issue and decide how best to implement it. You can also capture and track corrective and preventive actions, and then monitor and review their effectiveness.

CAPA management provides features that automate the process to help drive continuous improvement. This approach supports the core disciplines for various quality standards, such as Six Sigma and ISO-9000. The solution is role based, supports electronic records and electronic signatures, and is fully compliant with part 11 of Title 21 of the Code of Federal Regulations (21 CFR Part 11).

CAPA management features in Supply Chain Management provide the following functionality:

- **Unlimited and flexible CAPA processes** – A CAPA process is a user-defined list of activities that must be performed to bring a CAPA case to a satisfactory conclusion.
- **A workflow-driven process** – The system automatically assigns CAPA work, based on the definition of your CAPA processes and CAPA worker groups.

- **Flexible assignment of activities** – Associate specific users or groups with each part of a CAPA process.
- **Integration with Outlook** – When work is assigned, the system can automatically send emails to notify the appropriate user that work needs their attention.
- **Create CAPA cases at the point of need** – The person who first recognizes an issue needs attention can create a CAPA case at the point of need in the system. The system automatically links each CAPA case to the record that it was created from (for example, the specific customer, quality order, or production order that was open when the case was created).
- **Trending analysis** – The CAPA workspace provides analytical tools to help you analyze CAPA trends.

The following table describes tasks that employees can perform when they work with CAPA management.

Expand table

Task	Description
Create a CAPA case	Create a new CAPA case record for a customer, vendor, product, or employee.
Work with a CAPA case	Add detailed information, such as activities, to a new or existing CAPA case.
Update the status of a CAPA case	Update the status of a CAPA case (for example, from *Opened* to *In process*).
Update the stage of a CAPA case	Update the stage in the process of working a CAPA case (for example, from *Evaluation* to *Investigation*).
Close a CAPA case	Change the status of an *Opened* case to *Closed* to indicate that the issue was resolved.
Rank a knowledge article	Rank a knowledge article to indicate whether it helped close a case.

Last updated on 06/22/2026

CAPA management administration

This topic explains how to enable and set up corrective and preventive action (CAPA) management features in Microsoft Dynamics 365 Supply Chain Management.

Prerequisites

Before you can use CAPA management features in Supply Chain Management, your system must meet the following requirements:

- You must be running Supply Chain Management version 10.0.44 or later.
- The feature named *Advanced quality management* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.
- If you want to require electronic signatures when CAPA cases are closed, the feature named *Electronic signature improvements* must also be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default.

Set up CAPA parameters

Before users can set up and use CAPA features, you must configure a few administrator settings.

1. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**.

2. On the **Quality management** tab, set the following fields:

    - **CAPA administrator** – Select the worker who should administer the CAPA program. For each CAPA worker group, the CAPA administrator that you specify here can be selected as an automatic group member and/or a default worker.
    - **Use case management workflow** – Select whether the case management workflow can work with CAPA cases.
    - **Require CAPA type** – Set this option to *Yes* if users must specify a CAPA type when they create a CAPA case. If you set this option to *No*, a CAPA type is optional.
    - **Empty case category** – Select the category to apply to new, empty cases. You must select a value if you want to use CAPA.
    - **Require root cause** – Set this option to *Yes* if users must specify a root cause when they create a CAPA case. If you set this option to *No*, a root cause is optional.

- **Copy documents** – Select whether the system should copy document handling details from CAPA processes to new CAPA cases.

Load standard worker groups and processes from a template

To get started quickly, you can load a set of standard CAPA processes and worker groups from a template that's provided with Supply Chain Management. You can use the standard records as-is or modify them to meet your specific needs. Learn more about how to work with CAPA processes in Set up CAPA case components.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **Create standard CAPA process templates**.

2. In the **Create standard CAPA process templates** dialog, set the following fields:

   - **Load** – Set this option to *Yes*.
   - **Name** – Leave this field set to *CAPAProcessTemplate* (the provided default template) unless you have another template that you want to use instead.

3. Select **OK**.

Require an electronic signature to close, cancel, or reopen a CAPA case

You can set up the CAPA features to require an electronic signature from any user who closes, cancels, and/or reopens a CAPA case.

An electronic signature confirms the identity of the person who is about to start or approve a computing process. In some industries, an electronic signature is as legally binding as a handwritten one.

Set up the electronic signature feature

CAPA cases use the standard electronic signature feature that's provided in finance and operations apps. Before you can use this feature, you must configure it and issue certificates to each relevant user. Learn more in Electronic signatures overview and Set up electronic signatures.

Turn the electronic signature requirement for CAPA cases on or off

To set up the electronic signature requirements for CAPA cases, follow these steps:

1. Go to **Organization administration** > **Setup** > **Electronic signature** > **Electronic signature requirements**.
2. In the left pane, select the row where the **Name** field is set to *Close/Cancel CAPA case*.
3. In the right pane, set the **Signature required** option to *Yes* to turn on the feature. Set it to *No* to turn off the feature.

Status changes that require a signature

The following table shows which status changes for CAPA cases require a signature when the electronic signature requirement is turned on.

Expand table

Initial status	New status	Signature required
Opened	In Process	No
Opened	Canceled	Yes
In Process	Opened	No
In Process	Canceled	Yes
In Process	Closed	Yes
Canceled	Opened	Yes
Canceled	In Process	Yes
Closed	Opened	Yes
Closed	In Process	Yes

Last updated on 07/27/2026

Set up CAPA case components (preview)

Article • 05/09/2025

[This article is prerelease documentation and is subject to change.]

Before you can start to create and work with corrective and preventive action (CAPA) cases, you must set up the components that are needed to categorize and process them.

Set up CAPA worker groups

CAPA worker groups let you group users together for CAPA purposes. You can assign a CAPA worker group to each activity and stage in your CAPA process. The system uses worker groups to validate worker assignments.

Each CAPA worker group can include a default worker. This worker is used if no specific worker is assigned.

When a CAPA case, CAPA process stage, or CAPA process activity that is assigned to a worker or worker group becomes active, the system sends the worker or worker group an email notification.

> **Tip**
>
> To get started quickly, you can load a set of standard CAPA worker groups from a template that is provided with Microsoft Dynamics 365 Supply Chain Management. You can use the standard groups as-is or modify them to meet your specific needs, as described in the rest of this section. Learn more in CAPA administration (preview).

To set up CAPA worker groups, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA worker groups**.
2. Use the buttons on the Action Pane to add new worker groups or edit existing ones as required. (You can also delete existing groups, but only if they aren't assigned to CAPA case activities.)
3. On the header of the new or selected worker group, set the following fields:
    - **CAPA worker group** – Enter a name for the worker group. Typical examples include *Investigator*, *Implementer*, *Approver*, and *Verifier*.
    - **Name** – Enter a short description of the worker group.

4. On the **Group settings** FastTab, set the following fields to set up details of the group. These details include whether all members of the group can change the stage of a CAPA case, and whether the CAPA administrator should be an implied member and/or default worker for the group.

    - **Allow any member to change stage** – Select this checkbox if all workers in the CAPA worker group are allowed to change the stage of CAPA cases that are assigned to the group. Clear this checkbox if you want to limit which workers in the group can move CAPA cases to the next stage.
    - **Implied member of this worker group** – Select this checkbox if the CAPA administrator who is assigned on the **Inventory management** parameters page should be an implied member of the CAPA worker group. Alternatively, the CAPA administrator can be assigned directly to the CAPA worker group. However, if the CAPA administrator is changed, extra maintenance is required.
    - **Default worker** – Select this checkbox if the CAPA administrator should be the default worker for this CAPA worker group.

5. On the **Worker assignments** FastTab, add or remove workers in the group.

    - To add a worker, use the **New** button on the **Overview** tab. Alternatively, on the **Assign** tab, use the right arrow button to move workers into the **Selected workers** list.
    - To remove a worker, use the **Delete** button on the **Overview** tab. Alternatively, on the **Assign** tab, use the left arrow button to move workers out of the **Selected workers** list.

6. On the **Overview** tab of the **Worker assignments** FastTab, set the following fields for each worker in the group:

    - **Allowed** – If the **Allow any member to change stage** checkbox is cleared on the **Group settings** FastTab, select this checkbox for each worker that should be allowed to move CAPA cases to the next stage. If the **Allow any member to change stage** checkbox is selected, this checkbox is unavailable.
    - **Default worker** – If the **Default worker** checkbox is cleared on the **Group settings** FastTab, select this checkbox for the worker who should be the default worker for the CAPA worker group. The default worker is used when CAPA cases are created and moved to the next stage. Each CAPA worker group can have a maximum of one default worker. Therefore, if you select this checkbox for a worker, it's automatically cleared for all other workers, including the administrator who is assigned on the **Group settings** FastTab.

Set up CAPA categories

CAPA categories let you group similar case types together. By organizing CAPA cases into categories, you help employees identify known solutions, such as knowledge articles, when similar issues frequently occur. This information is also used by the *Trending analysis by category* feature. Therefore, managers can review whether the frequency of specific issues is declining over time.

To set up CAPA categories, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA categories**.
2. Use the buttons on the Action Pane to add new CAPA categories as required. (You can also delete existing categories, but only if they aren't assigned to active CAPA cases.)
3. For each new CAPA category, set the following fields:
    - **CAPA category** – Enter the name of the CAPA category. The name must be unique.
    - **Description** – Enter a description of the CAPA category.
    - **CAPA subcategory type** – Select a subcategory for the CAPA category. The list includes several predefined subcategories (*None*, *Customer*, *Vendor*, and *Product*). It also includes the *User defined* subcategory type. If you select this subcategory type, users can select from a set of custom subcategories when they create a CAPA case that uses this CAPA category. The next procedure explains how to set up custom CAPA subcategories.

To set up custom CAPA subcategories for a category that uses the *User defined* subcategory type, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA categories**.
2. Select the category that you want to define subcategories for. The selected category must have the **CAPA subcategory type** field set to *User defined*.
3. On the Action Pane, select **User defined CAPA subcategory**.
4. Use the buttons on the Action Pane to add new subcategories as required. (You can also delete existing subcategories.)
5. For each subcategory, set the following fields:
    - **CAPA subcategory** – Enter the name of the subcategory.
    - **Description** – Enter a short description of the subcategory.

Set up CAPA processes

CAPA processes are hierarchical processes that let you manage and resolve CAPA cases. Each CAPA process consists of a series of sequential stages. Each stage can include one or more automatically generated activities. When you create a CAPA case, you assign the CAPA process that is required to guide it to completion.

> **Tip**
>
> To get started quickly, you can load a set of standard CAPA processes from a template that is provided with Supply Chain Management. You can use the standard processes as-is or modify them to meet your specific needs, as described in the rest of this section. Learn more in CAPA administration (preview).

Manage and approve CAPA processes

To name, describe, and approve CAPA processes, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA processes**.

   The **CAPA processes** page shows a list of existing CAPA processes. For each selected process, the following information is shown:

   - **Name** – The name of the CAPA process. For existing processes, this field is read-only.
   - **Description** – A short description of the CAPA process.
   - **Approved** – A value that indicates whether the CAPA process is approved for use in CAPA case management. Only approved CAPA processes are available to users when they create and process a CAPA case. You can leave this option set to *No* while you develop a new process, and then set it to *Yes* when you're ready to start to use it.

2. Use the buttons on the Action Pane to add new CAPA processes or edit existing ones. (You can also delete existing processes.)

   - To add a new process, select **New**.
   - To edit the name, description, or approval status of a selected process, select **Edit**.
   - To delete a selected process, select **Delete**.

Configure CAPA process details

To define the stages and activities that make up a CAPA process, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA processes**.

2. Select or create the CAPA process that you want to work with.

3. On the Action Pane, on the **Process** tab, select **Details**.

   You can use the page that appears to create or edit the structure of the new or selected process. The page has two panes.

   - The left pane shows a hierarchical list of stages and activities that make up the process. The top level is for the process itself. The second level is for the stages. One or more activities can then be nested below each stage. Usually, one level of stages is enough. However, you can create deeper levels for substages as you require.
   - The right pane shows details about the selected stage or activity. Workers must complete the stages in order, from top to bottom. However, the activities that belong to a stage can be done in any order or simultaneously. Activities can be set as mandatory. In this case, they must be completed before the process can move to the next stage.

   > **Tip**
   >
   > If you want to create a new process that is similar to an existing process, you can get started quickly by copying the existing process. On the Action Pane, on the **Process** tab, select **Copy from**. Then select the process that you want to copy.

4. Set up the top-level stages. To add a new stage at the bottom of the current stage list, select the top-level heading (the process name), and then, on the Action Pane, select **New** > **Create level**. (To create a substage for an existing stage, select the parent stage, and then select **New** > **Create level**.)

5. For each new stage, review or enter the following information in the right pane:

   - **Name** – This field is read-only. For a new stage, its value comes from the value that you enter in the **Purpose** field. It can't be changed later.
   - **Activity number** – This field is read-only. The value is automatically generated.
   - **CAPA worker group** – Select or view the CAPA worker group that represents the group of CAPA workers who are responsible for the activity. By default, this group is also assigned to the activities that belong to the stage. However, you can override the group for each stage as required.
   - **Responsible** – Select the worker from the selected CAPA worker group who is responsible for the activity. If you don't select a worker, the designated default worker for the worker group is used when a CAPA case is processed.
   - **Notify group** – Specify who should be notified by email when this stage becomes active. Select *Yes* to notify the whole worker group. Select *No* to notify only the

responsible worker. Select *Inherit* to inherit the setting from the parent stage in the hierarchy.
    - **Email status updates** – Specify whether email should be sent to the responsible worker or worker group when this stage is closed or reopened. The available values are *Yes*, *No*, and *Inherit*.
    - **Print on report** – Select whether information about this stage should be included on the printed CAPA case report. The available values are *Yes*, *No*, and *Inherit*.
    - **Check for required activities** – Select this checkbox if activities that belong to this stage and that are marked as mandatory must be completed before the stage can be closed.

6. Add activities to each stage. To add a new activity at the bottom of the current activity list for a stage, select the stage, and then, on the Action Pane, select **New** > **Create action**, **New** > **Create appointment**, **New** > **Create event**, or **New** > **Create task**, depending on the type of activity that you want. All the activity types work in nearly the same way, but slightly different scheduling settings are available for each.

7. For each new activity, enter the following information in the right pane:

    - The **Name**, **Purpose**, and **Activity number** fields work the same way that they work for stages.
    - Use the **Required** field to mark an activity as mandatory. If the **Check for required activities** field is set to *Yes* for the parent stage, mandatory activities must be completed before the parent stage can be closed.
    - Use the scheduling fields (such as **Start time** and **End time**) to set the start and end dates and times for the activity. These fields are used to calculate when the activity should be performed relative to the day when the activity is created. The availability of scheduling fields varies by activity type.
    - Set the notification options as required. All these settings work the same way that they work for stages. By default, they are set to inherit their setting from the parent stage.

8. Continue to work until you finish setting up all the elements that you need for your process. Then, on the Action Pane, select **Save**.

View all cases that use a selected CAPA process

To view all CAPA cases that use a selected CAPA process, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA processes**.
2. Select or open the CAPA process that you want to view cases for.
3. On the Action Pane, on the **Process** tab, select **All cases** or **All CAPA cases**.

Set up CAPA resolution types

CAPA resolution types let users select a resolution reason when they resolve a CAPA case. You can use CAPA resolution types to identify and categorize typical reasons why CAPA cases can be resolved.

To set up CAPA resolution types, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA resolution types**.
2. Use the buttons on the Action Pane to create new CAPA resolution types as required. (You can also delete existing resolution types.)
3. For each new CAPA resolution type, enter a name and a description.

Set up CAPA sources

CAPA sources let users select a source for each CAPA case. You can use CAPA sources to track the source of each case, such as *Internal audit*, *External audit*, or *Ad-hoc testing*.

To set up CAPA sources, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA sources**.
2. Use the buttons on the Action Pane to create new CAPA sources as required. (You can also delete existing sources.)
3. For each new CAPA source, enter a name and a description.

Set up CAPA types

CAPA types let users select a type to categorize each CAPA case.

To set up CAPA types, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA types**.
2. Use the buttons on the Action Pane to create new CAPA types as required. (You can also delete existing types.)
3. For each new CAPA type, enter a name and a description.

Set up major/minor classification codes

CAPA types let users select a *major/minor classification code* for each CAPA case.

To set up major/minor classification codes, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **Major/minor classification codes**.
2. Use the buttons on the Action Pane to create new major/minor classification codes as required. (You can also delete existing classification codes.)
3. For each new CAPA classification code, enter a name and a description.

Set up CAPA root causes

CAPA root cause codes let users select the root cause of an issue when they resolve a CAPA case.

To set up CAPA root cause codes, follow these steps.

1. Go to **Inventory management** > **Setup** > **CAPA management** > **CAPA root causes**.
2. Use the buttons on the Action Pane to create new CAPA root causes as required. (You can also delete existing root causes).
3. For each new CAPA root cause, enter a name and a description.

Manage CAPA cases (preview)

Article • 05/09/2025

[This article is prerelease documentation and is subject to change.]

Use corrective and preventive action (CAPA) cases to record, update, track, follow up on, and close issues that your customers, vendors, or employees raise.

Use the CAPA case workspace to view, open, manage, and analyze CAPA cases

The CAPA case workspace provides a central location where you can create, view, and manage all CAPA cases in the system.

The workspace provides several tabs where you can view various lists of cases and activities. Here are some examples:

- Cases and activities that are assigned to you
- Open cases and activities
- Cases and activities that are due during the current week

You can also search for CAPA cases that are related to a specific customer, vendor, sales order, purchase order, return order, or released product.

From the workspace, you can quickly view details, set the status of a listed case or activity, move a case to the next process stage, and more.

To open the workspace, go to **Inventory management** > **Workspaces** > **CAPA management**.

View CAPA cases on list pages

To view all CAPA cases that are related to a selected customer, vendor, sales order, purchase order, return order, or released product, open or select the relevant record, and then follow one of these steps.

- **For customers or vendors:** On the Action Pane, on the **General** tab, in the **Accounts** group, select **CAPA case**.
- **For sales orders, purchase orders, or return orders:** On the Action Pane, on the **General** tab, in the **CAPA** group, select **View CAPA cases**.
- **For released products:** On the Action Pane, on the **General** tab, in the **Maintain CAPA cases** group, select **View CAPA cases**.

To view and work with all CAPA cases in the system, follow one of these steps.

- Go to **Inventory management** > **Periodic tasks** > **CAPA management** > **All CAPA cases**.
- Go to **Common** > **Common** > **CAPA management** > **All CAPA cases**.

To view and work with only the CAPA cases that you're responsible for, follow one of these steps.

- Go to **Inventory management** > **Periodic tasks** > **CAPA management** > **My CAPA cases**.
- Go to **Common** > **Common** > **CAPA management** > **My CAPA cases**.

FastTabs on the CAPA case details page

When you open a CAPA case record from the workspace or any list page, the details page provides the following FastTabs. Use the fields and settings on these FastTabs to view or edit information about the CAPA case.

- **General** – View or edit general information about the selected CAPA case. Many of the values on this FastTab are set when the case is created.
- **Email notifications** – View, add, and edit people who should be emailed when selected events occur for the current CAPA case (for example, when the status of the case or one of its activities is changed to *Closed*, *Canceled*, or *Reopened*).
- **Case log** – View, add, or edit information about the CAPA case. The system automatically adds log entries when specific events occur (for example, when the case is created, its status is changed, or activities are completed). Additionally, you can manually add log entries.
- **Associations** – View or edit information about records that are associated with the CAPA case. Examples of these records include sales order, item, vendor, and batch order records. Often, one or more of these associations are automatically set, based on where the user was when they created the case. However, you can add more associations as you work with the case.
- **Knowledge article** – View or edit information about knowledge articles that are associated with the CAPA case.
- **Administration** – View administrative details about the CAPA case. Examples include the date when the case was opened and the user who opened it.
- **Resolution** – View or edit information about how the CAPA case was resolved.

Create a new CAPA case

You can create CAPA cases from many different pages in the system, including pages where you work with records that CAPA cases might originate from. Examples of those records

include customer, vendor, sales order, purchase order, return order, and released product records. You can also create CAPA cases from the **All CAPA cases** and **My CAPA cases** pages. When you create a CAPA case from a related or originating record, the case is automatically linked to that record.

1. Go to the customer, vendor, sales order, purchase order, return order, or released product record that the CAPA case originates from.

2. Depending on the page that you're working on, follow one of these steps.

    - **For customers or vendors:** On the Action, on the **General** tab, in the **New** group, select **CAPA case**.

    - **For sales orders, purchase orders, or return orders:** On the Action Pane, on the **General** tab, in the **CAPA** group, select **Create CAPA case**.

    - **For released products:** On the Action Pane, on the **General** tab, in the **Maintain CAPA cases** group, select **Create CAPA case**.

    - **For nonconformance records:** On the Action Pane, select **Functions** > **Create CAPA case**.

    - **From the All CAPA cases or My CAPA cases page:**
        - To create a CAPA case that isn't linked to an existing case, on the Action Pane, select **New** > **CAPA case**.
        - To create a CAPA case that is linked to an existing case, select the parent case in the grid, and then, on the Action Pane, select **New** > **Dependent CAPA case**.

    - **From the CAPA management workspace:** On the Action Pane, select **Create new** > **CAPA case**. Alternatively, on the **CAPA case summary** FastTab, select **New CAPA case**.

3. In the **New CAPA case** dialog, on the **General** tab, set the following fields:

    - **Name** – Enter or select the name of a person from the global address book to associate that person with the CAPA case. If you started from a customer, vendor, sales order, purchase order, or return order, this field is automatically set based on the record that was selected when you created the CAPA case.
    - **Case ID** – The system-generated identification number of the CAPA case.
    - **Status** – Select the status of the CAPA case. The default status is *Opened*. This status indicates that the case isn't being worked on yet. When work on the case begins, you or the assigned worker should change the status to *In process*.
    - **Description** – Enter a short description of the CAPA case. The description is used to identify the case in lists and on reports. It's also shown as the heading of the case

when you open it.

- **Priority** – Select the priority of the CAPA case.
- **Parent case** – If you want to associate the CAPA case with another case, select the parent case. If you selected a parent case when you created this case, the association is automatically set.
- **CAPA category** – Select a category for the CAPA case. The category is used to analyze trends for reporting purposes.
- **CAPA subcategory** – If subcategories are defined for the category that you selected, select one. The subcategory is used to analyze trends for reporting purposes.
- **Description** – Enter a brief description of the CAPA case.
- **CAPA process** – Select the CAPA process that should be followed to resolve this case. The CAPA process guides workers who are assigned to the case through the steps that are required to resolve it. It defines a series of stages. These stages must be completed in order. Within each stage, the CAPA process defines activities that should be completed before the process is moved to the next stage.

4. If you want to add a log entry to the case, on the **Case log** tab, enter the details of the log entry. You can view and add log entries from the details page for a CAPA case.

5. Select **OK** to create the case and open its details.

Work through a CAPA process

A CAPA process guides workers who are assigned to a case through the steps that are required to resolve it. It defines a series of stages that must be completed in order. Each stage can include one or more activities. The activities can be completed in any order or simultaneously. Some activities might be mandatory. All mandatory activities must be completed before the process can be moved to the next stage.

Based on the configuration of the CAPA process, a worker or worker group is automatically assigned to each stage and activity. The system uses email to notify each responsible worker or worker group when a case, stage, or activity is assigned to them. The email includes links so that the case, stage, or activity can be opened directly from the message. Workers can always track which cases and activities are assigned to them by opening the **CAPA management** dashboard.

CAPA processes are defined by an administrator or manager. The **CAPA process** field of the CAPA record is used to assign CAPA processes to cases as they are created. Your company can define as many CAPA processes as it needs. Learn more in Set up CAPA case components (preview).

The workflow for CAPA processes consists of the following steps.

1. Create a CAPA case, and assign a CAPA process to it. The case initially has a status of *Opened*.

2. Select or open the case (for example, from the **CAPA management** workspace). Then select **Change status** > **In process**. (If you're in the **CAPA management** workspace, the button is on the toolbar. If you're on the details page or another page, it's on the **CAPA case** tab of the Action Pane.) This status change indicates that the case is being actively worked on and enables it to move through the various stages of the process.

3. The process starts with the first stage (for example, *Definition*). The system generates the activities that are configured for the stage. (For example, there might be a single activity that is named *Identify the problem*.)

4. The system emails the **Employee responsible** contacts for the case, the active stage, and each active activity that belongs to that stage.

5. Workers can now work on each activity that they are assigned to, enter notes on the details page for the activity, and fill in information as required. Employees can access the details page for an activity in several ways:

    - Select a link in the email that was sent to them when the activity was generated.
    - Open the **CAPA management** workspace, and browse the activities that are listed on the various tabs (such as **My open activities**).
    - Open the **CAPA management** workspace, and select any tab that lists CAPA cases (such as **My open cases**). Select a case, and then, on the toolbar, select **View activities**. A list shows all activities for the selected CAPA case that belong to stages that have been started. Select an activity to open its details page.
    - Open the details of a CAPA case. On the Action Pane, on the **CAPA case** tab, select **Case process**. In the process tree, expand a stage, and select an activity. (The tree shows activities only for stages that have been started). Select the **Activity number** link to view the details for the selected activity.

6. As workers finish working on each activity, they close it (that is, mark it as completed). There are several ways to close an activity:

    - In the **CAPA management** workspace, select the activity on any tab where it appears. Then, on the toolbar, select **Set as complete**.
    - On the activity details page, on the Action Pane, on the **Activity** tab, select **Set as complete**.
    - On the activity details page, on the **Status** FastTab, set the **Closed** option to *Yes*.

7. After all mandatory activities for the current stage are closed, an employee who has the required permissions can move the case to the next stage. You can skip a stage as

required. However, after you move to a stage, you can't return to a previous one. There are several ways to move a CAPA case to the next stage in its process:

- In the **CAPA management** workspace, select the CAPA case on any tab where it appears. On the toolbar, select **Change stage**, and then select the stage that you want to move the case to.
- On the CAPA case details page, on the **CAPA case** FastTab, select **Change stage**, and then select the stage that you want to move the case to.

8. The selected new stage begins. The system generates the activities that are configured for the stage, sends out emails to the responsible employees, and updates the **CAPA management** workspace, just as it did for the first stage in the process.

9. The process continues until all the required activities are completed and you're ready to close the case. Often, you begin by opening the CAPA case details and filling in the fields on the **Resolution** FastTab to document the outcome of the case. You then mark the case as closed. There are several ways to close a CAPA case:

    - In the **CAPA management** workspace, select the CAPA case on any tab where it appears, and then, on the toolbar, select **Set as complete**.
    - On a CAPA case list or details page, on the Action Pane, on the **CAPA Case** tab, select **Change status** > **Closed**.

> **Tip**
>
> To get a graphical overview of the process hierarchy for the current CAPA case, follow these steps.
>
> 1. Open the details page for the relevant CAPA case.
> 2. In the rightmost pane, select the **Related information** button ⓘ to open the **Related information** FactBox pane.
> 3. On the **Process tree** FastTab, review the list of stages in the current process. You can expand any stage that has been started to view the activities that belong to it. Select and hold (or right-click) an activity to open its details.

Analyze CAPA case statistics

Microsoft Dynamics 365 Supply Chain Management provides graphical displays that you can use to analyze CAPA case generation and progress. Use the statistics to identify trends, frequent issues, bottlenecks, and areas for improvement in your CAPA processes.

Statistical charts are provided in the **CAPA management** workspace and on the **Trending analysis** page. Although the charts in both places are similar, there are a few minor differences in the data that they show.

Analyze statistics using the CAPA management workspace

To view statistics in the **CAPA management** workspace, follow these steps.

1. Go to **Inventory management** > **Workspaces** > **CAPA management**.
2. Select the **Statistics** FastTab. Two charts are shown.
3. Use the **Number of cases by** dropdown list to select the type of statistics that you want to view in the left chart.
4. Use the **Trending of cases by** dropdown list to select the period that you want to view in the right chart.
5. Use the buttons at the top of each chart to select its graphical style (for example, bar chart, line chart, or pie chart).

Analyze statistics using the Trending analysis page

To view statistics on the **Trending analysis** page, follow these steps.

1. Go to **Inventory management** > **Inquiries and reports** > **CAPA management** > **Trending analysis**.
2. On the **Data** tab, select the date range, and turn on each type of chart that you want to view.
3. Select the **Analytics by category** tab to view the selected charts.
4. Use the buttons at the top of each chart to select its graphical style (for example, bar chart, line chart, or pie chart).

Review signatures for a CAPA case

The CAPA features can optionally be set up to require an electronic signature from any user who closes, cancels, and/or reopens a CAPA case. To review the signatures that are applied to a CAPA case, follow these steps.

1. Open or select the CAPA case that you want to review (for example, on the **All CAPA cases** page).
2. On the Action Pane, on the **CAPA case** tab, select **Signature review**.

Inventory journals

08/29/2025

This article describes how you can use inventory journals to post various types of physical inventory transactions.

In Supply Chain Management, use inventory journals to post physical inventory transactions of various types, such as the posting of issues and receipts, inventory movements, the creation of bills of materials (BOMs), and the reconciliation of physical inventory. All these inventory journals work in a similar way, but they're divided into different types.

Types of inventory journals

The following types of inventory journals are available:

- Movement
- Inventory adjustment
- Transfer
- BOM
- Item arrival
- Production input
- Counting
- Tag counting

Movement

When you use an inventory movement journal, you can add cost to an item when you add inventory, but you must manually allocate the extra cost to a particular general ledger account by specifying a general ledger offset account when you create the journal. This inventory journal type is useful if you want to overwrite the default posting accounts.

Inventory adjustment

When you use an inventory adjustment journal, you can add cost to an item when you add inventory. The extra cost is automatically posted to a specific general ledger account, based on the setup of the item group posting profile. Use this inventory journal type to update gains and losses to inventory quantities when the item should keep its default general ledger offset account. When you post an inventory adjustment journal, you post an inventory receipt or issue, change the inventory values, and create ledger transactions.

Transfer

Use transfer journals to transfer items between stocking locations, batches, or product variants without associating any cost implications. For example, you can transfer items from one warehouse to another warehouse within the same company. When you use a transfer journal, you must specify both the "from" and "to" inventory dimensions (for example, for Site and Warehouse). The on-hand inventory for the defined inventory dimensions changes accordingly. Inventory transfers reflect the immediate movement of material. In-transit inventory isn't tracked. If you need to track in-transit inventory, use a transfer order instead. When you post a transfer journal, two inventory transactions are created for each journal line:

- An inventory issue at the "from" location.
- An inventory receipt at the "to" location.

BOM

When you report a BOM as finished, you can create a BOM journal. By using a BOM journal, you can post the BOM directly. This posting generates an inventory receipt of the product, together with an associated BOM and an inventory issue of the products that are included in the BOM. This inventory journal type is useful in simple or high-volume production scenarios where routes aren't required.

Item arrival

Use the item arrival journal to register the receipt of items (for example, from purchase orders). You can create an item arrival journal as part of arrival management from the **Arrival overview** page, or you can manually create a journal entry from the **Item arrival** page. If you enable the item arrival journal name to check for picking locations, Supply Chain Management looks for a location for received items and, if there's room, generates location destinations for the incoming items.

Production input

Production input journals work like the item arrival journals but are used for production orders.

Counting

Counting journals let you correct the current on-hand inventory that is registered for items or groups of items, and then post the actual physical count, so that you can make the adjustments that are required to reconcile the differences. You can associate counting policies with counting groups to help group items that have various characteristics, so that those items

can be included in a counting journal. For example, you can set up counting groups to count items that have a specific frequency, or to count items when stock falls to a particular level. For information about how to define counting groups, see Define inventory counting processes.

Tag counting

Use tag counting journals to assign a numbered tag to a count lot. The tag contains a tag number, item number, and item quantity. To ensure that a tag is used only one time, and that all tags are used, every item number has a unique set of tags with its own number sequence. You can set three status values for each tag:

- **Used** – The item number is counted for this tag.
- **Voided** – The item number is voided for this tag.
- **Missing** – The item number is missing for this tag.

When you post a tag counting journal, you create a new counting journal based on the tag counting journal lines. For more information about tag counting, see Inventory tag counting.

Working with journals

Only one user at a time can access a journal. If several users need to access journals at the same time to create journal lines, they must select journals that aren't currently being used. This approach prevents information from being overwritten. In situations where multiple departments use the same journal type, it's helpful to create multiple journal names (for example, one per department). It can also be helpful to divide journals so that each posting routine is entered in its own unique inventory journal. For posting routines that are associated with inventory transactions, create one journal for periodic inventory adjustments and another for inventory counting.

Posting journal lines

You can post the journal lines that you create at any time until you lock an item from additional transactions. The data that you enter in a journal remains in that journal, even if you close the journal without posting the lines.

Data entity support for inventory journals

Data entities support the following types of integration scenarios:

- Synchronous service (OData)
- Asynchronous integration

Learn more in Data entities.

> **Note**
>
> Not all inventory journals are OData-enabled, so you can't use the Excel data connector to get data published, updated, and imported back to Supply Chain Management.

Another difference between the journal data entities is the ability to use composite entities that include both the header and line data. Currently, you can use the composite entities for:

- Inventory adjustment journal
- Inventory movement journal

These two inventory journals only support the *Initialize stock* scenario as part of a data management import project:

- When you don't specify a journal header number but specify a number sequence for the journal type, the import job automatically creates journal headers per 1,000 lines. For example, importing 2,020 lines results in the following three journal headers:
  - Header 1: contains 1,000 lines
  - Header 2: contains 1,000 lines
  - Header 3: contains 20 lines
- The import process assumes that unique line information exists per inventory dimension, which can be a product, storage, and tracking dimension. Therefore, you can't import journal lines where only the date field differs on the lines within the same import project.

Related information

- Data entities

Inventory journal approval workflows

This article describes how to set up and use inventory journal approval workflows for various types of physical inventory transactions, such as issues and receipts, inventory movements, bills of materials (BOMs), and the reconciliation of physical inventory. Inventory journal workflows help ensure that only approved inventory journals can be posted to transactions.

> **Note**
>
> Inventory journal approval workflows apply only to transactions recorded using the Inventory Management module. They don't work with inventory journals triggered from the Warehouse Management module.

Create your inventory journal approval workflows

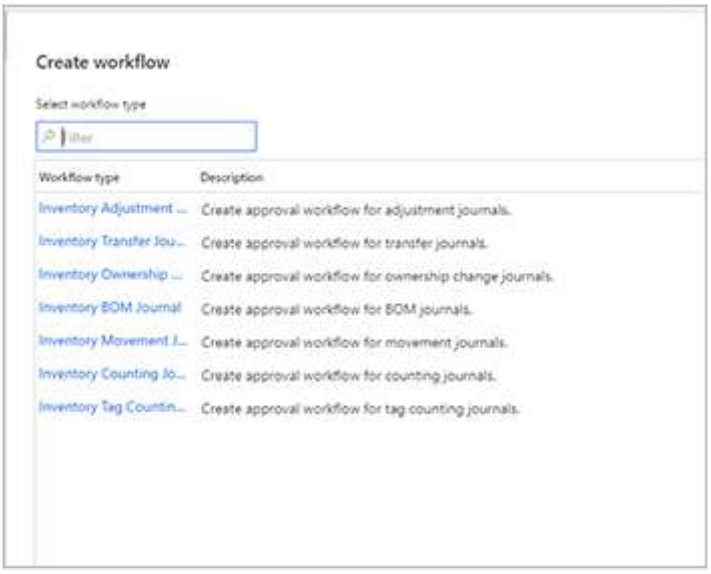
To set up this feature, create a workflow for each inventory journal type you want to control. Because different inventory journal types can have different approval hierarchies and workflow steps, you can configure individual workflows for each inventory journal type.

Workflows support version control, and each has a workflow ID and an active version. You can choose to activate each new workflow version immediately upon creation or keep it inactive. If you need different workflows for the same journal type, create multiple workflows for that journal type, and then assign each of these workflows to a different journal name that uses that type.

To create your inventory journal approval workflows:

1. Go to **Inventory Management** > **Setup** > **Inventory management workflows**.
2. Select **New** on the Action Pane.
3. Choose the inventory journal type for which you want to set up a workflow:
    - *Inventory tag counting journal*
    - *Inventory ownership change journal*
    - *Inventory movement journal*
    - *Inventory transfer journal*
    - *Inventory counting journal*
    - *Inventory BOM journal*

- *Inventory adjustment journal*



4. The workflow editor app launches on your machine. (You might be asked to approve this action.) Use it to design your workflow as needed. For details about how to use the workflow editor, see Workflow system overview.

5. After saving and closing the workflow editor app, choose whether to activate this workflow version or keep it inactive.

> **Note**
>
> Workflows provide version control, which means that you can view a list of versions you created and choose which one is active. To view the list of available versions and choose which to activate, select a workflow listed on the **Inventory management workflows** page. On the Action Pane, open the **Workflow** tab, and select **Versions**. Only one version can be active at a time for each workflow ID.

Assign approval workflows to inventory journal names

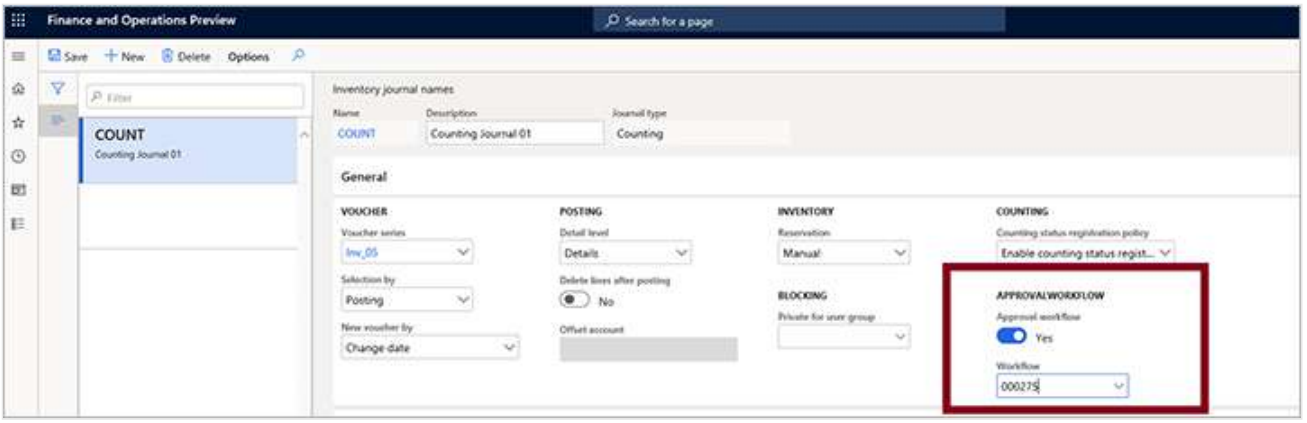
Next, assign an inventory journal workflow to each inventory journal name. For each inventory journal type, you can set up multiple inventory journal names.

To associate an inventory journal workflow with an inventory journal name:

1. Go to **Inventory management** > **Setup** > **Journal names** > **Inventory**.

2. Select a journal name from the list column to open its settings page.

3. On the **General** FastTab, set **Approval workflow** to **Yes**. If you're prompted to approve the action, select **Yes**.



4. Open the **Workflow** drop-down list and select the appropriate workflow. The list shows each active workflow that you created by using the workflow editor app.

Create an inventory journal and send it for approval

After you associate an inventory journal name with its matching inventory journal approval workflow, you can create new inventory journals that use that name and then send these journals for approval by using that workflow. You can't post the inventory journal until the approvers configured in the workflow approve it.

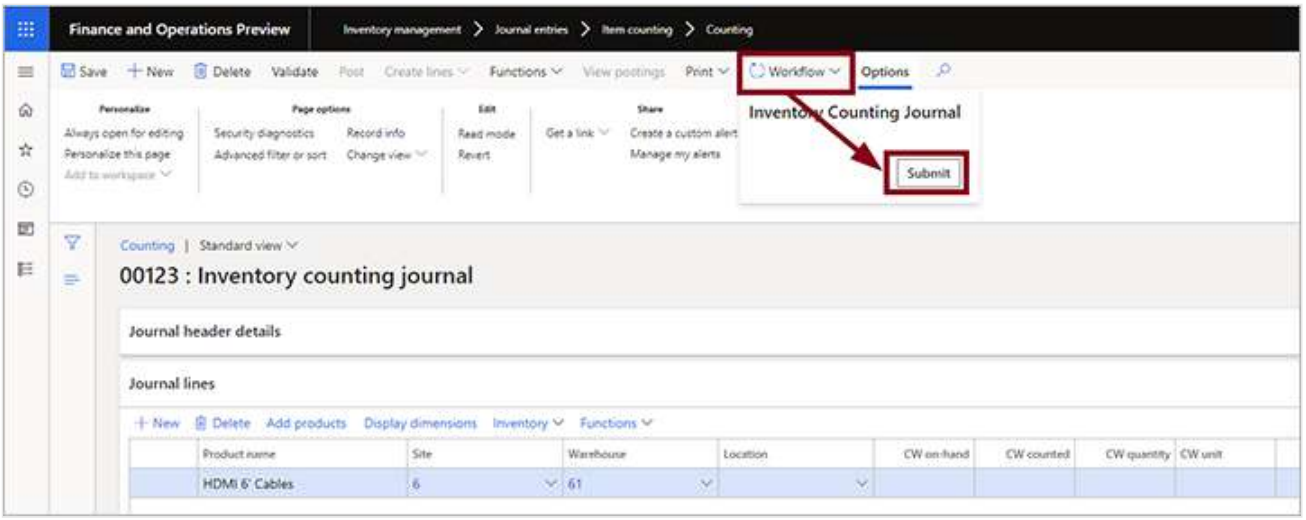
1. On the navigation pane, expand **Inventory management** > **Journal entries** > **Items** and then select an inventory journal type.

2. Select **New** to create a new journal of your selected type.

3. The **Create inventory journal** dialog box opens. Fill out the form as needed and then select **OK** to save the journal.

4. Complete the journal as required.

5. When you create or open an inventory journal with an approval workflow associated with it, the **Workflow** button is active in the Action Pane. When you're ready to submit the journal for approval, select the **Workflow** button to open a drop-down dialog box and then select **Submit**. The approval request routes to the relevant approver, who is alerted by using the notification method configured for the workflow.



To recall an approval request, open the relevant journal, select the **Workflow** button, and then select **Recall**. This action resets the workflow.

When your journal is approved, you can post it. To post the journal, select **Post** from the Action Pane. If the **Post** button isn't active, the journal isn't approved yet.

Respond to an inventory journal approval request

If you're an approver, you receive a message each time your approval is needed (as configured in the relevant workflow). Then, you can approve or reject a journal approval request by following these steps:

1. On the navigation pane, expand **Inventory management** > **Journal entries** > **Items** and then select an inventory journal type.
2. Open the relevant journal and review it.
3. Select the **Workflow** button on the Action Pane to open a drop-down dialog box. Select one of the following options:

    - **Approve** - To approve the request.
    - **Reject** - To reject the request.
    - **More** > **Request change** - To send a message to the requester asking them to change something specific and then resubmit.
    - **More** > **Delegate** - To delegate the approval to another user.
    - **More** > **Recall** - To recall the approval request (resets the workflow).
    - **More** > **Workflow history** - To view the history of this approval workflow so far.

Review the approval history

As with other types of workflows, you can use the **Workflow history** page to view the approval workflow history for any journal.

To review the workflow history for a journal:

1. On the navigation pane, expand **Inventory management** > **Journal entries** > **Items** and then select an inventory journal type.
2. Open the relevant journal.
3. Select the **Workflow** button on the Action Pane to open a drop-down dialog box. Select **Workflow history**. For more information, see View workflow history.

Inventory locations

Inventory locations determine where you store and pick items in warehouses that don't use warehouse management processes (WMS).

This article applies to features in the Inventory management module. It doesn't apply to features in the Warehouse management module.

The term location refers to the place that items are stored and drawn from.

For each location, you can also specify the place the item is inserted. By default, they're the same. Items are usually inserted and drawn from the same side of a location, but not always. For example, items that are stored in live storage racks are inserted from one aisle and drawn from another. The main input is given by a location name, which is usually determined by its coordinates: warehouse, aisle, rack, shelf, and bin. You can enter this name or ID manually or generate it from the location coordinates. For example, `01-02-03-4` represents aisle 1, rack 2, shelf 3, and bin 4 in the Inventory locations page.

Location properties

A location has the following characteristics:

- Size (height, width, depth, and thereby volume)
- Warehouse, aisle, rack, shelf, and bin position
- Location type (bulk location, picking location, inbound dock, outbound dock, production input location, inspection location, or kanban supermarket)

Check text can be used in online systems to verify that the operator has selected the correct location for a specific item. This check text can be created manually or by default.

Sort codes

Use sort codes to optimize the handling of picking lines, which describe the information that is required for picking items from inventory, including the picking order. Sort codes can be specified by the aisle and other coordinates, or assigned manually for the location.

Blocked locations

Occasionally, you might want to indicate that a location is blocked for a period of time, for example, to allow for repairs. At other times, you might want to indicate blocking of only the input or only output.

Tree structure

In the Inventory locations page, you can view the warehouse layout in a tree structure based on the coordinates of inventory locations, in a defined display format.

Maintain inventory locations via the warehouse form

You can copy locations from one warehouse to another and create locations through a wizard. Before running the wizard, make sure that you define the default location names on the **Warehouse** page.

Inventory statuses

This article describes how to use inventory statuses to categorize and keep track of inventory.

Set up and use inventory statuses

You can use inventory statuses to categorize inventory. You can then initiate appropriate actions, such as replenishment or putaway work.

Here are some examples of ways that you can use inventory statuses:

- Create inventory statuses for on-hand inventory, inbound transactions, and outbound transactions.
- Specify a default inventory status for warehouse transactions.
- Change an inventory status for items before arrival, during arrival, or when the items are put away during inventory movement.
- Use an inventory status to price items that are returned and to plan item coverage during master planning.

An inventory status is one of the dimensions in the storage dimension group. Inventory statuses can be categorized as available or unavailable, and you can use the **Inventory blocking** parameter to block items that have an unavailable inventory status. Items that have a blocked status are considered physical inventory, and they can't be used on a production order, sales order, transfer order, or outbound transaction.

You can use warehouse items that have either available or unavailable inventory statuses for inbound work. For example, you create an available status that is named *Ready*, an unavailable status that is named *Damaged*, and a blocked status that is named *Blocked*. When you create a purchase order for received or returned items, if any items are damaged or broken, you can change the inventory status of those items to *Damaged* on the purchase order line. After these items are received, the status is automatically set to *Blocked*. If you scan the damaged items by using a mobile device, Supply Chain Management can use location directives and work templates to show information about an appropriate location or range of locations where you can put away those items. For returned items, an issue type of *Reservation* is created on the **Inventory transactions** page.

You can specify which inventory statuses are blocking statuses by using the **Inventory blocking** check boxes on the **Inventory statuses** page. You can't use inventory statuses as blocking

statuses for sales orders, transfer orders, or project integrations.

For outbound work, you can use different nonblocking inventory statuses to control which inventory to reserve against. If you have items that have a status of *Blocking*, and master planning is run on these items, the items are considered missing, and inventory is automatically replenished. Furthermore, for quality orders associated with outbound work, it isn't possible to update the **Inventory status** as part of the quality order validation.

> **Note**
>
> You can't change the status of inventory at locations where open work exists. For example, if you did a purchase receive for an item, but didn't do the putaway step, then open work would exist for the receiving location and you would get an error if you tried to change the status of inventory at that location. Completing or cancelling the related work would allow you to change the status.
>
> Usually, the status of on-hand inventory related to open warehouse work is only changed by workers using the Warehouse Management mobile app, for example while executing a movement process.

After you set up inventory statuses, you can set the default inventory status for a site, item, and warehouse. You can also set a default status for sales, transfer, and purchase orders. The default status for sales orders and outbound transfer order can't have the **Inventory blocking** option set to *Yes*. The inventory status that is inherited from the default settings on a site, warehouse, item, purchase order, transfer order, or sales order can be changed by using the mobile device, or on the purchase order, sales order, or transfer order line.

To plan coverage for items that have an available inventory status, select the **Coverage plan by dimension** option for a storage dimension on the **Storage dimension groups** page. When you open the **Item Coverage** wizard, items that have an available status appear on the **Status** page. To create coverage settings for these items, select the inventory status ID for the available inventory statuses. Based on the coverage settings, you can calculate the item requirements and forecast the supply and demand of available items during master planning. You can't create an item coverage setup that has a blocked inventory status. Alternatively, use the **Item coverage** page to create or modify the item coverage parameters.

Change inventory statuses

You can change inventory statuses either by using the **On-hand by location** page or by using a batch job.

To change inventory status of individually selected records, follow these steps:

1. Go to **Warehouse management** > **Inquiries and reports** > **On-hand by location**.
2. Use the **Site**, **Warehouse**, and **Location** fields to find the relevant location.
3. On the **Locations** tab, select the location.
4. On the **On-hand** tab, select the relevant records, and then select the **Inventory status change** button.

To set up a batch job task that selects and updates records, follow these steps:

1. Go to **Warehouse management** > **Periodic tasks** > **Warehouse management inventory status change**.
2. On the **Parameters** FastTab, set **To inventory status** to the status value you want to update the selected records to.
3. On the **Records to include** FastTab, select the **Filter** button and set up a query that selects which records to change.
4. On the **Run in background** FastTab, set **Batch processing** to *Yes*. If you want to run the job at a regular interval, select **Recurrence** and assign the interval.

Use batch disposition codes to mark batches as available or unavailable

This article describes how to set up and use *batch disposition codes*. Each batch disposition code has a status of either *Available* or *Unavailable*. You assign batch disposition codes to inventory batches to indicate whether each batch is available for master planning, reservation, picking, and shipping.

To use batch disposition codes, you must set up the codes and assign them to the batches that you want to manage.

> ⓘ **Note**
>
> For items that are enabled for warehouse management processes (WMS) and that use a reservation hierarchy where the *Batch number* dimension is below the *Location* dimension, the system enforces batch disposition codes during reservation only when the line's warehouse is enabled for WMS, or when the **Batch reservation policy for non advanced warehouses** parameter is set to *Advanced*. Learn more in Batch reservation policy for non-WMS warehouses.

Set up batch disposition codes

Set up each batch disposition code that you want to use in your system. You can create as many codes as you want. For example, you can create codes to identify the different reasons why a batch might be available or unavailable. However, you often need just two codes: one for *available* and one for *unavailable*. You can also create custom codes that enable a batch to be used for some operations but not others.

Follow these steps to set up batch disposition codes.

1. Go to **Inventory management** > **Setup** > **Batch** > **Batch disposition master**.
2. The **Batch disposition master** page lists your current batch disposition codes, and lets you create, delete, and edit them. Follow one of these steps:
    - To edit an existing code, select it in the list pane.
    - To create a new code, select **New** on the Action Pane.

3. Set the following fields on the header of the new or selected code:

    - **Batch disposition code** – Enter the display name for the code.
    - **Description** – Describe how the code should be used.
    - **Batch disposition status** – Select the status that applies to batches that the code is assigned to:
        - *Unavailable* – The batches can't be used for master planning, reservation, picking, or shipping. When you select this value, all the **Block** options on the **Setup** FastTab are set to *Yes*, and all the **Nettable** options are set to *No*. However, you can change some of these settings to add exceptions.
        - *Available* – The batches can be used for master planning, reservation, picking, and/or shipping. When you select this value, all the **Block** options on the **Setup** FastTab are set to *No*, and all the **Nettable** options are set to *Yes*. These settings are read-only while the **Batch disposition status** field is set to *Available*.

4. If you set the **Batch disposition status** field to *Unavailable*, you can customize the block status of each operation (reserve, pick, and ship) for each type of order (sales, transfer, and production). For production orders, you can choose to block or unblock the production picking journal. You can also choose to block or unblock master planning. Use the options on the **Setup** FastTab to block or unblock each operation as you require. Set the **Nettable** option to *Yes* to enable master planning, or set it to *No* to block master planning.

Assign batch disposition codes to batches

After you define the batch disposition codes that you require, follow these steps to assign them to batches.

1. Go to **Warehouse management** > **Setup** > **Inventory** > **Batches**.
2. Select one or more batches to assign a batch disposition code to.
3. On the Action Pane, on the **Reset** tab, select **Reset batch disposition code**.
4. In the **Change the restrictions on the inventory batch** dialog box, set the **New batch disposition code** field to the name of the code that you want to assign.
5. Select **OK** to apply the new setting and save your change.

    On the **Batches** page, the values in the **Batch disposition code** and **Batch disposition status** columns are updated so that they reflect the new settings for the selected batches.

Master planning example

This example shows how batch disposition codes can affect master planning.

For this example, batch disposition codes are set up in the following way:

- *P-Available:*
  - **Batch disposition status:** *Available*
  - **Nettable:** *Yes*
- *P-Unavailable:*
  - **Batch disposition status:** *Unavailable*
  - **Nettable:** *No*

There's a product (*Product-1*) that has two batches: *Batch-A* and *Batch-B*. These batches are set up in the following way:

- *Batch-A:*
  - **Batch disposition code:** *P-Available*
  - **On-hand quantity:** 1
- *Batch-B:*
  - **Batch disposition code:** *P-Unavailable*
  - **On-hand quantity:** 1

There's a sales order (*SO1*) for a quantity of 2 of product *Product-1*. The delivery date is three days from today.

You run master planning and set the following values that are relevant to this example:

- **Planned order:** *Purchase order*
- **Replenishment strategy:** *Requirement*
- **Lead time:** *0*

As a result of the planning run, the system uses the available batch (*Batch-A*) to cover a quantity of 1 of product *Product-1* for sales order *SO1*. However, it can't use batch *Batch-B* because that batch is marked as unavailable for planning. Therefore, to cover the remaining quantity, the system creates a planned purchase order (*PPO1*) for a new batch of product *Product-1*.

The following illustration shows a timeline for the planning result.

Create a new warehouse layout

07/02/2025

This article describes how to set up information about the locations in a warehouse. These instructions only apply for the Inventory management module (when you aren't using warehouse management processes (WMS)), not when you're using the WMS-enabled warehouse functionality that's available in the Warehouse management module. You can use this procedure in demo data company USMF, or on your own data.

Set the default location capacity

1. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**.
2. Select the **Locations** tab.
3. In the **Standard width** field, enter a number.
4. In the **Standard depth** field, enter a number.
5. In the **Standard height** field, enter a number.
6. Select **Save**.
7. Close the page.

Define the location name format

1. Go to **Inventory management** > **Setup** > **Inventory breakdown** > **Warehouses**.
2. Select **New**.
3. In the **Warehouse** field, type a value.
4. In the **Name** field, type a value.
5. In the **Site** field, select the desired record in the lookup.
6. Toggle the expansion of the **Location names** section. The options in this section define the default format for location names. In our example, we'll include the aisle number, rack number, and shelf number.
7. Set the **Include aisle** option to *Yes*.
8. Set the **Include rack** option to *Yes*.
9. In the **Format** field, for the rack, type a value.
10. Set the **Include shelf** option to *Yes*.
11. In the **Format** field, for the shelf, type a value.

Define warehouse locations

1. On the Action Pane, select **Warehouse**.

2. Select **Location Wizard**.
3. Select **Next**.
4. Deselect the **Outbound docks** option
5. Deselect the **Bulk locations** option
6. Select **Next** until you come to the option to select **Finish**.
7. Close the page.
8. Refresh the page.

Warehouse blocking limitations

The Inventory management module doesn't support blocking or closing an entire warehouse for future transactions. As a workaround, you can rename the warehouse to indicate that it shouldn't be used for future transactions. Alternatively, you can block individual locations within the warehouse as needed. For details about blocking specific locations, see Inventory locations.

Maintain bar code types

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure shows you how to set up a new bar code definition which can then be used as part of the picking list report. You can walk through this procedure in demo data company USMF, or using your own data. If you're using USMF you can use the example values that are shown. These tasks would typically be carried out by a warehouse manager.

1. Go to **Bar codes**.
2. Select **New**.
3. In the **Bar code setup** field, type a value.
4. In the **Description** field, type a value.
5. In the **Bar code type** field, select an option. If you're using USMF, you can select *Code 39*.
6. In the **Mask ID** field, specify the bar code mask ID. Bar code masks are used to create bar codes and to quickly identify bar codes that are scanned into a point of sale (POS) system. Learn more in Set up bar code masks.
7. In the **Size** field, enter a number.
8. In the **Maximum length** field, enter a number.
9. Select **Save**.
10. Close the page.
11. Go to **Inventory and warehouse management parameters**.
12. In the **Bar code setup** field, enter or select a value. Select the bar code setup that you created before, but be aware that the bar code format must match the format of the unique identifier for the record type used in the process. For example, for picking routes, the bar code format should match the format of the picking route reference, which is typically a number sequence.
13. Select **Save**.
14. Close the page.

Last updated on 04/10/2025

Check the availability of stock

08/29/2025

This procedure shows you how to check on-hand and physical on-hand inventory for a specific item number. It also shows you how to get supply information related to an item. Physical on-hand inventory is the on-hand inventory that's available (purchased, received, and registered). On-hand inventory includes the available on-hand inventory, but also the inventory that's been ordered and is expected, but not yet received or registered.

If you're using USMF demo data you can use the example values that are shown in this article.

Check on-hand inventory for an item

1. Go to **Inventory management** > **Inquiries and reports** > **On-hand list**.
2. On the **Filters** pane, enter search criteria to find the products and/or locations that you want to look up. For example, if you're using the USMF demo data company, you could set **Item number** to *M9201*.
3. On the **Filters** pane, select **Apply**.
4. On-hand inventory is displayed for your selected criteria.

    - If you want to change the set of columns shown in the list, select **Dimensions** on the Action Pane.
    - To see more information about a listed item, select the item and then choose the type of information you're looking for on the Action Pane.

Check physical on-hand inventory

1. Go to **Warehouse management** > **Inquiries and reports** > **Physical on-hand inventory**.
2. In the **Item number** field, specify the item you're looking for. You can also use the **Site** and **Warehouse** fields to filter the list of items.
3. Select **Refresh** at the right side of the Action Pane.
4. Physical on-hand inventory is displayed. If you want to change the set of columns shown in the list, select **Display Dimensions** on the Action Pane.

Check on-hand inventory by location

1. Go to **Warehouse management** > **Inquiries and reports** > **On-hand by location**.
2. Use the fields at the top of the page to define the site, warehouse, and location you want to look up. For example, if you're using the USMF demo data company, you could set **Warehouse** to *51*.

3. Select **Refresh** at the right side of the Action Pane.
4. Select a row in the **Locations** section to see the on-hand inventory for that location in the **On hand** section. To learn more about an item listed in the **On hand** section, select the item and then choose the type of information you're looking for from the **On hand** section toolbar.

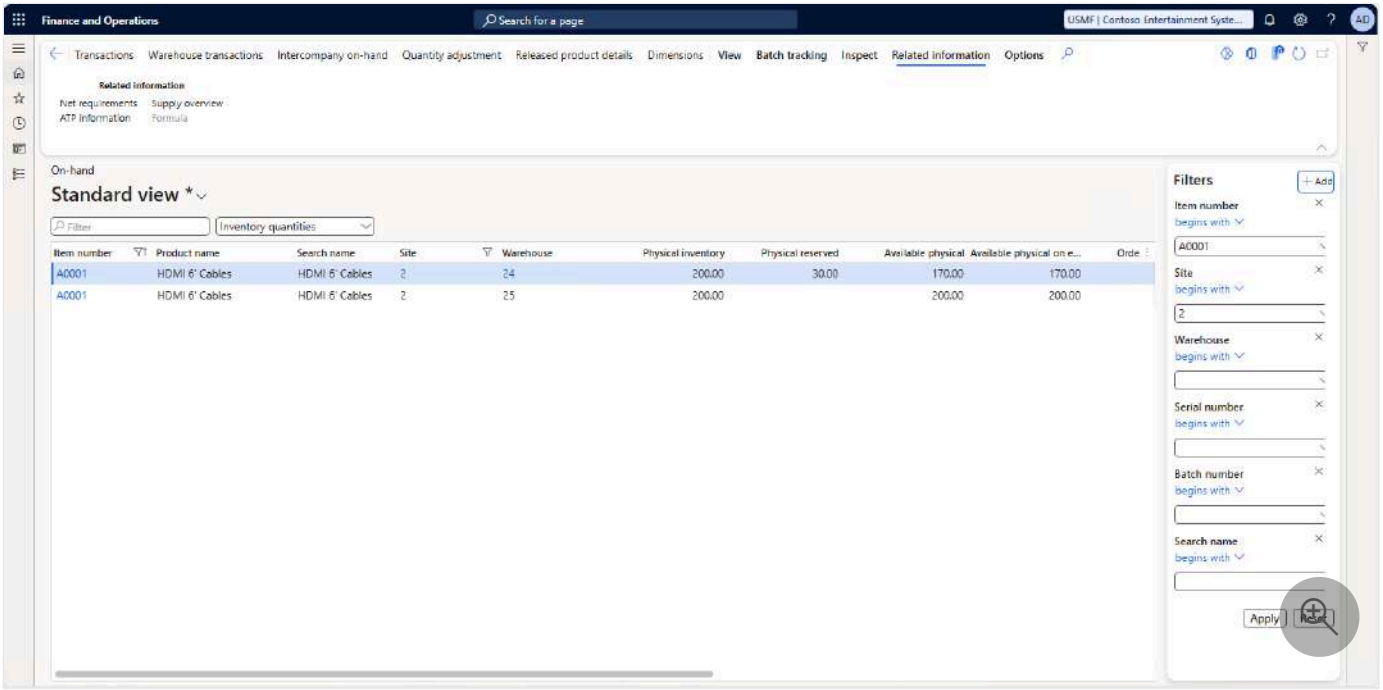
Inventory on-hand list

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to use the **On-hand list** page to inspect on-hand inventory details. Use this page to understand where the goods are, what's available, what's expected, and what's reserved for use.

The on-hand inventory list provides a summarized view of all inventory and warehouse transactions in your system. On the **On-hand list** page, you can filter by dimension values (product, storage, and/or tracking dimensions) and break down output values by dimension values. The values that are shown on the page change based on the filter and display dimensions that you set. This article shows a few of the ways that the various filtering and output options work together, and how they affect the results that are presented.

In addition, you can inquire about the inventory and warehouse transactions to get an explanation of the values in the list, change the on-hand values, and find related information.



Query your on-hand inventory

The **On-hand list** page is automatically updated when transactions are made in inventory. Those transactions might be forecasted, physical, or financial transactions.

To check the availability of inventory, follow these steps:

1. Go to **Inventory management** > **Inquiries and reports** > **On-hand list**.

2. In the **Filters** pane, specify the product and locations that you want to view on-hand information for. Add filters as needed by using the **Add** button. To remove filters, use the **Remove** (**X**) button. Select **Apply** to view the results. The more filters you specify, the more specific the on-hand results are. Therefore, you see fewer rows and/or lower on-hand values.

3. On the Action Pane, select **Dimensions** to open the **Dimensions display** dialog box, where you can specify the dimensions that are used to present your on-hand inventory. The more dimensions you specify, the more granular the results are. For example, if you add the **Location** storage dimension, a **Location** column is added to the grid, and the results are expanded. Instead of showing one row per warehouse, they now show one row per warehouse location.

   > **Tip**
   >
   > - You can save the set of dimensions that you use most often. The **On-hand list** page then automatically shows those dimensions each time that you open it. To save a dimension set, set the **Save setup** option to *Yes* in the **Dimensions display** dialog box before you close it.
   > - The on-hand information is easiest to understand when the dimensions that are shown align with the filters that you're using. Use the **examples** later in this article to understand how different combinations of filters and dimensions lead to different results.
   > - You can further filter the results by using the **Filter** field at the top of the grid and the dropdown lists in the column headers. Unlike the **Filters** pane, these filters apply only to the presentation of results. They don't change the result values.

The **On-hand** grid provides the following columns of inventory information.

Expand table

Column	Description
Physical inventory	The physical quantity that's available in inventory.
Physical reserved	The total quantity that was physically reserved.
Available physical	The available (not reserved) quantity that's available in physical inventory. **Available physical** is a calculated field. The value equals the **Physical inventory** value minus the **Physical reserved** value.
Available physical on exact dimensions	The available physical quantity for all the dimensions that are shown in the grid.
Ordered in total	The total quantity that's included on inbound orders or that has a positive quantity in various inventory journals.
On order	The total quantity that's included on outbound orders or that has a negative quantity in various inventory journals.
Ordered reserved	The total quantity that's reserved on ordered receipts. The value in this field represents the total quantity of items in outbound transactions that have a status of *Ordered reserved*. Items that are reserved as ordered aren't physically available in inventory. Therefore, they can't be directly picked and delivered.
Available for reservation	The total quantity of on-hand inventory that can be reserved. **Note:** If the **Reserve ordered items** checkbox is selected on the **Inventory and warehouse management parameters** page, the value in this field includes expected receipts. If the checkbox is cleared, the value excludes expected receipts.
Total available	The total available quantity. **Total available** is a calculated field. The value equals the **Available physical** value plus the **Ordered in total** value minus the **On order** value.

Apply filters to scope on-hand calculations to items and dimensions you're looking for

Use the **Filters** pane to filter the on-hand inventory list so that it includes only records where the field values match the filtering criteria. To define a filter, follow these steps:

1. In the **Filters** pane, find the field that you want to filter on.
2. In the field below the name of the target field, select a logical operator (for example, *starts with*, *equal to*, or *greater than*).
3. Enter or select the value to look for.

> **Important**
>
> The **On-hand list** page is assembled from a detailed on-hand inventory table that includes all available dimensions. However, the list on this page is a summary. Therefore, it might combine rows from the source table by aggregating values according to the dimensions that are shown.
>
> The filters that you define in the **Filters** pane apply to the source table, not to the aggregated list. This behavior can sometimes produce unexpected results. Use the **examples** later in this article to understand how this behavior can affect your results.
>
> However, the **filters that are provided in the grid** *do* apply to the aggregated list. These filters include both the QuickFilter at the top of the grid and the filter for each column heading.

You can modify the set of filters that is available in the **Filters** pane by following these steps.

- To remove a filter from the pane, select its **Close** button (**X**).
- To add a filter, select **Add** at the top of the **Filters** pane. The **Add filter fields** dialog box that appears shows a list of the available fields. It also shows information about the data type and table for each field. Use the column headings to filter and sort the list as you require, and then select the checkbox for each field that you want to add to the **Filter** pane. When you finish, select **Insert** to apply your changes.

Select the dimensions you want on-hand results for

Dimensions provide more information about each item in the on-hand inventory list. They also give you more ways to sort and filter the list. The dimensions that you select to show affect how rows are aggregated on the **On-hand list** page. This aggregation can affect how rows from the source tables are combined in the results that are shown. Use the examples later in this article to understand how this behavior can affect your results.

To customize the selection of inventory dimensions that is shown, follow these steps:

1. On the Action Pane, select **Dimensions**.

   The **Dimension display** dialog box that appears shows every dimension.

2. Select the checkbox for each dimension that you want to include in the grid.

3. If you want your selection to be the default the next time you open the **On-hand list** page, set the **Save setup** option to *Yes*. If you set this option to *No*, your selection is used only during the current session. Therefore, the next time you open the page, the current default selection is used.

4. Select **OK** to close the dialog box and apply your changes.

Investigate and act on the on-hand information

The on-hand information on the **On-hand list** page is aggregated based on the filters and dimensions that you specify. In SQL terms, filters control the `WHERE` clause of the on-hand calculation, and dimensions control the `GROUP BY` clause. These clauses control how many records and columns are shown in the on-hand list. Nevertheless, you might still need to further inspect a specific value in the on-hand information.

To learn more about the transactions that participated in the on-hand calculation, follow these steps:

1. On the Action Pane, select **Transactions**. The Inventory transactions page appears. The same filters and dimensions that you used in the on-hand list are applied to this page.
2. On the Action Pane, select **Warehouse transactions**. The Warehouse transactions page appears. The same filters and dimensions that you used in the on-hand list are applied to this page.

Inspect the Action Pane to find useful actions that are related to your on-hand inventory. For example, you can perform the following actions:

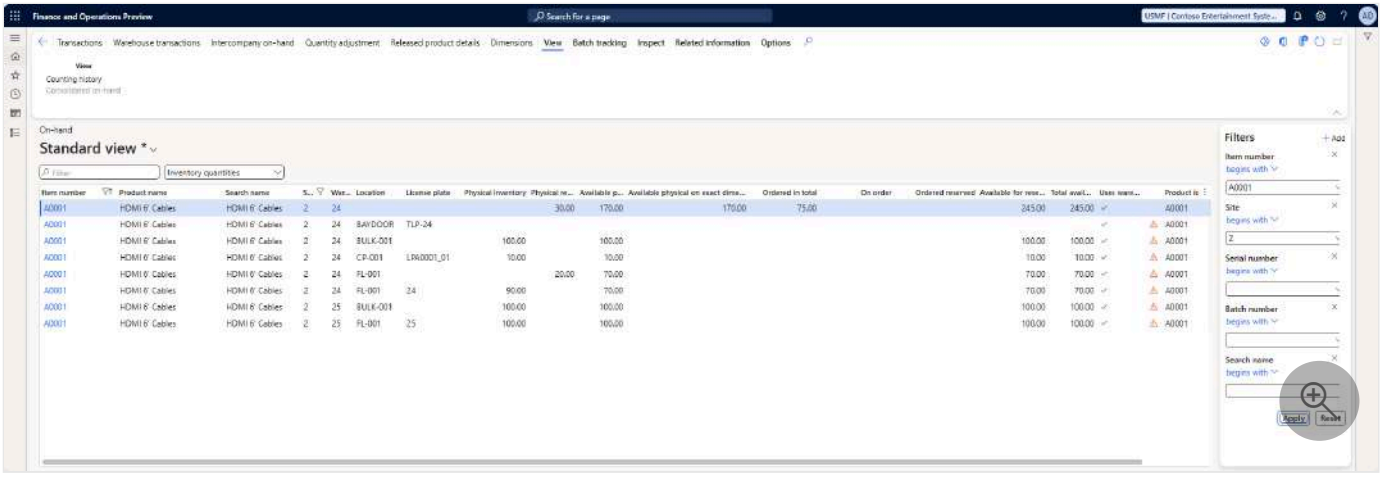
- Update your on-hand quantity by selecting **Quantity adjustment**.
- Investigate on-hand inventory in other companies by selecting **Intercompany on-hand**.

Understand on-hand information for warehouse-enabled items

On the **On-hand list** page, items that are enabled for warehouse management processes (WMS) differ from non-WMS items in the following ways:

- A check mark in the **Uses the warehouse management process** column indicates WMS-enabled items. They also show helpful warnings. You can learn more about each warning by hovering over it.

- For both WMS-enabled items and non-WMS items, values in the physical inventory columns follow the same aggregation principles of filtering and requested dimensions. The value is placed on the most specific storage dimension. In the example that follows this list, **Physical inventory** is shown per license plate, except in the case of location *BULK-001* in Warehouse *24* (in row 7), because that location isn't license plate–enabled.
- Values that are shown for **Physical reserved** work differently for WMS-enabled items and non-WMS items. Because WMS-enabled items use reservation hierarchies, **Physical reserved** values are presented at the hierarchy level that is associated with the item. Therefore, in the example that follows this list, additional rows 1 and 5 are added next to rows that represent **Physical inventory** values. Different processes reserve at different levels. In the example, row 1 is related to sales process reservations that are made at the warehouse level, whereas row 5 is related to a counting operation.
- The list might include empty rows (such as row 2 in the example that follows this list). These rows indicate that there's currently no on-hand inventory, related reservation, or related order on the dimension, but there was in the past.



Filter on the output of the inventory on-hand list

Several columns in the **On-hand** grid let you sort or filter by values in that column by selecting the column heading. A QuickFilter at the top of the grid provides additional filtering options. These filters apply to the results, not to the source tables. Use the examples later in this article to understand how this behavior can affect your results.

> **Note**
>
> You can't filter and sort by all columns. Most of the quantity columns don't include sorting and filtering controls, because they're calculated fields. The **On order** column is an exception.

Examples

Your system includes a detailed (non-aggregated) inventory table that shows the following on-hand inventory.

Expand table

Item Number	Site	Warehouse	Physical Inventory	Available Physical
IA0001	1	1	1	1
IA0001	1	2	2	2
IA0001	1	3	1	1

Scenario 1

The **On-hand list** page shows the following final dimensions:

- Item number
- Site
- Warehouse

In the **Filters** pane, set up the following filtering criteria:

- **Item Number** | *is exactly* | *IA0001*
- **Available Physical** | *less than or equal* | *1*

Here's the resulting output.

Expand table

Item Number	Site	Warehouse	Physical Inventory	Available Physical
IA0001	1	1	1	1
IA0001	1	3	1	1

Scenario 2

The **On-hand list** page shows the following final dimensions:

- Item number
- Site

In the **Filters** pane, set up the following filtering criteria:

- **Item Number** | *is exactly* | *IA0001*
- **Available Physical** | *less than or equal* | *1*

Here's the resulting output.

Expand table

Item Number	Site	Physical Inventory	Available Physical
IA0001	1	2	2

The settings in the **Filters** pane apply to the detailed (non-aggregated) inventory table that is shown at the beginning of this section. Therefore, the criterion **Available Physical** | *less than or equal* | *1* finds two rows from that table (the first and third rows, each of which shows an **Available Physical** value of *1*). However, in this scenario, the **On-hand list** page isn't set up to show the **Warehouse** dimension. Therefore, it aggregates the two original rows into a single resulting row, because both rows have identical values in all the dimensions that are shown. This row appears to violate the filtering criterion, because the **Available Physical** value is shown as *2*. However, the result is correct, because the settings in the **Filters** pane apply to the source table, not to the aggregated table that is shown on the **On-hand list** page.

Last updated on 06/15/2026

Inventory transaction details

Use the **Transactions details** page to view details of any selected inventory transaction.

> **Tip**
>
> Many transactions and updates are categorized as being either *physical* or *financial*. You can learn more about these categories in Physical and financial updates.

Inventory transactions page performance improvement

Supply Chain Management version 10.0.39 introduced the *Inventory transaction details page's performance improvement* feature, which improves the performance of the **Inventory transactions** page. As of version 10.0.43, this feature is turned on by default. As of Supply Chain Management version 10.0.45, it's mandatory and can't be turned off.

To allow the **Inventory transactions** list page to load more quickly, it now provides a **Filters** pane that lets you limit the sets of transactions listed. The next time you open the page, it will remember your last-used filter settings. The page won't list any transactions until you select **Apply** on the **Filters** pane. In addition, the page now shows only inventory-related fields.

> **Important**
>
> The *Inventory transaction details page's performance improvement* feature changes the form used to create the **Inventory transactions** page from `InventTrans` to `InventTransNew`. The feature also changes the navigation so that the new form opens when you go to **Inventory management** > **Inquiries and reports** > **Transactions** (which now opens a URL that resembles `https://contoso.operations.dynamics.com/?cmp=usmf&mi=InventTransNew`). This same form also creates the **Transaction details** page. After upgrading to a version of Supply Chain Management that has this feature turned on, you must reproduce any customizations that you made to the old form on the new form.

Open the Transaction details page

To open the **Transactions details** page, follow these steps.

1. Go to **Inventory management** > **Inquiries and reports** > **Transactions**.

2. The **Inventory transactions** page opens. Find and select the transaction that you want to inspect.
3. On the **Filters** pane, set filters to narrow down the list of inventory transactions and then select **Apply**.
4. On the Action Pane, select **Transaction details**.

FastTabs overview

The **Transaction details** page is split into several FastTabs. The following table describes the purpose of each FastTab.

Expand table

FastTab	Description
General	This FastTab shows basic information about the selected inventory transaction. In addition to the fields that appear on the **Inventory transactions** page, it includes the additional fields that are described later in this article.
Updates	This FastTab shows information that is related to the physical, financial, and settlement aspects of the selected inventory transaction. Depending on the current status of the transaction, some fields might be blank. However, those fields will automatically be set when transactions are posted. In addition to the fields that appear on the **Inventory transactions** page, this FastTab includes the additional fields that are described later in this article.
Ledger postings	This FastTab shows the posting type and ledger account that are used for the physical update, financial update, physical revenue, physical charges, financial revenue, and financial charges that are related to the selected inventory transaction.
References	This FastTab shows additional information about the source transaction that created the selected inventory transaction. For example, this information might include details from the purchase order or sales order.
Related information	This FastTab shows additional information about the selected inventory transaction. These fields might not be set if you aren't using some features, such as procurement categories or projects.
Financial dimensions – physical	This FastTab shows the financial dimension values that were used when the physical update was posted. If the physical update hasn't been posted, the fields will be blank.
Financial dimensions – financial	This FastTab shows the financial dimension values that were used when the financial update was posted. If the financial update hasn't been posted, the fields will be blank.
Inventory dimensions	This FastTab shows the inventory dimension values that are assigned to the selected inventory transaction. These values include the site, warehouse, size, color,

FastTab	Description
	configuration, location, batch number, serial number, inventory status, license plate, and owner.

Fields on the General FastTab

The following table describes the fields on the **General** FastTab that don't also appear on the **Inventory transactions** page.

Expand table

Field	Description
Party	The name of the relevant party for the selected inventory transaction. For example, a purchase order transaction shows the name of the vendor on the purchase order, and a sales order transaction shows the name of the customer. This field isn't available for all types of inventory transactions.
Inventory reference	If another inventory transaction is related to the selected inventory transaction, the type of that other transaction. For example, if a purchase order is marked against a sales order, the **Inventory reference** field of the purchase order transaction will be set to *Sales order*. Marking automatically occurs for direct delivery orders and intercompany orders. When you use marking with costing methods other than *standard cost* and *moving average*, the system will create settlements and adjustments to the exact transactions that are marked. In this way, you can achieve "actual" costing that overrides the logic for first in, first out (FIFO); last in, first out (LIFO); or weighted average.
Inventory number	The specific transaction that is related to the selected inventory transaction. For example, if a purchase order is marked against a sales order, the **Inventory number** field of the purchase order transaction will be set to the sales order number.
Project ID	If the selected inventory transaction is related to a project, this field is set to the project number.
Lot ID	The unique lot ID that the system has assigned to the selected inventory transaction.
Reference lot	If another inventory transaction is related to the selected inventory transaction, the lot ID of that other transaction. For example, if a purchase order is marked against a sales order, the **Reference lot** field of the purchase order transaction will be the **Lot ID** value of the sales order line's inventory transaction.
Dimension number	A unique ID that represents the combination of all the inventory dimension values that are assigned to the selected inventory transaction.
Value open	A value that indicates whether the selected inventory transaction has been settled by the inventory closing process. If this field is set to *Yes*, the transaction hasn't been settled.

Field	Description
Expected date	For receipt transactions, the date when the inventory receipt is expected to occur. For example, this field might show the expected receipt date on an inventory blocking order or the delivery date on a purchase order line.
Inventory date	This field is set when a registration transaction was done on the receipt order before a physical receipt was posted.
Non-financial transfer	A value that indicates whether the selected inventory transaction is a non-financial transfer. A non-financial transfer occurs when a change in inventory dimensions isn't financially tracked on the **Item model group** page.
Transfer lot ID	If the selected inventory transaction is a non-financial transfer, this field is set to the **Lot ID** value of the other inventory transaction that the selected transaction is settled against.

Fields on the Updates FastTab

The following table describes the fields on the **Updates** FastTab that don't also appear on the **Inventory transactions** page.

Expand table

Field	Description
Physical voucher	The voucher number from the general ledger where the physical posting for the selected inventory transaction was generated.
Route	The route that is related to the selected inventory transaction. This field is set only for production picking list transactions where the bill of materials (BOM) or formula line is related to a specific item.
Packing slip	The packing slip number that was entered for a purchase order product receipt transaction.
Physical cost amount	The amount that was posted to the general ledger for the physical update. For a standard cost product, this amount represents the standard cost. For other costing methods, it represents the weighted average for the product at the time of posting.
Physical revenue	The amount of deferred revenue that was posted to the general ledger for the physical update.
Load ID	If the current transaction is related to a load in Transportation management, this field shows the unique number of the load that included the item.
Physically posted	A value that indicates whether the selected inventory transaction has been physically posted. If the current transaction is posted to the general ledger, there will also be a physical voucher.

Field	Description
Financially posted	A value that indicates whether the selected inventory transaction has been financially posted. If the current transaction is posted to the general ledger, there will also be a financial voucher.
Physical charge posted	A value that indicates whether the physical charges that are related to the selected inventory transaction have been posted.
Financial charge posted	A value that indicates whether the financial charges that are related to the selected inventory transaction have been posted.
Financial voucher	The voucher number in the general ledger where the financial posting was generated.
Invoice	The invoice number that was generated, for example, for a purchase order or sales order.
Adjustment	The amount that was adjusted on the selected inventory transaction from the inventory close and adjustment process.
Profit and loss, posted amount	The amount of the selected inventory transaction that was posted to the profit and loss statement.
Unposted invoice	The invoice number of a related purchase order that appears on the **Pending vendor invoice** page.
Financially closed	The date when the transaction was fully settled.
Covered CW quantity	The catch weight quantity that is covered by the settlement.
Settled quantity	The quantity that has been settled for the selected inventory transaction.
Amount settled	The value that has been settled for the selected inventory transaction.

Initialize stock levels in the warehouse

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure shows you how to manually update the on-hand inventory by using an Inventory movement journal. (You can also update on-hand inventory by importing transactions in data entities.) You can run this guide in demo data company *USMF* where all the prerequisites like journal name, item setup, posting profiles, and accounts are available. The guide suggests specific values for the item and dimensions that are used. If you choose a different item, you might need to enter values for different dimensions.

1. Go to **Inventory management** > **Journal entries** > **Items** > **Movement**.
2. Select **New**.
3. In the **Name** field, select *IMov*. Use different journal name templates for different business purposes.
4. In the list, select the link in the selected row.
5. In the **Offset account** field, enter the value *140200*. This offset account is the default account on the journal lines. You can override the default to assign different offset accounts per line.
6. Select **OK**.
7. Select **New**.
8. In the **Item number** field, select *A0001*.
9. In the list, select the link in the selected row.
10. Select the **Inventory dimensions** tab.
11. In the **Site** field, select site *1*.
12. In the **Warehouse** field, select warehouse *13*.
13. In the list, select the link in the selected row.
14. In the **Location** field, select location *13*.
15. In the **Quantity** field, enter a number.
16. Select **Save**.
17. Select **Post**.
18. Check or uncheck the **Transfer all posting errors to a new journal** check box. If you enable this option, any lines that fail to post are copied to a new journal. You can use the information in the log to correct the issues and then re-post the lines.
19. Select **OK**.

20. Close the page.
21. Close the page.

Link transfer order lines with sales order lines

Microsoft Dynamics 365 Supply Chain Management lets you create transfer order lines directly from sales order lines. This functionality is useful when the goods that you must supply are located in a different warehouse than the warehouse that you're shipping from.

The feature described in this article expands on that functionality by linking and marking the related transfer and sales order lines together. This link makes it easier to track the relationship between the sales and transfer orders, and helps you manage your inventory more effectively. The feature adds the following capabilities and benefits:

- View all transfer orders that were generated for a specific sales order line.
- View all sales orders that are related to a specific transfer order line.
- When transfer lines are created from a sales order, you can choose to add them either to an existing transfer order or to a newly created transfer order.
- You receive a warning if you try to create multiple transfer orders for the same sales order line.
- Automatically mark new transfer order lines with their related sales order line. Marking matches specific inventory receipts (transfer order line inventory transactions) with inventory issues (sales order line inventory transactions) for the purpose of inventory costing.
- Automatically reserve transfer order quantities for the sales order that they were created from. In this way, you prevent them from being used to fulfill another sales order by mistake.

Prerequisites

Before you can use the feature described in this article, your system must meet the following requirements:

- You must be running Dynamics 365 Supply Chain Management version 10.0.41 or later.
- The feature named *Pair transfer order lines with sales order lines* must be turned on in Feature management.

Add and link lines to a new or existing transfer order from a sales order

To create transfer order lines directly from sales order lines, link the lines together, and (optionally) reserve the transferred inventory, follow these steps:

1. Go to **Sales and marketing** > **Sales orders** > **All sales orders**.
2. Open the sales order for which you want to add lines to a transfer order.
3. On the **Sales order lines** FastTab, select the lines that you want to add to the transfer order.
4. On the toolbar of the **Sales order lines** FastTab, select **Product and supply** > **New** > **Transfer order**.
5. In the **Transfer order** dialog box, set the following fields:
    - **From warehouse** – Select the warehouse that the items should be transferred from (source warehouse).
    - **To warehouse** – Select the warehouse that the items should be transferred to (destination warehouse). This warehouse is the one that is associated with the sales order line. It should be selected by default.
    - **Add to an existing transfer order** – If you want to add the items to an existing transfer order, select the transfer order in the list. The list shows only open transfer orders that use the source and destination warehouses that are selected in this dialog box. If you want to create a new transfer order, leave this field blank.
    - **Ship date** – The date when the items should be shipped.
    - **Reserve items automatically** – If you want the items in the source warehouse to be reserved automatically for the transfer order, set this option to *Yes*.
6. Select **OK**.

The new or selected transfer order opens. You can now view the transfer order lines and other details.

View transfer order lines related to a sales order

When you review sales orders, you can confirm whether the required transfer order lines exist for each sales order line.

1. Go to **Sales and marketing** > **Sales orders** > **All sales orders**.

2. Open the sales order that you want to review.

3. On the **Sales order lines** FastTab, on the toolbar, select **Product and supply** > **View** > **Related transfer orders**.

4. On the **Paired transfer order and sales order lines** page, you can review the following information about all the transfer order lines that are linked to the selected sales order:

    - **Item number** – The item number of product on the sales order line and the transfer order line. Select the link to view the item details.
    - **Sales order** – The identifier of the sales order. Select the link to open the sales order.
    - **Line number** – The line number of the sales order line.
    - **Sales quantity** – The sales quantity of the sales order line.
    - **Transfer number** – The identifier of the transfer order. Select the link to open the transfer order.
    - **From warehouse** – The source warehouse of the transfer order.
    - **To warehouse** – The destination warehouse of the transfer order. This warehouse is also the warehouse for the related sales order line.
    - **Line number** – The line number of the transfer order line.
    - **Transfer quantity** – The transfer quantity of the transfer order line.
    - **Ship date** – The ship date of the transfer order line.
    - **Receive date** – The receipt date of the transfer order line.
    - **Remaining** – The remaining status of the transfer order line. Possible values include *Nothing*, *Receive updates*, and *Shipping updates*.

5. To view more information about a selected line, select one of the following buttons on the Action Pane:

    - **Sales order line transactions** – View all inventory transactions that are related to the sales order line.
    - **Transfer order line transactions** – View all inventory transactions that are related to the transfer order line.

View sales orders related to a transfer order line

When you review transfer orders, you can check whether they contain lines that are related to a specific sales order. This process helps you understand the context of the transfer order and why it was created.

1. Follow one of these steps:

- Go to **Inventory management** > **Inbound orders** > **Transfer order**.
- Go to **Inventory management** > **Outbound orders** > **Transfer order**.

2. Open the transfer order that you want to review.
3. On the **Transfer order lines** FastTab, select the line that you want to view the related sales order for.
4. On the toolbar of the **Transfer order lines** FastTab, select **Inventory** > **Related sales order**.
5. On the **Paired transfer order and sales order lines** page, you can review information about the sales order line that is related to the selected transfer order line. The grid columns and Action Pane buttons are the same as the ones that are described in the previous section.

Automatic marking between sales and transfer order lines

Marking matches specific inventory receipts (transfer order line inventory transactions) with inventory issues (sales order line inventory transactions) for the purpose of inventory costing. When you create a transfer order line from a sales order line, the system automatically marks the two lines together, but only if they're for *nonsettled items*.

> **Important**
>
> Nonsettled items are items from transactions that haven't been matched or processed according to the inventory model that you're using. Examples of inventory models include standard cost, moving average, and non-valuated. Automatic marking isn't supported for settled items. It also isn't supported for catch-weight items. For settled and catch-weight items, you must do the marking manually.

To view and edit markings from a sale order line, follow these steps:

1. Go to **Sales and marketing** > **Sales orders** > **All sales orders**.
2. Open the sales order that you want to review.
3. On the **Sales order lines** FastTab, select the line that you want to view the marking for.
4. On the toolbar of the **Sales order lines** FastTab, select **Inventory** > **Maintain** > **Marking**.
5. The **Marking** dialog box shows the marked quantities. You can edit the markings as required.

To view and edit markings for a specific inventory transaction, follow these steps:

1. Go to **Sales and marketing** > **Sales orders** > **All sales orders**.
2. Open the sales order that you want to review.
3. On the **Sales order lines** FastTab, select the line that you want to view transactions for.
4. On the toolbar of the **Sales order lines** FastTab, select **Inventory** > **View** > **Transactions**.
5. On the **Inventory transactions** page, select the transaction that you want to inspect. You can inspect both shipment transactions and receipt transactions.
6. On the Action Pane, on the **Inventory** tab, in the **View** group, select **Marking**.
7. The **Marking** dialog box shows the marked quantities. You can edit the markings as required.

To view and edit markings from a transfer order line, follow these steps:

1. Follow one of these steps:

    - Go to **Inventory management** > **Inbound orders** > **Transfer order**.
    - Go to **Inventory management** > **Outbound orders** > **Transfer order**.

2. Open the transfer order that you want to review.

3. On the **Transfer order lines** FastTab, select the line that you want to view the related sales order for.

4. On the toolbar of the **Transfer order lines** FastTab, select **Inventory** > **Transactions**.

5. On the **Inventory transactions** page, select the transaction that you want to inspect.

6. On the Action Pane, on the **Inventory** tab, in the **View** group, select **Marking**.

7. The **Marking** dialog box shows the marked quantities. You can edit the markings as required.

Automatically reserve transferred items for their matching sales orders

You can automatically reserve transfer order quantities for the sales order that they were created from. This reservation prevents these quantities from being used to fulfill another sales order by mistake. For this functionality to work, the following conditions must be met:

- The **Reserve items automatically** option must be set to *Yes* when the transfer order line is created from the sales order line.

- The inventory transactions for the related sales order line and transfer order line must be marked together automatically. (Automatic marking is supported only for nonsettled items.)

If the preceding conditions are met, the transferred stock is automatically reserved against the sales order line when it's received. In this case, the inventory transaction record that is created for the sales order line has an issue status of *Reserved ordered*, and the reservation is triggered.

If the conditions aren't met, the transferred stock isn't automatically reserved against the sales order line. In this case, the inventory transaction record that is created for the sales order line has an issue status of *On order*.

Transfer physical inventory within the warehouse

This procedure shows how to create and post an inventory transfer journal to register movement of an item from one location in a warehouse to another. Before you start, set up an inventory journal name for inventory transfers. You can follow this procedure in the demo data company USMF using the example values that are shown, or you can use your own data if you have products and locations set up. A warehouse employee normally carries out these tasks.

Create an inventory transfer journal

1. Go to **Inventory management** > **Journal entries** > **Items** > **Transfer**.
2. On the Action Pane, select **New**.
3. In the **Name** field, enter or select a value.
4. Select **OK**.

Create journal lines

You can specify *From* and *To* dimensions for each journal line. These dimensions are essential for this journal type. You can transfer items to locations by using different rules. In this example, you transfer an item within the same warehouse, from a license plate controlled location to a location that isn't license plate controlled.

1. On the **Journal lines** FastTab, select **New**.
2. In the **Item number** field, enter or select a value. If you're using USMF, select *A0001*.
3. In the **From site** field, enter or select a value. If you're using USMF, select *2*.
4. In the **To site** field, enter or select a value. If you're using USMF, select *2*.
5. In the **From warehouse** field, enter or select a value. If you're using USMF, select *24*.
6. In the **To warehouse** field, enter or select a value. If you're using USMF, select *24*.
7. In the **From location** field, enter or select a value. If you're using USMF, select *FL-001*.
8. In the **To location** field, enter or select a value. If you're using USMF, select *BULK-001*.
9. In the **Quantity** field, enter a number.
10. On the **Line details** FastTab, select the **Inventory dimensions** tab.
11. In **From inventory dimensions**, in the **License plate** field, enter or select a value. If you're using USMF, select *24*.
12. Select **Save**.

Post the inventory transfer journal

1. On the Action Pane, select **Post**.
2. Select **OK**.

View inventory transactions

To see the transactions that were created when you posted your journal, follow these steps:

1. On the **Journal lines** FastTab, select the line you want to inspect.
2. On the **Journal lines** FastTab toolbar, select **Inventory** > **Transactions**.

Adjust stock levels in the warehouse (basic warehousing)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure walks you through the process of creating and posting an inventory adjustment journal in order to adjust stock levels of products in the warehouse. You need to have an inventory journal name set up for inventory adjustments before you start this. You can walk through this procedure in demo data company USMF, or using your own data. These tasks would normally be carried out by a warehouse employee.

Create an inventory adjustment journal

1. Go to **Inventory management** > **Journal entries** > **Items** > **Inventory adjustment**.
2. Select **New**.
3. In the **Name** field, select the drop-down button to open the lookup.
4. In the list, select on the inventory adjustment journal name you want to use. Some other fields are populated based on the setup of the inventory adjustment journal name you select.
5. Select **OK**.

Create journal lines

1. Select **New**.
2. In the list, mark the item number field.
3. In the **Item number** field, select an item. If you're using demo data company USMF, type *D0001*.
4. In the **Site** field, select the drop-down button to open the lookup.
5. In the list, select a site.
6. In the **Warehouse** field, select the drop-down button to open the lookup.
7. In the list, select a warehouse. If you selected an item with location as a mandatory dimension, you must specify the location here.
8. In the **Quantity** field, enter a number. The cost price field specifies the cost per unit for inventory receipts. If the cost isn't specified for the item number or if you wanted to

change it manually, you would do this here.

Validate and post the inventory adjustment journal

1. Select **Validate**.
2. Select **OK**.
3. Select **Post**. When you post this kind of journal, an inventory receipt or issue is posted, the inventory level and value are changed, and ledger transactions are generated.
4. Select **OK**.
5. Close the form.
6. Close the page.

Inventory tag counting

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides information about tag counting, which you use to compare the actual contents of a warehouse with the on-hand inventory.

By creating lines on the **Tag counting** page, you place a tag number on each inventory item, such as a number from 1 to 500. During the count, you enter the item number and the quantity on a corresponding tag. This tag can then be used as the basis for input in the tag counting journal.

After you post the tag counting journal, a new counting journal is created on the **Counting** page. The new journal is based on the tag counting journal lines that you created.

To tag-count items by a specific inventory dimension, select the dimension on the **Display dimension** page that is displayed when you create the tag counting journal. For example, to count items in a specific warehouse, select the **Warehouse** check box. If **Lock items during count** on the **General** tab of the **Inventory and warehouse management parameters** page is set to *Yes*, items can't be physically updated during counting. However, items in tag counting journals aren't locked during counting. Inventory transactions aren't created until the tag counting lines are posted and transferred to a counting journal. If tags are entered randomly, and you want to identify missing tags, select the **Tag** column header to sort the lines by tag.

Count inventory in a warehouse

This article describes the process of creating and posting an inventory counting journal to count a specific item at a location in the warehouse. The procedure applies to the Inventory management module when you're not using warehouse management processes (WMS). The procedure doesn't apply to WMS-enabled warehouse functionality that's available in the Warehouse management module. You can walk through this procedure in the demo data company USMF, or use your own data. If you use your own data, make sure that you set up products and locations, and create an inventory journal name for counting journals. A warehouse employee normally performs inventory counting.

Create an inventory counting journal

1. Go to **Inventory management** > **Journal entries** > **Item counting** > **Counting**.
2. Select **New**.
3. In the **Name** field, select the inventory counting journal name you want to use from the drop-down list. Some other fields are populated based on the setup of the inventory counting journal name that you select.
4. In the **Worker** field, select the drop-down button to open the lookup.
5. In the list, **Select** the worker you want to use.
6. Select **OK**.

Create journal lines

1. Select **New**.
2. In the **Item number** field, select the desired record from the drop-down list. If you're using demo data company USMF, select *A0001*.
3. In the **Site** field, select the desired record from the drop-down list. If you're using demo data company USMF, select site *2*.
4. In the **Warehouse** field, select the desired record from the drop-down list. If you're using demo data company USMF, select warehouse *24*.
5. In the **Location** field, select the desired record from the drop-down list. If you're using demo data company USMF, select location *BULK-001*.
6. In the **Counted** field, enter a number. If you enter a counted number that's different from the number shown in the **On-hand** field, the **Quantity** field is updated to show the discrepancy.

7. Select **Save**.

Post the inventory counting journal

1. Select **Post**. When you post an inventory counting journal, if the counted amount differs from the amount that's reported in the **On-hand** field, an inventory receipt or issue is posted. The inventory level and value change, and ledger transactions are generated.
2. Select **OK**.

View inventory transactions

1. Select **Inventory**.
2. Select **Transactions**. You can see related transactions that are created when you post your inventory counting journal.

This article describes how to configure basic inventory counting processes by creating a counting group and a counting journal. It also shows you how to enable counting policies at the warehouse and item levels.

For more information about advanced warehouse scenarios, see Cycle counting.

Create a counting group

1. Go to **Inventory management** > **Setup** > **Inventory** > **Counting groups**.
2. Select **New**.
3. In the **Counting group** field, enter a value.
4. In the **Name** field, type a value.
5. In the **Counting code** field, choose one of the following values:
    - *Manual* – Add lines to the counting journal every time you run the job. In other words, you decide the counting interval for the counting group.
    - *Period* – Add lines to the counting journal according to the period interval set in the **Counting period** field. When you choose this option, the job for creating new lines in the counting journal adds them only at the specified interval, regardless of how often you run the job. For example, suppose **Counting period** is set to *7* and counting journal lines were last generated on January 1. If another job is started on January 5, then no lines are generated in the counting journal because seven days haven't passed. However, if you start the job again on January 8, then lines are generated because seven days have passed.

- *Zero in stock* – If on-hand inventory reaches zero (0), generate lines in the counting journal when the job is run. If the on-hand inventory reaches 0 after a count, lines are generated the next time that you start the count.
- *Minimum* – Insert lines in the counting journal if the on-hand inventory is equal to or less than the minimum that is specified.

6. If you set **Counting code** to *Period*, enter the period interval (in days) in the **Counting period** field.

7. Select **Save**.

Create a counting journal name

1. Go to **Inventory management** > **Setup** > **Journal names** > **Inventory**.

2. Select **New**.

3. In the **Name** field, type a value.

4. In the **Description** field, enter a value.

5. In the **Journal type** field, select *Counting*.

6. In the **Voucher series** field, select the number sequence to use for generating voucher IDs for new counting journals.

7. In the **Detail level** field, select the level of detail to apply when posting the journal.

8. In the **Reservation** field, choose the method used to reserve items during counting. Choose one of the following values:

   - *Manual* – The items are reserved manually on the **Reservation** page.
   - *Automatic* – The order quantity is reserved from the available on-hand inventory for the item.
   - *Explosion* – The reservation is part of the master planning of the transaction.

9. Select **Save**.

Set standard counting journal name

1. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**.

2. Open the **Journals** tab.
3. In the **Counting** field, select the journal you created for this purpose. This journal name is the default for inventory journals of the *Counting* type.
4. Open the **General** tab. If you want to lock items during the counting process to prevent updates for packing slips, picking lists, or picking list registrations, set **Lock items during count** to *Yes*. Otherwise, set it to *No*.

Set the counting policy for an item

1. Go to **Product information management** > **Products** > **Released products**.
2. Open the item that you want to set counting policies on. You must select an item that is inventory tracked. Non-stocked products can't be counted.
3. Select **Edit**.
4. Expand the **Manage inventory** FastTab.
5. In the **Counting group** field, assign a counting group. This product is now included when inventory counting journal lines are created by using this counting group.
6. Select **Save**.

Implement advanced counting scenarios

To prevent double-counting mistakes, the system normally only allows items to be part of a single active counting journal at a time. However, if your company processes require it, you can relax this constraint to count items independently per warehouse or turn this integrity check off completely. The following subsections explain how.

Count items independently per warehouse

To set the counting policy to allow items to be counted independently in each warehouse, and ensure that items with identical dimension values can only be included within the same counting journal, follow these steps:

1. Go to **Product information management** > **Products** > **Released products**.
2. Open the item that you want to be counted. You must select an item that is inventory tracked. Non-stocked products can't be counted.
3. On the Action Pane, open the **Manage inventory** tab and, from the **Warehouse** group, select **Warehouse items**.
4. On the Action Pane, select **New**.
5. On the **General** FastTab, set the **Warehouse** field to the warehouse you want to set up specific counting policies for.

6. On the Action Pane, select **Save**.
7. Repeat from step 4 for each warehouse where the item should be counted.
8. Repeat from step 2 for each item that should be counted independently in each warehouse.
9. Go to **Inventory management** > **Journal entries** > **Items counting** > **Counting**.
10. On the Action Pane, select **New**.
11. On the **Overview** FastTab, select the **Site** and **Warehouse**.
12. On the **Counting by** FastTab, set **Warehouse** to *Yes*.
13. Select **OK** to create the journal.
14. In the newly created counting journal, add items as usual.

Disable counting status registration

To disable counting status registration, which allows duplicate item and dimension combinations to be placed in multiple active counting journals, follow these steps:

1. Go to **Inventory management** > **Setup** > **Journal names** > **Inventory**.
2. Select or create a journal name with a **Journal type** of *Counting*.
3. Set **Counting status registration policy** to *Disable counting status registration*.

This article explains how to use the inbound consignment inventory processes.

Consignment inventory is inventory that a vendor owns but stores at your site. When you're ready to consume or use the inventory, you take over the ownership of the inventory. This article includes information about how to physically receive vendor-owned inventory on hand without creating general ledger transactions, how to start a production process where the vendor-owned inventory can be physically reserved, and how to change the ownership of the raw material to process the consumption as part of the production order processing. It also includes information about how vendors can monitor consumption of their inventory by using the vendor collaboration interface.

Overview of the consignment process

In this example scenario, company USMF has a consignment agreement with vendor *US-104* for the raw material *M9211CI*.

1. A USMF employee manually creates a consignment replenishment order based on the expected demand. The order is created for vendor *US-104* and a line is added for item *MS9211CI*.
2. The vendor is informed about the expected delivery. This notification can happen in one of three ways:

    - Someone working at USMF sends the order information to the vendor.
    - The vendor monitors the expected inventory on-hand by using the vendor collaboration interface.
    - Someone working at USMF filters the data on the **On-hand inventory** page to show only the records for vendor *US-104*, where the receipt status is *Ordered*, and then sends this information to the vendor.

3. The inventory is delivered from *US-104* to USMF.
4. When the material arrives at USMF, the consignment replenishment order is updated with a product receipt. Only the physical quantities of the vendor-owned inventory are recorded. No general ledger transactions are created, because the inventory is still owned by the vendor.
5. The vendor monitors updates to the physical on-hand inventory by using the **On-hand consignment inventory** page.
6. Now that the physical inventory is on-hand, the production process reserves the vendor-owned inventory and starts the production order for the finished goods that are going to consume the raw material M9211CI.
7. The owner of the reserved raw materials that are going to be consumed in today's production is changed from *US-104* to USMF. This change is made by using an Inventory ownership change journal. This process creates purchase orders where the **Origin** field is set to *Consignment*.
8. The vendor monitors the consumption (change of ownership) on the **Products received from consignment inventory** page and issues an invoice based on the agreements between the two companies.
9. The production process consumes the raw material via a production picking list. The physical reservation is automatically updated to reflect that the on-hand inventory is owned by USMF.
10. The invoice from *US-104* is processed against the purchase orders that were autogenerated when the inventory ownership change journal was processed. Payment is made to vendor *US-104* for the inventory that was consumed.

USMF carries out additional periodic processes:

- A transfer journal is used to process the physical movement of the vendor-owned inventory between different warehouses.
- An **Item counting** journal is used to update the physical inventory on-hand. The vendor can also use counting to update the on-hand inventory, if they have permission to do this.

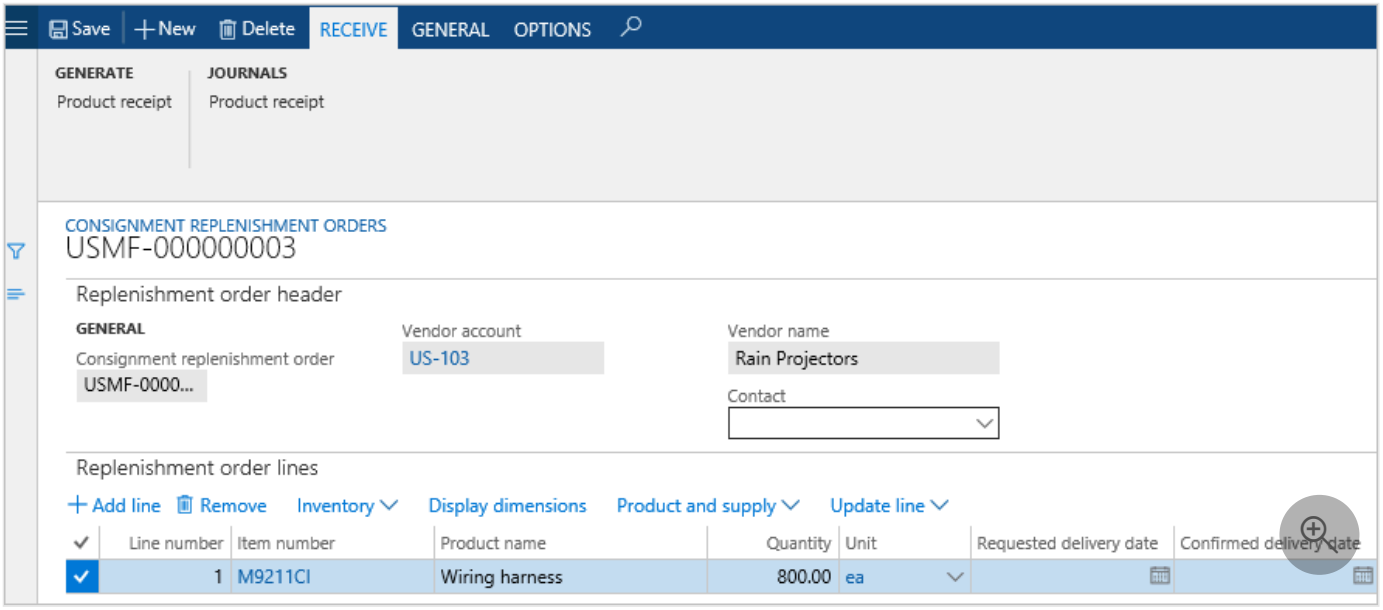
The vendor, *US-104*, can monitor the updates by using the **On-hand consignment inventory** page.

Consignment replenishment orders

A consignment replenishment order is a document that is used to request and keep track of inventory quantities of products that a vendor intends to deliver within a certain date interval by creating ordered inventory transactions. Typically, the order is based on the forecast and actual

demand of the specific products. The inventory to receive against the consignment replenishment order remains the vendor's ownership. You only record the possession of the products related to the physical receipt update, so no general ledger transaction updates occur.

The **Owner** dimension is used to separate information about which inventory is owned by the vendor and which is owned by the receiving legal entity. Consignment replenishment order lines have an *Open order* status as long as the full quantity of the lines isn't received or canceled. When the full quantity is received or canceled, the status is changed to *Completed*. The physical on-hand inventory that's related to a consignment replenishment order can be recorded using either a registration process or a product receipt update process. Registration can be done as part of the item arrival process or by manually updating the order lines. When the Product receipt update process is used, a record is made in the product receipt journal, which can be used to acknowledge the receipt of goods to the vendors.



Inventory ownership change journal

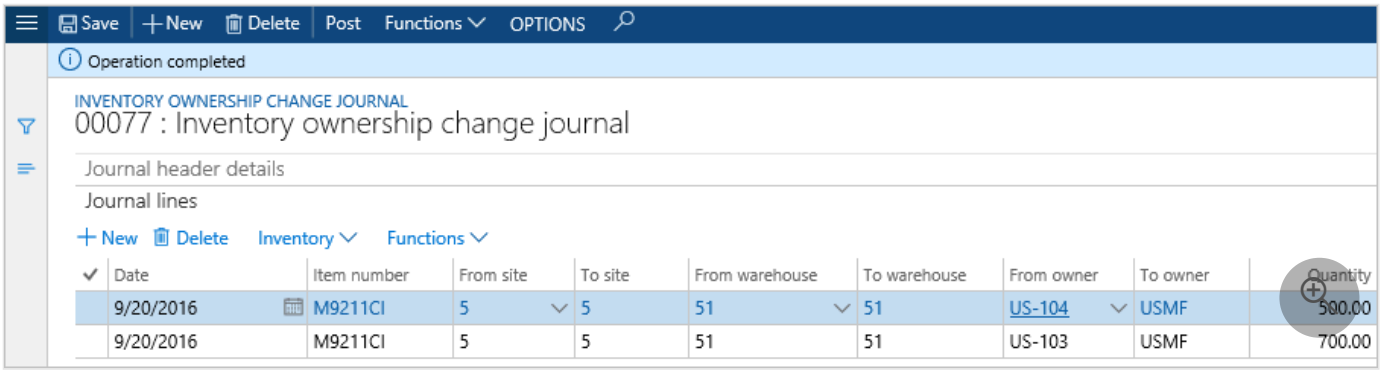
The **Inventory ownership change** journal is used to record the transfer of ownership of consignment inventory from the vendor to the legal entity that consumes it. The journal doesn't create expected inventory transactions. Like any inventory journal, it must be identified with an Inventory journal name. These names are created on the **Inventory journal names** page, and the **Journal type** must be set to *Ownership change*.

The only inventory transactions created are those that relate to a posted journal. When the journal is posted:

- The vendor-owned inventory is issued using an *Ownership change* reference with a *Sold* status.

- The legal entity that consumes the inventory receives on-hand inventory by using a product receipt updated inventory transaction on the purchase order. This action sets the status of the order to *Received*. Purchase orders used for consignment have the **Origin** field set to *Consignment*.

You can't update the quantity on consignment purchase order lines after the order is created.



Vendor collaboration in consignment processes

If your vendors use the vendor collaboration interface, they can use it to monitor the consumption of inventory at your site. The vendor collaboration interface has three pages related to the inbound consignment process:

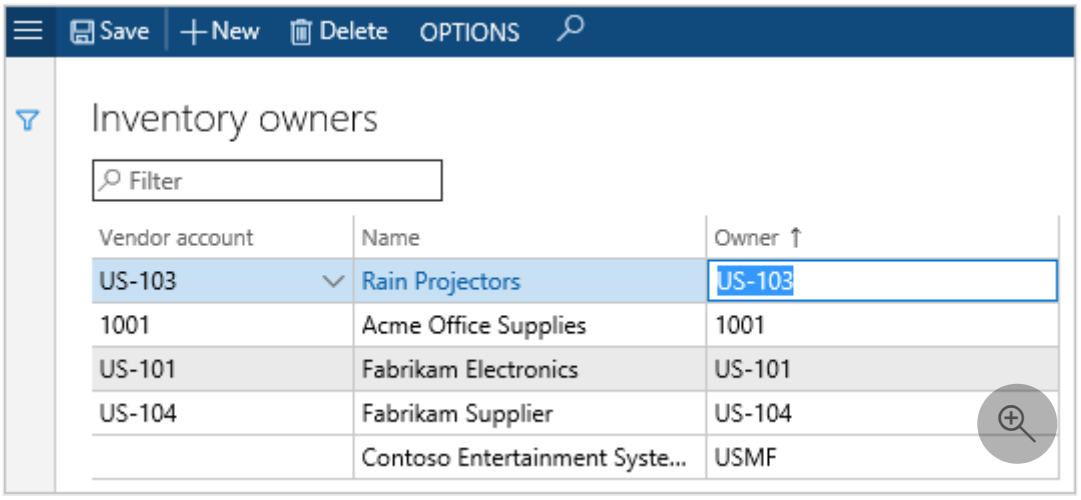
- **Purchase orders consuming consignment inventory** – Shows detailed purchase order information related to the ownership change from the consignment process.
- **Products received from consignment inventory** – Shows information about the items and quantities that have product receipts updated during the ownership change process.
- **On-hand consignment inventory** – Shows information about the consignment items that they're expected to deliver, and the items that are already physically available at the customer site.

For more information about setting up vendors to use vendor collaboration, see Manage vendor collaboration users.

Inventory owners

To record physical inbound consignment inventory, you need to define a vendor owner. You define the vendor owner on the **Inventory owner** page. When you select a **Vendor account**, it generates default values for the **Name** and **Owner** fields. The value in the **Owner** field is visible to the vendor, so you might want to change it if your vendor account names aren't easy for external people to recognize. You can edit the **Owner** field, but only up to the point when you save the

Inventory owner record. The **Name** field is populated with the name of the party that the vendor account is associated with, and you can't change it.



Tracking dimension group

Items for use in consignment processes must be associated with a **Tracking dimension group** where the **Owner** dimension is set to **Active**. The Owner dimension always has the **Physical inventory** and **Financial inventory** options selected. The **Coverage plan by dimension** is never selected.
