    "Parameter": {
        ...
    },
    "Adjustment": {
        "Lines": {}
    }
}
```

   The following table lists the tax group applicability in Globalization Studio.

   Expand table

Header.Business process	Lines.Business Unit	Header.Ship From Zip Code	Tax Group
Journal			Group A
Sales		30160	Group B

According to the Tax calculation input, the **Business Process** value on the header is **Sales**, and the **Ship From Zip Code** value on the header is **30159**. This input is based on the setup of the applicability rules in Globalization Studio. Because there's no matching line, the error message occurs.

> **Note**
>
> If the value in the applicability rule is blank, the rule is applicable to any value.

Mitigation

Follow these steps to mitigate the error.

1. In Globalization Studio, go to **Globalization features** > **Tax calculation**.
2. Create a new version of the feature.
3. Add a line for the corresponding information.

Expand table

Header.Business process	Lines.Business Unit	Header.Ship From Zip Code	Tax Group
Journal			Group A
Sales		30160	Group B
Sales		30159	Group B

4. Publish the feature setup version.
5. In Dynamics 365 Finance, go to **Tax** > **Setup** > **Tax configuration** > **Tax calculation parameters**, and then select the new version.

Last updated on 11/22/2024

How to enable debug mode in Tax Calculation

To enable the debug mode in Tax Calculation in Dynamics 365 Finance, take the following steps:

1. Add *&debug=vs%2CconfirmExit&* to the URL of the Application Object Server (AOS), and then refresh the page.
2. When you select **Sales tax** to calculate the sale tax, a text file that is named *TaxServiceTroubleshootingLog.txt* is opened. The *TaxServiceTroubleshootingLog.txt* file contains `TaxableDocument` and the calculation parameter. These results are returned from the tax calculation and exception information for troubleshooting.

Sample

jsonc

```
==============================Tax calculation input
JSON:================================

Tax calculation FAQ

This article provides answers to frequently asked questions about the functionality of the Tax Calculation.

Will the Tax Calculation be available on tier-1 machines and on-premises machines?

Yes.

Do I have to continue to maintain tax codes and sales tax groups in finance and operations and Globalization studio, or can I maintain them in only one place?

You can create and maintain a tax setup in the Tax calculation feature in Globalization studio. When you select the Tax feature on the **Tax calculation parameters** page in finance and operations, the setting synchronizes from Globalization studio to finance and operations.

Do you have any plans to support Russia, Brazil, and India?

Microsoft doesn't currently plan to support Russia, Brazil, or India. For more information about country/region support, see Release plans on Dynamics 365 and Microsoft Power Platform release plans.

Brazil tax reform taxes are supported with Tax calculation, details: Tax Reform Overview.

What is the recommendation for global implementations that involve countries or regions such as India? Can I use the Goods and Services Tax (GST) engine that Microsoft provides and the Tax Calculation on the same instance of Dynamics 365 Finance or Dynamics 365 Supply Chain Management, or do I have to have separate instances?

You can use different tax engines for different legal entities. For example, for a legal entity in India, you can use GST that is based on Global Tax Engine (GTE). Then, for other legal entities, you can enable the Tax Calculation.

If I post a transaction with incorrect tax, how can I correct it?

The correction process is the same as it currently is. If you discover that the tax is incorrect before you post the transaction, you can either make a tax amount adjustment or adjust the applicability rule by changing tax groups. If you discover that the tax is incorrect after you post the transaction, you can either reverse the posted document or post a tax adjustment journal.

What are the triggers for calling the Tax Calculation?

The triggers for the Tax Calculation in finance and operations apps are the same as the current triggers for the existing tax engine.

On the Tax calculation parameters page, why is the list of values in the Feature setup name field blank?

You need to complete and publish the Tax calculation feature in Globalization studio.

Why can't I turn on the Enable advanced tax calculation parameter?

The **Enable advanced tax calculation** parameter isn't yet supported in some countries and regions. Make sure that the primary address of the legal entity is in one of the supported countries/regions.

Connect to an external tax solution provider via the Universal Tax Rate API

A connection to an external tax solution provider helps simplify and reduce the effort of maintaining the tax rates and tax applicability rules for Tax calculation. This result is especially critical when you implement Tax calculation for countries or regions where a significant number of tax jurisdictions must be covered.

The Universal Tax Rate API is a set of standard application programming interfaces that Microsoft has defined in Tax calculation, based on the tax calculation data model. It's an extended feature of Tax calculation that enables external tax services to be connected under the same framework.

Through this extension, external tax solution providers can provide tax rate determination, tax calculations, and extended tax functionality via standardized APIs. This extension introduces the following benefits:

- **Seamless integration with Microsoft Dynamics 365 applications** – The external tax solution is seamlessly integrated into Dynamics 365 applications. This integration ensures a smooth and unified experience across Dynamics 365 applications.
- **Improved scalability** – By connecting to an external tax solution provider, you can take advantage of its infrastructure and expertise to efficiently handle large-scale tax calculations.
- **Reduced maintenance overhead** – External tax solution providers are responsible for maintaining up-to-date tax rates and tax applicability rules. Therefore, they can help save you time and effort.
- **Enhanced accuracy** – External tax services often have access to comprehensive tax databases and advanced algorithms. Therefore, tax calculations are more accurate.
- **Flexibility and customization** – The standardized APIs let you integrate with various external tax solution providers. Therefore, you can select the one that best fits your business needs.
- **Compliance with local regulations** – External tax solution providers are well-versed in local tax laws and regulations. Therefore, they can ensure that your tax calculations comply with the specific requirements of each jurisdiction.

> ⓘ **Note**

The Universal Tax Rate API shares the same integration of Tax calculation. Different tax solution providers might support different regions, scopes, scenarios, and extended functionality. For more information, contact the tax solution providers.

The following functionality is available via the Universal Tax Rate API that the tax solution providers support:

- **Encrypted connection** – The Universal Tax Rate API supports an encrypted connection via Azure Key Vault. This connection helps ensure the security and privacy of data that's transmitted to external tax solution providers.
- **Address validation** – This functionality lets you validate addresses that are maintained in the global address book. It helps ensure accurate tax calculations by confirming that addresses are valid and complete.
- **Sales tax calculation** – External tax solution providers can use the Universal Tax Rate API to calculate sales tax, based on factors such as the location and the product type.
- **Posted tax transactions** – This functionality enables tax transaction postings in the external tax solution system of the tax solution providers. Tax reporting is generated after the posting in the external tax solution system.
- **Accrual of use tax** – The Universal Tax Rate API enables external tax solution providers to accrue use tax. Use tax is a type of tax that's imposed on the use, storage, or consumption of taxable items or services that weren't taxed at the time of purchase in the United States.

Availability

The Universal Tax Rate API is available in Dynamics 365 Finance or Dynamics 365 Supply Chain Management version 10.0.38 and later.

Versions

We recommend that you import and set up your Tax calculation configuration with the version that matches your Finance or Supply Chain Management version.

Expand table

Finance or Supply Chain Management version	Tax configuration version
10.0.48	Tax Calculation Data Model for ISV Integration 50.78.13
10.0.39	Tax Calculation Data Model for ISV Integration 40.65.5

Enable a tax solution provider

To enable a tax solution provider, follow these steps:

1. Enable the following features in Feature management:

    - Tax calculation service
    - Enable external tax solution providers for Tax calculation service
    - Globalization features
    - Enable Globalization feature setup for Tax calculation service
    - Electronic reporting globalization feature JSON import/export

2. Engage and select one tax solution provider. Install the independent software vendor (ISV) application when the tax solution provider requires it for the complete and extended functionality.

3. Set up a client ID and client secret for the application access credentials that your tax solution provider provides.

4. Import the tax calculation data models provided by Microsoft from the global repository or the Dataverse repository via Globalization Studio.

    - **Configuration providers** > **Microsoft** > **Repositories** > **Global** > **Open** > **Import**
        - Tax Calculation Data Model for ISV integration.xml (version 40.65.5)

    > **Note**
    >
    > If you want to import the tax data model from the Dataverse repository, make sure you have enabled the option **Enable Finance and Operations User Impersonation in Dataverse** under **Power Platform admin center** > **Environments** > **your environment id** > **settings** > **Features**.
    >
    >
    >

5. Load the ISV provided tax configuration and tax features via Globalization Studio. Follow the implementation guidance that your tax solution provider provides.

    - **Tax configurations** > **Exchange** > **Load from XML**
        - ISV tax configuration.xml (version 40.65.5.x)
    - **Tax calculation** > **Import from JSON**
        - ISV tax solution.json (version x)

    > **Note**
    >
    > The ISV distributes the preceding .xml and .json files for load and import into the Tax calculation setup. The name of the files can be vary per different ISV naming rules.

6. In Globalization Studio, select **Tax calculation** > **Add**, and create and configure the customer ISV tax feature for your credentials, parameter values, mapping rules, and so on. Follow the implementation guidance that your tax solution provider provides.
7. Go to **Tax** > **Setup** > **Tax configuration** > **Tax calculation parameters**.
8. On the **General** tab, in the **Tax solution provider** section, enable the **Enable tax solution provider** option.
9. Configure the tax solution provider.
10. You can now perform transactions as usual. When Tax calculation is required, the client collects information from the transaction, such as the sales order or purchase order, and it packages that information as a payload. A request is then sent to your tax solution provider to calculate the tax.
11. The calculation result is returned from your tax solution provider to your Finance system and presented on the sales tax transaction page.
12. When you post a sales tax–related voucher in Finance, a Posted tax transaction request is sent to your tax solution provider to record the necessary tax information in its tax solution system for tax reporting.

Supported countries/regions

The Universal Tax Rate API can be enabled for for any country/region.

For more information about supported countries/regions, contact your tax solution providers.

Available tax solution providers

- Vertex (available)
- Avalara (planned)
- Wolters Kluwer (available)
- Thomson Reuters (available)

For additional details on release information, available solutions, and supported countries/regions, we recommend reaching out to your tax solution providers.

Last updated on 03/20/2026

Configure a tax solution provider

This article explains how to configure a tax solution provider for Tax calculation. After you complete the steps according to the implementation guidance that your tax rate provider provides, select your tax feature setup in Tax calculation parameters for the corresponding legal entity.

To configure a tax solution provider, follow these steps:

1. Go to **Tax** > **Setup** > **Tax configuration** > **Tax calculation parameters**.
2. On the **General** tab, in the **Tax solution provider** section, select **Enable tax solution provider**.
3. In the **Feature** section, in the **Name** field, select your tax feature setup.
4. If the feature setup defines new tax codes, the **Maintain mandatory fields for new tax codes** page appears. For each tax code, select a settlement period and a ledger posting group. To bulk update the mandatory fields, select all tax codes and then select **Bulk update**.
5. Select **Confirm**. A log file is downloaded in your browser. This file contains the information for the imported and updated tax codes, tax groups, and item tax groups for the current legal entity.
6. In the **Business process** field, select the processes that access the external tax service for tax calculation.

   > ⓘ **Note**
   >
   > To learn about the supported business processes that you should select, contact your tax solution provider.

7. Select **Enable address validation**, and select the country/region keys that your tax rate provider supports.

   > ⓘ **Note**

To ensure an accurate location-based tax calculation, your tax rate provider validates and corrects the addresses in the master data. After you enable address validation, a **Validate** button is available when you add or maintain the addresses in the master data.

For batch mode validation, go to **Organization administration** > **Global address book** > **Global address book**, and then, on the **Registration** tab, select **Address validation**.

8. For US legal entities, enable the **Accrue use tax** option, and maintain the fields in the **Overcharge tolerance** section to activate the assessment and processing of vendor-charged sales taxes for Accounts Payable (AP) invoicing scenarios. For more information, see Use tax assessment.

Last updated on 03/21/2026

Set up a client ID and a client secret

This article explains how to set up a client ID and a client secret for the Universal Tax Rate API.

> **Note**
>
> You can create a support request to ask Microsoft support to connect you with the Tax Calculation - Universal Tax Rate API product team for detailed guidance on setting up the client ID and client secret in your environment.

Prerequisites

Before you can access a tax provider's service, you must set up your client ID and client secret for the Universal Tax Rate API. Your tax provider provides these values. When you receive them, store them in a Microsoft Azure Key Vault, and configure Key Vault parameters for Dynamics 365 finance and operations apps. After you set up the client ID and client secret in the key vault, you can select the corresponding Key Vault secret name in the tax feature setup.

Create a key vault in the Azure portal

You must store all the secrets and certificates that are used in the Tax Calculation service in an Azure Key Vault. This approach helps ensure that you don't work directly with the secrets, and that the secrets are securely stored. When you must use digital signing or secure a connection to external web services, set the reference to the Key Vault secrets instead of using the secrets and certificates directly. For more information, see About Azure Key Vault.

Create a key vault

To create a key vault, follow these steps:

1. From the Azure portal, open the menu or **Home**, and select **Create a resource**.
2. Enter **Key vault** in the search field.
3. Select **Key vault** in the list of results.
4. In the **Key Vault** section, select **Create**.

5. In the **Create key vault** section, set the following fields:

    - **Subscription** – Select a subscription.
    - **Resource group** – Select a resource group, or select **Create new**.
    - **Name** – Enter a unique name. For this example, use **TaxProvider-vault**.
    - **Location** – Select a location.

    Leave the other fields set to their default values.

    > ⓘ **Note**
    >
    > In the Set up Key Vault parameters in finance and operations apps section of this article, the name that you enter in the **Name** field is referred to as **<KeyVaultName>**.

6. Select **Next**, and set the **Permission model** field to **Vault access policy**.

7. Select **Review + Create**.

8. After the deployment finishes, expand the **Deployment details** section, and select the **Key vault** detail.

    > ⓘ **Note**
    >
    > Copy and save the **Vault URI** value. You must enter it in the **Key Vault URL** field when you complete the procedure in the Set up Key Vault parameters in finance and operations apps section.

9. Select **Next**, and set the **Permission model** field to **Vault access policy**.

10. Select **Secrets**, and then select **Generate/Import**.

11. Set the following fields:

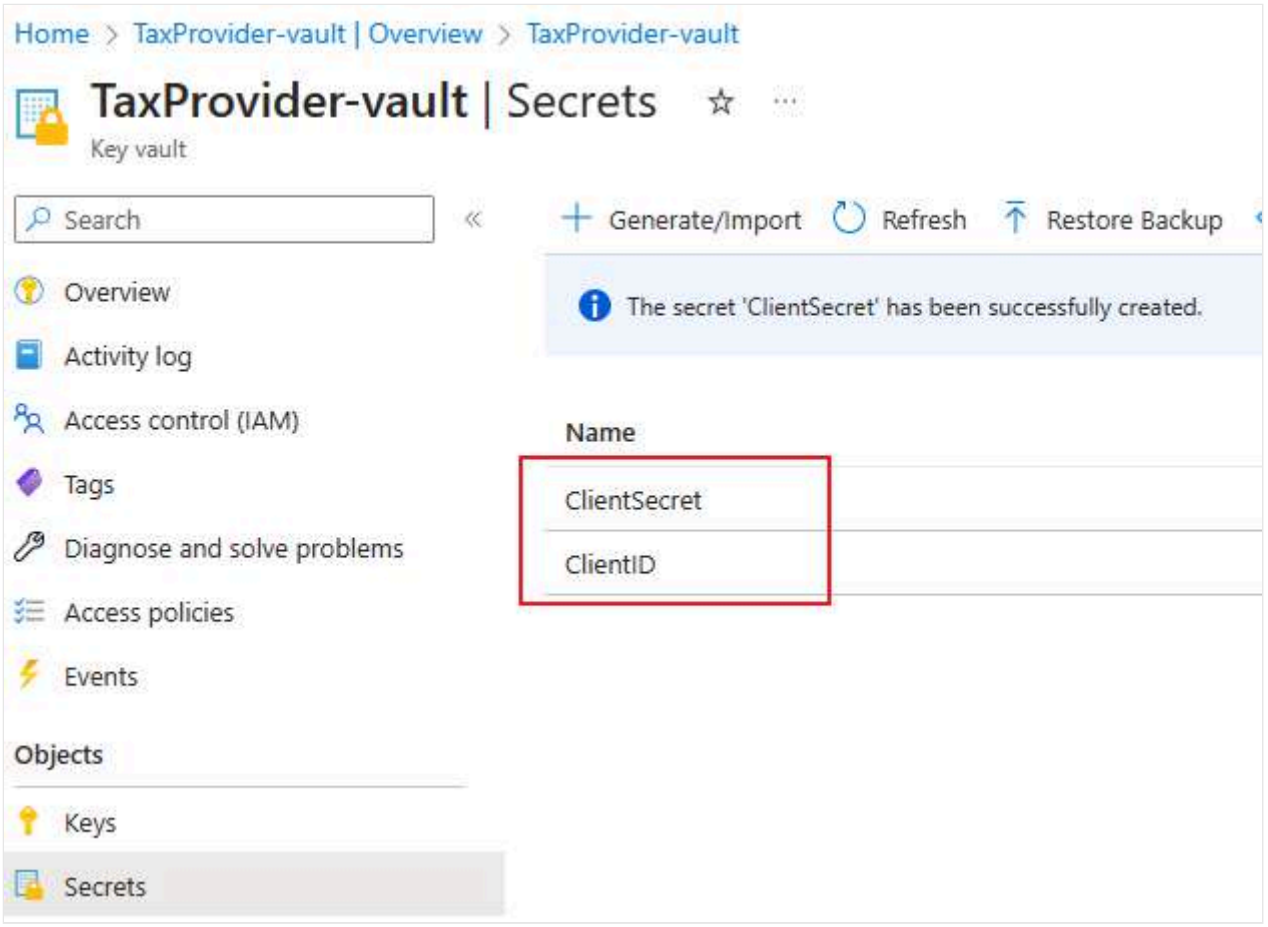
    - **Upload options** – Specify **Manual**.
    - **Name** – Enter a name for the secret. For example, enter **ClientID**.
    - **Secret value** – Enter the client ID that you get from the tax provider.

12. Select **Create**.

    > ⓘ **Note**

> The secret name is a mandatory parameter for integration with the key vault. Therefore, specify it in the application. In the Set up Key Vault parameters in finance and operations apps section, it's referred to as the **<SecretName>** parameter.

13. Repeat step 10 for the client secret.



Set up permissions

This section explains how to complete the following procedures:

- Create an app registration.
- Set up the access policy of the key vault.
- Set up Key Vault parameters in finance and operations apps.

Create an app registration

To access Key Vault, you must create an app registration in Azure Active Directory (Azure AD).

To create an app registration, follow these steps:

1. In Azure AD, search for **register**, and then select **App registrations**.

2. Set the **Name** and **Supported account types** fields, and then select **Register**.

3. Copy and save the **Application (client) ID** value. Specify it in the application. In the Set up Key Vault parameters in finance and operations apps section, it's referred to as the **Key Vault client** parameter.

4. Create a new client secret.

> **Note**
>
> The client secret is a mandatory parameter for integration with the key vault. Copy it and specify it in the application. In the Set up Key Vault parameters in finance and operations apps section, it's referred to as the **Key Vault secret key** parameter.

Set up the access policy of the key vault

Set up the access policy to grant the app registration the correct level of secure access to the secret that you created.

1. Open the Key Vault storage that you created earlier.
2. Go to **Settings** > **Access policies**, and select **Create**.
3. In the **Secret permissions** section, select the **Get** and **List** operations.
4. Select **Next**.
5. In the **Select principal** step, select the app registration that you created earlier.
6. Select **Next** until you reach the **Review + create** step, and then select **Create**.

Set up Key Vault parameters in finance and operations apps

After you finish the prerequisite steps, set up the Key Vault parameters to link to the key vault in finance and operations apps.

1. Go to **System administration** > **Setup** > **Key vault parameters**.

2. Select **New** to create a new instance.

3. Enter a name and description. On the **General** tab, set the following fields that are required for integration with Key Vault storage:

- **Key Vault URL** – Enter the key vault URI that you saved in the Create a key vault section.
- **Key Vault client** – Enter the interactive client ID of the Microsoft Entra ID application that's associated with the Key Vault storage for authentication.
- **Key Vault secret key** – Enter the secret key that's associated with the Microsoft Entra ID application that's used for authentication with the Key Vault storage.

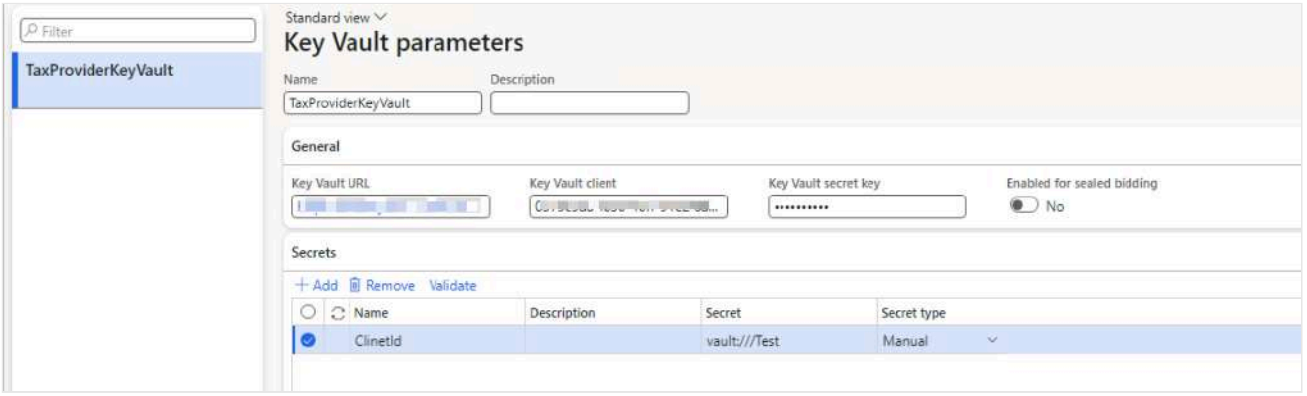
4. On the **Secrets** tab, select **Add** to add your secret. For each secret, set the following fields:

   - **Name**
   - **Description**
   - **Secret** – Enter a secret reference to the Key Vault secret.

   The format of a secret must resemble the following example: **vault://<KeyVaultName>/<SecretName>/<SecretVersion>**.

   The **<KeyVaultName>** and **<SecretVersion>** attributes are **optional**. However, the **<SecretName>** attribute is **required**. In most cases, you can define a Key Vault secret key in the following format: **vault:///<SecretName>**.

   If the secret version isn't defined in the Key Vault secret key, the system retrieves the active secret that has the latest expiration date.



> **Note**
>
> You must create the Key vault parameters in each legal entity that connects to the external tax solution provider for tax calculation.

Last updated on 03/19/2026

Use tax assessment

Use tax assessment is a feature that US legal entities can use to calculate the tax liability for purchases that are subject to use tax. Use tax is a type of sales tax that applies when a taxable item is purchased from an out-of-state vendor or an online retailer that doesn't collect sales tax from the buyer. The buyer is responsible for paying the use tax to the state where the item is used, stored, or consumed.

By using the **Accrue use tax** option in Tax calculation parameters, US legal entities can comply with the tax laws and regulations of their states by automatically generating use tax transactions, based on the purchase transactions and the tax rates of the states.

Enable the **Accrue use tax** option to activate the use tax assessment–related fields and functionality in Accounts Payable (AP) invoicing scenarios. After you enable it, the following fields and parameters are activated for use tax assessment.

- The **Vendor charged sales tax** field is available on the header of a vendor invoice. Use it to record the total sales tax amount that the vendor charges on the invoice. If you import the vendor invoice, the amount in the **Imported sales tax** field automatically carries over to the **Vendor charged sales tax** field.

- The **Accrue sales tax type** field is available in the vendor master and on the header of the vendor invoice. It controls the tax assessment process. Select one option for each vendor in the vendor master to set the default behavior for processing of the **Vendor charged sales tax** value. On the header of the vendor invoice, you can select a different behavior for each invoice transaction.
  - **Default** – Use the default behavior, which ignores the amount in the **Vendor charged sales tax** field. The system calculates and populates the sales tax amount and sales tax transactions through sales tax logic. No other assessment is done.
  - Adjust sales tax
  - **Accrue use tax** – This option is available if you enabled the **Accrue use tax** option according to the guidance in Configure a tax solution provider. The system populates use tax transactions when the **Vendor charged sale tax** value is less than the tax liability that your tax solution provider calculates. For more details, contact your tax solution provider.
  - **Advanced** – Select this option when your tax solution provider supports advanced use tax assessment processes that consider the fields in the **Overcharge tolerance** section. For more details, contact your tax solution provider.

- The fields in the **Overcharge tolerance** section are available in both Tax calculation parameters and the vendor master. Use them to perform advanced tax transaction handling when the **Vendor charged sales tax** value differs from the tax calculation result. For more details, contact your tax solution provider.

Adjust sales tax

The **Adjust sales tax** option is available after you enable the **Adjust sales tax amount per vendor charged sales tax** feature (in version 10.0.39 and later). Select this option if you want to fully accept the sales tax amount that the vendor charges. In this case, the system generates a sales tax adjustment transaction to override the tax calculation result.

> **Note**
>
> The **Adjust sales tax amount per vendor charged sales tax** feature is a standalone core feature. It doesn't require that you enable a tax solution provider. You can enable the feature to activate the **Vendor charged sales tax** and **Accrue sales tax type** fields without connecting to an external tax solution provider.

Stock transfer orders for India

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use transfer orders to process inventory transfers between warehouses. In India, if the shipping and receiving branches of the organization have different tax registration numbers, calculate and post the India Goods and Services Tax (GST) for the transfer order. You can define the tax base as the current cost price of the item being transferred or a special transfer price. Post the tax amount as GST payable for the transfer shipment and as GST recoverable upon the transfer receipt. Use an **Interim transit** account as an offset account for the posting, and nullify it when the transfer order is fully received.

The **Stock transfer** functionality that's available for India supports this process.

> **Note**
>
> Unrealized profit or loss isn't posted during the shipment or receipt of a stock transfer line if the unit price differs from the inventory cost price of the item. If mutual settlements and profit or loss transactions are required for internal transfers between your own company's warehouses, use other functionality. For example, you can configure purchase orders and sales orders invoices or intercompany invoices for intracompany transfers.
>
> For more information, see Set up intercompany trade.

Set up stock transfers

Enable stock transfer functionality

In the **Feature management** workspace, enable the following features:

- *(India) Improvements in unit price and cost price handling in Stock transfer orders* (As of Supply Chain Management version 10.0.43, this feature is turned on by default. As of version 10.0.45, it's mandatory and can't be turned off.)
- *Enable uniform tax amount and GST transaction ID for both shipment and receipt transaction of a stock transfer order* (As of version 10.0.43, this feature is mandatory and can't be turned off.)

For more information, see Feature management overview.

You also need to configure the India GST functionality to enable GST calculation for stock transfer orders. For more information, see India Goods and Services Tax (GST) overview.

Set up default transfer type and price type for transfer orders

You can define a default transfer order type and a default price type for transfer orders that you create manually. On the **Inventory and warehouse management parameters** page, on the **Transfer orders** tab, select **Stock transfer** in the **Transfer type** field to enable the **Stock transfer** functionality for all newly created transfer orders. In the **Price type** field, select a default price type for newly created stock transfer orders:

- **Cost price** – The cost price, or the on-hand price, of the item is used for stock transfer orders.
- **Transfer price** – The transfer price that you set up for the item is used for stock transfer orders.

> ⓘ **Note**
>
> For the **Cost price** price type, the system calculates a running average cost price, based on the inventory dimensions that you specify for an item line. The system stores this running average price in the **Cost price** field when you create or update the line. The system never recalculates the saved cost price when you post shipping and receiving transactions.

Configure Master planning parameters

You can define a default transfer order type and a default price type for transfer orders that you create when confirming planned orders in the **Master planning** module. On the **Master planning parameters** page, on the **Standard update** tab, select **Transfer type** and **Price type** in the **Firm - Transfer** group.

Set up item master parameters

To calculate GST for an item in a stock transfer order, you need to configure certain parameters on the **Released product details** page, such as **HSN codes** and **Tax rate type**. For more information, see Assign HSN codes and SACs to products.

Configure transfer pricing

You can configure the prices that the system uses when processing stock transfers for an item. To do this, open the **Transfer price** page from the **Released product details** page.

Configure stock transfer posting

You must configure the **Interim transit** account. Complete this configuration on the following pages:

- In the **Inventory management** module, on the **Posting** page, on the **Transfer order** tab, specify the **Interim transit** account.
- On the **Tax setup** page, select **Setup**, and on the **Setup** page specify the **Interim transit for stock transfer** account for all GST components that you can create for GST on stock transfer. For more information, see Define main accounts.

> ⓘ **Note**
>
> The accounts that you use to post interim transit amounts should have **Interim transit** specified in the **Posting type** field on the **Posting validation** tab of the **Main accounts** page.

You must also set up main accounts to post inventory cost for transfer orders. Specify the following accounts from the **Inventory** tab on the **Posting** page in **Inventory management**:

- **Inventory issue**
- **Inventory receipt**
- **Inter-unit payable**
- **Inter-unit receivable**
- **Inventory expenditure, loss**

> ⓘ **Note**

The **Inventory expenditure, loss** account is required to post the scrap amount when receiving a transfer order with scrap.

Configure posting to General ledger based on financial dimension links to sites

In the standard finance and operations functionality, you can post transfer orders to General ledger only if *both* of the following conditions are met:

- You enable a dimension link, so there's a link between the **Site inventory** dimension and some financial dimension.
- The transfer order movement occurs between warehouses that belong to different sites. This condition applies to the **From**, **Transit**, and **To** warehouses. If the **From** warehouse and **Transit** warehouse belong to the same site, the transfer order shipment isn't posted to General ledger. Similarly, if the **Transit** warehouse and **To** warehouse belong to the same site, the transfer order receipt isn't posted to General ledger.

If you must post stock transfers to General ledger and track inventory in transit warehouses, enable a dimension link and create separate sites for transit warehouses.

For more information, see Configure and manage financial dimension links to sites.

> **Note**
>
> Financial dimensions come from product master data and the dimension link. You can't change financial dimensions in transfer orders.

Create and post a stock transfer order

The following example scenario shows frequently performed actions that are associated with transfer orders where the **Transfer type** field is set to **Stock transfer** and the dimension link is enabled.

1. Go to **Inventory management** > **Outbound orders** > **Transfer order** and create a new transfer order.

2. In the **From warehouse** field, select the supply warehouse that the items are dispatched from.

3. In the **To warehouse** field, select the receiving warehouse that the items are delivered to.

> ⓘ Note
>
> If the **From** warehouse and **Transit** warehouse belong to the same site, the transfer order shipment isn't posted to General ledger. Similarly, if the **Transit** warehouse and **To** warehouse belong to the same site, the transfer order receipt isn't posted to General ledger.

4. In the **Transfer type** field, select **Stock transfer** to apply GST to the transfer of items.

> ⓘ Note
>
> If you select **Transfer order** in the **Transfer type** field, the transfer order is posted based on the standard transfer order process.

5. In the **Price type** field, select a default price type for transfer order lines.

6. On the **Transfer order lines** tab, create a new line. In the **Item number** field, select the item to transfer.

7. In the **Transfer quantity** field, enter the quantity of the items to transfer. In the **Unit** field, change the default unit of measurement, if required.

> ⓘ Note
>
> Changes to the unit of measure of stock on a transfer order line are restricted.

8. In the **Price type** field, select the price type for the transfer order line, from the following options:

   - **Cost price** – The cost price, or the on-hand price, of the item is used for the transfer order line.
   - **Transfer price** – The transfer price that is set up for the item is used for the transfer order line.

> ⓘ Note

If the **Price type** field is set to **Transfer price**, the **Transfer quantity** field shows the quantity of the items that are defined for the combination of an item and a dimension on the **Transfer price** page. This value can be modified.

9. In the **Unit price** field, enter the cost price or the transfer price for one unit of the item.

> ⓘ **Note**
>
> The unit price on a stock transfer order line is recalculated based on the inventory dimensions that are specified on the line until the first shipment is posted for the line.
>
> Shipment of a stock transfer order line that has a unit price of 0 (zero) can be controlled through the **Prevent shipment with zero unit price** field in Inventory and warehouse management parameters.

10. Select **Tax information** to review the tax configuration for the transfer order.
    - At the line level, on the **Invent transfer order from location** tab, you find tax information that is linked to the shipment (from warehouse).
    - At the line level, on the **Invent transfer order to location** tab, you find tax information that is linked to the receipt (to warehouse).
11. Go to **Inquiries** > **Tax document**, and verify that the tax is calculated correctly.
12. Select **Ship** > **Ship transfer order**. Then, on the **Shipment** page, post the transfer order shipment:
    a. Select the **Explode lines** checkbox, and then, in the **Update** field, select **All**.
    b. Select **Setup** > **Tax document**, and review the tax settings and amounts. Make any adjustments that are required.
    c. Close the **Tax document** page, and then select **OK** on the **Ship** page to post the operation.
13. Select **Receive** > **Receive**. Then, on the **Receive** page, post the transfer order receipt:
    a. Select the **Explode lines** checkbox, and then, in the **Update** field, select **All**.
    b. Select **Setup** > **Tax document**, and review the tax settings and amounts. Make any adjustments that are required.
    c. Close the **Tax document** page, and then select **OK** on the **Receive** page to post the operation.

> **Note**
>
> If the "Enable uniform tax amount and GST transaction ID for both shipment and receipt transaction of a stock transfer order" feature is enabled in the **Feature management** workspace, only a previously posted shipment can be received. You must select **Shipment** in the **Update** field when you post a receipt, and you must select a previously posted shipment in the **Shipment voucher** field.

You can also cancel a previously posted stock transfer order shipment if no receipts are posted for this order. On the **Transfer orders** page, select **Transfer order** > **Transfer order history**. On the **Transfer order history** page, select a previously posted shipment. Select **Cancel**, and confirm the cancellation of the shipment. The shipment is canceled, and all inventory movements and GST that was posted for the shipment are reversed. The "Transfer Order Cancellation" feature in the **Feature management** workspace must be enabled to cancel transfer order shipments.

The rest of this article provides several examples that show how to post stock transfer orders under different conditions.

Example 1: Standard transfer order posting

This example uses the following preconditions:

- Current inventory cost price at the moment when the shipment is posted = 100 Indian rupees (Rs.)
- From warehouse = Site 1
- Transit warehouse = Site 2
- To warehouse = Site 3

Transfer order shipment posting

Expand table

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
Inventory issue	Site 1		100
Inventory inter-unit receivable	Site 1	100	
Inventory inter-unit payable	Site 2		100

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
Inventory receipt	Site 2	100	

Transfer order receipt posting

Expand table

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
Inventory issue	Site 2		100
Inventory inter-unit receivable	Site 2	100	
Inventory inter-unit payable	Site 3		100
Inventory receipt	Site 3	100	

You can calculate the balance on the inventory in transit as *InventoryIssue-Site2* – *InventoryReceipt-Site2*. The receipt nullifies this balance.

Example 2: Standard transfer order posting without a transit site

This example uses the following preconditions:

- Current inventory cost price when you post the shipment = 100 Rs.
- From warehouse = Site 1
- Transit warehouse = Site 1
- To warehouse = Site 3

Transfer order shipment posting

No posting to the general ledger occurs.

Transfer order receipt posting

Expand table

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
Inventory issue	Site 1		100
Inventory inter-unit receivable	Site 1	100	
Inventory inter-unit payable	Site 3		100
Inventory receipt	Site 3	100	

In this case, the system **doesn't track an inventory in transit balance**.

Example 3: Stock transfer order that has tax on the transfer price (GST)

This example uses the following preconditions:

- Current inventory cost price when you post the shipment = 100 Rs.
- Unit price that is specified on the line = 120 Rs. This price can be the inventory cost price at the moment when the line was created or updated, or it can be the transfer price of the item.
- Taxable value (base amount) = 120.00.
- GST rate = 10 percent.
- From warehouse = Site 1.
- Transit warehouse = Site 2.
- To warehouse = Site 3.

Transfer order shipment posting

Expand table

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
Inventory issue	Site 1		100
Inventory inter-unit receivable	Site 1	100	
Inventory inter-unit payable	Site 2		100
Inventory receipt	Site 2	100	

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
GST payable	Site 1		12
Interim account	Site 1	12	

Transfer order receipt posting

Expand table

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
Inventory issue	Site 2		100
Inventory inter-unit receivable	Site 2	100	
Inventory inter-unit payable	Site 3		100
Inventory receipt	Site 3	100	
GST receivable	Site 3		12
Interim account	Site 3	12	

The balance on the inventory in transit can be calculated as *InventoryIssue-Site2* – *InventoryReceipt-Site2*. The balance is nullified upon the receipt.

> **Note**
>
> - The **Inventory issue** and **Inventory receipt** accounts are probably the same balance account, such as **Finished goods**.
> - The settings for dimension links and sites (that is, a separate site for the transit warehouse) are recommended if you must track the in-transit inventory in General ledger.

Example 4: Stock transfer order with standard cost

This example uses the following preconditions:

- Create an item that uses the **Standard cost** inventory model.

- Create and activate different item prices for the item, where **Costing type** = **Standard cost** and **Price type** = **Cost**:
  - Price = 115 for Site 1
  - Price = 112 for Site 2
  - Price = 111 for Site 3
- The inventory cost price is defined by the standard cost on the **From warehouse** site and equals 115 Rs. in this case.
- From warehouse = Site 1.
- Transit warehouse = Site 2.
- To warehouse = Site 3.

Transfer order shipment posting

Expand table

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
Inventory issue	Site 1		115
Inventory inter-unit receivable	Site 1	115	
Inventory inter-unit payable	Site 2		115
Inventory receipt	Site 2	112	
Cost change variance	Site 2	3	

Transfer order receipt posting

Expand table

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
Inventory issue	Site 2		112
Inventory inter-unit receivable	Site 2	112	
Inventory inter-unit payable	Site 3		112

Ledger account name	Financial dimension linked to site	Debit amount (Rs.)	Credit amount (Rs.)
Inventory receipt	Site 3	111	
Cost change variance	Site 3	1	

You can calculate the balance on the inventory in transit as *InventoryIssue-Site2* – *InventoryReceipt-Site2*. The balance is nullified upon receipt.

Goods in transit from vendor (Russia)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to work with the Counting act for goods in transit (INV-6) report for Russia in Microsoft Dynamics 365 Finance.

The item counting process (INV-6) is used to identify the quantity and value of inventory items that are in transit when inventory is counted.

The item counting process is done in the context of nomenclatures, shipping documents, and vendors.

Set up an inventory profile for a transferable item

To reflect the goods and materials that are in transit, you can set the kind of inventory for the **Basic** kind of activity. The **Kind of inventory** field can have the following values:

- Common
- Purchased items in route

To set up an inventory profile for a transferable item, follow these steps:

1. In Dynamics 365 Finance, go to **Inventory management** > **Setup** > **Dimensions** > **Inventory profiles**.
2. Select **New** to create an inventory profile for an item.
3. In the **Inventory profile** field, enter the name of the inventory profile.
4. In the **Name** field, enter a description of the inventory profile.
5. On the **Setup** FastTab, in the **Kind of activity** field, select **Basic**.

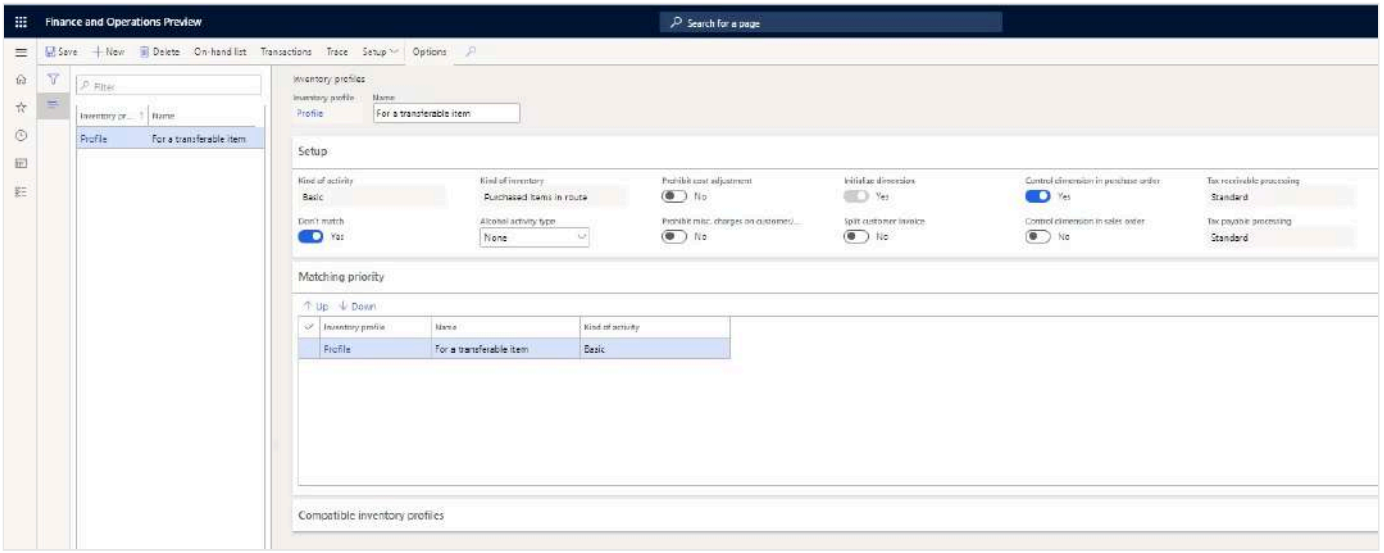
6. Set the **Don't match option** to **Yes** to prevent on-hand inventory that uses this inventory profile from being automatically matched with a compatible inventory profile.

7. In the **Kind of inventory** field, select **Purchased items in route**. The **Initialize dimension** and **Control dimension in purchase order** options are automatically set to **Yes**.

   > ⓘ **Note**
   >
   > The **Kind of inventory** field is available only if you select **Basic** in the **Kind of activity** field.

8. On the **Matching priority** FastTab, select **Up** or **Down** to change the order of the inventory profile.

9. Select **Save**, and close the page.



Set up a number sequence for the Counting act (INV-6) report

To set up a number sequence for the Counting act (INV-6) report, follow these steps:

1. In Dynamics 365 Finance, go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**.
2. On the **Number sequences** tab, in the **Number sequence code** field, select a number sequence for the **Counting act (INV-6)** reference.
3. Select **Save**, and close the page.

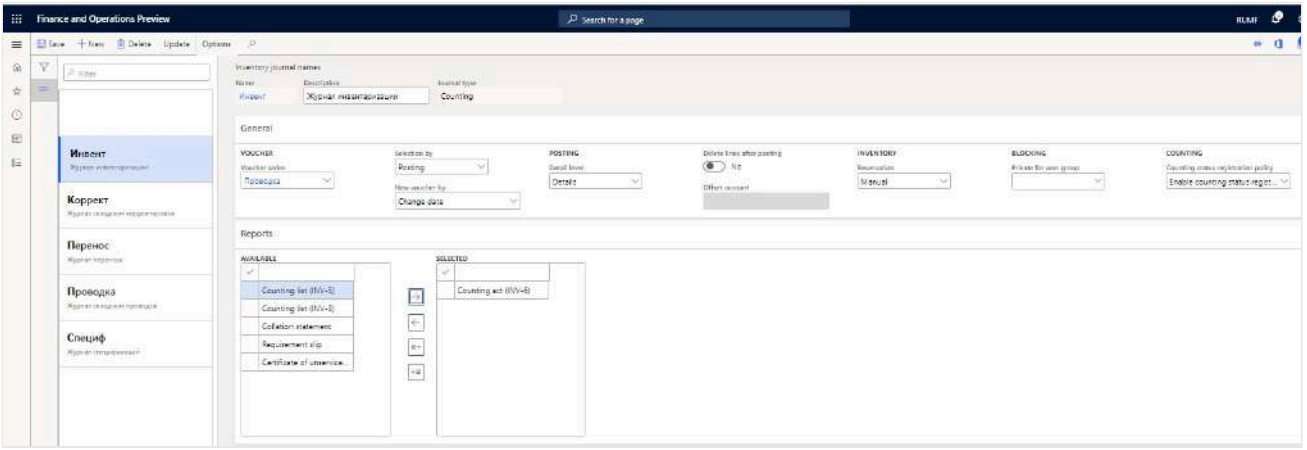
Set up an inventory journal name for the Counting act (INV-6) report

To set up an inventory journal name for the Counting act (INV-6) report, follow these steps:

1. In Dynamics 365 Finance, go to **Inventory management** > **Setup** > **Journal names** > **Inventory**.
2. Create a journal name.
3. In the **Name** field, enter the inventory journal name.
4. In the **Description** field, enter a description.
5. In the **Journal type** field, select **Counting**.
6. On the **Reports** FastTab, in the **Available** field, select **Counting act (INV-6)**, and then select the left arrow button to move the report to the **Selected** field.

   > **Note**
   >
   > If the **Available** field is blank, select **Update** on the Action Pane to update the list of available reports.

7. Select **Save**, and close the page.



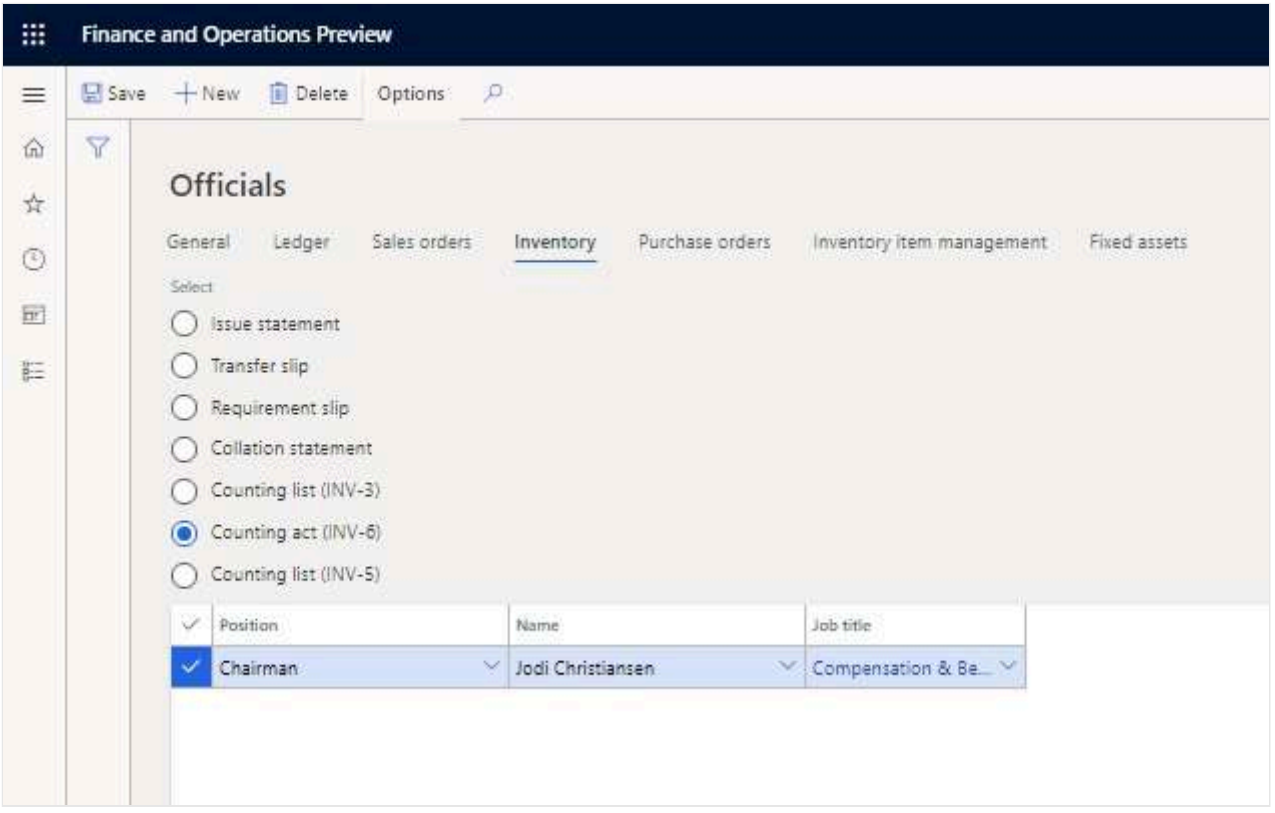
Add officials to the Counting act (INV-6) report

You can specify the company officials who are involved in the item counting process for the **Counting act (INV-6)** report.

To add officials to the Counting act (INV-6) report, follow these steps:

1. In Dynamics 365 Finance, go to **Organization administration** > **Setup** > **Contacts** > **Officials**.
2. On the **Inventory** tab, select the **Counting act (INV-6)** option.
3. Select **New** to create an official for the **Counting act (INV-6)** report.
4. In the **Position** field, select the designation of the official.
5. In the **Name** field, enter the name of the official.
6. In the **Job title** field, select the job title of the official.

> **Note**
>
> By default, the job title is copied from the selected employee's record.



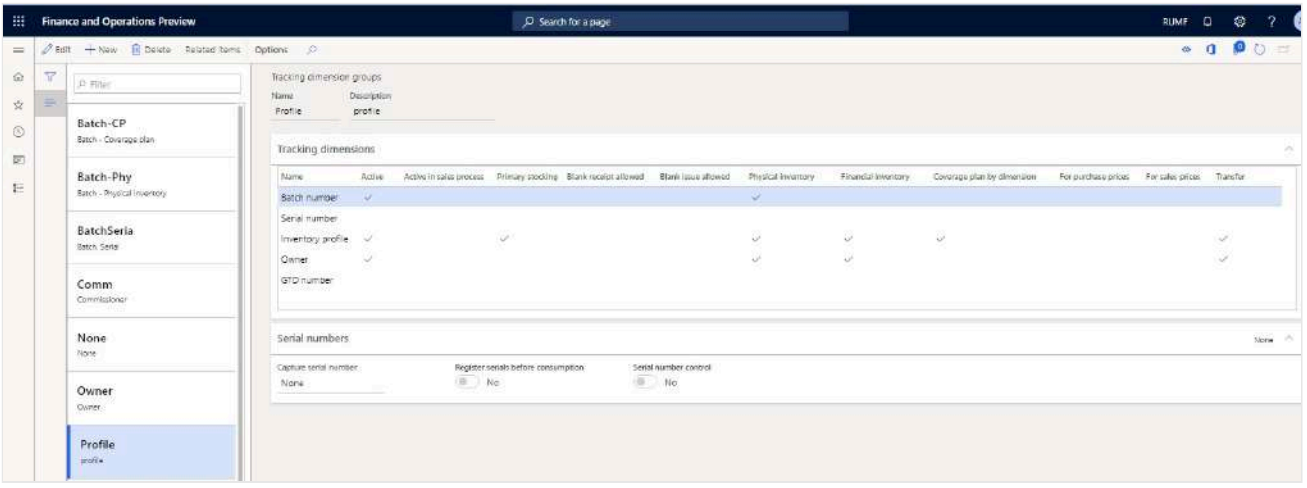
7. Select **Save**, and close the page.

Create an inventory tracking dimension group for the Counting act (INV-6) report

To create an inventory tracking dimension group for the Counting act (INV-6) report, follow these steps:

1. In Dynamics 365 Finance, go to **Product information management** > **Setup** > **Dimension and variant groups** > **Tracking dimension groups**.
2. Select **New** to create a dimension group.
3. In the **Name** field, enter the name of the dimension group.
4. In the **Description** field, enter a description.
5. On the **Tracking dimensions** FastTab, on the **Inventory profile** line, select the **Active**, **Primary stocking**, **Physical inventory**, **Financial inventory**, **Coverage plan by dimension**, and **Transfer** checkboxes.
6. On the **Owner** line, select the **Active**, **Physical inventory**, **Financial inventory**, and **Transfer** checkboxes.

   > **Note**
   >
   > To make the report reflect the details of shipping and payment documents, on the **Batch number** line, select the **Active** and **Physical inventory** checkboxes.

7. Select **Save**.

Create a purchase agreement

To create a purchase agreement, follow these steps:

1. In Dynamics 365 Finance, go to **Accounts payable** > **Purchase orders** > **Purchase agreements**.

2. Select **New** to open the **Create purchase agreement** dialog.

3. On the **Vendor** FastTab, in the **Vendor account** field, select the vendor account.

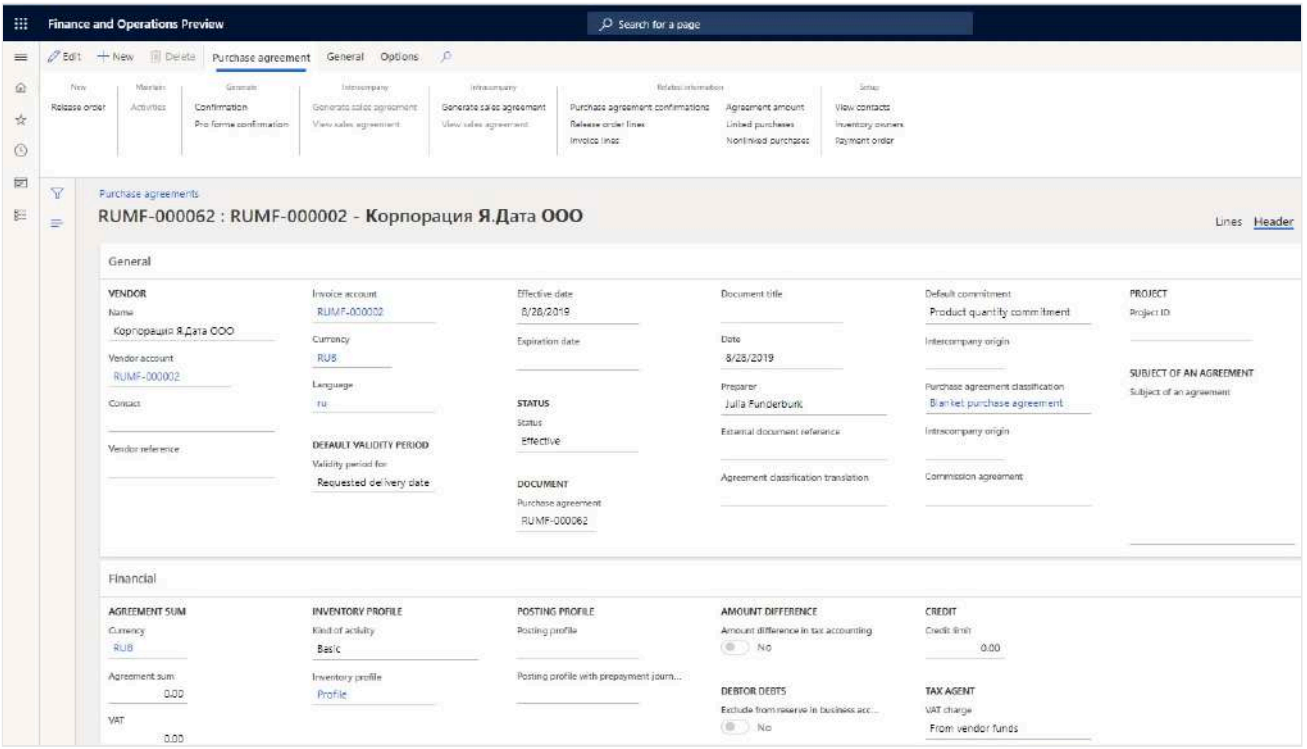
4. In the **Purchase agreement classification** field, select **Blanket purchase agreement**.

5. On the **General** FastTab, in the **Document** section, in the **Purchase agreement** field, enter the ID of the purchase agreement.

6. Specify other details, and then select **OK**.

7. On the **Purchase agreements** page, switch to the **Header** view, and then, on the **Financial** FastTab, in the **Inventory profile** section, set the following fields:

    - In the **Kind of activity** field, select **Basic**.
    - In the **Inventory profile** field, select the inventory profile that you created earlier.

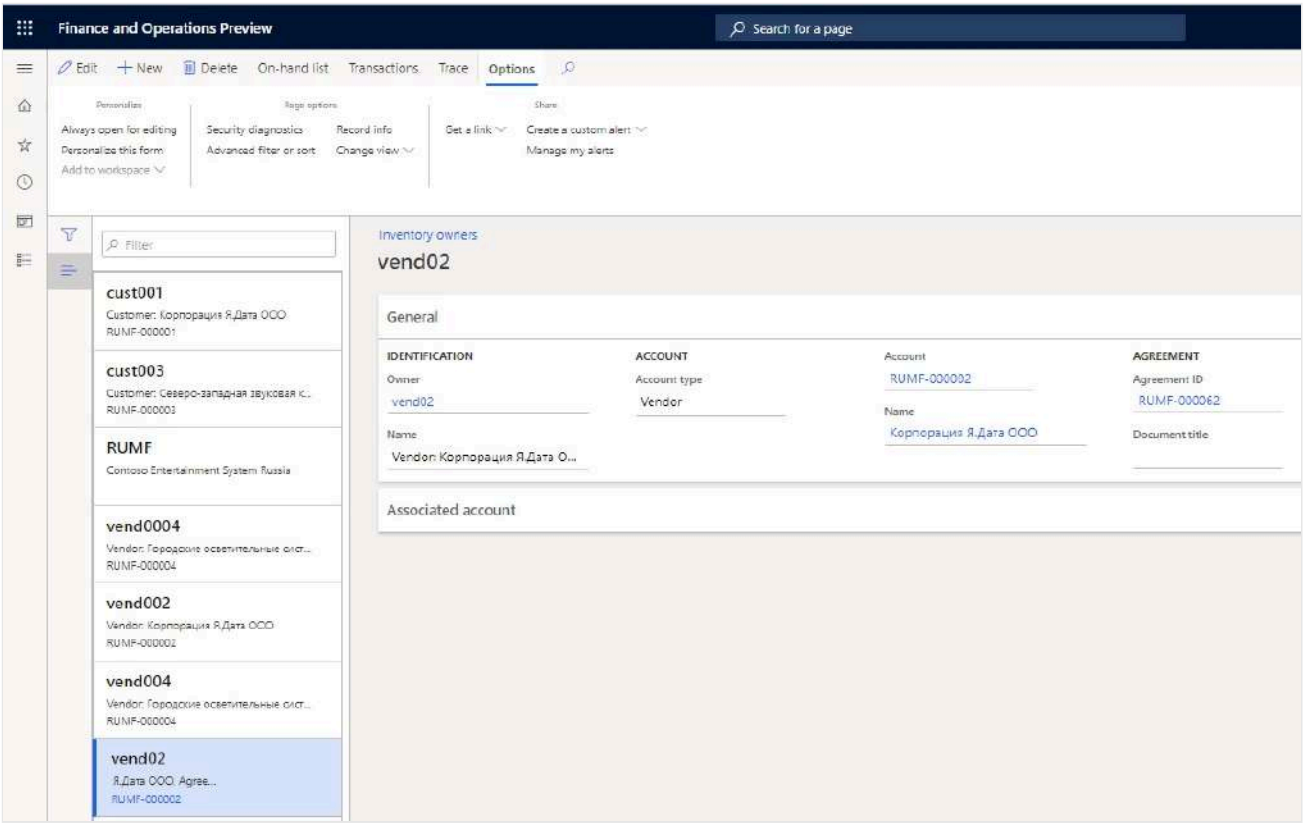


8. On the Action Pane, on the **Purchase agreement** tab, in the **Generate** group, select **Confirmation** to update the status of the purchase agreement to **Effective**.

Add an inventory owner to the Counting act (INV-6) report

To add an inventory owner to the Counting act (INV-6) report, follow these steps:

1. In Dynamics 365 Finance, go to **Inventory management** > **Setup** > **Dimensions** > **Inventory owners**.
2. Select **New** to add an inventory owner.
3. In the **Owner** field, enter the owner code.
4. In the **Account type** field, select **Vendor**.
5. In the **Account** field, select the principal code. The **Name** field is filled in automatically.
6. In the **Agreement ID** field, select the purchase agreement that you created earlier. In this way, you associate the new owner with the agreement.



7. Select **Save**.

Register goods and materials that are in transit

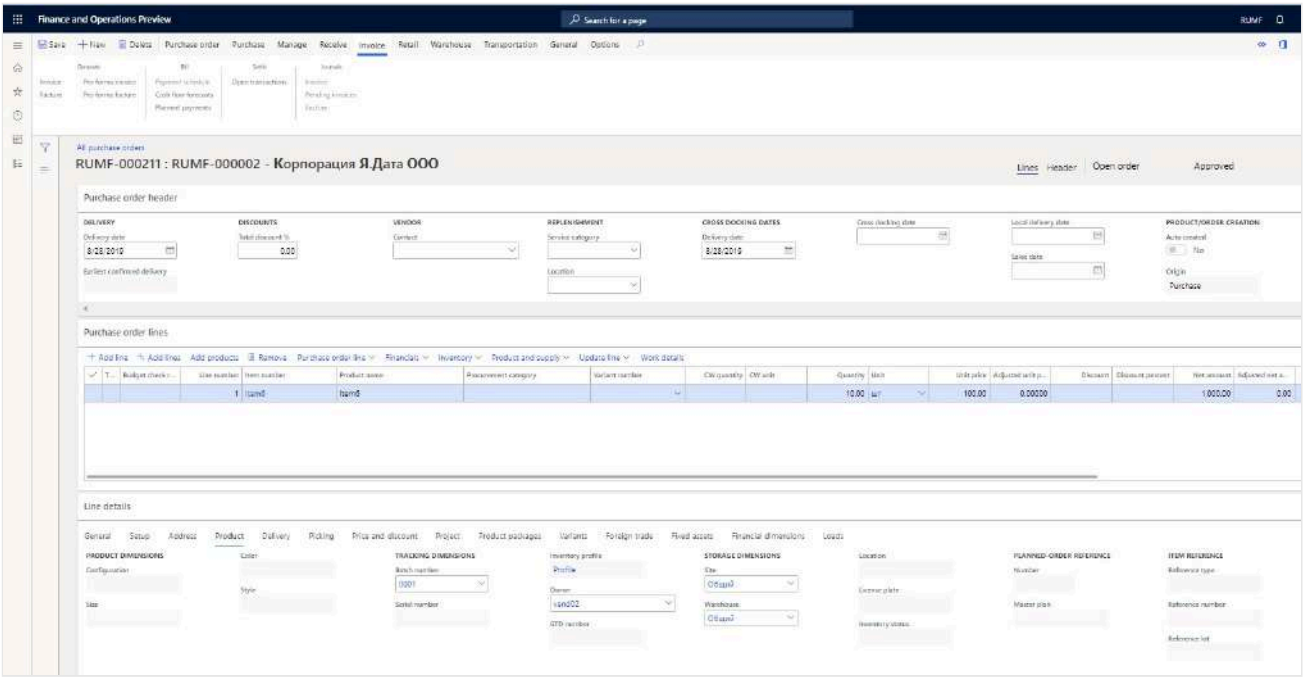
To register goods and materials that are in transit, follow these steps:

1. Create a new purchase order. In the **Purchase agreement** field, select the purchase agreement that you created earlier, and then, on the purchase order line, in the **Item number** field, select the item number.

> **Note**
>
> The **Tracking dimension** field for the item should be set to the inventory profile that you created earlier.

2. On the **Line details** FastTab, on the **Product** tab, in the **Tracking dimension** section, validate that the **Inventory profile** field is set to the inventory profile that you created earlier.

3. In the **Owner** field, select the record that you created earlier.



4. Post the invoice in the usual way.

Generate a Counting act (INV-6) report

You can use the **Print of counting act (INV-6)** dialog to generate a **Counting act (INV-6)** report as a Microsoft Excel file. You must generate this report to track items that are transferred between warehouses and to create a counting list of the items in the transfer that have been purchased. The counting list can contain on-hand inventory holdings.

To generate a Counting act (INV-6) report, follow these steps:

1. In Dynamics 365 Finance, go to **Inventory management** > **Journal entries** > **Item counting** > **Counting**.

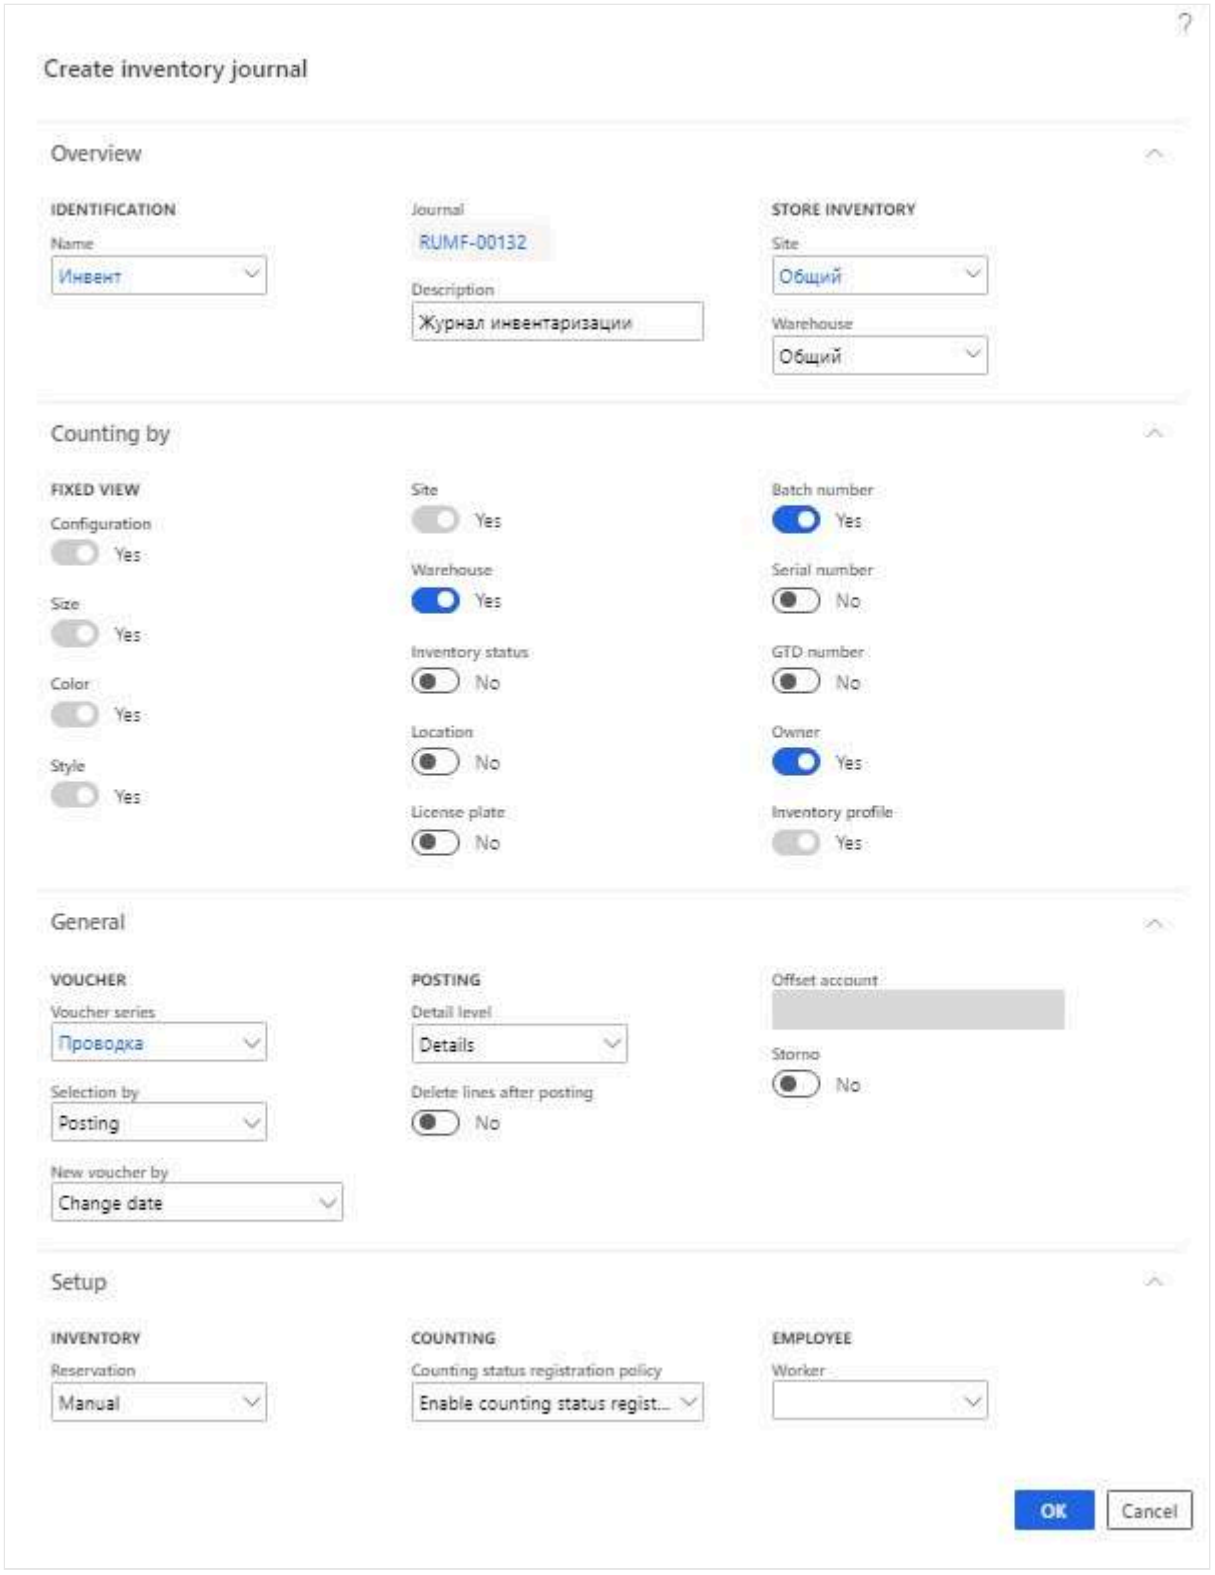
2. Select **New** to open the **Dimensions display** dialog.

3. On the **Overview** FastTab, validate that the **Name** field is set to the inventory journal name that you created earlier.

4. In the **Store inventory** section, set the **Site** and **Warehouse** fields.

5. On the **Counting by** FastTab, validate that the **Inventory profile** and **Owner** options are set to **Yes**.

> **Note**
>
> You can also set the **Batch number** and **Warehouse** options to **Yes**, if those dimensions are applicable.

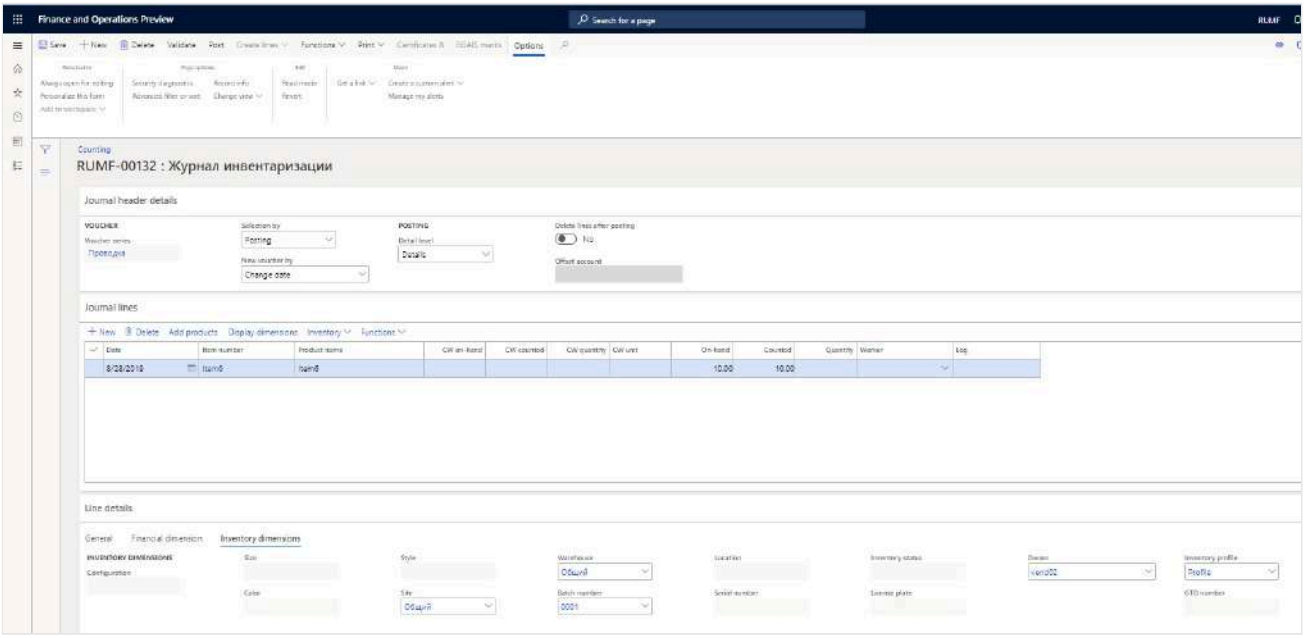


6. Select **OK** to create an inventory counting journal for the items in the transfer.

7. On the **Counting** page, in the **Journal lines** FastTab, create a line, and select the item number that you created earlier.

8. On the **Line details** FastTab, on the **Inventory dimensions** tab, in the **Inventory profile** and **Owner** fields, select the records that you created earlier. The **On-hand** field on the journal line is automatically updated.

9. On the **Journal lines** FastTab, select **Functions** > **Create counting list** to create a counting list. For each line, the **Counted** field is updated with the value that is specified in the **On-hand** field.



10. On the Action Pane, select **Print** > **Counting act (INV-6)** to open the **Print of counting act (INV-6)** dialog.

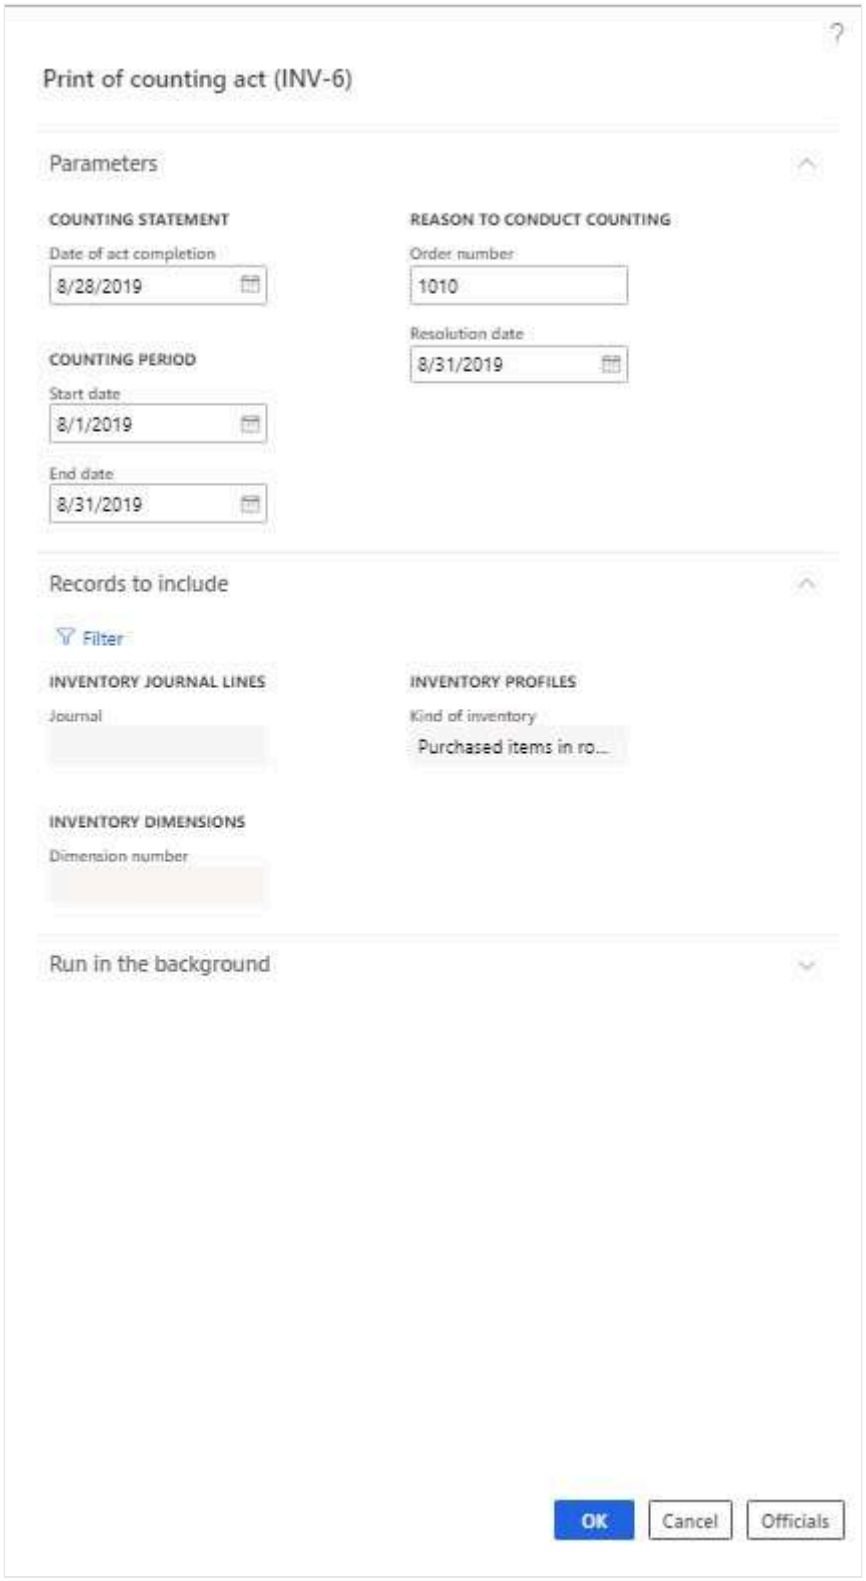
11. In the **Date of act completion** field, select the date when the counting process is scheduled to be completed.

12. In the **Start date** and **End date** fields, select the start and end dates of the inventory counting period.

13. In the **Order number** field, enter the order number that you're generating the **Counting act INV-6** report for.

14. In the **Resolution date** field, select the transaction date of the order that you're generating the **Counting act INV-6** report for.

> **Note**
>
> The values in the **Journal**, **Dimension number**, and **Kind of inventory** fields are based on the inventory counting transactions. To change the values of these fields, select **Filter**. For example, you can modify these values to generate the report for a different journal or a different dimension.



15. Select **OK** to generate the **Counting act (INV-6)** report.

Approvals Management mobile app overview

Many businesses use approval workflows to ensure that new requests (such as proposed purchase requisitions and purchase orders) are valid, within budget, and in line with all business practices and standards. Unfortunately, this extra layer of security can sometimes add delays to the purchasing process. Therefore, Dynamics 365 Supply Chain Management now provides a mobile approval experience that adds flexibility, efficiency, resiliency, and responsiveness to the approval process.

The Approvals Management mobile app provides the following capabilities for managing approval requests:

- View requests that are assigned to you.
- Approve or deny requests.
- Delegate requests to another approver.
- Ask requesters to make changes.

The following illustration shows an example where the Approvals Management mobile app is being used to manage multiple purchase order requests.

> **Note**
>
> Use of the Approvals Management mobile app requires a license. You can find complete and up-to-date licensing information in the Dynamics 365 Licensing Guide. Licensing terms are subject to change without notice.

The Approvals Management mobile app replaces the now-deprecated Purchase order approval mobile workspace.

Next steps

- Onboard the Approvals Management mobile app
- Manage approvals using the Approvals Management mobile app

Last updated on 11/07/2025

Onboard the Approvals Management mobile app

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how administrators can prepare your Microsoft Dynamics 365 Supply Chain Management and Dataverse environments to support the Approvals Management mobile app. It also explains how to install the app on your mobile devices.

Prerequisites

Before you can start to onboard the Approvals Management mobile app, you must meet the requirements that are outlined in this section.

License requirements

Use of the Approvals Management mobile app requires a license. You can find complete and up-to-date licensing information in the Dynamics 365 Licensing Guide. Licensing terms are subject to change without notice.

System requirements

To run the Approvals Management mobile app, you must be using Supply Chain Management version 10.0.41 or later.

Region requirements

The Approvals Management mobile app is available in all regions where Supply Chain Management and Power Apps are supported. However, it isn't available for Microsoft Cloud for Sovereignty.

Set up Dataverse for your Supply Chain Management environment

The Approvals Management mobile app uses Dataverse virtual tables that are connected to Supply Chain Management. Therefore, a Dataverse environment must be integrated with your Supply Chain Management environment. If Dataverse isn't already set up for your environment, follow the instructions in Microsoft Power Platform integration with finance and operations apps.

When you create the Dataverse environment where you want to install the app, be sure to enable Dynamics 365 apps.

The Power Apps component framework feature must be enabled for your environment.

Allow publishing of canvas apps in Dataverse

The Approvals Management mobile app is a canvas app. Therefore, before you can install it in Dataverse, you must enable the **Allow publishing of canvas apps with code components** option for your environment.

1. Sign in to the Power Platform admin center.
2. On the navigation pane, select **Environments**, and then select the environment that is integrated with Supply Chain Management.
3. On the toolbar, select **Settings**.
4. On the **Settings** page, expand the **Product** section, and select **Features**.
5. Set the **Allow publishing of canvas apps with code components** option to *On*.

Install the mobile app in Dataverse

To make the Approvals Management mobile app available to users when they sign in using the Power Apps mobile app, you must install it using the Power Platform admin center. The installation process also sets up the required user roles and other dependencies in Dataverse.

Follow these steps to install the Approvals Management mobile app.

1. Sign in to Power Platform admin center.
2. On the left navigation pane, select **Resources** > **Dynamics 365 apps**.
3. Search for and select the app named *Dynamics 365 Approvals Management*.
4. On the top toolbar, select **Install**.
5. Select the environment where you want to install the app, review the packages that will be installed, and select the **I agree to the terms of service** checkbox.
6. Select **Install**.

Grant access to the mobile app in Dataverse

After the mobile app solution is installed in your Dataverse environment, you must share it with your users. The Approvals Management mobile app is a canvas app. To share it, follow the instructions in Share an app.

Each relevant user must also have the *Finance and Operations Basic User* role.

- To assign a role to a group team, follow the instructions in Manage the security roles of a team. We recommend that you use group teams if you must assign the role to multiple users. Learn more about how to manage team members in Manage team members.
- To assign a role directly to a user, follow the instructions in Assign a security role to a user.

Set up user accounts to manage approvals in Supply Chain Management

Each Supply Chain Management user who should be able to use the Approvals Management mobile app must have one or all of the following standard security roles:

- *Buying agent* – This role allows a Supply Chain Management user account to use the app to manage purchase orders.
- *Purchasing agent* – This role allows a Supply Chain Management user account to use the app to manage purchase requisitions.
- *Purchasing manager* – This role allows a Supply Chain Management user account to use the app to manage both purchase orders and purchase requisitions.

Users who have the *System administrator* role can use the app to manage all types of approval requests.

Follow these steps to add the required security roles to a Supply Chain Management user.

1. Sign in to your Supply Chain Management environment by using an administrator account.
2. Go to **System administration** > **Users** > **Users**.
3. Use the filter to find a user who should be able to use the app.
4. Open the details page for the selected user by selecting the link in the **User ID** column.
5. On the **User's roles** FastTab, on the toolbar, select **Assign roles** to open the **Assign roles to user** dialog box.
6. In the **Role name** column, find and select the *Buying agent*, *Purchasing agent* and/or *Purchasing manager* roles, as needed.
7. Select **OK** to apply your settings and close the dialog box.

> ⓘ **Note**

User role organization assignments aren't supported. If one or more organizations that differ from a selected user's **default company** have been assigned to any security role that is set for that user, app installation fails.

Learn more about how to set up roles and security in Supply Chain Management in Security roles.

Set up approval workflows

To enable the approval process for a document type, you must set up approval workflows for it in Supply Chain Management. Learn more in Workflow system overview.

After your approval workflows are set up, approval requests appear in the Approvals Management mobile app just as they do when the same user signs in to Supply Chain Management to manage approvals in the web client.

Install and open the mobile app

Follow these steps to install and use the Approvals Management mobile app on a mobile device.

1. Install the Power Apps mobile app by following the instructions in Install the Power Apps mobile app.
2. Open the Power Apps mobile app, and sign in by using the same corporate account that you use to sign in to Supply Chain Management.
3. Use the **Search** field to search for *Approvals Management*. Because the Approvals Management mobile app is a canvas app, you can add it to your favorites list in Power Apps by swiping left on it after you find it.
4. Open the Approvals Management mobile app, and start to use it.

Clear the Power Apps cache on a mobile device after an update of the back-end setup

If the back-end setup is updated in Supply Chain Management after you install the Power Apps mobile app on a mobile device (for example, if the legal entity setup is changed), you might have to clear the cache in Power Apps to update the local setup data. Power Apps can then reload the settings that otherwise might not take effect until the cache is cleared.

Follow these steps to clear the Power Apps cache on a mobile device.

1. Sign in to the Power Apps mobile app.
2. Select the image for your user account in the upper left of the page to open the settings menu.
3. Select **Clear cache** to open the **Clear cache** dialog box.
4. Select **Confirm**.

Last updated on 12/09/2025

Manage approvals using the Approvals Management mobile app

This article explains how to use the Approvals Management mobile app to approve, reject, or delegate approval requests.

User requirements

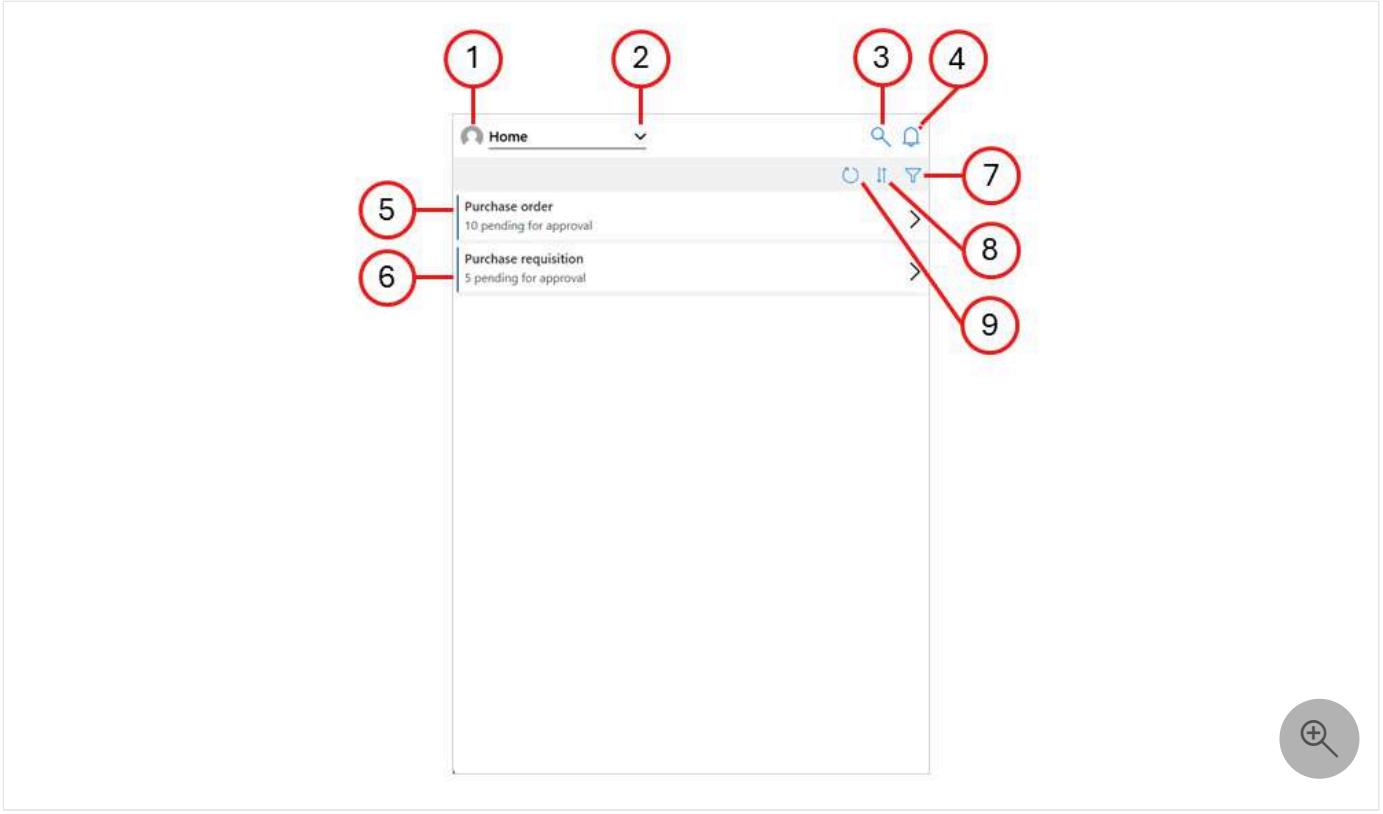
To manage purchasing requests from the Approvals Management mobile app, you must meet the following requirements:

- You must sign in to Microsoft Power Apps by using a domain account, and that domain account must match a user account in Dynamics 365 Supply Chain Management that has the same Microsoft Entra ID user name.
- Your user account in Supply Chain Management must be assigned the required security roles for the types of approvals that you must manage. For more information, see Set up user accounts to manage approvals in Supply Chain Management.

Home page

When you open the Approvals Management mobile app and sign in, the home page appears. This page provides an overview of requests that are awaiting your approval.

The following illustration highlights the user interface (UI) elements on the home page. Many of these elements are common to all pages in the app.



Legend:

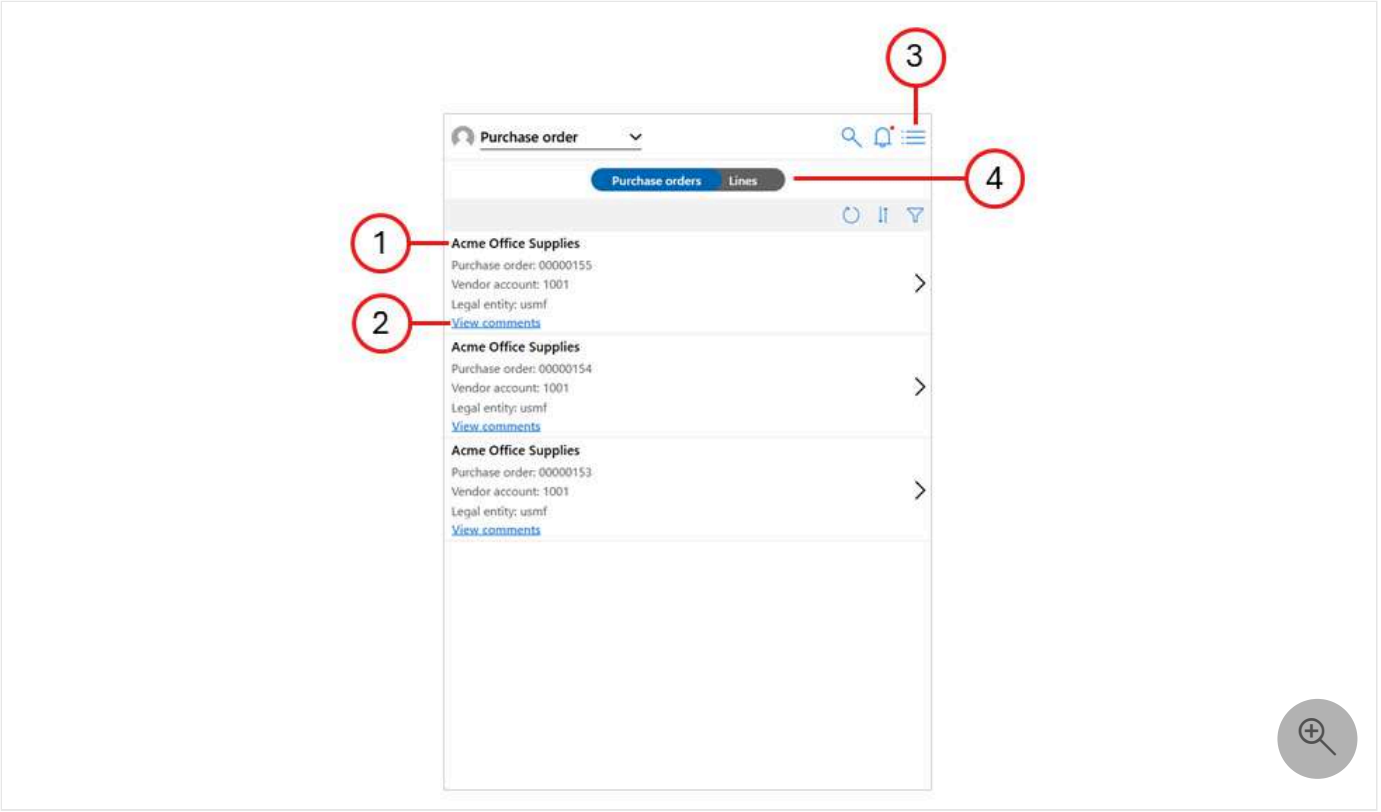
1. **About button** – View information about the app, such as terms and conditions, and the current version.
2. **Navigator** – Move between the main pages of the app (such as **Home**, **Purchase orders**, and **Purchase requisitions**).
3. **Search** – Search for specific documents to approve. For example, you can search for a specific order number, vendor account, vendor name, legal entity, or item number.
4. **Alerts** – Read your notifications. A red dot indicates that you have new notifications.
5. **Purchase orders** – If you can manage purchase orders, this item shows the number of purchase orders that are awaiting your approval. Select it to view the list of purchase orders.
6. **Purchase requisitions** – If you can manage purchase requisitions, this item shows the number of purchase requisitions that are awaiting your approval. Select it to view the list of purchase requisitions.
7. **Filter** – Filter the list by defining specific values to look for. This capability is useful on pages that show longer lists.
8. **Sort** – Select how items are sorted in the list.
9. **Refresh** – Manually refresh the list. (The list is automatically refreshed every 30 seconds.)

List pages

List pages show a list of orders, requisitions, or line items that are awaiting your approval. The type of item that is shown depends on how you opened the list page. From a list page, you can select any item in the list to view more details about it. If you turn on multiselect, you can select one or more items, and then approve, reject, delegate, or request changes for all of them directly from the list page.

List pages without multiselect

List pages where multiselect is turned off show a list of items that you can navigate and select to view more details. The following illustration highlights the UI elements on a list page where multiselect is turned off.

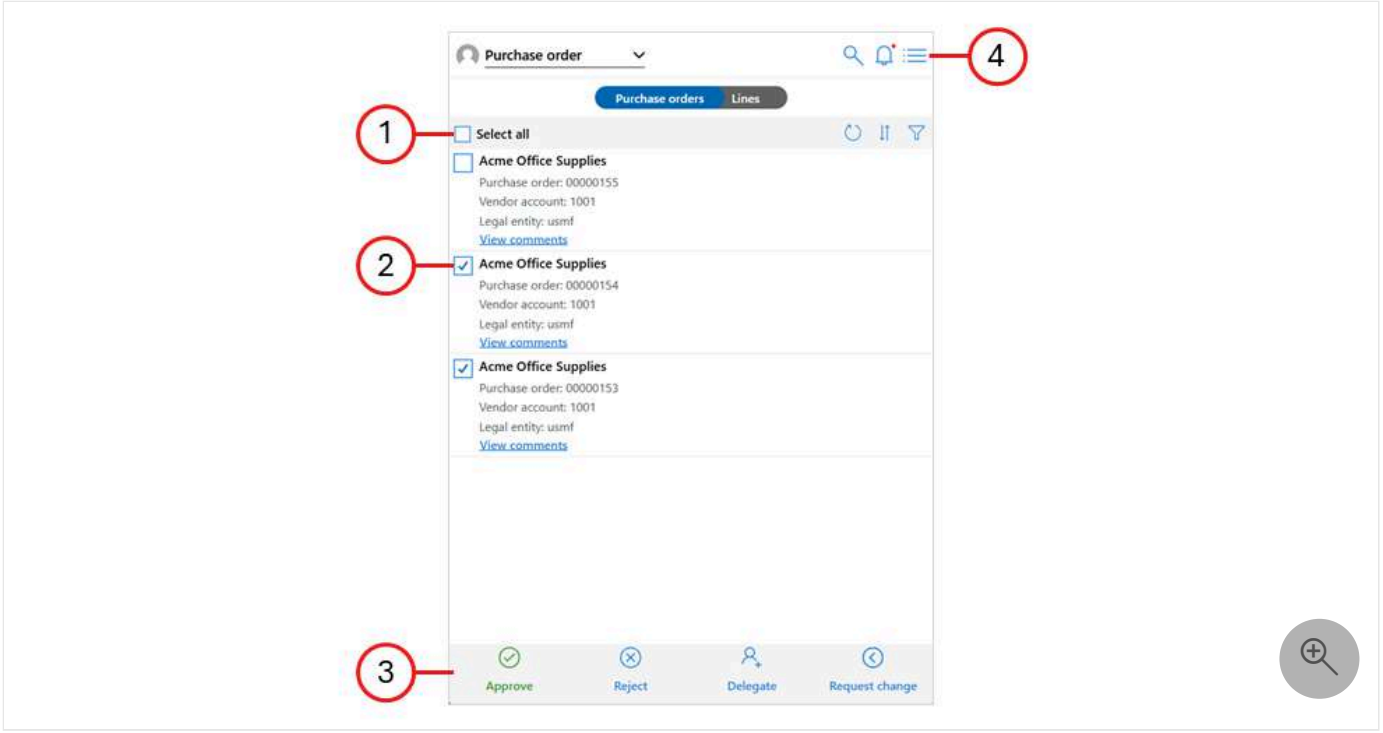


Legend:

1. **List item** – Each item in the list represents an individual document header or line. A summary of the item is shown. Select the item to view details about it.
2. **View comments** – View comments about the related item. These comments are usually comments that the requester wrote for the reviewer.
3. **Multiselect** – Turn multiselect on or off. (In this illustration, multiselect is turned off.)
4. **Header/Lines selector** – Select whether to view a list of document headers or individual lines.

List pages with multiselect

On list pages where multiselect is turned on, you can select one or more items in the list at the same time. You can then approve, reject, delegate, or request changes for all of those items directly from the list page. The following illustration highlights the UI elements on a list page where multiselect is turned on.



Legend:

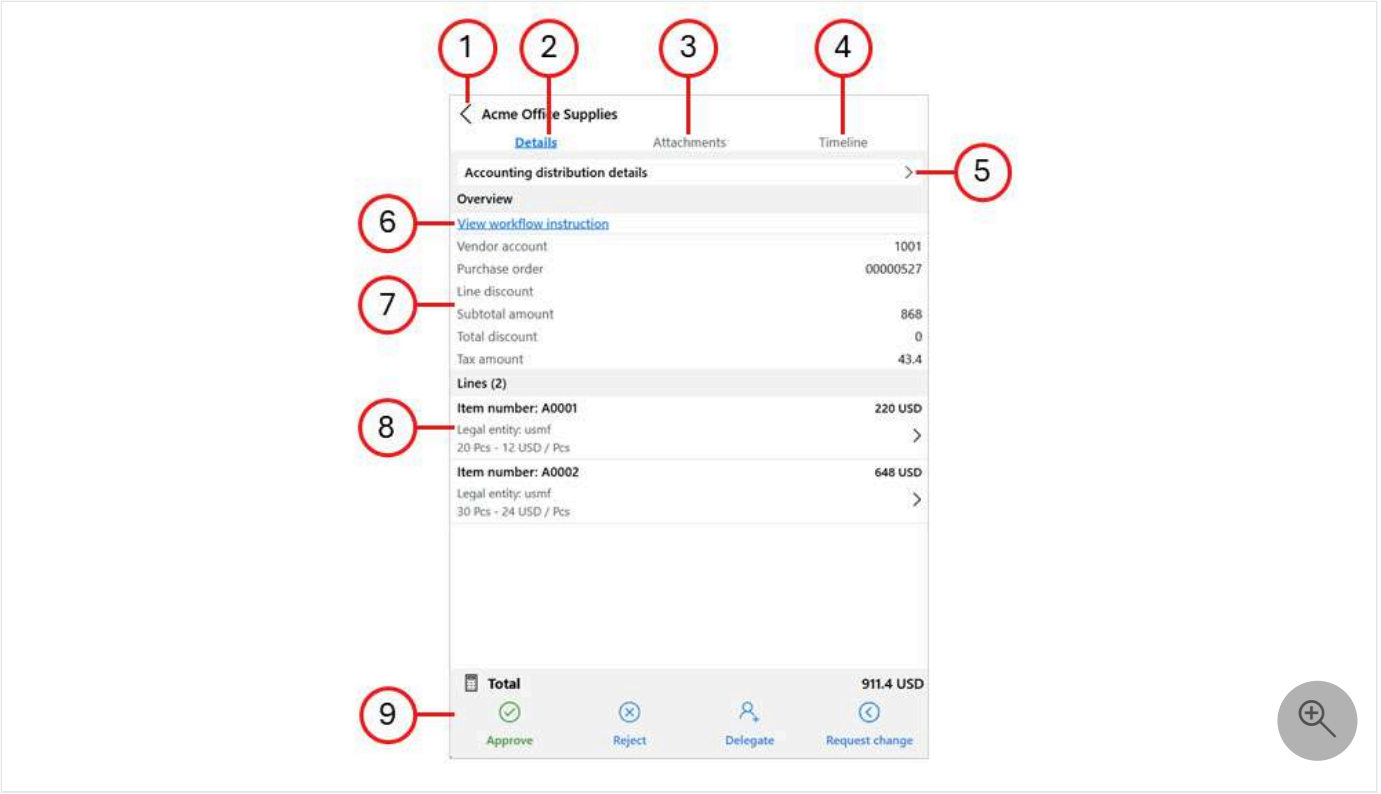
1. **Select all** – Select or clear the selection of all items in the list.
2. **Checkbox** – Select or clear the selection of the related item.
3. **Action buttons** – Approve, reject, delegate, or request changes for all the selected items.
4. **Multiselect** – Turn multiselect on or off. (In this illustration, multiselect is turned on.)

Detail pages

Detail pages show detailed information about a specific document header or line item. The details that are provided vary slightly, depending on whether you view header details or line details.

Header details

Header details pages show information about the selected document as a whole. The following illustration highlights the UI elements on a header details page.

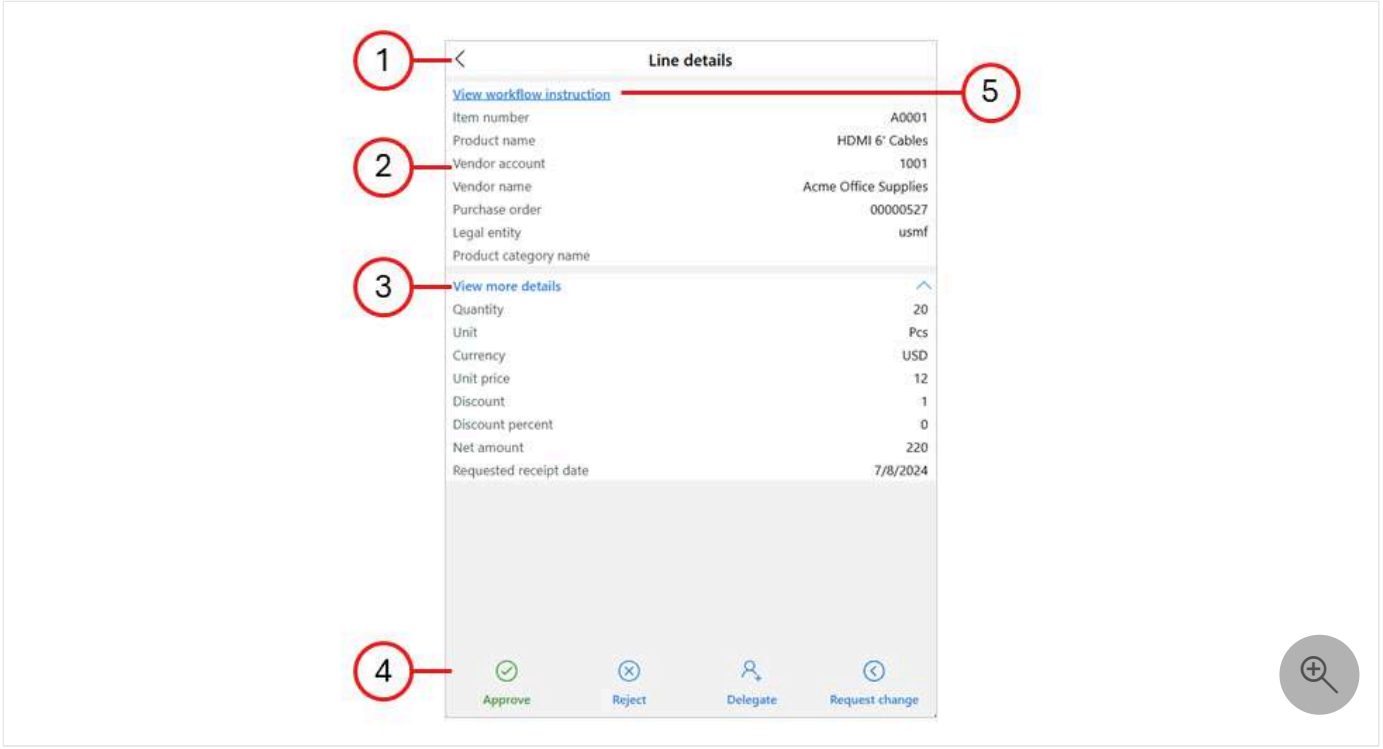


Legend:

1. **Back** – Return to the page that you came from.
2. **Details tab** – View general information about the document. (In this illustration, this tab is selected.)
3. **Attachments tab** – View and open any attachments that are associated with the document.
4. **Timeline tab** – View a timeline of events that are related to the document.
5. **Accounting distribution details** – View accounting distribution details that are linked to the document.
6. **View workflow instructions** – View instructions for the workflow.
7. **Header details** – Shows detailed information about the document.
8. **Lines** – Lines are listed under the header details. Each line shows a summary of the line item. Select a line to view more details about it.
9. **Action buttons** – Approve, reject, delegate, or request changes for the document.

Line details

Line details pages show information about a specific document line. The following illustration highlights the UI elements on a line detail page.



Legend:

1. **Back** – Return to the page that you came from.
2. **Standard details** – View general information about the line item.
3. **Extra details** – Expand or collapse additional information about the line item.
4. **Action buttons** – Approve, reject, delegate, or request changes for the line.

   > **Note**
   >
   > Not all line details pages include these buttons.

5. **View workflow instructions** – View instructions for the workflow.

Approvals Management mobile app FAQ and known issues

06/30/2025

This article provides answers to several frequently asked questions (FAQ) about the Approvals Management mobile app. It also describes some known issues that affect the app and explains how to work around them.

What platforms and mobile devices are supported?

The Approvals Management mobile app runs within the Power Apps mobile app. All platforms that the Power Apps mobile app supports can also run the Approvals Management mobile app. Learn more in System requirements, limits, and configuration values for Power Apps.

Why isn't anything shown when I sign in to the mobile app?

If no features are visible in the Approvals Management mobile app, you probably lack the permissions that are required to access them. Access to each feature is controlled by security roles that are assigned to your user account in Dynamics 365 Supply Chain Management. Learn more in Onboard the Approvals Management mobile app.

What versions of Supply Chain Management support the mobile app?

The Approvals Management mobile app requires Supply Chain Management version 10.0.41 or later.

Does the mobile app support Microsoft Intune deployment?

Yes, the Approvals Management mobile app supports deployment through Intune. Learn more in Manage your mobile app with Microsoft Intune.

Can I customize and extend the mobile app?

No, you can't currently customize or extend the Approvals Management mobile app.

Does the mobile app support offline mode?

No, the Approvals Management mobile app doesn't currently support offline mode.

Is there multi-language support?

Yes, the Approvals Management mobile app is available in all the same languages as Supply Chain Management, except right-to-left (RTL) languages. We plan to add RTL support in a future release, after it's added to the canvas app platform.

Where can I go to discuss the mobile app with the community and submit suggestions to Microsoft?

The Dynamics 365 Procurement and Sourcing group on Viva Engage is a great place to go if you want to exchange tips, ask questions, or submit suggestions for improvement. Viva Engage group participants include Microsoft partners, customers, experts, and employees.

I receive the following error: "Error when trying to retrieve data from the network." How can I diagnose the issue?

If you receive an error message that states, "Error when trying to retrieve data from the network," follow these steps to diagnose and fix the issue.

1. Run the Approvals Management mobile app in a browser as described in Run an app in a web browser.
2. If you receive the same error while you run the app in a browser, set up your browser to capture an HTTP Archive file (HAR) file. Then reload the tab where the app is running.
3. Use a tool such as the Google HAR analyzer to redact all secrets from the HAR file.
4. Contact Microsoft Support, and share the redacted HAR file with them.
5. Microsoft Support will help you diagnose and fix the issue.

The content of the HAR file might reveal an error that resembles the following example:

```
text
```

```
SecLib::CheckPrivilege failed. User: <EntraObjectID>, PrivilegeName:
prvReadRelationship, PrivilegeId: <PrivilegeID>, Required Depth: Basic,
BusinessUnitId: <BusinessUnitID>, MetadataCache Privileges Count: <CacheCount>,
User Privileges Count: <UserPrivilegeCount>
```

This error can occur because the *Approvals Management app* role doesn't have the privileges that are required to read the `Relationship` table. Instead, that privilege is provided by the *Finance and Operations Basic User* role in Dataverse. To fix this issue, add the *Finance and Operations Basic User* role to each user or team that uses the app.

When I update the mobile app, I receive the following error: "Could not delete solution...because it has been modified." How can I fix the error?

The Approvals Management mobile app is a canvas app. The update process fails with an error if it detects that the canvas app has been customized. This behavior helps prevent the updater from overwriting your customizations. To fix the error, remove any customization layers by restoring the oldest version of the app. If the oldest version is more than six months old, you must manually delete the `msdyn_ApprovalsManagementAnchor` and `msdyn_ApprovalsManagement` solutions, and then reinstall the app from Dynamics 365 apps or AppSource.

Consider cloning the canvas app before you remove your customizations, just in case you want to copy the customizations to the updated app.

To delete the solutions, follow these steps:

1. Open the Power Apps Maker portal for your environment.
2. On the left navigation pane, select **Solutions**.
3. Open the **Managed** tab to view managed solutions.
4. Find and delete each of the following solutions. The **Search** field in the top-right corner of the page can help you find the solutions quickly. The **Delete** button is available in the **Commands** menu (three dots) provided for each solution.

    - Dynamics 365 Approvals Management Anchor Solution
    - Dynamics 365 Approvals Management Solution

> **Note**

Microsoft doesn't support **customizing or extending** the Approvals Management mobile app.

Are there any known issues that affect the release of the mobile app?

Yes, the Approvals Management mobile app has a few known issues that we expect to correct in an upcoming release. The following subsections describe these issues.

Limited file type support for attachments

The current release provides only limited support for viewing file attachments on the job details page. We plan to add support for more file types in the final release.

Supported attachment types:

- URL (link)
- PNG/JPEG/JPG/BMP/GIF (image)
- PDF (document)

Unsupported attachment types:

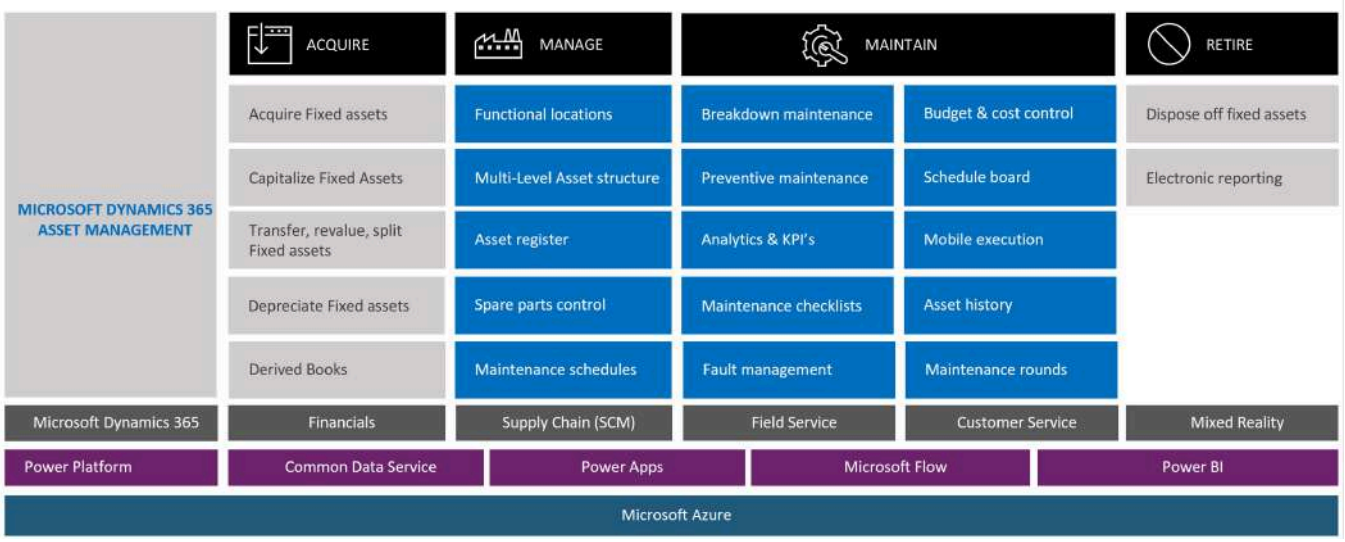
- Note
- All other file types

Asset management overview

07/10/2025

Asset Management is an advanced module for managing assets and maintenance jobs in Dynamics 365 Supply Chain Management. Asset Management integrates seamlessly with several other finance and operations apps.

The following illustration shows the interfaces between Asset Management and other finance and operations apps.



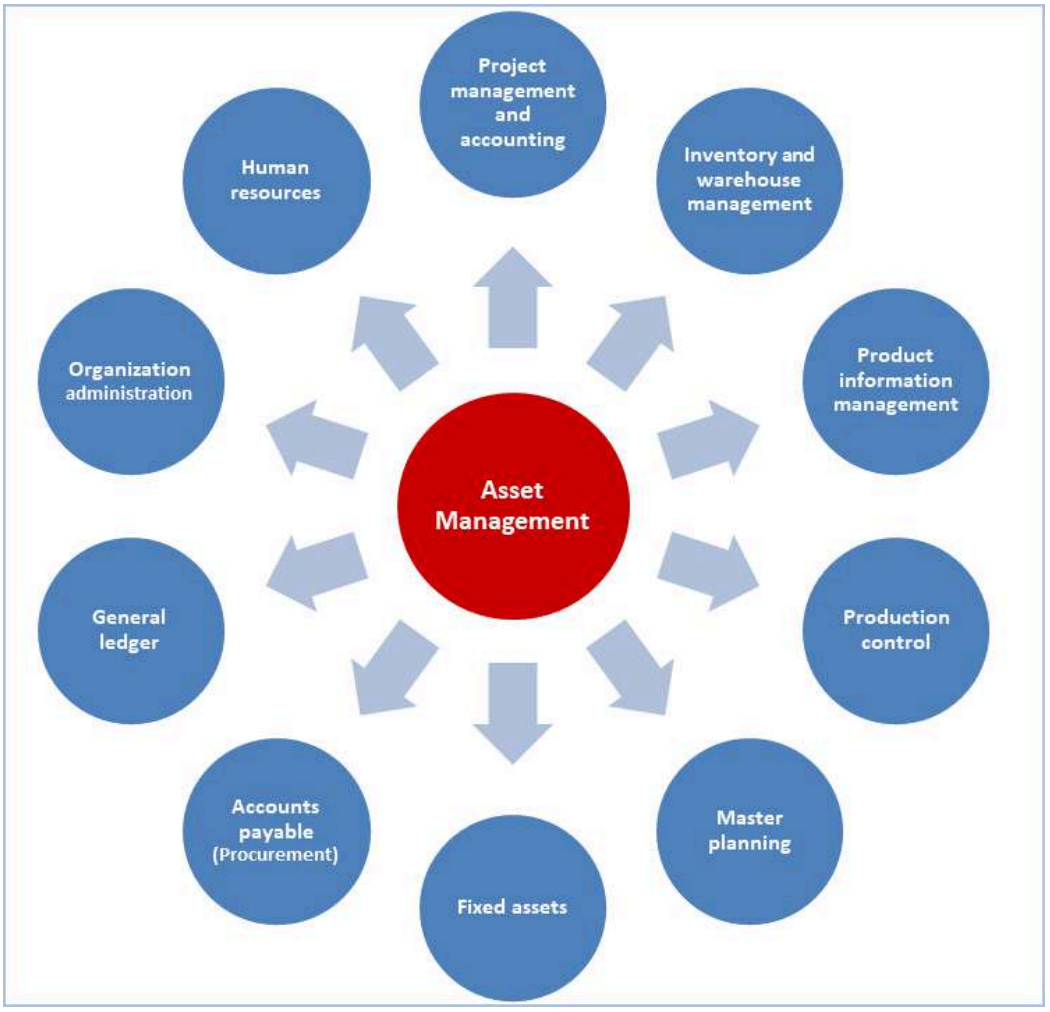
Asset Management enables you to efficiently manage and service many types of equipment in your company (such as machines, production equipment, and vehicles). Asset Management supports solutions across numerous industries.

Functional locations and assets

07/10/2025

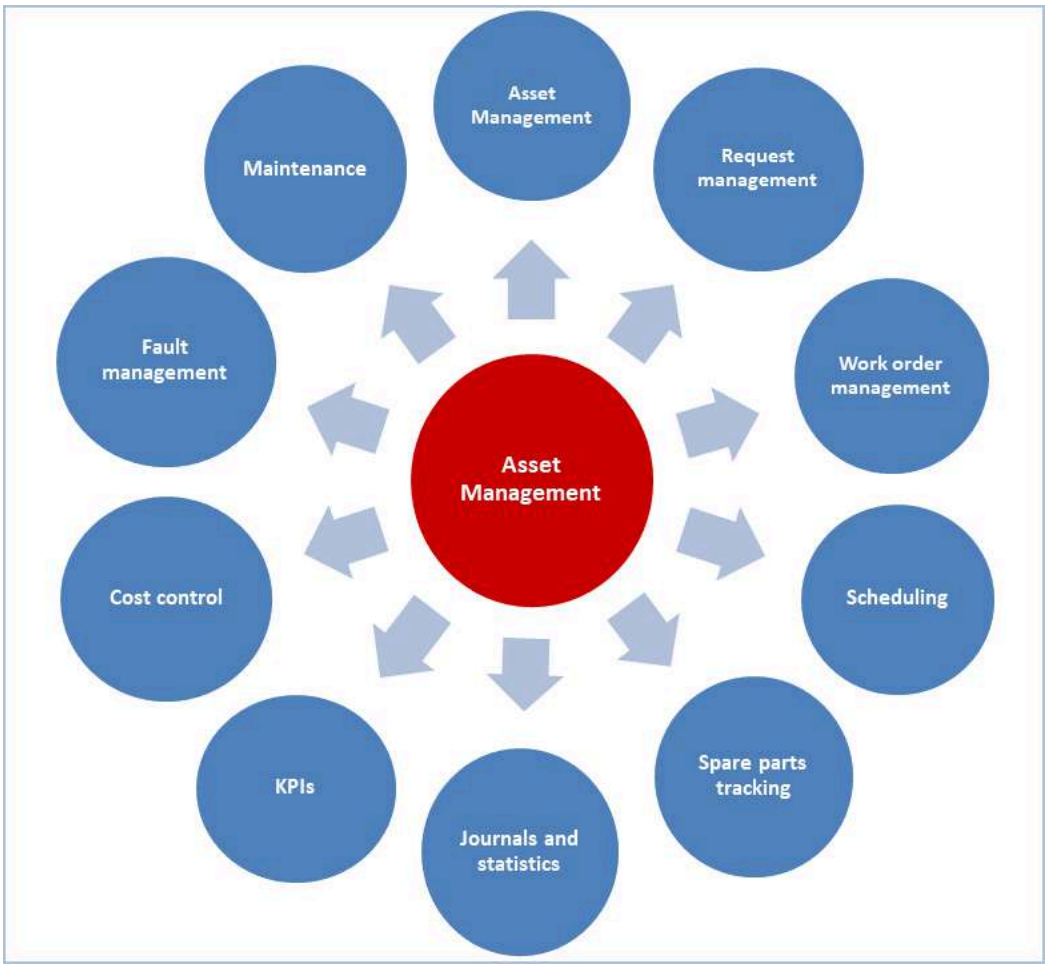
This article describes functional locations and assets in Asset Management.

Asset Management is integrated seamlessly with several modules for Supply Chain Management and other finance and operations apps. The following illustration shows the interfaces with other modules.



Asset Management lets you efficiently manage and perform all tasks that are related to managing and servicing many types of equipment in your company. This equipment includes machines, production equipment, and vehicles. Asset Management also supports solutions across numerous industries.

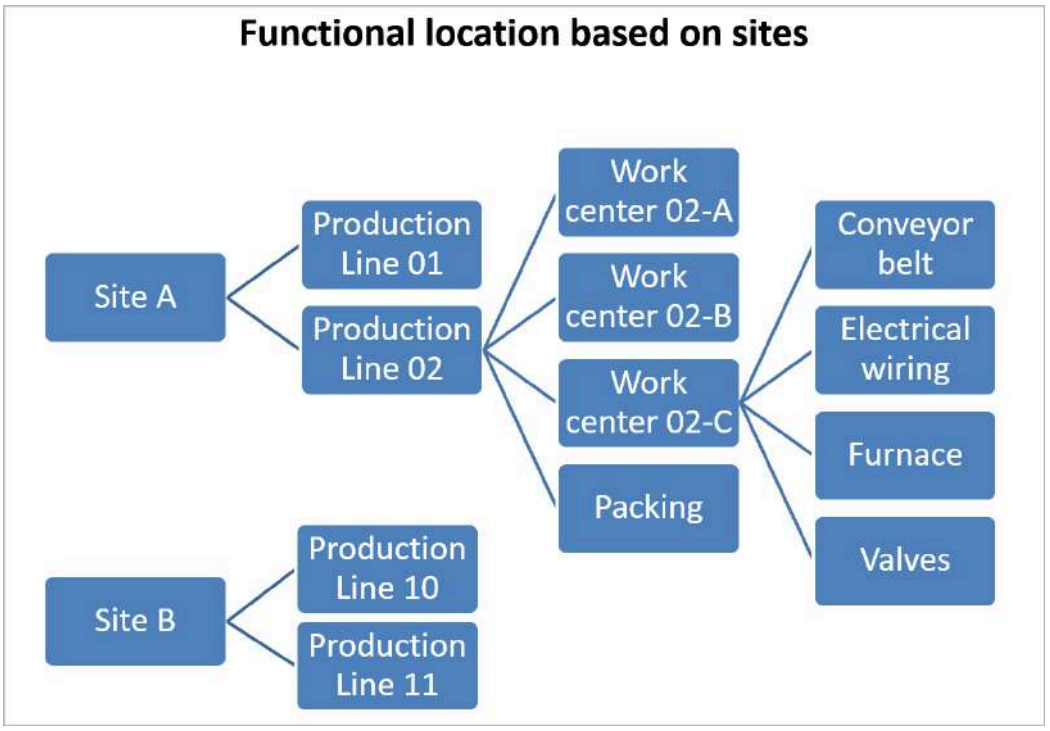
The following illustration shows an overview of the main functionality that is covered by Asset Management.



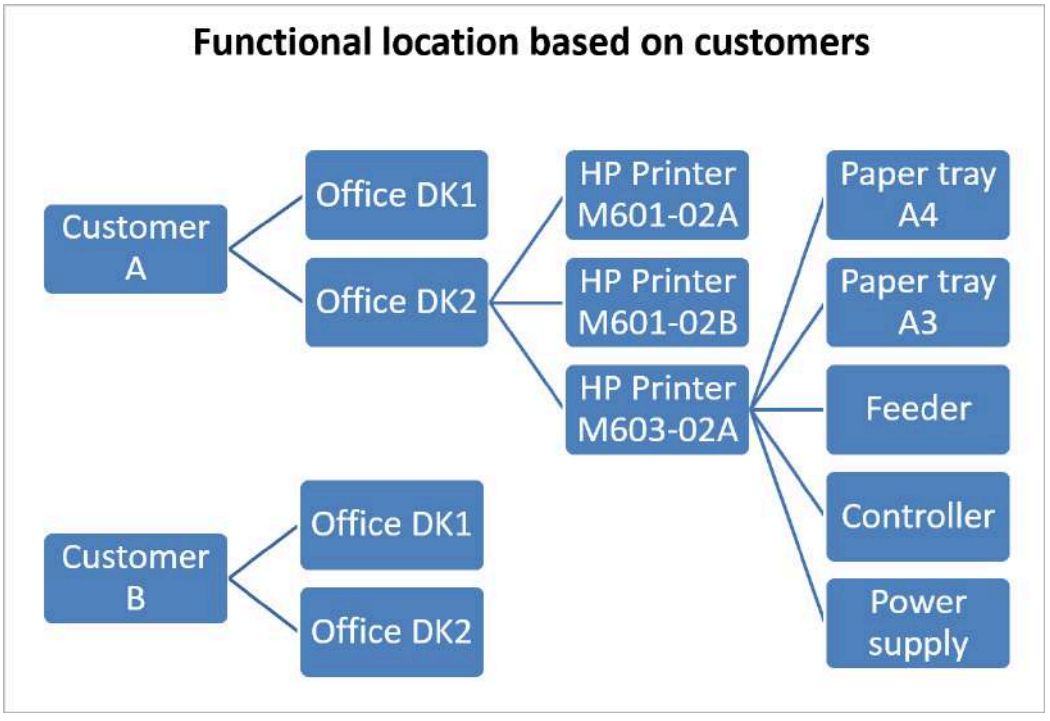
Functional locations are used to manage assets on locations. This management includes tracking of asset costs on functional locations. Functional locations are structured hierarchically, and locations can have sublocations. The structure of functional locations is static. In other words, locations can't change place. Assets can be installed on functional locations and, as required, can be installed on other functional locations later.

Asset costs always follow the location of the asset. In other words, if you install an asset on a new functional location, the asset automatically uses the financial dimensions that are related to the new functional location. Therefore, asset costs are always related to the functional location that the asset is currently installed on. This automatic handling of financial dimensions helps guarantee complete tracking of costs when your company does project controlling and reporting on functional locations.

The way that you build your hierarchy of functional locations depends on your company's requirements for maintaining internal equipment or servicing customer equipment. The following figure shows an example of functional locations that are based on geographical locations.



The following figure shows an example of functional locations that are based on customers.



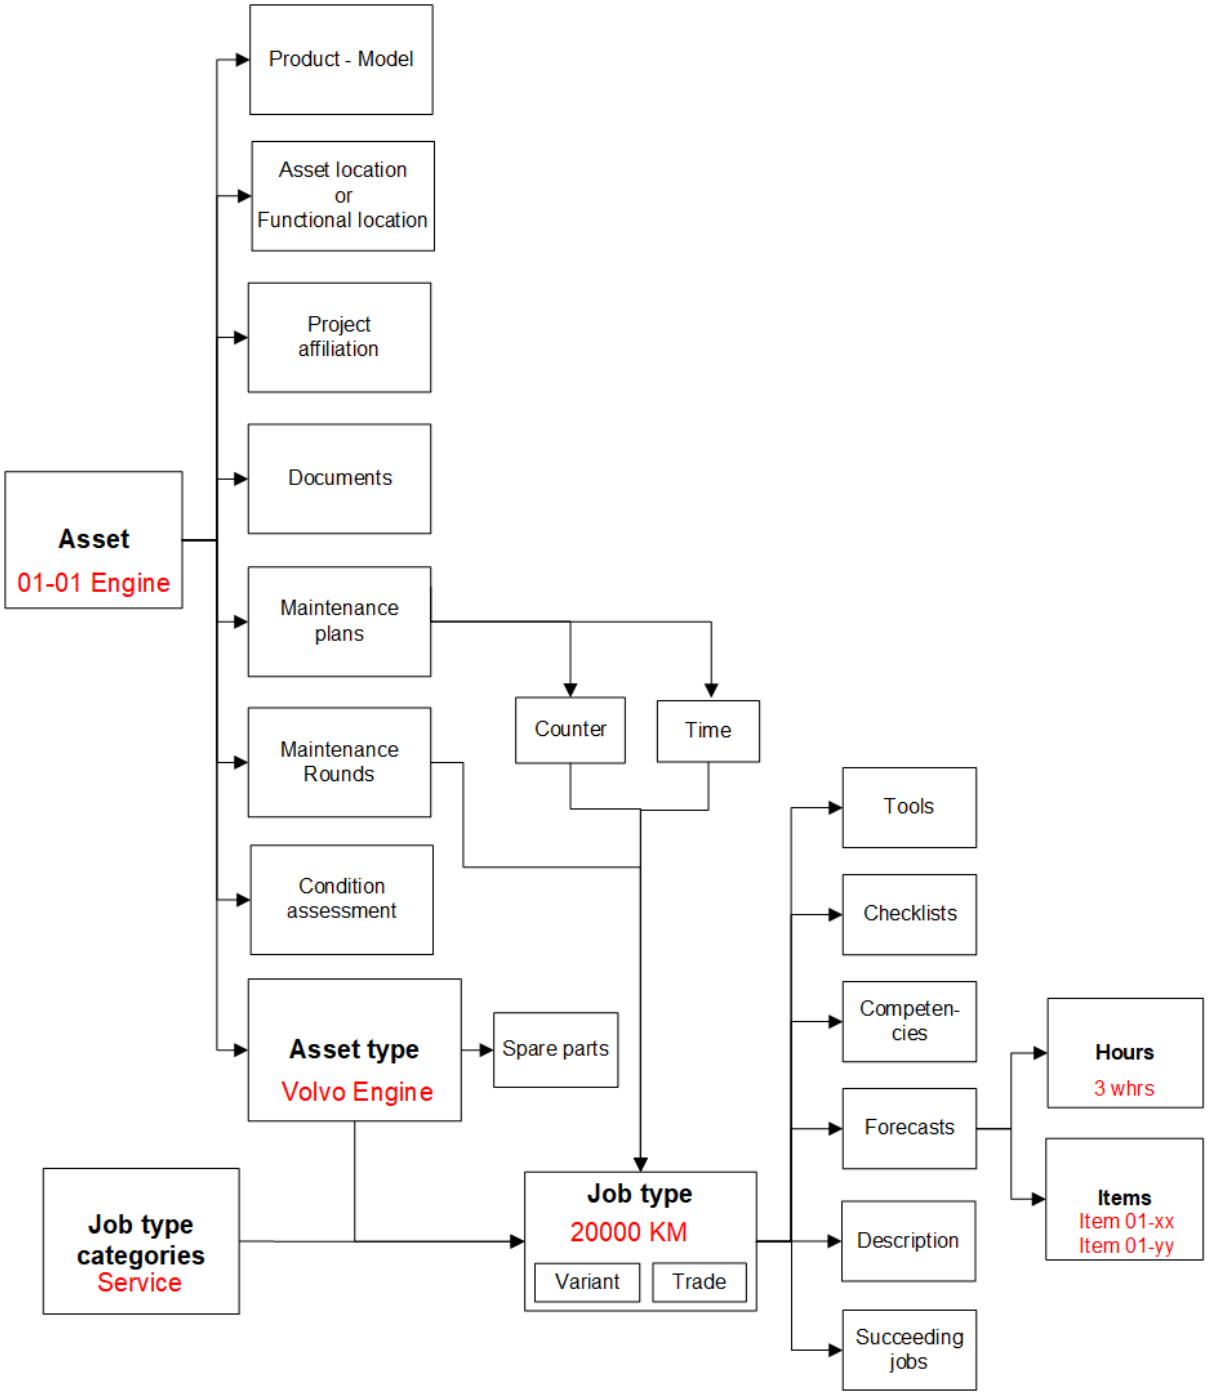
Assets and work orders

07/10/2025

This article describes assets and work orders in Asset Management. Assets and work orders are the central parts of Asset Management. An *asset* is a machine or machine part that requires continuous maintenance and service. Assets can be created in a hierarchical structure, and they can be related to functional locations. Maintenance jobs can be planned at all levels in the asset structure.

Asset data and job types

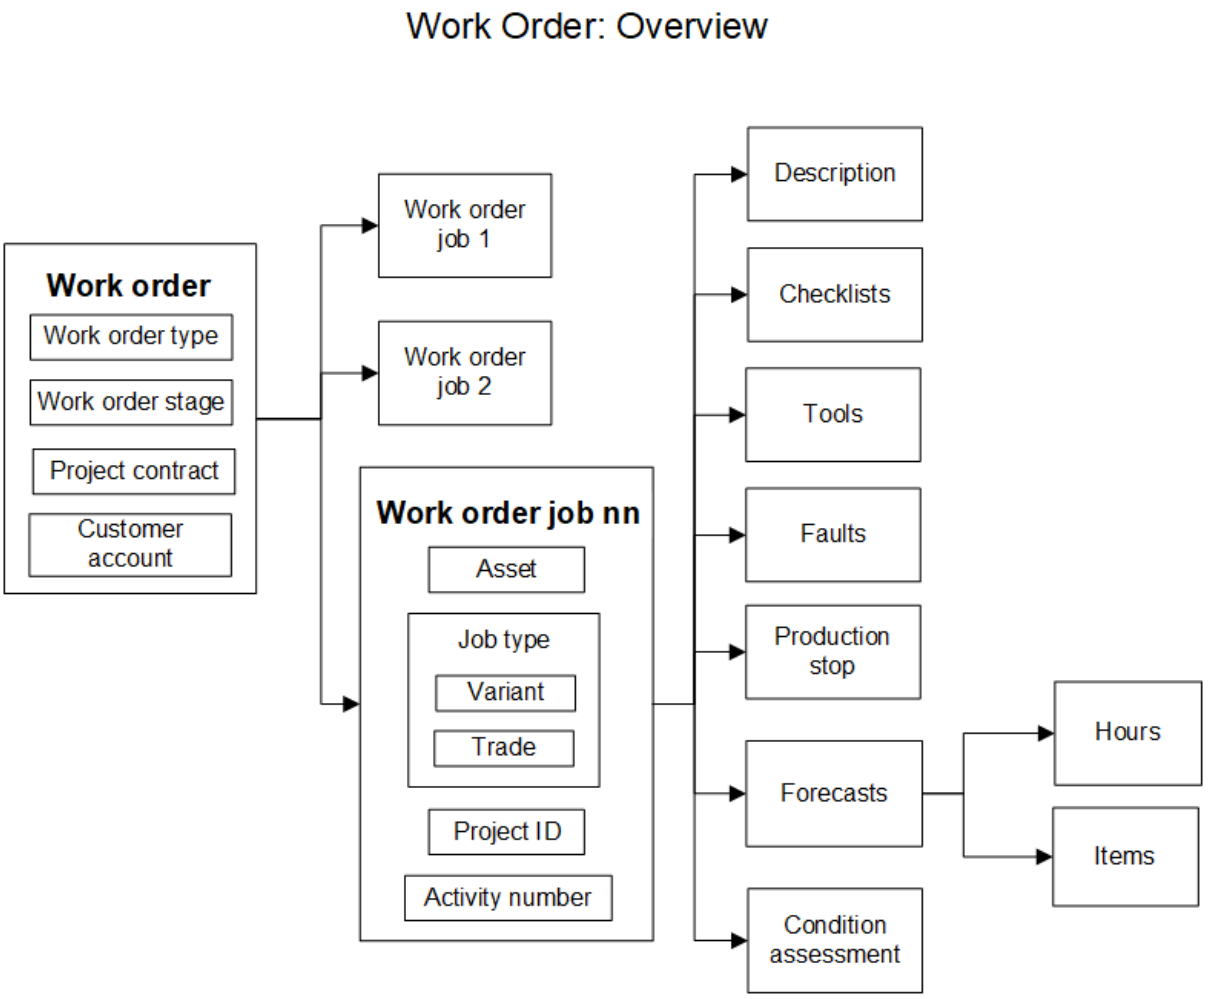
Various data, such as product information and asset specification, and required maintenance plans are set up on each asset. The following illustration shows an overview of asset data and the affiliation of assets to job types. Red text is used for examples that show inheritance and dependencies.



Key data in a work order

Every work order has a work order type, such preventive maintenance, corrective maintenance, or inspection. The work order contains one or more work order jobs. Every work order job defines a job that must be performed on an asset and a related job type. Examples of related job types include 10,000 km, 50,000 km, 1-year overhaul, and safety inspection. One work order can be related to multiple assets.

The following illustration shows an overview of the key data in a work order.

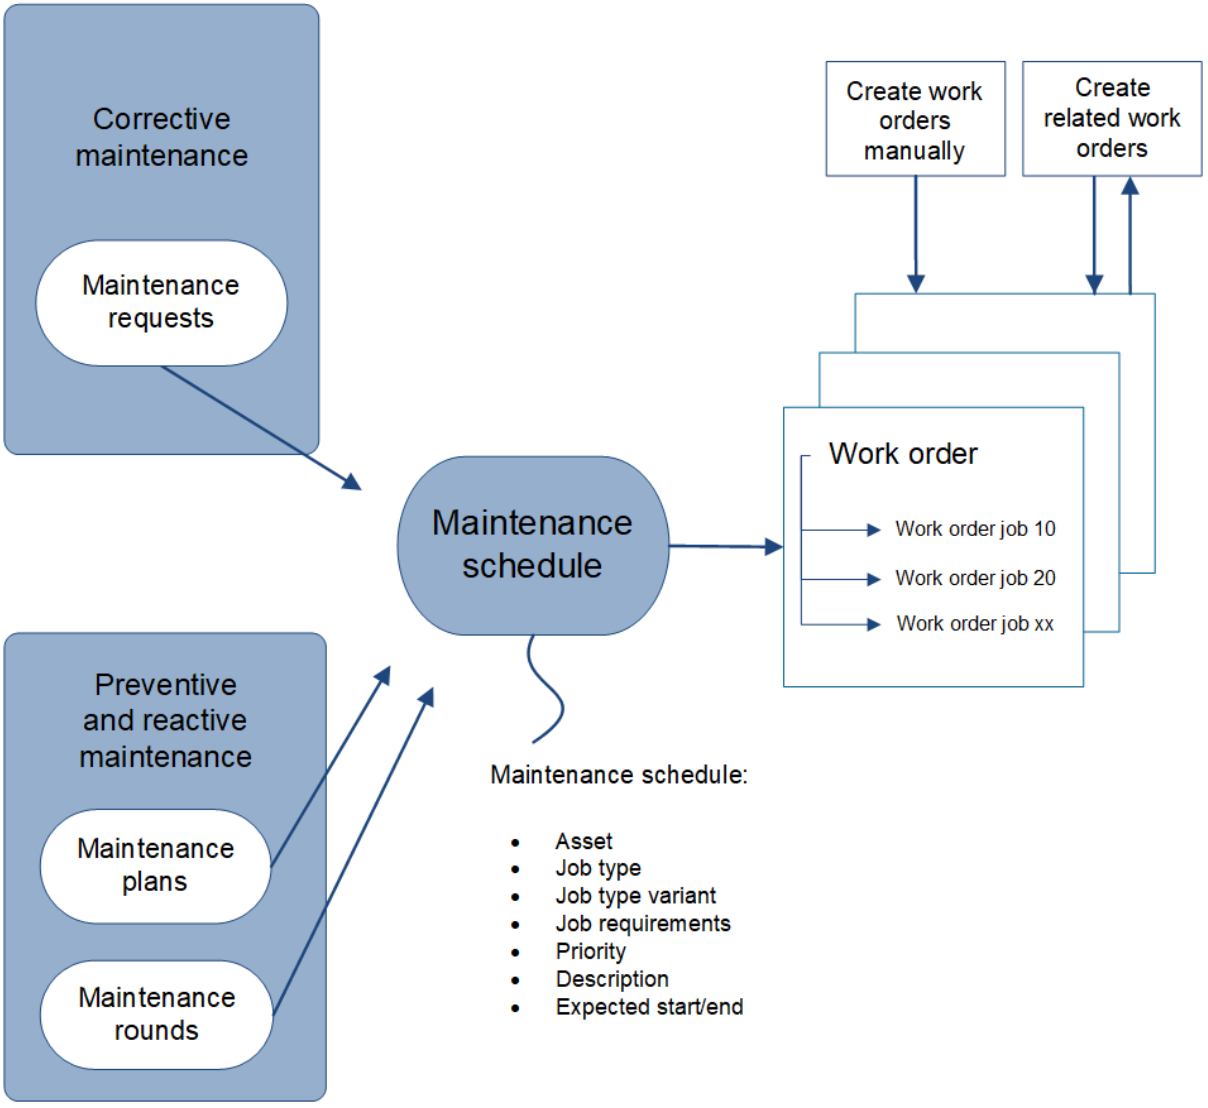


A work order can be related to another work order, and job types can contain succeeding jobs that create a work order. In general, there are no dependencies between work orders. Therefore, they can change their work order lifecycle state and can be scheduled independently of each other.

Creating work orders automatically or manually

Work orders can be created in various ways that are related to corrective, preventive, or reactive maintenance. You can also create work orders manually. The following illustration shows an overview of the process for automatic or manual creation of work orders.

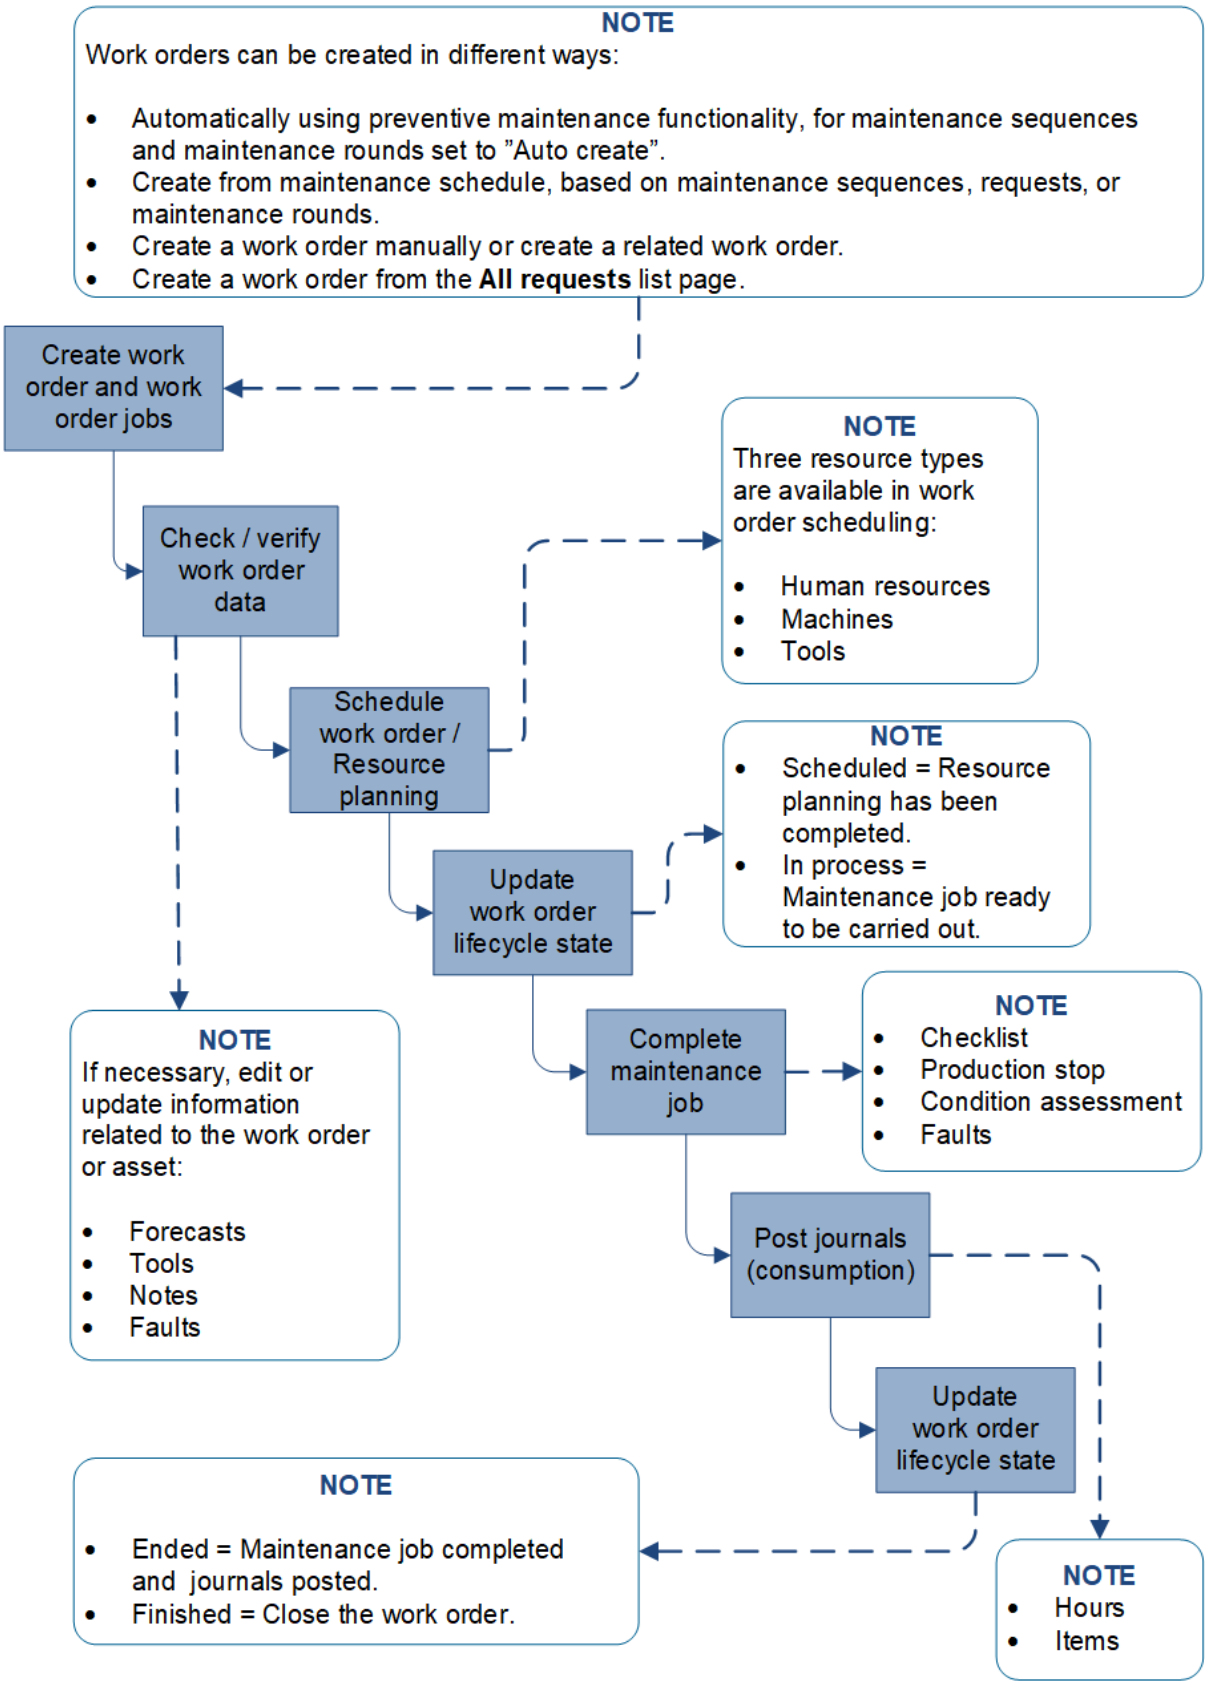
Process flow – Creating work orders



Processing a work order

Several steps must be completed when you want to schedule and run a maintenance job on a work order. The following illustration shows an overview of the processing for a work order.

Work Order - Flow Diagram



> ⓘ Note
>
> In general, when you work in Dynamics 365 Supply Chain Management and the **Asset Management** module, you select **New** to create a new record, you select **Edit** to update an existing record, and you select **Save** to save new or edited data.

Next steps

- Introduction to assets
- Introduction to work orders

Functional location lifecycle states

Article • 01/06/2025

This article describes how to set up functional location lifecycle states and lifecycle models in Asset Management. Functional location lifecycle states define the states that a functional location can go through, for example, created, active, and ended. You're able to view all functional locations, regardless of their lifecycle state, in the **All functional locations** list page. You can change the state of a functional location by selecting it in the **All functional locations** list page and selecting **Update functional location state**.

Set up functional location lifecycle states

1. Select **Asset management** > **Setup** > **Functional locations** > **Lifecycle states**.
2. Select **New** to create a new functional location state.
3. Insert the state ID in the **Lifecycle state** field and a name for the functional location state in the **Name** field. In the **Lifecycle models** field, you can see the number of functional location lifecycle models that uses the functional location state.
4. On the **General** FastTab, select *Yes* on the **Active** toggle button if the functional location should be active at this state.
5. Select *Yes* on the **Create assets** toggle button if it should be possible to automatically create an asset with the same name as the functional location and install it on the functional location at this state.

   > **Note**
   >
   > This toggle button relates to the **Asset type** field on the **General** FastTab on the **Functional location types** page (**Asset management** > **Setup** > **Functional locations** > **Functional location types**).

6. Set **Rename location** to *Yes* to make it possible to change the name of the functional location at this state.
7. Set **New sub locations** to *Yes* to make it possible to add new sub locations to the functional location at this state.
8. Set **Install assets** to *Yes* to make it possible to install assets on the functional location at this state.

9. Set **Install assets** to *Yes* to make it possible to delete the functional location at this state.

10. Select an asset state in the **Lifecycle state** field if you want the asset lifecycle state for all assets installed on the functional location to be automatically updated at this state. For example, if you close down a functional location and set the functional location lifecycle state to *Ended*, you might want to automatically change the lifecycle state of the assets installed on that functional location to *Not in use*.

> **Note**
>
> Functional location lifecycle states, lifecycle models, and types are related and used in the same way as work order lifecycle states, work order lifecycle models, and work order types.

Set up functional location lifecycle models

When you have created the lifecycle states required for your functional locations, they can be divided into groups. This is done to create the lifecycle model flow that could be used for different types of functional locations. As a minimum, one standard functional location lifecycle model should be created.

1. Select **Asset management** > **Setup** > **Functional locations** > **Lifecycle models**.
2. Select **New** to create a new lifecycle model.
3. Insert the lifecycle model ID in the **Lifecycle model** field and a name for the lifecycle model in the **Name** field. In the **Functional location types** and **Lifecycle states** fields, you can see the number of functional location types that uses the lifecycle model and the number of states selected in the lifecycle model.
4. On the **Lifecycle states** FastTab, select the states that should be included in the model. This is done by selecting a state in the **Lifecycle states remaining** section and selecting the button.
5. If you want to select all the available states for a model, select the button. All states are transferred to the **Lifecycle states selected** section.
6. If you want to remove a selected state from the model, select the state in the **Lifecycle states selected** section and then select the button.
7. Select **Lifecycle state updates** to define which lifecycle states can follow a selected state.

Maintenance attribute types

Article • 01/09/2023

This article explains how to create attribute types in Asset Management. Attributes are used to describe the properties of various elements. You can set up attributes on the following elements:

- Functional location types
- Create functional locations
- Asset types
- Assets

The attributes that you can set up vary, depending on the element. For example, for a functional location, you can set up attributes for the configuration and physical size of the location. For an asset type or an asset, you can set up attributes for engine volume, power consumption, and maximum load capacity under different conditions.

Create attribute types

You can create your own attribute types. Additionally, you can transfer product dimensions to the **Attribute types** page.

1. Select **Asset management** > **Setup** > **Attribute types**.
2. The first time that you set up attribute types, select **Create product dimensions** to automatically transfer standard product dimensions.
3. Select **New** to create a new attribute type.
4. In the **Attribute type** field, enter a name for the attribute type.
5. In the **Description** field, enter a description.
6. In the **Unit** field, select the relevant attribute unit, as required.
7. In the **Data type** field, select a data type for the unit.
8. If you selected **String** as the data type, follow these steps to create values for the attribute type:
   a. Select the attribute type, and then select **Values**.
   b. In the **Attribute values** field, select **New**.
   c. In the **Attribute type** field, select an attribute type (dimension).
   d. In the **Value** field, enter a related value.

e. In the **Description** field, enter a description.
f. Save the record.
g. Return to the **Attribute types** page.

9. Save the record.

   The **Functional location types** field shows the number of functional locations that are using the attribute type. The **Asset types** field shows the number of asset types that are using it.

Functional location types

06/17/2025

This article describes how to create functional location types in Asset Management. Functional location types are used to manage requirements for functional locations, including how assets are installed on a functional location. You can set up asset types, maintenance plans, functional location attributes, and asset attribute requirements to be used on a functional location that uses the specific functional location type. When you create a functional location, the functional location type is mandatory.

> **Note**
>
> To work with functional locations, you must create a default functional location to be used only for the purpose of creating new assets. For that default functional location, you should create a default functional location type that is simple and allows multiple assets to be installed on the default functional location. To learn more about how to set up functional locations, go to Create functional locations.

Create a default functional location type

This procedure shows how to create a default functional location type to be used for a default functional location.

1. Select **Asset management** > **Setup** > **Functional locations** > **Functional location types**.
2. Select **New** to create a functional location type.
3. Insert a functional location type ID in the **Functional location type** field, for example, *Default*, and a name in the **Name** field.
4. Select a lifecycle model in the **Functional location lifecycle model** field.
5. Select *Yes* on the **Multiple assets** toggle button to allow more assets to be installed on a functional location (the default functional location) using this type.

Now, the default functional location type to be used only on a default functional location is created. You shouldn't add any more requirements or restrictions to this default functional location type.

Create Functional Location Types

1. Select **Asset Management** > **Setup** > **Functional locations** > **Functional location types**.
2. Select **New** to create a functional location type.

3. Insert a functional location type ID in the **Functional location type** field and a name in the **Name** field.
4. Select a lifecycle model in the **Functional location lifecycle model** field. To learn more about functional location lifecycle states and lifecycle models, go to Functional location lifecycle states.
5. Select *Yes* on the **Multiple assets** toggle button if it should be possible to install several assets on a functional location using this functional location type. If you select *No*, you can only install *one* asset on a functional location using this functional location type.
6. Select *Yes* on the **Update asset dimension** toggle button if you want assets installed on a functional location of this type to automatically use the financial dimensions related to the functional location. This means that if you change financial dimensions in the Create functional locations form, and the functional location uses a functional location type with this toggle button set to *Yes*, financial dimensions are automatically updated on all assets installed on that functional location.
7. The **Asset type** field is used if you want to automatically create *one* asset for the functional location with the same ID and name as the functional location you're creating. For example, this might be relevant if you create a static functional location, such as a building or a pipeline. In that case, select the asset type you want to use for the automatically created asset. Remember that if you make a selection in this field, the **Multiple assets** toggle button must be set to *No*.
8. On the **Asset types** FastTab, select the asset types to be related to the functional location type. Select **Add line** and select the asset types. If you add asset types here, only assets using those asset types can be installed on a functional location using this functional location type. If no asset types are selected on the **Asset types** FastTab, all asset types might be installed.
9. On the **Maintenance plans** FastTab, select the maintenance plans that should automatically be set up on new functional locations using this functional location type. Select **Add line** and select the maintenance plans. If you add maintenance plans here, only those plans can be used on a functional location using this functional location type.
10. On the **Asset attribute requirements** FastTab, set up the asset attributes that should automatically be set up on new functional locations using this functional location type. Select **Add line** and select the attribute. These attribute requirements function as guidelines. They aren't validated against attributes set up on an asset (to see the attributes, go to **Asset management** > **Assets** > **All assets**, select an asset in the list page, and on the Action Pane, open the **General** tab and select **Attributes**). The attribute requirements are shown when you install assets on functional locations.
11. On the **Permitted types** FastTab, select the functional location types that should be valid for sub functional location types related to a parent functional location type, which uses the selected functional location type.
12. On the **Attributes** FastTab, select the functional location attributes that should automatically be set up on functional locations using this functional location type. Select

Add line and select the attribute.

> **Note**
>
> On the **General** FastTab, you can get an overview of the number of asset types, maintenance plans, asset attribute requirements, permitted types, attributes, and functional locations set up on the functional location type. The **Functional locations** field shows the number of functional locations that use the functional location type. You can use the **Copy** button to copy settings from a functional location type to the selected functional location type.

Introduction to functional locations

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides an overview of functional locations in Asset Management. Functional locations are elements of a technical structure, such as the functional units in a system. Functional locations are created hierarchically, and you install assets on them. The setup of functional locations in your company depends on the company's requirements.

Here are some examples of how you can use functional locations:

- **Functional** – The functional locations can be user-oriented and used to manage assets that have similar behavior.
- **Process-related** – The functional locations can be workflow-oriented.
- **Spatial** – The functional locations can represent geographical locations or sites.

Each functional location is managed independently in Asset Management. Here are some of the useful features of functional locations:

- Set up functional location specifications.
- Set up asset specification requirements.
- Set up maintenance sequences for preventive and reactive maintenance.
- Manage installed assets.
- Track active requests and work orders that are related to installed assets.
- Track faults that are registered on assets.
- Track maintenance costs on the assets that are related to a functional location at any given time.

Functional locations provide traceability of assets in relation to requests, work orders, fault registrations, condition assessments, production stop registrations, and asset counter registrations.

> **Note**

Even if an asset is installed on various functional locations during its lifetime, the costs can be related to each location. In other words, asset costs are always related to the functional location that the asset was installed on at a given time.

Functional locations are **not** flexible. Therefore, after you set up a functional location hierarchy, you can't move locations around in it.

After you create a functional location hierarchy, the next step is to install assets on it. Learn more in Install assets on functional locations.

All functional locations

Select **Asset management** > **Functional locations** > **All functional locations** to open the **All functional locations** list page. This page shows all functional locations and some of the information that is related to each. To view only active functional locations, select **Active functional locations**. To view only the functional locations that you're related to as a worker, select **My active functional locations**. (This relation is set up on the **Workers** page. Learn more in Maintenance workers and worker groups.)

On the **All functional locations** list page, select a link in the **Functional location** column to view the details of the selected record. To edit the functional location, select the **Edit** button. The details view shows detailed information that is related to the location. It also includes a **Related information** pane on the right. This pane shows the functional location hierarchy. You can expand and collapse the **Related information** pane.

The buttons on the Action Pane are organized on tabs. The following table briefly describes the buttons that are related to Asset Management.

Expand table

Button name	Description
Edit	Switch between edit mode and view mode for the page.
New	Create a new functional location.
Delete	Delete the selected functional location.
Rename	Rename the selected functional location.
Copy functional location structure	Copy the functional location hierarchy.
Install asset	Install an asset, including child assets, on the functional location.

Button name	Description
Replace asset	Replace the asset hierarchy with another asset hierarchy on the functional location.
Cost control	Open the **Functional location cost control** page, where you can do a cost calculation for the selected functional location.
Hour control	Open the **Functional location hour control** page, where you can do a cost calculation for the selected functional location.
Assets	Open the **All assets** page, where you can view a list of assets that are related to the selected functional location.
Requests	Open the **Active requests** page, where you can view a list of requests that are related to the selected functional location.
Work orders	Open the **Active work orders** page, where you can view a list of work orders that are related to the selected functional location.
Faults	Open the **Asset faults** page, where you can view a list of asset fault registrations that are related to the selected functional location.
Update functional location state	Update the stage of the selected functional location.
Lifecycle state log	View a log that shows the stages of the selected functional location.

Create functional locations

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to create a functional location in Asset Management.

When you create a functional location structure, be aware once you have created a functional location, you cannot move it from the original location. This means that you should carefully consider the structure of your functional locations before you start creating them in Asset Management. If you regret a functional location, you can delete it, provided that it has not yet been taken into use.

To be able to work with functional locations, you start by creating two "categories" of functional locations:

- Create *one* default functional location with not sub locations. This functional location is used only as the standard location for assets when you create new assets.
- Create the functional location structures required for managing maintenance jobs in your company.

Create a default functional location

When you use functional locations, start by creating one default location to be used when you create new assets. This functional location is the one you select in **Asset management** > **Setup** > **Asset management parameters** > **Assets** link > **Default functional location** field. The default functional location can be used when you create new assets, and you have not yet set up a functional location structure for those assets.

1. Select **Asset management** > **Functional locations** > **All Functional locations**.
2. In **All functional locations**, select **New**.
3. Insert an ID in the **Functional location** field, for example, "0000" or "Default", to indicate that this is a special functional location.
4. Insert name for the default functional location in the **Name** field.
5. Do *not* select a parent in the **Parent** field – leave this field blank.
6. In the **Functional location type** field, select the functional location type to be used for the default functional location. See Functional location types for more information on how to

set up functional location types.

7. Select **OK**. You should not add further data to this functional location as it is only used as a temporary location for new assets until you install the assets on the functional locations used by your company.

Create functional locations

The following procedure describes how you create the functional locations required for maintenance management in your company.

1. Select **Asset management** > **Functional locations** > **All Functional locations**. You can create a functional location from grid view or details view.
2. Select the **New** button.
3. Insert an ID in the **Functional location** field.
4. Insert a name for the functional location in the **Name** field.
5. If the functional location is a sub location in a structure, select the parent location in the **Parent** field.
6. Select a type in the **Functional location type** field.
7. Select **OK**.
8. Select the functional location and click the **Edit** button to add further information.

> ⓘ **Note**
>
> Depending on your setup of functional location lifecycle states, you may have to create all sub locations for a functional location, and then change the functional location lifecycle state before you can start installing assets. See Install assets on functional locations for more information on asset installation. See Functional location lifecycle states to learn more about setup of functional location lifecycle states.

In Details view, you will see FastTabs on which you can add and edit information about the functional location.

General Information

This section provides an overview of parent and child information in the functional location structure. In the **Details** section, you can see the number of asset attributes, maintenance plans, and assets related to the functional location. In the **Inventory** section, you can select the site and warehouse to which the functional location is related. Site and warehouse is used in connection with work order item forecasts. When creating an item forecast, site and warehouse

information from the functional location of the asset is automatically used. In the **Lifecycle state** section, information about the functional location lifecycle state is displayed.

Installed assets

Refer to Install assets on functional locations for more information on asset installation. You can use the **View** button on this FastTab to show more fields on the FastTab. The **Valid from** and **Sub asset** fields can be shown in the grid.

Asset attribute requirements

On this FastTab you can add specific attribute requirements for the assets that you install on the functional location. These requirements are for information purposes only. They do not prevent you from installing assets with other attribute requirements. Select **Add line** and select the attribute type. Then you insert the relevant **Value**, select a threshold in the **Threshold criteria** field and save the record.

Maintenance plans and Maintenance rounds

Here you can add maintenance plans and maintenance rounds to the functional location, including a start date. The assets installed on a functional location may have other maintenance plans set up. All maintenance plans and maintenance rounds can be used for scheduling asset calendar entries for a functional location and its currently installed assets.

> **Note**
>
> If you update the setup of asset types, asset brands, and asset models on maintenance plans in **All functional locations** detail view > **Maintenance plans** FastTab after you have scheduled maintenance plans, existing maintenance schedule entries related to that functional location are automatically deleted. In order to create new schedule entries, which correspond with the updated maintenance plan setup on the functional location, you must run a new maintenance plan schedule for that functional location.

Address

Insert the functional location address on the **Address** FastTab. Addresses on functional locations are inherited, meaning if a sub location has no address defined, the address of the parent location is used.

Workers

On this FastTab, you can add workers affiliated with the functional location, and you can select a functional location as primary for the worker.

Attributes

On this FastTab, you can set values for functional location attributes. These attributes can be used to describe properties or characteristics pertinent to the functional location, for example, structural properties, building type, area descriptions, or location above or under ground.

Select **Add line** and select the attribute type. Next, insert the **Value** related to the attribute type and save the record.

Financial dimensions

You can select financial dimensions for the functional location. Functional location types can be set up to allow for automatic update of financial dimensions from a functional location. This means that assets installed on a financial dimension automatically get the financial dimensions for the functional location. This is useful if you want different cost centers, depending on locations.

When data regarding **Site**, **Warehouse**, **Address**, and **Financial dimensions** are updated on a parent functional location, the related sub functional locations can be updated accordingly if you make that selection during the update. A dialog opens, providing you with the update options.

Copy a functional location structure

If your company has several functional locations with similar location structures, you can use the copy function in Asset Management to quickly create a number of similar location hierarchies. When you copy a specific functional location or an entire structure, the new location or structure has the same name as the one you copied. After the copy procedure is done, you can easily change the name or other settings on the new functional location, provided that the functional location lifecycle state selected for the new functional location allows it.

1. In **All functional locations**, select the functional location you want to copy. For example, you select a top location (parent) if you want to copy the entire functional location structure including sub locations.

2. Select the **Copy functional location structure** button. The location you selected in the list page is shown in the **Copy from** field.
3. Insert the name of the new location in the **New functional location** field.
4. In the **Parent to paste under** field, you should only insert a parent ID if the location you are creating should be part of an existing functional location structure.
5. Click **OK**. The new functional location structure is shown in **All functional locations**.

> **Note**
>
> When you copy a functional location structure, functional location lifecycle states in the new structure are set to the "first state" that you have created for functional locations. Whether you can rename or delete a functional location using the **Rename** and **Delete** buttons in **All functional locations**, depends on the current lifecycle state of the functional location.

Delete a Functional Location

A functional location with related sub locations can be deleted if no assets have been installed on any of the functional locations you are trying to delete, and if the current functional location lifecycle state allows it.

1. In **All functional locations**, select the functional location you want to delete.
2. If required, update the functional location to a functional location lifecycle state that allows deletion of a functional location.
3. Select **Delete**.

> **Note**
>
> If you cannot delete a functional location, instead you can handle deletion by setting up a functional location lifecycle state for this purpose. For example, you can set up a "Scrapped" or "Deleted" stage, which should not be an active stage, in the **Functional location lifecycle states** form.

Last updated on 05/07/2025

Change the type of existing functional locations

This article explains how to change the functional location type of an existing functional location.

Prerequisites

Before you can use this feature, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management 10.0.38 or later.
- The feature that's named *Change types on assets and functional locations* must be turned on in Feature management. As of Supply Chain Management version 10.0.43, this feature is turned on by default. As of version 10.0.45, it's mandatory and can't be turned off.

Change the functional location type of one or more existing functional locations

To change the functional location type of one or more existing functional locations, follow these steps:

1. Go to **Asset management** > **Functional locations** > **All functional locations**.

2. On the **All functional locations** list page, select one or more functional locations that you want to change the type for. If you select multiple functional locations, all of them must be of the same type.

3. On the Action Pane, on the **Functional locations** tab, in the **Maintain** group, select **Change functional location type**.

4. In the **Change functional location type** dialog box, on the **Parameters** FastTab, set the following fields:

    - **New functional location type** – Select the new type to assign to the selected functional locations.
    - **Attributes** – Set this option to *Yes* to append the attribute types that are associated with the new functional location type to the selected functional locations.
    - **Asset attribute requirements** – Set this option to *Yes* to append the asset attribute requirements that are associated with the new functional location type to the selected

functional locations.

- **Maintenance plans** – Set this option to *Yes* to append the maintenance plans that are associated with the new functional location type to the selected functional locations.

5. On the **Run in background** FastTab, set the **Batch processing** option to *Yes* to run the process of changing functional location types as a batch job.

6. Select **OK** to apply your settings.

> **Note**
>
> Each functional location type has settings that define which supporting data applies to functional locations of that type. This supporting data includes information such as asset types, maintenance plans, and asset attribute requirements. When you change the functional location type, the supporting data for existing functional locations might not match the supporting data for the new functional location type.

Install assets on functional locations

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

After you've created functional location structures, the next step is to install assets on the relevant functional locations. This article explains how to install assets on those functional locations in Asset Management. For information about how to create assets, see Introduction to assets.

If you've created an asset structure, the whole asset structure must be installed on a functional location. Therefore, only parent assets (top-level assets that have no parent asset) can be selected on a functional location. All related child assets (sub-assets) will also be installed on the functional location. When you install assets on a functional location, the financial dimensions of the functional location might be automatically transferred to them, depending on the setup on the functional location type that is selected for the functional location. For more information about how to set up functional location types, see Functional location types.

> **Note**
>
> You can set up asset types on the functional location type that is used for a functional location. In this case, when you install assets on the functional location, only parent assets that have the same asset type are shown in the list of assets that can be installed on the functional location.

After you've installed assets on a functional location, you can replace a parent asset or an asset structure as you require. As when you install assets, you select a parent asset to replace. All related child assets will also be replaced.

Install an asset structure on a functional location

1. Select **Asset management** > **Functional locations** > **All Functional locations** or **Active functional locations**.
2. Select the functional location to install an asset on.
3. Select **Install asset**.

The **Attributes** section shows a list of the asset attribute requirements that are set up on the functional location type that is selected for the functional location. The attributes are for informational purposes only. The system doesn't validate the attributes against the asset attributes that are set up on the asset that you're installing. You must do that validation after you select an asset in the **Asset** field.

4. In the **Asset** field, select the parent asset to install. All related child assets are automatically included in the installation.

   The **Asset attributes** section to the right of the asset list shows the asset attributes that are related to the selected asset.

5. In the **Effective** field, select the date and time that the asset installation is valid from. After that date and time, costs for the asset and related sub-assets will be related to the functional location.

   > ⓘ **Note**
   >
   > The asset attributes that are set up on the asset are added to the **Attributes** section. For example, the **Weight** attribute requirement has been added as a requirement on both the asset and the functional location. If the asset has attribute requirements of the same type as the functional location, the values of the asset's attribute requirements are entered in the **Value** fields. Therefore, you can validate the asset values against the attribute requirements that are set up on the functional location. The attribute requirements that are set up on the functional location are marked with a check mark.

6. Select **OK**.

   > ⓘ **Note**
   >
   > To change the installation of an asset by installing it on a new functional location, follow steps 1 through 6 of this procedure. When you install an asset on a new functional location, the asset is automatically uninstalled from the previous functional location. Any active maintenance requests or work orders that were created on the asset before you installed it on a new functional location are **not** automatically transferred to the new functional location. If those maintenance requests and work orders are still required for the asset, you must manually re-create them after the asset is installed on the new location.

7. To view a list of all the assets, including sub-assets, that are installed on the functional location, select the functional location on the **All Functional locations** page, and then select **Assets**.

8. To view a list of active maintenance requests, active work orders, or fault registrations that are related to the assets that are installed on a functional location, select the functional location on the **All Functional locations** page, and then select **Requests**, **Work orders**, or **Faults**.

> **Note**
>
> When asset-related data is changed, it's automatically updated on the functional location that the asset is installed on. This automatic update pertains to changes to maintenance requests, work orders, asset fault registrations, maintenance downtime registrations, and asset measure registrations.

Automatically create one asset on a functional location

You can set up functional location stages and functional location types to handle the automatic creation of *one* asset on a functional location. The asset gets the same ID and name as the functional location. This functionality might be useful when you're handling maintenance on a large, static asset, such as a building.

Before you can automatically create an asset on a functional location, the following setup data must be available:

- Create a functional location type to handle the automatic creation of an asset. In the **Asset type** field, select an asset type. Learn more in Functional location types.
- Create a functional location lifecycle state to handle the automatic creation of an asset. Set the **Create asset** option to **Yes**. Learn more in Functional location lifecycle states.

After the setup data is available, you're ready to create an asset.

1. On the **All Functional locations** page, make sure that the functional location where you want the asset to be automatically created uses the functional location type that you created for this purpose.
2. Select the functional location in the list.
3. Select **Update functional location state**, and then select the lifecycle state that you created for this purpose. One asset is now automatically installed on the functional location. This asset has the same name as the functional location.

Last updated on 05/07/2025

Asset types

Article • 01/06/2025

This article explains how to create asset types. It also describes the elements that are related to asset types. Asset types are used as general categories for assets. Examples include CNC machines, measuring equipment, and truck engines. Asset types are used to manage the maintenance job types (maintenance tasks), asset lifecycle states, counters, asset attributes, condition assessment templates, and asset models that can be selected for an asset. When you create an asset, you must specify the asset type.

For each asset type, variations of the asset type setup can be created. For example, if you have an asset type that is named *Trucks*, you can create variations of that asset type for different asset manufacturers and asset models. To each asset type setup, you can add the required spare parts and maintenance plans.

First, you set up the required asset types. Next, you create the asset models that should be related to the asset types. Finally, on the **Asset type defaults** page, you create all the variations of asset types that are required for your equipment.

Create an asset type

1. Select **Asset management** > **Setup** > **Asset types** > **Asset types**.
2. Select **New** to create an asset type.
3. In the **Asset type** field, enter an asset type ID.
4. In the **Name** field, enter a name.
5. In the **Asset lifecycle model** field, select an asset lifecycle model. For more information about asset lifecycle states and asset lifecycle models, see Asset lifecycle states.
6. Set the **Total** option to *Yes* if summarized key performance indicator (KPI) values should be calculated for assets that have this asset type.
7. Select **Save**.
8. On the **Maintenance job types** FastTab, select the maintenance job types that should be related to the asset type:
    - To select a maintenance job type, select it in the **Maintenance job types remaining** field, and then select the right arrow button → to move it to the

Maintenance job types selected section.

- To select all available maintenance job types, select the button. All maintenance job types are transferred from the **Maintenance job types remaining** field to the **Maintenance job types selected** field.
- To cancel the selection of a maintenance job type, select it in the **Maintenance job types selected** field, and then select the left arrow button to move it to the **Maintenance job types remaining** field.

9. You can also select the counters that should be related to the asset type. On the **Counters** FastTab, make your selections by using the methods that are described for maintenance job types in step 8. For more information about the setup of counters, see Counters.

10. You can also select the attribute types that should be related to the asset type. On the **Attribute types** FastTab, make your selections by using the methods that are described for maintenance job types in step 8. Then, to create the preferred sequence of attribute types, select an attribute type in the **Attribute types selected** field, and use the up arrow and down arrow buttons to move it. The sequence of attribute types will be shown on assets that use this asset type. For more information about asset attributes, see Maintenance attribute types.

    > ⓘ **Note**
    >
    > When you add new attribute types on the **Attribute types** FastTab, existing assets are automatically updated with that information.

11. You can also select the condition assessment templates that should be related to the asset type. On the **Condition assessments** FastTab, make your selections by using the methods that are described for maintenance job types in step 8. For more information about condition assessment templates and registrations, see Condition assessment.

12. The **Asset model** FastTab shows all the combinations of asset manufacturers and models that are set up on the selected asset type. To see the combinations divided according to manufacturer, select **Asset model** to open the **Asset model** page.

    On the **Asset model** page, you can add asset model–asset type relations. Additionally, on the **Asset types** page, you can add asset manufacturer–asset model relations directly to an asset type. Finally, on the **Asset model** page (**Asset management** > **Setup** > **Assets** > **Asset model**), you can create new asset manufacturer–asset model–asset type relations. Therefore, there are three ways to set up and edit asset manufacturer–asset model–asset type relations. All the

available combinations are shown from different perspectives, and you can select your preferred point of entry when you work with the setup.

> ⓘ Note
>
> - If you select counters on an asset type, the selections are automatically updated on the **Counters** page (**Asset management** > **Setup** > **Assets** > **Asset types** > **Counters**).
> - The fields in the **Details** section on the **General** FastTab show the number of maintenance job types, counters, attributes, and so on, that are set up on the selected asset type.

Typically, work orders that are manually created are related to corrective maintenance, whereas work orders that are automatically created are related to preventive maintenance. When you manually create work orders, only the maintenance job types that are selected on the **maintenance job types** FastTab of the **Asset types** page can be used. However, automatically created work orders can use all the maintenance job types you create on the **Maintenance job types** page (**Asset management** > **Setup** > **Jobs** > **Maintenance job types**).

Create asset type setup lines

1. Select **Asset management** > **Setup** > **Assets** > **Asset types** > **Asset type setup**. Alternatively, select **Asset management** > **Setup** > **Assets** > **Asset types** > **Asset types**, select an asset type, and then select **Asset type setup**.

2. The first time that you use the **Asset type setup** page, you might find the **Create combinations** button useful. You can use this button to quickly create all combinations of an asset model on an asset type. Select **Create combinations**, select the asset type to create combinations for, and then select **OK**.

   > ⓘ Note
   >
   > If you won't use all the asset type setup combinations that were automatically created, you can delete a setup by selecting it and then selecting **Delete**.

3. Select **New** to manually create an asset type setup.

4. Depending on how specific the asset type setup should be, make selections in the **Asset type**, **Manufacturer**, and **Model** fields.

5. If a warranty agreement is related to the asset type, select the agreement in the **Vendor warranty** and **Customer warranty** fields.

6. On the **Spare parts** FastTab, select **Add** to add spare parts to the selected asset type setup.

7. To approve a spare part, select the spare part line, and then select **Approve**. You can select multiple lines for approval.

8. To see whether a spare part is used somewhere else in Asset Management (for example, in relation to assets and work orders), select the spare part line, and then select **Item where used** to open the **Item where used** page. To see all active spare parts in the list, select the **Active** check box. To see only approved spare parts, select the **Approved** check box.

9. On the **Maintenance plans** FastTab, select **Add** to add maintenance plans to the selected asset type setup.

10. To copy an asset type setup to another setup, you can use the Copy function. Select the asset type setup to copy a setup to, select **Copy setup**, and select the asset type setup to copy the setup from. The settings of the various options determine how much information is included. When you've finished, select **OK** to copy the setup.

> ⓘ **Note**
>
> If you have many spare part lines and maintenance plan lines that you'll reuse, the Copy function lets you quickly and easily set up data for many asset type setup combinations.

Spare parts on the asset type setup

As was described in the "Create asset type setup lines" section, spare parts are set up on asset models on the **Asset type setup** page. Therefore, when you open the **Asset type setup** page, you see only the spare parts that are related to the selected combination of an asset type, asset manufacturer, and asset model. To see a list of all spare part records, open the **Spare parts** page (**Asset management** > **Inquiries** > **Spare parts**).

On the **Spare parts** page, you can also create new spare parts for existing combinations of an asset type, asset manufacturer, and asset model. You can decide whether you prefer to create spare part records on the **Asset type setup** page or the **Spare parts** page. The **Asset type setup** page provides an overview of data on the selected

combination of an asset type, asset manufacturer, and asset model, whereas the **Spare parts** page provides a complete overview of all asset type setup lines. If the **Spare parts** page contains many records, the **Asset type setup** page might give you a better overview.

To see whether the spare part on the selected line is used anywhere else in Asset Management (for example, in relation to assets and work orders), select **Item where used** to open **Item where used** page.

Condition assessment

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to create a condition assessment template and registration on an asset in Asset Management. Condition assessment is performed at regular intervals, and the primary objective is to create and maintain condition data on assets. Seen from a preventive maintenance perspective, it is important to monitor key information such as current condition, and remaining life span. Furthermore, if you carry out condition assessment at regular intervals, you will be able to monitor and compare conditions on the machinery in your factory.

Condition assessment can be used to measure and monitor many conditions on your equipment. Example: You could measure vibrations on your machinery. After you have registered vibration measurements in Asset Management on various types of equipment, you can search for the latest registered assessment and view vibration measurements.

Condition assessment is created on assets. You set up a condition assessment template on an asset type before you carry out the condition assessment procedure. The reason for using templates for condition assessment is to avoid variation of condition data on similar assets. The sequence for setting up and using condition assessment in Asset Management is: First you set up the required condition assessment templates. Next, you associate templates with asset types in the **Asset types** form. Finally, you can create condition assessment registrations on an asset in the **Asset** form.

Create a condition assessment template

1. Select **Asset management** > **Setup** > **Asset types** > **Condition assessment**.
2. Select **New** to create a new template.
3. Insert and ID for the template in the **Template** field.
4. Insert a name for the template in the **Name** field.
5. On the **Condition assessment lines** FastFab, add the lines required for the condition assessment, including selection of the appropriate condition type and measurement unit.
6. On the **Asset types** FastTab, add the asset types that should use the condition assessment template.

7. In the **Lines** and **Asset types** fields in the **Details** group at the top of the screen, you will see the number of assessment lines and asset types related to the selected condition assessment template.

Create condition assessment registration on an asset

1. Select **Asset management** > **Assets** > **All Assets**.
2. In the list, select the asset for which you want to create a condition assessment registration.
3. On the **General** tab, click **Condition assessment**.
4. Click **New** to make a new registration.
5. Select the date for the condition assessment in the **Date** field.
6. Select the name of the worker who carried out the assessment registration in the **Worker** field.
7. In the **Lines** field, you see the number of assessment lines set up on the condition assessment.
8. Select a template for the condition assessment in the **Template** field. The name of the template is automatically inserted in the **Name** field, and the related registration lines are inserted on the **Condition assessment lines** FastTab.
9. You can insert notes relating to the selected condition assessment on the **Notes** FastTab.
10. For each condition assessment line, insert measurement data in the **Value** field.
11. You can insert a comment relating to the selected registration line on the **Condition assessment lines** FastTab > **Comments** field. If you add a comment on a line, the **Comment** check box is automatically selected.

After you have made a condition assessment registration on an asset, you can print a condition assessment report.

> ⓘ **Note**
>
> You can also register condition assessment on a work order (**Asset management** > **Work orders** > **All Work orders** > **Condition assessment** button.)

Last updated on 05/07/2025

Asset manufacturers and models

Article • 08/15/2024

This article explains how to set up asset manufacturers and related models in Asset Management. Models can be related to asset types.

Set up product-model relations

1. Select **Asset management** > **Setup** > **Assets** > **Manufacturer and model**.
2. Select **New** to create a new product.
3. In the **Manufacturer** field, enter a name for the asset manufacturer.
4. In the **Description** field, enter a description.
5. On the **Models** FastTab, select **Add** to create an asset model that should be related to the asset manufacturer.
6. In the **Model** field, enter a name for the asset model.
7. In the **Description** field, enter a description.
8. In the **Asset type** field, select the asset type that the manufacturer model should be related to.

   > ⓘ **Note**
   >
   > You can also set up relations for asset types, manufacturers, and models in the **Asset types** lookup. Learn more in Asset types.

   In the **Details** FastTab, the **Models** field shows the number of asset models that are set up on the selected asset manufacturer. The **Assets** field shows the number of assets that are using the selected manufacturer.

   The **Assets** field shows the number of objects that are using the manufacturer model.

> ⓘ **Note**
>
> An asset type can have no asset manufacturer model relations, it can be related to one asset manufacturer model, or it can be related multiple asset manufacturer

models. If an asset type is related to at least one manufacturer model, only the combinations that are set up in the **Manufacturer model** lookup can be selected on those Asset Management pages where a combination of an asset type, manufacturer, and model can be set up. These pages include **All assets**, **Asset service levels**, **Job type defaults**, and **Maintenance budget lines**. If some asset types aren't related to any manufacturer model, only those asset types, and manufacturer models that also have no relation to asset types, are shown on the pages.

Select a manufacturer and model on an object

1. Select **Asset management** > ***Assets** > **All assets**.
2. In the **Asset** column, select the link for the asset. The **Details** page appears.
3. Select **Edit**.
4. On the **General** FastTab, select values in the **Manufacturer** and **Model** fields.

Counters

Article • 01/06/2025

The article explains how to create counter types in Asset Management. Counter types are used to make counter registrations on assets, for example, regarding number of production hours, or quantity produced on the asset. Asset types are related to the counter types. This means that a counter can only be used on an asset if the counter is set up on the asset type used on the asset.

Before you can make counter registrations on assets, you first create the counter types you want to use in **Counters**. Next, you can create counter registrations on assets in **Counters**.

Counters can be used on maintenance plans. A maintenance plan line can be of type *Counter*, for example, relating to number of production hours or quantity produced.

A counter registration can be updated manually or automatically based on production hours or quantity produced. A counter can be set up to use one of three update methods (selected in the **Update** field in **Counters**):

- Manual - you must manually register counter values.
- Production hours - the counter is automatically updated based on number of production hours.
- Production quantity - the counter is automatically updated based on quantity produced.

> ⓘ **Note**
>
> If quantity produced is used, *all* registered items are included in the counter registration, good quantity and error quantity. It's always possible to make manual counter registrations, if necessary.

Create counter types for asset counter registrations

1. Go to **Asset management** > **Setup** > **Asset types** > **Counters**.
2. Select **New** to create a new counter type.
3. Insert an ID in the **Counter** field, and a counter name in the **Name** field.
4. On the **General** FastTab, select a counter unit in the **Unit** field.
5. In the **Update** field, select the update method to be used for the counter.

6. Select *Yes* on the **Inherit counter values** toggle button if child assets in an asset structure should automatically inherit counter registrations made on the parent asset.
7. In the **Total aggregate** field, select the summation method to be used for a counter using this counter type. *Sum* is the standard selection used to continuously add registered values to the total value. *Average* can be used if a counter is set up to monitor a threshold, for example, regarding temperature, vibrations, or wear and tear on an asset.
8. In the **Deviation over** field, insert the upper level in percent for validating if manual counter registrations are within an expected range. The validation is based on a linear increase in existing counter registrations.
9. In the **Deviation under** field, insert the lower level in percent for validating if manual counter registrations are within an expected range. The validation is based on a linear decrease in existing counter registrations.
10. In the **Type** field, select the type of message (information, warning, error) to be shown if deviations outside the defined range occur when you make manual counter registrations.
11. On the **Asset types** FastTab, add the asset types that should be able to use the counter.
12. On the **Related asset counters** FastTab, add the counter that you want to be automatically updated when this counter is updated.

> **Note**
>
> A related counter is automatically updated only if the related counter has the asset type, to which it's related, in the counter setup. For example, suppose you set up a counter for *Production hours* and add the asset type *Truck Engine*. When that counter is updated, a related counter *Oil* is also updated with the same counter values. The setup in **Counters** includes the setup on *Hours*. Also, on the *Oil* counter, the asset type *Truck Engine* should be added to the **Asset types** FastTab to ensure the counter relation.

When asset types are added to a counter type in **Counters**, that counter is automatically added to the asset types on the **Counters** FastTab in Asset types.

Asset Management parameters

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to set up the general parameters for Asset Management, which relate to assets, work orders, and work order scheduling. Select **Asset management** > **Setup** > **Asset management parameters** to open the page.

> **Note**
>
> If you'd like to set up a system that includes demo data for testing Asset Management features, see Deploy a demo environment for instructions.

The Assets tab

The **Assets** tab provides the following settings:

- **Default functional location** is the standard functional location that's automatically selected on assets when you create new assets.
- In the **Standard calendar** field, select a calendar to be used for calculating asset KPIs if no resource is selected on an asset.
- In the **View** field, select the standard view that's shown when you open **Asset view** (**Asset management** > **Assets** > **Asset view**).
- **Default request type** is the standard maintenance request type that's automatically selected when you create a new request.
- The project selected in the **Forecast project** field stores forecasts on job types. For each job type, the system automatically creates a new activity on the forecast project. The system then saves forecasts on the job type to the forecast project.
- In the **Model** field, select the forecast model used on job type and work order forecasts.

The Work orders tab

The **Work orders** tab provides the following settings:

- **Default work order type** defines standard settings when creating a work order.
- **Preventive work order type** defines the work order type used when creating work orders from maintenance plans. If you leave this field blank, the work order type in the **Default work order type** field is used.
- In the **Related work order mask** field, you define the maximum number of work orders that can be related to a work order. For example, `##` allows you to have up to 99 work orders related. If you define a mask as described here, related work orders are numbered `[work order ID of the work order to which a work order is related] -01`, `-02`, `-03`, and so on. If you don't define a mask in this field, a related work order gets the next sequential work order ID.
- Select *Yes* for **Copy faults** if you want to automatically copy faults registered on maintenance requests to related work orders.
- In the **Level** field, you define the functional location level that is automatically inserted on a work order if all related work order jobs refer to the same functional location. If the work order jobs don't all relate to the same functional location on the defined level, the **Functional location** field is left blank on the work order. For example, if you insert the number *1* in this field, that number is the top level in a functional location structure. If you insert the number *0* in this field, you haven't defined a specific functional location level, only that all work order jobs on a work order must be related to the same functional location for that functional location to be added to the work order.
- Select the journals used when posting consumption on a work order on the **General** FastTab in the **Hour**, **Item**, and **Expense** fields.
- In the **Product language source** field, select which language to use for product names in Asset management reports. You can select the language set up on the company account, or the language set up for the user currently logged in.
- Select *Yes* for **Real time update** if you want to automatically update changes to job type defaults, maintenance plans, and maintenance rounds.
  - If you select *No*, changes to job type defaults, maintenance plans, and maintenance rounds aren't updated automatically in Asset Management.
  - Select *No* if you have large amounts of data being synchronized, for example, many assets or functional locations set up on maintenance plans or maintenance rounds, or a large number of maintenance plans or rounds.

    - If you make changes to job type defaults or maintenance plans or maintenance rounds, and you have selected *No* to real time update, a warning might not be shown if the changes influence:
        - Functional locations set up on maintenance plans or rounds
        - Objects set up on maintenance plans or rounds
        - Maintenance plans setup
    - Maintenance rounds setup
- On the **Category** FastTab, define default categories relating to consumption on work orders.

The Work order scheduling tab

The **Work order scheduling** tab provides the following settings:

- **Schedule time fence** defines the period in days, calculated from the expected start date of the work order, during which work order jobs are planned.

- **Default scheduled start date** - Controls how the system pre-fills the **Scheduled start** field on the **Schedule work order** dialog when you schedule one or more work orders or work order lines. Choose one of the following options:
    - *Expected start date from header* – Use the earliest **Expected start** date assigned among the selected work order headers. This option is the default.
    - *Scheduled start date from lines* – Use the earliest **Scheduled start** date already set on the selected work order lines. This option is useful when line schedules are planned in advance and you want the dialog to honor those dates instead of the header's expected start.

- **Service level** - A rating score calculated together with the rating score in the **Criticality** and **Start date** fields. The number in this field is divided by the number in the **Service level** field on a work order. For example, if you insert the value *5.00* in this field, and a work order has **Service level** of *20*, the rating score for **Service level** is *0.25*.

- **Criticality** - A rating score calculated together with the rating score in the **Service level** and **Start date** fields. The number in this field is multiplied by the number in the **Criticality** field on a work order. For example, if you insert the value *10.00* in this field, and a work order has criticality *5*, the rating score for criticality is 50.

- **Start date** - A rating score calculated together with the rating score in the **Service level** and **Criticality** fields. This field indicates daily score as a negative value and is compared to the **Expected start** field on a work order. For example, if you insert the value *10.00* in this field,

and the expected start date of a work order is three days from now, the rating result is minus 30.00. Adding the results of 0.25 and 50 from the examples in the **Service level** and **Criticality** fields described earlier provides a total of plus 20.25. That number is compared to all other work order rating scores during work order scheduling, and the highest rating scores are then planned first.

- **Responsible worker** - A rating score calculated together with the **Responsible maintenance worker group**, **Preferred maintenance worker**, **Preferred maintenance worker group**, **Asset location**, and **Start date** rating score values. If you insert the value *50.00* in this field, and a responsible worker is selected on a work order, the worker gets 50 points in the overall worker calculation during work order scheduling.

- **Responsible maintenance worker group** - A rating score calculated together with the **Responsible worker**, **Preferred maintenance worker**, **Preferred maintenance worker group**, **Asset location**, and **Start date** rating score values. If you insert the value *50.00* in this field, and a responsible worker is selected on a work order, the worker gets 50 points in the overall worker calculation during work order scheduling.

- **Limit to responsible** - This setting limits the number of workers available for work order scheduling. Select *No* if you want to calculate a score for all workers, regardless if they're set up as responsible workers or part of a responsible maintenance worker group. Select *Yes* if you want to calculate a score for workers who are set up as responsible worker on the work order, and/or included in a responsible maintenance worker group selected on the work order.

- **Preferred maintenance worker** - A rating score calculated together with the **Responsible worker**, **Preferred maintenance worker**, **Preferred maintenance worker group**, **Asset location**, and **Start date** rating score values. The four rating scores are calculated and added together to provide a score used for selecting which worker should be assigned to which work order during work order scheduling. If you insert the value *10.00* in this field, and a worker is selected as preferred maintenance worker on a work order, that worker gets 10 points in the overall worker calculation during work order scheduling.

- **Preferred maintenance worker group** - A rating score calculated together with the **Responsible worker**, **Preferred maintenance worker**, **Preferred maintenance worker group**, **Asset location**, and **Start date** rating score values. If you insert the value *10.00* in this field, and a worker is assigned to a preferred maintenance worker group selected on a work order, that worker gets 10 points in the overall worker calculation during work order scheduling.

- **Limit to preferred** - This setting limits the number of workers available for work order scheduling. Select *No* if you want to calculate a score for all workers, whether they are set up as preferred maintenance workers or part of a preferred maintenance worker group. Select *Yes* if you only want to calculate a score for workers who are set up as preferred maintenance workers, and/or included in a preferred maintenance worker group.

- **Location** - A rating score calculated together with the **Responsible worker**, **Preferred maintenance worker**, **Preferred maintenance worker group**, **Asset location**, and **Start date** rating score values. If you insert the value *3,000.00* in this field, a worker gets 3,000 points in the calculation if the worker is located in the same factory or facility as the asset on which a job is to be scheduled.
  - If your company uses functional locations, workers get full score if they're located on the functional location related to the asset. If the functional location of the asset has a parent asset, workers on that functional location get half score. If that location also has a parent, workers on that location get one-third score. If that location also has a parent, workers on that location get one-fourth score, and so on.
  - If your company uses asset location, which isn't recommended, location, area, and zone are used to calculate location scores. Workers get full score if they're located in the location and area and zone related to the asset. If worker location only matches location and area, the rating score for the worker is two-thirds of the full score. If worker location only matches location, the rating score for the worker is one-third of the full score.

- **Limit to location** - This setting limits the number of workers available for work order scheduling. Select *No* if you want to calculate a score for all workers across all functional locations. Select *Yes* if you only want to calculate a score for workers who are associated with the work order's functional location.

  > ⓘ **Note**
  >
  > The three *Limit to* fields increase the speed of work order scheduling by limiting the number of scores calculated for workers.

- **Worker's start date** - A rating score calculated together with the **Responsible worker**, **Preferred maintenance worker**, **Preferred maintenance worker group**, **Asset location**, and **Start date** rating score values. This field indicates daily score as a negative value and is compared to the **Expected start** field on a work order. If you insert the value *10.00* in this field, and the expected start date of a work order is tomorrow, the rating result is minus 10.00.

- Assuming that no responsible worker and responsible maintenance worker group are selected on a work order to be scheduled - you add and subtract the rating score values in the examples in the **Preferred maintenance worker**, **Preferred maintenance worker group**, **Asset location**, and **Start date** fields described earlier, you get a total of 3,010.00. This total means a high score for the worker who is already selected as preferred maintenance worker and included in the preferred maintenance worker group on the work order, and the worker is also located in the same facility as the asset for which a job needs to be scheduled. This means there's a good chance that the worker in question is selected to complete the job during work order scheduling.
- If you insert the value *0.00* in one of the eight fields described earlier, that rating score isn't used during work order scheduling.

The Document types tab

Select the document types that you want to print attachments for when they're related to a work order report. Select a document type in the **Available** section and select . To remove a selected document type, select the document type in the **Selected** section and select .

The Number sequences tab

Select the required number sequences in this section. Two number sequences exist for assets: one for manually created assets and one for assets created through pending assets.

Last updated on 05/07/2026

Asset lifecycle states

09/24/2025

This article explains asset lifecycle states and lifecycle models in Asset Management. Asset lifecycle states are used to define whether an asset is active or inactive. For example, you can set up asset lifecycle states such as **Created**, **Active**, and **Terminated**.

Asset lifecycle states can be set up in asset lifecycle models, where you can define the required lifecycle states for various types of assets. You first set up lifecycle states. You then create a lifecycle model and select lifecycle states for it.

1. Select **Asset management** > **Setup** > **Assets** > **Lifecycle states**.
2. Select **New** to create a new asset lifecycle state.
3. In the **Lifecycle state** field, enter the lifecycle state ID.
4. In the **Name** field, enter a description.

   The **Lifecycle models** field shows the number of asset lifecycle models that use the asset lifecycle state.
5. Set the **Active** option to **Yes** if this lifecycle state should be an active lifecycle state (in other words, if work orders can be created for assets that are in this lifecycle state).
6. Set the **Delete open calendar lines** option to **Yes** if open asset calendar lines that have an asset lifecycle state of **Created** should be deleted when they are in this lifecycle state. This setting is useful if you want to clean up any open maintenance schedules that are no longer relevant for the asset (for example, if the asset is no longer active).

> **Note**
>
> Asset lifecycle states, asset lifecycle models, and asset types are related. They're used in the same way as work order lifecycle states, work order lifecycle models, and work order types.

After you've created the required asset lifecycle states, you can set up lifecycle states in asset lifecycle models.

1. Select **Asset management** > **Setup** > **assets** > **lifecycle models**.
2. Select **New** to create a new asset lifecycle model.
3. In the **Lifecycle model** field, enter the lifecycle model ID.

4. In the **Name** field, enter a description.

   The **Lifecycle states** field shows the number of asset lifecycle states that are selected in the asset lifecycle model. The **Asset types** field shows the number of asset types that use the lifecycle model.

5. On the **Lifecycle states** FastTab, select the asset lifecycle states that should be included in the asset lifecycle model:

   - To use a lifecycle state for the model, select it in the **Lifecycle states remaining** section, and then select the right arrow button to move it to the **Lifecycle states selected** section.
   - To use all the available lifecycle states for the model, select the **All available lifecycle states** button. All lifecycle states are transferred to the **Lifecycle states selected** section.
   - To remove a lifecycle state from the model, select it in the **lifecycle states selected** section, and then select the left arrow button to move it to the **Lifecycle states remaining** section.

6. Select **Lifecycle state updates** to define the asset lifecycle states that can follow a selected lifecycle state.

7. You use the **Asset state** FastTab if you handle assets that you receive for repair. In the **Inbound/outbound** section, you can select asset lifecycle states to indicate the workflow of an asset that you receive for repair. If you offer loan assets to customers or departments, in the **Loan** section, you can select lifecycle states for loan assets.

> ⓘ **Note**
>
> You can link work order lifecycle states to asset and maintenance request lifecycle states. If you configure this link, changing the work order's lifecycle state also changes the linked asset and maintenance request to a new lifecycle state.

Asset service levels

Article • 01/09/2023

This article explains asset service levels in Asset Management. Asset service levels are related to assets, and are transferred to maintenance requests and work orders. They are used to calculate the priority of work orders during work order scheduling. Asset service levels can be changed, if changes are required.

For more information about the setup that is related to the calculation of rating scores for work order scheduling, see Asset Management parameters. You must set up at least one default record for the asset service level. This default record is used if no other match is found during work order scheduling.

Example 1: The default service level that is used if no other match is found. In this record, you select only a service level.

Example 2: A high service level that is used to schedule jobs for a Volvo truck engine. In this record, you select a relevant asset type (such as **Truck Engine**), a manufacturer (**Volvo**), and a service level.

Set up asset service levels

1. Select **Asset management** > **Setup** > **Asset service levels**.
2. Select **New** to create a record.
3. Depending on the detail level that is required for the asset service level, make relevant selections in the **Functional location**, **Asset type**, **Manufacturer**, **Model**, **Asset**, **Work order type**, and **Service level** fields.

> **Note**
>
> When the asset service level is used for maintenance requests and work orders, Asset Management goes through all asset service level records to check for a possible match. It always checks the most specific combination first. In other words, Asset Management first checks for a match for the **Work order type** field. If no match is found, it checks for a match for the **Asset** field, and so on. As you can see in the layout of the **Asset service levels** page, this behavior means that, to find the most specific combination, Asset Management checks each record from right to left for a match. If no match is found, the default record that has no selections in those fields is used.

4. In the **Service level** field, select a number that indicates the service level (priority).

> **Note**
>
> If you change an asset service level record on the **Asset service levels** page after you've already used it on a work order, the service level on maintenance requests and work orders isn't updated accordingly.

Asset criticality types

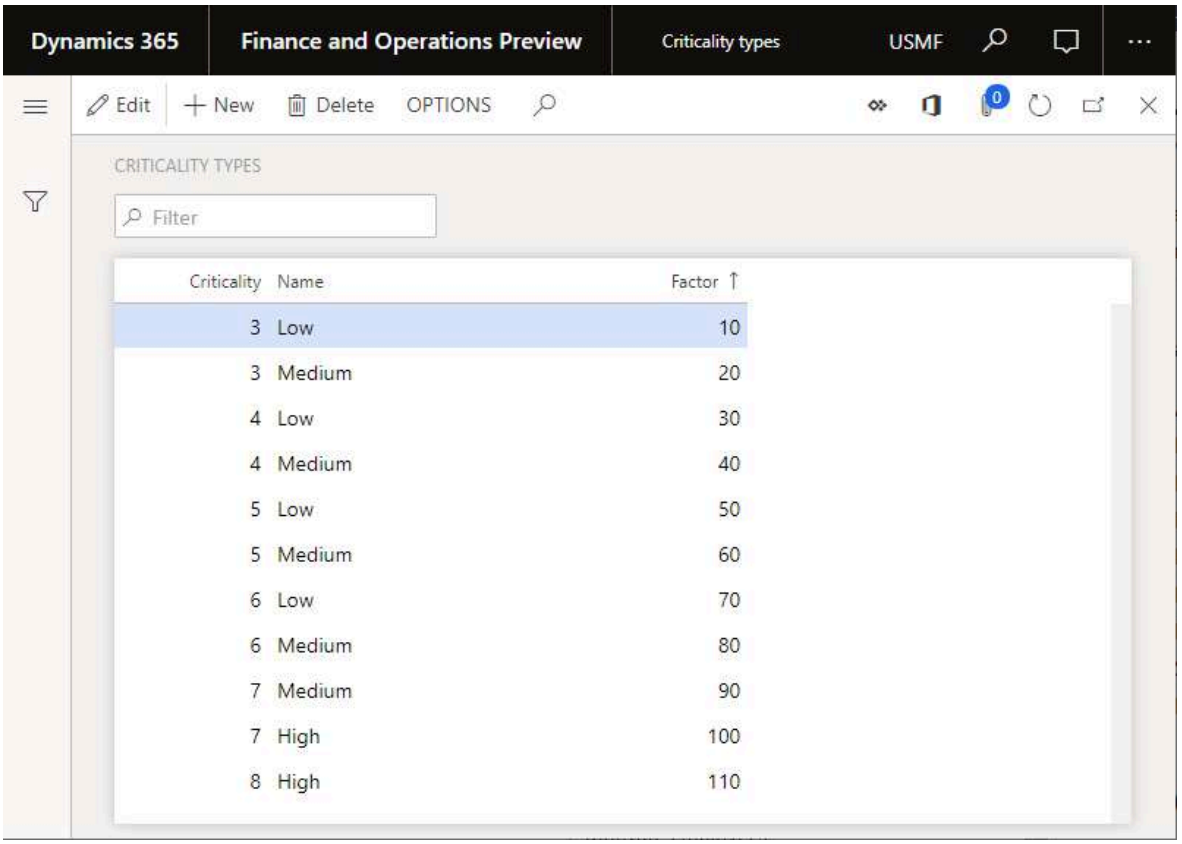
Article • 01/09/2023

The article explains asset criticality types in Asset Management. Asset criticality is related to assets and is transferred to work orders. It can't be changed on a work order. Asset criticality is used to calculate work order criticality during work order scheduling. In other words, it's used to calculate the extent to which a maintenance job on an asset affects the production schedule and productivity in your company. For more information about the setup that is related to the calculation of rating scores for work order scheduling, see Asset Management parameters.

To set up criticality, you first create the criticality types that should be used in the asset setup. You then set up asset criticalities.

Set up criticality types

1. Select **Asset management** > **Setup** > **Assets** > **Criticality types**.
2. Select **New** to create a record.
3. In the **Criticality** field, enter a number that indicates the criticality.
4. In the **Name** field, enter a name for the criticality type.
5. In the **Factor** field, enter a factor. This factor is used during the calculation of work order scheduling to determine the criticality record that should be used. (The record that has the highest factor is always used.) This setting is relevant if, as shown in the following illustration, criticality lines are created that have the same criticality value.



Set up asset criticalities

1. Select **Asset management** > **Setup** > **Asset criticalities**.

2. Select **New** to create a record.

3. Depending on the required level of detail for asset criticality, make relevant selections in the **Functional location**, **Asset type**, **Manufacturer**, **Model**, **Asset**, **Job type category**, **Job type**, **Job type variant**, and **Job requirement** fields.

   > **Note**
   >
   > When an asset criticality is selected, Asset Management goes through all asset criticality records to check for a possible match. It always checks the most specific combination first. In other words, Asset Management first checks **Job requirement**. If no match is found, it checks **Job type variant**. If no match is found, it checks **Job type**, and so on. As you can see in the layout of the page, this behavior means that, to find the most specific combination, Asset Management checks each record from right to left for a match. If no match is found, the "default" record that has no selections is used.

4. In the **Criticality** field, select one of the criticality values that you created in the previous procedure.

Notes about criticality setup

- If you change an asset criticality in this setup after you've already used it on a work order, the criticality on the work order isn't updated accordingly.
- The criticality on a work order is recalculated every time that a work order line is added to or deleted from the work order.
- If a work order contains several work order jobs, the highest criticality, according to the **Factor** field on the **Criticality types** page, is always used on the work order.
- Generally, asset criticality can change over a period. Criticality can be affected by the purchase of new equipment, refurbishments, and so on. Consider reevaluating your asset criticalities at regular intervals (for example, once per year or every other year) to make sure that your criticality definitions match your current production setup.

Asset documents

Article • 01/09/2023

This article explains asset documents in Asset Management.

In Asset Management, you can set up documents so that they are automatically related to job types, asset manufacturers, asset types, or assets, for example. This functionality is useful when updated document versions are released. In that case, you just have to put the updated document in the standard location that you use for your Supply Chain Management documents, and attach the document to the asset document record that you've created. The updated document can then be accessed from the **All assets**, **Active assets**, **My active assets**, **All work orders**, and **Active work order jobs** menu items. The process for attaching documents to an asset document record uses the standard document handling system.

Example 1: A document that is related to a job type might describe a procedure for that job type.

Example 2: A document that is related to a combination of an asset type, manufacturer, and model might be the standard manual for the selected asset manufacturer model.

Create asset document relation

1. Select **Asset management** > **Setup** > **Asset documents**.
2. Select **New** to create an asset document record.
3. Depending on how specific you want the document relation to be, make relevant selections in one or more of the following fields: **Asset type**, **Manufacturer**, **Model**, **Asset**, **Job type category**, **Job type**, **Job type variant**, and **Job requirement**. The options that are available in the **Job type variant** and **Job requirement** fields depend on your selection in the **Job type** field.

   > ⓘ **Note**
   >
   > When the system searches for documents that should be related to an asset or a work order, Asset Management goes through all asset document records to check for a possible match. It always checks the most specific combination first. In other words, Asset Management first checks for a match for the **Job requirement** field. If no match is found, it checks for a match for the **Job type variant** field. If no match is found, it checks for a match for the **Job type** field,

and so on. As you can see in the layout of the **Asset documents** page, this behavior means that, to find the most specific combination, Asset Management checks each record from right to left for a match. Several documents might be related to an asset or a work order. You can edit the service level on a maintenance request or a work order as you require.

4. Select **Attachments**. The standard **Document handling** page appears.

5. Set up the documents or notes that should be attached to the asset document record. After you attach documents, the **Attachments** field shows the number of documents that are related to the record.

Maintenance workers and worker groups

08/14/2025

This article explains maintenance workers and worker groups in Asset Management. In Asset Management, you can connect maintenance workers to functional locations. (For more information about functional locations, see Create functional locations.) This functionality might be useful if, for example, you're scheduling a maintenance job on a machine that is located in functional location 01, and you want to allocate maintenance workers from the same location to perform the job.

You can also create maintenance worker groups and associate maintenance workers with them. This functionality is useful when you do simple work order scheduling, and you want to schedule a group of maintenance workers on a work order. You can use maintenance workers and maintenance worker groups to set up preferred maintenance workers and responsible maintenance workers.

Create workers

1. Select **Asset management** > **Setup** > **Workers** > **Workers**.
2. Select **New** to add a worker to the list.
3. In the **Worker** field, select the worker.
4. Set the **Active** option to *Yes* to schedule the worker on work orders.

   On the **General** FastTab, the **Resource** and **Description** fields are automatically filled in if a resource is selected for the worker. The **Calendar** field is also automatically filled in if the worker is set up as a resource and a calendar is allocated to that resource on the **Resources** page (**Organization administration** > **Resources** > **Resources**).
5. On the **Groups** FastTab, select **Add**, and then select a maintenance worker group for the worker. A worker can be affiliated with more than one group.
6. In the standard setup, a worker's affiliation with a group is effective from the date when you add the group, and it never expires. This date is shown in the **Effective** field. To see the **Effective** field, select **View** > **All**. If the worker's affiliation with a group should be limited to a specific period, use the **Effective** and **Expiration** fields to define the period.
7. On the **Functional locations** FastTab, select **Add**, and then select a functional location for the maintenance worker. Also specify which location is the primary functional location for the worker.

> **Note**
>
> When you add functional locations to a worker, all active assets that are related to those functional locations appear on various menu items, such as **My active assets** and **My active functional locations**. They also appear in the asset lookups that are shown when you create a new asset, maintenance request, or work order.

The fields on the **Details** FastTab show the number of maintenance worker groups and functional locations that the selected maintenance worker is related to.

Create worker groups

1. Select **Asset management** > **Setup** > **Workers** > **Maintenance worker groups**.
2. Select **New** to add a worker group to the list.
3. In the **Maintenance worker group** field, enter a group ID.
4. In the **Name** field, enter a name.
5. On the **Workers** FastTab, select **Add**, and then select a maintenance worker for the worker group. For information about the **Effective** and **Expiration** fields, see step 6 in the previous procedure.
6. If a resource group should be related to the selected maintenance worker group, select **Copy from resource group**. In the **Group** field, select the resource group to copy calendar settings from. Then, in the **Worker group** field, select the worker group to copy the resource group's calendar settings to. This step is relevant only if you want maintenance workers to use the calendar that is related to a resource (work center) during work order scheduling.

   The field on the **Details** FastTab shows the number of maintenance workers that are set up on the selected maintenance worker group.

Introduction to assets

This article provides an overview of assets in Asset Management. An *asset* is any type of equipment, such as a machine or a machine part, that requires maintenance, service, or repair.

An asset is automatically updated with related information. For example, this related information might be about new or updated work orders. You can create assets by using either the **All assets** menu item or the **Pending assets** menu item. This article explains how to create assets by using the **All assets** menu item. For information about how to create assets by using the **Pending assets** menu item, see Create assets based on purchase orders.

All assets

Select **Asset management** > **Assets** > **All assets**. The **All assets** list page shows all assets and some of the information that is related to them. To view only active assets, select **Active assets**. To view only assets that are installed on the functional locations that you're related to as a maintenance worker, select **My active assets**. (This relation is set up on the **Workers** page. Learn more in Maintenance workers and worker groups.)

In the **All assets** grid view, select a link in the **Asset** column to view the details of the selected record. To edit the record, select the **Edit** button. The details view shows detailed information that is related to the asset. A **Related information** pane on the right contains additional asset-related information. Expand the pane to show the related information for the selected asset.

The buttons on the Action Pane are organized on tabs. The following table briefly describes the buttons that are related to Asset Management.

Expand table

Button name	Description
Edit	Edit the selected asset.
New	Create a new asset.
Delete	Delete the selected asset.
Move asset	Move assets to another asset structure, or to another location in the same asset structure.
Replace asset	Replace one child asset in an asset hierarchy with another asset.

Button name	Description
Install asset	Install an asset on a functional location.
Copy asset	Copy an asset hierarchy to another asset.
Requests	Open the **Active requests** list page, where you can view maintenance requests that have been created for the selected asset.
Event history	View an overview of the various registrations that have been made on the asset.
Asset BOM	View a list of all items (spare parts and other items) that are used on an asset.
Work orders	Open the **Active work orders** list page, where you can view work orders for the asset.
Checklist	View an overview of maintenance checklists and measurements that have been registered on the asset.
Maintenance downtime	Create or view maintenance downtime registrations on the asset.
Project transactions	View all posted transactions that are related to work orders that have been created for the asset.
Asset measures	Create or view asset measures on the asset.
Maintenance schedule	Open the **Open maintenance schedule** list page, where you can view maintenance plans, maintenance requests, and maintenance rounds that are associated with the asset, and that have a status of **Created**.
Update asset state	Update the asset lifecycle state. You can select multiple assets on the **All assets** list page and then update the asset lifecycle state for all of them at the same time. You can add remarks, which are visible in the lifecycle state log. Remarks require Supply Chain Management version 10.0.46 or higher with *Remarks can be associated with each change in lifecycle states* enabled in Feature management (As of Supply Chain Management version 10.0.49, this feature is turned on by default).
Lifecycle state log	Open a log that shows the lifecycle states of the selected asset. The log includes any remarks that were added by users during manual lifecycle changes. Remarks require Supply Chain Management version 10.0.46 or higher with *Remarks can be associated with each change in lifecycle states* enabled in Feature management (As of Supply Chain Management version 10.0.49, this feature is turned on by default).
Asset documents	View a list of the documents that are attached to an asset. These documents are set up at **Asset management** > **Setup** > **Asset documents**.
Attributes	Create or view asset attributes.
Image	Select an image for the asset.

Button name	Description
Parent assets	View parent asset history for the selected asset.
Functional locations	View functional location history for the selected asset.
Condition assessment	Register condition assessment measurements on the asset.
Faults	Open the **Asset faults** list page, where you can view faults that have been registered on the asset.
Cost control	Compare budget costs and actual costs on the asset.
Hour control	Compare forecast hours and actual hours on the asset.
Asset KPIs	Calculate and view key performance indicators (KPIs) for the asset.
Job types	View an overview of the current default job types for the asset.
Criticality types	View or update asset criticality types.
Spare parts	View a list of approved and alternative spare parts that can be used on the asset.
Asset consumption	Print a report that shows consumption registrations on the asset.
Asset fault	Print a report that shows fault registrations on the asset.

Last updated on 07/23/2026

Create an asset

Article • 01/06/2025

This article describes how to create an asset in Asset Management.

1. Go to **Asset management** > **Assets** > **All assets** or **Active assets**.
2. Select **New**.
3. In the **Create assets** dialog, insert data regarding **Asset** (the asset ID) and the asset name. Select date and time for the asset in the **Effective** field. From that date, you're able to install the asset on a functional location and move and replace the asset in an asset structure.
4. In the **Asset type** field, select the asset type for the asset (mandatory field). If necessary, select **Asset manufacturer** and **Asset model** for the asset. If only one product is up, that product is automatically selected in the **Asset manufacturer** field. The selections available in the **Asset manufacturer** and **Asset model** fields depend on the setup in Asset manufacturers and models.
5. In the **Parent asset** group, the **Asset** field is blank as default. If you select a parent asset, then all fields in the **Parent asset** group are automatically filled out.

   > ⓘ Note
   >
   > When you select a parent asset, two or three tabs are available: The **My assets** tab contains assets related to the functional locations to which you (the maintenance worker who is logged on the system) can be allocated. If no functional locations are set up on a maintenance worker on the Maintenance workers and worker groups page, the **My assets** tab isn't shown. The **Active assets** tab contains a list of all assets with asset lifecycle state *Active*. The **Asset view** tab displays a tree view of functional locations and assets installed on those locations.

6. The default functional location you have set up is suggested for the asset in the **Asset** group **Functional location** field. Select another functional location if necessary.

   > ⓘ Note

After you have created an asset, you can install it on another functional location, if required. Only top-level assets (assets without a current parent asset) can be installed on a functional location. This means that you install the top level and any child assets on the selected functional location. Read more about installing assets on functional locations in Introduction to functional locations.

7. Select **OK**.
8. Select the asset in the **All Assets** list and select the **Edit** button to add further information to the asset.

General information

The functional location to which the asset is related is shown in the **Functional location** field. If the asset is a parent asset, the number of children related to the asset is shown in the **Children** field. If the asset is a sub asset to an existing asset, the ID of the parent asset is shown in the **Parent** field.

You can edit **Asset manufacturer** and **Asset model** information on the asset, which is used to manage spare parts, alternative spare parts, and job type defaults. Learn more in Asset manufacturers and models. You can also add information about **Model year** and **Serial number**, if necessary.

Current lifecycle state is used to define if the asset is active or inactive. When creating an asset, the stage is always set to the first stage in the asset stage group. When you're ready to activate an asset, select **Update asset state**, and select the lifecycle state that you have defined as *Active*, and select **OK**.

> **Note**
>
> When an asset is set to *Inactive*, it's no longer possible to create work orders for the asset. Also, you can't schedule preventive maintenance jobs for an inactive asset.

The **Service level** and **Criticality** fields relate to work orders created for the asset. The fields show the **Service level** and **Criticality** numbers calculated for the current setup for the asset. Refer to Asset service levels and Asset criticality types regarding setup of those values.

Asset

You can select a **Resource** for the asset. The resource selection determines which calendar is used for work order scheduling. Resource selection is often used for fixed assets. Resources and resource groups are set up in **Organization administration** > **Resources** > **Resource groups** or **Resources**.

In the **Fixed assets number** field, you can select a fixed asset to be related to the asset. This is relevant if your asset is related to an investment project.

- If the asset is related to a fixed asset, you can create a work order type to be used for work orders related to an investment project.
- Information about fixed assets for an asset is related to the **Fixed assets** module in Dynamics 365 Supply Chain Management. This means that in **Fixed assets** > **Fixed assets** > **Fixed assets**, you can get an overview of the Asset Management projects that are related to a fixed asset by selecting the asset in the list and viewing the contents on the **Related information** pane, **Associated projects** section.

Details

In the **Active from** field, the date on which you updated the asset lifecycle state to an active state (refer to Asset lifecycle states regarding setup of asset lifecycle states), is shown. If the asset is no longer active, and you have updated the asset lifecycle state to an inactive lifecycle state, the date from which the asset is inactive is shown in the **Active to** field. If necessary, you can manually change those dates.

If necessary, you can insert an expected date for replacement of the asset in the **Replacement date** field. An estimated value for replacing the asset can be inserted in the **Replacement value** field. For example, you can use replacement information to compare it with the costs of maintaining an asset, and then make a decision for purchasing a new asset if maintenance costs on the existing asset increase rapidly.

Notes

You can add notes related to the asset on the **Notes** FastTab. Select the **Add timestamp** button before you write the note, if you want to add user information and a date/timestamp to the note.

Attributes

On this FastTab, you can set values for asset attributes. These attributes can be used to describe properties or characteristics pertinent to the asset, for example, size, weight, or machine configuration.

Select **Add line** and select the attribute type. Next, insert the **Value** related to the attribute type and save the record.

> ⓘ Note
>
> You can get an overview of asset attribute types and their relation to the assets in **Asset attribute** and **Asset attribute overview**. Refer to Asset attribute overview for more information.

Vendor

On the **Vendor** FastTab, select a vendor account for the asset. Also, if a vendor warranty has been granted, you can insert warranty information here.

Address

On the **Address** FastTab, you can insert the address of the equipment. If no address is inserted on the asset, the asset uses the address of a parent asset, if the parent asset has an address. If no address is related to the asset or any parents in the asset hierarchy, the address of the functional location on which the asset is installed can be used. If that functional location doesn't have an address related to it, the address of the parent functional location is used on the asset.

Asset management plans

Maintenance plans are used for scheduling preventive maintenance jobs at regular intervals on the asset. On this FastTab, you can set up maintenance plan lines for the selected asset. Maintenance rounds can be set up for various assets, on which you need to carry out a similar task at regular intervals. On the **Functional location maintenance plans** tab, you see the maintenance plans related to the functional location on which the asset is installed.

> ⓘ Note
>
> If you delete a maintenance plan line or a maintenance round related to an asset in **All Asset**, you also automatically delete all maintenance schedules with status *Created* that have been created based on that maintenance plan or maintenance round.

Functional location maintenance plans

The **Functional location maintenance plans** FastTab provides an overview of the maintenance plans related to the functional location on which the asset is installed.

Maintenance rounds

The **Maintenance rounds** FastTab lets you add or remove maintenance rounds, which are related to the asset.

Financial dimensions

The **Financial dimensions** FastTab lets you select financial dimensions for the asset.

Change the asset type of existing assets

This article explains how to change the asset type of an existing asset.

Prerequisites

Before you can use this feature, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management 10.0.38 or later.
- The feature that's named *Change types on assets and functional locations* must be turned on in Feature management. As of Supply Chain Management version 10.0.43, this feature is turned on by default. As of version 10.0.45, it's mandatory and can't be turned off.

Change the asset type of one or more existing assets

To change the asset type of one or more existing assets, follow these steps:

1. Go to **Asset management** > **Assets** > **All assets**.
2. On the **All assets** list page, select one or more assets that you want to change asset type for. If you select multiple assets, all of them must be of the same asset type.
3. On the Action Pane, on the **Asset** tab, in the **Maintain** group, select **Change asset type**.
4. In the **Change asset type** dialog box, on the **Parameters** FastTab, set the following fields:
    - **New asset type** – Select the new asset type to assign to the selected assets.
    - **Attributes** – Set this option to *Yes* to append the attribute types that are associated with the new asset type to the selected assets.
    - **Maintenance plans** – Set this option to *Yes* to append the maintenance plans that are associated with the new asset type to the selected assets.
5. On the **Run in background** FastTab, set the **Batch processing** option to *Yes* to run the process of changing asset types as a batch job.
6. Select **OK** to apply your settings.

> ⓘ **Note**

Each asset type has settings that define which supporting data can be used for assets of that type. This supporting data includes information such as maintenance job types, counters, and attribute types. When you change the asset type, the supporting data for existing assets might not match the supporting data for the new asset type.

For example, asset *A1* has an asset type of *AT1*. Two maintenance job types, *JT1* and *JT2*, are selected for asset type *AT1*. Work orders have been created for asset *A1*, and maintenance job types *JT1* and *JT2* are selected for those work orders. Later, the asset type of asset *A1* is changed to *AT2*. Maintenance job types *JT3* and *JT4* are selected for asset type *AT2*. Therefore, after the asset type is changed, the work orders have maintenance job types that aren't associated with the asset type of the asset for those work orders.

Multi-level assets

08/13/2025

This article explains how to create and delete multi-level assets. You can create assets and related sub-assets in a hierarchical tree structure. In this way, you can show relations and dependencies among assets. Maintenance jobs can be related to all levels of the tree structure. Statistics can also be created for an individual level or as a sum of all sub-asset levels.

On the **All Assets** list page (**Asset management** > **Assets** > **All assets**), the **Asset** column lists assets in hierarchical order. The **Parent** column shows the related parent. Additionally, if assets and sub-assets have already been created, the **Asset tree** section in the **Related information** pane shows the assets in a tree structure.

For information about how to create an asset, see Create an asset. To create a sub-asset, select the parent asset in the **Parent** field on the **General** FastTab.

Copy an asset or asset structure

If your company has several similar asset structures, you can use the Copy function in Asset Management to quickly create them.

1. Select **Asset management** > **Assets** > **All assets**.
2. On the **All assets** list page, select the asset to copy. For example, if you want to copy the whole asset structure, including sub-assets, select a parent asset.
3. Select **Copy asset**. In the **Copy from** section, the **Asset** field is set to the asset that you selected on the list page.
4. In the **Copy to** section, in the **Asset** field, enter the name of the new asset.
5. If the asset that you're creating should be part of an existing asset structure, in the **Parent asset** section, in the **Asset** field, select a parent ID.
6. Select **OK**. The new asset structure is shown on the **All assets** list page. All asset attributes, maintenance plans, and maintenance rounds that are related to the asset that you copied are transferred to the new asset or asset structure.

When you copy an asset structure, the sub-assets in the new structure have the same name as the sub-assets that you copied. After the copy procedure is completed, you can easily change the name and other settings for an asset. Select the asset on the **All assets** list page, and then select the **Edit** button.

> **Note**

When you copy an asset or asset structure, the lifecycle state of the new assets is reset to whatever state you defined as the initial lifecycle state for assets. The functional location is reset to the default functional location.

Delete an asset or asset structure

If an asset has related sub-assets, you can delete it only if no maintenance requests, work order jobs, fault registrations, or condition assessments are registered on any of the assets.

1. On the **All assets** list page, select the asset to delete.
2. Select **Delete**.

> **Note**
>
> If you can't delete an asset by using this procedure, another way to handle deletion is to set up an asset lifecycle state for this purpose. For example, you can set up a **Scrapped** or **Deleted** lifecycle state on the **Asset lifecycle states** page.

Move, replace, and install assets

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to move, replace, and install assets in Asset Management. You can create individual assets that have no relations to other assets, or you can create an asset structure that includes a parent asset (top-level asset) and related child assets (sub-assets). In Asset Management, there are three approaches to moving and changing the location of an asset:

- **Move** – Move an asset either to another asset structure or to another location in the same asset structure.
- **Replace** – Temporarily remove an asset from an asset structure so that it can be repaired or refurbished, and then add the refurbished asset back to the asset structure later. Alternatively, permanently replace a used asset with a new asset.
- **Install** – Install a parent asset and any related child assets on a functional location.

> **Note**
>
> The asset that you move, replace, or install might be related to another functional location. In that case, the asset might use financial dimensions of the functional location. On the **Functional location types** page, you set up the handling of financial dimensions on functional locations.

Move asset

Use the **Move asset** function to move an asset either to another asset structure or to another location in the same asset structure. You can also move an asset out of an asset structure so that it becomes a standalone asset that has no structure relations.

> **Note**
>
> Don't use this function if assets are being repaired or temporarily replaced. Instead, use the **Replace asset** functionality that is described later in this article.

1. Select **Asset management** > **Assets** > **All assets** or **Active assets**.
2. In the list, select the asset to move. If the asset has child assets, you also move those assets.
3. Select **Move asset**.
4. To move the asset so that it becomes part of an asset structure, select the new parent asset in the **Parent asset** field. If you're moving a child asset, and you want to make it a standalone asset that has no structure relations, leave the **Parent asset** field blank.
5. By default, the **Effective** field is set to the current date and time. However, you can select a different date and time that the asset move is valid from.
6. Select **OK**.

Replace asset

Use the **Replace asset** function in connection with repairs, refurbishment, or permanent replacement of a worn-out asset by a new asset. This function is used to replace child assets in an asset structure. For parent assets (that is, assets that don't currently have a parent asset), this replacement is done on a functional location. For more information about how to replace parent assets on a functional location, see Install assets on functional locations.

> **Note**
>
> If a repair shop is related to your production department, you can create functional locations such as **Repair**, **Scrap**, and **Storage** to handle the repair and replacement of assets.

1. Select **Asset management** > **Assets** > **All assets** or **Active assets**.
2. In the list, select the child asset to replace. If the asset has child assets, you also replace those assets.
3. Select **Replace asset**.

   The **Structure change** field shows the last date and time that the selected asset and related child assets were moved in the asset structure.
4. In the **Selected asset** section, in the **Target functional location** field, select the functional location to move the asset to. For example, select the **Repair** or **Scrap** location.

   In the **Parent asset** section, the **Effective** field shows the last date and time that the parent asset and related child assets were installed or moved on the current functional location.

5. In the **New asset** section, in the **Asset** field, select the asset to insert as a temporary or permanent replacement for the selected asset. This asset might currently be located on another functional location, such as **Storage**.
6. In the **Effective from** section, the **Effective** field is set to the current date and time by default. However, you can select a different date and time that the asset replacement is valid from.
7. Select **OK**.

Install asset

Use the **Install asset** function to install an asset structure on a functional location.

> **Note**
>
> Always select a parent asset. The parent asset and related child assets will be moved to the selected functional location.

1. Select **Asset management** > **Assets** > **All assets** or **Active assets**.
2. In the list, select the parent asset to install on another functional location.
3. Select **Install asset**.

   The **Attributes** section shows the asset attributes that are set up on the parent asset.
4. In the **Functional location** field, select the new location.
5. By default, the **Effective** field is set to the current date and time. However, you can select a different date and time that the installation on the asset structure is valid from.
6. Select **OK**.

Last updated on 05/07/2025

Create assets based on purchase orders

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how you can create a list of asset items that can be used as a basis for creating assets for maintenance jobs in Asset Management. Based on the asset items, you are able to view a list of the purchase order lines that have been created on those items. The purpose of this functionality is to easily create an asset in Asset Management based on a purchase order.

First, you set up the items to be used for creating assets from a purchase order in **Asset items**. After creating a purchase order line, you create the assets in **Pending assets**. It is possible to decide at which stage of the purchase order the asset should be created.

Select asset items

1. Click **Asset management** > **Setup** > **Assets** > **Items**.
2. Click **New** to create a new asset item.
3. Select the item in the **Item number** field. When you leave that field, the item name is automatically inserted in the **Product name** field.
4. On the **General** FastTab, select an asset type for the item.
5. Select asset manufacturer and model for the item.
6. Save the item.

Create assets from pending assets

1. Click **Asset management** > **Assets** > **Pending Assets**.
2. You will see an updated list of the purchase orders based on the items selected in **Asset items**.
3. You can filter the status of purchase orders to select at which lifecycle state the asset should be created. For example, you may only want to create assets when a product receipt has been posted on a purchase order.
4. Select the **Reference number** link on a purchase order line to view detailed information about the item.

5. If you want to edit which dimensions are displayed on the **Inventory dimensions** FastTab, click the **Display Dimensions** button, and make your selections.
6. If you want to create an asset based on a purchase order line, select the check box in the **Mark** column for that line on the list page, and click **Create assets**. A message will be displayed informing you of the asset ID.
7. Select the asset in the **All assets** list and click **Edit** to add more information to the asset.
8. In **Pending assets**, if you want to delete a line because you don't want to create an asset, select the check box in the **Mark** column for that line, and click **Discard pending assets**. A message will be displayed informing you of the asset ID. You are not deleting the purchase order or sales order, just the record from which you could have created an asset in **Asset Management**.

> ⓘ **Note**
>
> All product dimensions (size, color, configuration etc.) are automatically transferred to the asset attributes. Tracking dimensions (serial number) are stored directly on the asset when the asset is created.

Find pending assets

You can run a **Pending asset count** to check for pending assets. For example, this function can be used for receiving a notification each time a pending asset is ready to be created as an asset.

1. Click **Asset management** > **Periodic** > **Assets** > **Pending asset count**.
2. Click **OK** to run the job and update the list in **Pending assets**.
3. You can set up this job to run as a batch job, for example, once each day.

Caution: If data is changed on a purchase order *after* you have created an asset based on the appertaining item, those changes will not be reflected on the asset.

Last updated on 05/07/2025

Asset BOMs

Article • 01/06/2025

This article describes asset bills of materials (BOMs) in Asset Management. The **Asset BOM** page shows a list of all items (spare parts and other items) that are used on an asset during its whole lifetime. When you create a new asset, you should consider setting up an asset BOM as a part of the setup procedure. In this way, you can track item history for the asset from the creation date.

After you've completed a maintenance job, and item consumption has been registered on a work order, you can track consumption of spare parts and other items that are used on the asset. This functionality lets you keep a complete item consumption record for all your assets. For example, you can use the record to monitor whether a specific spare part is often replaced, or to keep track of the spare parts or other items that are currently used on an asset.

> **Note**
>
> On a work order, item consumption might include both spare parts and other, additional items, such as lubricants, bolts, and gaskets.

An asset BOM can be automatically updated based on the setup in Asset Management. If a work order lifecycle state has been created to handle finished or completed work orders, and if the **Update asset BOM** option for that work order lifecycle state is set to *Yes* on the **Work order lifecycle states** page, all items that are used on the work order will be automatically updated on the **Asset BOM** page when the work order is updated to that lifecycle state.

You can also manually update an asset BOM by creating new item lines on the **Asset BOM** page.

On the **Asset BOM** page, you can track spare parts history for assets after item consumption is registered on a work order. To use this functionality, you must select the item groups that should be used for spare parts registration on the **Spare parts item groups** page.

To use asset BOM functionality, you must first set up the required spare parts items groups. Then, if you want the asset BOM to be automatically updated when a work order is completed, you can set up a work order lifecycle state to handle that update.

Set up spare parts item groups

The setup of spare parts history is based on item groups that are created in the **Inventory and warehouse management** module. In Asset Management, you set up item groups so that you can track spare parts history for the items in the selected item groups.

1. Select **Asset management** > **Setup** > **Asset** > **Spare parts item groups**.
2. Select **New** to set up an item group.
3. In the **Item group** field, select the group. The name of the group is automatically entered in the **Name** field.

View and update asset BOMs

After you post item consumption on a work order, you can view the registered item consumption on the **Asset BOM** page.

1. Select **Asset management** > **Assets** > **Active assets**. Select the asset in the list, and then select **Asset BOM**.

   > ⓘ **Note**
   >
   > To view all item consumption registrations on all assets, select **Asset management** > **Inquiries** > **Assets** > **Asset BOM**.

2. Select **Update asset BOM**. You can add assets, asset types, and resources to the update as you require by selecting **Select**. Select **OK** to start the update. You can also set up the Update function as a batch job.

3. If you want to see more information that is related to the items, you can add inventory dimensions. Select **Inventory** > **Dimensions display**, and then select the check boxes for the dimensions that you want to see. To keep this setup for all assets on the **Asset BOM** page, set the **Save setup** option to *Yes*.

4. To get an overview of where in Asset Management the item on the selected line is used, in relation to assets, job type defaults, spare parts, and work orders, select **Item where used**.

5. If you want to see only active item lines, select **View** > **Current**. To see all item lines, including lines where the expiration date is earlier than the current date, select **View** > **All**.

> **Note**
>
> When you've completed a work order, if some items or spare parts that are related to the related asset have expired or have been replaced by other items or spare parts, we recommend that you update the asset BOM accordingly.

Create a new item line in an asset BOM

You can manually create item lines for assets.

1. On the **Asset BOM** page, select **New**.
2. In the **Asset** field, select the asset to add an item line for.
3. In the **Line number** field, enter a sequential line number.
4. In the **Effective** field, enter a start date for the item.
5. If the item will expire, in the **Expiration** field, enter an end date.
6. In the **Item number** field, select the item. The name is automatically entered in the **Product name** field.
7. In the **Quantity** field, enter the quantity that is used. The **Unit** field is automatically updated.

Asset event history

Article • 01/09/2023

This article explains how to access asset event history in Asset Management. The **Asset event history** page shows the registration history that has been made during the lifetime of an asset. You can access this page from the **All assets**, **Active assets**, and **My active assets** menu items. Select an asset, and then select **Event history**.

On the **Details** FastTab of the **Asset event history** page, you can do a search on all the available information. For example, you can use the asset event history to find the following information:

- When a job type was last used on an asset
- When a specific worker entered a remark on a work order job

The timeline is updated every time that the page is opened. It contains the following information:

- Changes that have been made on the asset: asset location, asset ID, name, and vendor warranty
- Asset parent
- Asset bill of materials (BOM)
- Asset lifecycle state log
- Functional location
- Maintenance requests
- Work orders, including posted item and notes
- Faults
- Condition assessments

Asset view

Article • 01/09/2023

This article describes the asset view in Asset Management. The **Asset view** page shows active assets and functional locations in a tree view. Therefore, you can easily get an overview of asset relations to functional locations. Additionally, you can view detailed information about functional locations, assets, and related bills of materials (BOMs). You can also get a quick overview of active maintenance requests and work orders that are related to an asset.

1. Select **Asset management** > **Assets** > **Asset view**.
2. To change the view that is shown on the page, select a new value in the **View** field.

> **Note**
>
> The default view that is shown when you open the **Asset view** page depends on the value that is selected in the **View** field on the **Assets** tab of the **Asset management parameters** page (**Asset management** > **Setup** > **Asset management parameters**).

On the right side of the page, FastTabs shows details of the selected view.

The breadcrumb trail that appears above the tree view shows the current selection in the tree view. This breadcrumb trail uses the following format:

Functional location ID / Functional location ID (if there is more than one functional location) > Asset ID / Asset ID (if there is more than one asset) - Item number.

If you've selected an asset in the tree view, you can select **Active requests** or **Active work orders** to view the maintenance requests or work orders that are related to the asset. You can also select **Open** > **Functional location**, **Asset**, or **Asset BOM** to open the related view.

The **Asset functional locations** option that you can select in the **View** field is also available in any asset lookup where you can select an asset. The tree view is shown on an **Asset view** tab, for example, where you create an asset, create a maintenance request, or create a work order.

Asset attribute overview

Article • 01/09/2023

This article provides an overview of asset attributes in Asset Management. Asset attributes are properties that are related to an asset type or an asset. If you've set up attribute types and used them on assets, you can get an overview of the attribute values that are set up on the assets. This overview is shown on two pages in Asset Management: **Asset attribute overview** and **Asset attribute**.

The **Asset attribute overview** page shows a separate line for each asset. The line shows all attribute types that are related to that asset. Follow these steps to open and use the **Asset attribute overview** page.

1. Select **Asset management** > **Inquiries** > **Assets** > **Asset attribute overview**.
2. In the **Asset type** field, select an asset type.
3. Select **OK**. A list shows all the assets that use the selected asset type. For each asset, all related asset attribute types are shown on the same line.

The **Asset attribute** page shows a separate line for each attribute type that is used on an asset. To open this page, select **Asset management** > **Inquiries** > **Assets** > **Asset attribute**.

Maintenance request lifecycle states

07/30/2025

Maintenance request lifecycle states define the stages that a request can go through. Examples include *Created*, *Active*, and *Ended*. When a maintenance request is converted to a work order, the maintenance request lifecycle state should be updated to *Ended* or *Closed* to indicate that the maintenance request is no longer active. On the **All maintenance requests** list page, you can view all maintenance requests, regardless of their lifecycle state.

Turn the depot repair option on or off

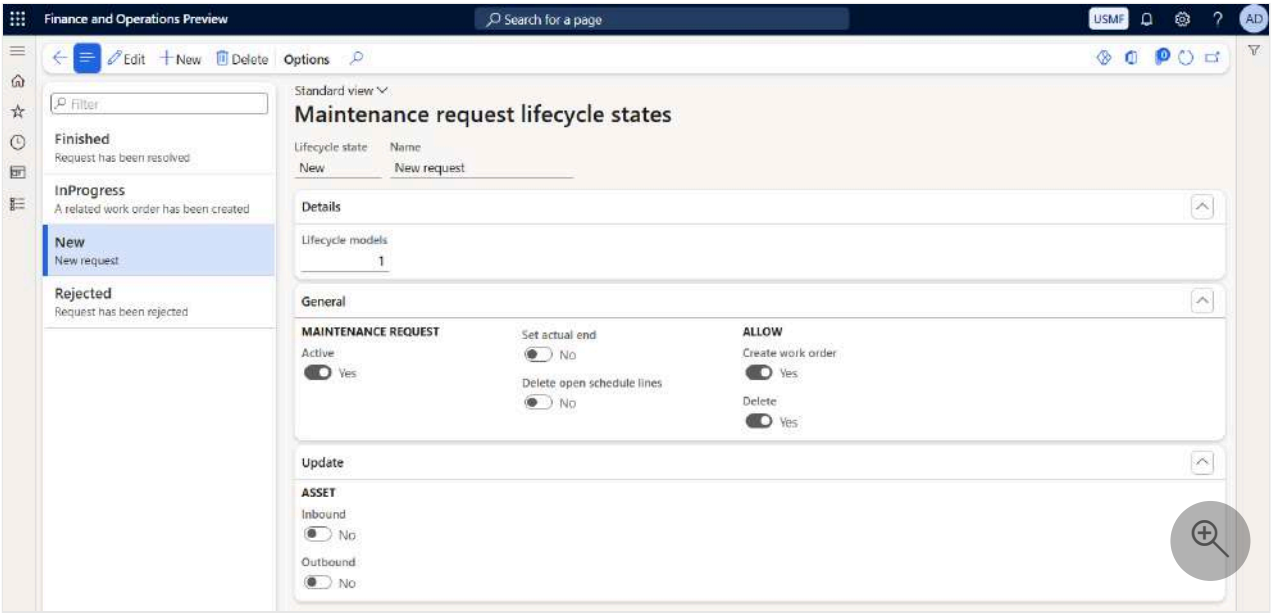
Depot repair is a maintenance request type that lets you receive assets from another location so that you can do a maintenance or repair job, and then return the asset after the job is completed. To use depot repair, you must enable its configuration key by following these steps:

1. Put your system into maintenance mode, as described in Maintenance mode.
2. Go to **System administration** > **Setup** > **License configuration**.
3. On the **Configuration keys** tab, expand the **Asset management** node and then select the check box for **Inbound/outbound**.
4. Turn off maintenance mode, as described in Maintenance mode.

Manage maintenance request lifecycle states

To manage the maintenance request lifecycle states that you need, follow these steps.

1. Go to **Asset management** > **Setup** > **Maintenance requests** > **Lifecycle states**.



2. Use the buttons on the Action Pane to add, remove, or edit a lifecycle state.

3. Make the following settings in the header of your new or selected lifecycle state:

    - **Lifecycle state** – Enter an ID for the lifecycle state.
    - **Name** – Enter a name for the lifecycle state.

4. For existing lifecycle states, the **Lifecycle models** field on the **Details** FastTab shows the number of maintenance request lifecycle models that use this lifecycle state.

5. Set the following options on the **General** FastTab:

    - **Active** – Choose whether a maintenance request should be active while it's in this lifecycle state.
    - **Set actual end** – Choose whether an actual end date and time should automatically be entered on a maintenance request that's in this lifecycle state.
    - **Delete open schedule lines** – Choose whether all maintenance schedule lines without a work order reference should be deleted automatically on a maintenance request that's in this lifecycle state.
    - **Create work order** – Choose whether a work order can be created from a maintenance request that's in this lifecycle state.
    - **Delete** – Choose whether a maintenance request can be deleted while it's in this lifecycle state.

6. If you use depot repair, then the **Update** FastTab is shown. Make the following settings here:

    - **Inbound** – Choose whether the asset lifecycle state of assets that are selected on a maintenance request should automatically be updated to **Inbound** when the maintenance request lifecycle state of that maintenance request is set to **Inbound**.
    - **Outbound** – Choose whether the asset lifecycle state of assets that are selected on a maintenance request should automatically be updated to **Outbound** when the maintenance request lifecycle state of that maintenance request is set to **Outbound**.

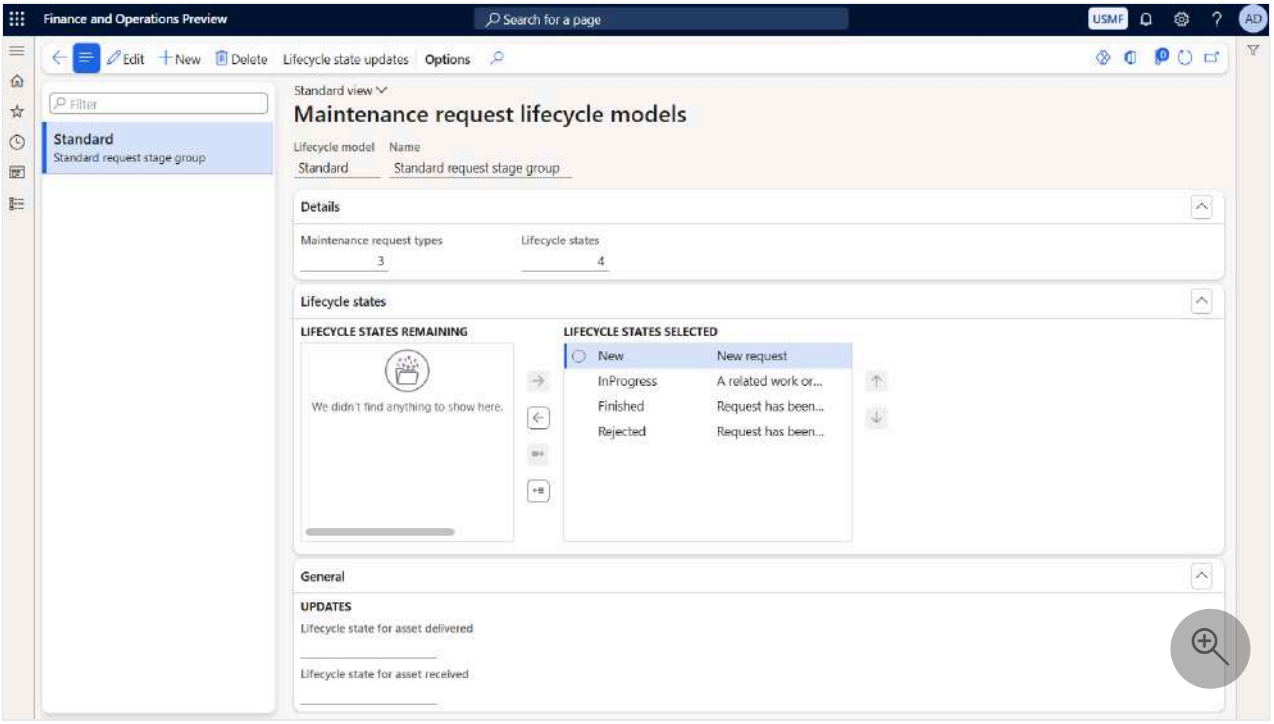
> ⓘ **Note**
>
> Maintenance request lifecycle states, lifecycle state groups, and lifecycle state types are related to, and used in the same way as, work order lifecycle states, lifecycle state groups, and lifecycle state types.

Set up maintenance request lifecycle models

After you've created the lifecycle states that are required for your maintenance requests, they can be divided into lifecycle state groups, or lifecycle models. Maintenance request lifecycle

models are used to create the flow that can be used for different types of maintenance requests. At a minimum, one standard maintenance request lifecycle model should be created.

1. Go to **Asset management** > **Setup** > **Maintenance requests** > **Lifecycle models**.



2. Use the buttons on the Action Pane to add, remove, or edit a lifecycle model.

3. Make the following settings in the header of your new or selected lifecycle model:

    - **Lifecycle model** – Enter an ID for the lifecycle model.
    - **Name** – Enter a name for the lifecycle model.

4. For existing lifecycle models, the **Details** FastTab displays the following information:

    - **Lifecycle states** – Shows the number of lifecycle states that are selected in this lifecycle model.
    - **Maintenance request types** – Shows the number of maintenance request types that use this lifecycle model.

5. On the **Lifecycle states** FastTab, move all of the lifecycle states that should be included in this lifecycle model into the **Lifecycle states selected** column.

    - Use the buttons between the columns to move one or more selected lifecycle states from one column to the other.
    - When a user changes the lifecycle state of a maintenance request, the states are displayed in the order shown in the **Lifecycle states selected** column, which should indicate the way maintenance requests typically progress from start to finish. Use the up and down buttons next to the **Lifecycle states selected** column to adjust the order of the lifecycle states.

6. If you use depot repair, then the **General** FastTab is shown. Make the following settings here:

    - **Lifecycle state for asset received** – Select the asset lifecycle state that assets selected on a maintenance request should automatically be updated to when they're received for depot repair.
    - **Lifecycle state for asset delivered** – Select the lifecycle state that assets selected on a maintenance request should automatically be updated to when they're returned after depot repair.

Maintenance request types

Article • 06/03/2022

Maintenance request types are used to categorize maintenance requests. For example, you might have maintenance request types that are related to preventive maintenance and corrective maintenance. Or you might have a special maintenance request type that is used to manage repair of assets (depot repair).

A maintenance request type defines the affiliation with a maintenance request lifecycle state group (maintenance lifecycle model). Maintenance request lifecycle models define the lifecycle states that can be set for a maintenance request. (Examples of maintenance request lifecycle states include **Created**, **Active**, and **Ended**.)

1. Select **Asset management** > **Setup** > **Maintenance requests** > **Maintenance request types**.
2. Select **New** to create a maintenance request type.
3. In the **Maintenance request type** field, enter an ID for the maintenance request type.
4. In the **Name** field, enter a name.
5. On the **General** FastTab, in the **Maintenance request lifecycle model** field, select a maintenance request lifecycle model.
6. In the **Work order type** field, select a work order type. When a maintenance request is converted to a work order, the work order automatically gets the work order type that is related to the maintenance request type.

The following illustration shows an example of the **Maintenance request types** page.

Responsible maintenance workers

Article • 06/03/2022

Responsible maintenance workers can be related to asset types, assets, functional locations, maintenance job type categories, maintenance job types, maintenance job type variants, and trades. They can be used on work orders and maintenance requests to indicate a preference about the maintenance workers who should be responsible for a work order. (However, those maintenance workers aren't necessarily the same workers who are scheduled to carry out the work order.) Use of this functionality is optional. For example, it can be used to select responsible workers or worker groups for specific work types or work areas.

During a work order lifecycle or a maintenance request lifecycle, responsible maintenance workers can be changed or updated. This change or update might be related to, for example, a change in the maintenance request lifecycle state or the work order lifecycle state.

The setup on the **Responsible maintenance workers** page is *not* used during work order scheduling.

> ⓘ **Note**
>
> In Asset Management, you can also set up *preferred* maintenance workers who might be allocated to work orders during work order scheduling.

Before you can set up responsible maintenance workers, you must set up the workers and maintenance worker groups that should be available for selection. For information about how to set up workers and maintenance worker groups, see Maintenance workers and worker groups.

Set up responsible maintenance workers

1. Select **Asset management** > **Setup** > **Workers** > **Responsible maintenance workers**.
2. Select **New** to create a record.
3. First create a default responsible maintenance worker or responsible maintenance worker group setup, where you set only the **Responsible maintenance worker group** field and/or the **Responsible worker** field. Leave the remaining fields blank.

This default setup will be used during work order scheduling if no other, more specific combination matches the contents of the work order.

> **Note**
>
> During the creation or update of a maintenance request, Asset Management goes through all responsible maintenance worker records to check for a possible match. It always checks the most specific combination first. In other words, Asset Management first checks for a match for the **Trade** field. If no match is found, it checks for a match for the **Maintenance job type variant** field. If no match is found, it checks for a match for the **Maintenance job type** field, and so on. As you can see in the layout of the page, this behavior means that, to find the most specific combination, Asset Management checks each record from right to left for a match (first **Trade**, then **Maintenance job type variant**, then **Maintenance job type**, then **Maintenance job type category**, then **Functional location**, then **Asset**, and finally **Asset type**). If no match is found, the default record that has no selections in those seven fields is used.

The following illustration shows an example of the **Responsible maintenance workers** page.

Maintenance requests

Article • 01/06/2025

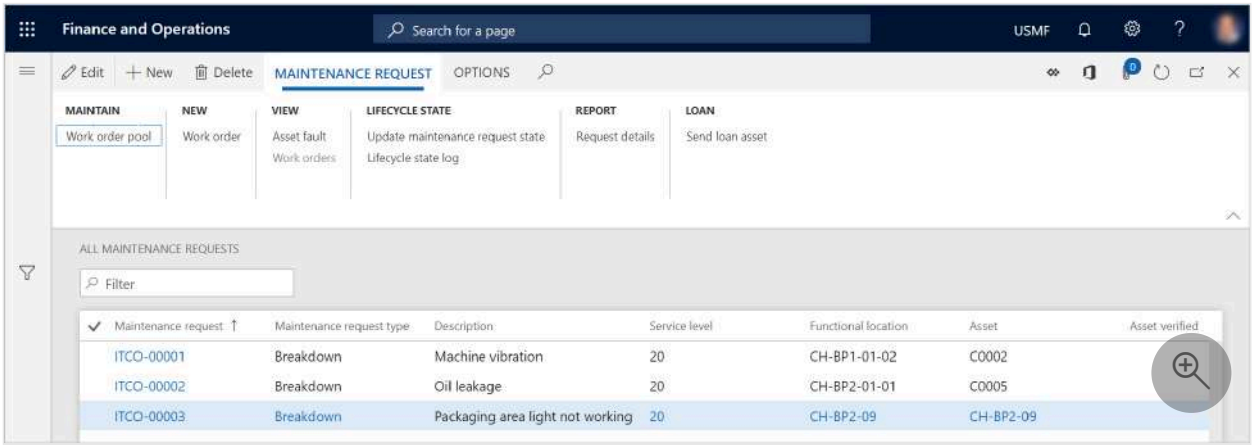
Maintenance requests are notes or declarations that are created to notify a manager or planner that an asset might require a maintenance or repair job, but without creating a work order. If the contents of a maintenance request are considered valid, a work order can then be created based on the maintenance request.

Maintenance requests can be created for any asset in Asset Management. Various types of maintenance requests can be created, depending on how your company uses maintenance requests. Here are some examples:

- Maintenance requests
- Notes
- Corrections or enhancements
- Investments
- Depot repair (This type is used when you receive assets from another location so that you can do a maintenance or repair job, and you then return the asset after the job is completed.)

View maintenance requests

To view maintenance requests, select **Asset management** > **Maintenance requests** > **All maintenance requests**, **Active maintenance requests**, or **My functional location maintenance requests**. Each list page shows some of the information that is related to a maintenance request.

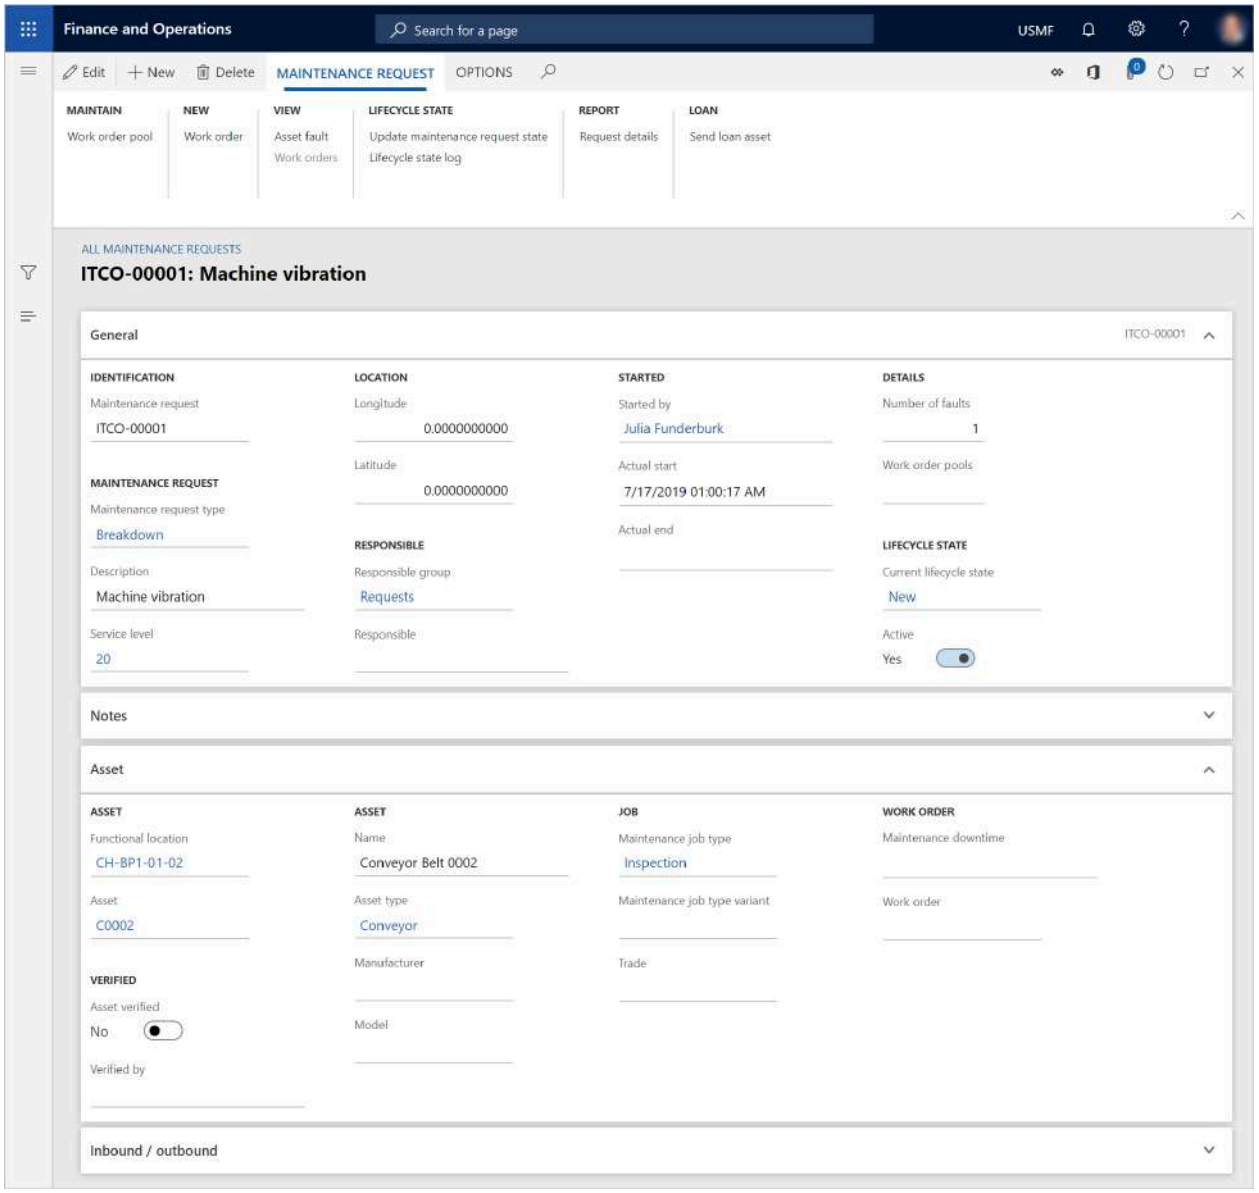


> **Note**
>
> Use the **My functional location maintenance requests** list page to view a list of maintenance requests that contain either functional locations that you're related to

as a worker or assets that are installed on functional locations that you're related to as a worker. (Read Maintenance workers and worker groups to learn more about how to set up functional locations on maintenance workers.)

Although customer account information is available in Asset Service Management (external maintenance), it isn't available in Asset Management (internal maintenance).

To open the details view of a record, on the **All maintenance requests** list page, in the grid view, select a link in the **Maintenance request** column.



The buttons on the Action Pane are organized on tabs. The following table briefly describes the buttons that are related to Asset Management.

Expand table

Button name	Description
Edit	Edit the selected maintenance request.
New	Create a new maintenance request.
Delete	Delete the selected maintenance request.
Work order pool	Connect the selected maintenance request to a work order pool.
Work order	Create a work order, based on the selected maintenance request.
Asset fault	Select **Asset faults** to create a fault registration on the selected maintenance request.
Work orders	Show a list of all work orders that are connected to the selected maintenance request.
Update maintenance request state	Update the maintenance request state.
Lifecycle state log	View a log that shows the lifecycle states of the selected maintenance request.
Maintenance request details	Print a report that shows details of the selected maintenance request.
Send loan asset	Select a loan asset that should be a temporary replacement for the asset that is selected on the selected maintenance request.
Return loan asset	Register the loan asset as returned.

Create maintenance requests

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Maintenance requests can be used if maintenance workers or production workers discover that equipment requires repair, but the repair job can't be done right away.

Example: While a maintenance worker is making a repair, they discover that another asset at the same location must be serviced. However, the maintenance worker doesn't have the time or the required spare parts to do the repair job. Therefore, they create a maintenance request on the asset and enters a short description of the issue.

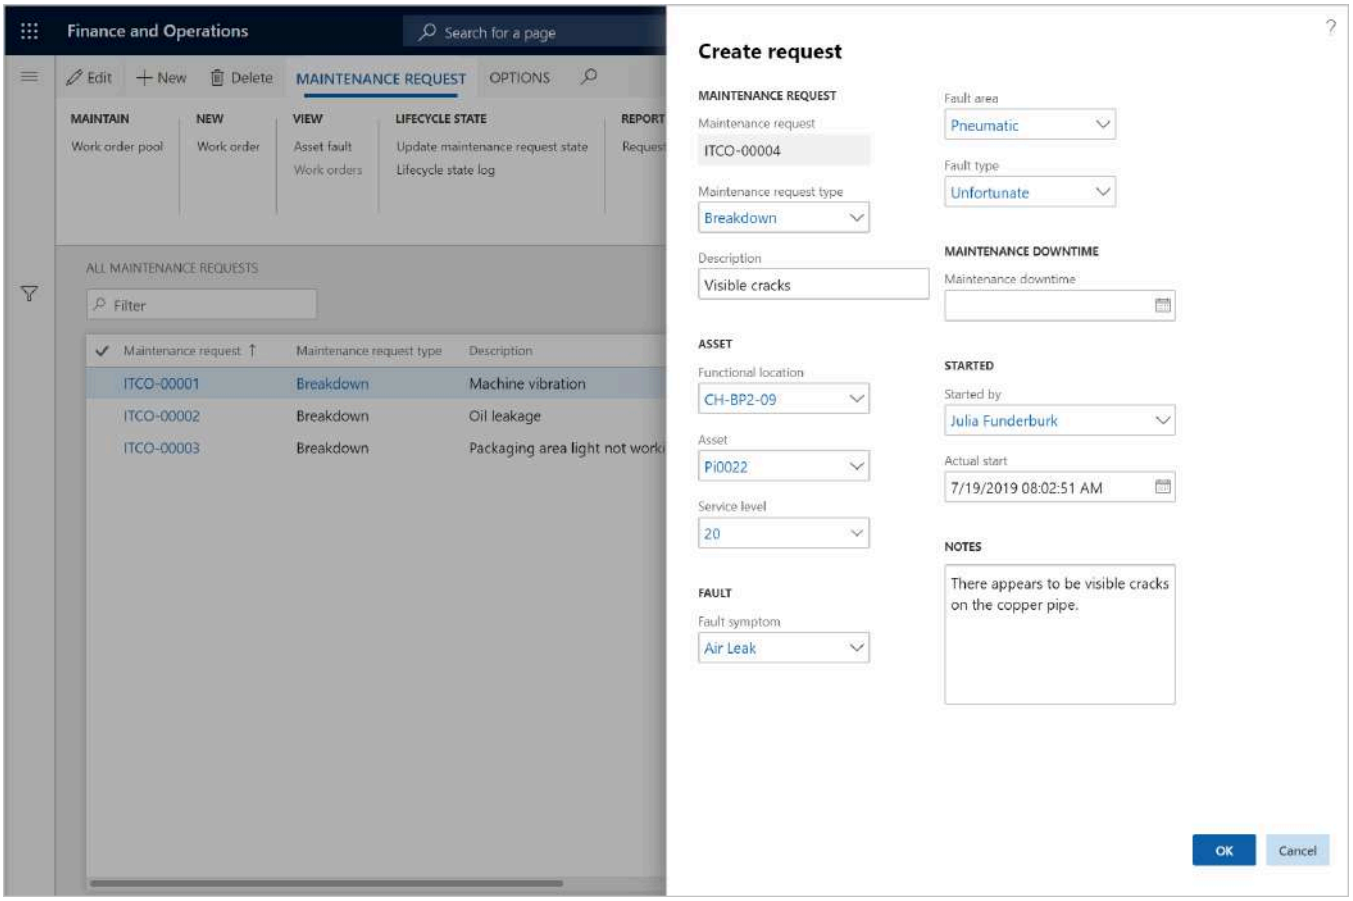
The **Active maintenance requests** section of the **Related information** pane on the right side of the **All assets** or **Active assets** page (**Asset management** > **Assets** > **All assets** or **Active assets**) shows the active maintenance requests that are attached to the selected asset.

1. Select **Asset management** > **Maintenance requests** > **All maintenance requests** or **Active maintenance requests**.
2. Select **New**.
3. In the **Create request** dialog box, in the **Maintenance request type** field, select the type of maintenance request. A default type is suggested.
4. In the **Description** field, enter a name or title that briefly describes the maintenance request.
5. In the **Functional location** and **Asset** fields, select a functional location or an asset, or a combination of a functional location and an asset, as you require. You can create a maintenance request without selecting an asset, and the asset can be added to the maintenance request later. If the maintenance worker who is signed in is related to a resource that is related to an asset, the **Asset** field is automatically set.

   If a maintenance request is already attached to the selected asset, a message bar appears at the top of the **Create request** dialog box to notify you about the ID of the existing maintenance request. A message bar also notifies you if the asset is covered by a warranty agreement.

6. In the **Service level** field, select a service level that indicates the urgency of the request.
7. If you selected an asset in step 5, you can use the **Fault symptom**, **Fault area**, and **Fault type** fields to create a fault registration.
8. If the maintenance request has caused maintenance downtime, enter the start date and time of the downtime.

   The **Started by** field is automatically set to your name.
9. The **Actual start** field is automatically set to the current date and time. However, you can change the value as you require.
10. In the **Notes** field, enter any additional notes that are required.
11. Select **OK**.



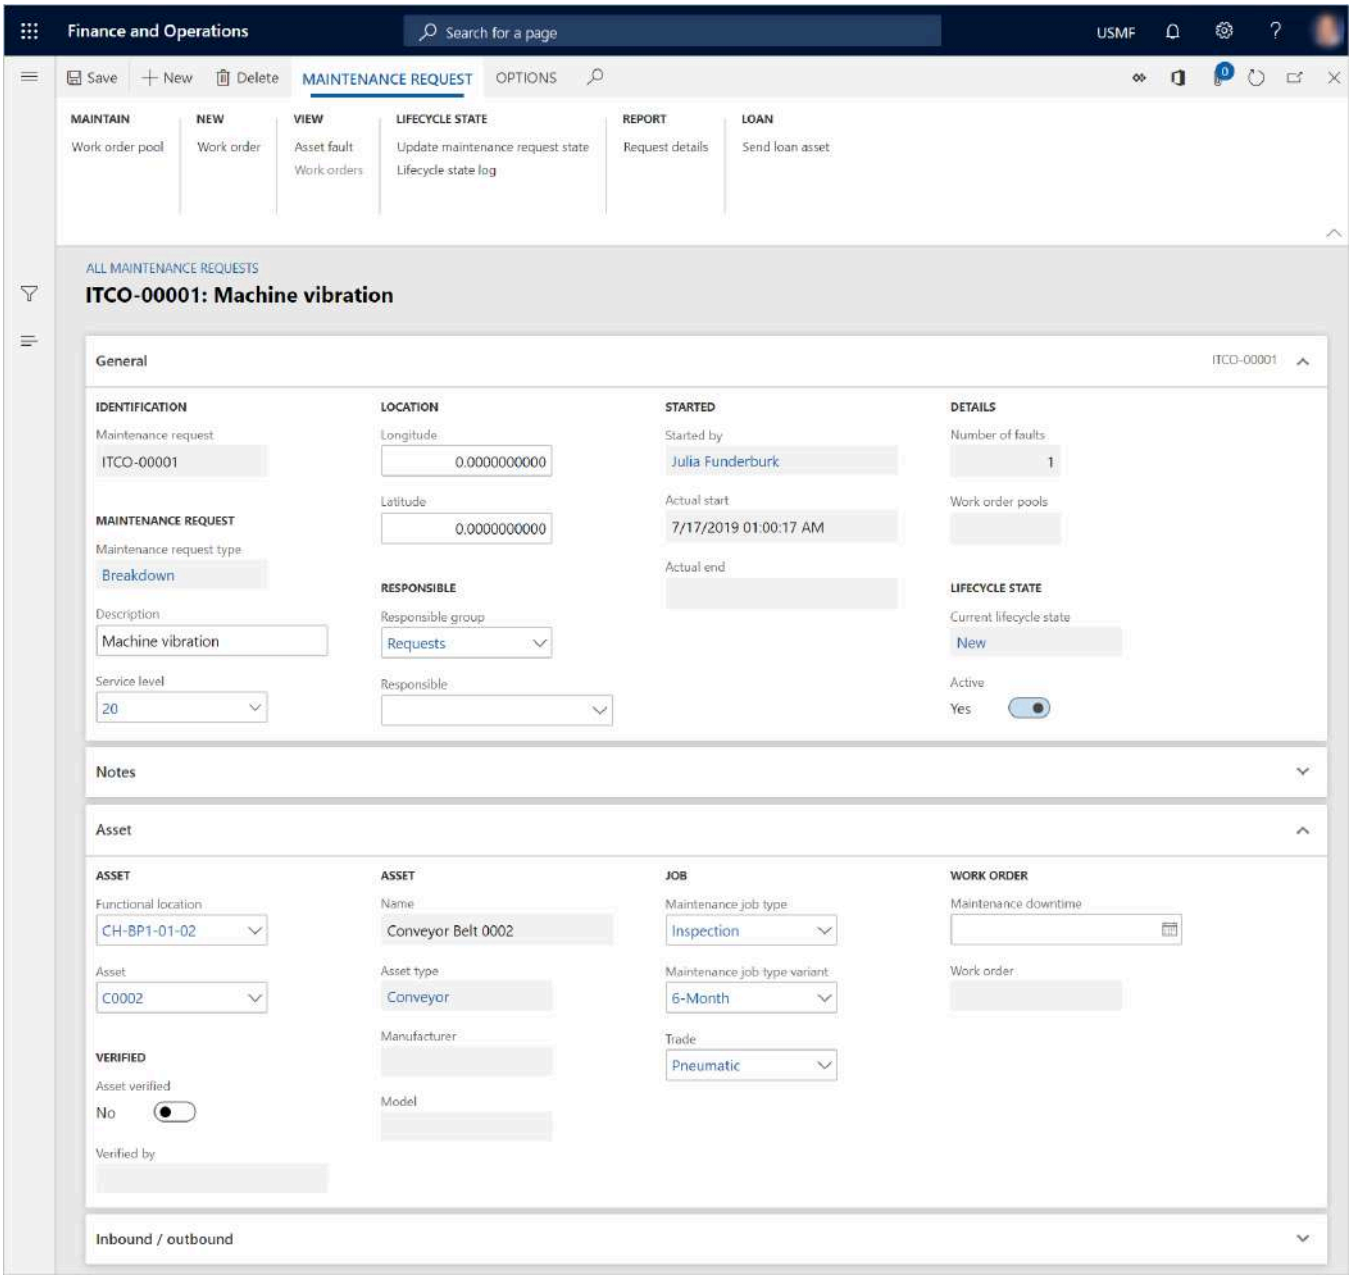
Subsequent processing of maintenance requests

After a maintenance request is created, but before it's converted to a work order, various information should be updated on it. Typically, a planner or another administrative employee completes this task.

- On the **All maintenance requests** or **Active maintenance requests** page, select the request to work with, and then select **Edit**.

In the details view, you can update various information. Here are some examples:

- Select and verify the asset. If you must select a different asset later, you can set the **Asset verified** option to **No**.
- Select a responsible maintenance worker group and/or a responsible maintenance worker. For more information about the required setup, see Responsible maintenance workers.
- Select a maintenance job type and, if this information is relevant, a related maintenance job variant and a job trade.
- In the **Latitude** and **Longitude** fields, enter geographic coordinates. Any coordinates that are added to a maintenance request are automatically transferred to a related work order.



> **Note**
>
> If you select an asset when you create a maintenance request, you can add one fault to the asset. After the maintenance request has been created, you can add more faults, as you require. To add faults, select **Asset fault** on the **All maintenance requests** page.

Last updated on 05/07/2025

Create work orders from maintenance requests

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

After you've created maintenance requests, you can easily convert them to work orders. This article describes the quickest way to work with maintenance requests, update several maintenance requests at the same time, and then create a work order for several maintenance requests at the same time. On the **Active maintenance requests** or **My functional location maintenance requests** page, you can also work with one maintenance request at a time and convert one maintenance request to a work order.

> **Note**
>
> Every maintenance request can be related to only one work order. However, multiple maintenance requests can be included in one work order, even if the maintenance requests have different assets.

1. Select **Asset management** > **Maintenance requests** > **All maintenance requests**.
2. Before you can create a work order from maintenance requests, you must select, at a minimum, a maintenance job type for the maintenance requests, and also a maintenance job type variant and trade, if this information is relevant. In the grid view, you can easily update information for a maintenance request.
3. When you're ready to create a work order, select the maintenance requests to include in it.
    - If you select several maintenance requests to convert to a work order, both the **Asset** field and the **Maintenance job type** field must be set before you create the work order.
    - If you select one maintenance request to convert to a work order, only the **Asset** field must be set before you create the work order. However, when you create the work order, you can select a maintenance job type (and a related maintenance job

type variant and trade, if this information is relevant) in the **Create work order** dialog box.

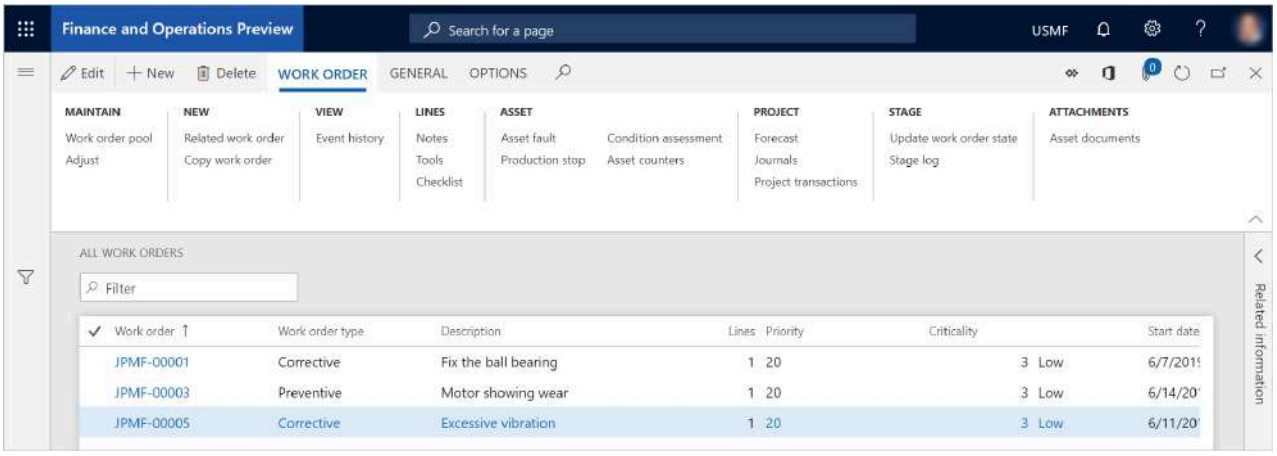
4. Select **Work order**.

5. In the **Create work order** dialog box, set the fields, and then select **OK**.

   A message bar might notify you that a new work order has been created.

   Additionally, when you create a work order that is based on a maintenance request, if the asset that is related to the maintenance request is included in a warranty agreement, a message bar notifies you about the warranty agreement.

6. Select **Asset management** > **Work orders** > **All work orders**, and open the new work order.



Last updated on 05/07/2025

Asset loans

Article • 06/15/2022

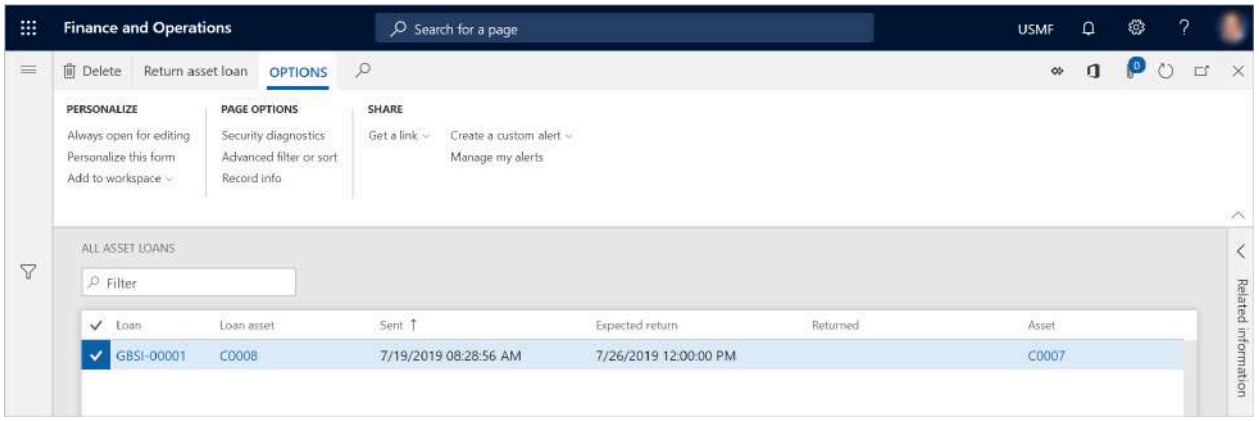
If your company receives assets for repair or maintenance jobs from either internal locations or customers, and if you temporarily loan assets to those locations or customers, Asset Management can track the asset loans.

Register asset loans on a maintenance request

1. Select **Asset management** > **Maintenance requests** > **All maintenance requests** or **Active maintenance requests**.
2. Select the maintenance request to register an asset loan on, and then select **Edit**.
3. On the **Request** page, select **Send loan asset**.
4. Select the asset, and enter the expected return date.
5. Select **OK**.

> **Note**
>
> - You can send a loan asset only if an asset of the same asset type is available.
> - The asset that you loan must have an asset lifecycle state that allows it to be used as a loan asset, such as **InStorage**. When the asset loan is registered, the asset lifecycle state of the asset is automatically updated to, for example, **OnLoan**.

To view a list of all the assets that you've loaned to other locations or customers, select **Asset management** > **Asset loan** > **All asset loans**. If the **Ended** check box is selected for an asset, the asset has been registered as returned to your company.



On the **Active asset loans** page, you can view a list of all the loan assets that haven't yet been returned to your company.

Register loan assets as returned

1. Select **Asset management** > **Asset loan** > **Active asset loans**.
2. Select the asset loan to register as returned, and then select **Return asset loan**.
3. In the **Returned** field, enter the date and time.
4. Select **OK**.
5. Refresh the **Active asset loans** list page, and notice that the asset loan no longer appears in the list.

Inbound and outbound assets

Article • 06/15/2022

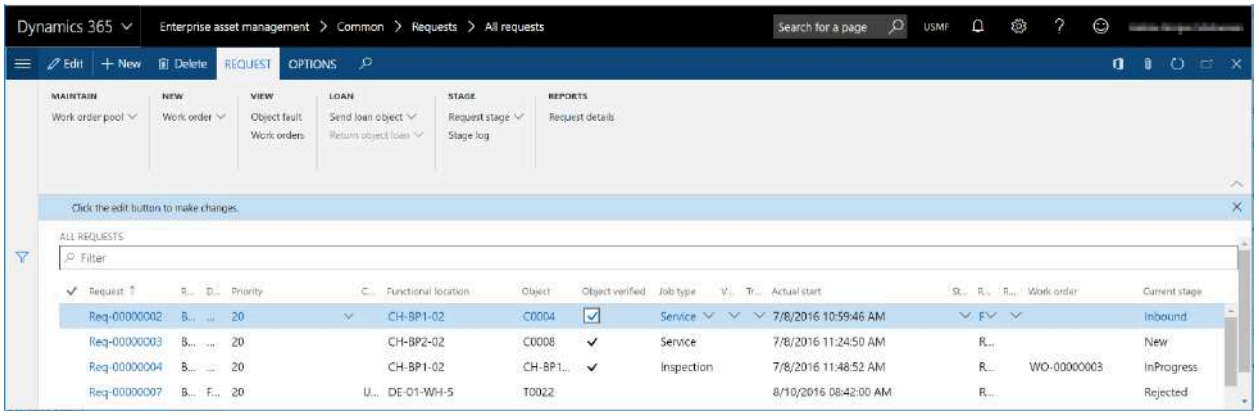
If your company does repair jobs or maintenance jobs on assets that are received from other locations or customers, Asset Management can track both inbound assets that are on their way to your company and outbound assets that are being returned.

> **Note**
>
> If you want to use inbound and outbound lifecycle states to manage assets that are coming in and being returned, you must set up maintenance request lifecycle states and lifecycle models to support these actions. Learn more in Maintenance requests.

The setup of Asset Management determines whether you can work with inbound and outbound assets.

Register assets as inbound

1. Select **Asset management** > **Maintenance requests** > **Active maintenance requests**.
2. Select the maintenance request.
3. Select **Update maintenance request state**.
4. Select **Inbound** (or another lifecycle state that you've created for inbound assets), and then select **OK**.



Register inbound assets as received

1. Select **Asset management** > **Inbound/outbound** > **Inbound assets**.
2. Select the asset or maintenance request.

3. Select **Receive assets**.
4. In the **Received** field, enter the date and time. Then select **OK**. The record is removed from the **Inbound assets** list page.

Register assets as outbound

When you've completed the maintenance or repair job, you can register the asset as returned.

1. Select **Asset management** > **Maintenance requests** > **Active maintenance requests**.
2. Select the maintenance request.
3. Select **Update maintenance request state**.
4. Select **Outbound** (or another lifecycle state that you've created for outbound assets), and then select **OK**.

Register outbound assets as delivered

1. Select **Asset management** > **Inbound/outbound** > **Outbound assets**.
2. Select the asset or maintenance request.
3. Select **Deliver assets**.
4. In the **Delivered** field, enter the date and time. Then select **OK**. The record is removed from the **Outbound assets** list page.

Maintenance request reports

Article • 06/03/2022

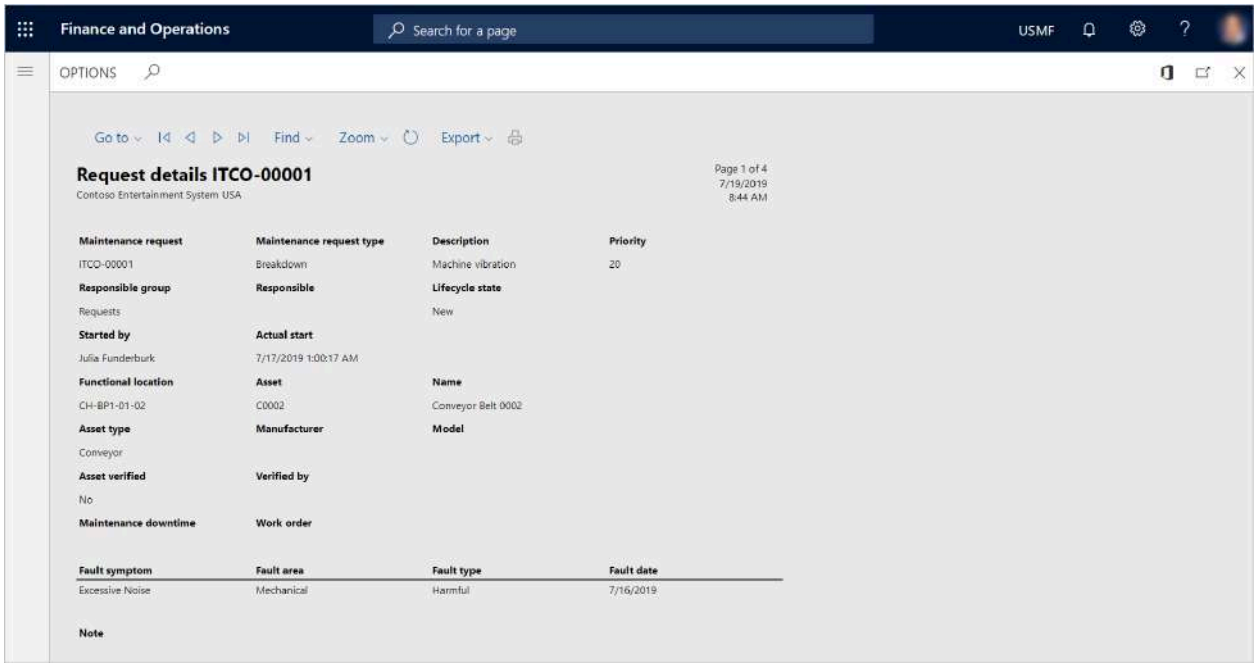
In Asset Management, you can generate two reports that are related to maintenance requests. One report shows details, and the other report provides a list that can be used for planning and follow-up.

Create a Maintenance request details report

The **Maintenance request details** report shows various information that is related to maintenance requests.

1. Select **Asset management** > **Reports** > **Maintenance requests** > **Maintenance request details**.
2. On the **Records to include** FastTab, you can select specific maintenance requests to include on the report.
3. On the **Run in the background** FastTab, you can set up report generation as a batch job, as you require.
4. Select **OK** to generate the report.

The following illustration shows an example of the **Maintenance request details** report.



Create a Maintenance request list report

The **Maintenance request list** report shows a list of all maintenance requests of the same request type.

1. Select **Asset management** > **Reports** > **Maintenance requests** > **Maintenance request list**.
2. On the **Records to include** FastTab, you can make selections to define which maintenance requests are included on the report.
3. On the **Run in the background** FastTab, you can set up report generation as a batch job, as you require.
4. Select **OK** to generate the report.

The following illustration shows an example of the **Maintenance request list** report for all active maintenance requests.

Maintenance job types, categories, variants, trades, and checklists

08/13/2025

An asset type is attached to every asset. Asset types define the maintenance job types (and therefore, the maintenance jobs) that can be performed on assets. When you create a work order, you must select a maintenance job type. You can select only the maintenance job types that are related to the setup of the asset type that is used for the asset.

For a graphical overview of assets and maintenance job types, and their connection to work orders, see Functional locations and assets.

Maintenance job type variants can be set up on a maintenance job type. Maintenance job type variants define variations of a job type, such as sizes (small, medium, or large), periods (weekly, biweekly, one month, or three months), and configurations (low standard, flexible, or high performance).

Maintenance job trades provide information about professional trades, such as mechanical, electrical, and hydraulic trades. Competency requirements can be set up on a maintenance job trade. All maintenance job trades can be used in relation to all maintenance job types. Selection of a maintenance job type variant and/or maintenance job trade on a work order is optional.

For each maintenance job type, variations of the maintenance job type setup can be created. For example, if you have a maintenance job type that is named *Service*, you can create the following variations for that maintenance job type: *Trucks 30,000 km*, *Cars 30,000 km*, and *Vans 30,000 km*.

Maintenance job type categories are used to collect a group of maintenance job types for overview purposes. Examples of maintenance job type categories might include *Calibration*, *Inspection*, *Overhaul*, and *Instrumentation*.

Maintenance checklist templates and maintenance checklist variables are used to set up maintenance checklists. Maintenance checklists are set up on maintenance job types and used on work orders.

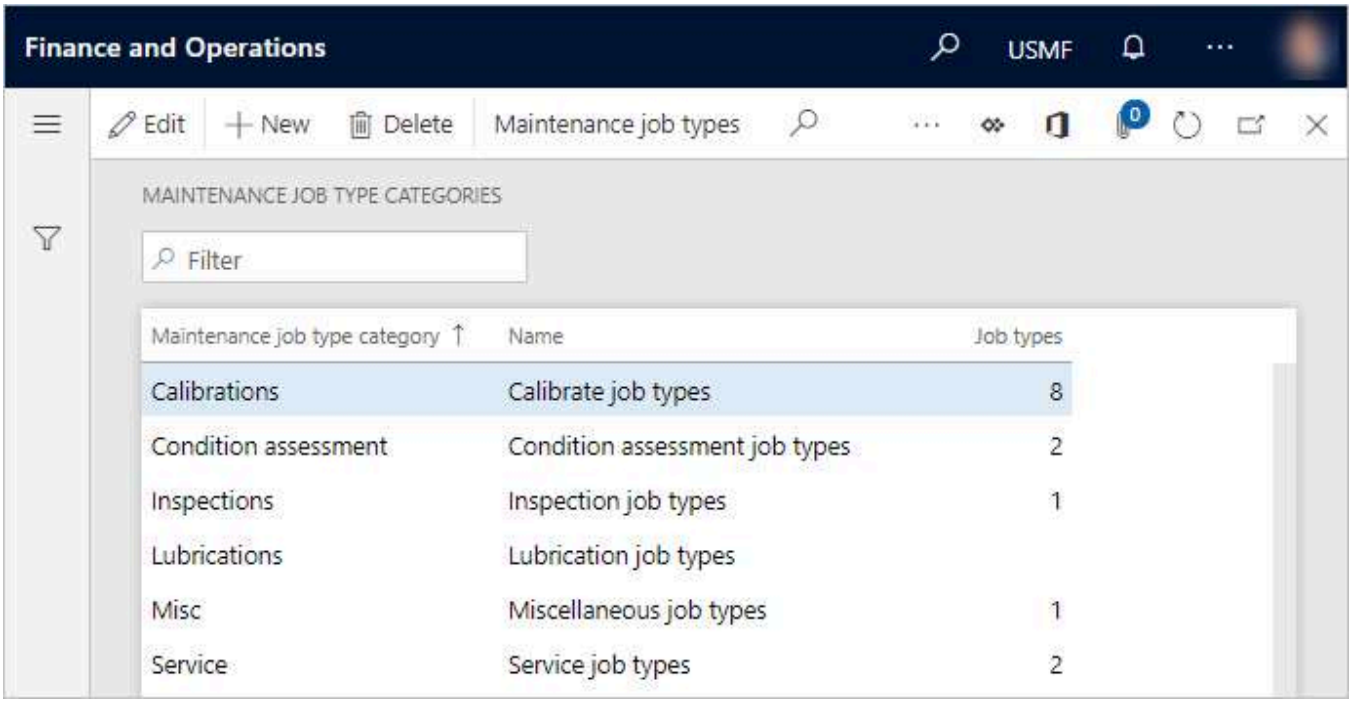
You first set up the required maintenance job type categories, maintenance job type variants, and maintenance job trades. You then create maintenance job types. Finally, on the **Maintenance job type defaults** page, you create all the variations of maintenance job types that are required for your equipment. On that page, you can also set up forecasts, maintenance checklists, and tools for a combination of maintenance job types.

> **Note**
>
> A maintenance job type can be related to only one maintenance job type category.

Create a maintenance job type category

1. Select **Asset management** > **Setup** > **Jobs** > **Maintenance job type categories**.
2. Select **New**.
3. In the **Maintenance job type category** field, enter an ID for the maintenance job type category.
4. In the **Name** field, enter a name.

   After you relate maintenance job type categories to maintenance job types, the **Job types** field shows the number of maintenance job types that are related to this maintenance job type category.

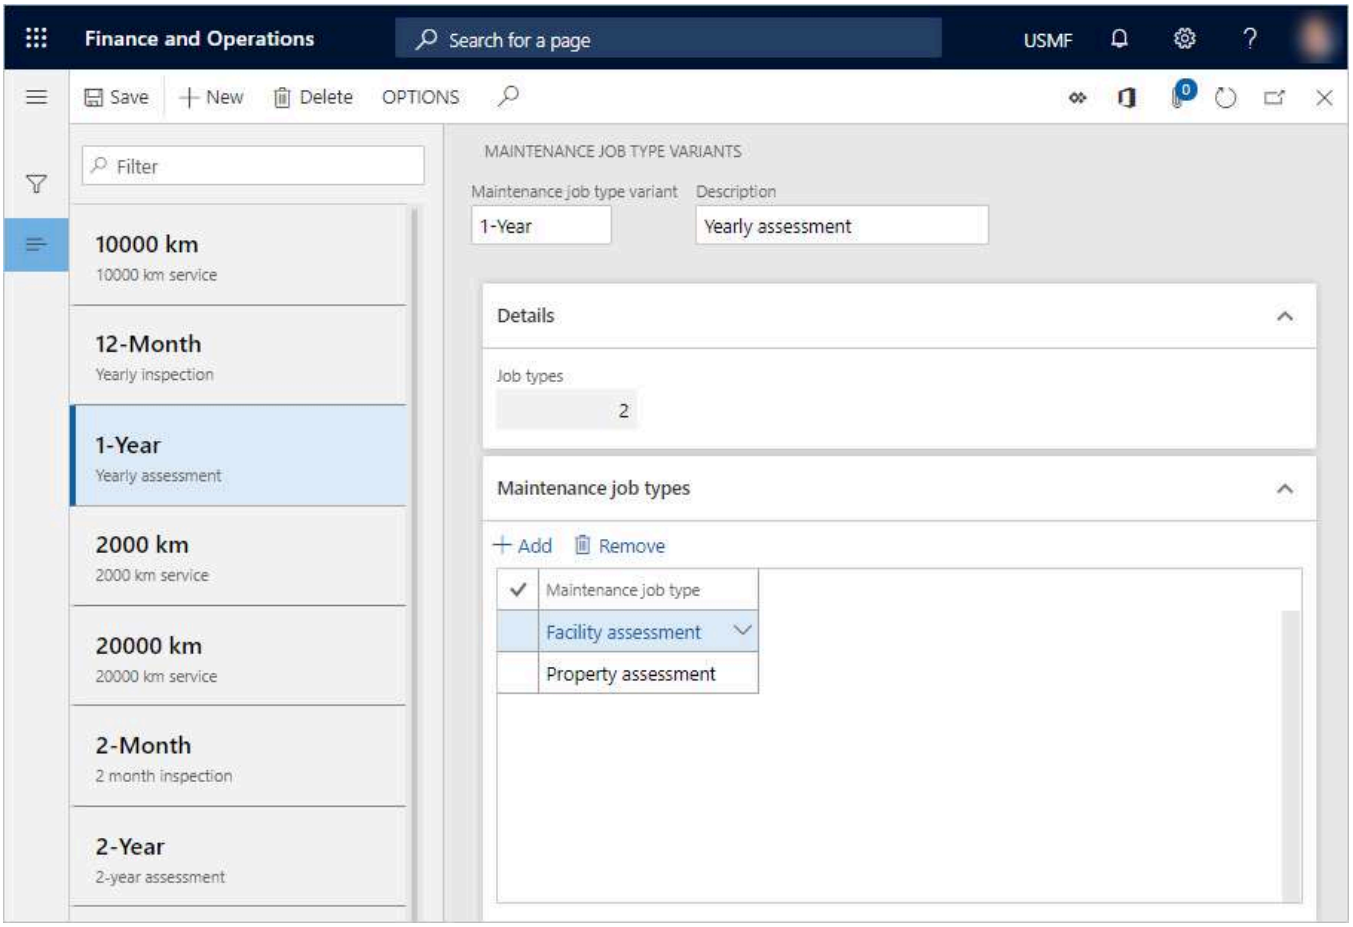


Create a maintenance job type variant

1. Select **Asset management** > **Setup** > **Jobs** > **Maintenance job type variants**.
2. Select **New**.
3. In the **Maintenance job type variant** field, enter an ID for the maintenance job type variant.

4. In the **Description** field, enter a description.
5. On the **Maintenance job types** FastTab, select **Add** to add a maintenance job type.
6. In the **Maintenance job type** field, select the maintenance job type.
7. Repeat steps 5 through 6 to add more maintenance job types to the maintenance job type variant.

   On the **Details** FastTab, the **Job types** field shows the number of maintenance job types that have been added to this maintenance job type variant.



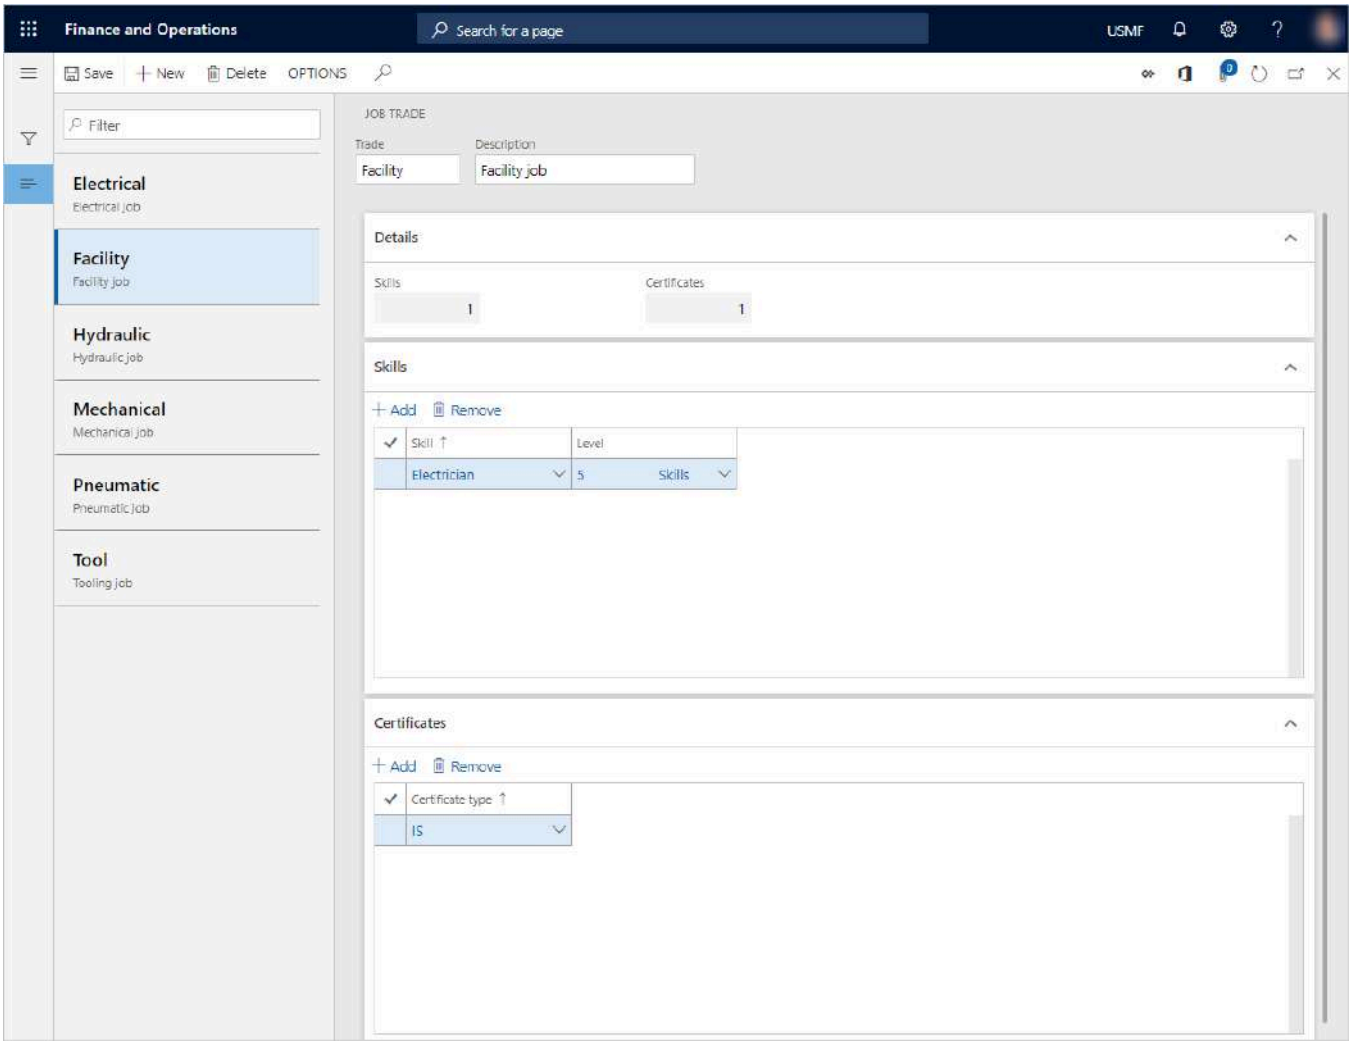
Create a maintenance job trade

1. Select **Asset management** > **Setup** > **Jobs** > **Maintenance job trade**.
2. Select **New**.
3. In the **Trade** field, enter an ID for the maintenance job trade.
4. In the **Description** field, enter a description.
5. On the **Skills** FastTab, select **Add** to add a new skill that should be related to the maintenance job trade.

6. In the **Skill** field, select the skill.
7. In the **Level** field, select the skill level.
8. Repeat steps 5 through 7 to add more skills to the maintenance job trade.

   On the **Details** FastTab, the **Skills** field shows the number of skills that have been added to this maintenance job trade.
9. On the **Certificates** FastTab, select **Add** to add a certificate to the maintenance job trade.
10. In the **Certificate type** field, select the certificate.
11. Repeat steps 9 through 10 to add more certificates to the maintenance job trade.

    On the **Details** FastTab, the **Certificates** field shows the number of certificates that have been added to this maintenance job trade.



Create a maintenance checklist variable

When you create maintenance checklist lines in the maintenance job type default, you must select a maintenance checklist type. *Variable* is one maintenance checklist type. It's used to

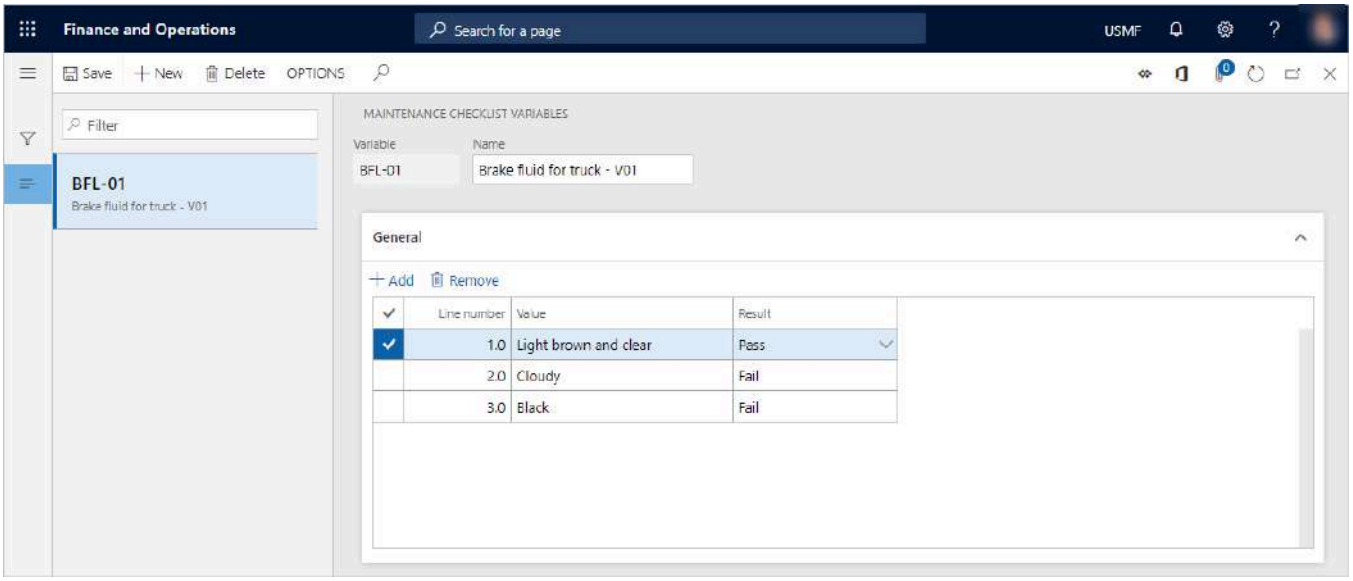
define a possible result in a range on a maintenance checklist line that is related to a work order line. A variable lets you create a set of predefined outcomes without having to make an exact measurement.

Example 1: You can measure oil level by defining three values: *Level too high*, *Level too low*, and *Level within range*. For each value, you define whether the value result is *Pass*, *Fail*, or *None*.

Example 2: You make a visual inspection of a piece of equipment to assess wear and tear.

1. Select **Asset management** > **Setup** > **Maintenance checklists** > **Maintenance checklist variables**.
2. Select **New**.
3. In the **Variable** field, enter an ID for the maintenance checklist variable.
4. In the **Name** field, enter a name.
5. On the **General** FastTab, select **Add** to add a line for a variable.

   A sequential line number is automatically entered in the **Line number** field. After you've added all the lines, you can change the line numbers as you require. When you select line and then press the **Down arrow** key, the next number in the sequence is automatically entered on the next line.
6. In the **Value** field, enter a value description.
7. In the **Result** field, select a result for the line.



Create a maintenance checklist template

Maintenance checklist templates can be used as a common set of tasks that a worker must perform to complete a work order correctly. The templates are referenced from maintenance checklist lines on the maintenance job type default. Templates can be referenced across multiple maintenance job type default lines. Therefore, you can easily reuse a set of common maintenance checklist tasks. Examples of maintenance checklist templates include general safety instructions, and a list of items and conditions that must be checked on a specific pump or similar models of a conveyor belt.

1. Select **Asset management** > **Setup** > **Maintenance checklists** > **Maintenance checklist templates**.
2. Select **New**.

   A template ID is automatically entered in the **Maintenance checklist template** field.
3. In the **Name** field, enter a name for the maintenance checklist template.
4. On the **Maintenance checklist lines** FastTab, select **Add** to add a template line.

   A sequential line number is automatically entered in the **Line number** field. After you've added all the lines, you can change the line numbers as you require. When you select line and then press the **Down arrow** key, the next number in the sequence is automatically entered on the next line.
5. In the **Type** field, select a type for the maintenance checklist line. For each maintenance checklist type, the **Line details** FastTab shows related fields. The following values are available:

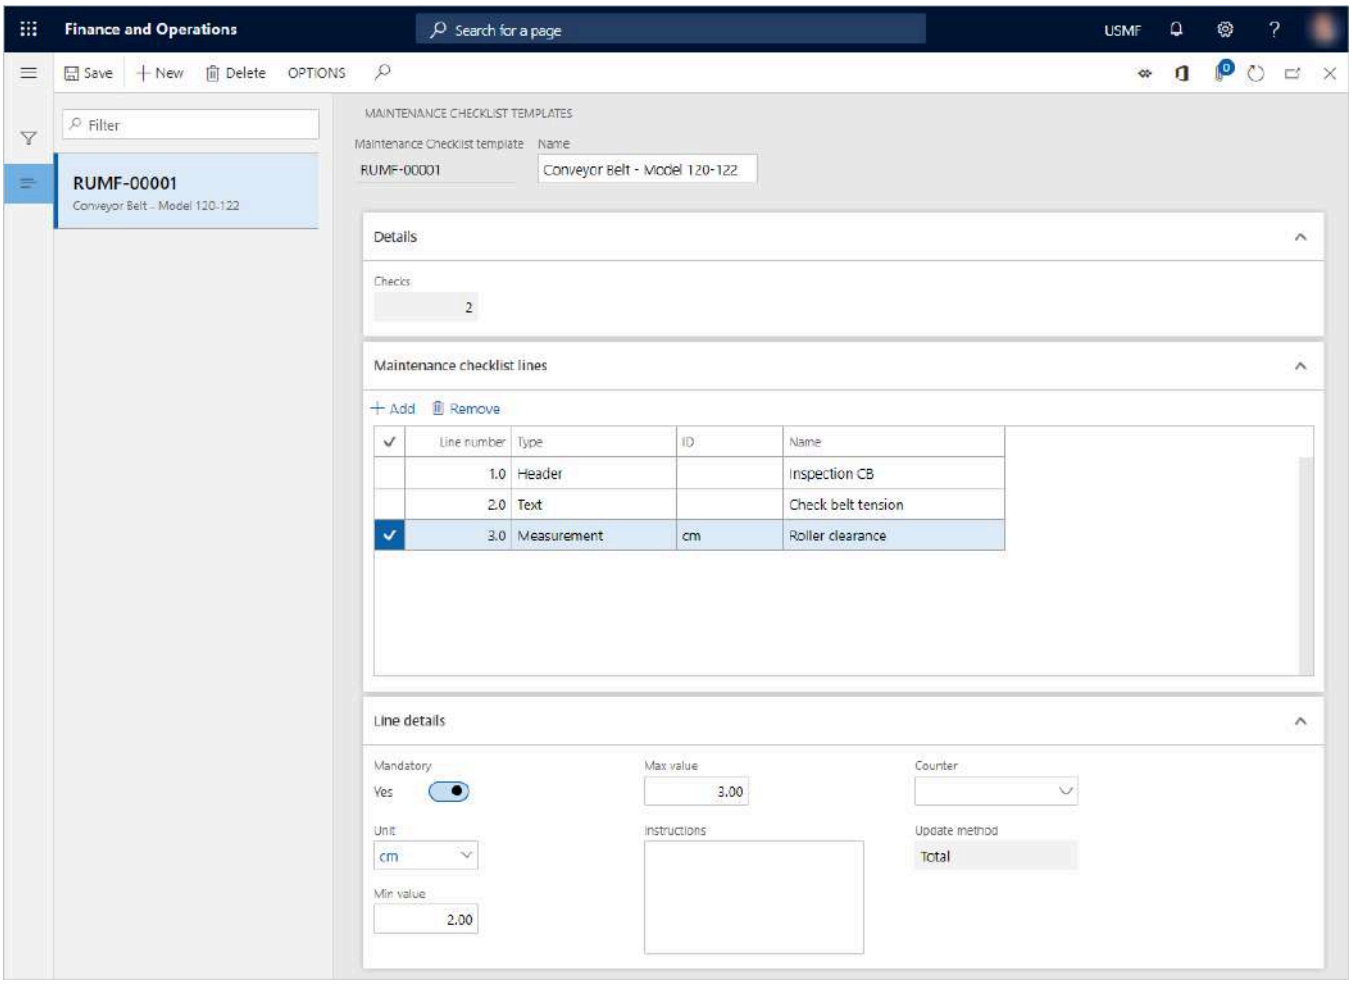
   - **Text** – The line has text that describes what to do. Use this maintenance checklist type if you want a worker to check or inspect something, but you don't expect a specific (measurable) result. After you select this type, enter a name or heading in the **Name** field. In the **Instructions** field, enter a description of what must be done. If the step is mandatory for the maintenance checklist, set the **Mandatory** option to *Yes*.
   - **Header** – The line is used as a heading to group the maintenance checklist lines that appear below it. This type is useful if you have several maintenance checklist lines that can be divided into specific areas. Headers provide an overview for the worker who will complete a maintenance checklist that has many maintenance checklist lines. After you select this type, enter a descriptive name in the **Name** field.
   - **Template** – The line is used to make a reference to an existing template. After you select this type, enter a name for the template in the **Name** field. In the **Template** field, select the template.

- **Variable** – The line is used to define a possible result in a range. For information about how to set up maintenance checklist variables, see the Create a maintenance checklist variable section. After you select this type, enter a descriptive name for the variable in the **Name** field. In the **Variable** field, select the variable. In the **Instructions** field, enter a description of what must be done. If the step is mandatory for the maintenance checklist, set the **Mandatory** option to *Yes*.

- **Measurement** – The line is used to record a specific measurement. You can set up the measurement that should be related to a predefined counter. After you select this type, enter a name for the template in the **Name** field. If this step is mandatory for the maintenance checklist, set the **Mandatory** option to *Yes*. If you want to use the measurement line as a counter registration, select the counter in the **Counter** field. The related **Unit** field is then automatically updated. If you've selected a counter, select the update method in the **Value** field. In the **Min. value** and **Max. value** fields, enter the allowed value range. In the **Instructions** field, enter a description of what must be done.

  > **Note**
  >
  > Any line of the **Measurement** type that doesn't have a counter setup is treated as an independent measurement registration that there's no automatic follow-up for in Asset Management. Likewise, if the selected counter type isn't present on the asset that is related to the work order, the maintenance checklist task is treated as an independent measurement. The counter value can be changed multiple times. It isn't posted until the **work order lifecycle state** is changed to a state where the **Process maintenance checklist** option is set to *Yes*.

On the **Details** FastTab, the **Checks** field shows the total number of checklist lines in your template. This number includes the nested lines in any existing template that you've referenced in your template.



Create a maintenance job type

1. Select **Asset management** > **Setup** > **Jobs** > **Maintenance job types**.
2. Select **New**.
3. In the **Maintenance job type** field, enter an ID for the maintenance job type.
4. In the **Name** field, enter a name.

   The **Details** FastTab shows an overview of the number of maintenance job type variants, skills, certificates, succeeding jobs, and asset types that have been created on this maintenance job type. The **Setup lines** field shows the number of maintenance job type default lines that have been set up on this maintenance job type. The **Assets** field shows the number of active assets that currently use this maintenance job type.
5. On the **General** FastTab, in the **Maintenance job type category** field, select a maintenance job type category.
6. Set the **Maintenance downtime activities** option to *Yes* if the maintenance job type requires a maintenance stop of the equipment before the job can be performed.
7. On the **Description** FastTab, enter a description of the maintenance job type.

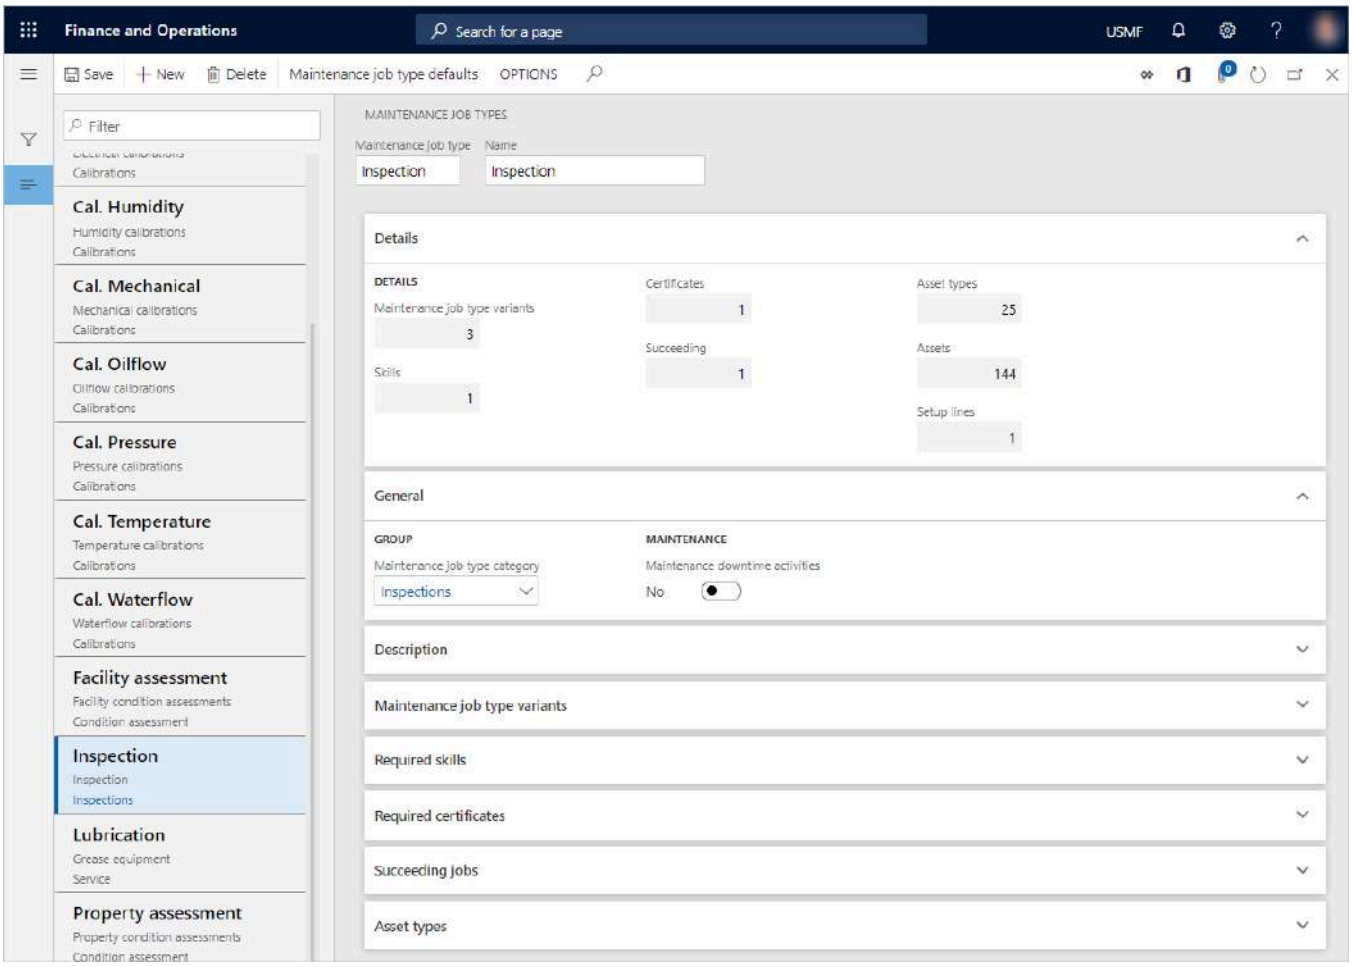
8. On the **Maintenance job type variants** FastTab, you can add variants to the maintenance job type.

9. On the **Required skills** and **Required certificates** FastTabs, you can add skills and certificate requirements to the maintenance job type.

10. If a specific maintenance job type must be performed next, add it on the **Succeeding jobs** FastTab. You can also set up a maintenance job type variant and trade that are related to the maintenance job type. If the succeeding job should start a specific number of days before or after the job that uses this maintenance job type has started, enter the number of days in the **Delay by days** field. Positive numbers represent days after the start of the related job, and negative numbers represent days before the scheduled start of the related job. For example, if you enter *5*, the succeeding job will start five days after the start of the job that is related to the maintenance job type. If you enter *-3*, the succeeding job will start three days before the scheduled start of the job that is related to the maintenance job type.

    > **Note**
    >
    > If you add more than one maintenance job type line, the sequence of the lines indicates the order that they should be performed in. The sequence starts at the top of the list.

11. On the **Asset types** FastTab, you can add asset types to the maintenance job type.



Create maintenance job type default lines and related forecasts, maintenance checklists, tools, description, and attachments

1. Select **Asset management** > **Setup** > **Jobs** > **Maintenance job type defaults**.

   –or–

   Select **Asset management** > **Setup** > **Jobs** > **Maintenance job types**, select a maintenance job type, and then select **Maintenance job type defaults**.

2. Select **New**.

3. In the **Functional location**, **Asset type**, **Manufacturer**, **Model**, and **Asset** fields, select appropriate values, depending on how specific the maintenance job type default should be.

4. In the **Maintenance job type** field, select a maintenance job type if it wasn't automatically selected.

5. In the **Maintenance job type variant** and **Trade** fields, select a maintenance job type variant and a maintenance job trade as you require.

6. Select **Forecast**.

7. On the **Maintenance job type default forecast** page, you can make forecasts on hours, items, and expenses. On the relevant tabs, select **Add**, and make selections to create the required forecasts for the maintenance job type.

8. On the **Item forecast** tab, you can select inventory dimensions that should be shown on the item line. Select **Inventory** > **Dimensions**, select the dimensions to show, set the **Save setup** option to *Yes*, and then select **OK**.

9. On the **Item forecast** tab, select **Item where used** to see an overview of where the item on the selected line is used in Asset Management in relation to assets, maintenance job type default, spare parts, and work orders.

   The **Maintenance forecast totals** FastTab shows an overview of forecast totals. This overview includes the total number of hours and forecast lines that have been created.

   > ⓘ **Note**
   >
   > To copy the forecast setup from another maintenance job type, select **Copy forecast**, and then select the maintenance job type to copy the setup from.

10. Select **Save** to save your changes.

11. Close the **Maintenance job type default forecast** page to return to the **Maintenance job type defaults** page.

12. Select **Maintenance checklist**.

13. On the **Maintenance job type defaults checklist** page, you can add maintenance checklist lines to the selected maintenance job type default. On the **Maintenance check lines** FastTab, select **New** to add a maintenance checklist line.

    Line numbers are automatically entered in the **Line number** field to indicate the sequence of the maintenance checklist lines. You can edit line numbers as you require. After you've created the first maintenance checklist line, select the line, and then press the **Down arrow** key to add a line below it. Alternatively, you can select a maintenance checklist line and then select **New**. In this case, a new line is added above the selected maintenance checklist line.

14. In the **Type** field, select the line type, and then add information that is related to the maintenance checklist type. For a description of the available types and related fields, see the Create a maintenance checklist template section.

> **Note**
>
> To copy the maintenance checklist setup from another maintenance job type, select **Copy maintenance checklist**, and then select the maintenance job type to copy the setup from.
>
> You can easily create a template from an existing maintenance checklist. You can then reuse the template across multiple maintenance checklists. The new template will be an exact copy of the active maintenance checklist. Select **Create template**, and then enter a name for the template. To replace the existing maintenance checklist with a single line that references the new template, set the **Replace** option to *Yes*. You can view the contents of the template in the **Maintenance checklist templates** details page.

15. Select **Save** to save your changes.
16. Return to the **Maintenance job type defaults** page.
17. Select **Tools**.
18. On the **Maintenance job type default tools** page, you can add the tools (resources) that should be used for the maintenance job type. Select **New**, and then select the tool in the **Resource** field.

    > **Note**
    >
    > To copy the tool setup from another maintenance job type, select **Copy tools**, and then select the maintenance job type to copy the setup from.

19. Select **Save** to save your changes.
20. Return to the **Maintenance job type defaults** page.
21. Select **Work description**.
22. On the **Work description** page, select **Edit**, and then add a description that is related to the selected maintenance job type default, as you require.
23. Select **Save** to save the description.

    If you add a work description here, it overrides any description that is set up for the maintenance job type on the **Maintenance job types** page. If you don't add a work description here, any description that is set up for the maintenance job type is used.

Descriptions are automatically transferred to work orders that use the maintenance job type or maintenance job type default.

24. Return to the **Maintenance job type defaults** page.

25. To set up attachments on a selected maintenance job type default line, select **Attach documents**. Attachments that are set up on a maintenance job type default line are automatically included on work order lines that use that maintenance job type default line.

26. Select **New**, and then select a document type.

27. Upload the document or file.

28. Set the fields on the **Attachments** page. The attachment setup uses standard document setup functionality.

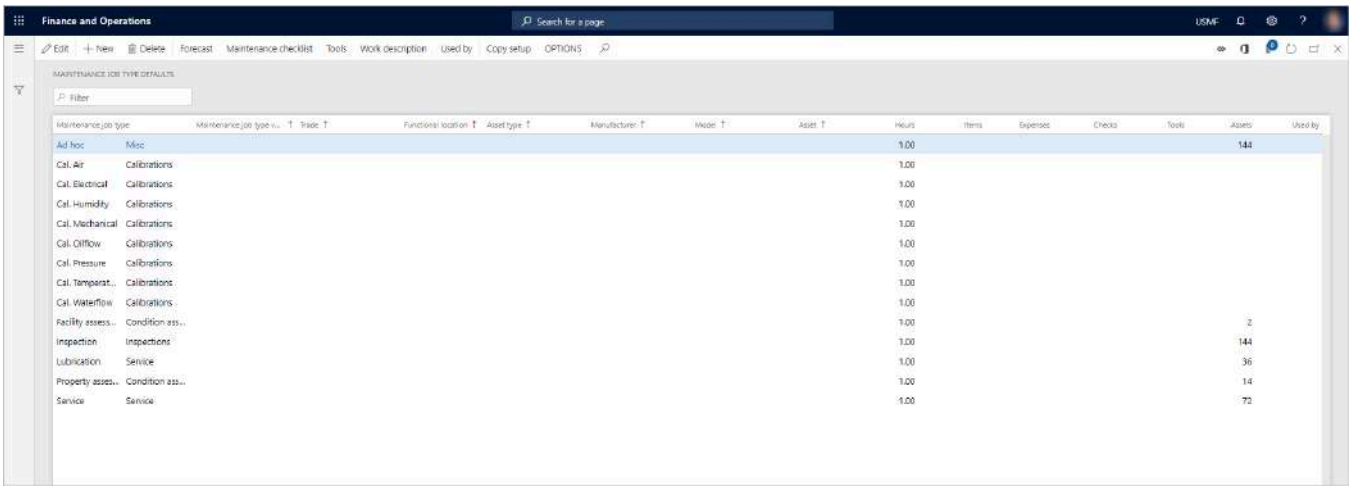
29. Select **Save** to save the attachment.

    > ⓘ **Note**
    >
    > Attachments on a maintenance job type default line are printed together with a work order report only if the document types of the attachments are selected on the **Document types** tab of the **Asset management parameters** page (**Asset management** > **Setup** > **Asset management parameters**). Examples of attachments include guidelines that explain how to complete a specific job or a predefined maintenance checklist (if you don't use the maintenance checklist functionality for maintenance job type default lines).

    On the **Maintenance job type defaults** page, each line shows the number of forecasted hours, and also the number of lines that have been created for items, expenses, maintenance checklists, and tools. The **Assets** field shows the number of active assets that are related to the maintenance job type default line.

30. To copy a maintenance job type default to another maintenance job type default, select the maintenance job type default line to copy another setup to, select **Copy setup**, and then select the maintenance job type default to copy.

31. To view a list of the maintenance plans or maintenance rounds that currently use a maintenance job type default line, select the line, and then select **Used by**.



When the system selects the available maintenance job type default that should be used on a work order line, the selection is based on the asset and the related asset type setup. Asset Management goes through all maintenance job type default records that are related to the maintenance job type that is related to the asset type to check for a possible match. It always checks the most specific combination first. In other words, to find the most specific combination, Asset Management first checks for a possible match for the **Trade** field. If no match is found, it checks for a match for the **Maintenance job type variant** field. If no match is found, it checks for a match for the **Maintenance job type** field, and so on (**Trade**, then **Maintenance job type variant**, then **Maintenance job type**, then **Asset**, then **Model**, then **Manufacturer**, and then **Asset type**). If no match is found, the default record where only the maintenance job type is selected is used.

A project activity ID is automatically related to each maintenance job type default line that you create. The project activity is created on the forecast project that is selected in the **Maintenance forecast project** field on the **Assets** tab of the **Asset management parameters** page. The purpose of the project activity is to manage forecasts on hours, items, and expenses in relation to work orders. Maintenance job type forecasts are automatically transferred to the work order line, and they're copied from the forecast project to the work order project that is created for the work order line. The purpose of the project activity is to manage forecasts in relation to work orders.

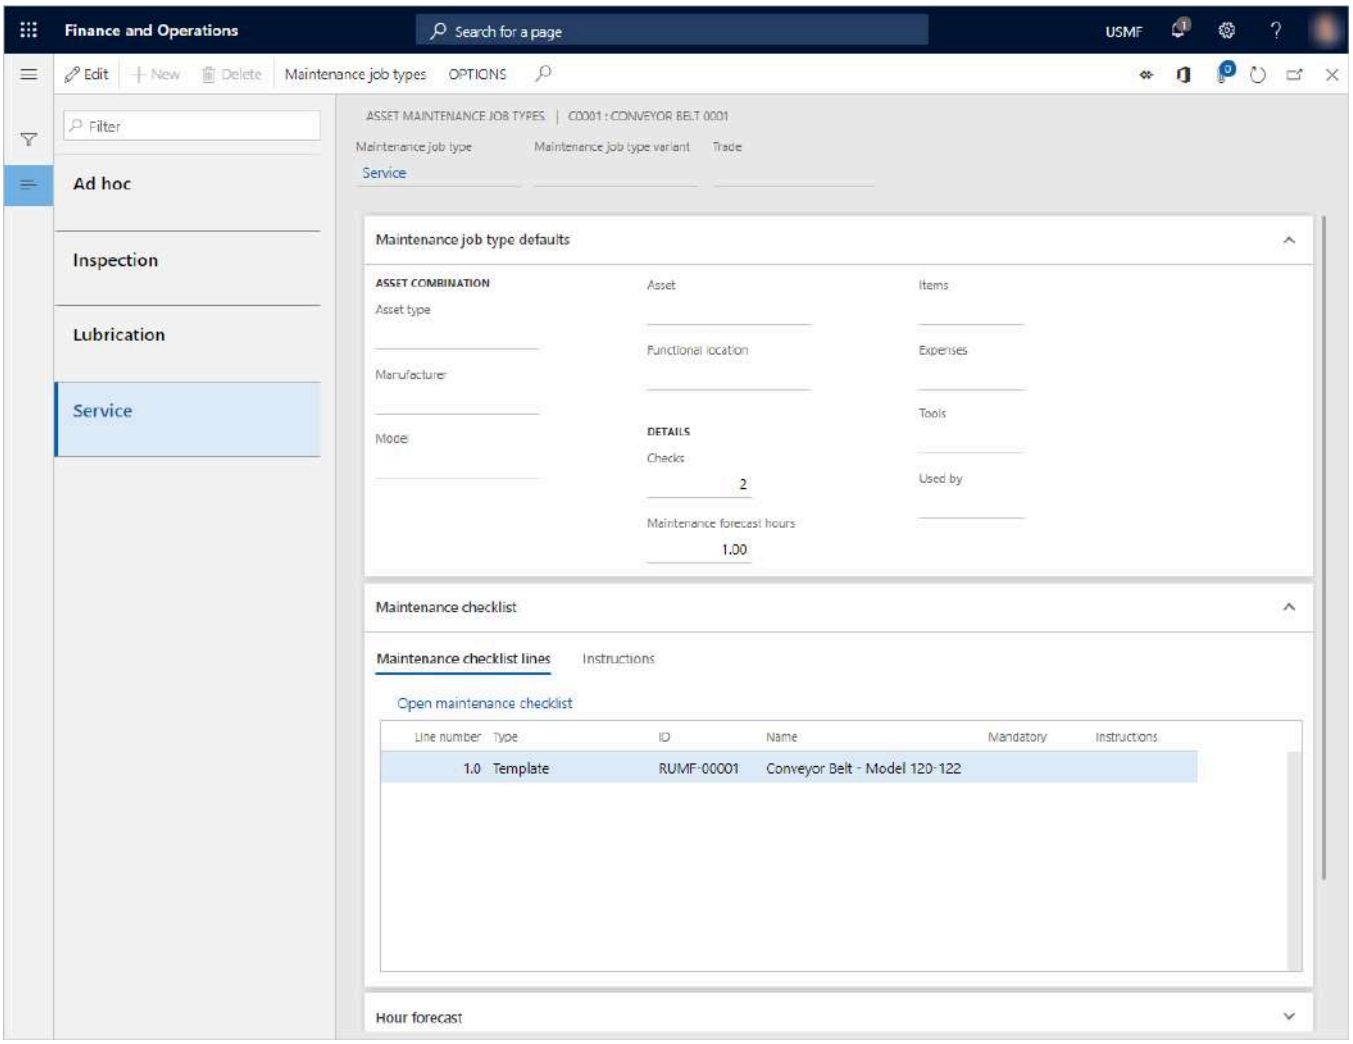
You can set up a batch job to update maintenance job type default references at regular intervals, or you can manually run the job. To create a batch job or run a manual update, select **Asset management** > **Periodic** > **Preventive maintenance** > **Update maintenance job type default references**.

Overview of maintenance job types that are related to assets

After you've created the required maintenance job type default combinations, you can use the **All assets** page to get an overview of the current maintenance job type default that is related to a specific asset. The overview shows all maintenance job type default combinations that can be used on the asset type that is selected for the asset. These combinations include combinations that have variations of maintenance job type variants and maintenance job trades.

1. Select **Asset management** > **Assets** > **All assets** or **Active assets**.
2. In the list, select the asset to see an overview of maintenance job type combinations for.
3. On the Action Pane, on the **General** tab, in the **Related information** group, select **Maintenance job types**.

   The left pane of the **Asset maintenance job types** page shows a list of all the maintenance job type combinations that are related to the selected asset.
4. Select a maintenance job type combination to see the related setup for maintenance checklists, forecasts, and tools. The **Details** section on the **Maintenance job type defaults** FastTab shows the number of related maintenance checklists, forecasted hours, items, and so on, that are related to the selected maintenance job type combination.
5. To view details for the selected maintenance job type, select **Maintenance job types**.



Automatic update of maintenance job type forecasts

In Asset Management, you can automatically update any changes to maintenance job type forecasts for hour costs, item costs, and expenses that have been updated in other modules. In this way, you help guarantee that your maintenance job type forecasts always use the latest cost prices.

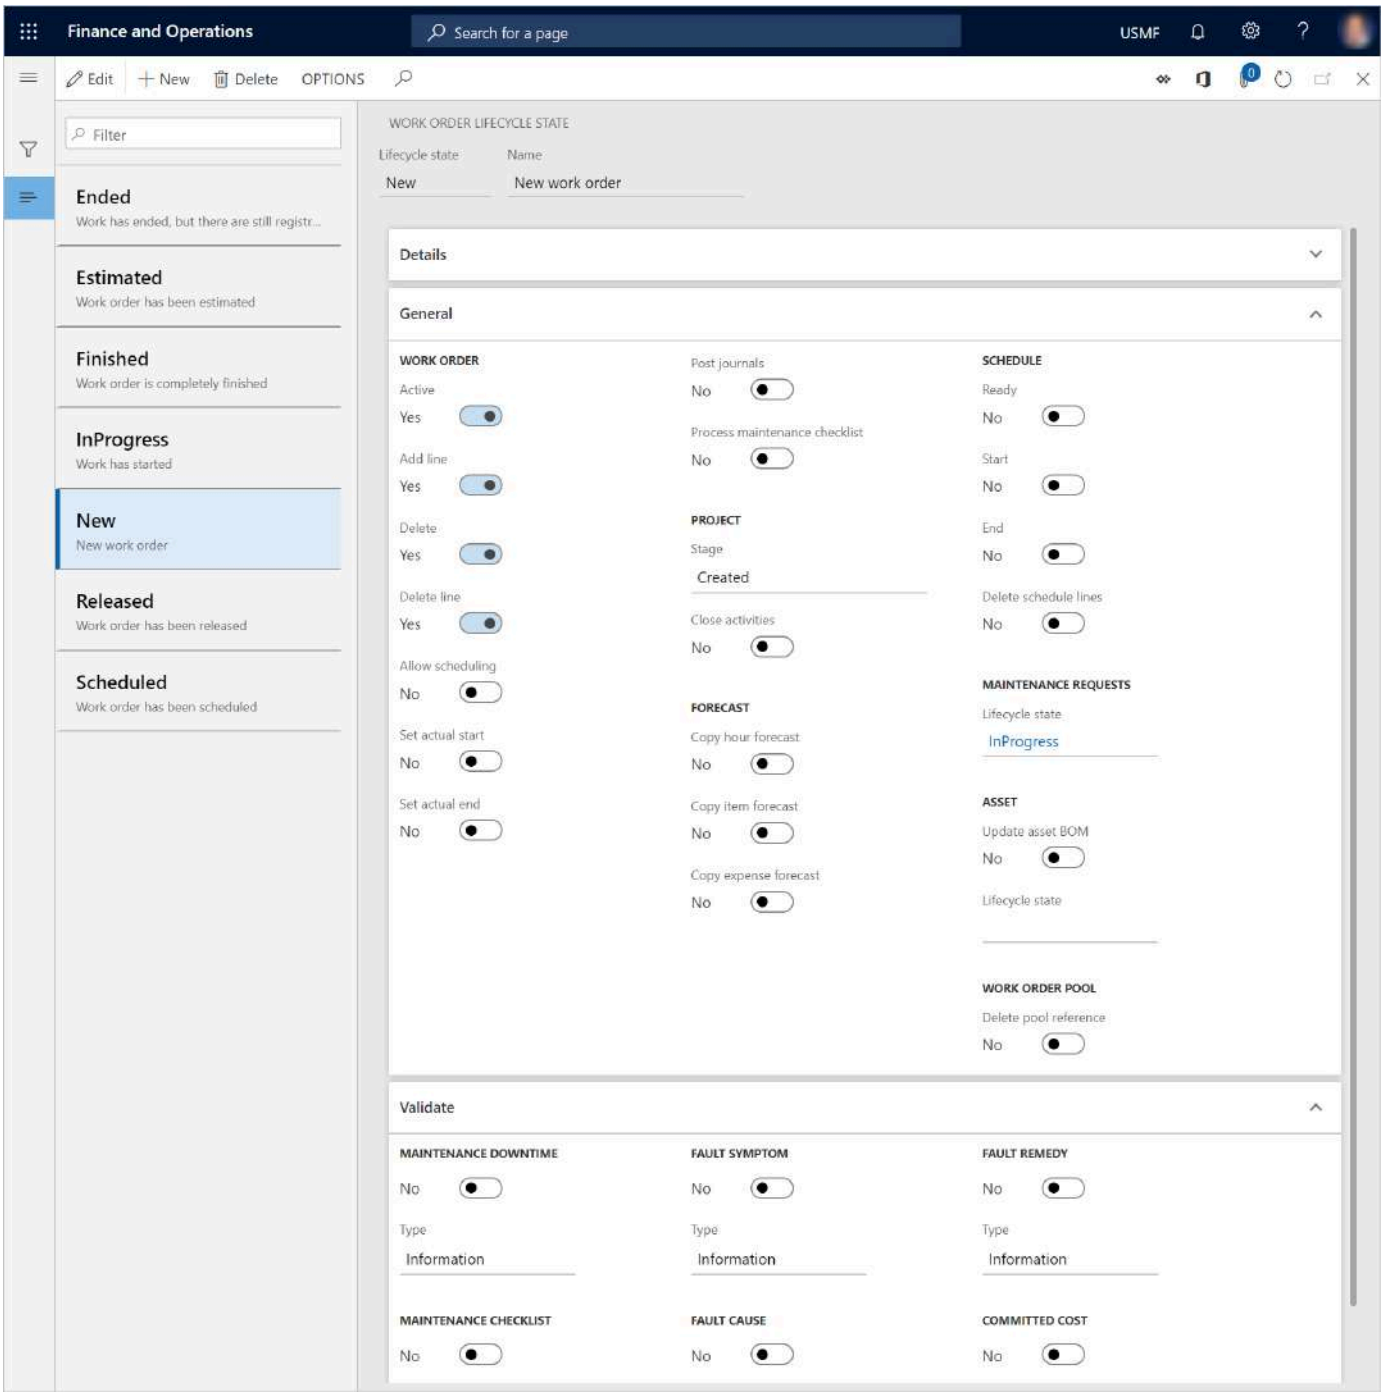
1. Select **Asset management** > **Periodic** > **Forecast** > **Update maintenance job type forecast**.
2. In the **Update maintenance job type forecast** dialog box, on the **Records to include** FastTab, you can add selections for specific maintenance job types as you require. Select **Filter**, and then select **Select** to make the selections.
3. On the **Run in the background** FastTab, you can set up the automatic update as a batch job, as you require.
4. Select **OK** to start the forecast update.

Work order lifecycle states

Work order lifecycle states define the states that a work order can go through. Examples include **Created**, **Scheduled**, **In progress**, and **Ended**. Work order lifecycle states can be manually updated on a work order, or they can be automatically updated (for example, during work order scheduling).

The work order lifecycle states that are required for your work orders must be attached to matching project stages on the **Project management and accounting parameters** page (**Project management and accounting** > **Project management and accounting parameters**). You first set up project stages in Project management and accounting. You then set up work order lifecycle states and work order lifecycle models in Asset Management.

The following table describes the options in the **Work order** and **Schedule** sections on the **General** FastTab of the **Work order lifecycle state** page (**Asset management** > **Setup** > **Work orders** > **Lifecycle states**).



Expand table

Option name	Description
Active	Set this option to *Yes* if the work order should be active while it's in this lifecycle state.
Add line	Set this option to *Yes* if work order jobs can be added to a work order that is in this lifecycle state.
Delete	Set this option to *Yes* if a work order can be deleted while it's in this lifecycle state.
Delete line	Set this option to *Yes* if work order jobs can be deleted from a work order that is in this lifecycle state.
Allow	Set this option to *Yes* if a work order can be scheduled while it's in this lifecycle state.

Option name	Description
scheduling	
Set actual start	Set this option to *Yes* if the user should be prompted to select an actual start date and time for a work order when it's updated to this lifecycle state.
Set actual end	Set this option to *Yes* if the user should be prompted to select an actual end date and time for a work order when it's updated to this lifecycle state.
Post journals	Set this option to *Yes* if work order journals should be automatically posted when a work order is updated to this lifecycle state. If an error occurs during journal posting, a message is shown, and the update of the work order lifecycle state is canceled. To view the journal lines for a work order, select **Asset management** > **Work orders** > **All work orders**, **Active work orders**, or **My active work orders**, select the work order in the list, and then select **Journals**. This setup of automatic work order journal posting at a specific lifecycle state is the same as when you select **Post journals** on the **Work order journals** page. **Note:** If you set this option to *Yes*, journals are automatically posted if no approval workflow has been set up. If your company uses the journal approval setup that is configured on the **Journal approval** page (**Project management and accounting** > **Setup** > **Journals** > **Journal approval**), a manager or clerk must validate and post consumption registrations.
Process maintenance checklist	Set this option to *Yes* if all attached maintenance checklists should be processed when a work order is updated to this lifecycle state. As part of this processing, any counter registrations that were made on a maintenance checklist are posted, and the result of the whole maintenance checklist is evaluated. Maintenance checklist lines that have *Pass* and *Fail* results are evaluated, and if at least one line fails, the whole maintenance checklist is marked as *Failed* in Asset Management.
Ready	Set this option to *Yes* if the work order job schedule status for all work order jobs that are created on a work order should automatically be updated to **Ready** when the work order is updated to this lifecycle state.
Start	Set this option to *Yes* if the work order job schedule status for all work order jobs that are created on a work order should automatically be updated to **Started** when the work order is updated to this lifecycle state.
End	Set this option to *Yes* if the work order job schedule status for all work order jobs that are created on a work order should automatically be updated to **Ended** when the work order is updated to this lifecycle state.
Delete schedule lines	Set this option to *Yes* if scheduling on all work order jobs that are created on a work order that has already been scheduled should be deleted when the work order is updated to this lifecycle state. In other words, capacity reservations on the asset, the related maintenance worker, and related tools will be deleted. For example, you set this option to *Yes* on a work order lifecycle state that is named **Estimated**. Then, when a work order is rolled back to this lifecycle state because rescheduling is required, scheduling can be deleted on that work order.

Set up project stages and work order lifecycle states

1. Select **Project management and accounting** > **Setup** > **Project management and accounting parameters**.

2. On the **Project stage** tab, for each stage that you want to use, select the check box for every project type that is required for your work orders. The project types define rules about the financial tasks that are allowed. Examples of financial tasks include creating a forecast, creating estimates, and creating beginning balances.

   > **Important**
   >
   > If a project stage isn't selected for a project type, but the project stage is used for a work order lifecycle state, the work order projects won't be updated in the appropriate manner.

3. Close the **Project management and accounting parameters** page.

4. Select **Asset management** > **Setup** > **Work orders** > **Lifecycle states**.

5. Select **New** to create a work order lifecycle state.

6. In the **Lifecycle state** field, enter an ID for the lifecycle state.

7. In the **Name** field, enter a name.

   On the **Details** FastTab, the **Lifecycle models** field shows the number of work order lifecycle models that use this lifecycle state.

8. On the **General** FastTab, in the **Work order** section, select the functions that should be available for this lifecycle state by setting the relevant options to *Yes*. For descriptions of the options, see the table earlier in this article.

9. In the **Project** section, in the **Stage** field, select the project stage that should be related to this lifecycle state.

10. In the **Project** section, set the **Close activities** option to *Yes* if project activities that are related to each work order job should be automatically closed when the work order is in this lifecycle state.

    > **Note**

To find the number of the project activity that is related to a work order job, select **Asset management** > **Work orders** > **All work orders**, **Active work orders**, or **My active work orders**. Open the work order, and then select the work order job. The activity number is shown in the **Activity number** field in the **Project** section on the **General** tab of the **Line details** FastTab.

11. In the **Forecast** section, set the **Copy hour forecast**, **Copy item forecast**, and/or **Copy expense forecast** option to *Yes* if work order project forecasts should automatically be copied to work order journals when the work order is in this lifecycle state.

12. In the **Schedule** section, set one of the options to *Yes* if the schedule status for work order jobs should be updated when the work order is in this lifecycle state. For descriptions of the **Ready**, **Start**, **End**, and **Delete schedule lines** options, see the table earlier in this article.

    > ⓘ **Note**
    >
    > To view schedule lines that are related to work order jobs, select **Asset management** > **Work orders** > **All work orders**, **Active work orders**, or **My active work orders**. Open the work order, select the work order job on the **Work order jobs** FastTab, and view related information on the **Line details** FastTab. The **Status** field on the **Schedule** tab shows the status of the work order job. The **Status** field can be set to the following values: *Scheduled*, *Ready*, *Started*, *Stopped*, and *Ended*.

13. In the **Maintenance requests** section, in the **Lifecycle state** field, select the maintenance request lifecycle state that related maintenance requests should be updated to. This update occurs automatically. It can be done only if the maintenance request lifecycle state is selected in the maintenance request lifecycle model that is used for the maintenance request.

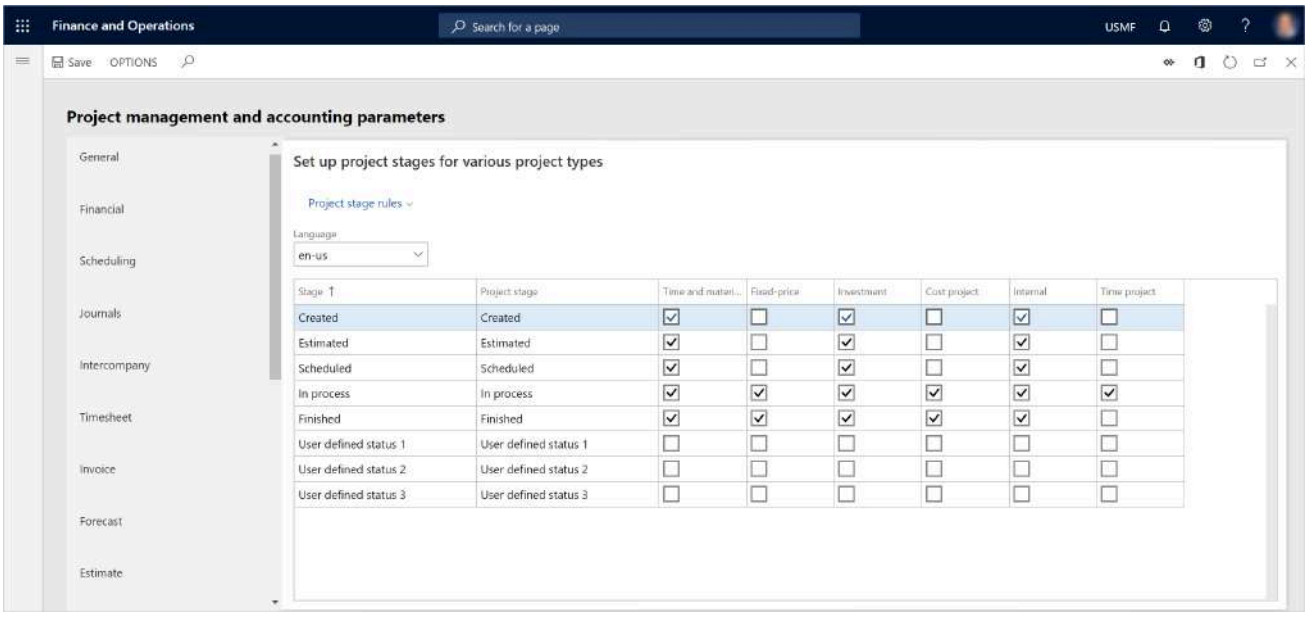
14. In the **Asset** section, set the **Update asset BOM** option to *Yes* if all items that are used on a work order should automatically be updated on the **Asset BOM** page when the work order is updated to this lifecycle state. This setting might be relevant if, for example, the work order lifecycle state defines the work order as completed or ended.

15. In the **Work order pool** section, set the **Delete pool reference** option to *Yes* if work orders that are in this lifecycle state should automatically be deleted from work order pools.

16. On the **Validate** FastTab, select the validation types that should be activated in this lifecycle state by setting the relevant options to *Yes*. Then, in the **Type** field for each validation type

that you select, select the type of message that should be shown if mandatory fields that are related to the validation type haven't been validated. If you select **Error**, the update of the work order lifecycle state is canceled until the related mandatory fields have been updated on the work order.

- The **Maintenance downtime**, **Maintenance checklist**, **Fault symptom**, **Fault cause**, and **Fault remedy** options are related to the options in the **Mandatory** section on the **Work order types** page (**Asset management** > **Setup** > **Work orders** > **Work order types**). To activate these validations, the related options must also be set to *Yes* on the work order type that is used for the work order.
- If the **Maintenance checklist** option is set to *Yes* for the lifecycle state that a work order is updated to, validation is done to verify that maintenance checklist lines that are marked as **Mandatory** have been registered as either **Checked** or **Not applicable**. If neither of those registrations has been made on the mandatory lines, an informational, error, or warning message is shown when the work order is updated to this lifecycle state.
- If the **Committed cost** option is set to *Yes* for the lifecycle state that a work order is updated to, total amount of committed costs (that is, the total amount of expenses that the legal entity has committed to pay) are calculated for each work order job. A message is shown if the committed cost amount is more than 0 (zero). You select the types of cost commitment that are included on the **Cost commitments** FastTab on the **Cost control** tab of the **Project management and accounting parameters** page (**Project management and accounting** > **Setup** > **Project management and accounting parameters**).
- If the **Maintenance downtime** option is set to *Yes* for the lifecycle state that a work order is updated to, maintenance downtime validation is done on the asset that is related to the work order. If a maintenance downtime registration has been made, but there's no **Ended** registration, a message is shown when the work order is updated to this lifecycle state.
- If the standard project setup doesn't include all the stages that you require for your Asset Management setup, you can set up user-defined project stages on the **Project stage** tab of the **Project management and accounting parameters** page. The following illustration shows the **Project stage** tab on the **Project management and accounting parameters** page.



17. On the **Security roles** FastTab, select the security roles that are allowed to change to this lifecycle state. If no roles are selected, then all users that have access to work order lifecycle states are able to change to this lifecycle state.

> **Note**
>
> If the lifecycle state that you update a work order to is inactive, journals that are related to the work order but that haven't yet been posted are automatically deleted. This behavior helps guarantee automatic cleanup of unused data. (A lifecycle state is inactive if the **Active** option for it is set to *No* on the **General** FastTab of the **Work order lifecycle state** page.)
>
> However, if you manually set a work order so that it's inactive, journals that are related to the work order but that haven't yet been posted are *not* automatically deleted. (To manually deactivate a work order, select **Asset management** > **Work orders** > **All work orders** or **Active work orders**. Open the work order, and switch to the **Header** view. On the **General** FastTab, select **Edit**, and then set the **Active** option to *No*.)

Relations among work order lifecycle models, work order types, and work order lifecycle states

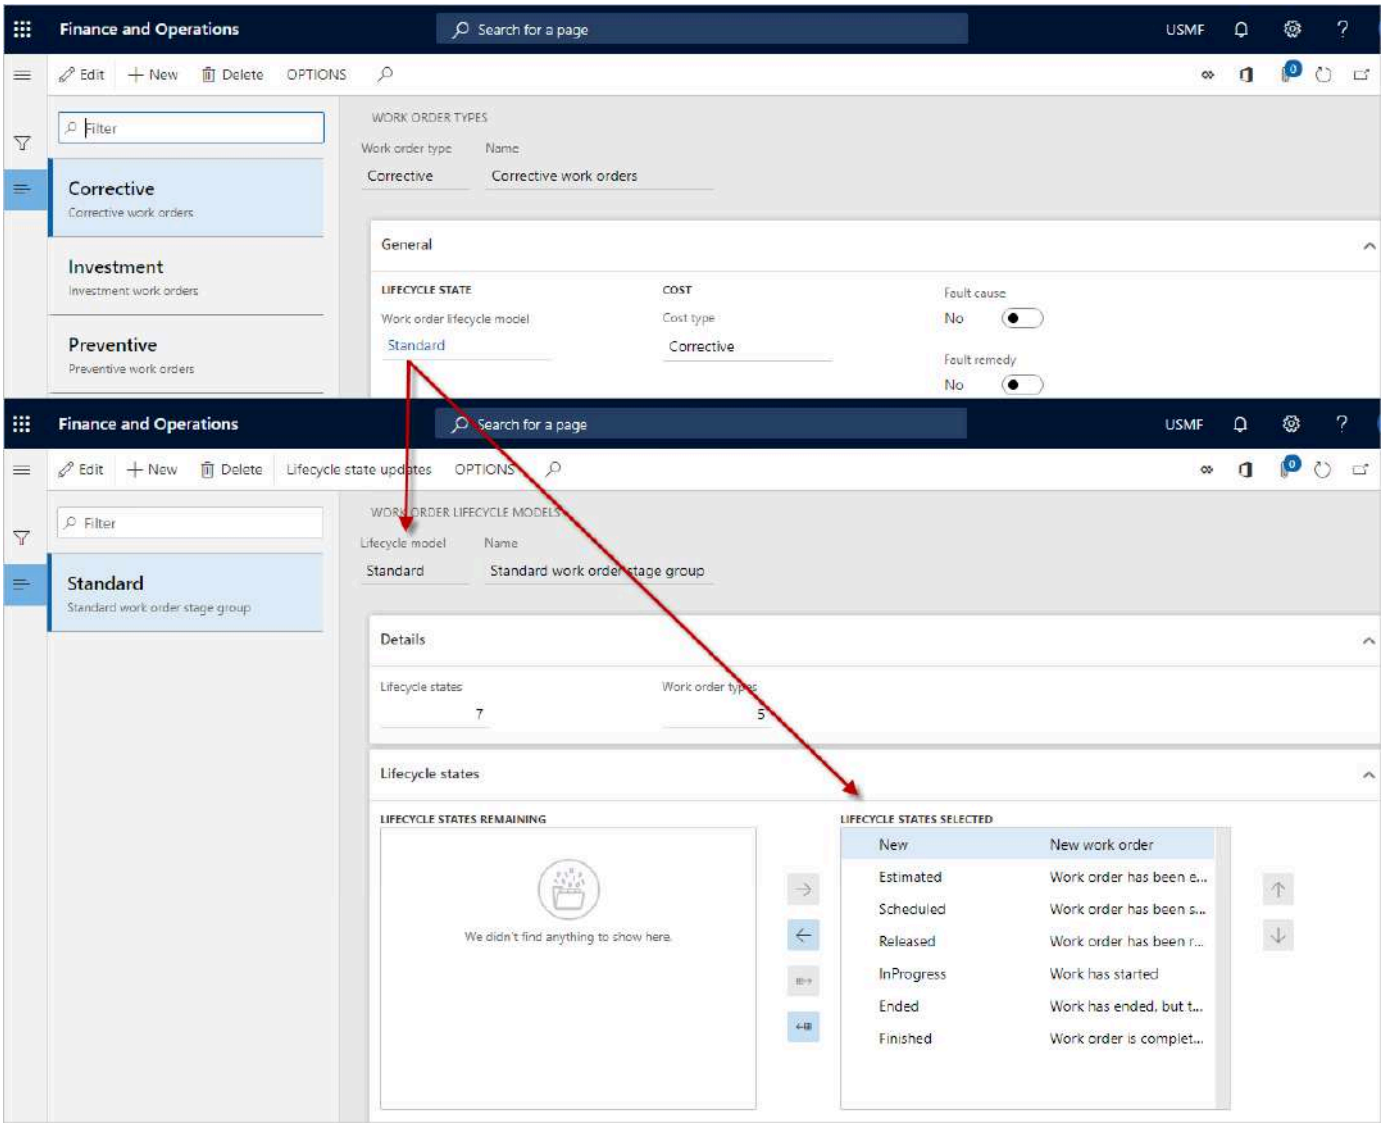
Lifecycle models refer to workflows, and lifecycle states are selected in a lifecycle model in sequential order. Lifecycle models are set up on work order types. Work order types determine the size or extent of workflows and work processes. For example, *Maintenance*, which is a standard work order type, might be related to a work order lifecycle model that has many lifecycle states. By contrast, you might have a *Corrective* work order type that is used for work

orders that haven't been scheduled, or for work orders where the job is completed before the work order is made because of an urgent situation. This work order type might be related to a work order lifecycle model that has only a few lifecycle states.

The reason for using types is that when a type is defined on, for example, a work order or an asset, the related work processes (lifecycle states) are automatically defined. For more information about how to set up work order types, see Work order types.

> **Note**
>
> Lifecycle states, lifecycle models, and types apply to functional locations, assets, and maintenance requests, in addition to work orders.

The following illustration shows the relation between work order types, lifecycle models, and lifecycle states.



Work order lifecycle models

After you've created the work order lifecycle states that are required for your work orders, they can be divided into work order lifecycle models. At a minimum, you should create one standard lifecycle model.

1. Select **Asset management** > **Setup** > **Work orders** > **Lifecycle models**.
2. Select **New** to create a work order lifecycle model.
3. In the **Lifecycle model** field, enter an ID for the lifecycle model.
4. In the **Name** field, enter a name.

   On the **Details** FastTab, the **Lifecycle states** field shows the number of lifecycle states that are selected in this lifecycle model. The **Work order types** field shows the number of work order types that use this lifecycle model.
5. On the **Lifecycle states** FastTab, select the lifecycle states that should be included in the lifecycle model:

   - To include a lifecycle state in the lifecycle model, select it in the **Lifecycle states remaining** section, and then select the right arrow button to move it to the **Lifecycle states selected** section.
   - To include all the available lifecycle states in the lifecycle model, select the **Select all available stages** button . All lifecycle states are moved to the **Lifecycle states selected** section.
   - To remove a lifecycle state from the lifecycle model, select it in the **Lifecycle states selected** section, and then select the left arrow button to move it to the **Lifecycle states remaining** section.
6. Select **Lifecycle state updates** to define the lifecycle states that can follow a selected lifecycle state.
7. On the **Updates** FastTab, in the **Scheduled state** field, select the lifecycle state that should always be selected for a work order that you've completed work order scheduling for, regardless of the previous lifecycle state of the work order.
8. In the **Unscheduled lifecycle state** field, select the lifecycle state that should always be selected for a work order if work order scheduling is deleted.
9. Save the work order lifecycle model.

Work order types

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Work order types are used to categorize work orders. For example, you might have work orders that are related to preventive maintenance or corrective maintenance.

A work order type defines an affiliation with a work order lifecycle model. A work order lifecycle model defines the work order lifecycle states that can be set on a work order. (Examples of work order lifecycle states include **Created**, **In Process**, and **Finished**.)

For more information about work order lifecycle states and project stages, see Work order lifecycle states.

1. Select **Asset management** > **Setup** > **Work orders** > **Work order types**.
2. Select **New** to create a work order type.
3. In the **Work order type** field, enter an ID for the work order type.
4. In the **Name** field, enter a name.
5. In the **Work order lifecycle model** field, select a lifecycle model.
6. Set the **One maintenance worker** option to **Yes** if all work order jobs that are related to a work order of this type should be scheduled to the same maintenance worker.
7. In the **Cost type** field, select **Corrective**, **Preventive**, or **Investment**, as appropriate. All work order jobs on a work order must have the same cost type.
8. In the **Mandatory** section, set the relevant options to **Yes** to specify which fault-related or maintenance downtime–related information is added to a work order of this type.

   > **Note**
   >
   > The options in the **Mandatory** section are related to the options on the **Validate** FastTab of the **Work order lifecycle states** page (**Asset management** > **Setup** > **Work orders** > **Lifecycle states**).

9. Select **Save**.

Work order project setup

06/17/2025

In the **Asset management** module, a project relation is required for every work order job. The project that is associated with a work order job lets you track costs on various projects that are related to Asset Management, such as internal maintenance projects, service management projects, and investment projects.

Project setup for a work order job

When you create a work order job on a work order, the project setup in the **Project management and accounting** module and the work order project setup in the **Asset management** module determine how projects can be used for cost control on the asset that is selected on that work order job. This section describes the following parts of the project setup that is used for a work order: the parent project (project ID), project type, project activities, and financial dimensions:

- When you create a work order job on a work order, a unique project ID and a related project activity are automatically created for it. However, if several work order jobs on a work order include the same asset, the same project ID is used for them. In other words, one project ID is created for every asset on a work order.
  - The parent project (project ID) for a work order job is found in the parent project setup. (For more information about the parent project setup, see the next section.) For example, if you associate a customer or a functional location with a specific parent project, the parent project is used every time that you create work orders for that customer or that functional location. If you don't relate a specific project ID to, for example, a functional location, the next relevant parent project in the work order project setup is used.
  - A project type is required for every project ID. The project type is found in the setup of the project group setup. (For more information about the project group setup, see the next section.) If no match is found in the project group setup, the project group setup on the parent project is used.
  - The setup for requiring project activities on forecasts and journals is copied from the parent project to the work order project. If the **Hour**, **Expense**, and **Item** options are set to *Yes* for the project that is used as a parent project, a project activity is mandatory on forecasts and journals. (To access these options, select **Project management and accounting** > **Projects** > **All Projects**, and then select the project that is used as a parent project. The options are in the **Require activity on journals** section on the **Setup** FastTab.)

- Financial dimensions are copied from the asset and merged with the parent project.

The next section explains how to set up parent projects and project groups. Parent project and parent groups are used to control work orders. They're also used for reporting about work orders.

Set up work order projects

Before you start to create work orders, you must set up work order projects. The **Work order project setup** page (**Asset management** > **Setup** > **Work orders** > **Project setup**) contains two tabs: **Parent project** and **Project group**.

On the **Parent project** tab, you can set up project relations that can be used if no project is set up on the asset that is selected on the work order job. A parent project setup isn't required if your company uses asset projects. It's relevant only if you want to use work order projects instead of asset projects. In that case, you must set up at least one parent project.

On the **Project group** tab, you can set up project groups that can be associated with work order types, asset types, and assets.

Project groups can be used to create specific categories (groups) that are used for cost control. For example, by creating project groups for specific asset types or work order types, you can do detailed tracking of maintenance costs by type.

Project groups aren't mandatory. If you don't set up project groups, the parent project is used to determine the project group, and a child project is created from the parent project's project group.

The setup allows for complete integration with the **Project management and accounting** module. Therefore, you can track the costs that are related to work orders in the related projects. The following procedure describes the setup for work order projects.

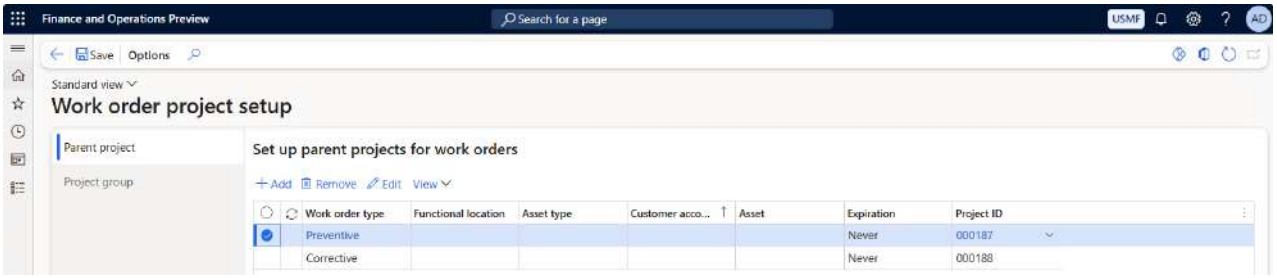
1. Select **Asset management** > **Setup** > **Work orders** > **Project setup**.
2. On the **Parent project** tab, select **Add**.
3. In the **Work order type**, **Functional location**, **Asset type**, and **Asset** fields, select values as you require. For each line that you add, you can set just one field or multiple fields. The number of fields that you set determines the combination that is used when a project ID is selected in Asset Management.

   If you select a functional location, the related child locations are automatically included. If you select an asset, you can create more work order project setup lines for the same asset, but you can select different projects for that asset.

4. In the **Project ID** field, select the project that should be related to the setup that you created in step 3.

5. If the project setup should be valid for only a limited period, select an end date in the **Expiration** field. Otherwise, select *Never*.

   By default, the start date is the date when you add the work order project to the page. It's controlled by the **Effective** field, which is hidden by default. To show the **Effective** field, select **View** > **All**. You can then use the **Effective** field together with the **Expiration** field to set up a limited period of validity for the work order project.



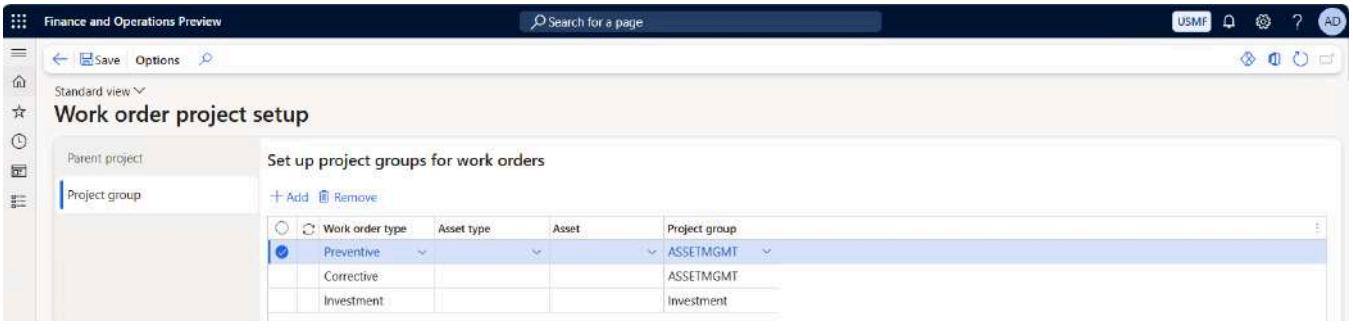
6. On the **Project group** tab, select **Add**.

7. In the **Work order type** field, select a work order type.

8. If you want the project group association to be more specific, select an asset type in the **Asset type** field or an asset in the **Asset** field.

9. In the **Project group** field, select the project group that should be related to the work order type. For example, a work order type that is named *Preventive maintenance* might be associated with a project group that is named *Prev Maint* or *Internal*. Alternatively, an *Investment* work order type that is used for work orders that are related to investments and fixed assets might be associated with a project group that is named *Invest* or *Investment*.

10. Select **Save**.



> **Note**

Every time that a work order line is created, Asset Management searches for a project group that should be related to the work order job project. The search is based on the setup that is described in this article. Every project group has a related project type. Project groups that have the *Time and material* or *Fixed-price* project type are valid only for assets that are related to a customer account.

For parent projects and project groups, when the system selects the available work order project or project group, the selection is based on the records that you created by using the preceding procedure. Asset Management goes through records that are related to the work order project to check for a possible match. It always checks the most specific combination first. In other words, for the work order parent project, Asset Management first checks for a possible match for the **Asset** field. If no match is found, it checks for a match for the **Asset type** field. If no match is found, it checks for a match for the **Functional location** field, and so on. As you can see in the layout of the **Work order project setup** page, this behavior means that, to find the most specific combination, Asset Management checks each record from right to left for a match. If no match is found, the default record where only a project ID is selected is used. The process for finding the related project group is similar. Asset Management first checks for a possible match for the **Asset** field, then the **Asset type** field, and then the **Work order type** field. If no match is found, the default record where only a project group is selected is used.

Service level and description

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you create a work order, you might want to define the service levels for it and add a general description to it. You can create work order service levels on the **Work order service levels** page and descriptions on the **Work order description** page.

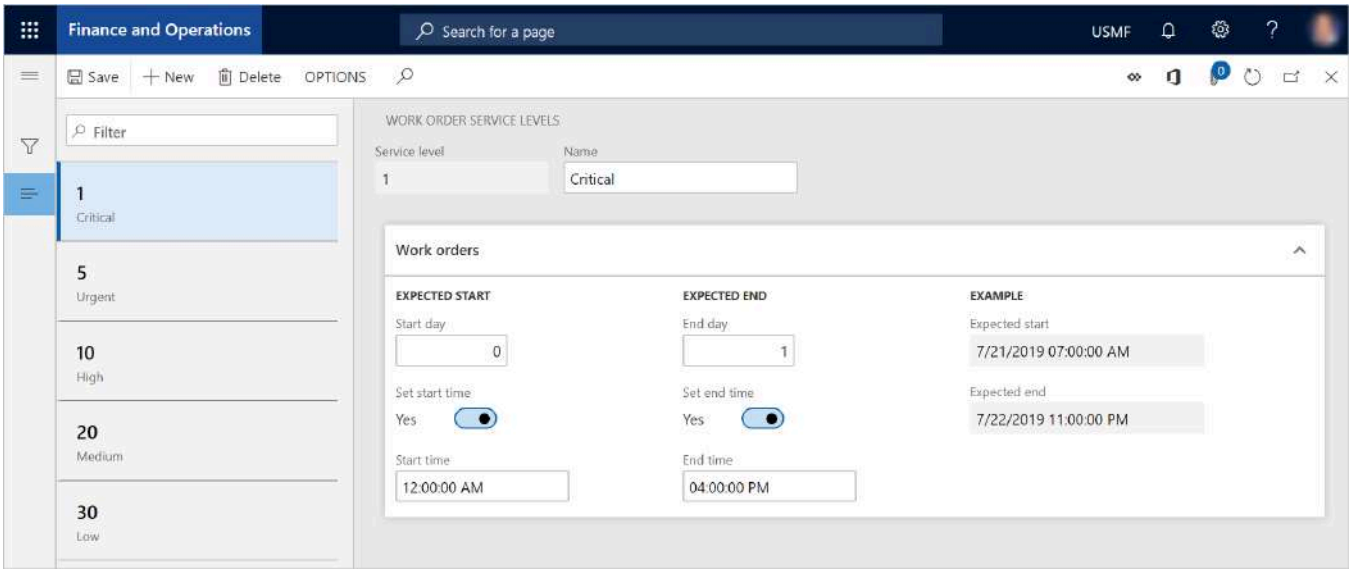
Create a service level

1. Select **Asset management** > **Setup** > **Work orders** > **Service level**.
2. Select **New**.
3. In the **Service level** field, enter the service level (for example, a number).
4. In the **Name** field, enter a name.

   On the **Work orders** FastTab, you can define expected start and end dates and times. The fields on this FastTab define the period that work orders should be started and ended during. They are used for work orders that are manually created and work orders that are created based on maintenance requests.
5. In the **Start day** field, enter a number of days to define the period that the work order should start during. The number of days is calculated from the creation date of the work order. For example, if the work order should start when it's created, enter **0**. If the work order should start within one week after it's created, enter **7**.
6. To set a start time for the work order, in addition to a start date, set the **Set start time** option to **Yes**. Then enter the start time in the **Start time** field. If you set the option to **No**, the current time of day is used.
7. In the **End day** field, enter a number of days to define the period that the work order should end during. The number of days is calculated from the start date of the work order. For example, if the work order should end within one week of its start date, enter **7**.
8. To set an end time for the work order, in addition to an end date, set the **Set end time** option to **Yes**. Then enter the end time in the **End time** field. If you set the option to **No**,

the current time of day is used.

9. Select **Save**.



Create a description

1. Select **Asset management** > **Setup** > **Work orders** > **Descriptions**.
2. Select **New**.
3. In the **Description** field, enter the description.
4. Select **Save**.

Scheduled execution

Article • 06/03/2022

You can use work order service levels to set up scheduled execution. (For more information about work order service levels, see Service level and description.) Scheduled execution provides flexibility in work planning for maintenance workers, because you can set up more detailed or less detailed requirements for the interval that a work order should be completed during. For example, a maintenance worker who completes a job faster than expected in a production facility might be able to move on to another nearby job that was planned for the current week but not necessarily for the current day. This approach allows for optimization of worker planning and job completion.

Scheduled execution setup, which is related to work orders, can be generic or specific. You can set up generic lines that aren't limited to specific work order types, asset types, and so on. Alternatively, you can create scheduled execution lines that apply to a specific work order type, asset type, maintenance job type, and so on.

1. Select **Asset management** > **Setup** > **Work orders** > **Scheduled execution**.
2. Select **New** to create a scheduled execution line.
3. In the **Functional location**, **Work order type**, **Asset type**, **Manufacturer**, **Model**, **Maintenance job type category**, **Maintenance job type**, **Maintenance job type variant**, and **Trade** fields, select values as you require.
4. In the **Service level** field, select a work order service level. If you leave this field blank, you make the most generic type of scheduled execution line. For an example of a generic line, see the first record in the illustration that follows. That line enables all work orders that have no work order service level to be scheduled for a specific date and time.
5. In the **Scheduled execution** field, select the time interval.
6. Select **Save**.

Fault management

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

In Asset Management, you can use the fault designer to set up fault symptoms, fault areas, and fault types on asset types. In this way, you can manage faults that are detected on assets. Additionally, fault causes and suggestions for fixing faults can be registered on a work order.

The process for fault registration and management consists of these steps.

1. Create a list of fault symptoms, fault areas, and fault types that might occur on your asset types.
2. In the fault designer, set up symptoms, fault areas, and fault types.

Here are some examples to help you understand the difference between fault symptoms, fault areas, and fault types.

Fault symptoms:

- Unbalanced voltages
- Short circuit
- Noise
- Leak
- Vibrations

Fault areas:

- Electrical
- Mechanical
- Hydraulic
- Pneumatic

Fault types:

- Faulty main stator winding
- Faulty diode
- Dirty windings
- Defective generator

- Defective sensor

Create fault symptoms

Follow these steps to create a list of symptoms that can be used in the fault designer.

1. Select **Asset management** > **Setup** > **Fault** > **Fault symptoms**.
2. Select **New** to create a record.
3. In the **Fault symptom** field, enter a name for the fault symptom.
4. In the **Description** field, enter a description.
5. Select **Save**.

Create fault areas

Follow these steps to create a list of areas or locations that can be used in the fault designer.

1. Select **Asset management** > **Setup** > **Fault** > **Fault areas**.
2. Select **New** to create a record.
3. In the **Fault area** field, enter a name for the fault area.
4. In the **Description** field, enter a description.
5. Select **Save**.

Create fault types

Follow these steps to create a list of fault types that can be used in the fault designer.

1. Select **Asset management** > **Setup** > **Fault** > **Fault types**.
2. Select **New** to create a record.
3. In the **Fault type** field, enter a name for the fault type.
4. In the **Description** field, enter a description.
5. Select **Save**.

Set up the fault designer

In the fault designer, you set up fault data on asset types.

1. Select **Asset management** > **Setup** > **Fault** > **Fault designer**.

2. In the left pane, select the type of asset to set up a fault record for.

3. On the **Fault symptom** FastTab, select **Add line**, and then, in the **Fault symptom** field, select a fault symptom.

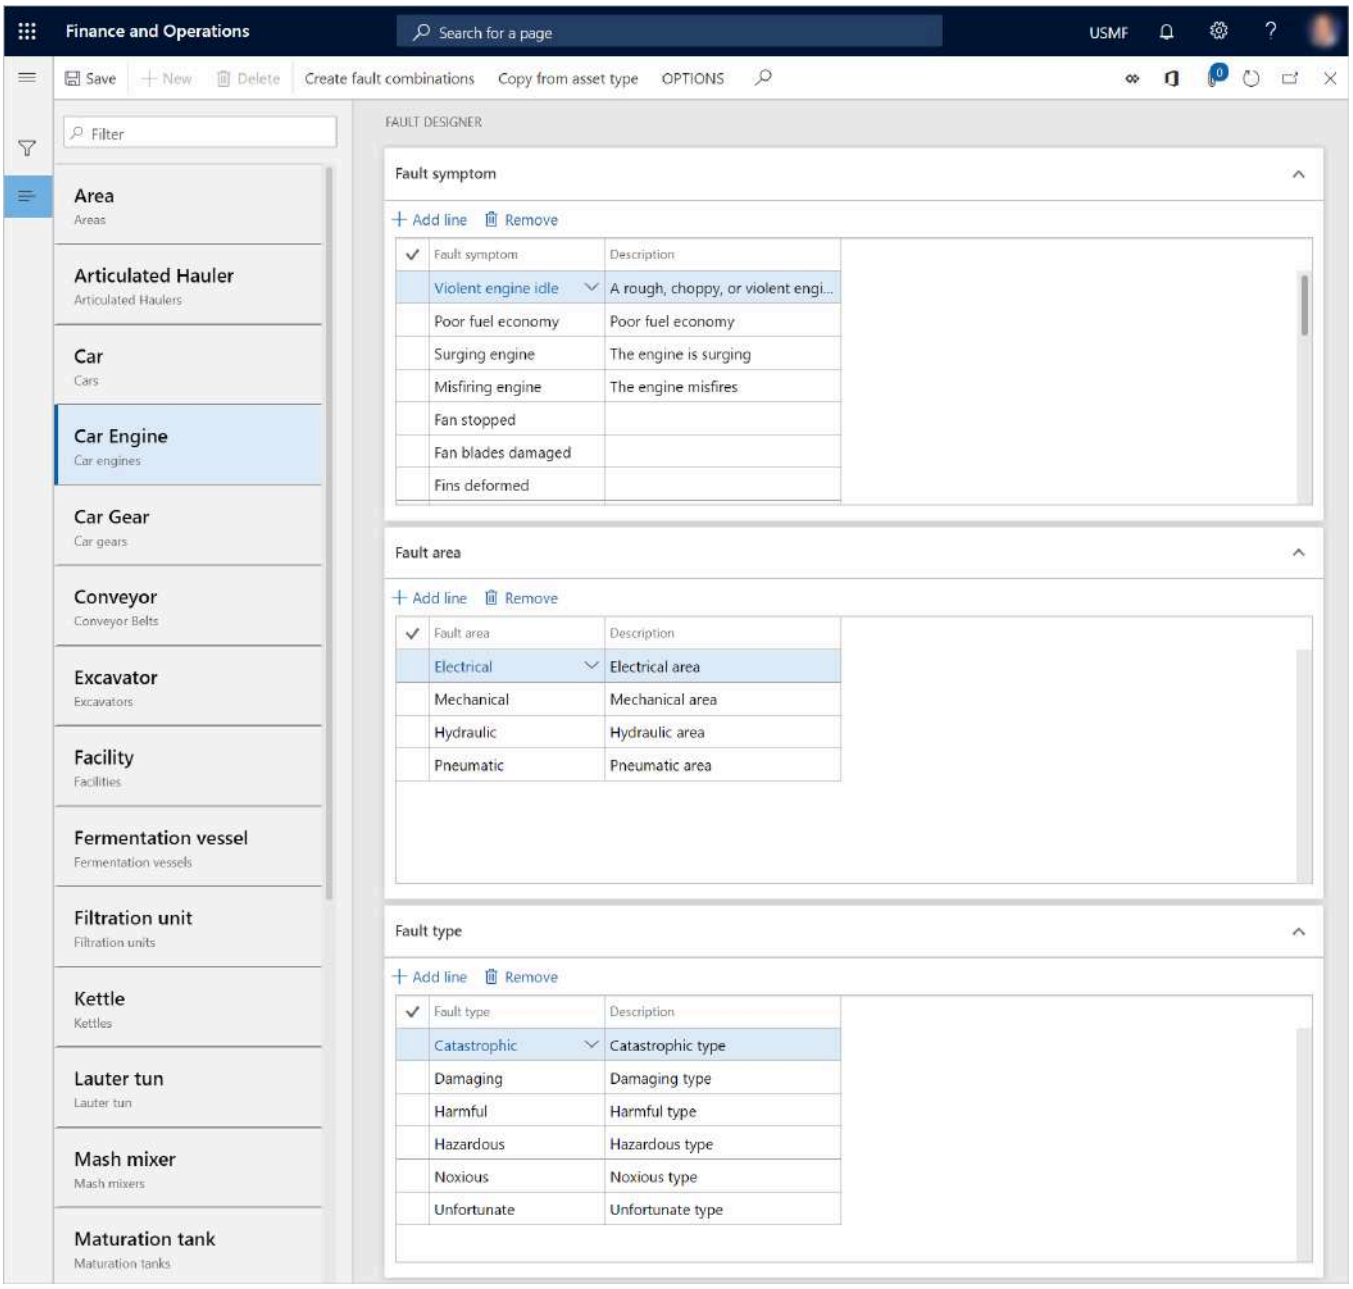
4. On the **Fault area** FastTab, select **Add line**, and then, in the **Fault area** field select a fault area.

5. On the **Fault type** FastTab, select **Add line**, and then, in the **Fault type** field, select a fault type.

6. To quickly create combinations of all existing fault symptoms, areas, and types for the selected asset type, select **Create fault combinations**. This function is useful if you've added many fault symptoms, areas, and types. It's easier to delete the lines for any combinations that aren't relevant to the asset type than to create new lines manually.

   > ⓘ **Note**
   >
   > To copy the setup of fault symptoms, areas, and types from one asset type to the selected asset type, select **Copy from asset type**.

7. Select **Save** to save your changes.



Create fault causes

Follow these steps to create a list of known fault causes that can be added to a work order or a maintenance request.

1. Select **Asset management** > **Setup** > **Fault** > **Fault causes**.
2. Select **New** to create a record.
3. In the **Fault cause** field, enter a name for the fault cause.
4. In the **Description** field, enter a description.
5. Select **Save**.

Create fault remedies

Follow these steps to create a list of suggestions for remedy and repair that can be added to a work order or a maintenance request.

1. Select **Asset management** > **Setup** > **Fault** > **Fault remedies**.
2. Select **New** to create a record.
3. In the **Fault remedy** field, enter a name for the fault remedy.
4. In the **Description** field, enter a description.
5. Select **Save**.

> **Note**
>
> You can change the names of your fault symptoms, areas, types, causes, and remedies as you require. The name changes are automatically reflected in the related fault registrations.

Introduction to work orders

Work orders are used to manage maintenance jobs, provide required information for them, and register consumption on them. Each work order can contain one or more work order jobs, and one or more assets can be connected to each work order. Each work order job defines a maintenance job that is scheduled on the asset.

Work orders can be created in the following ways:

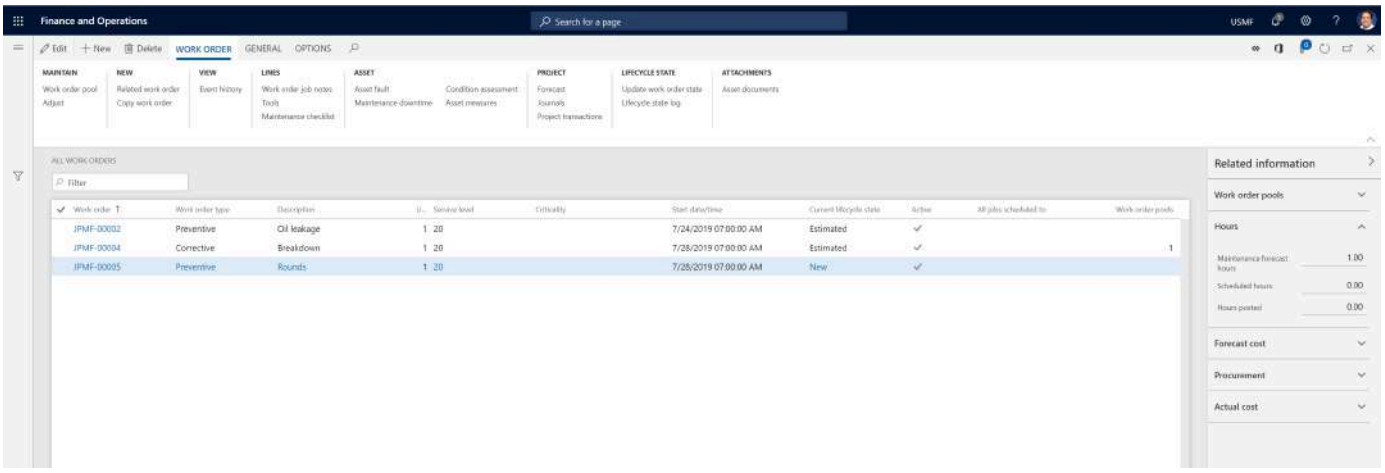
- For calendar-based maintenance plans where the "Auto create" setting is turned on, automatically by using Schedule maintenance plans.
- For maintenance rounds where the "Auto create" setting is turned on, automatically by using Schedule maintenance rounds.
- For preventive maintenance jobs or maintenance requests, from Maintenance schedule.
- Manually
- From the **All maintenance requests**, **Active maintenance requests**, or **My functional location maintenance requests** page.

> **Note**
>
> Work order jobs that are related to the same asset are related to the same project ID.

All work orders

Select **Asset management** > **Work orders** > **All work orders** to open the **All work orders** list page. This page shows all work orders and some of the information that is related to each.

The illustration below shows an example of the **All work orders** list page.



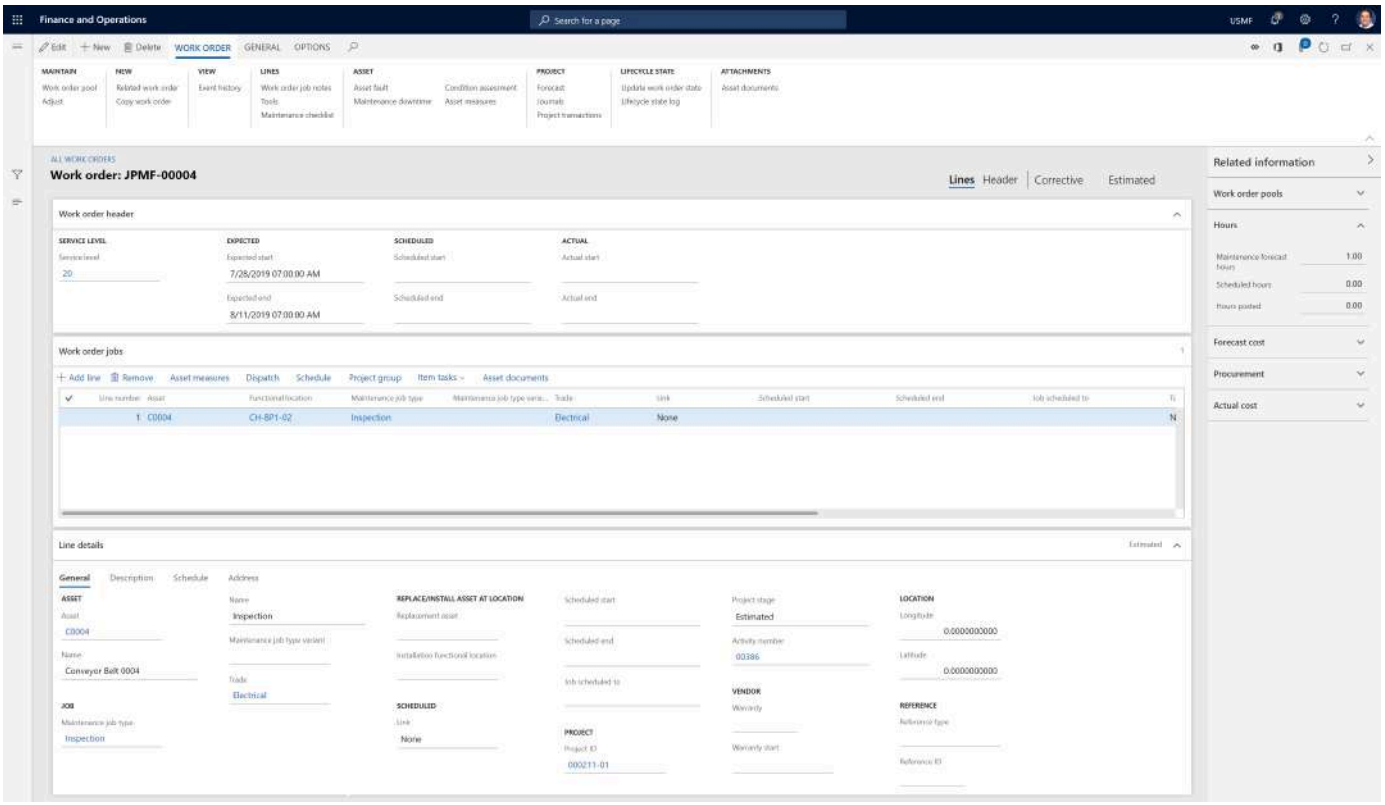
To view a list of only active work orders, select **Asset management** > **Work orders** > **Active work orders**.

To view a list of work order jobs that contain assets that are installed on functional locations that you're related to as a worker, select **Asset management** > **Work orders** > **My functional location work order maintenance jobs**. (The relation between workers and functional locations is set up on the **Workers** page. Learn more in Maintenance workers and worker groups.)

Here are some ways that you can use the **All work orders** page:

- In the grid view, select a link in the **Work order** column to show the details view for the selected record. You can then select **Edit** to open the record for editing.
- In the details view, you view detailed information that is related to the work order.
- In the details view, select the **Lines** tab to view details of the work order job, or select the **Header** tab to view details of the work order.
- Expand the **Related information** pane on the right side of the page to view additional information that is related to the selected work order.

The illustration below shows an example of the **All work orders** details view.



The buttons on the Action Pane are organized on tabs. The following table briefly describes the buttons that are related to Asset Management:

Expand table

Button name	Description
Edit	Edit the selected work order.
New	Create new work order.
Delete	Delete the selected work order.
Work order pool	Add the selected work order to a work order pool, or remove it from work order pool.
Adjust	Adjust information about expected start and end, service level, responsible maintenance worker, or responsible maintenance worker group on selected work orders.
Related work order	Create a new work order related to the selected work order job. This is useful if you want to register primary and secondary work orders.
Copy work order	Create a new work order that is based on an existing work order.
Event history	View the registration history for the work order.
Work order maintenance job notes	Create a description on a work order, or insert notes or remarks about it. First, select **Add timestamp** to add your user name and a timestamp to the note. Notes are shown on the **Description** tab on the **Line details** FastTab of the **Work order** page.

Button name	Description
Tools	Create a list of required tools on a work order. Tools are set up as resources in **Organization administration** > **Resources** > **Resources**.
Maintenance checklist	View the checklist for the asset that is connected to the work order.
Asset fault	View or register fault information on an asset. This information is used for fault management.
Maintenance downtime	Specify maintenance downtime for a work order.
Condition assessment	Register condition assessment measurements on a work order.
Asset counters	Create or view counter registrations on the asset.
Forecast	View or create forecasts on a work order.
Journals	View or create work order journals. Journal lines can be copied from forecasts.
Project transactions	View all posted transactions that are related to work orders created for the asset.
Update Work order state	Update the work order lifecycle state. You can add remarks, which are visible in the lifecycle state log. Remarks require Supply Chain Management version 10.0.46 or higher with *Remarks can be associated with each change in lifecycle states* enabled in Feature management (As of Supply Chain Management version 10.0.49, this feature is turned on by default).
Lifecycle state log	View a log that shows the lifecycle states of the selected work order. The log includes any remarks that were added by users during manual lifecycle changes. Remarks require Supply Chain Management version 10.0.46 or higher with *Remarks can be associated with each change in lifecycle states* enabled in Feature management (As of Supply Chain Management version 10.0.49, this feature is turned on by default).
Asset documents	View the list of documents attached to assets that are related to a work order. These documents are set up in **Asset management** > **Setup** > **Asset documents**.
Schedule	Schedule the selected work orders.
Dispatch	Schedule the selected work order for one worker.
Delete schedule	Delete the scheduling for the selected work order.
Scheduled work order maintenance	Open the **Scheduled work order maintenance jobs** list page.

Button name	Description
jobs	
Work order purchase requisition	Open the **Work order purchase requisition** list page.
Work order purchase	Open the **Work order purchase** list page.
Cost control	Compare budget costs and actual costs on the work order.
Hour control	Compare forecasted hours and actual hours on the work order.
Work order report	Print a work order report.
Work order consumption	Print a consumption report.

The buttons in the **Project** group on the **Work order** tab of the Action Pane are related to the functionality for forecasts, journals, and invoicing in the **Project management and accounting** module.

> **Note**
>
> To include forecasts that have been created on a work order when you run master scheduling, use the forecast model that is selected on the **Asset management parameters** page.

Last updated on 07/27/2026

Manually created work orders

08/13/2025

You can create work orders manually in two places:

- On the **All work orders** or **Active work orders** page.
- On the **All maintenance requests** or **Active maintenance requests** or **My functional location maintenance requests** page.

Create work order

1. Go to **Asset management** > **Work orders** > **All work orders** or **Active work orders**.
2. Select **New**.
3. In the **Create work order** dialog, select a work order type in the **Work order type** field.
4. If necessary, select a **Description**.
5. In the **Asset** field, select the asset.

   > ⓘ Note
   >
   > When you select an asset, three tabs might be available in the **Asset** drop-down:
   >
   > - **Active assets** – This tab contains a list of all assets that have an "Active" asset lifecycle state.
   > - **Asset view** – This tab displays a tree view of functional locations and the assets installed on them.
   > - **My assets** – This tab contains assets that are related to the functional locations that you (the worker who is signed in to the system) might be allocated to. (For information about the setup, see Maintenance workers and worker groups.) If no functional locations are set up on a worker in Maintenance workers and worker groups, the **My assets** tab isn't available.

6. In the **Maintenance job type** field, select a maintenance job type for the work order.
7. If necessary, select **Maintenance job type variant** and **Trade**.
8. If necessary, you can change the work order service level in the **Service level** field.
9. Select **Expected start** and **Expected end** dates in the related fields.

10. Select **OK** to create the work order.

11. On the **All work orders** list page, you can edit the work order as you require.

Note the following points:

- In the details view on the **All work orders** list page, you can add several assets to a work order by adding lines on the **Work order maintenance jobs** FastTab. On an asset, you can select only the maintenance job types that are defined on the asset type that is selected on the asset.
- If you change an asset service level or an asset criticality after you've used the asset on a work order, the service level or criticality on the work order isn't updated accordingly. For more information about service levels and criticalities, see Asset service levels and Asset criticality types.
- Criticality on a work order is recalculated every time a work order job is added to or deleted from the work order.
- In the **All work orders** details view > **Header** tab > **Schedule** FastTab, in the **Responsible group** or **Responsible** field, you can select a responsible maintenance worker group or a responsible maintenance worker. These settings can be changed while the work order is active. For example, they can be changed when the work order lifecycle state changes. The automatic selection that is made during work order creation is based on the setup on the **Responsible maintenance workers** page. If you add or remove work order jobs after you've created a work order, and if the **Responsible group** and **Responsible** fields are blank when you update the work order, Asset Management tries to find a responsible maintenance worker group or a responsible maintenance worker for a possible match on the setup page. If the **Responsible group** or **Responsible** field is already set when you update the work order, no changes are made. For more information about responsible maintenance workers and worker groups, see Responsible maintenance workers.
- From the Maintenance status page, you can do a calculation to get an overview of the workload for incoming and completed work orders.
- In the details view of the **All work orders** page, on the **Line details** FastTab, you can use the **Latitude** and **Longitude** fields to add geographic coordinates for the asset that is selected on the work order job.

Create related work order

You can create a work order that is related to an existing work order. This capability is useful if, for example, you want to work with primary and secondary work orders. A new work order is based on a work order job from an existing work order.

1. Select **Asset management** > **Work orders** > **All work orders** or **Active work orders**.

2. Select the work order to create a related work order for.

3. On the Action Pane, on the **Work order** tab, in the **New** group, select **Related work order**.

4. In the **Create related work order** dialog, in the **Work order job** field, select the work order job to create a related work order for.

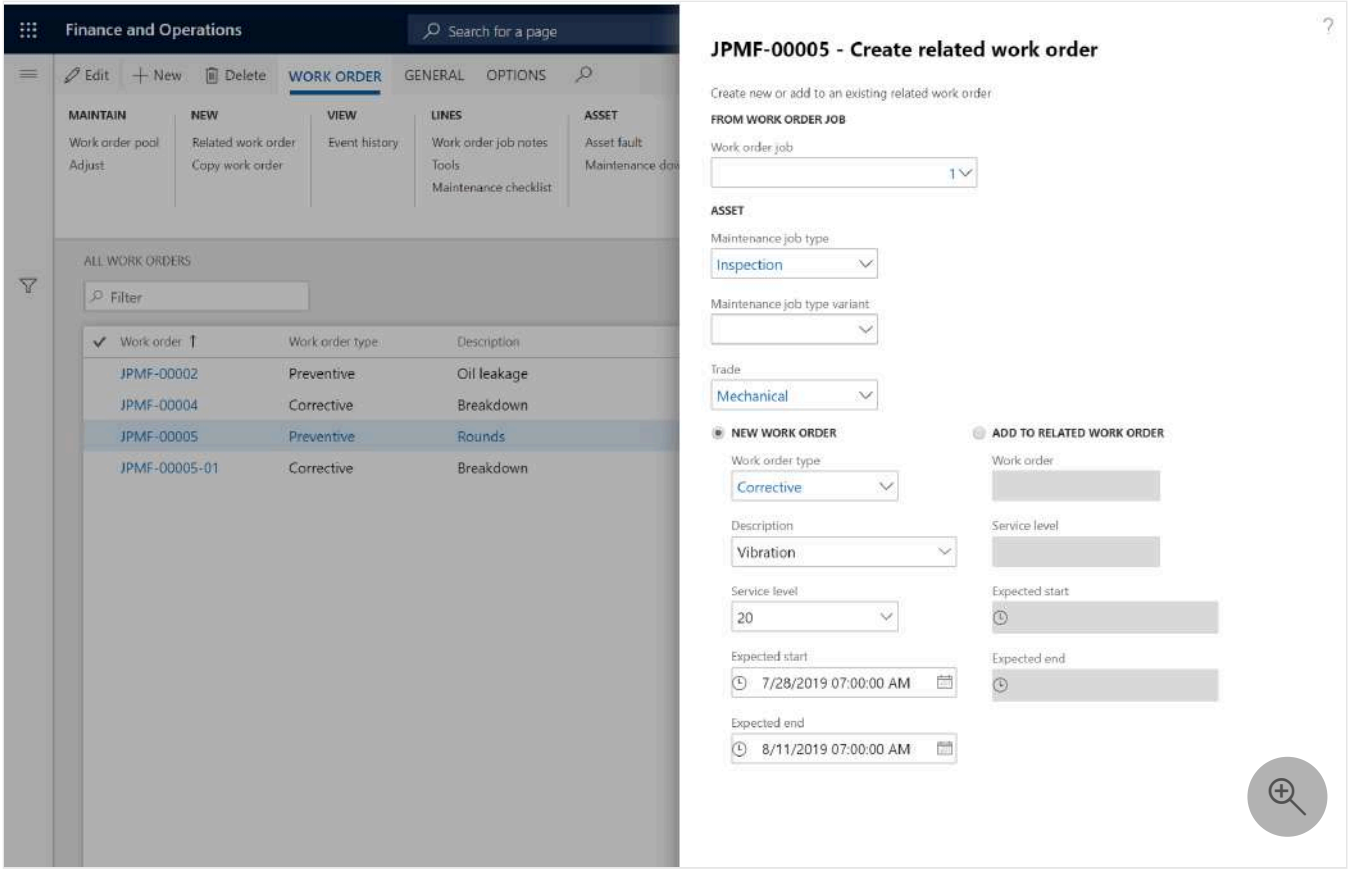
5. Select a maintenance job type in the **Maintenance job type** field.

6. Select a related maintenance job type variant and trade in the **Maintenance job type variant** and **Trade** fields, as you require.

7. If this work order is the first related work order that has been created for the selected work order, follow these steps:
   a. Select the **New work order** option.
   b. In the **Work order type** field, select a work order type.
   c. In the **Description**, enter a description.
   d. In the **Service level** field, change the work order service level as you require.
   e. In the **Expected start** and **Expected end** fields, select the expected start and end dates.
   f. Select **OK**. The new related work order is shown on the **All work orders** list page.

8. If the work order that you're creating this related work order for already has related work orders, follow these steps to add a new work order job to an existing related work order:
   a. Select the **Add to related work order** option.
   b. In the **Work order** field, select the related work order to add a new work order job to.
   c. In the **Service level** field, change the work order service level as you require.
   d. In the **Expected start** and **Expected end** fields, change the expected start and end dates as you require.
   e. Select **OK**. The work order job is added to the existing related work order.

The following illustration shows an example of the **Create related work order** dialog.



> **Note**
>
> If you've set up a related work order mask in **Asset management parameters** > **Work orders** tab > **Related work order mask** field, work order IDs are created according to the mask setup. If no related work order mask is set up, the next available work order ID is used for related work orders.

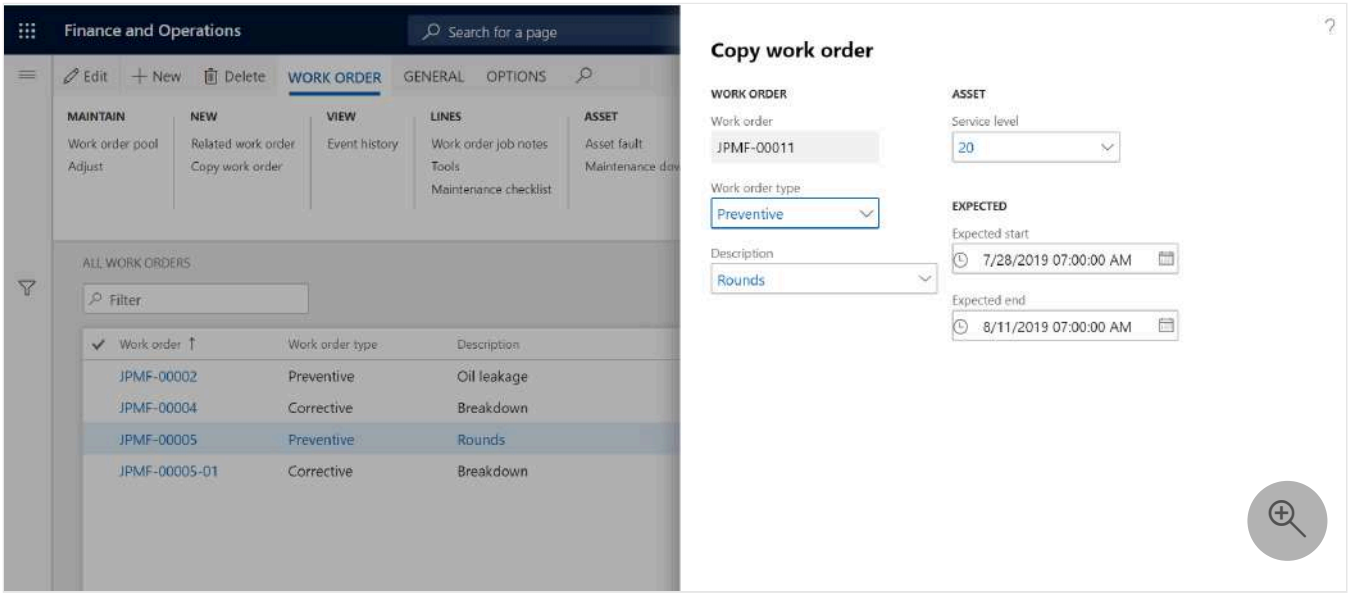
Copy a work order

You can quickly create a new work order from an existing work order. This way of working with work orders differs from the creation of work orders based on maintenance plans. It's useful if, for example, a work order contains many work order jobs, and the various jobs should be completed on different assets at regular intervals.

1. Select **Asset management** > **Work orders** > **All work orders** or **Active work orders**.
2. Select the work order to copy content from.
3. On the Action Pane, open the **Work order** tab and, from the **New** group, select **Copy work order**.
4. The work order setup from the selected work order is shown. You can edit some of the fields as you require.
5. Select **OK** to create the new work order.
6. On the **All work orders** list page, you can edit the work order as you require.

> **Note**
>
> When the new work order is created, some information is copied directly from the existing work order. Information about forecasts, tools, maintenance checklists, functional location, addresses, and scheduling isn't copied. Instead, it's initialized from the current setup in Asset Management. Therefore, if that information was changed between the time when the first work order was created and the time when you made a copy of the work order, the changes are included in the new work order. Examples include changes to forecasts and updates to maintenance checklists.

The following illustration shows an example of the **Copy work order** dialog.

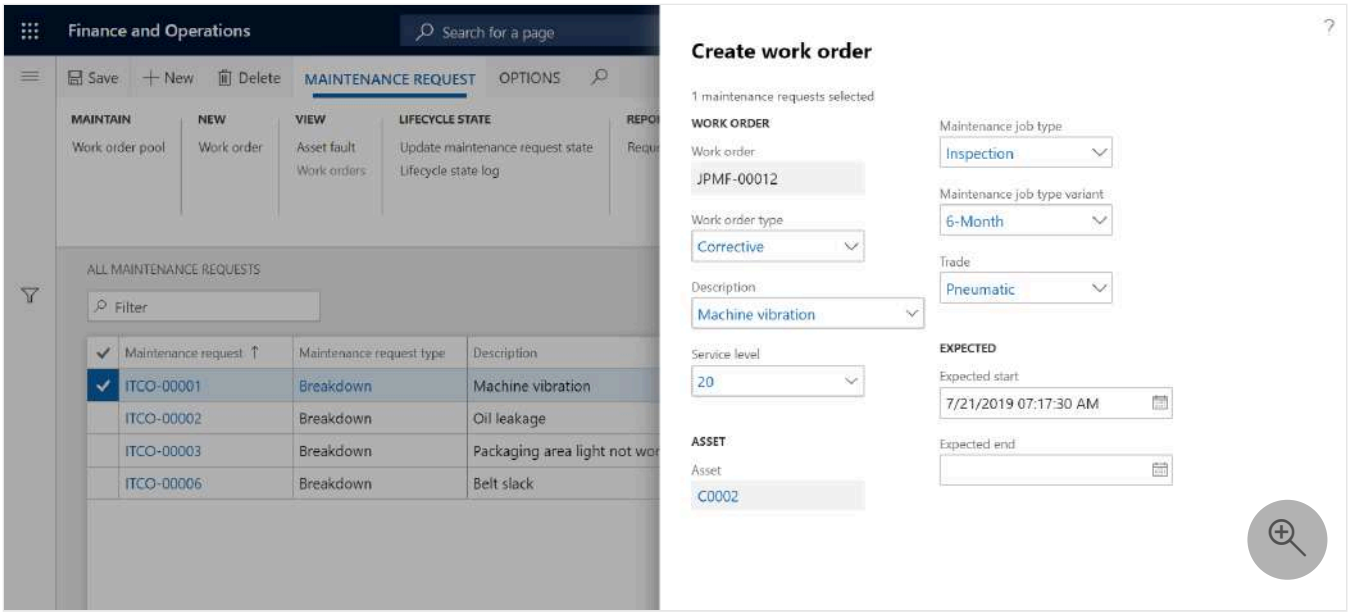


Create a work order based on a maintenance request

1. Select **Asset management** > **Maintenance requests** > **All maintenance requests** or **Active maintenance requests**.
2. Select the maintenance request to create a work order for, and select **Edit**.
3. On the Action Pane, open the **Maintenance request** tab and, from the **New** group, select **Work order**.
4. In the **Work order** dialog, set the fields. If a maintenance job type has been selected in the maintenance request, you can select a different maintenance job type when you create the work order, as you require.
5. Select **OK**. A message notifies you that the work order has been created.
6. To view the work orders that are connected to a maintenance request, on the **All maintenance requests** or **Active maintenance requests** list page, select the maintenance

request. Then, on the Action Pane, on the **Maintenance request** tab, in the **View** group, select **Work orders**.

The following illustration shows an example of the **Create work order** dialog.



> **Note**
>
> If you want work orders to be created automatically, you can schedule maintenance plan jobs, or you can set up "Auto create" maintenance plans or maintenance rounds on an asset. Work orders that are created from maintenance requests on the **All maintenance schedule** list page have the maintenance job types that are selected on the maintenance requests.

Maintenance forecasts

Article • 01/29/2025

When you create a work order, you create work order jobs that have related assets and maintenance job types. When you select a maintenance job type that contains maintenance forecasts, the forecasts are automatically copied to the work order.

You might be able to add forecast lines to a work order or delete them from a work order. The setup of the work order lifecycle state, the related project type, and the stage rules that are related to the project type determine whether you can add or edit forecast lines. For more information about work order lifecycle states and related project stages, see Forecasts, work orders, and projects.

1. Go to **Asset management** > **Work orders** > **All work orders** or **Active work orders**.
2. Select the work order in the list, and then, on the Action Pane, on the **Work order** tab, in the **Project** group, select **Forecast**. The **Work order maintenance forecast** page shows forecast lines from the maintenance job type that is selected on the work order job.

Add an hours forecast to a work order

1. On the **Work order maintenance forecast** page, select the work order job to add a forecast to.
2. On the **Hours** FastTab, select **Add** to create a new line.
3. In the **Category** field, select a category.
4. In the **Hours** field, enter the number of forecasted hours.
5. In the **Line property** field, select the type of charge that should be used on the line.

Add an items forecast to a work order

There are three ways to add items to a work order maintenance forecast. You can create lines for items (spare parts) that aren't included on the spare parts list or the asset bill of materials (BOM), you can select spare parts from the approved spare parts list, or you can select items from the asset BOM.

- On the **Work order maintenance forecast** page, select the work order job to add a forecast to.
- On the **Items** FastTab, add items to the maintenance forecast by using the appropriate method.

To create a line for a spare part that isn't on the spare parts list or the asset BOM, follow these steps:

1. Select **Add**.
2. In the **Item number** field, select the item.
3. In the **Sales quantity** field, enter the quantity.
4. In the **Unit** field, select the unit of measure for the quantity.
5. In the **Cost price** and **Currency** fields, enter appropriate values.
6. In the **Line property** field, select a line property.
7. To change the list of dimensions that is shown on the item lines, select **Inventory** > **Display dimensions**, select the dimensions, and then set the **Save setup** option to *Yes*.

To add a spare part from an approved spare parts list, follow these steps:

1. Select **Add spare parts**.
2. Select the spare part, and edit the related information as you require.
3. Select **OK**.

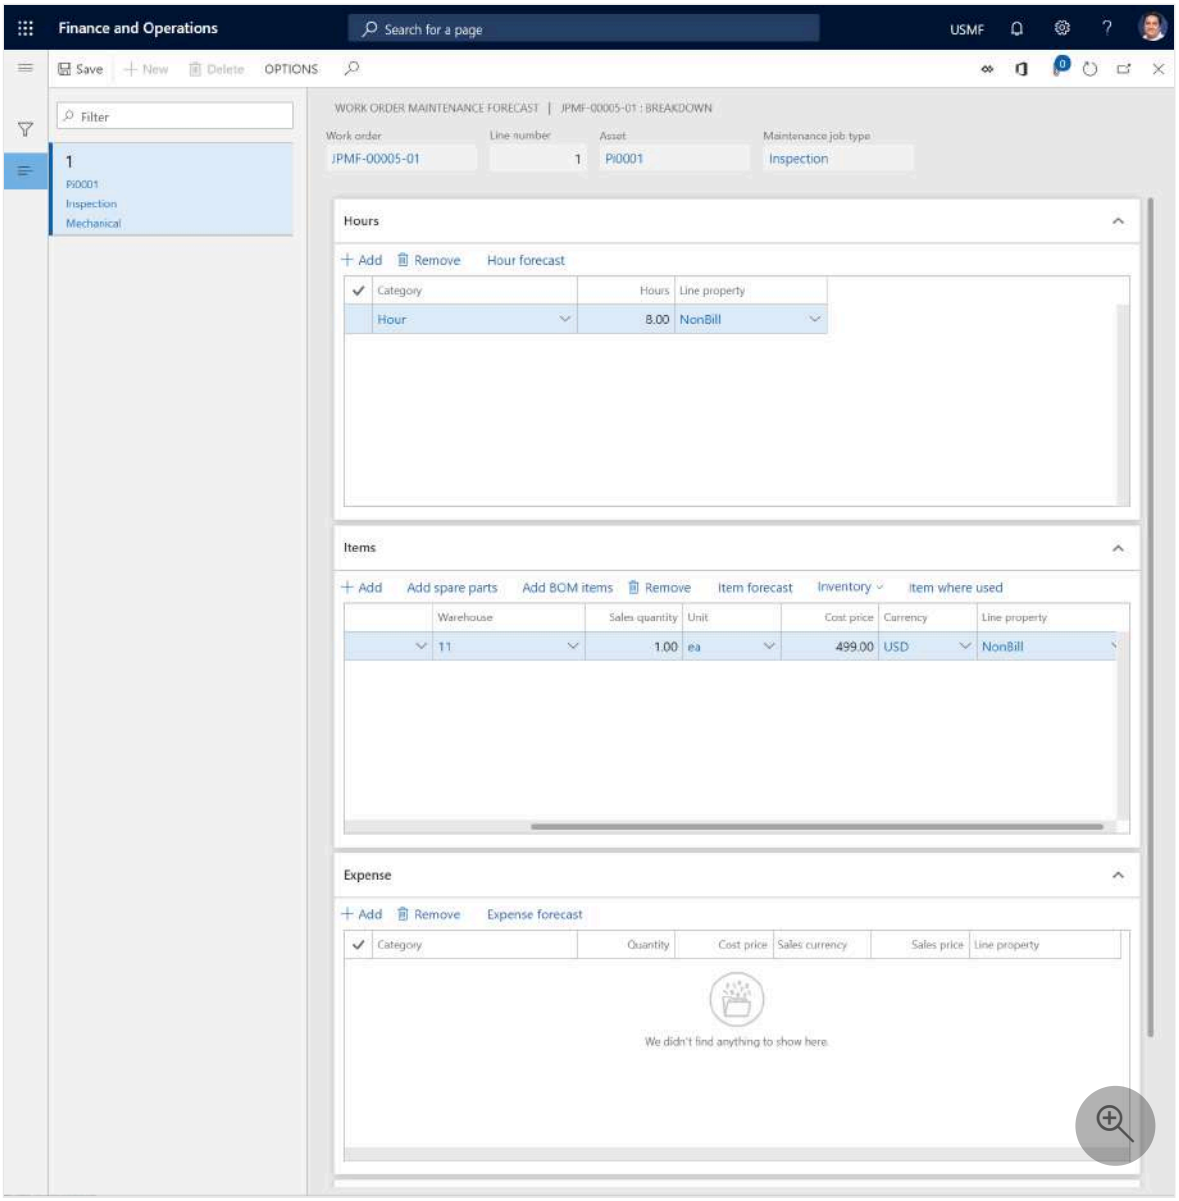
To add an item from the asset BOM, follow these steps:

1. Select **Add BOM items**.
2. Select the item, and edit the related information as you require.
3. Select **OK**.

To get an overview that shows where the item on the selected line is used in relation to assets, maintenance job type defaults, spare parts, and work orders in Asset Management, select **Item where used**. For more information about this overview, see Item where used.

Add an expense forecast to a work order

1. On the **Work order maintenance forecast** page, select the work order job to add a forecast to.



2. On the **Expense** FastTab, select **Add** to create a line.
3. In the **Category** field, select a category.
4. In the **Quantity** field, enter the quantity.
5. In the **Cost price**, **Sales currency**, and **Sales price** fields, enter appropriate values.
6. In the **Line property** field, select the type of charge that should be used on the line.

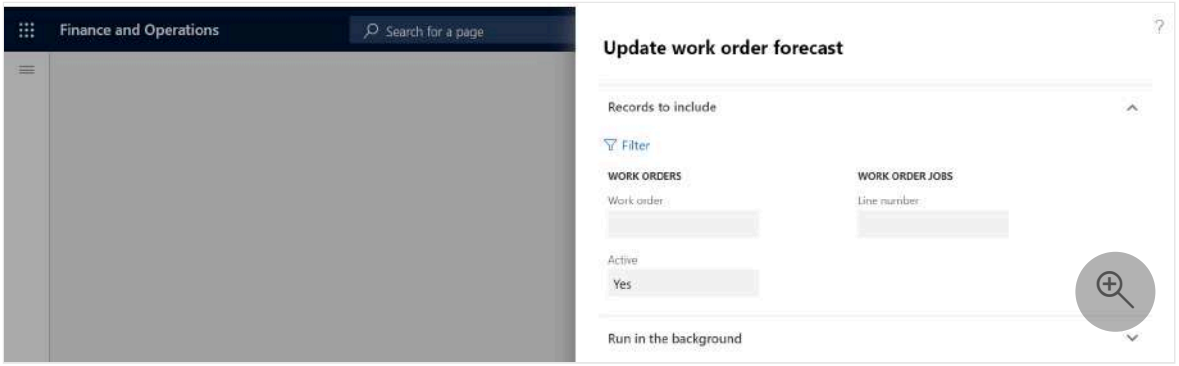
Note

The **Maintenance forecast totals** FastTab shows an overview of the number of lines that were created for the selected work order job and the work order on each FastTab. It also shows the total forecasted work hours for the work order job and the work order.

Automatic update of work order forecasts

If hour costs, item costs, and expenses are updated in other modules, work order forecasts in Asset Management can automatically be updated to reflect those changes. This capability helps guarantee that the latest cost prices are always used in your work order forecasts. You can also do similar updates for maintenance job type forecasts.

1. Go to **Asset management** > **Periodic** > **Forecast** > **Update work order forecast**.



2. In the **Update work order forecast** dialog box, on the **Records to include** FastTab, you can select **Filter** to add selections that are related to specific work orders or work order jobs, as you require.

3. On the **Run in the background** FastTab, you can set up the automatic update as a batch job, as you require.

4. Select **OK** to start the forecast update.

Procurement

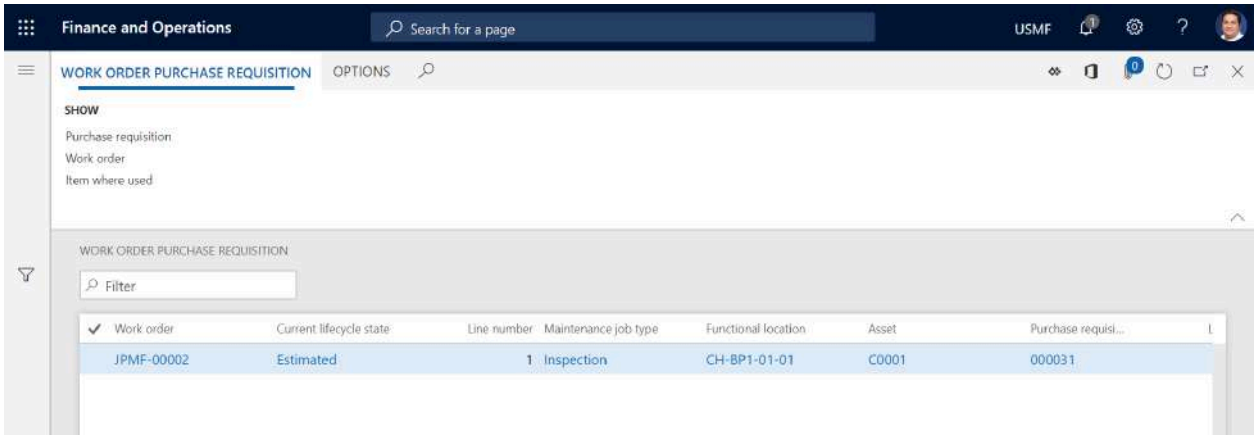
Article • 06/15/2022

In Asset Management, you can get an overview of purchase requisitions and purchase orders that are related to work orders. You can also create a purchase order or a purchase requisition from a work order.

The **Work order purchase requisition** list page (**Asset management** > **Procurement** > **Work order purchase requisition**) shows a list of purchase requisitions that are related to work orders. When you select a work order job on this page, you can use the buttons in the **Show** group on the **Work order purchase requisition** Action Pane tab to perform various actions:

- To open the related purchase requisition, select **Purchase requisition**.
- To open the related work order, select **Work order**.
- To get an overview that shows where the item on the selected line is used in relation to assets, maintenance job type defaults, spare parts, and work orders in Asset Management, select **Item where used**. For more information about this overview, see Item where used.

The illustration below shows an example of the **Work order purchase requisition** list page.

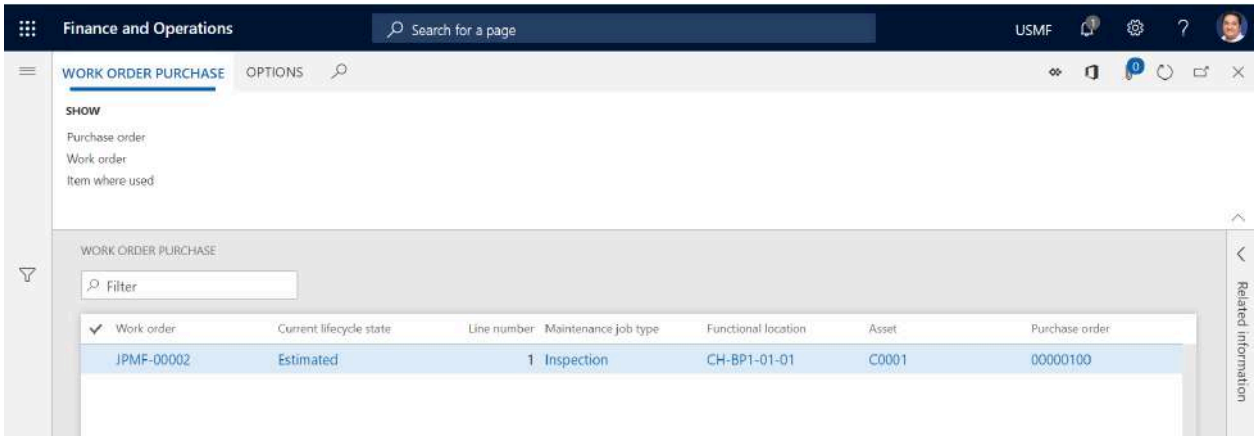


The **Work order purchase** list page (**Asset management** > **Procurement** > **Work order purchase**) shows a list of purchase orders that are related to work orders. When you select a work order job on this page, you can use the buttons in the **Show** group on the **Work order purchase** tab of the Action Pane to perform various actions:

- To open the related purchase order, select **Purchase order**.
- To open the related work order, select **Work order**.
- To get an overview that shows where the item on the selected line is used in relation to assets, maintenance job type defaults, spare parts, and work orders in

Asset Management, select **Item where used**. For more information about this overview, see Item where used.

The illustration below shows an example of the **Work order purchase** list page.



On both the **Work order purchase** list page and the **Work order purchase requisition** list page, a symbol that is related to delivery date control appears on the right side of each line. If the symbol is an exclamation point in a red circle, delivery of the related purchase order or purchase requisition might be delayed.

For a purchase order, the date that is related to the purchase order line is used to calculate a possible delay. To view this date, on the **Purchase order** page, select the purchase order line. The date is shown in the **Confirmed delivery date** field on the **Setup** tab of the **Line details** FastTab. If the **Confirmed delivery date** field isn't set, the date in the **Delivery date** field on the **Purchase order header** FastTab is used for the calculation. One of those dates is compared to the available date on the work order or work order job, in the following order:

1. Actual start date on the work order
2. Scheduled start date on the related work order job
3. Scheduled start date on the work order
4. Expected start date on the work order

For a purchase requisition, the date in the **Requested date** field on the **Purchase requisition header** FastTab of the **Purchase requisitions** page is used to calculate a possible delay. The date in that field is compared to the available date on the work order or work order job, in the same order that is used for a purchase order.

Create a purchase order from a work order

On the **All work orders** list page, you can select a work order job, and then create a related purchase order or a related purchase requisition. In this way, you help guarantee that project relations exist between the purchase order or purchase requisition and the work order.

1. Select **Asset management** > **Work orders** > **All work orders** or **Active work orders**.
2. Select the work order to create a purchase order for, and then select **Edit**.
3. On the **Work order maintenance jobs** FastTab, select the work order job to create the purchase order for.
4. Select **Item tasks** > **Purchase order from work order job**.
5. On the **Project purchase orders** list page, click **New**.
6. Create the purchase order.

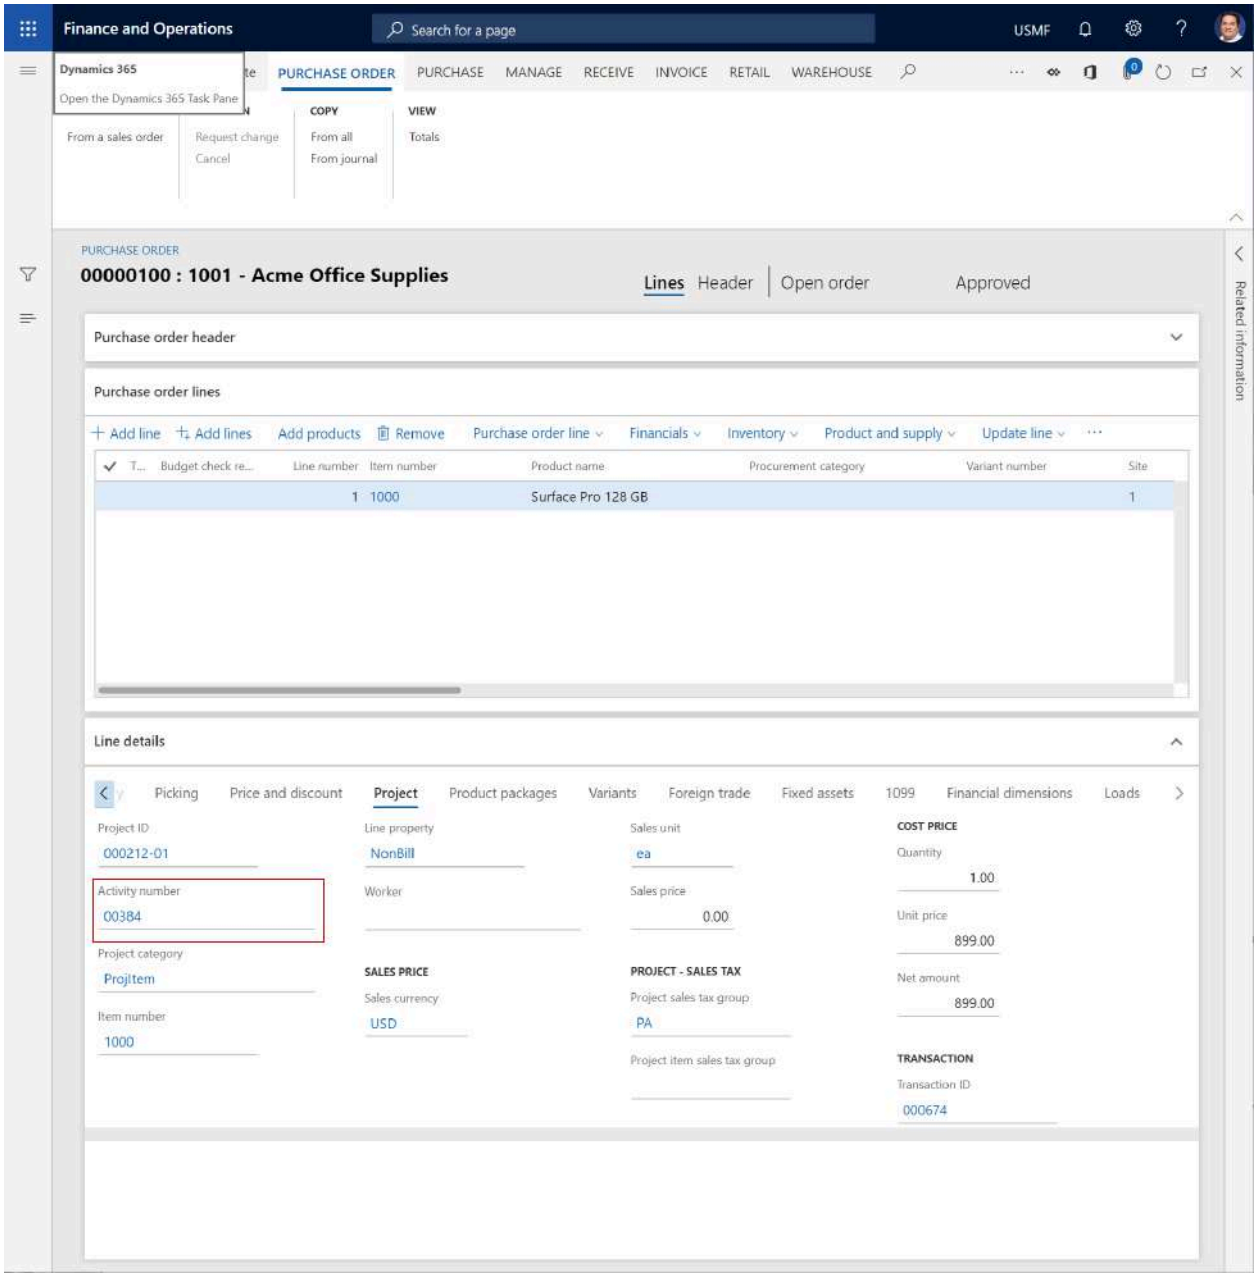
> ⓘ **Note**
>
> To create a related purchase requisition, follow the same steps. However, select **Item tasks** > **Purchase requisition from work order job** in step 4.

Project relation between work order and purchase order or purchase requisition

A purchase order line or purchase requisition line is related to a work order job via the work order project and the related project activity number. When you create a purchase order or purchase requisition from a work order job, the related project activity number is mandatory. If all the work order jobs in the related work order have the same maintenance job type, the project activity number is automatically entered on the purchase order or purchase requisition. If the work order jobs have different maintenance job types, you must manually enter the project activity number on the purchase order or purchase requisition.

To view or enter the activity number that is related to a purchase order line, on the **Work order purchase** list page, select the purchase order record, and then, in the **Purchase order** column, select the link for the purchase order. You can find the **Activity number** field on the **Project** tab of the **Line details** FastTab.

The illustration below shows an example of the **Purchase order** page, with focus on the **Activity number**.



Likewise, to view or enter the activity number that is related to a work order purchase requisition line, on the **Work order purchase requisition** list page, select the purchase requisition record, and then, in the **Purchase requisition** column, select the link for the purchase requisition. You can find the **Activity number** field on the **Project** tab of the **Line details** FastTab.

Material availability check for work orders

Supervisors can do a material availability check for work orders. This process is relevant for organizations that want to confirm that all the required spare parts are available before workers start maintenance work. For example, a supervisor is responsible for all corrective maintenance at a manufacturing site. As a standard procedure, the supervisor checks whether all the materials that are required for each work order are available. After availability is confirmed, the supervisor releases the materials to maintenance workers for processing.

Prerequisites

Before you can use this feature, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.37 or later.
- The feature that's named *Material availability check on maintenance work orders* must be turned on in feature management. As of Supply Chain Management version 10.0.43, this feature is turned on by default. As of version 10.0.45, it's mandatory and can't be turned off.

How the material availability check works

The material availability check for work orders uses a standard master planning run to calculate the inventory availability of all required materials. Material demand for work orders is generated by journal lines in the project item journal that's related to each work order. A journal line can be created, or it can be copied from the work order's item forecast. Learn more in Maintenance forecasts.

Supervisors use a dedicated page to run the material availability check for a selected range of work orders. From this page, supervisors can run the master plan and then view the material availability status for each of the selected work orders. The page also provides information about material availability of the individual spare parts that are required for the selected work orders.

Check material availability for work orders

Follow these steps to check material availability for work orders.

1. Go to **Asset management** > **Work orders** > **All work orders**.

2. Use the **Filter** field and the column header filters to select the range of work orders that you want to check material availability for. All work orders that are shown on the page will be checked.

3. On the Action Pane, on the **Work Order** tab, select **Material availability check**.

   The **Work order material availability check** page that appears is divided into two sections. The **Work orders** section in the upper part of the page shows the work orders. The **On-hand inventory** section in the lower part of the page shows journal lines that are related to the work order that's selected in the **Work orders** section.

4. In the **Work orders** section, select a work order. Confirm that there's a check mark in the **Journal lines created** column for the order. If there's no check mark, use one of the following methods to create the journal lines:

   - **Create the journal lines from a forecast:**

     a. Select **Forecast** on the toolbar.

     b. On the **Work order maintenance forecast** page, on the **Items** FastTab, confirm that there are item forecast lines for the order. If there are no lines, you can add them by selecting **Add**, **Add spare parts**, or **Add BOM items** on the toolbar.

     > **Tip**
     >
     > The system will automatically generate item forecast lines for work orders if you set up default forecasts on the **Maintenance job type defaults** page.

     c. Close the **Work order maintenance forecast** page to return to the **Work order material availability check** page.

     d. Select **Copy journals from forecast** on the toolbar.

     e. In the **Copy from forecast** dialog box, set the **Item** field to **Yes**.

     f. Select **OK**.

     g. Select **Refresh** at the top of the page.

     h. Confirm that there's now a check mark in the **Journal lines created** column.

   - **Create the journal from the Work order journals page:**

a. Select **Journals** on the toolbar.
b. On the **Work order journals** page, on the **Items** FastTab, add a line to the grid.
c. Close the **Work order journals** page to return to the **Work order material availability check** page.
d. Select **Refresh** at the top of the page.
e. Confirm that there's now a check mark in the **Journal lines created** column.

5. Run the material availability check by selecting **Material availability check** on the toolbar.

> ⓘ **Note**
>
> You can select multiple work orders for the material availability check.

6. In the **Material availability check** dialog box, set the following fields:

- **Run mode** – Select one of the following values to specify the type of check that you want to do:
  - *Master planning + Availability check* – First, master planning is run for the products that are related to the work orders. A material availability check for the orders is then run based on the master planning result.
  - *Availability check only* – A material availability check is run based on data from the latest version of the master planning.

  > 💡 **Tip**
  >
  > If you're currently just exploring the feature (for example, by using demo data), select *Master planning + Availability check*.

- **Plan** – Select the master plan to use when master planning is run. Typically, the master plan that represents the dynamic master plan should be used.

7. Select **OK** to run the check.

In the **Work orders** section of the **Work order material availability** page, a symbol in the **Ready to be released** column indicates the material availability status of each selected work order.

Expand table

Symbol	Description
⃠	The check couldn't be run for this work order because there's no material demand for it. Make sure that there's a journal line for the order.
✓	All materials for the work order are fully available.
⚠	Some or all of the materials for the work order aren't available.

8. In the **Work orders** section, select a work order. In the **On-hand inventory** section, a symbol in the **Material availability** column indicates the availability of each material for the selected work order.

Expand table

Symbol	Description
✓	The required material is fully available. The **Requested quantity** field shows the quantity that's requested by the work order. For material in this status, the quantity in the **Requested quantity** field equals the quantity in the **On-hand settled** field.
⚠	The required material is unavailable or only partially available. For material in this status, the quantity in the **Requested quantity** field isn't fully covered by the quantity in the **On-hand settled** field. Instead, it's covered by a combination of the quantities in the **On-hand settled**, **Planned order settled**, and/or **Order settled** fields.

> **Tip**
>
> To get more information about how the demand for the requested quantity is covered, select **Inventory** > **Explosion** on the toolbar in the **On-hand inventory** section.

The material availability check is now completed. If you want, you can now update the state of orders that are ready to be worked on by maintenance workers, as described in the next section.

Update a work order state

After you've confirmed that all materials are available for a work order, you can update the work order state. In this way, you can indicate that the order is now ready to be worked on by maintenance workers.

1. If the **Work order material availability check** page isn't already open, open it as described in the previous section.

2. If you need help finding the work orders that you're looking for, use the **Material availability** field to filter the work orders in the **Work orders** section. Select one of the following options:

    - *All* – Show all work orders.
    - *Upcoming* – Show only work orders where some or all materials aren't available.
    - *Available* – Show only work orders where all materials are available. These orders are ready to be worked on by maintenance workers.

    For this procedure, select *Available* to show the work orders where all materials are available. You can now change the work order state of these orders to indicate that they're ready to be worked on by maintenance workers.

3. In the **Work orders** section, select one or more orders that you want to update.

4. Select **Update work order state** on the toolbar.

5. In the **Update work order state** dialog box, select the next work order state for the selected work orders.

6. Select **OK** to confirm the change.

Aggregated material availability check

The *aggregated material availability check* feature aggregates supply and demand per item to provide a comprehensive view of potential material shortages. You can use this feature to view inventory levels and the total material requirements across selected work orders. This consolidated view makes it easy to identify and assess any deficiencies in your inventory. It helps you gain a comprehensive understanding of your material needs, so that you can take proactive measures to address any shortages.

Prerequisites for this feature

Before you can use the aggregated material availability check feature, your system must meet the following requirements:

- Your system must meet the prerequisites that are listed at the beginning of this article.
- You must be running Supply Chain Management version 10.0.44 or later.

- The feature named *Aggregated material availability check* must be turned on in Feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

View information about aggregated material availability

To gain an overview of the total material requirements by spare part and warehouse dimension across all selected work orders, follow these steps:

1. If the **Work order material availability check** page isn't already open, open it as described earlier in this article.
2. In the bottom section of the page, on the **Aggregated on-hand inventory** tab, review the information that is shown.

Last updated on 07/27/2026

Manual update of asset counters

Article • 06/15/2022

Counters are used to create registrations on an asset, such as registrations about the number of hours that the asset has been in operation or the quantity that has been produced.

The counter type that is selected for a counter might be set to inherit counter values. In other words, the **Inherit asset counter values** option is set to **Yes** on the **General** FastTab of the **Counters** page (**Asset management** > **Setup** > **Asset types** > **Counters**). In this case, when you create a new counter line of that type, every child asset that uses the same counter type is automatically updated.

On the **All assets** page, you create hours or quantity counter registrations on an asset, based on your readings on the asset.

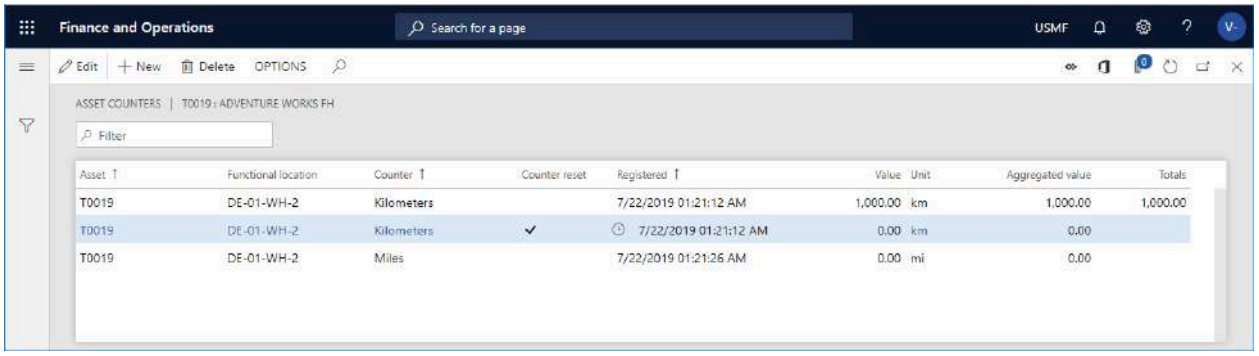
1. Select **Asset management** > **Assets** > **All assets**.
2. Select the asset, and then, on the Action Pane, on the **Asset** tab, in the **Preventive** group, select **Counters**. The **Asset counters** page shows a list of all previous counter registrations that have been made on the selected asset.
3. Select **New** to create a registration. The asset ID is automatically entered in the **Asset** field.
4. In the **Counter** field, select the relevant counter. Only counters that are related to the asset type selected on the asset are available for selection. The related unit is automatically entered in the **Unit** field.
5. In the **Registered** field, select the date and time for the counter registration.
6. In the **Value** field, enter the number since the last counter registration. Alternatively, in the **Aggregated value** field, enter the total count number.

Note the following points:

- If you physically install a new counter on an asset, you must register the change on the asset on the **Asset counters** page. Next, you must create two registration lines that have identical timestamps. The first line must be for the counter that you're replacing. On the line that is related to the new counter, select the **Counter reset** check box. In the **Totals** field, the total count number is the sum of the counter totals of all registered values on that counter type.

- If the **Counter reset** check box is selected on an asset using a maintenance plan that has a "Once from..." or "Once reached..." interval type, the counter is still active on the new counter line, because you create a separate counter line and start over with a new counter.

The illustration below shows an example of the **Asset counters** page.



On the **Asset counters** page (**Asset management** > **Inquiries** > **Assets** > **Asset counters**), you can make counter registrations on several assets at the same time, as you require.

> **Note**
>
> You can set up a range to define deviations in manual counter registrations. You can also specify the type of message that is shown if registrations are outside the defined range. For more information about how to set up counters, see Counters.

Automatic update of asset counters

Article • 06/15/2022

For information about manual registration of asset counters, see Manual update of asset counters. For information on how to set up asset counters, see Counters.

Counter values can also be automatically updated from production registrations, based on the production hours or production quantity (that is, the quantity that is produced). This update is done on the **Update asset counters** page. You can update one or several assets by setting one parameter, **From date**. This parameter specifies the start date for production registrations (production hours or production quantities). In other words, it specifies the date that counter values should be updated from.

All assets that are related to a resource, *and* that have asset counters that are set up to be updated based on the production hours or production quantity, will be included in an automatic update. New counter values will be created.

For counters that are based on the production quantity, the count includes both the good quantity and the error quantity that are registered. If the unit that is used for production quantity registration differs from the unit that is used for the counter, the quantity is converted so that it corresponds to the counter unit.

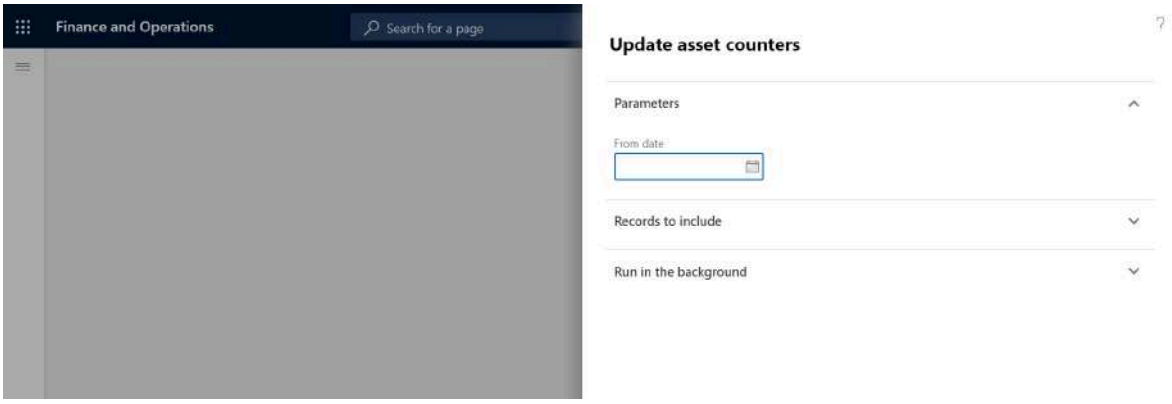
As mentioned above, automatic counters can be updated from production registrations. Therefore, the asset for which you want to automatically update counters must be related to a resource (machine). When produced quantities or production hours have been registered on the resource, you can update the related asset counters.

1. Select **Asset management** > **Periodic** > **Assets** > **Update asset counters**.
2. In the **From date** field, select the start date of the automatic update.

   > ⓘ **Note**
   >
   > The date in this field is the "work in progress" date from **Route transactions** (**Production control** > **Inquiries and reports** > **Production** > **Route transactions** > **Physical date** field).

3. On the **Records to include** FastTab, you can select specific assets, asset types, or resources for the automatic update. Select **Filter**, and make the relevant selections.
4. On the **Run in the background** FastTab, you can set up the automatic update as a batch job, as you require.

The illustration below shows an example of the **Update asset counters** dialog.

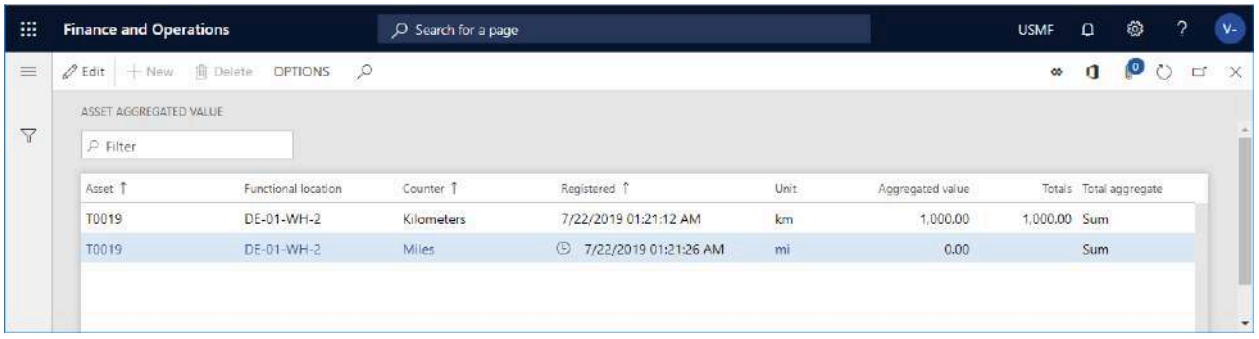


5. Select **OK**.

After the automatic asset counter update is done, you can view the counter registrations that are related to the asset on the **Asset counters** page. Select **Asset management** > **Assets** > **All assets**, select the asset, and then, on the Action Pane, on the **Asset** tab, in the **Preventive** group, select **Counters**.

On the **Asset aggregated value** page, you can get an overview of the latest registration that have been made on all counter types on all assets. Select **Asset management** > **Inquiries** > **Assets** > **Asset aggregated value**. This page resembles the **Asset counters** page, but you can't add or edit registrations. It's for overview only.

The illustration below shows an example of the **Asset aggregated value** page.



Note the following points:

- You can still create manual counter value registrations for counter types that are automatically updated. Learn more in Manual update of asset counters.
- You can set up counters that are related to another counter. In this case, when a counter is updated, related counters are automatically updated at the same time. For more information about how to set up related counters, see Counters.

Maintenance checklists

Set up maintenance checklists on maintenance job types. Fill in maintenance checklists as part of the process of completing a work order. For more information about how to set up maintenance checklists on maintenance job types, see Maintenance job type categories and maintenance job types, maintenance job type variants, maintenance job trades, and maintenance checklists.

When you work with maintenance checklists on a work order, you can fill in the predefined maintenance checklists that are related to maintenance job types. You can also add more maintenance checklist lines manually or from a maintenance checklist template.

Fill in a maintenance checklist

1. Go to **Asset management** > **Work orders** > **All work orders** or **Active work orders**.
2. Select the work order. On the Action Pane, open the **Work order** tab and, in the **Lines** group, select **Maintenance checklist**.
3. The **Work order maintenance job checklist** page shows the checklists for all work order jobs. If the work order jobs have different maintenance job types, the maintenance checklists might differ for each work order job. Select a work order job to work with the related maintenance checklist. The **Line details** FastTab shows details of the selected maintenance checklist line.
4. Complete all the maintenance checklist lines, one at a time, in the order that they appear. You complete a maintenance checklist line by filling in the fields on the **Line details** FastTab. The information that is required to complete a line can vary, depending on the line type. For example, on a line of the *Text* type, you add a note that explains the result of your check. On a line of the *Measurement* type, you enter the counter value that you read on the equipment, and you can also add a note as you require. A maintenance checklist line of the *Header* type is used as a heading to group the maintenance checklist lines that appear below it. You don't have to fill in a header. As for all other types of maintenance checklist lines, you can add a note to a line of the *Header* type.
5. If instructions are related to a maintenance checklist line, the **Instructions** check box is selected. Read instructions for the selected maintenance checklist line in the **Instructions** field on the **Line details** FastTab.

6. When you complete a maintenance checklist line, select the **Checked** check box on that line to mark it as completed. To discard a maintenance checklist line because it isn't relevant to the work order job, select the **N/A** check box on the line. If the **Mandatory** check box is selected on a maintenance checklist line, you must select either the **Checked** check box or the **N/A** check box.

> ⓘ **Note**
>
> You can only update maintenance checklist registrations if the work order is in an Active lifecycle state.

Add a maintenance checklist line

Create maintenance checklists from the definition on the maintenance job type default. The system transfers these checklists to a work order job. Add maintenance checklist lines to a work order job as needed. Maintenance checklist lines that you manually add get the **Manual** reference.

1. On the **Work order maintenance job checklist** page, select the work order job to add a maintenance checklist for.

2. On the **Maintenance checklist lines** FastTab, select a maintenance checklist line. To insert a new line after the selected line, press the **Down arrow** key. The next number in the sequence is automatically entered in the **Line number** field. To insert a new line before the selected line, select **Add line**.

3. On the **Name** field, enter a name for the maintenance checklist line.

4. In the **Type** field, select a type for the maintenance checklist line. The **Line details** FastTab contains related fields for each maintenance checklist type.

    - *Text* – Use this type to add a maintenance checklist line that has text that describes what must be done. For example, use this type if you want a worker to check or inspect something, but you're not expecting a specific (measurable) result. After you select this type, on the **Lines details** FastTab, in the **Instructions** field, enter text that describes what must be done.
    - *Header* – Use this type as a heading to group the maintenance checklist lines that appear below it. This type is useful if you have several maintenance checklist lines that

you can divide into specific areas. After you select this type, in the **Name** field, enter a descriptive name.

- *Template* – This type isn't applicable when you manually add a maintenance checklist line on a work order job.
- *Variable* – Use this type to define a possible result in a range on the maintenance checklist line. For information about how to set up maintenance checklist variables, see Maintenance job type categories and maintenance job types, maintenance job type variants, maintenance job trades, and maintenance checklists. After you select this type, in the **Name** field, enter a name to describe the variable. On the **Line details** FastTab, in the **Variable** field, select the variable. In the **Instructions** field, enter text that describes what must be done.
- *Measurement* – Use this type to record a specific measurement on the maintenance checklist line. After you select this type, in the **Name** field, enter a name for the measurement. On the **Line details** FastTab, in the **Counter** and **Unit** fields, select appropriate values. In the **Instructions** field, enter text that describes what must be done.

5. When you finish manually adding maintenance checklist lines, fill in the lines as described in the previous section.

Add maintenance checklist lines from a template

In addition to the maintenance checklist lines that the maintenance job type provides, you can add maintenance checklist lines directly to a work order job from a maintenance checklist template. This capability is useful when a work order requires a standard set of tasks that the maintenance job type doesn't already include. Learn more about how to create maintenance checklist templates in Maintenance job type categories and maintenance job types, maintenance job type variants, maintenance job trades, and maintenance checklists.

1. On the **Work order maintenance job checklist** page, select the work order job to add maintenance checklist lines to.

2. On the **Maintenance checklist lines** FastTab toolbar, select **Add lines from template**.

3. In the dialog box, in the **Maintenance checklist template** field, select the template that contains the lines you want to add.

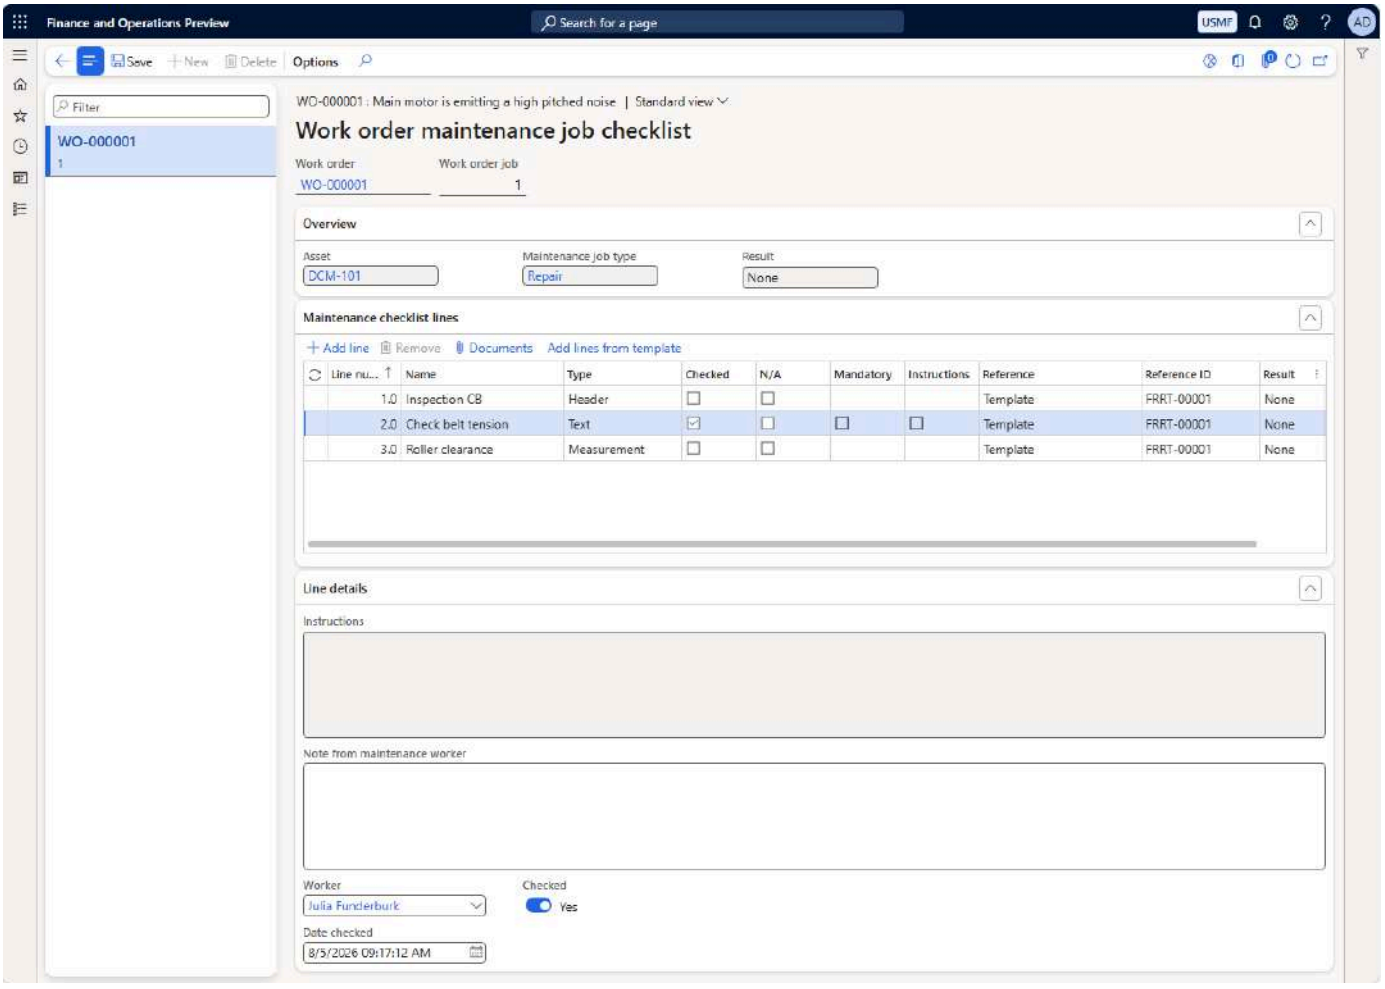
4. Select **OK**. The lines from the template are appended after any existing maintenance checklist lines on the work order job, and they're assigned a **Reference** of *Template*. A

message shows how many lines were added from the template.

You can add lines from more than one template, and you can combine template lines with manually added lines. The template governs maintenance checklist lines that you add from a template. As with lines that have the *Job type* reference, you can't delete template lines individually on the work order job. If a template line doesn't apply to the current work order job, select the **N/A** check box on the line to exclude it.

> **Note**
>
> On the **Work order maintenance job checklist** page, you can only delete maintenance checklist lines that you or other maintenance workers created manually, and that have the *Manual* reference. You can't delete maintenance checklist lines that have the *Job type* reference or the *Template* reference. If one of those lines doesn't apply to the work order job, select the **N/A** check box on the line to exclude it. When you select **N/A**, the line remains on the work order for traceability, but it's excluded from the mandatory maintenance checklist validation.

The following illustration shows an example of a maintenance checklist.



Last updated on 08/10/2026

Maintenance downtime for work orders

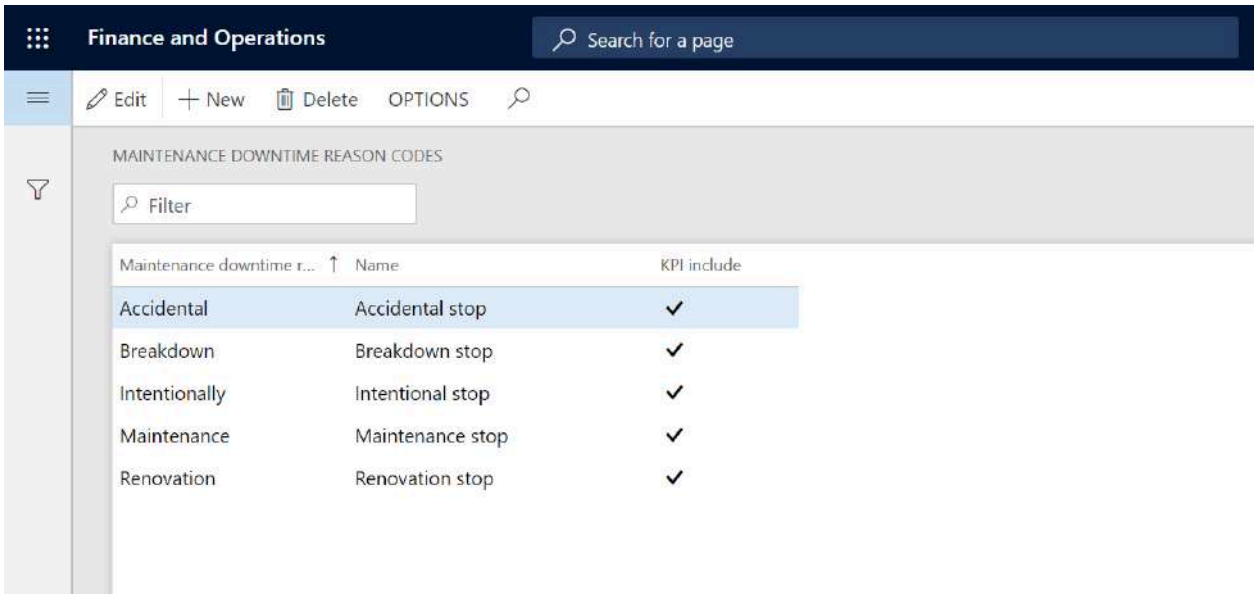
Article • 06/15/2022

You can create maintenance downtime registrations on the asset that is selected on a work order. This capability is useful if you want to register maintenance downtime on one or more machines in the production area. You first create the maintenance downtime reason codes that you want to use, such as **Breakdown** and **Planned stop**. This step is done on the **Maintenance downtime reason codes** page. You can then create maintenance downtime registrations on the **Maintenance downtime** page and add the relevant maintenance downtime reason codes.

Create maintenance downtime reason codes

1. Select **Asset management** > **Setup** > **Work orders** > **Maintenance downtime reason codes**.
2. Select **New**.
3. In the **Maintenance downtime reason code** field, enter an ID for the maintenance downtime reason code.
4. In the **Name** field, enter a name.
5. Select the **KPI include** check box if the reason code should be included in calculations of key performance indicators (KPIs) for the asset. In general, planned production stops should not be included in KPI calculations, because they don't affect expected performance.
6. Select **Save**.

The illustration below shows an example of the **Maintenance downtime reason codes** page.



After you've created the maintenance downtime reason codes that you want to use, you can create maintenance downtime registrations for work orders and assets.

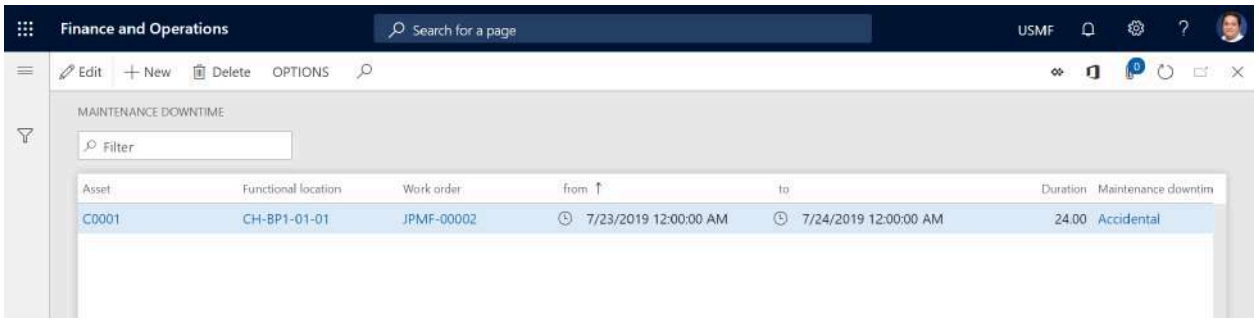
Create maintenance downtime registrations

1. Click **Asset management** > **Work orders** > **All work orders** or **Active work orders**.
2. Select the work order, and then, on the **Work order** tab, in the **Asset** group, select **Maintenance downtime**.
3. Select **New**.
4. In the **From** and **To** fields, define the date and time interval for the maintenance downtime registration.

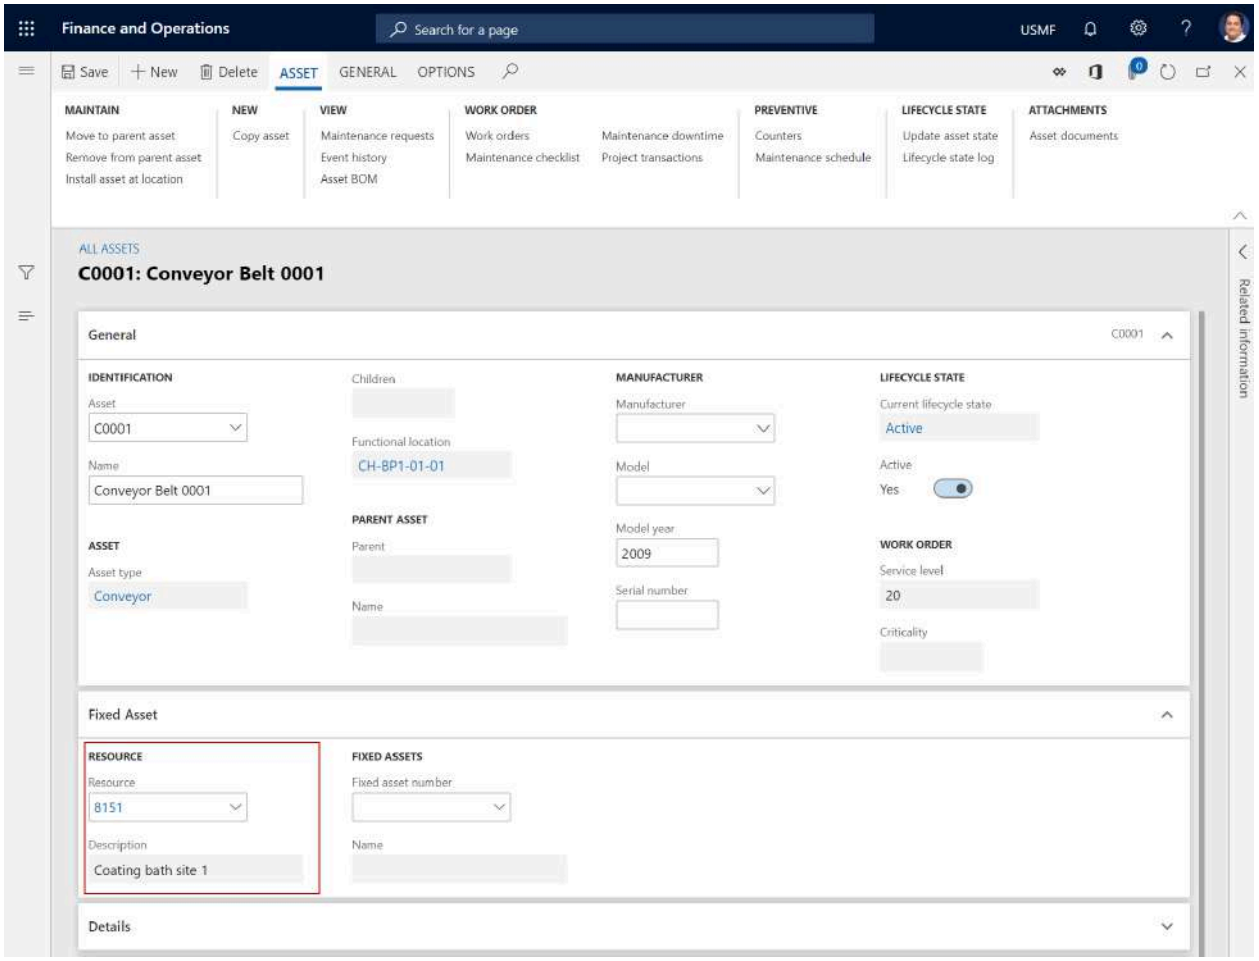
> **Note**
>
> When you leave the **To** field, the duration in hours is automatically inserted in the **Duration** field.

5. In the **maintenance downtime reason code** field, select a reason code.
6. Repeat steps 3 through 5 to add more registrations.
7. Select **Save**.

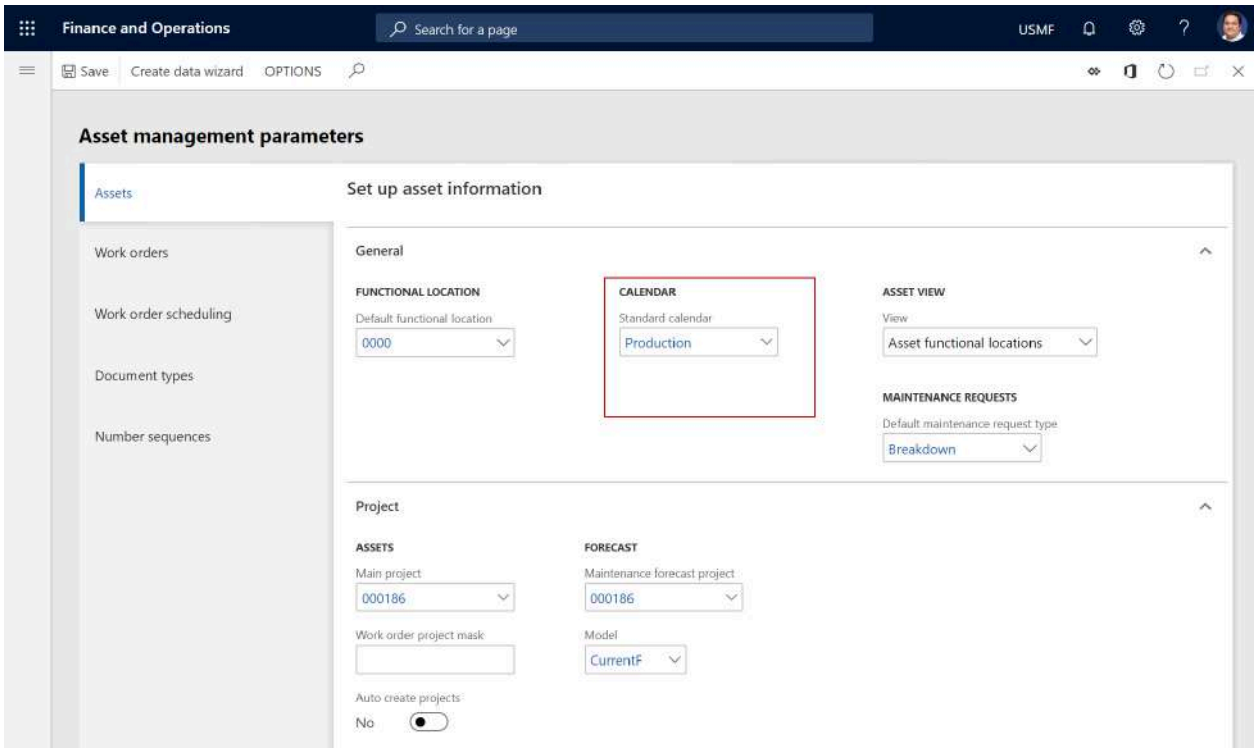
The illustration below shows an example of maintenance downtime registration.



The calendar that is used to calculate a maintenance downtime registration depends on your selection in the setup of assets and parameters. If a resource is selected on an asset in the **Resource** field on the **Fixed asset** FastTab of the **All assets** page, the calendar that is set up for the associated resource group is used, as shown in the following illustration.



If no resource is selected on the asset, the standard calendar that is selected on the **Asset management parameters** page is used, as shown in the following illustration.



To see an overview of all maintenance downtime registrations, click **Asset management** > **Inquiries** > **Maintenance downtime**.

> **Note**
>
> All calendars that are used in the **Asset Management** module are set up in **Organization administration** > **Setup** > **Calendars** > **Calendars**.

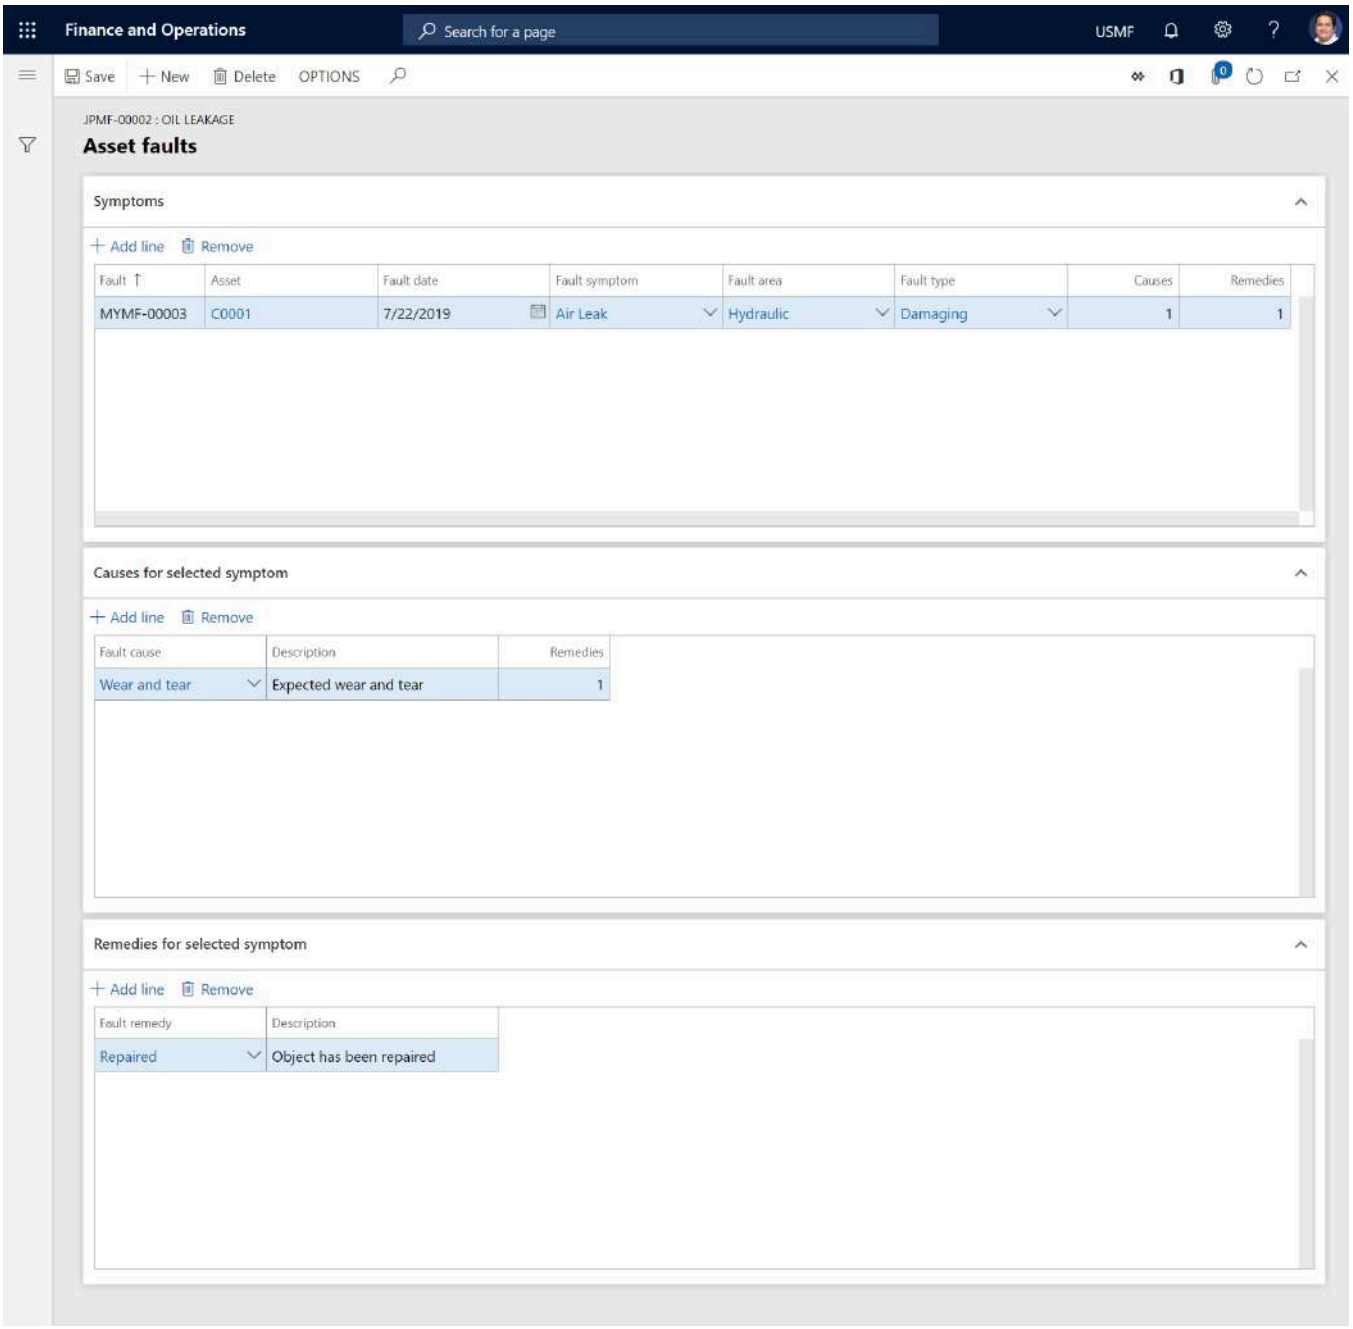
Add fault to work order

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can add faults that were set up in the fault designer to a work order. One or more fault records must be connected to the asset types that are used for the asset that is selected in the work order. For more information about the setup, see Fault management.

1. Select **Asset management** > **Work orders** > **All Work orders** or **Active work orders**.
2. Select the work order to make a fault registration on, and then, on the Action Pane, on the **Work order** tab, in the **Asset** group, select **Asset fault**.
3. On the **Symptoms** FastTab, select **Add line**. A sequential fault number is automatically entered in the **Fault** field.
4. In the **Fault symptom** field, select the relevant symptom.
5. In the **Fault area** and **Fault type** fields, select the appropriate values.
6. In the **Fault date** field, the current date is automatically inserted. You can select a different date as you require.
7. On the **Causes for selected symptom** FastTab, add a line to describe the cause of the issue.
8. On the **Remedies for selected symptom** FastTab, add a line to describe a possible solution to the issue.
9. Select **Save**.

The illustration below shows an example of a fault registration.



View asset faults

In the **Asset faults** list, you can get an overview of all faults registered on assets.

On the **Asset faults** list page, you can get an overview of all faults that have been registered on assets. To open the page, select **Asset management** > **Inquiries** > **Asset fault** > **Asset faults**.

Print asset fault report

From the **All assets** list page, you can print an asset fault report that shows all fault registrations and a graphical overview of fault statistics.

1. Select **Asset management** > **Assets** > **All assets**.

2. Select the asset to print a fault report for.

3. On the Action Pane, on the **General** tab, in the **Reports** group, select **Asset fault**.

4. Enter a specific period, or select a fault type.

5. Select **OK** to print the report.

> **Note**
>
> To print a fault report for several assets or asset types, select **Asset management** > **Reports** > **Assets** > **Asset fault**.

Work order report

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can generate a work order report that shows detailed information about one or more work orders that you select.

1. Select **Asset management** > **Reports** > **Work orders** > **Work order report**.
2. Select "Yes"/"No" on the toggle buttons as you require, to determine the details to be included in the report.
    - In the **Print settings** section, you can select whether to include attachments from the setup of the related maintenance job type.
3. On the **Records to include** FastTab, you can filter the contents of the report by **Work order**.
4. On the **Run in the background** FastTab, you can set up generation of the work order report as a batch job, as you require.
5. Select **OK** to generate the report.

The following illustration shows an example of how the report parameters can be set up.

Work order pools

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can use work order pools to group work orders that have something in common. Here are some examples of things that you can create work order pools for:

- Work crews, for example, Maintenance Crew A or Maintenance Crew B
- Professional skills, such as electricians or plumbers
- Physical locations
- Time schedules, such as weeks or other periods

As you require, you can put one work order in multiple work order pools.

Create a work order pool

On the **All work order pools** or **Active work order pools** list page, you can get an overview of your work order pools and create new pools.

1. Select **Asset management** > **Work order pools** > **All work order pools** or **Active work order pools**.
2. Select **New**.
3. In the **Pool** field, enter an ID for the work order pool.
4. the **Name** field, enter a name.
5. Set the **Active** option to **Yes** to indicate that the work order pool is active.
6. Set the **Delete work order relations** option to **Yes** if work orders should automatically be removed from the work order pool.
7. In the **Delete lifecycle state** field, select the work order lifecycle state. For example, the work order lifecycle state for completing a work order could be set to automatically delete relations to work order pools.

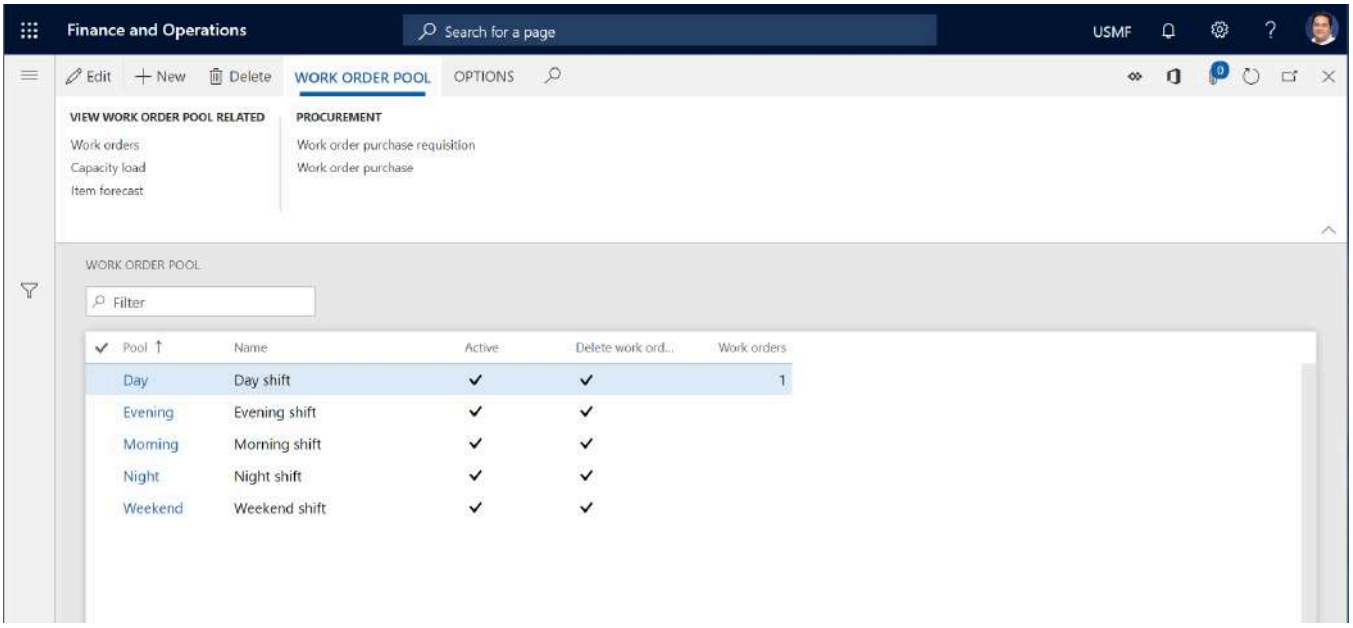
You can start adding work orders to your work order pool right away.

8. On the **Work orders** FastTab, select **Add line**.
9. In the **Work order** field, select a work order. The related fields are automatically updated.
10. Repeat steps 8 through 9 to add more work orders.
11. If the work orders that you added should be done in a specific order, in the **Sort order** field, you can enter the numbers **1**, **2**, **3**, and so on, to specify that order.
12. To view a list of all the work orders that are included in the work order pool, on the Action Pane, on the **Work order pool** tab, in the **View work order pool related** group, select **Work orders** to open the **All work orders** list page.
13. To calculate and view capacity load for the maintenance schedule, unscheduled work orders, and scheduled work orders, on the Action Pane, on the **Work order pool** tab, in the **View work order pool related** group, select **Capacity load** to open the **Calculate capacity load** dialog.
14. To calculate and view forecasts for items (spare parts and other required items) that are related to maintenance schedule, unscheduled work orders, and scheduled work orders, on the Action Pane, on the **Work order pool** tab, in the **View work order pool related** group, select **Item forecast** to open the **Calculate item forecast** dialog.
15. To view a list of purchase requisitions that are related to the work orders in the work order pool, on the Action Pane, on the **Work order pool** tab, in the **Procurement** group, select **Work order purchase requisition** to open the **Work order purchase requisition** list page.
16. To view a list of purchase orders that are related to the work orders in the work order pool, on the Action Pane, on the **Work order pool** tab, in the **Procurement** group, select **Work order purchase** to open the **Work order purchase** list page.

> ⓘ **Note**
>
> When a work order pool is no longer relevant to your work planning, set the **Active** option for that pool to **No** in the list view of the **Work order pool** page.

To delete all worker order lines, set the **Delete work order relations** option to **Yes**. This option is useful if, for example, you want to create an empty pool that you can use later for other work orders. When you're ready to use the work order pool to create new work order relations later, remember to set the **Delete work order relations** option to **No**.

The illustration below shows an example of the **Work order pool** list page.



Add a work order to a work order pool

As described in the previous section, you can add work orders to a work order pool when you create that pool. You can also add work orders to a work order pool on the **All work orders** or **Active work orders** list page.

1. Select the work order, and then, on the Action Pane, on the **Work order** tab, in the **Maintain** group, select **Work order pool**.
2. Select the work order in the list, and click **Work order pool**.
3. In the **Maintain work order pool** dialog, in the **Add/remove** field, select **Add**.
4. In the **Pool** field, select the work order pool.
5. Select **OK**.
6. To put the work order that you added in a specific order in the work order pool, on the **All work order pools** or **Active work order pools** list page, select the pool, and then select **Edit**. Then, on the **Work order pool** page, on the **Work orders** FastTab, use the **Sort order** field to adjust the sort order of the work orders that are included in pool.

To remove a work order from a work order pool, repeat these steps, but select **Remove** in step 3.

Active work order maintenance jobs overview

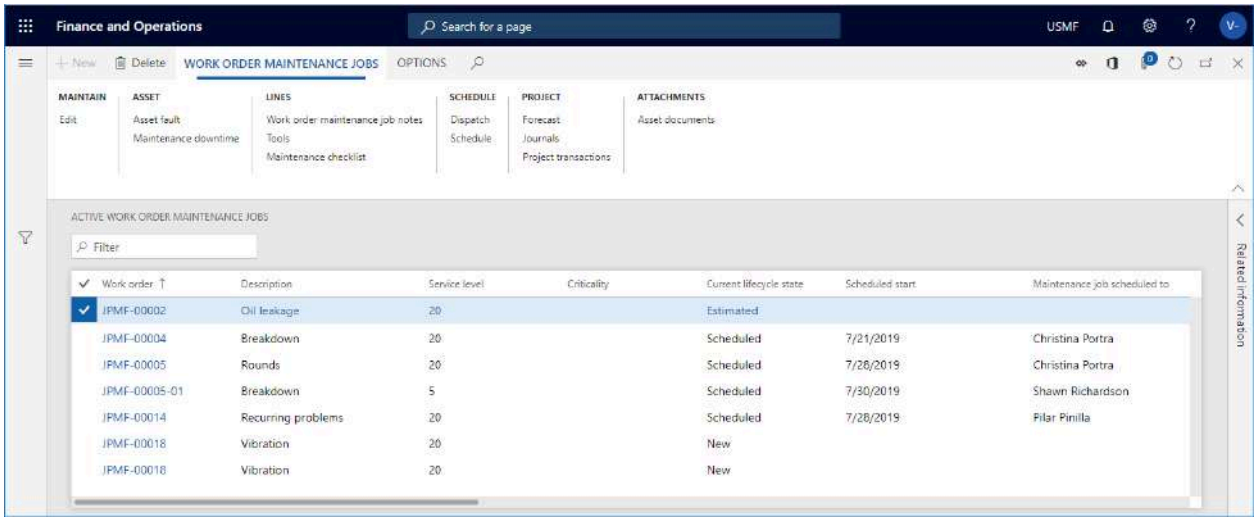
Article • 06/15/2022

On the **Active work order maintenance jobs** list page, you can get an overview of work orders, in terms of the number of work orders that have been created on specific assets, asset types, manufacturers, models, maintenance job types, and so on. By selecting a work order job and then selecting **Edit**, you can open the related work order. By selecting a work order job and then selecting one of the buttons on the **Work order maintenance jobs** tab of the Action Pane, you can view data for the work order that the work order job is related to.

To open the list page, select **Asset management** > **Work orders** > **Active work order maintenance jobs**. The page lists all active work order jobs, and it also shows some of the information that is related to the work order or work order job.

In the % column, a number shows completion of the work order as a percentage. Completion is based on two calculations: posted hours compared to forecasted hours, and the number of maintenance checklists that have been completed.

The illustration below shows an example of the **Active work order maintenance jobs** list page.



For a short description of the buttons on the **Active work order maintenance jobs** list page, refer to Introduction to work orders where identical buttons are described.

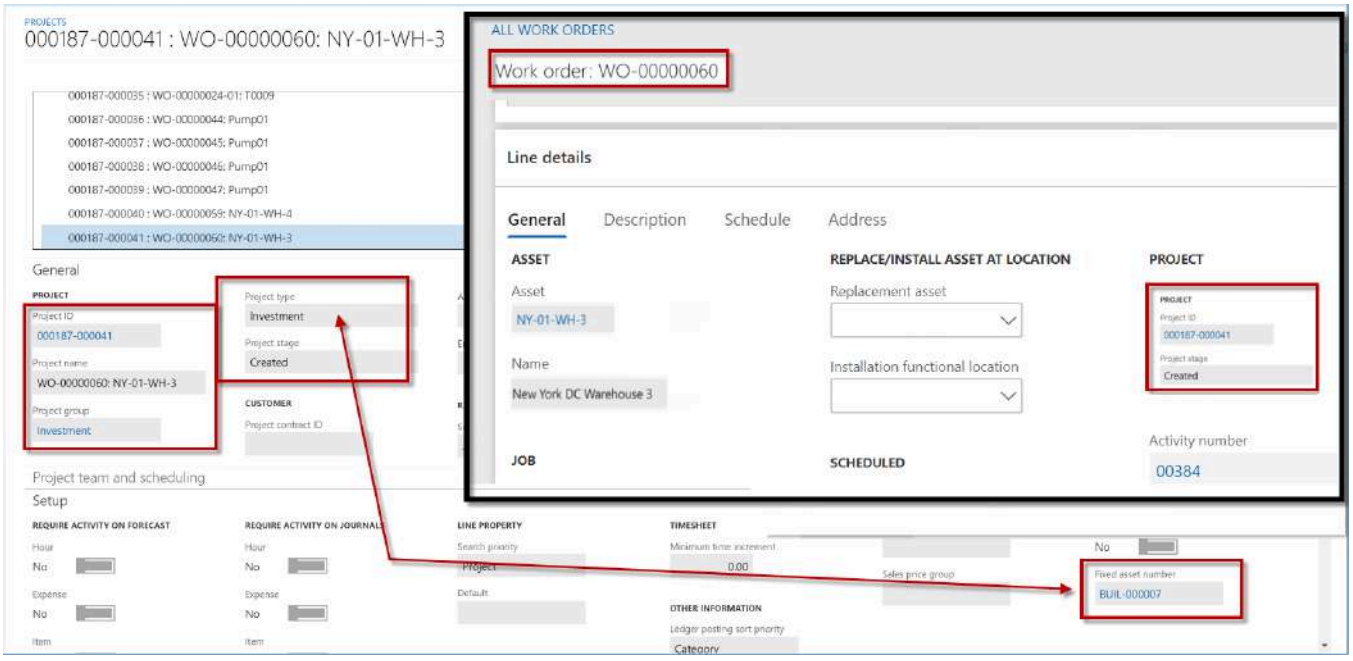
Work orders and fixed assets

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

In Asset Management, assets can be related to fixed assets, and you can create work orders for those assets. If you use this functionality, you can get a complete overview of fixed assets, related investment projects, and the costs that are registered on the investment projects in the **Project management and accounting** and **Fixed assets** modules in the finance and operations apps.

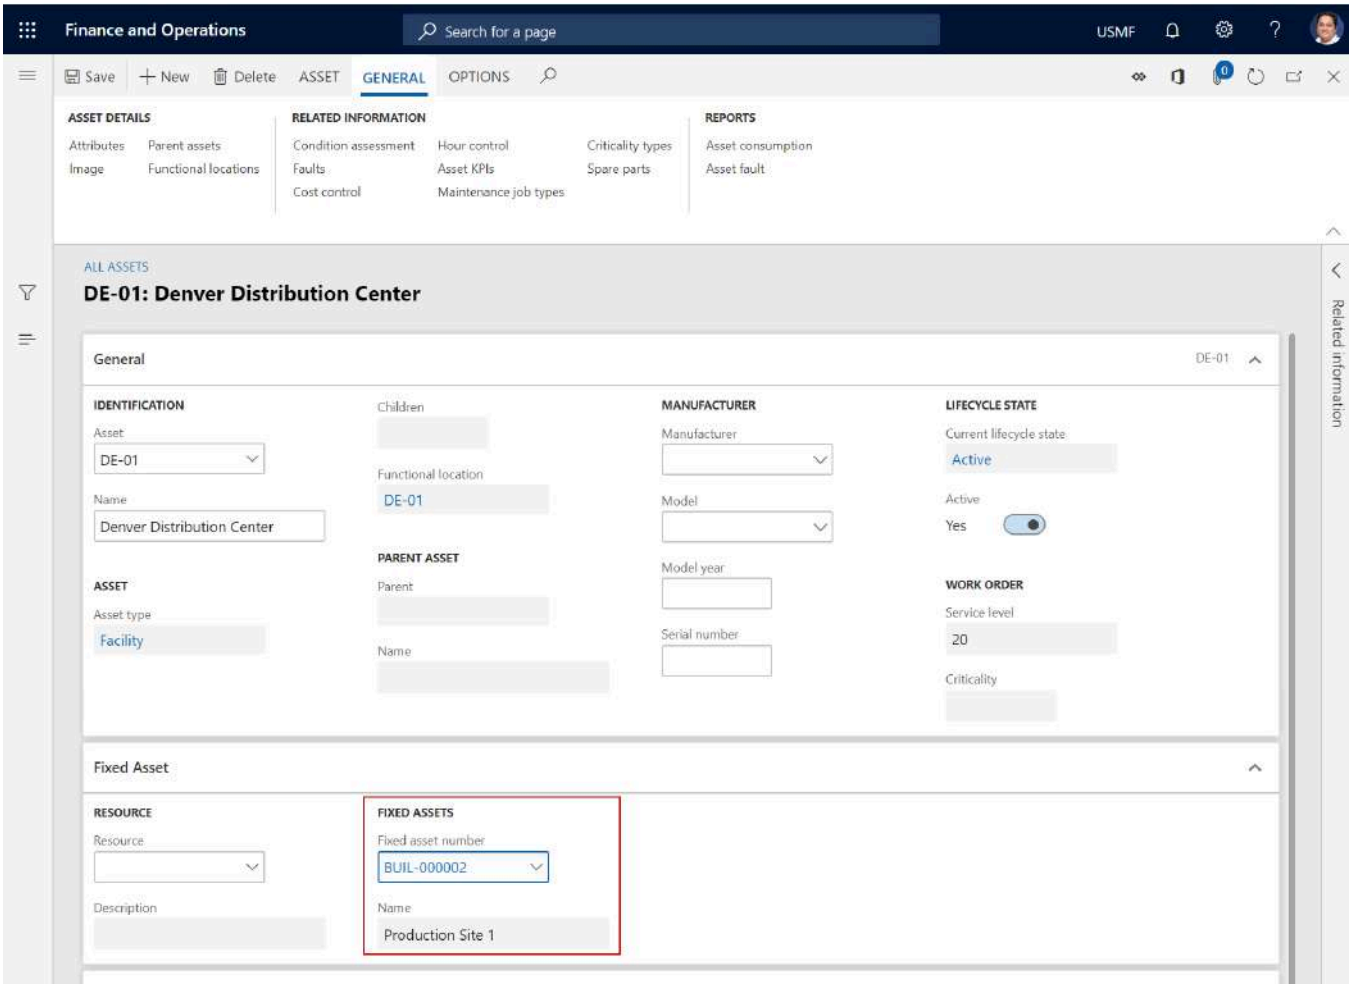
> **Note**
>
> The **Fixed asset number** field on the work order job project is set only if **Investment** is selected as the project type on the work order job project.

The illustration below shows the relation between an investment project in the **Project management and accounting** module and a work order job project.

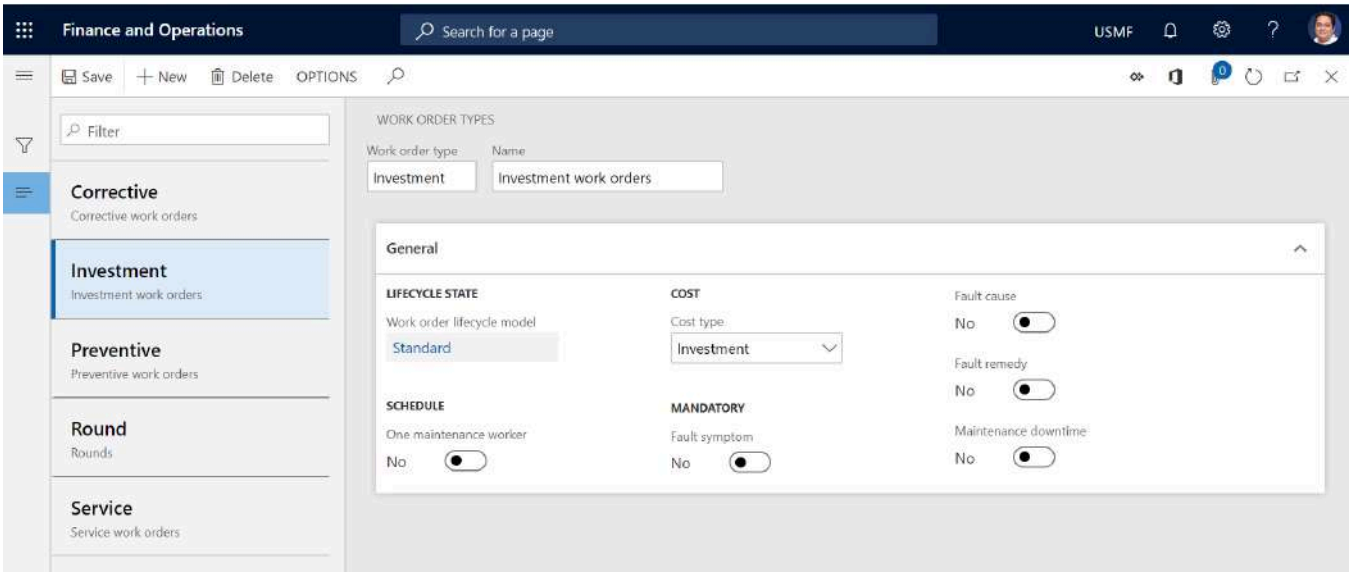


The following procedure describes the relation between assets, work orders, work order job projects, and fixed assets.

1. You create an asset that you relate to a fixed asset.

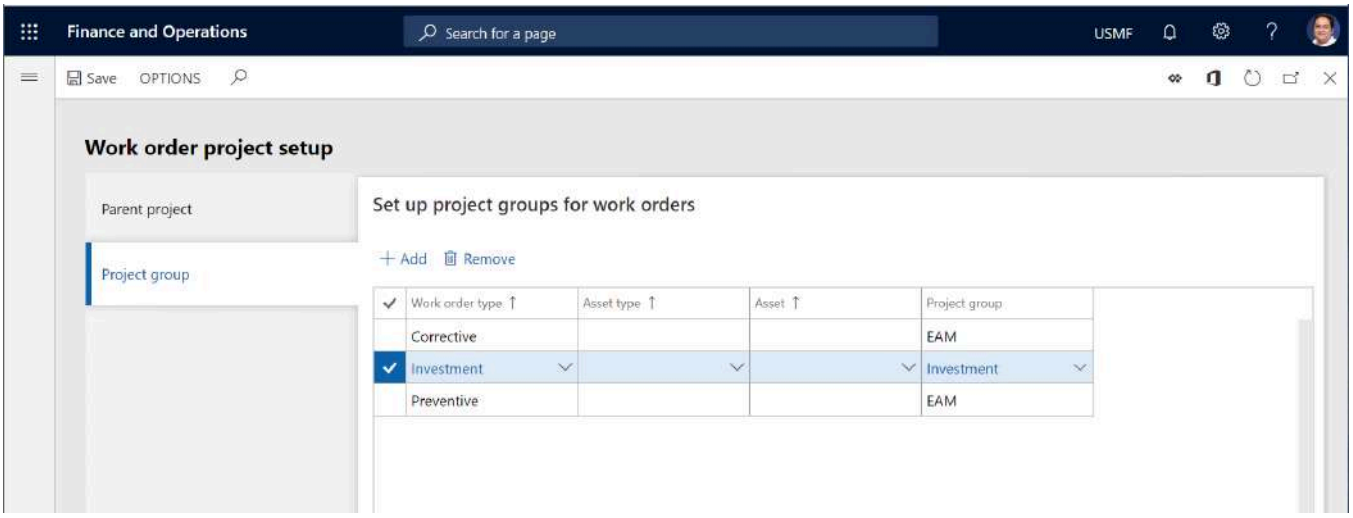


2. When you set up work order types on the **Work order types** page (**Asset management** > **Setup** > **Work orders** > **Work order types**), you create a work order type for handling investments. Learn more in Work order types.



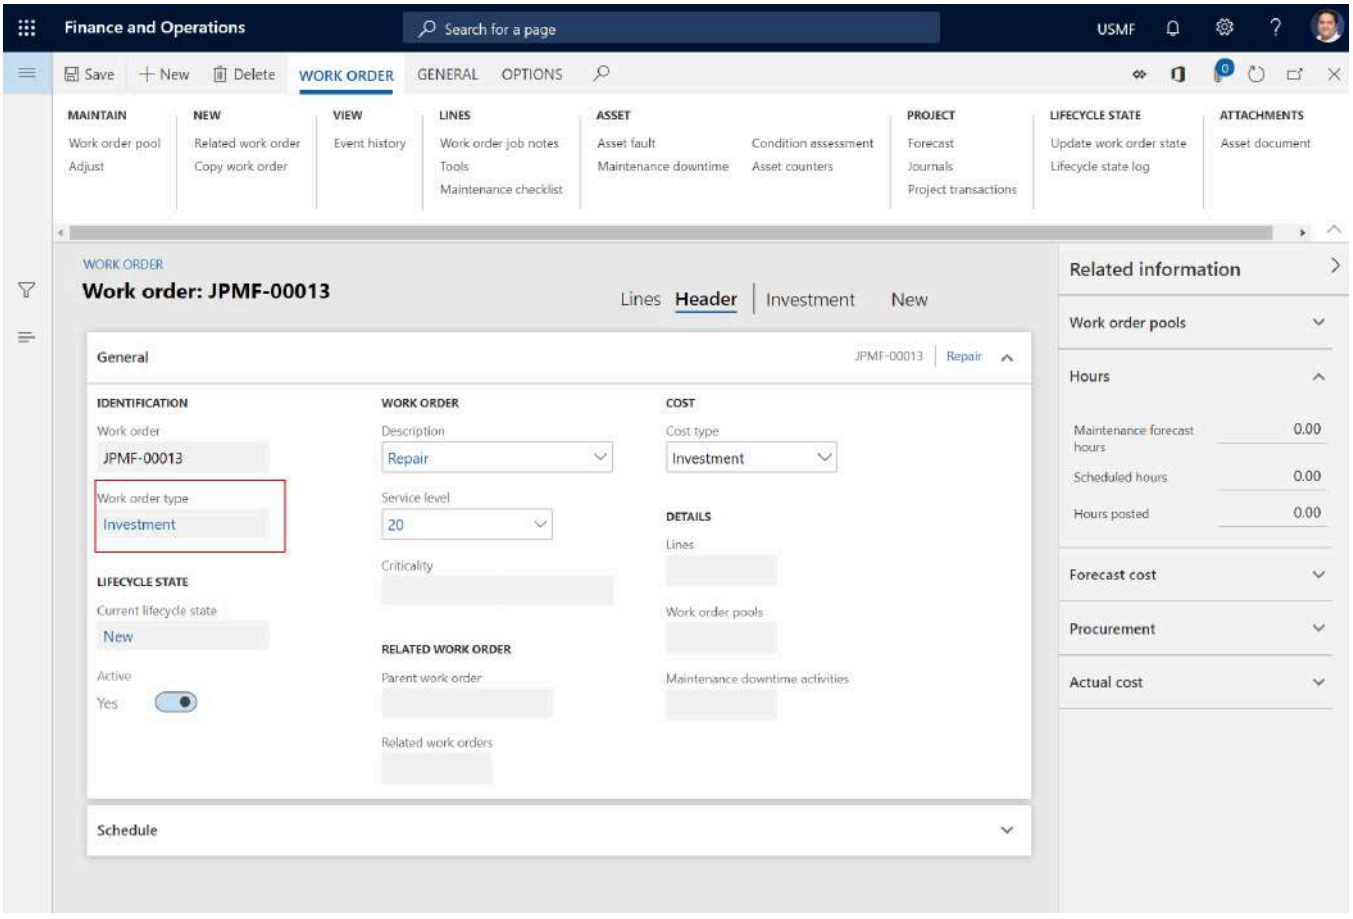
3. When you set up work order project groups on the **Project group** tab of the **Work order project setup** page (**Asset management** > **Setup** > **Work orders** > **Project setup**), you create a relation between the work order type that is used for investments and the project group that was created for investments on the **Project groups** page in the **Project**

management and accounting module (**Project management and accounting** > **Setup** > **Posting** > **Project groups**).



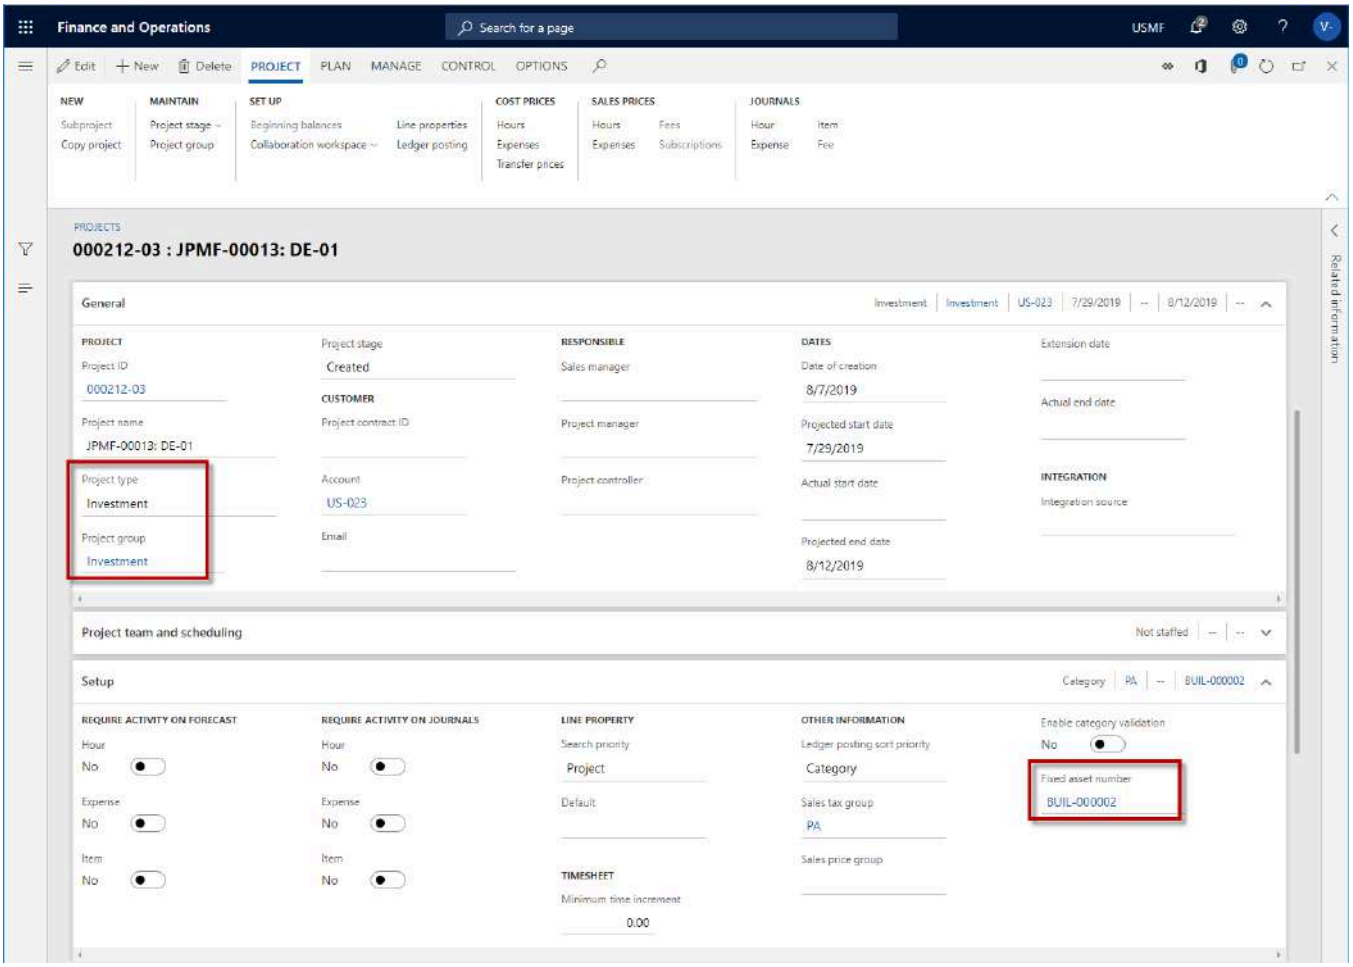
4. When you create a work order that is related to a fixed asset, you select the work order type that is used to handle investments, such as **Investment**.

5. When the work order is created, the related work order type is shown on the **All work orders** page.



6. When the work order is created, the project that is related to the work order is created on the **All projects** page in the **Project management and accounting** module (**Project management and accounting** > **Projects** > **All projects**). To view project-related

information, select the link in the **Project ID** field on the **General** tab on the **Line details** FastTab in the details view of the **All work orders** page in the **Asset management** module (**Asset management** > **Commom** > **Work orders** > **All work orders**).



7. To see an overview of the projects associated with a fixed asset, select **Fixed assets** > **Fixed assets** > **Fixed assets**, and then, in the **Fixed asset number** field, select the link for the fixed asset to open the details view. Expand the **Related information** pane on the right side of the page, and select the **Associated projects** FastTab.

Forecasts, work orders, and projects

08/13/2025

In Asset Management, integration with the **Project management and accounting** module helps optimize cost control, so that users can track costs on maintenance job type forecasts and work order jobs.

Tracking of maintenance job type forecasts requires two settings:

1. Select a project in **Asset management** > **Setup** > **Asset management parameters**, and then, on the **Assets** tab, on the **Project** FastTab, in the **Maintenance forecast project** field, select a project.
2. When you create a maintenance job type default line, an activity number is automatically created for the line on the **Maintenance job type defaults** page (**Asset management** > **Setup** > **Jobs** > **Maintenance job type defaults**).

Maintenance job type forecasts serve two purposes:

- You can track costs on maintenance job type forecasts in the **Project management and accounting** module.
- Forecasts are automatically transferred to a work order job project when you select a maintenance job type on a work order job.

To track costs on work order jobs, you must first set up work order projects. Learn more in Work order project setup.

Work order job projects

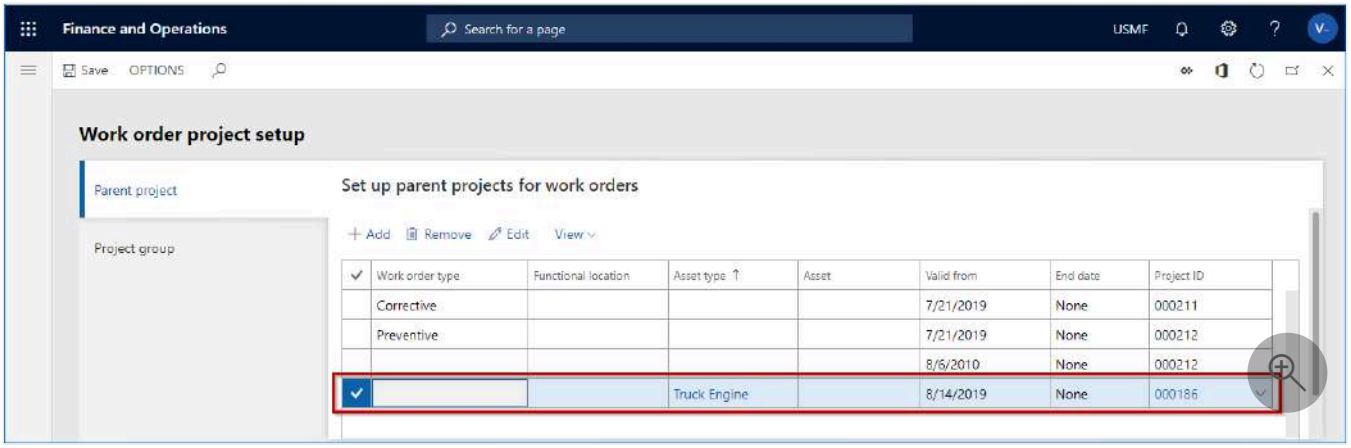
When you create a work order job on a work order, the work order project is determined by the setup of the parent project for work orders on the **Work order project setup** page (**Asset management** > **Setup** > **Work orders** > **Project setup**).

Work order job projects are created by using a combination of the following work order information:

- The work order type selected on the work order
- The functional location related to the asset on the work order job
- The asset type that is related to the asset on the work order job
- The expected start and end times that are set on the work order

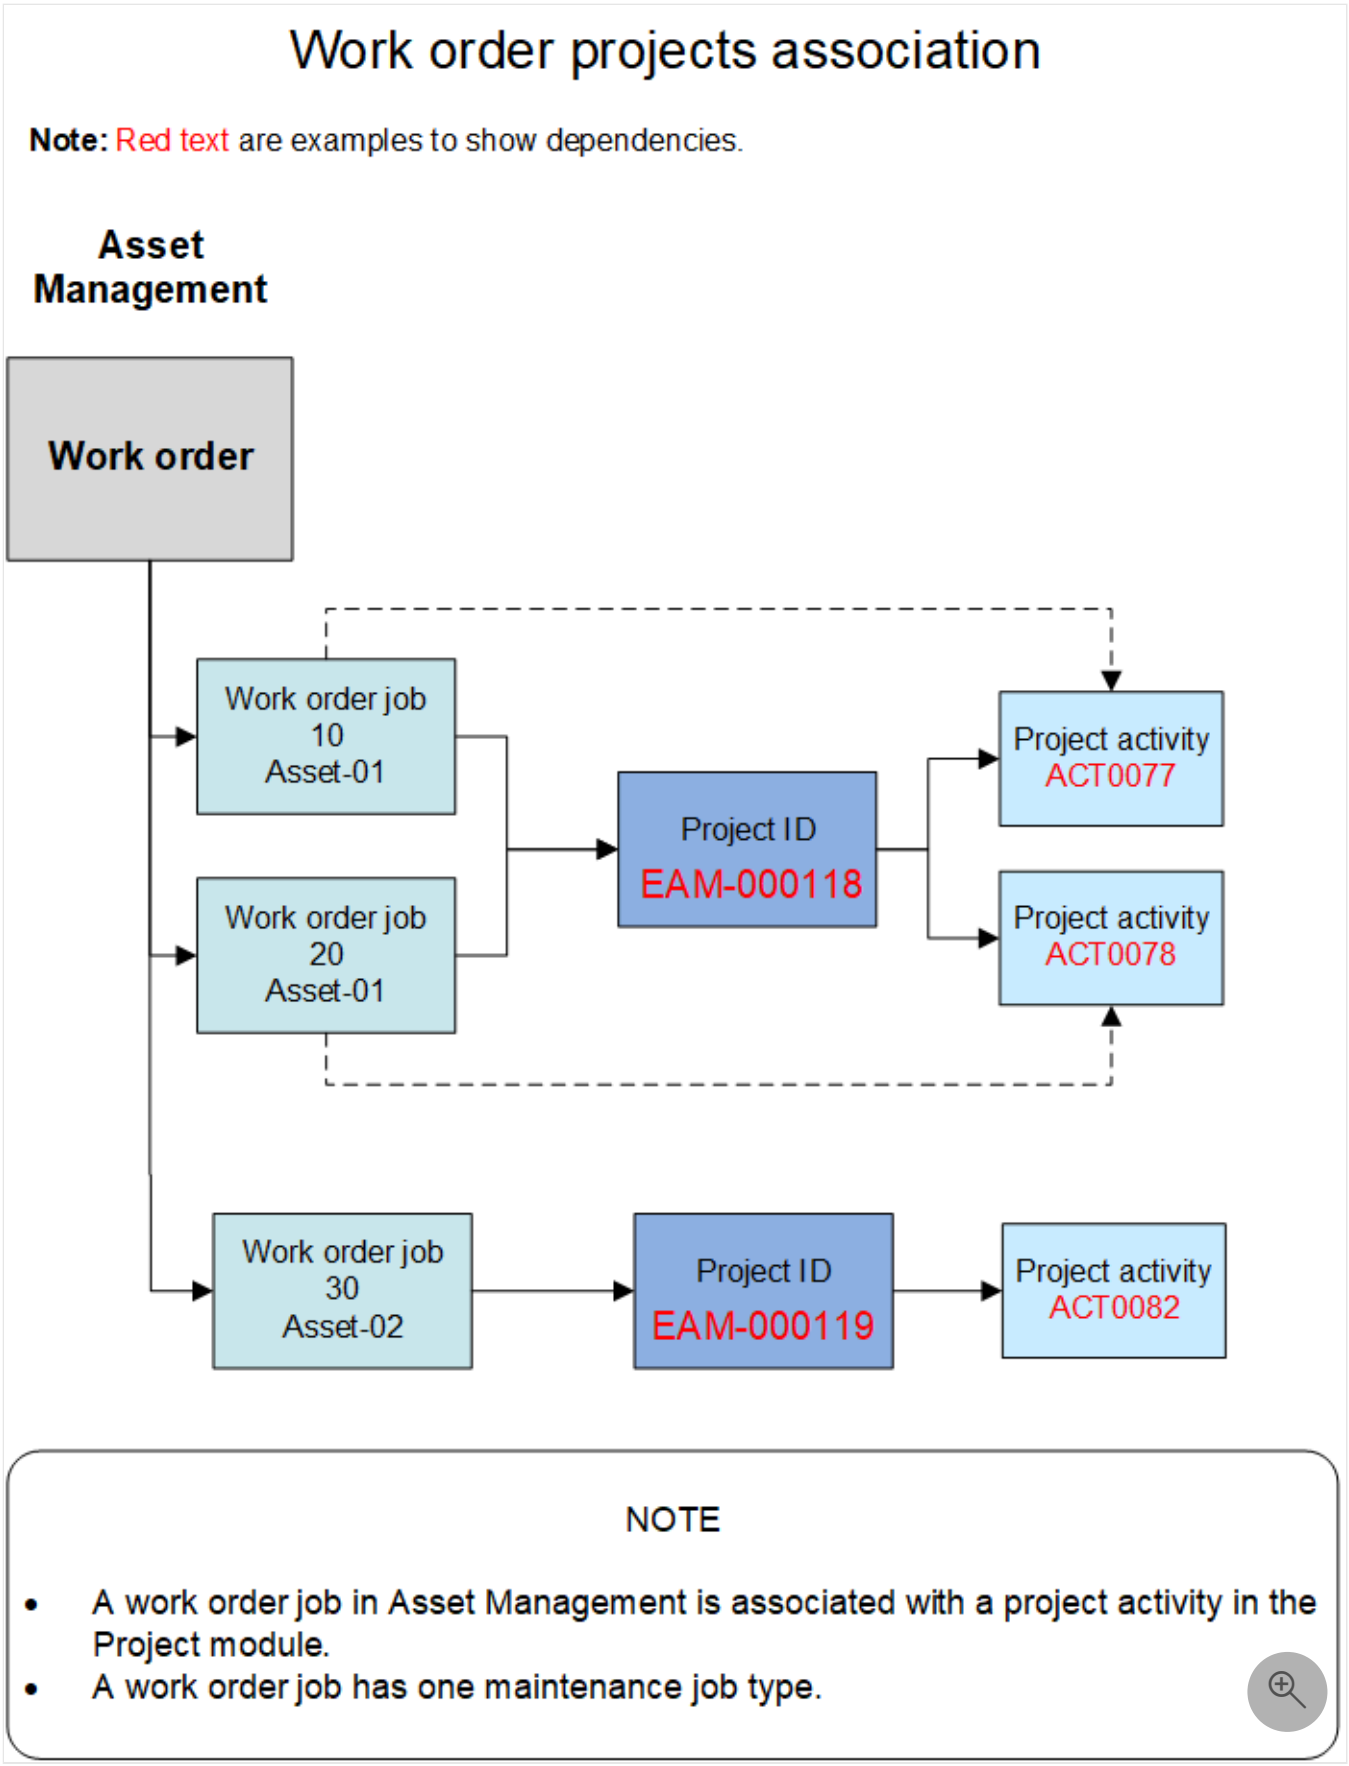
Some of this information might not be found on a work order. Therefore, the search for a work order parent project is done by using the available combination of data and selecting the project ID that corresponds to work order data.

For example, in the following illustration, because of the way that the *Truck Engine* asset type is set up, every work order job that is created with the *Truck Engine* asset type will be a sub-project of project ID 000186.



The purpose of the project ID on the work order job, and the related activity number, is to track costs that are related to the work order job, and the asset that is selected on it, in the **Project management and accounting** module. (To view the project ID and activity number, select **Asset management** > **Work orders** > **All work orders**, and then select the work order. On the **Line details** FastTab, the **Project ID** field shows the project ID, and the **Activity number** field shows the activity number.) For more information about cost control in Asset Management, see Cost and date control.

The following illustration shows a graphical overview of work order projects and related project activities.



When a new work order job is created on a work order, a work order project is automatically created for the job. The financial dimensions for the asset that is related to the work order job are automatically transferred to the work order project.

The project activity that is created for a work order job has related information attached to it. This information is about the maintenance job type, maintenance job type variant, and trade.

It's useful if, for example, you create a purchase order from a work order (see Procurement), or if you use the **Project management and accounting** module for time registration.

If the asset was installed on a functional location but is later installed on a different functional location, the financial dimensions that are related to the new functional location are automatically updated on the asset. Then, when you create a work order job for the asset, the work order project for the work order job automatically gets the financial dimensions that are now related to the asset. Therefore, when you use functional locations, costs can always be tracked on the functional locations that an asset was installed on at any given time. The automatic update of financial dimensions helps guarantee complete traceability of costs for project control and reporting.

Work order projects, work order lifecycle states, project stages, and project types

To help guarantee that work order lifecycle states and related project stages on work orders are used correctly, consider the dependencies in relation to the **Project management and accounting** module:

- In the **Project management and accounting** module, project stages are set up on project types on the **Project management and accounting parameters** page.
- On the **Project management and accounting parameters** page, use the check boxes to select relevant project stages for all the project types that you'll use. In the following illustrations, five stages (**Created**, **Estimated**, **Scheduled**, **In process**, and **Finished**) have been selected for the **Time and material** and **Internal** project types. Those five stages are relevant to both internal maintenance jobs and service maintenance jobs.
- In the **Asset Management** module, project types are defined by the project groups that you set up on the **Work order project setup** page > **Project group** tab (**Asset management** > **Setup** > **Work orders** > **Project setup**).
- The project groups that are set up on the **Work order project setup** page are used when you create work orders. When a work order is created, a work order project is automatically created for the work order.
- Every work order lifecycle state must have a related project stage.
- The project stage that is related to a work order lifecycle state must be defined as an active stage for the project group that is defined in the work order project. The work order project is automatically created on a work order.
- When you create a new work order, the automatic allocation of a work order project is based on the setup on the **Work order project setup** page.

The following illustrations show the associations between work order project groups, related project types, project stages, and work order lifecycle states.

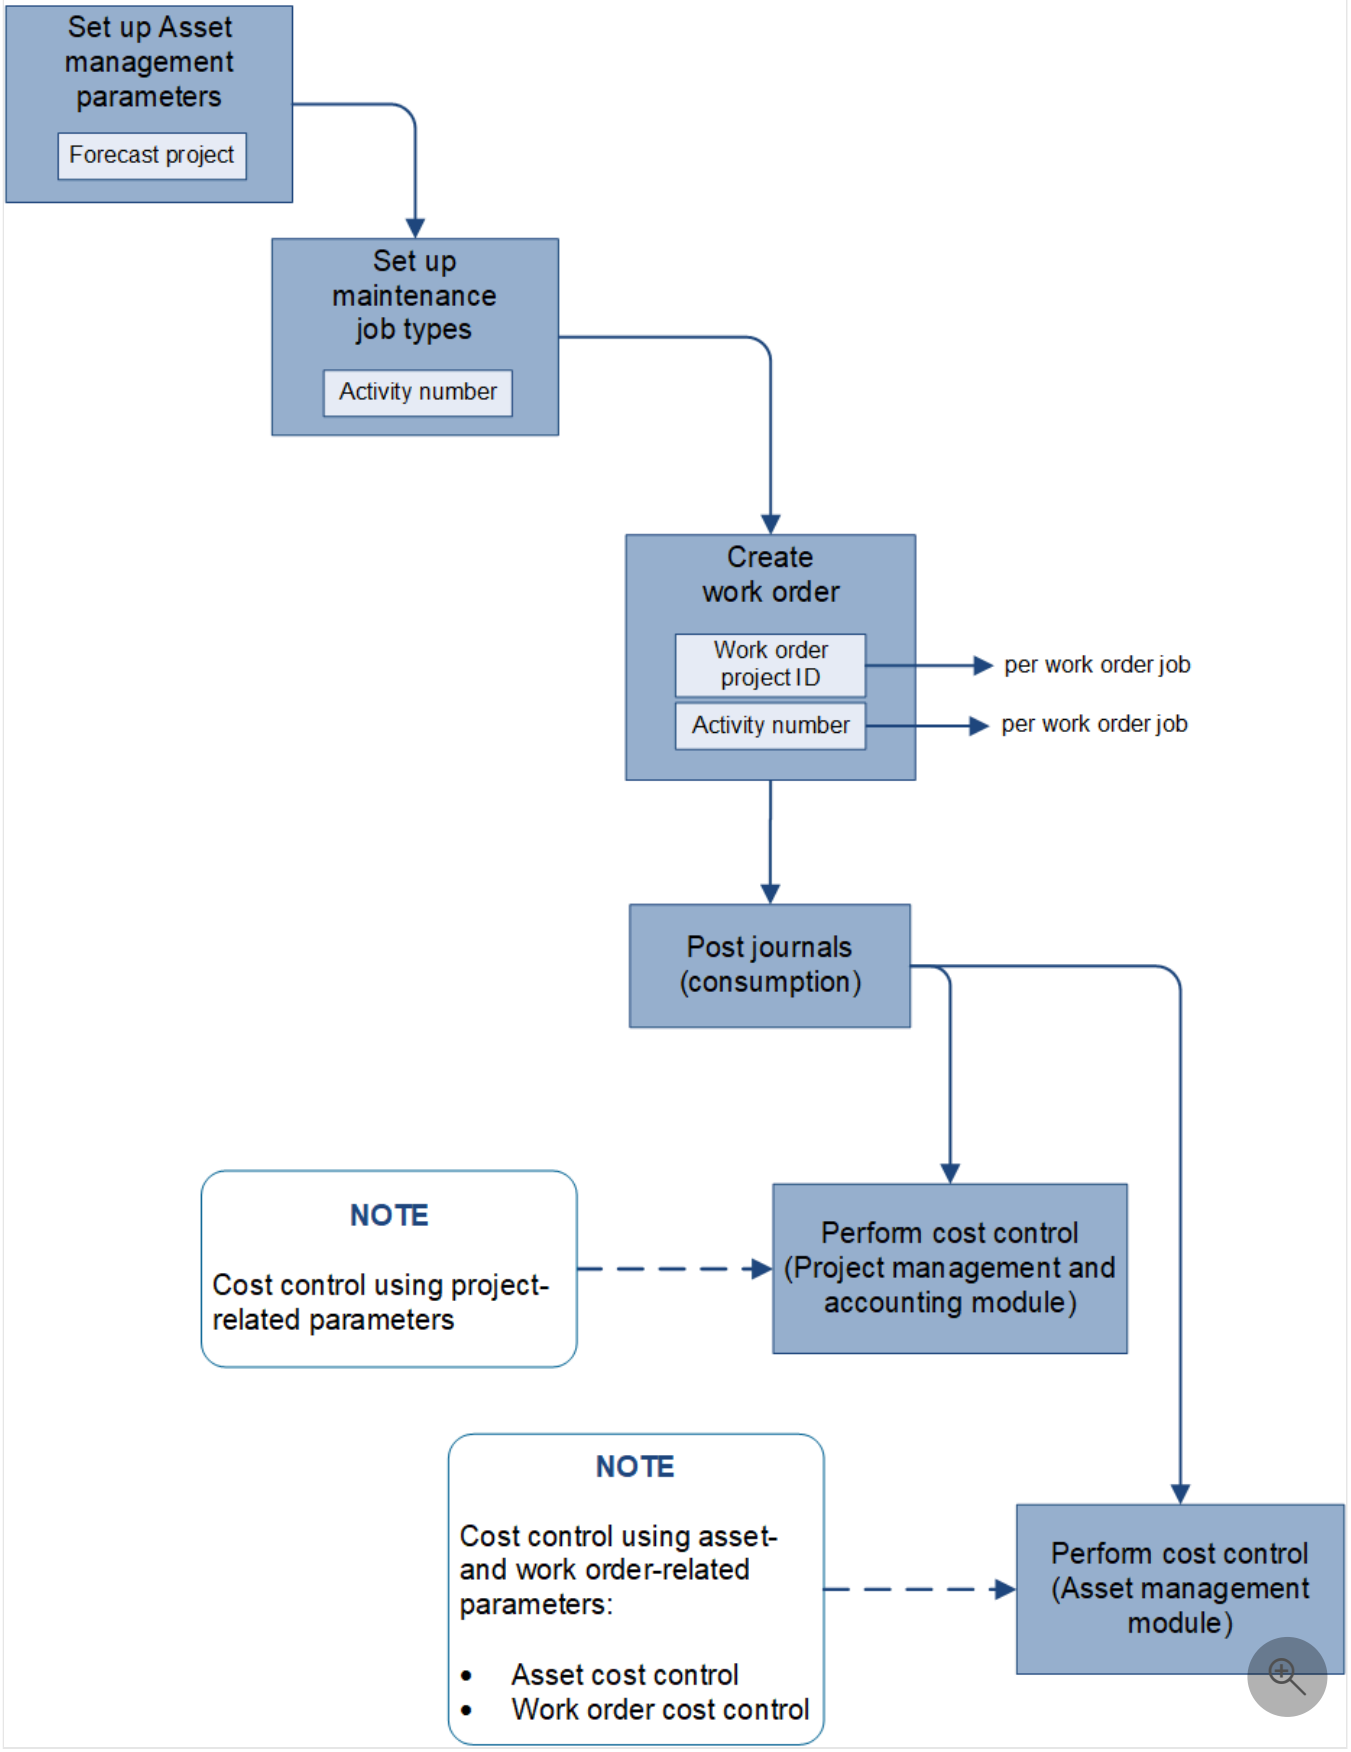
The following illustration shows a graphical overview of the various projects that are created in the **Asset management** module to enable integration with the **Project management and accounting** module. It also shows the work processes that the projects are related to.

Project Integration - Flow Diagram



Bill for maintenance on customer-owned assets

The *Work order billing* feature lets you create, process, and bill maintenance work that is done on assets that your customers own. This feature lets you perform the following tasks:

- Connect customers to the assets that they own.
- Select a customer and view the assets that customer owns when you create a work order.
- Set up a parent project for each customer.
- Register hours, items, expenses, and fees against the work order, and then create an invoice proposal for the customer later.
- Check customer credit limit before dispatching a work order.

In addition, the feature provides the following functionality:

- The project contract from a customer's parent project is automatically copied to the relevant work order project.
- Asset management can now use the *fee* project transaction type on both work order forecasts and work order journals.

Turn the work order billing feature on or off

To use the work order billing feature, it must be turned on for your system. As of Supply Chain Management version 10.0.32, this feature is mandatory and can't be turned off. If you're running a version older than 10.0.32, then admins can turn this functionality on or off by searching for the *Work order billing* feature in the **Feature management** workspace.

Example scenario

To learn how this feature works, work through the following example scenario.

To work through this scenario by using the sample records and values that are specified here, you must be on a system where the standard demo data is installed. You must select the **USMF** legal entity before you begin.

You can also use this scenario as guidance for using the feature when you work on a production system. However, in that case, you must substitute your own values, and you might be missing some types of required records that the standard demo data provides.

Step 1: Create a new project contract for the customer

1. Go to **Project management and accounting** > **Projects** > **Project contracts**.
2. On the Action Pane, select **New**.
3. In the **New project contract** dialog box, set the following values:
    - **Name:** *Pelican Wholesales*
    - **Funding type:** *Customer*
    - **Funding source:** *US-013* (*Pelican Wholesales*)
4. Select **OK**.

Step 2: Create a new parent project for the customer

The parent project that you create here will be used when work orders for the customer are created.

1. Go to **Project management and accounting** > **Projects** > **All projects**.
2. On the Action Pane, select **New**.
3. In the **New project** dialog box, set the following values:
    - **Project type:** *Time and material*
    - **Project name:** *Pelican Wholesales work orders*
    - **Project group:** *TM*
    - **Project contract ID:** *Pelican Wholesales* (the contract that you created earlier)
    - **Start date:** Select today's date.
4. Select **Create project**.
5. The new project is opened. Make a note of the **Project ID** value. You will have to enter it later.

Step 3: Create a new work order type in Asset management

1. Go to **Asset management** > **Setup** > **Work order** > **Work order types**.
2. On the Action Pane, select **New**.
3. A new record is added to the list. Set the following values for it:

- **Work order type:** *Service*
- **Name:** *Service work orders*
- **Work order lifecycle state:** *Standard*

Step 4: Link the customer account to the parent project

You must now link the customer account to the parent project in the project setup in Asset management.

1. Go to **Asset management** > **Setup** > **Work orders** > **Project setup**.
2. On the **Parent project** tab, select **Add** to add a line.
3. On the new line, set the following values:
    - **Customer account:** *US-013* (*Pelican Wholesales*)
    - **Project ID:** Enter the project ID that you made a note of earlier.

Step 5: Link the project group and type to the work order project

You should still be on the **Project setup** page (**Asset management** > **Setup** > **Work orders** > **Project setup**).

1. On the **Project group** tab, select **Add** to add a line.
2. On the new line, set the following values:
    - **Work order type:** *Service* (the work order type that you created earlier)
    - **Project group:** *TM*

> ⓘ **Note**
>
> The project contract on the work order project is always inherited from the parent project.

Step 6: Link an asset to the customer ID

1. Go to **Asset management** > **Assets** > **Active assets**.
2. In the **Filter** field, enter *VE-102*, and select to filter by **Asset**.
3. Select the asset to open its settings.

4. On the **Customer** FastTab, set the **Customer account** field to *US-013* (*Pelican Wholesales*).

   The **Name** field is automatically updated to *Pelican Wholesales*.

Step 7: Create a new work order on the asset

1. Go to **Asset management** > **Work orders** > **Active work orders**.
2. On the Action Pane, select **New**.
3. In the **Create work order** dialog box, set the following values:
   - **Work order type:** *Service*
   - **Description:** *Repair Truck*
   - **Customer account:** *US-013* (*Pelican Wholesales*)
   - **Asset:** *VE-102*

     > ⓘ **Note**
     >
     > The lookup shows only assets that are linked to the selected customer account.

   - **Maintenance job type:** *Repair*
   - **Trade:** *Mechanic*
   - **Service level:** *4*
4. Select **OK**.

Step 8: Review the work order and start to work on it

In this section, you will work on the work order that you created in the previous section.

1. Follow these steps to verify that the parent project is the *Pelican wholesales Work order* project:
   a. In the **Work order maintenance jobs** section, select a line.
   b. On the **Line details** FastTab, inspect the **Project ID** value. It should be a hyphenated number in the form <*Parent-Project-ID*>-<*Project-ID*>. This value is a link.
   c. Select the project ID link to open a page where you can view the parent project and project names.

2. On the Action Pane, on the **Work order** tab, in the **Lifecycle state** group, select **Update work order state**.
3. In the **Update work order state** dialog box, in the **Select** column, select the check box for the row where the **Lifecycle state** field is set to *In progress*.
4. Select **OK**.
5. In the **Lifecycle state: InProgress** dialog box, select **OK**.

Step 9: Post the hours that were spent on the work order and create a new invoice proposal

In this section, you will continue to work on the work order that you worked on in the previous section.

1. On the Action Pane, on the **Work order** tab, in the **Project** group, select **Journals**.

   The **Work order journals** page appears. Here, you can register the time that you spent on the work order.
2. On the **Hours** FastTab, select **Add line**.
3. On the new, line, set the **Hours** field to *4*.
4. On the Action Pane, select **Post journals**.
5. Close the **Work order journals** page to return to the work order.
6. On the Action Pane, on the **Invoicing** tab, select **New invoice proposal**.
7. In the **Create invoice proposal** dialog box, in the **Project transactions** section, select the **Select** check box for every line that you want to invoice.
8. Select **OK** to close the dialog box and view the new invoice proposal.

Credit limit check

The credit limit check feature checks work order dispatches to confirm whether a forecasted work order will cause the customer to exceed their credit limit. If the credit limit is exceeded, a warning or error is triggered based on the feature's configuration.

Each customer's total outstanding credit is calculated as the sum of outstanding sales orders and project credit (work orders accrue toward project credit).

Prerequisites

To use the credit limit feature, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.44 or later.
- The feature named *Credit limit check on work order dispatch* must be turned on in feature management. As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.

Configure the credit limit check

To configure the credit limit check, follow these steps:

1. Go to **Asset Management** > **Setup** > **Asset management parameters**.
2. Open the **Work orders** tab.
3. Make the following settings on the **Credit limits** FastTab.

    - **Credit limit check on work order dispatch** – Set to *Yes* to turn on the credit limit check.
    - **Message when exceeding credit limit** – Choose what to do to if the limit is exceeded. Select one of the following values.
        - *Warning* – Display a warning but allow the user to override the warning and proceed with dispatching the work order.
        - *Error* – Display an error and block the user from dispatching the order.

Set customer credit limits

To set the credit limit for a customer, follow these steps:

1. Go to **Credit and collections** > **Customers** > **All customers**.
2. Select and open a customer record (if you're following the examples provided previously, you could choose *US-013* (*Pelican Wholesales*)).
3. On the **Credit and collections** FastTab, enter the customer's credit limit in the **Credit limit** field.
4. On the Action Pane, select **Save**.

Integrate asset management with fixed assets

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

By integrating the **Asset management** and **Fixed assets** modules, you can link fixed assets with maintenance assets. Fixed assets users can then create a maintenance asset from a new or existing fixed asset, and Asset management users can associate a maintenance asset with an existing fixed asset. This feature also makes it easy for Fixed assets users to view the costs that were posted from work orders for related maintenance assets.

> **Note**
>
> In this article, *maintenance assets* refer to assets from the **Asset management** module, and *fixed assets* refer to assets from the **Fixed assets** module.

Set a default location for new maintenance assets that are created from fixed assets (optional)

This optional configuration lets you set a default functional location for new maintenance assets that are created from fixed assets. You typically complete this configuration this just one time, if you complete it at all.

To complete the configuration, follow these steps:

1. Go to **Asset management** > **Setup** > **Asset management parameters**.
2. On the **Fixed assets** tab, in the **Functional location** field, select the default location.
3. On the Action Pane, select **Save**.

Work with integrated maintenance assets and fixed assets

This section provides a collection of procedures that show various ways that you can work with the integrated Asset management and Fixed assets features.

Associate an existing maintenance asset with a fixed asset

To associate an existing maintenance asset with a fixed asset, follow these steps:

1. Go to **Asset management** > **Assets** > **All assets** (or **Active assets**).
2. Select an asset.
3. On the **Fixed asset** FastTab, in the **Fixed asset number** field, select an existing fixed asset.
4. On the Action Pane, select **Save**.

View the fixed asset that is associated with a selected maintenance asset

To view the fixed asset that is associated with a selected maintenance asset, follow these steps:

1. Go to **Asset management** > **Assets** > **All assets** (or **Active assets**).
2. Select an asset.
3. On the **Fixed asset** FastTab, in the **Fixed asset number** field, select the link.

   The **Fixed assets** page for the selected asset is opened. (Typically, this page is found at **Fixed assets** > **Fixed assets** > **Fixed assets**.)

View the maintenance asset that is associated with a selected fixed asset

To view the maintenance asset that is associated with a selected fixed asset, follow these steps:

1. Go to **Fixed assets** > **Fixed assets** > **Fixed assets**.
2. Select an asset.
3. On the Action Pane, on the **Asset management** tab, in the **View** group, select **Maintenance asset**.

   The **Maintenance asset** page for the asset that is associated with the selected fixed asset is opened. (Typically, this page is found at **Asset management** > **Assets** > **All assets**.)

View maintenance costs that are associated with a fixed asset

Asset management work orders can be posted for maintenance assets, and each of those work orders typically has a cost. When a fixed asset is associated with a maintenance asset, you can go directly from the fixed asset to view the related costs.

To view the maintenance costs that are associated with a fixed asset, follow these steps:

1. Go to **Fixed assets** > **Fixed assets** > **Fixed assets**.
2. Select an asset.
3. On the Action Pane, on the **Asset management** tab, in the **View** group, select **Maintenance cost**.

   The **Maintenance cost** page is opened and shows the related costs.

Create a new maintenance asset for an existing fixed asset

To create a new maintenance asset for an existing fixed asset, follow these steps:

1. Go to **Fixed assets** > **Fixed assets** > **Fixed assets**.
2. Select an asset.
3. On the Action Pane, on the **Asset management** tab, in the **New** group, select **Create maintenance asset**. (If this option is unavailable, a maintenance asset might already be associated with the selected fixed asset.)
4. Finish creating the asset as described in Create an asset.

Create a new fixed asset and add a new maintenance asset for it

To create a new fixed asset and add a new maintenance asset for it, follow these steps:

1. Go to **Fixed assets** > **Fixed assets** > **Fixed assets**.
2. On the Action Pane, select **New**.
3. Finish creating the fixed asset as described in Create a fixed asset.
4. On the Action Pane, on the **Asset management** tab, in the **New** group, select **Create maintenance asset**.
5. Finish creating the asset as described in Create an asset.

Remove the association between two assets

In some cases, you might have to disassociate a maintenance asset from its fixed asset. For example, if you want to create a new maintenance asset from a fixed asset, you must first remove any existing association.

To remove an existing association between a maintenance asset and a fixed asset, follow these steps:

1. Go to **Asset management** > **Assets** > **All assets** (or **Active assets**).
2. Find and open the maintenance asset.
3. On the **Fixed asset** FastTab, clear the value from the **Fixed asset number** field.
4. On the Action Pane, select **Save**.

Preventive maintenance overview

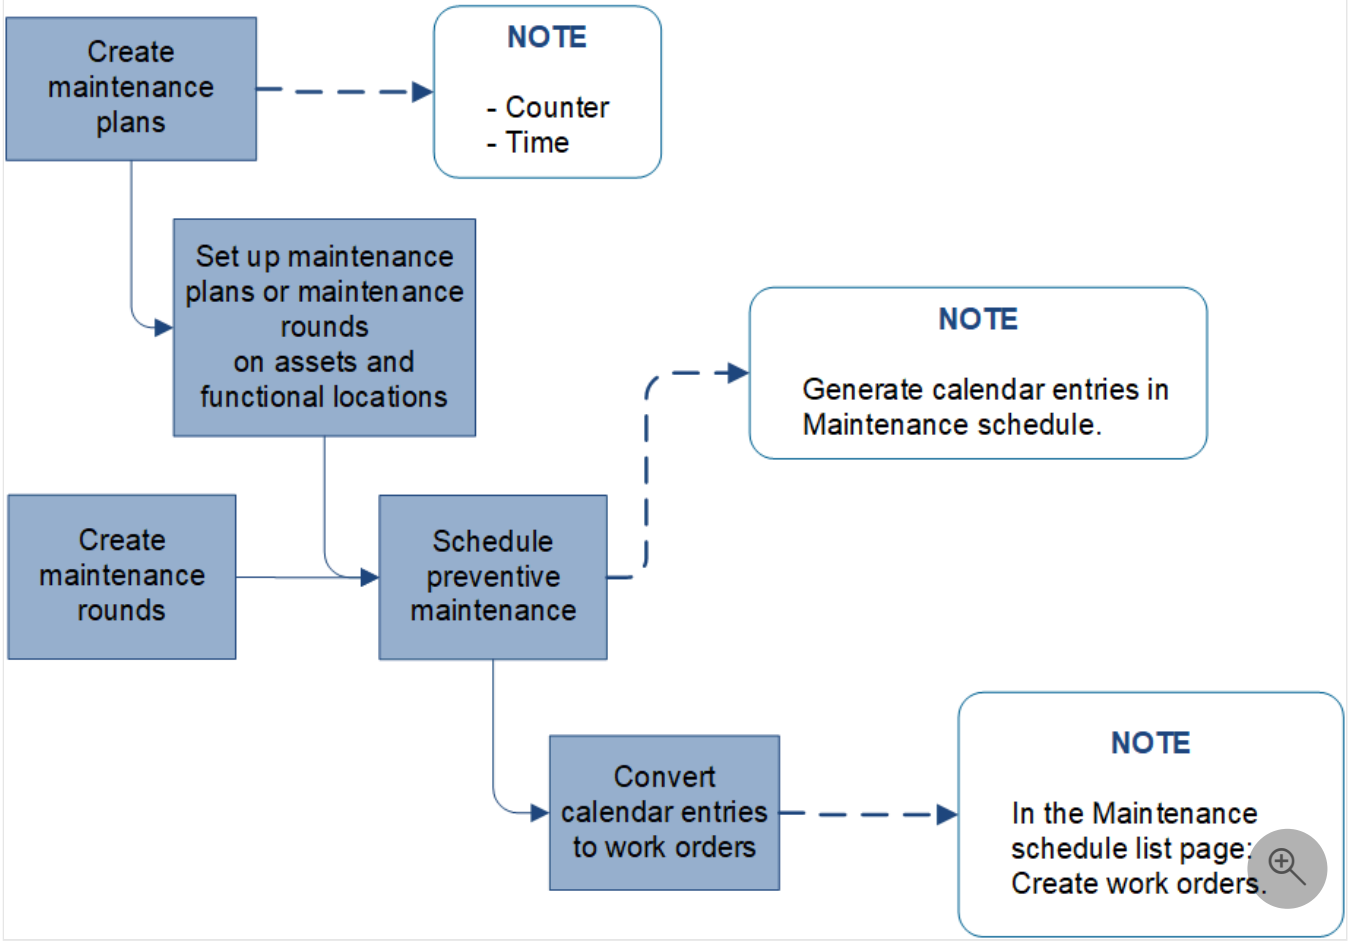
08/12/2025

This article explains preventive maintenance in Asset Management. Preventive maintenance is a discipline involving planned maintenance jobs, for example, regular service, calibration, and inspections. In Asset Management, you can create maintenance plans and set them up on assets and functional locations. You can also set up maintenance rounds on functional locations. Maintenance plans on assets are active regardless of where the asset is installed. Maintenance plans and maintenance rounds on functional location are active for the assets currently installed at the location. Instead of setting up maintenance plans on assets, or setting up maintenance rounds on functional locations, you can create maintenance rounds that include multiple assets on which you need to perform related types of maintenance jobs in the same work routine. Maintenance rounds created from assets (instead of on functional locations) let you select several assets for one maintenance round, even if they aren't installed on the same functional location.

Maintenance plans are used for preventive maintenance on individual assets. Maintenance rounds are used for preventive maintenance on a group or a set of assets. Maintenance plans and maintenance rounds are used for generating work order proposals. The work order proposals are saved as maintenance schedule lines, which can be bundled and converted into work orders.

The following illustration provides an overview of the work flow from creating maintenance plans and maintenance rounds to creating work orders for assets, based on those maintenance plans and maintenance rounds.

Flow Diagram: Schedule Preventive Maintenance Work Orders



Maintenance plans

07/10/2025

A maintenance plan defines when a pre-planned preventive maintenance job is to be carried out on an asset. Maintenance plans can be related to assets, asset types, functional locations, or functional location types, but first you create the maintenance plans to be used in your company.

A maintenance plan can have multiple maintenance plan lines. Maintenance job type and interval are specified on the maintenance plan line. There are two types of maintenance plan lines:

- Time
- Counter

Maintenance plan lines of type "Time" are used for recurring planned maintenance based on a fixed time interval. Maintenance plan lines of type "Counter" are used for planned maintenance or reactive maintenance based on asset counter registrations. A maintenance plan may include several maintenance plan lines of both types.

> ⓘ **Note**
>
> If no counter values have been registered for a counter type on an asset, the maintenance plan lines are omitted.

First, you create the maintenance plans you require for your preventive maintenance jobs and select the asset types, assets, functional location types, and functional locations that should be related to each maintenance plan. Afterwards, if required, you can also add maintenance plans to an asset or a functional location, which is done in **All assets** > select asset > **Asset maintenance plans** FastTab, or **All functional locations** > select functional location > **Maintenance plans** FastTab.

If you add a maintenance plan to asset types or functional location types, it means that when you create new assets or functional locations with those asset types or functional location types, the asset or functional location will automatically be added to the maintenance plan. The start date of the relation to a maintenance plan will be the current date, which may need to be adjusted.

Set up maintenance plans

This section describes how to set up maintenance plan lines and provides examples of how they can be used.

1. Go to **Asset management** > **Setup** > **Preventive maintenance** > **Maintenance plans**.
2. Select **New** to create a new sequence.
3. Insert an ID in the **Maintenance sequence** field, and a name in the **Name** field.
4. In the **Plan date** field, insert the start date from which planning can be done on the maintenance plan. Note that time-based maintenance plan lines may have other plan dates.
5. Select "Yes" in the **Active** toggle button to activate the maintenance plan.

   > ⓘ **Note**
   >
   > If you deactivate a maintenance plan, no schedule posts will be created in the maintenance schedule when you run a schedule maintenance plan job.

6. The **Tolerance days before** and **Tolerance days after** fields relate to maintenance plan lines in which the **Suppress overlapping maintenance jobs** check box is selected (refer to step 17). The "Tolerance" fields are used to extend the interval in days in which, if several maintenance plans overlap, the most comprehensive / largest job is created as a maintenance schedule line during maintenance plan scheduling, while more frequent, overlapping jobs are omitted during maintenance plan scheduling. Insert number of days in the **Tolerance days before** field, for example "2".
7. If you have inserted a value in **Tolerance days before**, also insert number of days in the **Tolerance days after** field, for example "2".

   > ⓘ **Note**
   >
   > The example described in this and the previous step means that if several maintenance plan lines overlap, and **Suppress overlapping maintenance jobs** is selected for one or more lines, the period of omitting maintenance schedule lines is extended to a total of five days (the expected start date on the maintenance schedule line *and* two days before *and* two days after that date).

8. The fields in the **Details** group on the **Details** FastTab show number of maintenance plan lines set up on the maintenance plan, and number of assets and functional locations related to the maintenance plan.

9. On the **Lines** FastTab, select **Add time line** or **Add asset counter line** to create a new maintenance plan line.

10. Insert a description for the line in the **Work order description** field. The description is transferred to related work orders.

11. In the **Maintenance job type** field, select the job type to which the maintenance plan line is related.

12. In the **Maintenance job type variant** and **Trade** fields, select the variant and trade related to the maintenance job type.

13. In the **Finish within days** and **Finish within hours** fields, you can insert expected end date in days or hours. The expected end date is inserted relative to the expected start date, which is calculated when maintenance schedule lines are created. For example, you can insert "7" in the **Finish within days** field to indicate that the related job should be completed within a week from the expected start date.

14. In the **Interval type** field, select the type of interval to be used on the maintenance plan line, for example, "Repeated..." or "Once...". Refer to the Interval types overview table below for a description of the relation between interval types and line types.

15. The **Period** field only relates to time-based line types. Select the period type related to the period frequency.

16. In the **Period frequency** field, insert the number of times the line should be used for planning preventive maintenance jobs. Example: If you have created a line of type "Counter", and your counter is production quantity, and you insert the number "20000" in this field, new maintenance sequence lines are created during preventive maintenance scheduling every time you are expected to produce 20,000 more items.

17. The **Suppress overlapping maintenance jobs** check box relates to time-based as well as counter-based line types. Select the check box to delete maintenance schedule entries that are created on the same date. This is relevant if, for example, you have created a 1-month inspection line, a 6-month inspection line, and a 1-year inspection line. For the 1-year inspection you only want that inspection to be done, not the other two inspections, which would also fit in the time frame. In order to set up this example correctly, you set up the 1-year inspection line as the first line, the 6-month line as the second line, and the 1-month line as the third line, and you select the **Suppress overlapping maintenance jobs** check box for the 1-month and 6-month lines. That way you ensure that when you reach the 1-year mark, the inspections for one month and six months are omitted, and a maintenance schedule line is only created for the 1-year inspection line.

> **Note**
>
> The example described in this step shows that the most comprehensive job, which contains the largest number of tasks, and which is not done so often, should always be inserted as the first line. The more frequent jobs are then inserted as separate lines in the order of frequency, placing the most frequent job at the bottom of the list.

18. The **Counter** field only relates to counter-based line types. Select the counter type to be used on the line. If a counter type isn't active on a related asset, the maintenance plan line is omitted.

19. The **Asset counter time fence in days** field only relates to counter-based line types. Insert a number that defines how many days back counter registrations are checked when maintenance plan scheduling is done. This means how far back are data (existing counter registrations) used as basis for calculating the trend that determines how many maintenance schedule lines are created.

    > *Example:* If counter registrations are expected to be made once a month, you may insert the number '365' in this field because maintenance plan scheduling will always be based on the last 12 months and therefore create maintenance schedule lines based on the trend of the past year. On the other hand, if you insert the number '10' in this field, you expect counter registrations to be made more often, for example, on a daily basis. This means that when you schedule maintenance plan, counter registrations for the last 10 days are used as the basis for the scheduling of maintenance schedule lines.

20. The **Plan date** field only relates to time-based line types. If the maintenance plan line has another planning date than the entire maintenance plan, select a date in the **Plan date** field on the line.

21. In the **Service level** field, you can select a work order service level as a further delimitation on the maintenance plan line - to be used as a service level on work orders.

22. Select the **Auto create** check box if you want a work order to be automatically created according to the selected maintenance plan line when scheduling maintenance plans.

23. If you have selected the **Auto create** check box, you can select a work order type for the autocreated work order in the **Work order type** field. If you have selected the **Auto create** check box, and you don't select a work order type in this field, the work order type

selected in **Asset management** > **Setup** > **Asset management parameters** > **Work orders** link > **Preventive work order type** field is used.

24. Use the **Season from** and **Season to** fields to create a repeated time-based maintenance plan line within a 12-month period. *Example:* Equipment used for maintaining green areas requires service each spring within a predefined period. Insert the start date of the period to be repeated in the **Season from** field.

25. Insert the end date of the period to be repeated in the **Season to** field.

26. In the **Resulting period** field, the current period to be repeated is shown. When the current period has passed, and you start a new year, the period shown in this field will be updated to reflect the next period in the repeat sequence.

27. On the **Assets** FastTab, select the assets that should be related to the maintenance plan.

28. On the **Asset types** FastTab, select the asset types that should be related to the maintenance plan.

29. On the **Functional locations** FastTab, select the functional locations that should be related to the maintenance plan. If necessary, you can make the setup more specific by selecting a related asset type, manufacturer, and model.

30. On the **Functional location types** FastTab, select the functional location types that should be related to the maintenance plan.

> **Note**
>
> When work orders are manually created on assets that are covered by a vendor warranty, a dialog box is shown to make the user aware of the warranty. The creation of the work order can then be canceled. The check for a warranty relation is omitted for work orders that are automatically created.

Interval types overview

Expand table

Interval type and description	Line Type: Time	Line Type: Counter
Interval type: Repeated from plan date The count starts from the plan date used. When you schedule maintenance plans, maintenance	The **Plan date** on the maintenance plan line is used. If no plan date is selected on the line, the	The **Plan date** for the maintenance plan is used. If the counter has been replaced, the latest replacement date is used as the plan date.

Interval type and description	Line Type: Time	Line Type: Counter
schedule lines are created when the interval is reached.	**Plan date** for the maintenance plan is used. Example: If the number "3" is inserted in the **Period frequency** field, and "Year" is selected in the **Period** field, a new maintenance schedule line will be created once every 3 years.	
Interval type: Repeated from start date The count starts from the start date on the asset relation. The date is selected in the **All asset** details view > **Asset maintenance plans** FastTab > **Start date** field, or in the **All functional locations** details view > **Maintenance plans** FastTab > **Start date** field. When you schedule maintenance plans, a maintenance schedule line is created when the interval is reached.	The start date of the maintenance plan line on asset or functional location is used. If that field is blank, the **Plan date** for the maintenance plan is used.	The start date of the maintenance plan line on asset or functional location is used. If that field is blank, the **Plan date** for the maintenance plan is used.
Interval type: Repeated from last work order The count starts from the actual end date and time of the latest work order that was completed on the asset with that specific maintenance job type / maintenance job type variant / trade combination. That date and time are shown in the **Actual end** field in the **All work order** details view.	The actual end date and time of the work order completed on the asset with that specific maintenance job type / maintenance job type variant / trade combination. If no completed work order is found, one of the dates used in the "Repeated from start date" interval type is used instead.	The actual end date and time of the work order completed on the asset *and* the maintenance job type / maintenance job type variant / trade combination. is used. If the end date and time was left blank on the work order, one of the dates used in the "Repeated from start date" interval type is used instead.
Interval type: Once from plan date See description for the "Repeated from plan date" interval type. Only difference is that this interval type is to be used only once.	See description for "Repeated from plan date" interval type. This interval is typically used for a one-time maintenance or service job.	See description for "Repeated from plan date" interval type above. This interval is typically used for a one-time maintenance or service job. **Note 1:** This interval type is only relevant if the counter is replaced every time you carry out a maintenance or service job. If, for some reason, a counter has been replaced before the end of the

Interval type and description	Line Type: Time	Line Type: Counter
		planned interval, a new time is calculated for the job from the time of the counter replacement. **Note 2:** If the counter is replaced when completing the maintenance or service job, this interval type functions as the "Repeated from plan date" interval type.
Interval type: Once from start date See description for the "Repeated from start date" interval type. Only difference is that this interval type is to be used only once.	See description for "Repeated from start date" interval type. This interval is typically used for a one-time maintenance or service job.	See description for "Repeated from start date" interval type. This interval is typically used for a one-time maintenance or service job. **Note 1** above also applies to this interval type. **Note 3:** If the counter is replaced when completing the maintenance or service job, this interval type functions as the "Repeated from start date" interval type.
Interval type: Once reached above This interval type only relates to counters and is used for indicating an upper limit set up on the maintenance plan line. Maintenance schedule entries will have the expected start date and time of the counter registration, meaning these entries will be created with an expected start date equal to or earlier than the system date.	Not applicable	The counter interval indicates an upper limit. If that limit is exceeded when you create a counter registration, a maintenance schedule line is created when you schedule preventive maintenance.
Interval type: Once reached below This interval type only relates to counters and is used for indicating a lower limit set up on the maintenance plan line. Maintenance schedule entries will have the expected start date and time of the counter registration, meaning these entries will be created with an expected start date equal to or earlier than the system date.	Not applicable	The counter interval indicates a lower limit. If that limit is passed when you create a counter registration, a maintenance schedule line is created when you schedule preventive maintenance.
Interval type: Linked from start date This interval type only creates a maintenance schedule line once. A	See description for "Once from start date" above. Example: You create two	See description for "Once from start date" above. Example: You create two lines in a maintenance plan for a

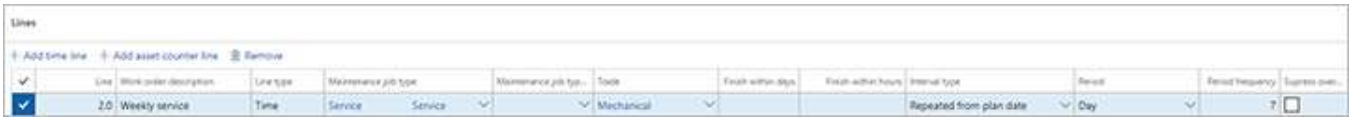
Interval type and description	Line Type: Time	Line Type: Counter
maintenance plan can contain more maintenance plan lines using this interval type, and those lines are linked. Typically, you'll create a maintenance plan that contains lines of only this interval type. Maintenance schedule lines are created by identifying the maintenance plan line that has the first expected start date and time.	lines in a maintenance plan for a service job on a car: one time-based line with a 1-year period, and one counter-based line with a 25,000 km limit. A maintenance schedule line is created for the limit that is reached first. For this line type you create the line with the 1-year period.	service job on a car: one time-based line with a 1-year period, and one counter-based line with a 25,000 km limit. A maintenance schedule line is created for the limit that is reached first. For this line type, you create the line with the 25,000 km limit. Example creating two counter lines: You can also set up a maintenance plan with two linked, counter-based lines in which the first line has a limit of 10,000 items quantity produced, and the second line relates to the machine or work center requiring service after running 3,000 hours.
Interval type: Linked from last work order This interval type only creates a maintenance schedule line once, based on the latest work order completed on the asset that matches the maintenance job type, maintenance job type variant, or trade combination. A maintenance plan can contain more lines using this interval type, and those lines are linked. Typically, you'll create a maintenance plan that contains maintenance plan lines of only this interval type. Maintenance schedule lines are created by identifying the maintenance plan line that has the first expected start date and time.	This interval type basically works as "Linked from start date" described above. Only difference is the date on which the interval type is based. The date used is the actual date and time on the latest work order completed on the asset *and* the maintenance job type / maintenance job type variant / trade combination.	This interval type basically works as "Linked from start date" described above. Only difference is the date on which the interval type is based. The date used is the actual date and time on the latest work order completed on the asset *and* the maintenance job type / maintenance job type variant / trade combination.
Interval type: Repeated on aggregated value (Counter only) When the maintenance plan is run, a scheduled maintenance line will be created each time that the accumulated value for an asset counter reaches the period frequency or an even multiple of the period frequency. (The period frequency is defined on the maintenance plan line.) For more information about how to enable and use this functionality,	Not applicable	**Example:** An hour counter is set up for asset AK-101. An asset plan line is also set up for the asset. The interval type of this line is *Repeated on aggregated value (Counter only)*, and the period frequency is *1000*. When the maintenance plan is run, a scheduled maintenance line will be generated when the aggregated value for the counter exceeds 1,000 hours. Then, when the aggregated value for the counter exceeds 2,000 hours, another scheduled maintenance line will be generated,

Interval type and description	Line Type: Time	Line Type: Counter
see the Counter-based maintenance enhancements section later in this article.		and so on for every additional 1,000 hours.
Interval type: Once on aggregated value (Counter only) When the maintenance plan is run, a scheduled maintenance line will be created when the accumulated value for an asset counter reaches the period frequency that is defined on the maintenance plan line. For more information about how to enable and use this functionality, see the Counter-based maintenance enhancements section.	Not applicable	**Example:** An hour counter is set up for asset AK-101. An asset plan line is also set up for the asset. The interval type of this line is *Once on aggregated value (Counter only)*, and the period frequency is *1000*. When the maintenance plan is run, a scheduled maintenance line will be generated when the aggregated value for the counter exceeds 1,000 hours.

> **Note**
>
> When maintenance schedule lines are created for time-based maintenance plan lines, expected time is always at the start of the day. For counter-based maintenance plan lines, expected time can be anytime during the day.

Here are some examples of how to set up time-based and counter-based maintenance plan lines:

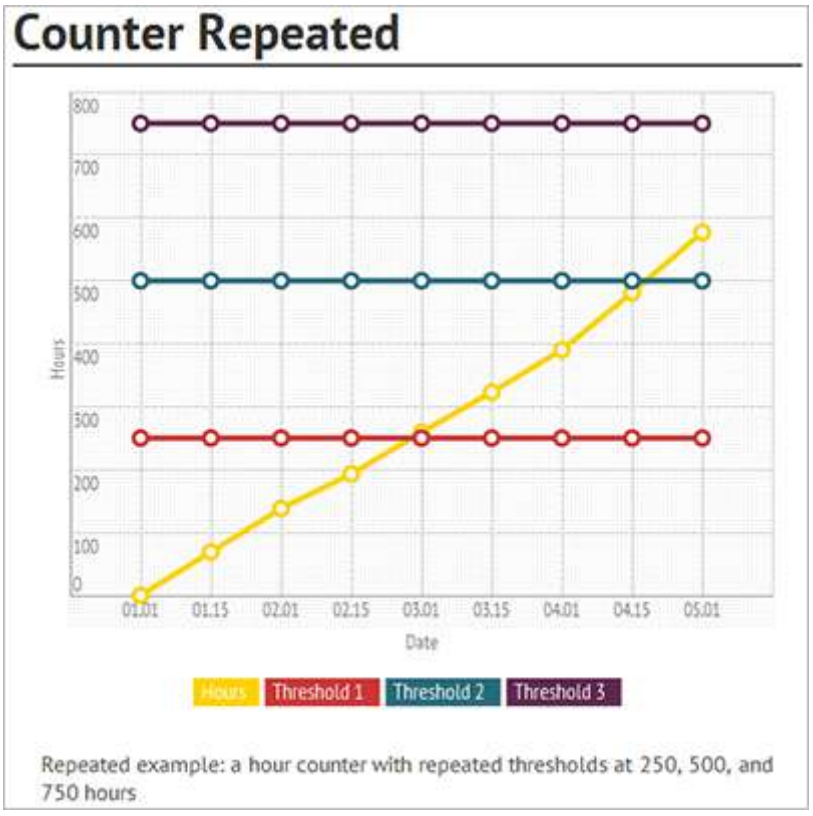
Example 1 - Time-based maintenance plan line: A lubrication job is set up in a fixed interval, occurring once a week. For that purpose, select "Repeated from plan date" in the **Interval type** field. See an example in the following illustration.



Example 2 - Time-based maintenance plan line: An inspection job is set up to be carried out approximately once a week. For that purpose, select "Repeated from last work order" in the **Interval type** field. See an example in the following illustration.

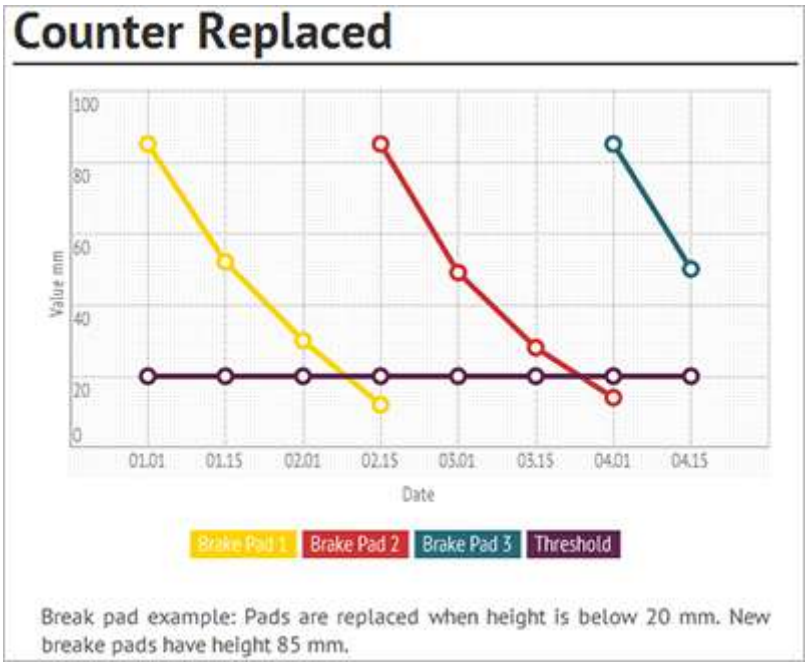
Example 3 - Counter-based maintenance plan line: The following graphic illustration shows an hour counter for which a new maintenance schedule line is created each time 250 hours have

passed. The interval type for this counter-based line is "Repeated from start date". The start date is the start date of the related assets in the **All assets** details view > **Asset maintenance plans** FastTab > **Start date** field, or in the **Functional location** details view > **Maintenance plans** FastTab > **Start date** field. This is an example of a *preventive* maintenance plan because the maintenance schedule line is automatically created each time the threshold (+ 250) is reached.

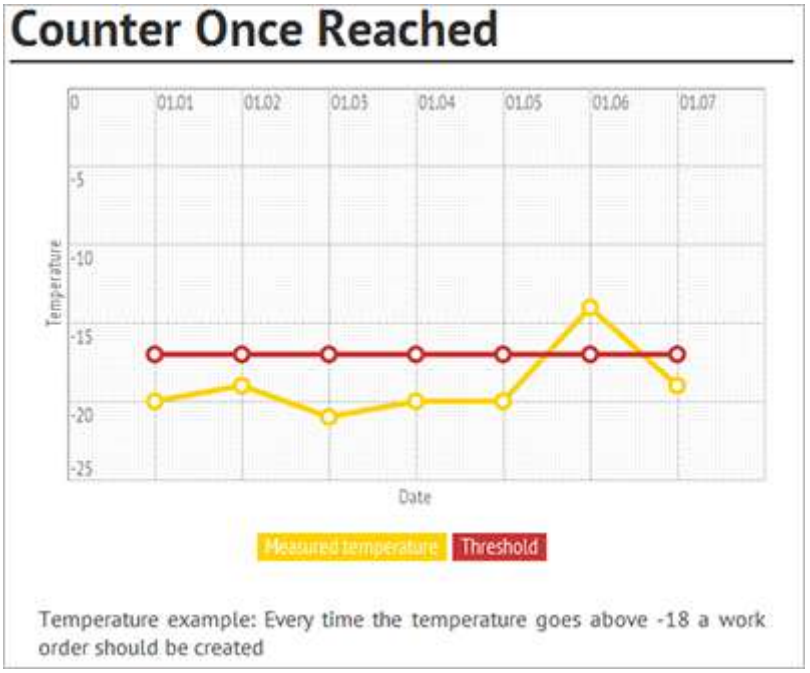


Repeated example: a hour counter with repeated thresholds at 250, 500, and 750 hours

Example 4 - Counter-based maintenance plan line: The following graphic illustration shows a decrease in counter value, measuring brake pad wear. A maintenance schedule line is created when a counter registration below 20 mm is created on the brake pad. The interval type for this counter-based line is "Once reached below" or "Once from last start date". This is an example of a *reactive* maintenance plan because the maintenance schedule line isn't created until a measurement below 20 mm is registered.



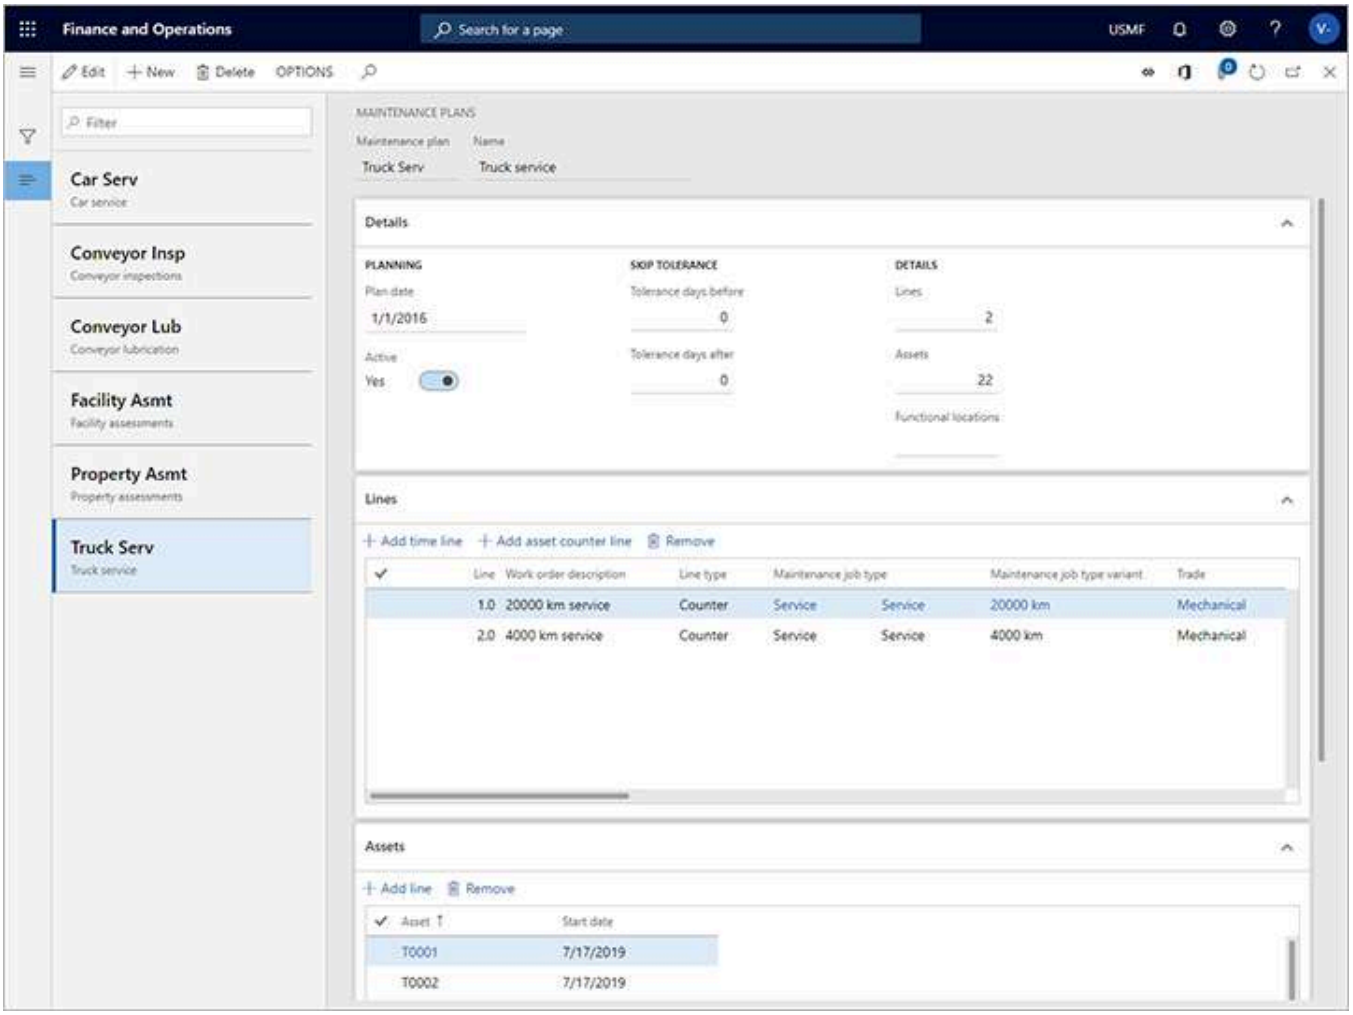
Example 5 - Counter-based maintenance plan line: The following graphic illustration shows a counter with a threshold of -18° Celsius. A maintenance schedule line is created when a counter registration above -18° Celsius is made. The interval type for this counter-based line is "Once reached above". This is an example of a *reactive* maintenance plan because the maintenance schedule line isn't created until a measurement higher than -18° Celsius is registered.



- When you create a new asset, and that asset uses an asset type related to a maintenance plan, the maintenance plan is automatically inserted in **All objects** > **Asset maintenance plans** FastTab. Also, in the **Asset type defaults**, on the **Maintenance plans** FastTab, the related maintenance plans will automatically be inserted.
- If you add or remove asset types or functional location types in **Maintenance plans**, that change will only reflect on new assets created after you made the change.

- If you add or remove assets or functional locations in **Maintenance plans**, that change will automatically be updated in **All assets** > **Asset maintenance plans** FastTab, or in **All functional locations** > **Maintenance plans** FastTab.

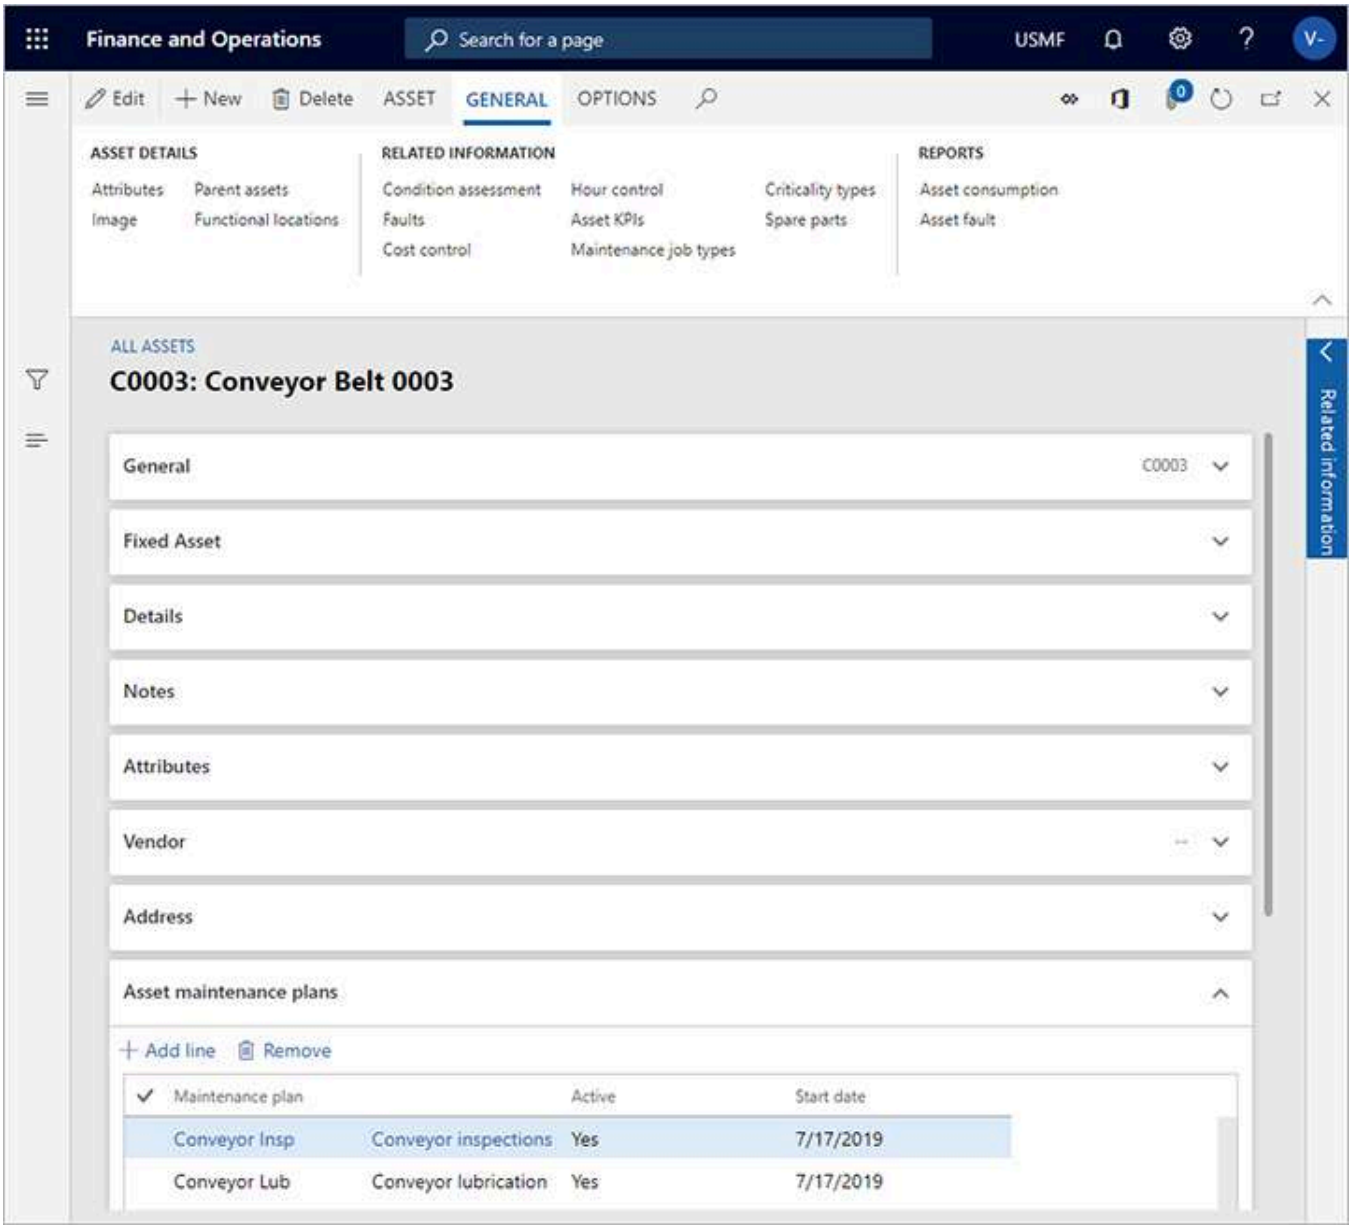
The following illustration shows an example of a "Truck service" maintenance plan on the **Maintenance plans** page.



Add a maintenance plan to an asset

1. Go to **Asset management** > **Common** > **Assets** > **All assets** or **Active assets**.
2. Select the asset on which you want to set up a maintenance plan and select **Edit**.
3. On the **Asset maintenance plans** FastTab, select **Add line** to add a maintenance plan to the asset.
4. In the **Maintenance plan** field, select the relevant maintenance plan.
5. In the **Start date** field, select the date from which planning of preventive maintenance jobs can be done.
6. Select **Save**. The **Active** field is automatically updated.

The following illustration shows an example of maintenance plans set up on an asset on the **All assets** page.



Counter-based maintenance enhancements

The *Counter-based maintenance enhancements* feature introduces the following functionality:

- The option to automatically insert a counter that has a value of *0* (zero) when an asset is created. This option can be useful when you use predictive maintenance that is based on counters. When the *Counter-based maintenance enhancements* feature isn't used, counters that have a value of *0* (zero) must be manually inserted.
- The ability to configure a counter so that it's automatically reset when a work order is completed. This functionality is useful when you want to schedule maintenance based on the aggregated value since the last work order was completed.
- A new type of maintenance plan interval that is named *Repeated on aggregated value (Counter only)*. This type triggers maintenance each time that an aggregated counter

reaches a multiple of a specific value. For example, maintenance can be triggered every 10,000 hours. Learn more in the Interval types overview section earlier in this article.

- Another new type of maintenance plan interval that is named *Once on aggregated value (Counter only)*. This type triggers maintenance when an aggregated counter reaches a specific value, such as 8,000 hours. Learn more in the Interval types overview section.

Create and initialize counters when an asset is created

Each time that you create an asset, related asset counters that are initialized to a value of *0* (zero) can automatically be created, provided that you set up your system and create the asset correctly.

1. Go to **Asset management** > **Setup** > **Asset types**.
2. Make sure that you have an asset type that is applicable to your planned new asset. Create an asset type as required. Make sure that all the relevant counters are selected on the **Counters** FastTab.
3. Go to **Asset management** > **Setup** > **Asset types** > **Counters**.
4. For each relevant counter, make sure that the **Total aggregate** field is set to *Sum*.
5. On the **All assets** page, create the asset.
6. Set the **Asset type** field to the asset type that you identified or created in step 2.
7. Finish setting up the new asset as required.
8. Go to **Asset management** > **Inquiries** > **Assets** > **Counters**. You should be able to find the initialized counters that are set up for your new asset.

> **Note**
>
> When initialized asset counters are created, the assumption is that the asset had never been used before it was added to the system. When the maintenance schedule is run for the first time, the calculation uses the date and the *0* (zero) counter value as a baseline for calculating future maintenance. If the asset wasn't new when it was added to the system, you can manually adjust the counter value so that it matches the actual counter value. To adjust a counter value, open the relevant asset on the **All assets** page, and then, on the Action Pane, on the **Asset** tab, in the **Preventative** group, select **Counters**. On the **Asset counters** page for the selected asset, adjust the value in the **Value** column for the initial counter record as required.

Automatically reset a counter value

You can configure the system to automatically reset a counter each time that a relevant work order reaches a selected status value.

1. Go to **Asset management** > **Setup** > **Preventive maintenance** > **Maintenance plans**.
2. In the list pane, select a maintenance plan. The counter reset will apply to all assets that use this plan.
3. In the **Lines** section, find an asset counter line that you want to reset a counter for, and select the **Reset counter** check box for that line. (Asset counter lines have a value in the **Counter** column. The counter that is specified in that column is the counter that will be reset for the relevant asset.)
4. Go to **Asset management** > **Setup** > **Work orders** > **Lifecycle states**.
5. In the list pane, select the work order lifecycle state that the relevant counter should be reset at.
6. On the **General** FastTab, set the **Reset counter** option to *Yes*.

Schedule maintenance plans

08/13/2025

Preventive maintenance scheduling generates calendar entries on assets based on the maintenance plans set up on the assets. You can schedule calendar entries based on selected maintenance plans, asset types, and assets.

1. Go to **Asset management** > **Periodic** > **Preventive maintenance** > **Schedule maintenance plans**.

2. You can select a time interval in the **Period** and **Period frequency** fields.

   > ⓘ **Note**
   >
   > The **Period** and **Period frequency** fields indicate how far ahead in time you want maintenance schedule lines to be created, based on the maintenance plans you have created (time-based or counter-based). In the figure shown later in this article, maintenance schedule lines (= work order proposals) are created from the current date and three months onwards.

3. Select *Yes* on the **Auto create if specified in the line** toggle button if work orders should automatically be created according to the maintenance plan line.

   > ⓘ **Note**
   >
   > If this toggle button is set to *Yes*, and the **Auto create** check box is also selected on maintenance plan lines in **Maintenance plans**, work orders are created based on the maintenance plan lines, and maintenance schedule lines with status *Work order created* are also created. If only one option is selected (**Auto create if specified in the line** toggle button in this dialog or **Auto create** check box in **Maintenance plans** form), only maintenance schedule lines are created with status *Created*. In that case, no work orders are created.

4. It's possible to generate calendar entries based on maintenance plans (time or counter), assets, asset types, functional locations, and functional location types. If necessary, select the **Filter** button and make your selections as needed.

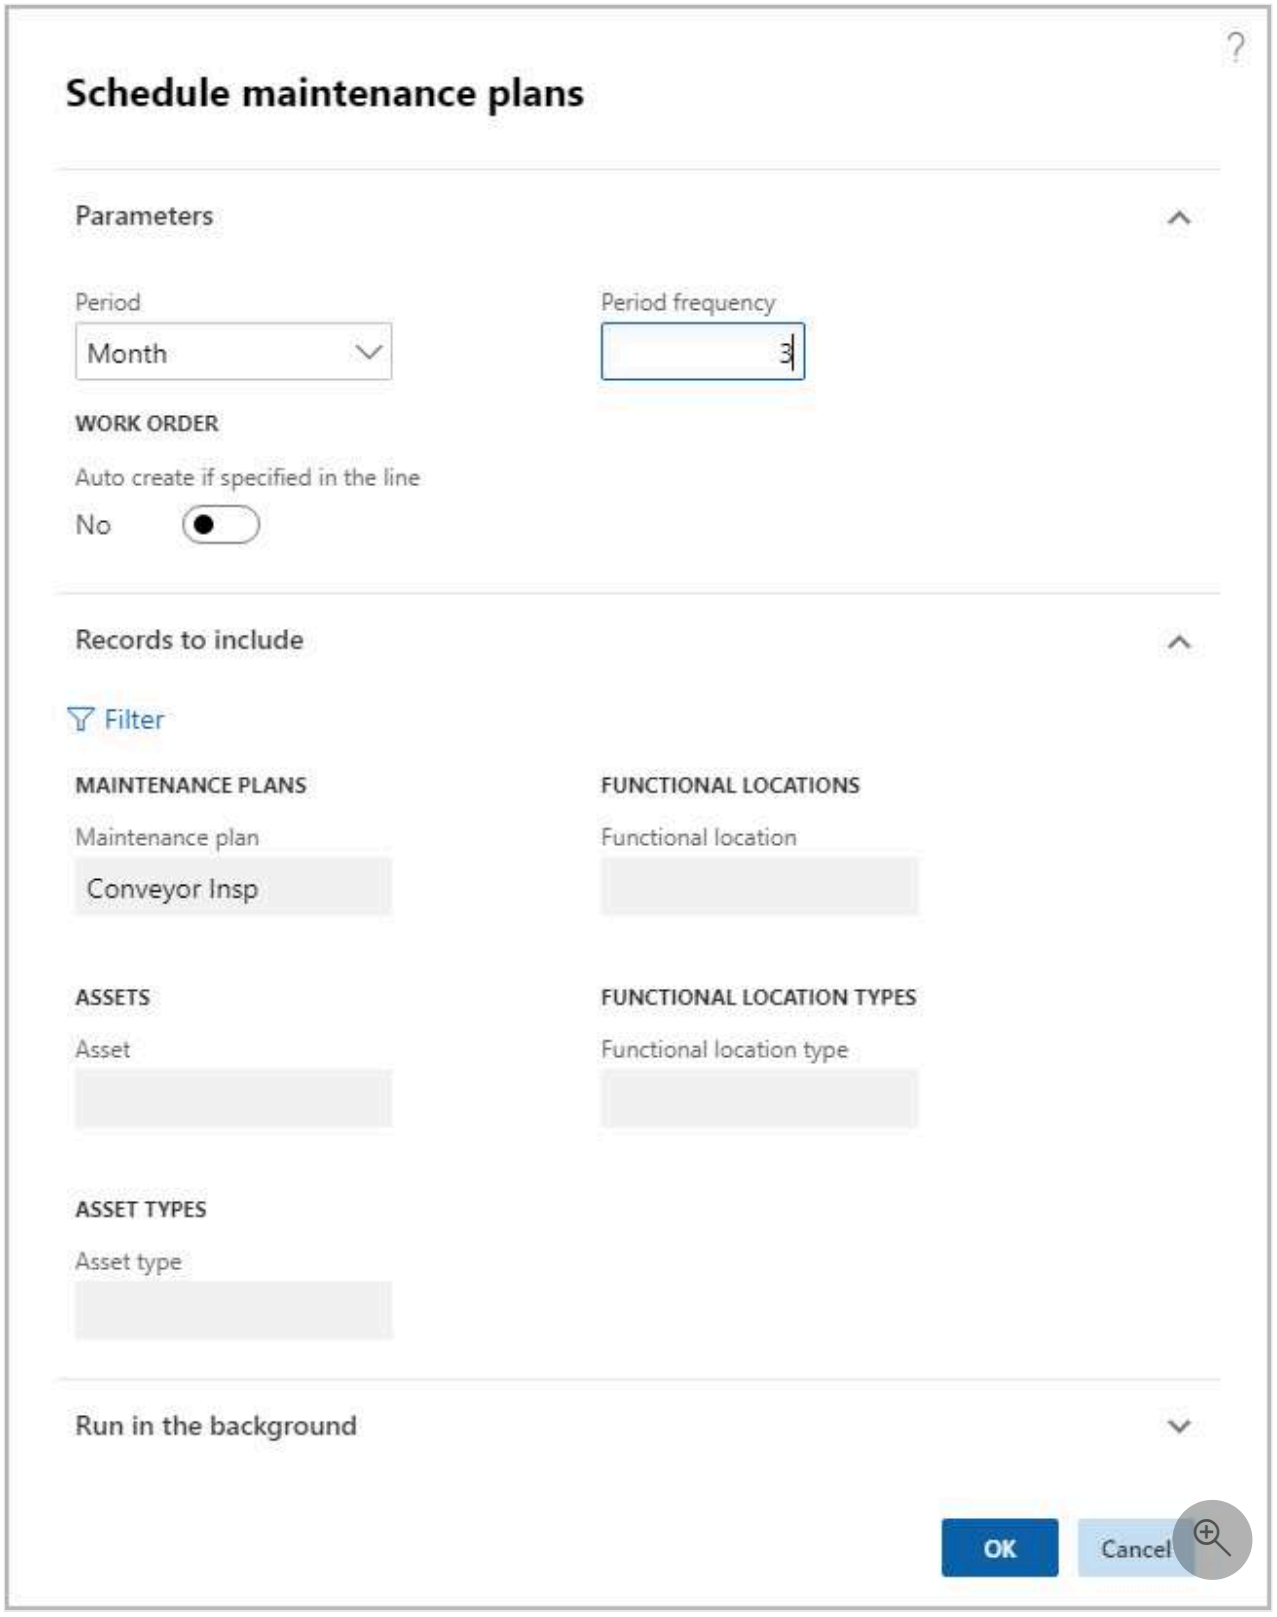
   Regarding scheduling of maintenance plans on functional locations: If you update the setup of asset types, manufacturers, and models on maintenance plans in **All functional locations** > **Maintenance plans** FastTab after you have scheduled maintenance plans, existing maintenance schedule entries related to that functional location are automatically

deleted. In order to create new calendar entries, which correspond with the updated maintenance plan setup on the functional location, you must run a new maintenance plan schedule for that functional location. Read more about the setup of asset types, manufacturers, and models on functional locations in Create functional locations.

Example: You want to create a maintenance plan for a specific functional location, meaning all assets set up on that functional location at any given time will be included when you schedule the maintenance plan. In that case, you create a maintenance plan and select the specific functional location, but you do NOT add any assets in the maintenance plan. The result is that when you schedule that maintenance plan, maintenance schedule lines will be created for all the assets related to the functional location at that time.

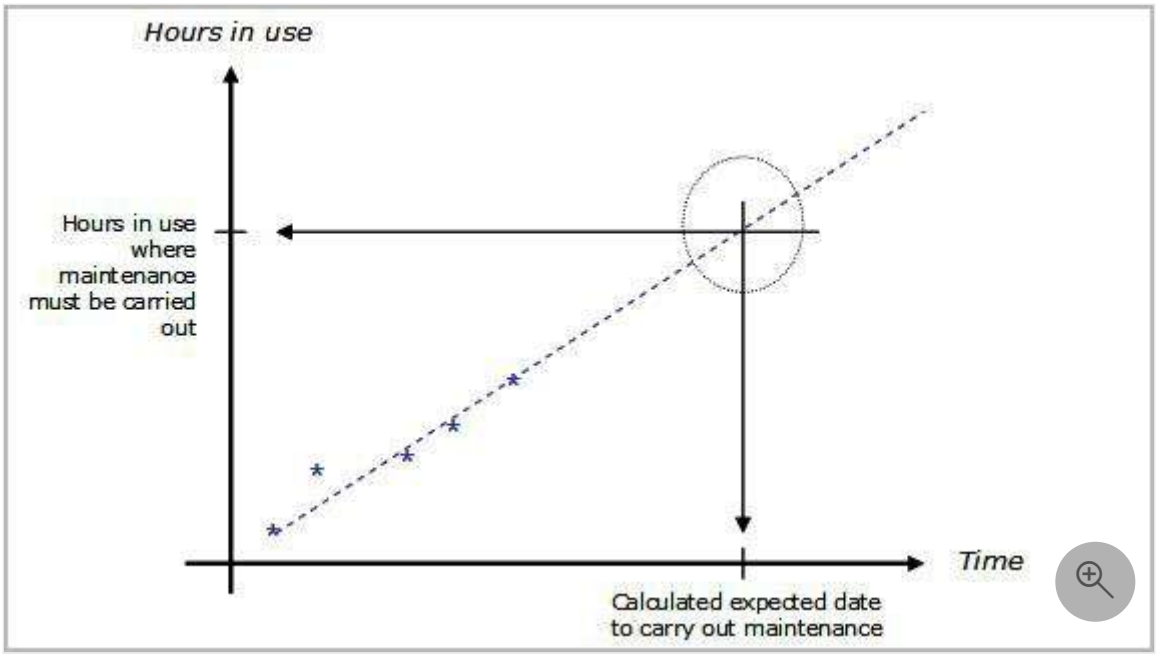
If you make changes to asset types, manufacturers, and models in **Asset types**, those changes only affect new assets that use the updated asset type. Read more about asset type setup in Asset types.

5. Select **OK** to start the generation of maintenance schedule entries on assets. The generated entries will be shown in the **All maintenance schedule** list page. The following illustration shows an example of the **Schedule maintenance plans** dialog.



- In the **Schedule maintenance plans** dialog, you can set up batch jobs on the **Run in the background** FastTab to automatically generate calendar entries at regular intervals.
- When you schedule preventive maintenance, maintenance schedule lines with expected start date and time earlier than the system date and time won't be created.

The following figure provides a graphic illustration of a time-based maintenance plan calculation.



Regarding counter-based maintenance plans: In the following figures, two different counter registration cycles are shown. They're based on a maintenance plan set up for asset *V0001*, expecting the asset (a car) to run approx. 2,000 km every month.

- In the first example, the expected 2,000 km aren't reached every month. According to the counter-based maintenance plan, the threshold is 2,000 km, meaning when you run a maintenance plan scheduling, a maintenance schedule line should be created each time the 2,000-kilometer threshold is reached. In example 1, there are four registration lines, but the 2,000-kilometer threshold is only reached once. This means that when you run schedule maintenance plans this asset, for example for a three-month period, only one maintenance schedule line will be created.

- In the second example, 2,000 km or more are registered every month. Therefore, three maintenance lines would be created if you schedule maintenance plans for this asset for a three-month period.

The examples described here show that all counter registrations made on an asset show a trend describing wear and tear on the asset. That trend is used as calculation basis at the time of maintenance plan scheduling.

Maintenance rounds

Article • 08/28/2024

In Asset Management, you can create maintenance rounds for various assets, on which you need to carry out a similar task at regular intervals. For example, lubrication jobs or safety inspection jobs that need to be carried out on several machines within the same intervals. First step is to create a maintenance round, including assets that require the same form of maintenance job. Next, you schedule the maintenance rounds. When you have completed the maintenance rounds schedule, you can see all the job records relating to the round in the **All maintenance schedule** and **Open maintenance schedule lines**.

> **Note**
>
> Maintenance rounds can also be set up on functional locations to be completed on the assets installed on the functional location at the time of creation of the round-based work order. For more information on the setup of maintenance rounds on functional locations, see Create functional locations.

Set up a maintenance round

1. Go to **Asset management** > **Setup** > **Preventive maintenance** > **Maintenance rounds**.
2. Select **New** to create a new maintenance round.
3. Make the following settings in the heading of the new record:
    - **Maintenance round** – Enter a unique ID for the new record.
    - **Name** – Enter a name for the maintenance round.
4. Make the following settings on the **Header** FastTab:
    - **Start date** – Select a start date for the round.
    - **Finish within days** – Enter the number of days the job should take to complete. The expected end date is calculated relative to the start date, which is calculated when maintenance schedule lines are created. For example, you can enter *7* in this field to indicate that the related job should be completed within a week of the start date.
    - **Finish within hours** – Enter the number of hours the job should take to complete.

- **Auto create** – Set to *Yes* if work orders should automatically be created from maintenance schedule lines that are created from this maintenance round.
- **Work order type** – Select the work order type to be used on work orders created from this maintenance round.
- **Service level** – Select the work order service level to be used on work orders created from this maintenance round.
- **Active** – Set to *Yes* to activate the maintenance round.
- **Assets** – This read-only value shows the number of assets related to the maintenance round.
- **Lines** – This read-only value shows the number of lines related to the maintenance round.

> **Important**
>
> If you set **Active** to *No*, the system won't add any lines for this round to the maintenance schedule when the *Schedule maintenance rounds* job runs.

5. On the **Asset lines** FastTab, select **Add** to add an asset to the maintenance round. Make the following settings for the new line:

   - **Line number** – A line number is automatically inserted in this field to indicate the sequence of the assets in the maintenance round.
   - **Asset** – Select the asset to be included in the maintenance round.
   - **Maintenance job type** – Select the maintenance job type for the asset.
   - **Maintenance job type variant** – If necessary, select a maintenance job type variant related to the maintenance job type.
   - **Trade** – If necessary, select a trade related to the maintenance job type.
   - **Period type** – Select the recurrence (such as *Day*, *Week*, or *Month*) for the maintenance round.
   - **Period frequency** – Enter the number of recurrences for the maintenance round. For example, if you have selected *Day* in the **Period type** field, and you enter the number *7* in this field, new maintenance round lines are created during preventive maintenance scheduling once a week.
   - **Start date** – Select a start date for the asset to be included in the maintenance round. This date might differ from the start date set on the maintenance round.

6. Repeat the previous step to add more assets to the maintenance round.

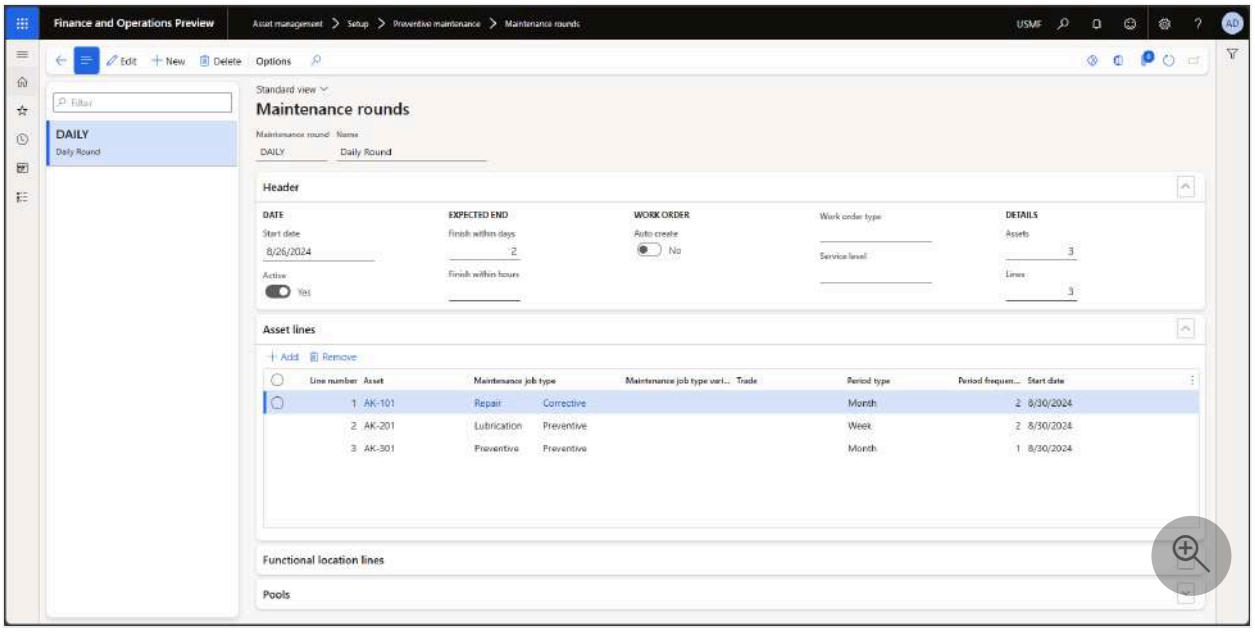
7. On the **Functional location lines** FastTab, select **Add** to add a functional location to the maintenance round. Refer to the descriptions of the related fields provided

previously. The same fields are available as for creating an asset line, but you can also select **Manufacturer** and **Model** for a functional location, if necessary. If you only select a functional location on a line, but make no selections in **Asset type**, **Manufacturer**, **Model**, **Maintenance job type**, **Maintenance job type variant**, and **Trade**, all assets related to that functional location at the time of maintenance scheduling will be included in the maintenance round.

8. On the **Pools** FastTab, select **Add** to select a work order pool to be included in the maintenance round. Several work order pools can be connected to one maintenance round.

9. On the Action Pane, select **Save**.

The following illustration shows an example of a maintenance round containing three assets.



Schedule maintenance rounds

When you've set up a maintenance round, you run a schedule job to schedule all the jobs related to the maintenance round.

1. Do one of the following steps:

    - Go to **Asset management** > **Periodic** > **Preventive maintenance** > **Schedule maintenance rounds**.

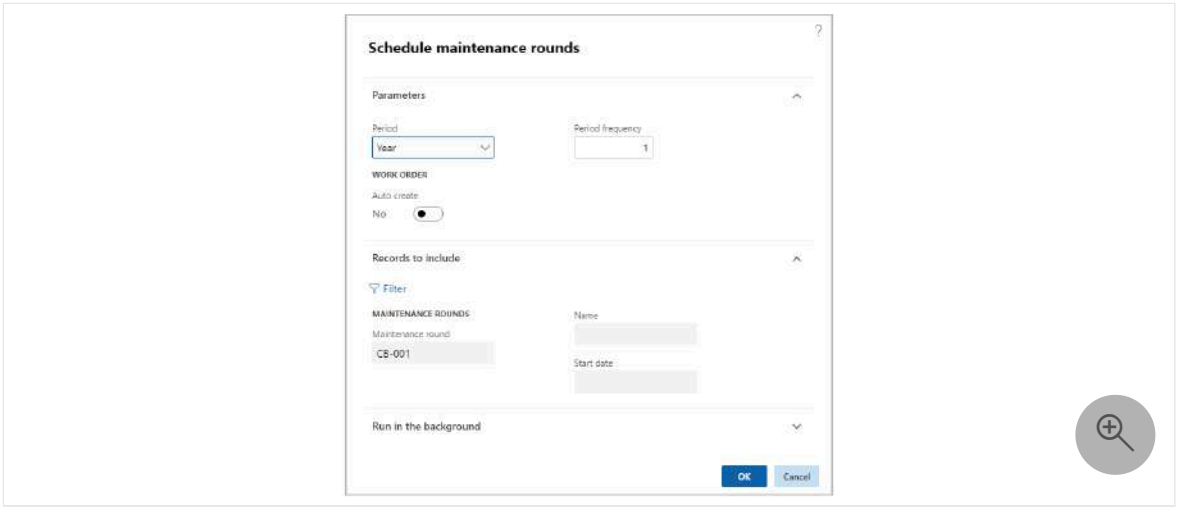
    - Go to **Asset management** > **Maintenance schedule** > **All maintenance schedule**. Select a maintenance schedule line in the grid. On the Action Pane,

open the **Maintenance schedule** tab and, from the **Schedule** group, select **Maintenance rounds**.

- Go to **Asset management** > **Maintenance schedule** > **Open maintenance schedule lines**. Select a maintenance schedule line in the grid. On the Action Pane, open the **Maintenance schedule** tab and, from the **Schedule** group, select **Maintenance rounds**.

- Go to **Asset management** > **Maintenance schedule** > **Open maintenance schedule pools**. Select a maintenance schedule line in the grid. On the Action Pane, open the **Maintenance schedule** tab and, from the **Schedule** group, select **Maintenance rounds**.

2. The **Schedule maintenance rounds** dialog opens.



Make the following settings:

- **Period** – Select the period type to use for the scheduling job.
- **Period frequency** – Enter the number of periods to be included in the scheduling job. The start of the scheduling is the current date.
- **Auto create** – Set to *Yes* if a work order should automatically be created based on a maintenance round.

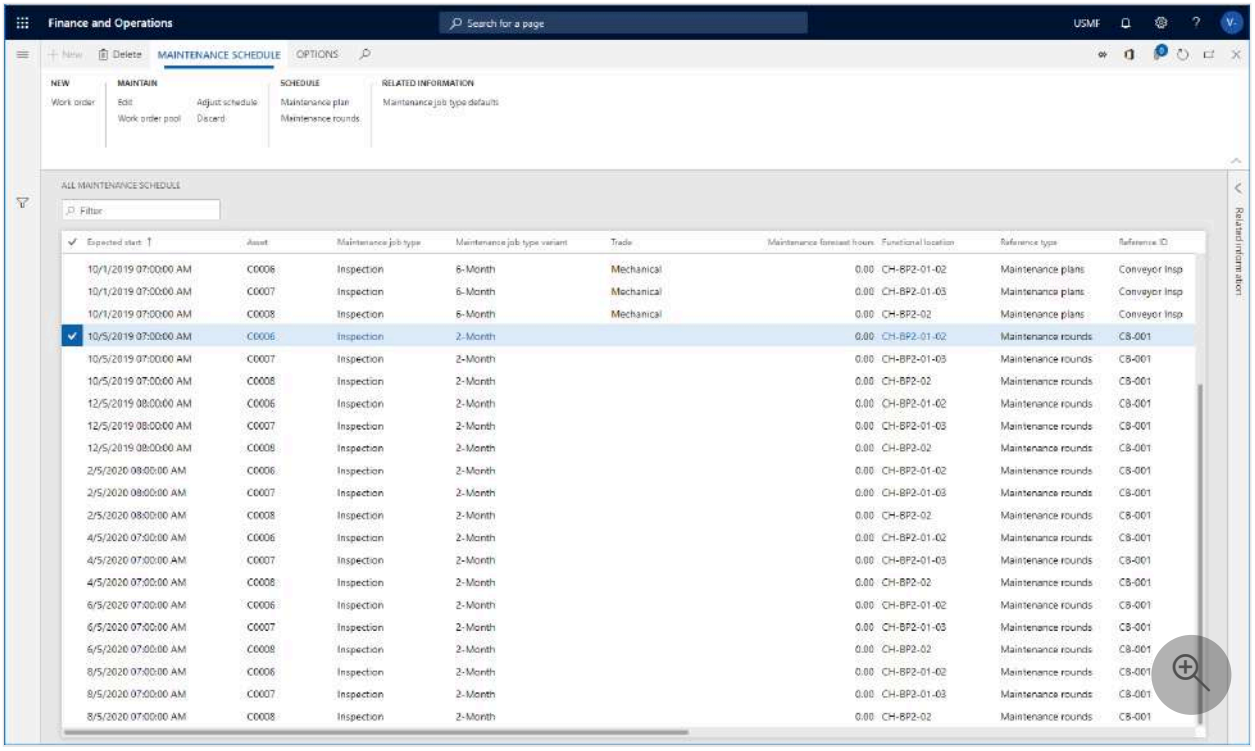
> **Note**
>
> If **Auto create** is set to *Yes* on the **Schedule maintenance rounds** dialog, and **Auto create** is also set to *Yes* on the **Maintenance rounds** page, the system creates work orders based on the maintenance round lines and also creates maintenance schedule lines with status *Work order created*. If only one of the **Auto create** toggle buttons is set to *Yes*, the system only creates maintenance schedule lines with status *Created*. In that case, no work orders are created.

3. If necessary, you can select specific rounds or another start date for the schedule job. To do so, select **Filter** and add the rounds to be included.

4. Select **OK**.

5. You're now able to see the maintenance rounds jobs in **Asset management** > **Maintenance schedule** > **All maintenance schedule** or **Open maintenance schedule lines**. If the scheduled rounds are connected to a work order pool, you also see maintenance schedule lines in **Open maintenance schedule pools**. Maintenance schedule lines created from a round have the reference type *Maintenance rounds*.

The following illustration shows the maintenance schedule lines listed on the **All maintenance schedule** page.



- When work orders are manually created on assets that are covered by a vendor warranty, a dialog box is shown to make the user aware of the warranty. The creation of the work order can then be canceled. The check for a warranty relation is omitted for work orders that are automatically created.
- You can set up a batch job on the **Run in the background** FastTab to schedule rounds at regular intervals.
- If a round is included in several work order pools (refer to Work order pools), one record is shown for each pool in **Open maintenance schedule pools**. This is done to optimize the filtering options for work order pools.

Maintenance schedule

Article • 01/06/2025

The maintenance schedule contains a list of all the expected preventive maintenance plans, maintenance requests, and maintenance rounds to be carried out. Some schedule lines might have been converted to work orders.

The four maintenance schedule views are slightly different, depending on which maintenance schedule lines you want to see.

Expand table

Menu item	Description of contents
All maintenance schedule	All maintenance schedule lines are shown.
My asset schedule	All maintenance schedule lines containing assets installed on functional locations to which you're related as a worker (set up in Maintenance workers and worker groups) are shown in this list.
Open maintenance schedule lines	Maintenance schedule lines with status *Created* - meaning they haven't yet been converted to a work order or discarded - are shown in this list.
Open maintenance schedule pools	Maintenance schedule lines related to a work order pool are shown in this list.

> **Note**
>
> If a maintenance schedule line is included in several work order pools (refer to Work order pools), one record is shown for each pool in **Open maintenance schedule pools**. This is done to optimize filtering options on work order pools.

To open a maintenance schedule:

1. Select **Asset management** > **Maintenance schedule** > **All maintenance schedule** or **Open maintenance schedule lines** or **Open maintenance schedule pools**.
2. To update the maintenance schedule, select **Maintenance plan** or **Maintenance rounds**.
3. You can edit a maintenance schedule line by selecting it and selecting **Edit**. For example, you can easily update the service level or the worker responsible for the job. You can only edit maintenance schedule lines that haven't yet been connected to a work order.

4. You can delete a maintenance schedule line by selecting it in the list page and selecting **Delete**.
5. You can discard a maintenance schedule line by selecting it in the list page and selecting **Discard**. This function is useful if, for example, an asset has a 2,000-km maintenance plan and a 10,000-km maintenance plan. Then, you might want to discard the line created from the 2,000-km maintenance plan when it coincides with 10,000 km, 20,000 km, 30,000 km, and so on. If you discard a maintenance schedule line related to a maintenance plan, that line will never again appear when that maintenance plan is scheduled.
6. You can select several maintenance schedule lines in **All maintenance schedule** and select **Work order pool**, if you want all selected lines to be included in the same work order pool.
7. You can select several maintenance schedule lines in **All maintenance schedule** or **Open maintenance schedule lines** or **Open maintenance schedule pools** and select **Adjust schedule** if you want to make the same adjustments on multiple lines. You can change expected start and end dates, service level, and the responsible maintenance worker group or responsible maintenance worker related to the selected maintenance schedule lines.

When a maintenance schedule line has been related to a work order, the work order ID will be displayed in the **Work order** field.

In the **All assets** details view, on the **Asset maintenance plans** FastTab, you can select maintenance plans for the asset. Later, if you delete a maintenance plan line related to an asset in **All assets**, you also automatically delete all maintenance schedule lines with status *Created* that have been created based on that maintenance plan. Learn more in Create an asset.

The following below shows the **All maintenance schedule** list page.

Maintenance schedule cost

Article • 06/03/2022

In Asset Management, you can calculate budget costs on maintenance schedule lines. This is useful if you want to get an overview of expected costs, for example, costs relating to planned preventive maintenance jobs for the next year. The calculations are based on existing maintenance schedule lines of type "Maintenance plans" and "Maintenance rounds" and "Maintenance requests".

1. Click **Asset management** > **Inquiries** > **Assets** > **Maintenance schedule cost**.
2. In the **Maintenance schedule cost** dialog, you can select a **Financial dimension set** if you want to see costs grouped in financial dimensions.

> ⓘ **Note**
>
> Financial dimension sets are set up in **General ledger** > **Chart of accounts** > **Dimensions** > **Financial dimension sets**.

3. You can use the **Level** field to indicate how detailed you want the maintenance schedule lines to be regarding functional locations. For example, if you insert the number "1" in the field, and you have a multi-level functional location structure, all maintenance schedule lines for a functional location will be shown on the top level, and therefore the hours on a line may be added up from functional locations located at a lower level. If you insert the number "0" in the **Level** field, you will see a detailed result showing all maintenance schedule lines on all the functional location levels to which they are related.
4. If you want to make a calculation for specific assets, click **Filter** on the **Records to include** FastTab, and select the relevant assets. If required, you can also specify an **Expected start** date for the cost calculation or select a different **Status** for the cost calculation
5. Click **OK** to start the cost calculation.
6. On the **Maintenance schedule cost** tab > in the **Group by...** Action Pane groups, click the relevant buttons to show the required detail level of the cost calculation. The selected Action Pane group buttons are highlighted. Click on a button to activate or deactivate it.
7. Click the **Calculate cost** button if you want to make a new cost calculation.

The illustration below shows the results of a maintenance schedule cost calculation.

Creating work orders

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

After you've scheduled preventive maintenance jobs, the next step is to create work orders for them. You can complete this step by using one of the maintenance schedules. The scheduled jobs in a maintenance schedule can have different reference types, as described in the following table.

Expand table

Reference type	Description
Maintenance plans	Preventive maintenance jobs that are based on the *Time* or *Counter* maintenance plan type.
Maintenance rounds	Preventive maintenance jobs that contain several assets that require a similar type of maintenance.
Maintenance request	A manually created request for maintenance or repair of an asset. This request can be converted to a work order.

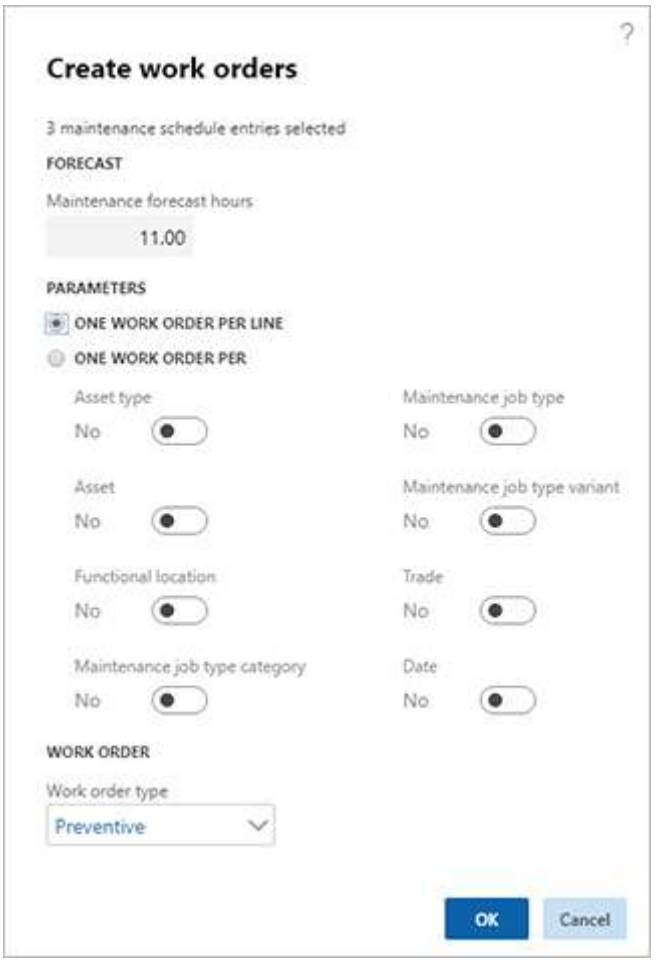
Create work orders based on your maintenance schedule

To create work orders that are based on your maintenance schedule, follow these steps:

1. Open one of the following pages, depending on how you want to select schedule items for your work orders:
    - All maintenance schedule (**Asset management** > **Management schedule** > **All maintenance schedule**)
    - Open maintenance schedule lines (**Asset management** > **Management schedule** > **Open maintenance schedule lines**)
    - Open maintenance schedule pools (**Asset management** > **Management schedule** > **Open maintenance schedule pools**)

2. In the grid, select the check box for every scheduled maintenance job that you want to create a work order for. Then, on the Action Pane, select **Work order**.

   The **Create work orders** dialog box appears. The **Maintenance forecast hours** field shows the total number of forecast hours for the selected lines.



3. In the **Parameters** section, specify the number of work orders that should be created. Select one of the following options:

   - **One work order per line** – Create one work order per maintenance schedule line.
   - **One work order per** – Create work orders that are grouped according to the settings of the other options that become available when you select this option.

4. In the **Work order type** field, select the work order type to use for all the work orders that you create.

5. Select **OK** to create the work orders according to your settings.

Group work order lines that are automatically created while a maintenance plan runs

This feature lets you define rules for grouping work order lines under a single work order when the system is set up to generate work orders automatically, based on a maintenance plan. Previously, automatically generated work orders could contain only one line. However, you can now group work orders by, for example, asset, asset type, or functional location. (Manually generated work orders could already be grouped in this way, as described in the previous section of this article.)

To set up grouping for automatically generated work orders, follow these steps:

1. Go to **Asset management** > **Setup** > **Preventative maintenance** > **Maintenance plans**.
2. For each plan where you want to generate grouped work orders, follow these steps:
   a. Select the plan in the list pane.
   b. On the **Lines** FastTab, make sure that the **Auto create** check box is selected on every line.
3. Go to **Asset management** > **Periodic** > **Preventive maintenance** > **Schedule maintenance plans**.
4. In the **Schedule maintenance plans** dialog box, in the **Period** section, specify the time horizon for the plan (how far to look ahead when finding scheduled maintenance jobs to generate work for).
5. Set the **Automatically create work order from schedule** option to *Yes*.
6. In the **Work order** section, select one of the following options:
   - **One work order per line** – Create one work order per maintenance schedule line.
   - **One work order per** – Create work orders that are grouped according to the settings of the other options that become available when you select this option.
7. If you want the options to apply when you run only some of your maintenance plans, on the **Records to include** FastTab, add filters as you require, just as you might do for other batch jobs in Microsoft Dynamics 365 Supply Chain Management.
8. On the **Run in the background** FastTab, set up batch and scheduling options as you require, just as you might do for other batch jobs in Supply Chain Management.
9. Select **OK** to run and/or schedule the selected maintenance plans.

Last updated on 12/30/2025

Maintenance downtime activities

Article • 06/15/2022

Maintenance downtime is used to get an overview of the capacity required to carry out maintenance jobs on specific assets during a specific period. For example, you can create a maintenance downtime registration for Production line 10 in Production Hall 29-A on production site 02. The maintenance downtime registration has a start and end time indicating the period in which the assets related to the maintenance stop are not available for production.

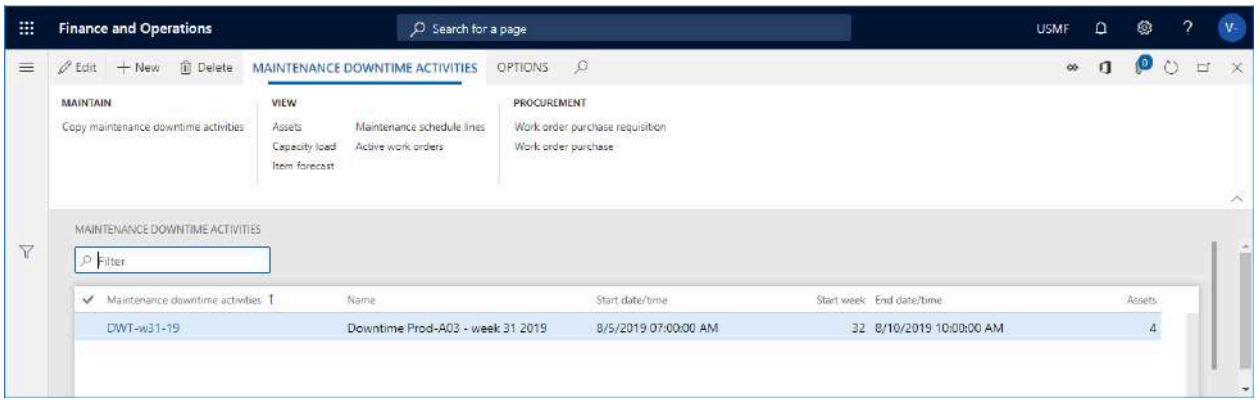
Maintenance downtime activities is an overview of maintenance schedule lines and work order maintenance jobs on related assets during a specified period. The lines related to work order maintenance jobs all have an expected start date within the maintenance stop period. You can extract useful information and make adjustments to planned maintenance jobs:

- Get an overview of required shut-down periods of production equipment (assets).
- Get an overview of planned maintenance (hours), grouped by competencies (responsible maintenance worker groups or maintenance workers), for example capacity load on electricians, smiths, or other maintenance work groups required to do the planned maintenance jobs.
- Make adjustments to maintenance schedule lines or work order maintenance jobs related to the assets, for example, change expected start and end times on a line, or select other maintenance workers to optimize the workflow for maintenance workers and maintenance worker groups.

When assets have been selected on a maintenance downtime registration, all open maintenance schedule lines and work order maintenance jobs relating to active work orders are included in the maintenance downtime registration.

Maintenance downtime activities

Click **Asset management** > **Maintenance downtime activities** > **All maintenance downtime activities** to open a list of all maintenance downtime activities and see some of the information related to the activities. Click on a link in the **Maintenance downtime activities** column to open the details view. The illustration below shows an example of the **Maintenance downtime activities** list.



Create a maintenance downtime activity

1. Click **Asset management** > **Maintenance downtime activities** > **All maintenance downtime activities** or **Active maintenance downtime activities**.

2. Click **New**.

3. Insert an ID in the **Maintenance downtime activities** field and a name in the **Name** field.

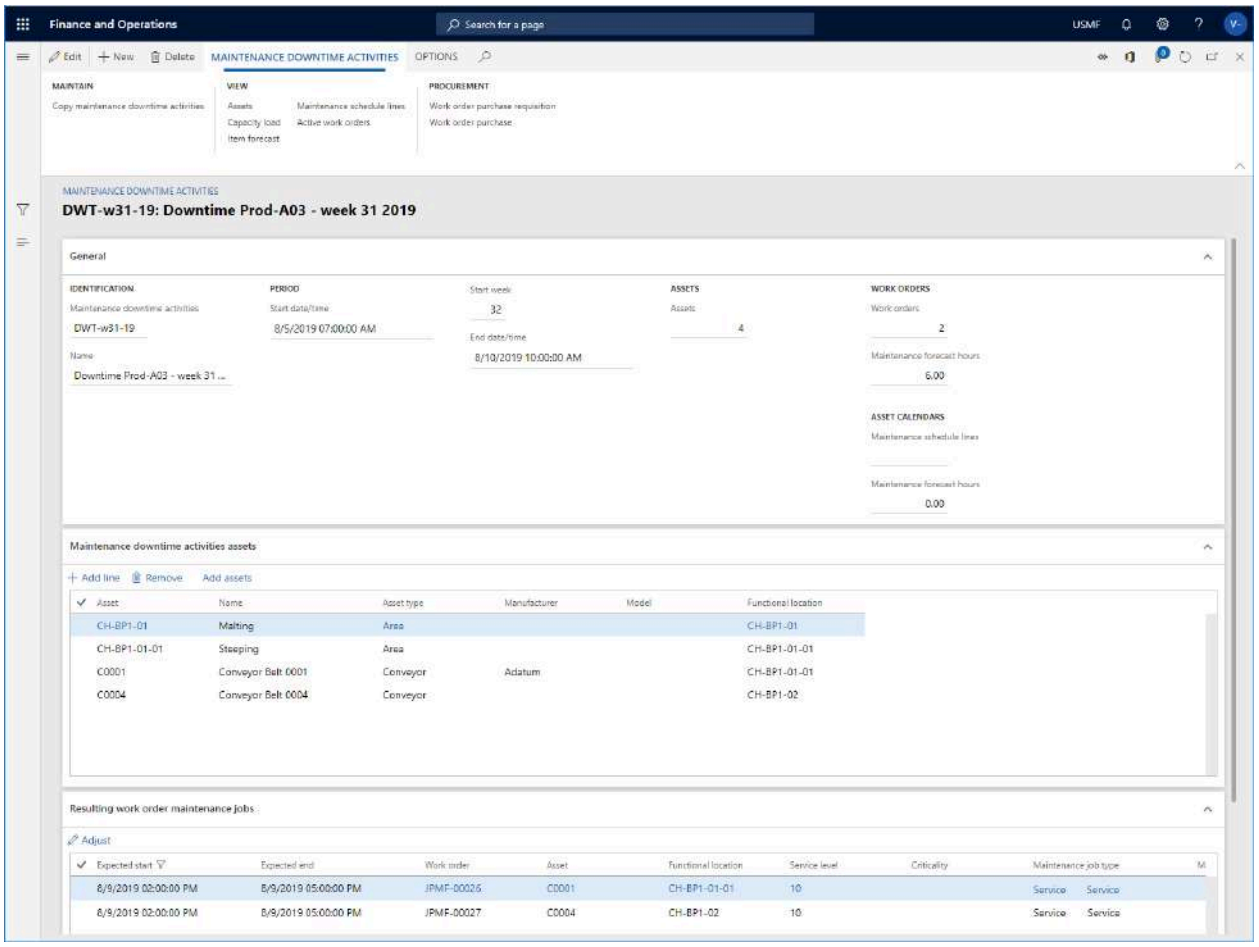
4. Insert the period for the maintenance stop in the **Start date/time** and **End date/time** fields.

5. On the **Maintenance downtime activities assets** FastTab> click **Add line** to add assets, one at a time, to the maintenance downtime activity.

6. Click **Save** when all assets have been added. The illustration below shows an example of a maintenance downtime activity with related assets and maintenance jobs.

7. The work order maintenance jobs and open maintenance schedule lines related to the selected assets are shown on the **Resulting work order maintenance jobs** and **Maintenance schedule lines** FastTabs. On the **General** FastTab > **Work orders** group > **Maintenance forecast hours** field and **General** FastTab > **Maintenance schedule** group > **Maintenance forecast hours** field , you see the total number of hours forecasted for work order maintenance jobs and maintenance schedule lines.

The illustration below shows an example of the **Maintenance downtime activities** details view.



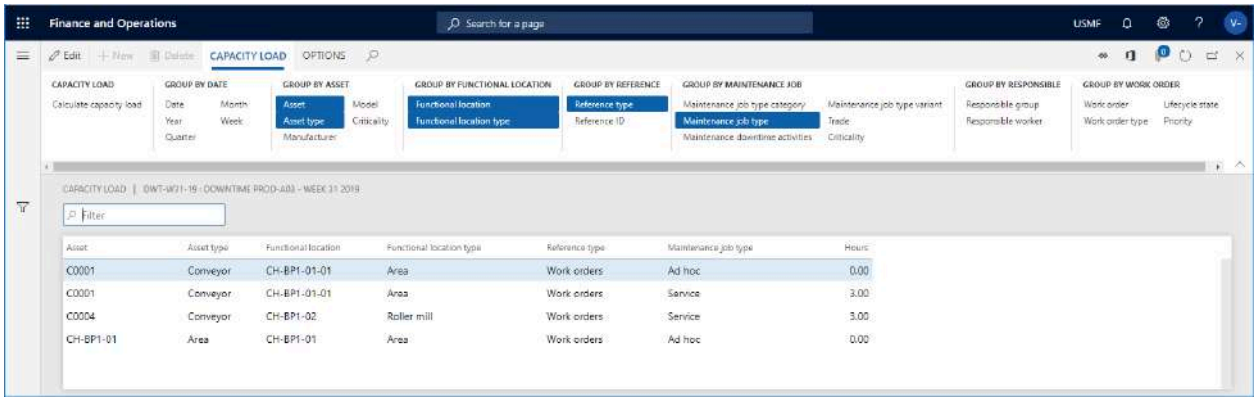
> **Note**
>
> The work order maintenance jobs and maintenance schedule lines related to the selected assets are automatically updated if new work orders or maintenance schedule lines are created after you created the maintenance downtime activity. For example, if you schedule maintenance plans or maintenance rounds on the related assets two days after the maintenance downtime activity was created, new maintenance schedule lines are automatically added to the maintenance downtime activity.

8. In **All maintenance downtime activities** > **Maintenance downtime activities** > select a maintenance downtime activity in the list and click **Capacity load** to open the **Calculate capacity load** dialog. Use this dialog to get an overview of capacity load on, for example, dates, assets, asset types, and maintenance job types. Note that the dates shown in the dialog are the start and end dates selected in **Maintenance downtime activities**. This calculation includes the assets related to the maintenance downtime activity.

9. In the **Calculate capacity load** dialog, edit start and end times if required, and select if you want to include work orders and maintenance schedules in the calculation. You can use the **Level** field to indicate how detailed you want the

capacity load calculation to be regarding functional locations. For example, if you insert the number "1" in the field, and you have a multi-level functional location structure, all assets for a functional location, which are selected on the maintenance downtime activity, will be shown on the top level, and therefore the hours on a line may be added up from functional locations located at a lower level. If you insert the number "0" in the **Level** field, you will see a detailed result showing all capacity load lines on all the functional location levels to which they are related.

10. Click **OK** to start the calculation. The total number of hours is shown in the **Capacity load** overview. On the **Capacity load** tab > the **Group by...** Action Pane groups, click the relevant buttons to get a more detailed overview of the allocation of forecasted hours. The illustration below shows the results of a **Capacity load** calculation.



11. After you get an overview of the capacity load, if you want to make adjustments on work order maintenance jobs or maintenance schedule lines, return to the **Maintenance downtime activities** details view and select the lines you want to adjust on the **Resulting work order maintenance jobs** and **Maintenance schedule lines** FastTabs.

12. Click the **Adjust** button and update expected start/end dates, service level, or responsible maintenance workers for the selected work order maintenance jobs or maintenance schedule lines.

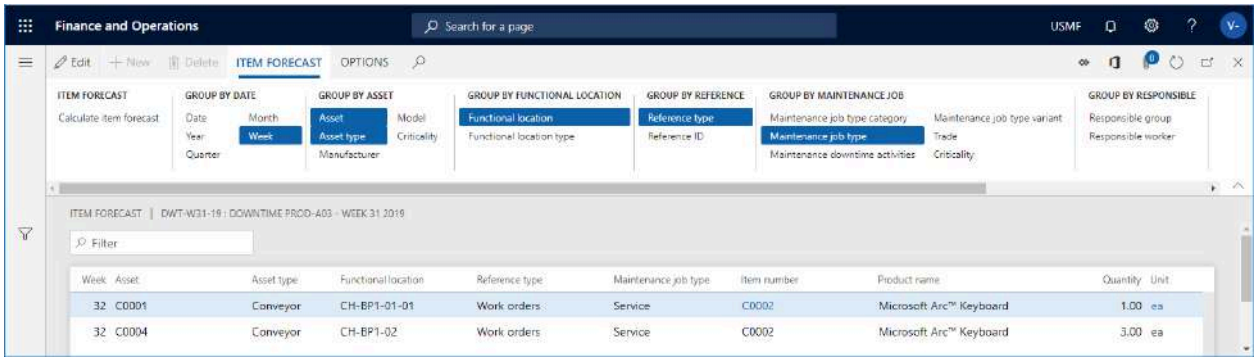
13. Click **OK** when you have made the required adjustments.

> **Note**
>
> Work order maintenance jobs and maintenance schedule lines that are not included in the maintenance downtime period after you have made adjustments are automatically removed from **Maintenance downtime activities**.

14. In **All maintenance downtime activities** > **Maintenance downtime activities** > select a maintenance downtime activity in the list and click **Item forecast** to open the **Calculate item forecast** dialog. Use this dialog to calculate forecasts for items (spare parts and other required items) and group them to get an overview, for example, by date, asset, asset type, and maintenance job type. Note that the dates shown in the dialog are the start and end dates selected in **Maintenance downtime activities**. This calculation includes spare parts and items related to the assets that are selected on the maintenance downtime activity.

15. In the **Calculate item forecast** dialog, edit start and end times if required, and select if you want to include work orders and maintenance schedules in the calculation. You can use the **Level** field to indicate how detailed you want the capacity load calculation to be regarding functional locations. For example, if you insert the number "1" in the field, and you have a multi-level functional location structure, all assets for a functional location, which are selected on the maintenance downtime activity, will be shown on the top level, and therefore the hours on a line may be added up from functional locations located at a lower level. If you insert the number "0" in the **Level** field, you will see a detailed result showing all capacity load lines on all the functional location levels to which they are related.

16. Click **OK** to start the calculation. The total number of item forecasts is shown in the **Item forecast** overview. On the **Item forecast** tab > the **Group by...** Action Pane groups, click the relevant buttons to get a more detailed overview of the allocation of forecasted items.The illustration below shows the results of an **Item forecast** calculation.



- You can copy assets from one maintenance downtime activity to another. In **All maintenance downtime activities**, select the **Copy maintenance downtime activities** button, and make your selections in the **From maintenance downtime activities** and **To maintenance downtime activities** fields, and click **OK**.
- In **All maintenance downtime activities**, click the **Maintenance schedule lines** button or the **Active work orders** button to open the related lists and view the lines related to the selected maintenance downtime activity.

Manage test instrument calibration with Asset Management (preview)

[This article is prerelease documentation and is subject to change.]

Calibration ensures that test instruments provide accurate and reliable measurements. This accuracy is critical for maintaining product quality, meeting regulatory requirements, and avoiding costly errors. Asset Management in Dynamics 365 Supply Chain Management provides tools to schedule, track, and document calibration activities for all your test instruments.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Maintaining accurate and reliable test instruments is essential for ensuring product quality, meeting regulatory requirements, and reducing operational risks. Supply Chain Management provides a connected framework that brings together quality control and asset management to achieve these goals.

- **Standardized instrument management** – Define test instrument types to guide quality teams in selecting the right tools for inspections and calibration. This approach ensures consistency, reduces errors, and supports compliance across all quality processes.
- **Full traceability and digital records** – Use test instrument tags as digital twins of physical instruments. These tags store calibration history, specifications, and usage data, enabling complete traceability and simplifying audits.
- **Automated quality tracking** – Quality orders not only capture inspection results but can also track instrument usage automatically. This usage data drives usage-based calibration schedules, ensuring instruments remain accurate without manual intervention.
- **Lifecycle control through asset management** – Model each test instrument as an asset, giving you full visibility into its lifecycle, from acquisition to calibration and retirement, while aligning with maintenance best practices.

- **Proactive calibration scheduling** – Implement maintenance plans to automate calibration scheduling. Plans can be time-based or usage-based, reducing the risk of missed calibrations and ensuring compliance with industry standards.
- **Efficient execution and documentation** – Generate maintenance work orders to perform and document calibration events. These work orders include all necessary details—tasks, resources, and compliance notes. These features help streamline execution and record keeping.

Prerequisites

To use Asset Management to maintain calibration of test instruments, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.46 or later.
- The following features must be turned on in feature management:
  - *Advanced quality management* (As of Supply Chain Management version 10.0.47, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.)
  - *Optional linking of test instruments to maintainable assets*

Set up calibration in Asset Management

To set up your system to manage test instrument calibration with Asset Management, complete the following steps. Follow the links to learn more about each step.

1. **Create assets for your test instruments** – Create assets for the test instruments that require scheduled calibration in Asset Management. When defining an asset, you must assign an **Asset type**, which categorizes the asset and helps standardize its management and maintenance processes. Learn more about defining assets in Create an asset.
2. **Set up test instrument types** – Test instrument types serve as categories for grouping similar test instruments. Each test instrument type must be linked to an **Asset type** to ensure consistency between quality management and asset management processes. Learn more about test instrument types in Quality management test instruments.
3. **Create test instrument tags** – Each tag represents a physical test instrument and links to the test instrument asset in Asset Management. For instructions, see the next section.
4. **Create a maintenance plan** – Create or edit a maintenance plan for the test instrument asset. A maintenance plan is a predefined schedule that automatically creates work orders

for recurring maintenance tasks such as calibrating test instruments based on time intervals or usage thresholds. Learn more in Maintenance plans.

Set up test instrument tags for test instruments managed with Asset Management

Each test instrument tag represents a physical test instrument and also links to the test instrument asset in Asset Management. Follow these steps to create a test instrument tag with an asset assigned:

1. Go to **Inventory management** > **Setup** > **Quality control** > **Test instruments** to open the test instruments page.

2. Select or create a test instrument type record where an **Asset type** is assigned, as described in Quality management test instruments.

3. On the Action Pane, select **Test instrument tags**.

4. On the Action Pane, select **New** to add a new tag. Then make the following settings in the header for the new tag:

    - **Tag number** – Enter a unique name, number, or code for the instrument.

    - **Test instrument type** – Specify the test instrument type that this tag belongs to. This field is prefilled to show the test instrument type that was selected when you opened the **Test instrument tags** page.

    - **Instrument usage status** – The current usage status of the test instrument. Although the field is read-only, you can manually change the status to *Out of service* or *Available* by using the buttons on the **Update usage status** tab of the Action Pane. The following status values are used:
        - *Available* – The test instrument is ready to be assigned to a new quality order.
        - *Calibration* – The test instrument is currently being calibrated. This status is automatically set when an open (in-progress) calibration record exists for this test instrument tag.
        - *Out of service* – The test instrument is out of service and can't be used for quality order tests. This status is automatically set when the lifetime usage maximum is reached.

5. On the **General** FastTab, make the following settings:

- **Asset** – Select the asset that represents the test instrument that requires scheduled calibration in Asset Management.
- **Usage increment** – If the field Fixed increment counter type is set on the related instrument type record, then this field is incremented each time a quality order is validated with the increment specified in the field Usage increment, on the related instrument type record.
- **Skip check for test instrument on open quality order** – Set this option to *No* to prevent test instrument tags that are already assigned to open quality orders from being assigned to new quality orders. Set it to *Yes* to skip this check (in this case, a test instrument tag might be assigned to more than one open quality order at a time).
- **Check if test instrument is being calibrated** – Select the action that is taken on a quality order when the **Instrument usage status** value of the instrument is *Calibration*. The default value for new tags is defined in Inventory and warehouse management parameters, but you can change it for individual test instrument tags. The following values are available:
  - *No check* – Skip this check.
  - *Warning only* – If the instrument is being calibrated, show a warning message, but allow the instrument to be used.
  - *Not allowed* – If the instrument is being calibrated, show an error message that states that the instrument can't be used.

6. On the Action Pane, select **Save** to save the new test instrument tag.

Last updated on 07/27/2026

Calculate capacity load

06/17/2025

In Asset Management, you can calculate capacity load on:

- Maintenance schedule lines
- Work orders that haven't yet been scheduled
- Scheduled work orders

This is useful if you want to get an overview of expected capacity load for a specific period. Calculation of capacity load can be done on all assets or selected assets. You can also make a calculation on maintenance downtime activities or work order pools.

1. Go to one of the following pages, depending on what you want to calculate capacity load for:

   - **Asset management** > **Inquiries** > **Capacity load**
   - **Asset management** > **Work order pools** > **All work order pools**
   - **Asset management** > **Work order pools** > **Active work order pools**
   - **Asset management** > **Maintenance downtime activities** > **All maintenance downtime activities**
   - **Asset management** > **Maintenance downtime activities** > **Active maintenance downtime activities**

2. Select the record you want to work with and then, on the Action Pane, select **Capacity load**.

3. In the **Calculate capacity load** dialog, select a period for the calculation in the **Start date/time** and **End date/time** fields.

4. Select *Yes* on the **Include maintenance schedule** toggle button if you want to include maintenance schedule lines in the calculation.

5. Select *Yes* on the **Include work order** toggle button if you want to include work order jobs in the calculation.

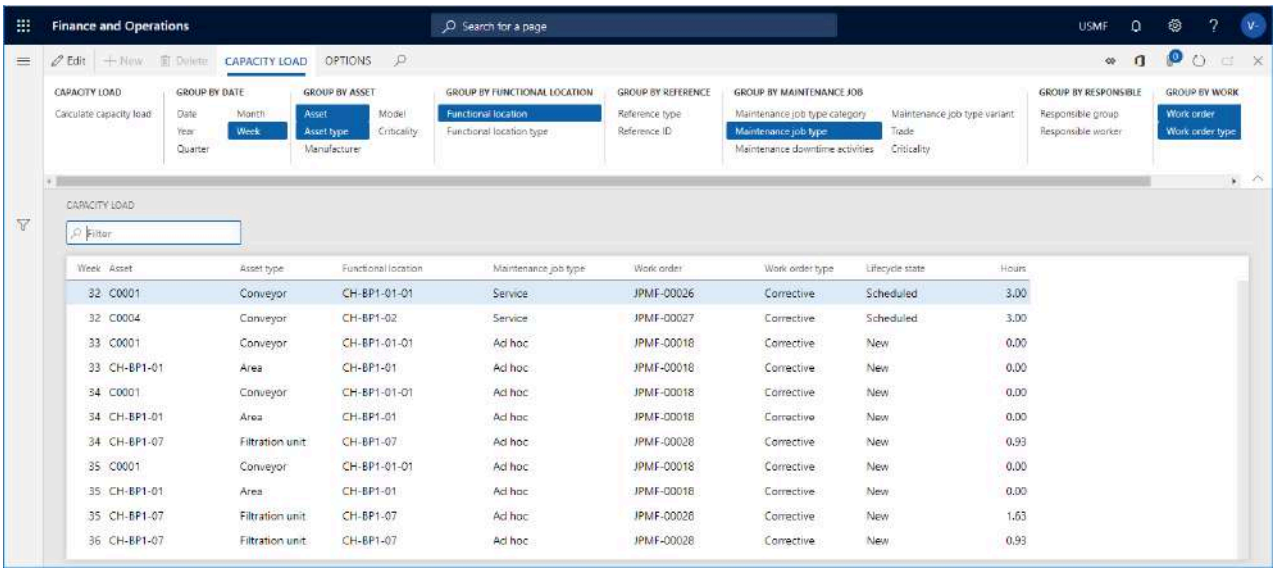
6. You can use the **Level** field to indicate how detailed you want the capacity load lines to be regarding functional locations.

   For example, if you insert the number *1* in the field, and you have a multi-level functional location structure, all maintenance schedule lines and work orders for a functional location will be shown on the top level, and therefore the hours on a line might be added up from functional locations located at a lower level.

If you insert the number *0* in the **Level** field, you'll see a detailed result showing all maintenance schedule lines and all work orders on all the functional location levels to which they're related.

7. Select **OK** to start the calculation.

8. In the **Group by...** groups, select the relevant buttons to show the required detail level of the calculation. In the following screenshot, the selected **Group by** buttons are highlighted in blue color. Select on a button to activate or deactivate it.



> **Note**
>
> If you want to focus only on capacity planning regarding scheduled work orders, see Calculate capacity load on scheduled work orders.

Calculate item forecast

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Just as you can make capacity load calculations, which are described in the previous section, you can also make item forecast calculations on:

- maintenance schedule lines
- work orders that have not yet been scheduled
- scheduled work orders

This is useful if you want to get an overview of expected item consumption (spare parts as well as other items required for completing work orders) for a specific period. Calculation of item forecast can be done on all assets or selected assets. You can also make a calculation on a maintenance downtime activity (**All maintenance downtime activities** or **Active maintenance downtime activities**), or on a work order pool (**All work order pools** or **Active work order pools**).

1. Click **Asset management** > **Inquiries** > **Item forecast**, or **Asset management** > **Work order pools** > **All work order pools** / **Active work order pools** > select work order pool in the list > **Item forecast** button, or **Asset management** > **Maintenance downtime activities** > **All maintenance downtime activities** / **Active maintenance downtime activities** > select maintenance downtime activity in the list > **Item forecast** button.

2. In the **Calculate item forecast** dialog, select a period for the calculation in the **Start date/time** and **End date/time** fields.

3. Select "Yes" on the **Include maintenance schedule** toggle button if you want to include maintenance schedule lines in the forecast calculation.

4. Select "Yes" on the **Include work order** toggle button if you want to include work order jobs in the forecast calculation.

5. You can use the **Level** field to indicate how detailed you want the item forecast lines to be regarding functional locations.

   For example, if you insert the number "1" in the field, and you have a multi-level functional location structure, all maintenance schedule lines and work orders for a

functional location will be shown on the top level, and therefore the hours on a line may be added up from functional locations located at a lower level.

If you insert the number "0" in the **Level** field, you will see a detailed result showing all maintenance schedule lines and all work orders on all the functional location level to which they are related.

6. Click **OK** to start the calculation.

7. In the **Group by...** groups, click the relevant buttons to show the required detail level of the calculation. In the screenshot below, the selected **Group by** buttons are highlighted in blue color. Click on a button to activate or deactivate it.

8. Click the **Display dimensions** button if you want to see the product, storage, or tracking dimensions related to the items. Select the relevant check boxes, and click **OK**.

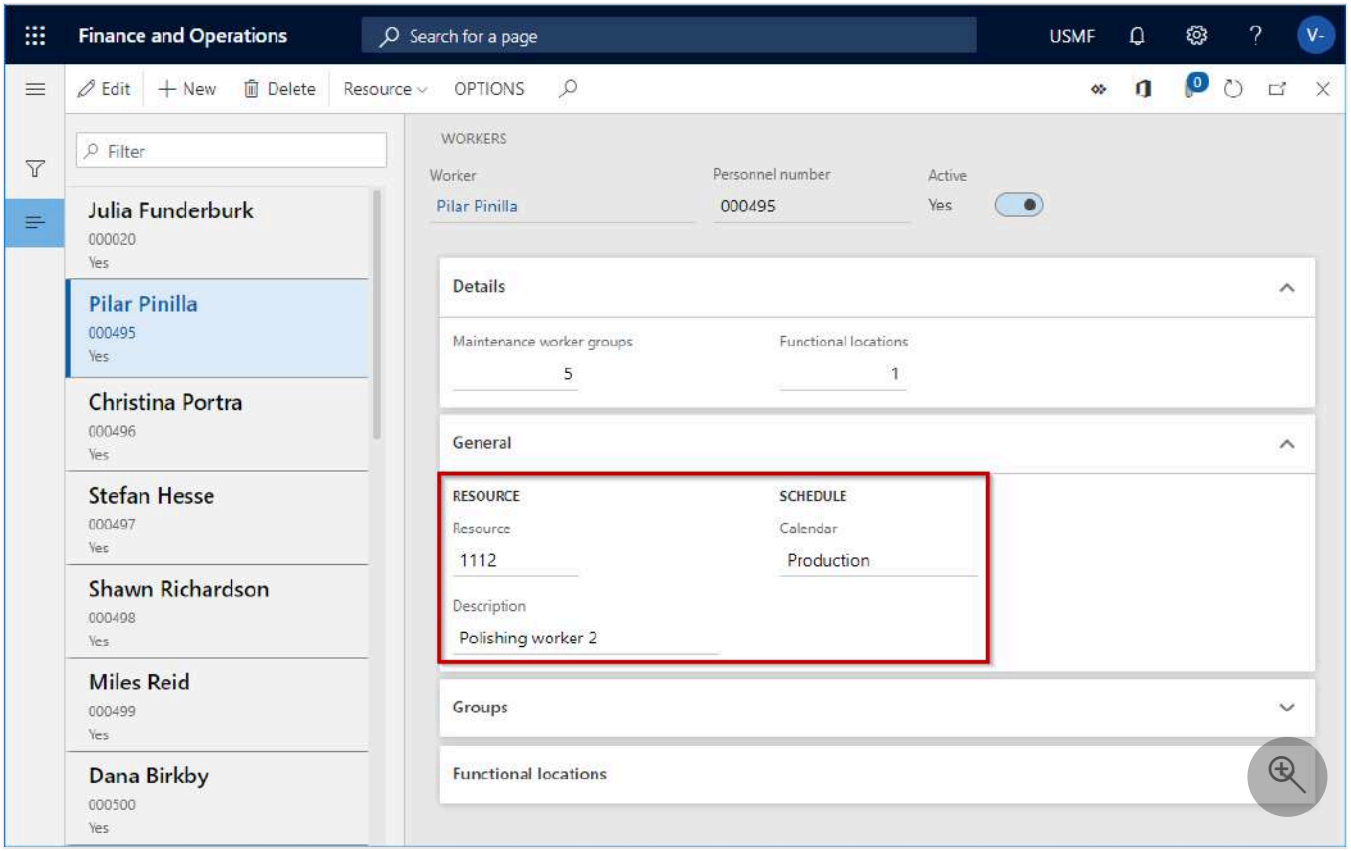
Maintenance worker calendar and scheduling

08/14/2025

When you schedule work orders, you create a schedule for maintenance workers, tools, and assets. In order to schedule maintenance workers, a calendar must be set up for each maintenance worker. Maintenance workers are related to a resource, and working time calendars are set up for resources. You set up the resource and calendar in **Asset management** > **Setup** > **Workers** > **Workers**, which is described in Maintenance workers and worker groups.

The following screenshot shows an example of a maintenance worker who is related to a resource that uses the working time calendar *Production*.



Calendar setup for tools and assets isn't needed in relation to work order scheduling. The assumption is that tools and assets are available 24 hours a day for maintenance.

Set up preferred maintenance workers

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

During work order scheduling, you can make a preference regarding which maintenance worker or worker group is allocated to complete the work order. The use of this functionality is optional, but it can help you make a choice for the most qualified maintenance worker to complete a job, based on worker skills and competencies. Only maintenance workers that are available at scheduling time will be scheduled. If a preferred maintenance worker setup matches a work order during scheduling, but the maintenance worker is allocated to other jobs, the work order will be scheduled to another available maintenance worker.

Before you can set up preferred maintenance workers, you must first set up the maintenance workers and worker groups. For a description about how to set up maintenance workers and worker groups, see to Maintenance workers and worker groups.

Set up preferred workers

A preferred maintenance worker or worker group can be related to one or more of the following:

- trade
- maintenance job type variant
- maintenance job type
- maintenance job type category
- asset
- asset type

The more selections you make for the same record, the more specific your setup will be.

1. Click **Asset management** > **Setup** > **Workers** > **Preferred maintenance workers**.
2. Click **New** to create a new record.
3. Start by creating a "default" maintenance worker or worker group. This means that you only make a selection in the **Preferred maintenance worker group** field or the **Preferred**

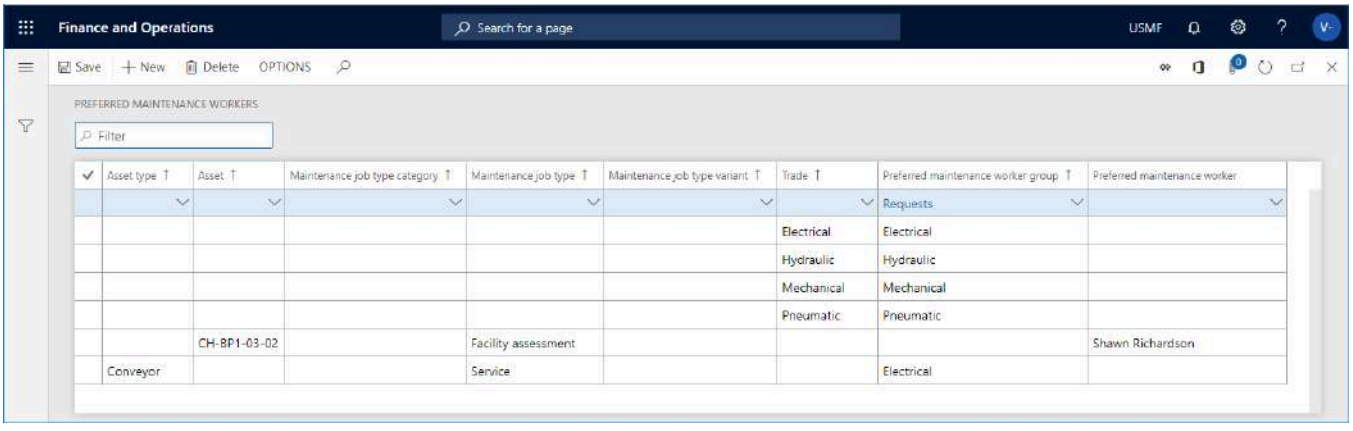
maintenance worker field. In the screenshot below, you see an example in the first record in which "Requests" is selected as **Preferred maintenance worker group**.

> **Note**
>
> The default setup will be used during work order scheduling if no other, more specific, combination matches the contents of the work order.

4. Repeat step 2 to create a new record. Make the required selections, depending on the detail level for the preferred worker or worker group.

   Example: In the screenshot below, in the sixth record, the maintenance worker Shawn Richardson is selected as preferred worker. Shawn will automatically be selected during scheduling of a work order that includes the asset "CH-BP1-03-02 and the maintenance job type "Facility assessment", if Shawn is available at the scheduled time.

   > **Note**
   >
   > Generally, when a preferred maintenance worker is selected during work order scheduling, Asset Management goes through all **Preferred maintenance workers** records to check for a possible match, always checking the most specific combination first. If no match is found, the "default" record with a selection in either the **Preferred maintenance worker group** field or the **Preferred maintenance worker** field is used.



You can also set up *responsible* maintenance workers who can be selected when a maintenance request or a work order is created. You can edit the selection in **All work orders** and **All maintenance requests**, if required. Learn more in Responsible maintenance workers.

During work order scheduling, different scores are calculated to determine which workers should complete the jobs related to a work order (those scores are set up in **Asset management parameters** > **Work order scheduling** link). If two or more preferred

maintenance workers or responsible maintenance workers get the same score during work order scheduling, one worker is randomly selected. Otherwise, it is always the worker with the highest score who is allocated to complete a work order.

Last updated on 05/07/2025

Schedule work orders

Article • 01/29/2025

This article explains how to schedule work orders in Asset Management.

The required number of hours for a work order is defined by the sum of forecasted hours minus posted hours. If more time is required, the forecast must be adjusted accordingly. On the **All work orders** page (**Asset management** > **Work orders** > **All work orders**) or the **Active work orders** page (**Asset management** > **Work orders** > **Active work orders**), you can view or edit forecasts on a work order. Select the work order, and then, on the **Work order** tab, select **Forecast**. After work orders are created and estimated, the next step is to allocate the required maintenance workers and tools.

> **Important**
>
> Work orders can be scheduled only if their work order lifecycle state allows for scheduling. To set up a lifecycle state so that it allows for scheduling, go to **Asset management** > **Setup** > **Work orders** > **Lifecycle states**, and then, on **General** FastTab, set the **Allow scheduling** option to *Yes*.

1. Go to **Asset management** > **Work orders** > **All work orders**.
2. In the list, select the work orders that you want to schedule. To find the correct work orders, you can sort the list by **Current lifecycle state** value, for example.
3. On the **General** tab, select **Schedule**.
4. In the **Schedule work orders** dialog box, you can add selections that are related to the expected start date and service level, as you require. If the scheduling process should observe capacity limitations for resources that are already scheduled for other jobs, make sure that the **Asset**, **Tool**, and **Worker** options are set to *Yes*.

   > **Note**
   >
   > If you set the **Asset**, **Tool**, and **Worker** options to *No*, existing reservations are ignored. The Action center shows a list of overlapping work order schedules. As you require, you can select a message link to open a work order and reschedule it.

5. To view detailed information about the scheduling process, set the **Verbose** option to *Yes*. In this case, the Action center shows detailed information about the

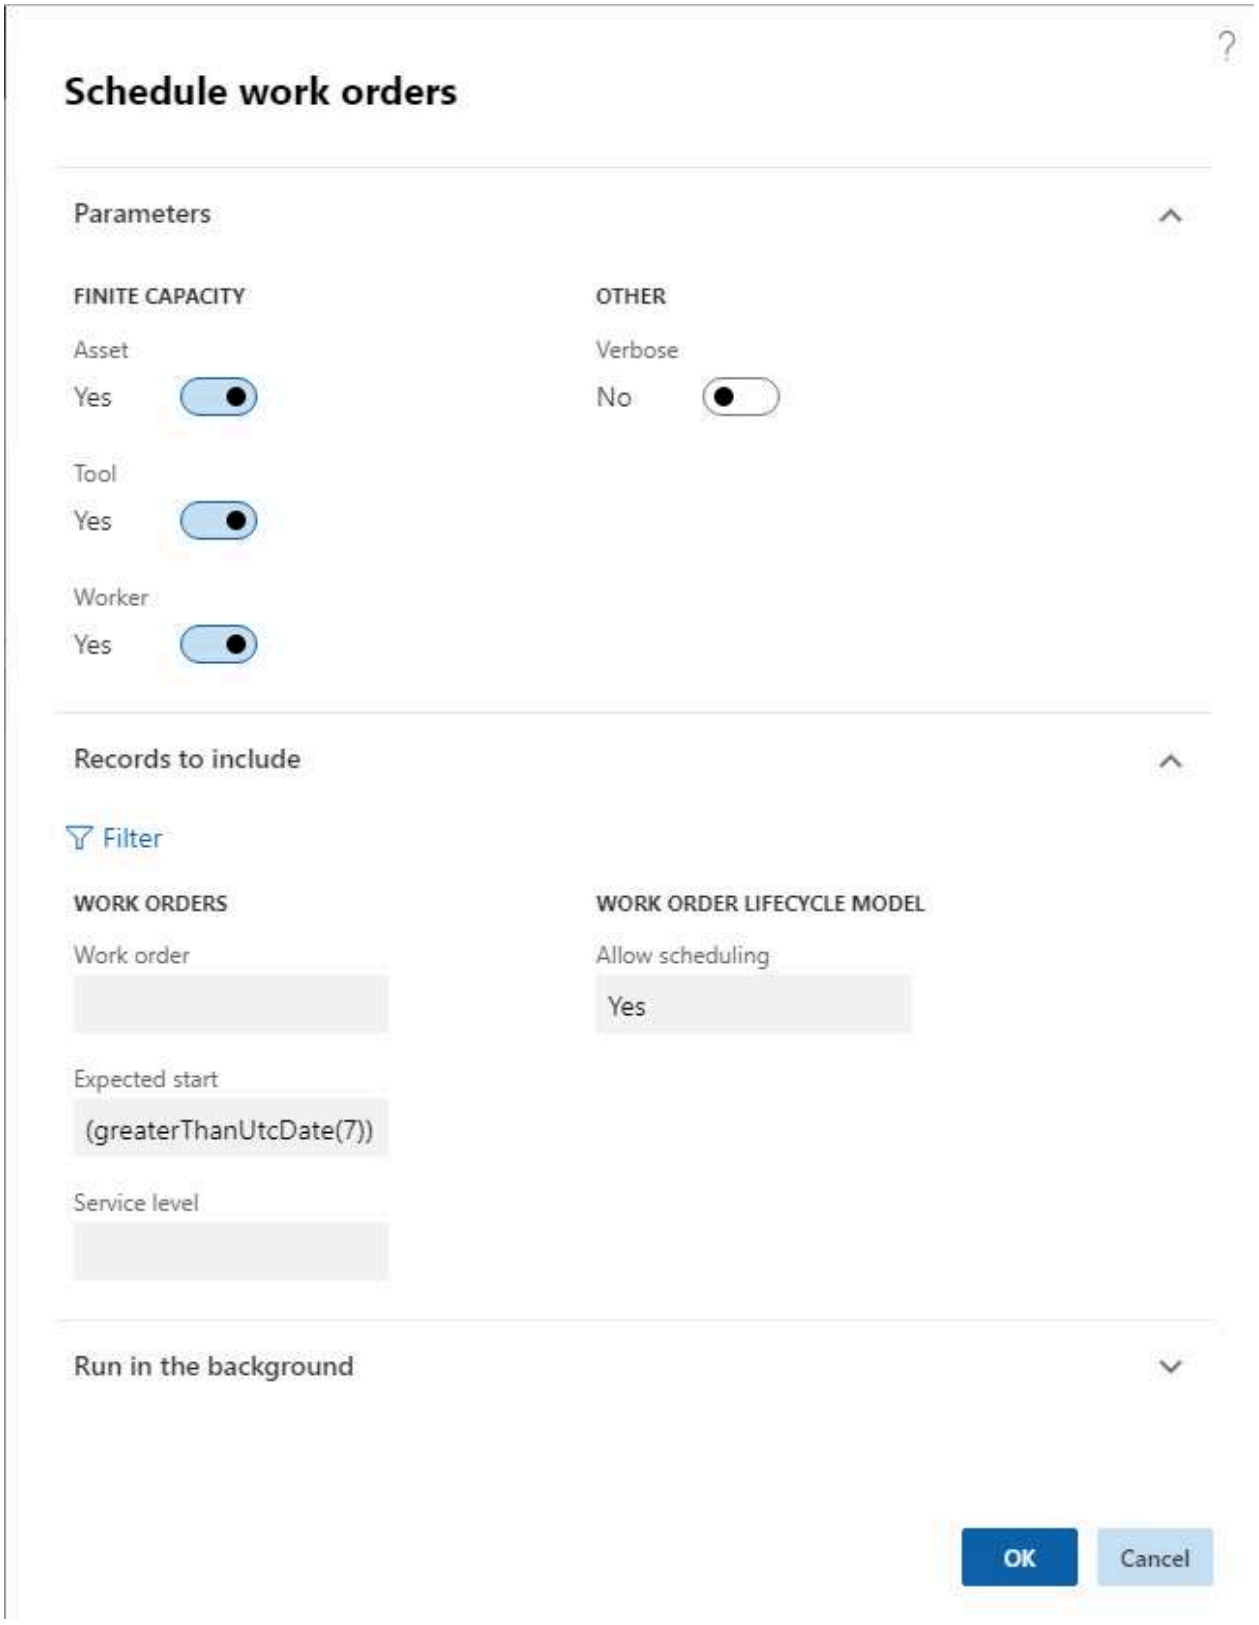
calculated scores on the work orders and maintenance workers.

6. Select **OK** to start the work order scheduling process.
7. When scheduling is completed, a message in the Action center shows the number of work orders that were scheduled. If you set the **Verbose** option to *Yes*, the Action center also shows more detailed information.

> **Note**
>
> Work orders are scheduled in one cycle per work order, not per work order job.
>
> You can also open the **Schedule work orders** dialog box by going to **Asset management** > **Periodic** > **Work orders** > **Schedule work orders**. Make your selections, and then select **OK** to start the work order scheduling process.
>
> On the **Run in the background** FastTab of the **Schedule work orders** dialog box, you can set up work order scheduling as a batch job.

Example

In the following illustration, the **Expected start** field in the **Schedule work orders** dialog box is set to the formula `(greaterThanUtcDate(7))`. This formula generates work order scheduling for all work orders where the expected start date is one week from the current date and later. This formula can be useful when you run work order scheduling on an ongoing basis, but you want to ensure that work orders that are scheduled for the next five to six days aren't rescheduled.



On the **Work order types** page (**Asset management** > **Setup** > **Work orders** > **Work order types**), if the **One maintenance worker** option is set to *Yes* for a work order type, that work order type sets up scheduling for a single maintenance worker. If that work order type is used on a work order, the **One maintenance worker** option is automatically set to *Yes* on the **Schedule** FastTab in the **Header** view of the **All work orders** details page. Then, during work order scheduling, all work order jobs that are created on the work order are scheduled to the same maintenance worker. As you require, you can change the setting of the **One maintenance worker** option on the **All**

work orders details page to enable either multiple workers or one worker to be scheduled on the work order jobs.

The scheduling process in Asset Management includes several factors in the scheduling calculation:

- Calculating scores for both work orders and maintenance workers. Scores for work orders and maintenance workers are set up in Asset management parameters.
- Checking for matching competencies (that is, skills and certificates) that are required to perform the job. Skills and certificates are set up on maintenance workers in the **Human resources** module. (Go to **Human resources** > **Workers** > **Workers**, select a worker in the list, and then, on the **Worker** tab, in the **Competencies** section, select the **Skills** and **Certificates** buttons.) Skills and certificates can also be added to maintenance job types and maintenance job trades. Learn more about competencies and maintenance job types in Maintenance job type categories and maintenance job types, maintenance job type variants, maintenance job trades, and maintenance checklists.

Scores used in work order scheduling

Calculating scores for a work order job is based on the expected start date and service level of the work order.

- **Start date calculation** – For every future date that is calculated from the expected start date, the start date score is subtracted and multiplied by the score. (In the examples that follow, the score is *10*.)
- **Criticality calculation** – The criticality score is multiplied by the criticality on the work order.
- **Service level calculation** – The service level score is divided by the service level on the work order.

In the following examples, the criticality score is *2*, and the service level scores are *5* and *100*.

Example 1

Expand table

Work order ID	Expected start date	Work order criticality	Work order service level	Calculation	Score
WO-00010816	Tomorrow	2	20	(-1 × 10) + (2 × 2) + (5 ÷ 20)	-5.75

Work order ID	Expected start date	Work order criticality	Work order service level	Calculation	Score
WO-00010817	Two days from now	2	20	(-2 × 10) + (2 × 2) + (5 ÷ 20)	-15.75
WO-00010818	Two days from now	3	5	(-2 × 10) + (2 × 3) + (5 ÷ 5)	-13

The work orders will be scheduled in the following order: WO-00010**816**, WO-00010**818**, WO-00010**817**.

Example 2

Expand table

Work order ID	Expected start date	Work order criticality	Work order service level	Calculation	Score
WO-00010816	Tomorrow	2	20	(-1 × 10) + (2 × 2) + (100 ÷ 20)	-1
WO-00010817	Two days from now	2	20	(-2 × 10) + (2 × 2) + (100 ÷ 20)	-11
WO-00010818	Two days from now	3	5	(-2 × 10) + (2 × 3) + (100 ÷ 5)	6

If the service level score is increased from *5* to *100*, the scheduling order will be WO-00010**818**, WO-00010**816**, WO-00010**817**.

All the rating scores that are related to calculating which maintenance workers should work on the work orders are set up as numbers. Those numbers are then added to each maintenance worker calculation during work order scheduling. The maintenance worker who has the highest score is selected for the work order. The following table provides a short description of the maintenance worker scores.

Expand table

Maintenance worker score	Description
Responsible worker	If the maintenance worker is selected as the responsible worker on the work order, the score is added.
Responsible maintenance	If the maintenance worker is part of the responsible maintenance worker group on the work order, the score is added.

Maintenance worker score	Description
worker group	
Preferred maintenance worker	If the worker is selected as the preferred maintenance worker on the asset, the score is added.
Preferred maintenance worker group	If the worker is part of the preferred maintenance worker group on the asset, the score is added.
Location	If your company uses functional locations, maintenance workers get the full score if they are in the functional location that is related to the asset. If the functional location of the asset has a parent location, maintenance workers in that functional location get one-half of the full score. If that location also has a parent, maintenance workers in that location get one-third of the full score. If that location also has a parent, maintenance workers in that location get one-quarter of the full score, and so on. If your company uses asset locations, which we don't recommend, the location, area, and zone are used to calculate location scores. Maintenance workers get the full score if they are in the location, area, and zone that are related to the asset. If the maintenance worker location matches only the location and area, the rating score for the maintenance worker is two-thirds of the full score. If the maintenance worker location matches only the location, the rating score for the maintenance worker is one-third of the full score.
Worker's start date	For every date that the scheduled start date is later than the expected start date, the score is subtracted.

Note

If a score is set to *0*, that score isn't calculated. This behavior is useful if, for example, you don't want to include a responsible worker in your scheduling.

Competencies used in work order scheduling

Skills and certificate requirements can be set up on maintenance job types (**Asset management** > **Setup** > **Jobs** > **Maintenance job types**) and maintenance job trades (**Asset management** > **Setup** > **Jobs** > **Maintenance job trade**).

Maintenance job types and maintenance job trades are selected on work order jobs. If skills or certificates have been selected on a maintenance job type or maintenance job trade, and that maintenance job type or maintenance job trade is used on a work order

job, only maintenance workers with matching skills and certificates are scheduled to work on the work order.

Work with scheduled work orders using a Gantt chart

The **Scheduled work orders gantt chart** provides a graphical interface where you can view and reschedule your work orders.

To view and work with the Gantt chart:

1. Go to **Asset management** > **Work orders** > **Scheduled work orders gantt chart**.
2. Use the drop-down lists and fields in the **Settings** section to set up which functional location, time span, and time scale to show in the Gantt chart.
3. Select **Apply**.
    - The Gantt chart updates to show the scheduled work orders that match your settings. Each work order is represented by a blue rectangle.
    - To reschedule a displayed work order, select and then drag it to the appropriate new date and time.
4. If you made any changes, select **Save** on the Action Pane to save them.

Dispatch work orders

The dispatch functionality in Asset Management schedules work orders and work order jobs.

Dispatch a work order

To dispatch a work order, follow these steps:

1. Go to **Asset management** > **Work orders** > **All work orders** or **Active work orders**.
2. In the grid, select the work order that you want to dispatch.
3. On the Action Pane, on the **General** tab, select **Dispatch**.
4. In the **Schedule work order** dialog box, set the following fields:
    - **Worker** – Select the worker.
    - **Schedule hours** – If the expected work hours differ from the forecast hours, enter the number of expected work hours.
    - **Scheduled start** – Specify the start date and time.
    - **Asset**, **Tool**, and **Worker** – Set one or more of these options to *Yes* if the scheduling process should observe capacity limitations for resources of the specified type that are already scheduled on other jobs.
    - **Ignore schedule** – Set this option to *Yes* to ignore closed days in the calendar. (This option applies to assets, workers, and tools.)
    - **Ignore scheduled execution** – Set this option to *Yes* to ignore any scheduling-related limitations that were selected on the work order. Learn more in Scheduled execution.
    - **Verbose** – Set this option to *Yes* if you want the system to show detailed information about the scheduling process. In this case, the Action center shows detailed information about the calculated scores on the work order.
    - **Update forecast** – Set this option to *Yes* to update the forecast so that it reflects any scheduling change that you made in this dialog box.
5. Select **OK**. The work order lifecycle state is automatically updated to the **Scheduled state** value that is specified on the **Lifecycle models** page (**Asset management** > **Setup** > **Work orders** > **Lifecycle models**).

> ⓘ **Note**

To delete the schedule on a work order, select it, and then, on the Action Pane, on the **General** tab, select **Delete schedule**. If you delete the schedule on a work order, remember to manually update the work order lifecycle state.

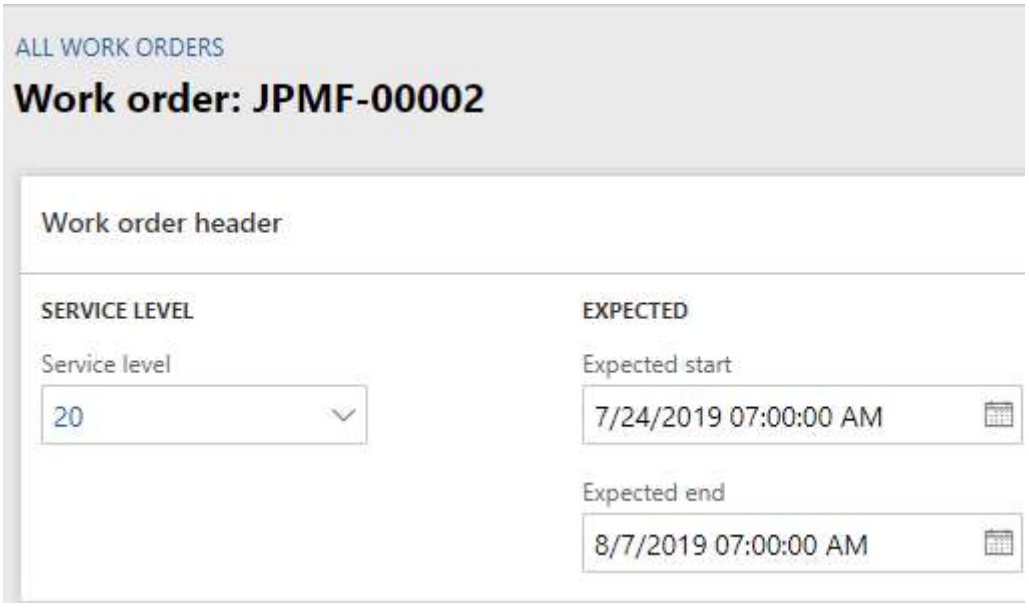
Schedule work order on specific date and time

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

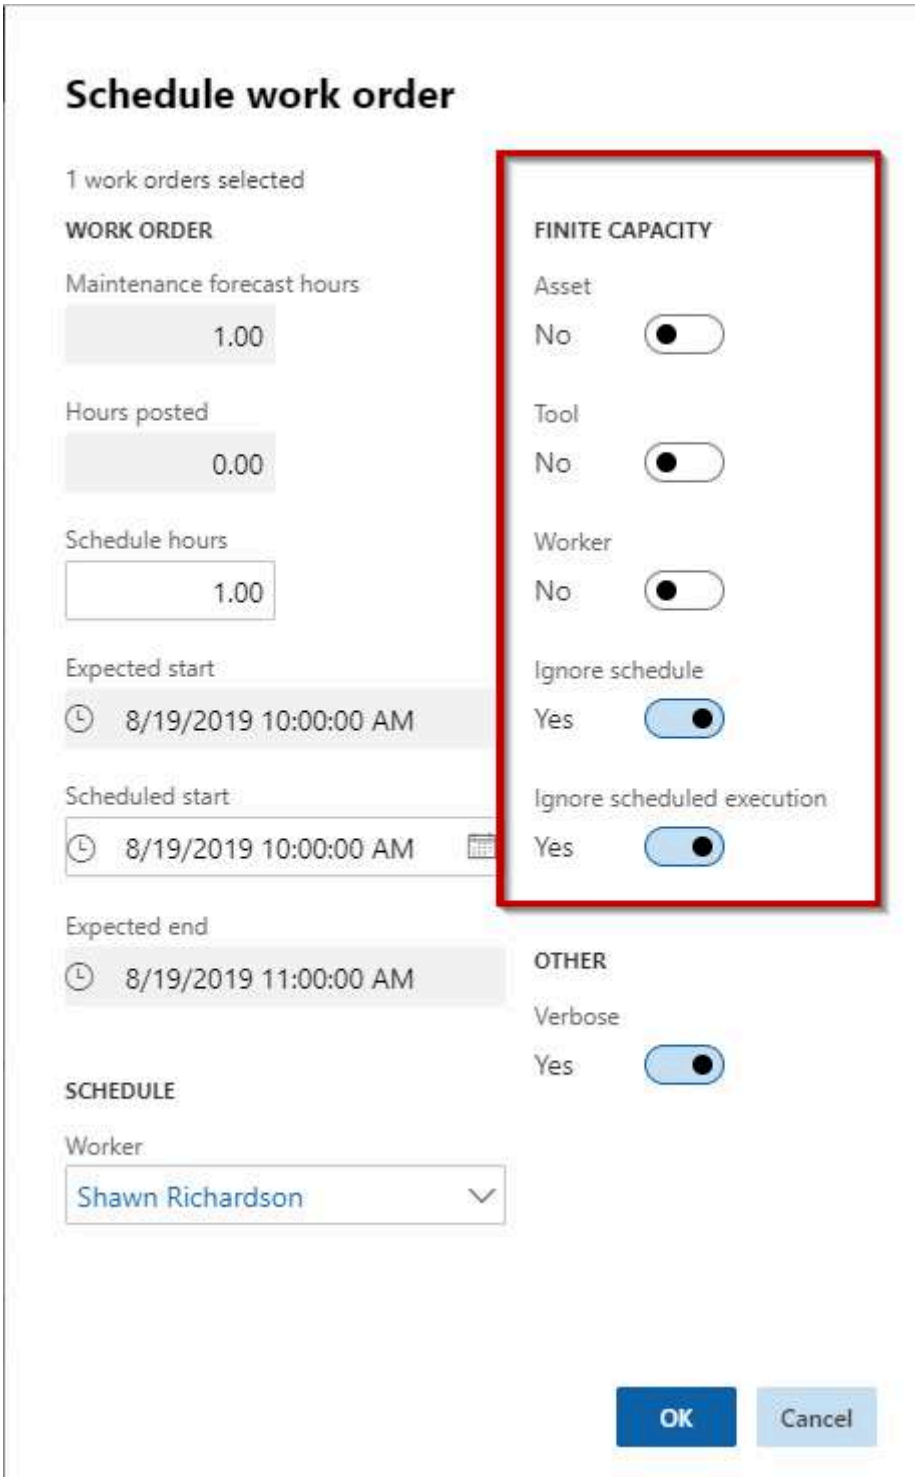
If a work order must be scheduled on a specific date *and* time, you can override the standard scheduling process in Asset Management and create a specific schedule for a work order.

1. Click **Asset management** > **Work orders** > **All Work orders** or **Active work orders**.
2. In the work order list, click on the Work order ID in the **Work order** column.
3. Click **Edit**.
4. On the **Work order header** FastTab, insert start and end dates and times in the **Expected start** and **Expected end** fields.



5. On the **General** tab, click **Schedule** to use the standard scheduling process, or click **Dispatch** if you want to assign the work order to a specific worker.
6. In order to override any existing capacity reservations to ensure that the work order is scheduled in the expected period, make the selections as shown in the figure below in the **Schedule work order** dialog > **Finite capacity** section. This means that the scheduling

process will ignore existing capacity reservations because the work order must start on the expected start time.



7. Click **OK** to start scheduling.
8. If the scheduling process results in double bookings, you will see a message on the screen, and you can adjust the related work orders.

> ⓘ **Note**
>
> In order to schedule a maintenance worker for the work order, that maintenance worker must be available at the expected start date and time. Worker availability is set up in the

worker calendar.

Scheduled work order maintenance jobs

Article • 06/15/2022

The **Scheduled work order maintenance jobs** page shows an overview of the work orders allocated to a resource. Work orders using resource types "Human resources", "Tool", and "Machine" are shown. For example, if a maintenance worker calls in sick, you can use this page to quickly find work orders allocated to the worker, and then allocate another maintenance worker to the job.

View scheduled work order maintenance jobs

1. Click **Asset management** > **Work orders** > **Scheduled work order maintenance jobs**. You see a list of all work orders set to work order lifecycle state "Scheduled" or "In progress".

2. You can sort the list, for example, by maintenance worker. You can also use the filter to limit the list to display work orders allocated to a specific resource or maintenance worker.

3. You can see notes on the work order and, if required, add new notes by selecting the work order job, and then click **Notes**.

4. If you want to allocate one maintenance worker to a work order, select the work order, and then click **Work order**.

5. The **Work order** page opens. Click **Dispatch** to schedule the work order to a specific maintenance worker.

> ⓘ **Note**
>
> Read more about scheduling several work orders or one work order in Schedule work orders and Dispatch work order.

The following screenshot shows an example of the **Scheduled work order maintenance jobs** page.

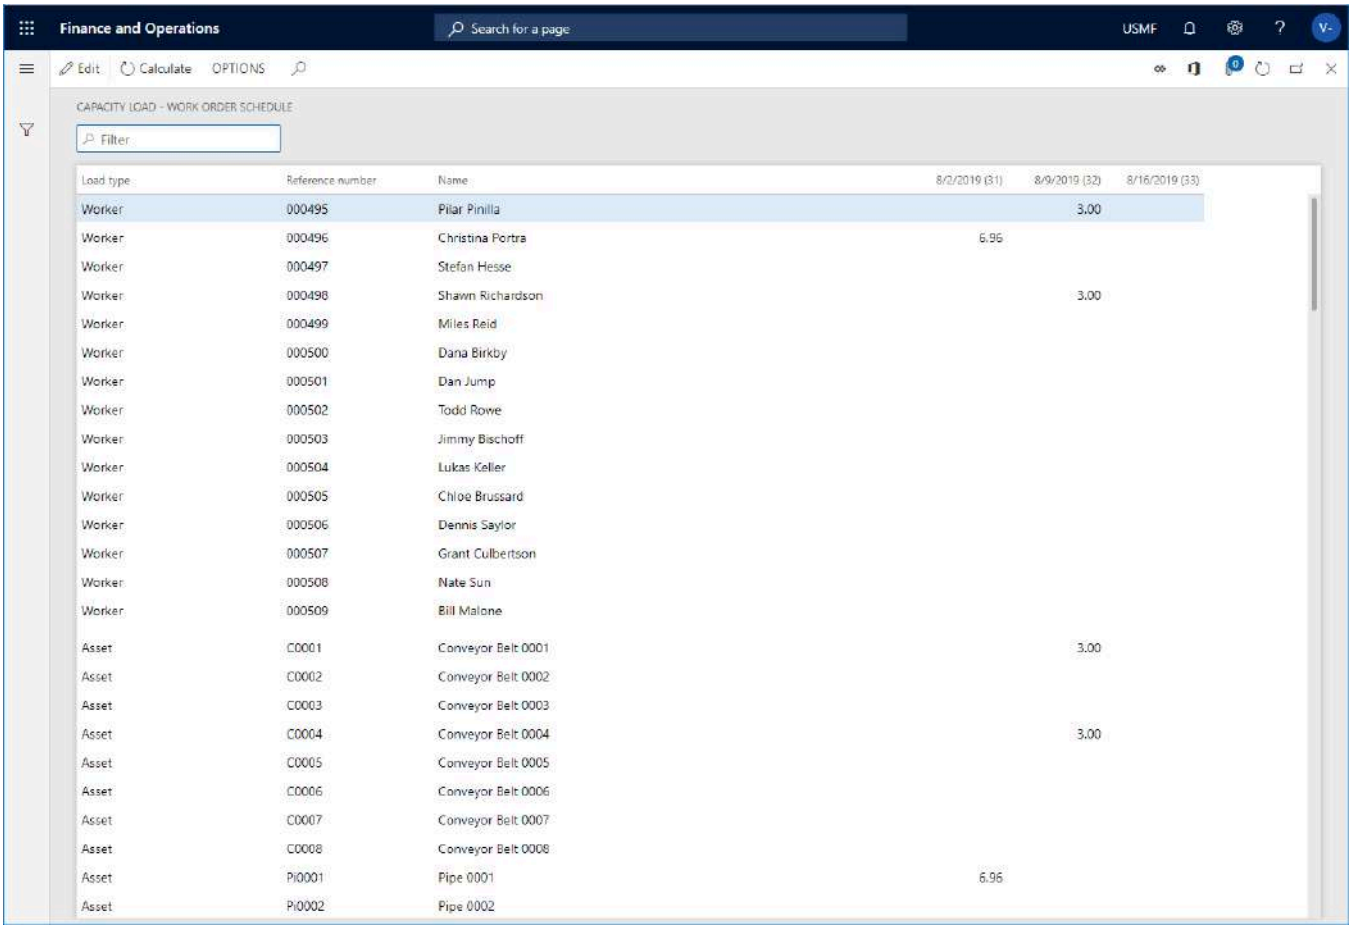
Calculate capacity load on scheduled work orders

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can calculate capacity load on scheduled work orders to get an overview of the work load on resources for a specific period. Calculations can be made for the following resources: Maintenance workers, worker groups, tools, and assets.

1. Click **Asset management** > **Inquiries** > **Schedule** > **Capacity load**.
2. In the **Calculate capacity load** dialog > **Show** field, select which load type you want to calculate: **Capacity**, **Reserved**, or **Remainder**.
3. Select **Yes** on the **Skip zero** toggle button if you do not want to show results containing zero.
4. Select the resource types for which you want to calculate capacity load by selecting **Yes** on the relevant toggle buttons: **Worker**, **Maintenance worker group**, **Tool**, and **Asset**.
5. Select the start date for the calculation in the **From date** field.
6. In the **Interval type** field, select the interval for the calculation: **Day**, **Week**, **Month**, or **Quarter**.
7. In the **Period frequency** field, insert the number of intervals you want to calculate. For example, if you have selected **Day** as the interval type, and you enter the number "5" in this field, a calculation of five days from the start date will be made.
8. Click **OK** to start the calculation.

The figure below shows the result of a calculation covering three weeks for the load type **Reserved**.



Load type	Reference number	Name	8/2/2019 (31)	8/9/2019 (32)	8/16/2019 (33)
Worker	000495	Pilar Pinilla		3.00	
Worker	000496	Christina Portra	6.96		
Worker	000497	Stefan Hesse			
Worker	000498	Shawn Richardson		3.00	
Worker	000499	Miles Reid			
Worker	000500	Dana Birkby			
Worker	000501	Dan Jump			
Worker	000502	Todd Rowe			
Worker	000503	Jimmy Bischoff			
Worker	000504	Lukas Keller			
Worker	000505	Chloe Brussard			
Worker	000506	Dennis Saylor			
Worker	000507	Grant Culbertson			
Worker	000508	Nate Sun			
Worker	000509	Bill Malone			
Asset	C0001	Conveyor Belt 0001		3.00	
Asset	C0002	Conveyor Belt 0002			
Asset	C0003	Conveyor Belt 0003			
Asset	C0004	Conveyor Belt 0004		3.00	
Asset	C0005	Conveyor Belt 0005			
Asset	C0006	Conveyor Belt 0006			
Asset	C0007	Conveyor Belt 0007			
Asset	C0008	Conveyor Belt 0008			
Asset	PI0001	Pipe 0001	6.96		
Asset	PI0002	Pipe 0002			

[!NOTE] If you select the load types **Capacity** or **Remainder** for your calculation, the same result will be displayed if no reservations have been made for the resources in the selected period.

For information about how to calculate capacity load on maintenance schedule lines and not scheduled work orders, refer to Calculate capacity load.

Register consumption

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When a maintenance job on a work order is complete, the next step is to register consumption and post the journals. Register consumption for the following types: hours, items, and expenses. Register and post the different consumption types on the **Work order journals** page. The journal setup in **Asset Management** is used for creating and posting separate journals for hours, items, and expenses in the **Project management and accounting** module.

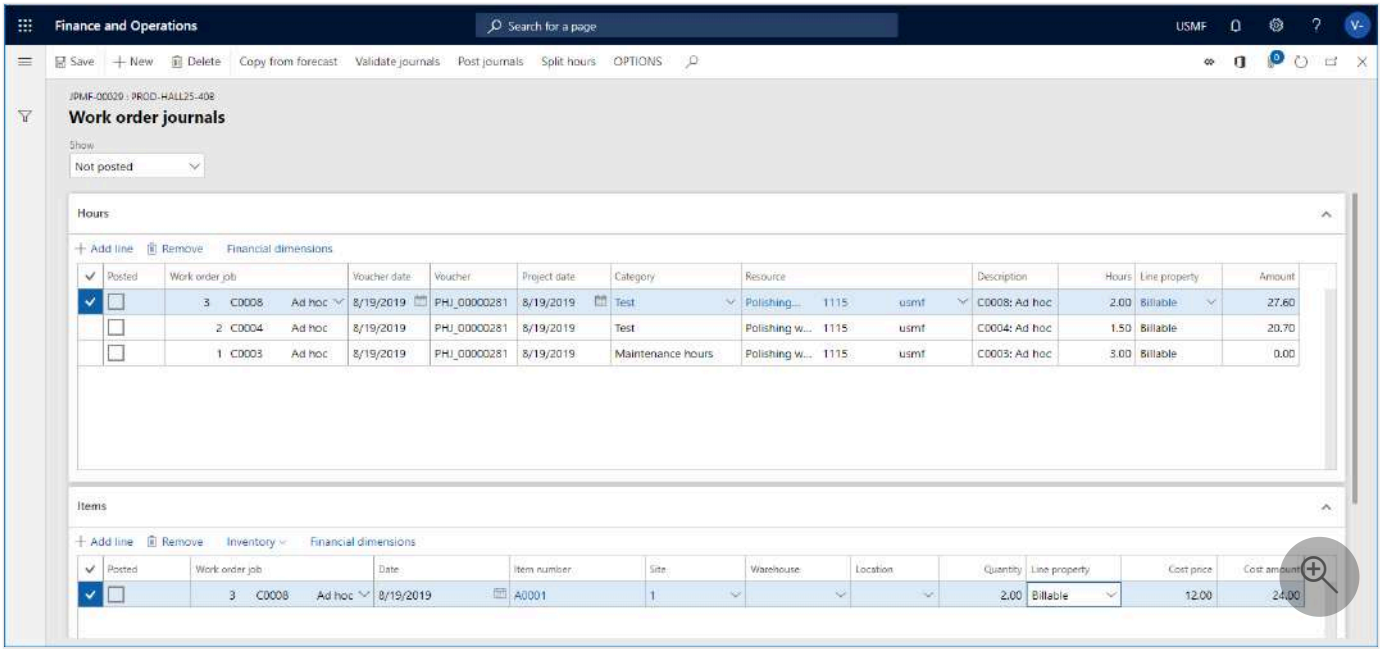
In some cases, you can add or delete forecast lines on a work order. The setup of a work order lifecycle state, the related project type, and the stage rules related to the project type determine if you can add or edit journal lines. Learn more about work order lifecycle states and related project stages in Forecasts, work orders, and projects.

> **Note**
>
> You can set up automatic posting of journals on a work order lifecycle state. Learn more in Work order lifecycle states.

1. Select **Asset management** > **Work orders** > **All Work orders** or **Active work orders**.
2. Select the work order, and select **Journals**.
3. Select **Copy from forecast** to transfer any forecast lines that might be connected to the work order. You can select which consumption types you want to transfer.
4. If necessary, add more consumption lines on the relevant FastTab by selecting **Add line** and filling out data on the line.
5. Select **Validate journals** to validate the journal lines before posting.
6. Select **Post journals** to post the journal lines.
7. After you post the consumption journals, you can update the work order lifecycle state. For example, to indicate that the work order is complete, update the lifecycle state to **Ended**.

- In the **Show** field at the top of the **Work order journals** page, select which journal lines you want to see: **All**, **Not posted**, or **Posted**. Posted journals have a check mark in the **Posted** check box.
- When you create item lines in the work order journal, product dimensions and tracking dimensions related to the item automatically transfer to the journal line.

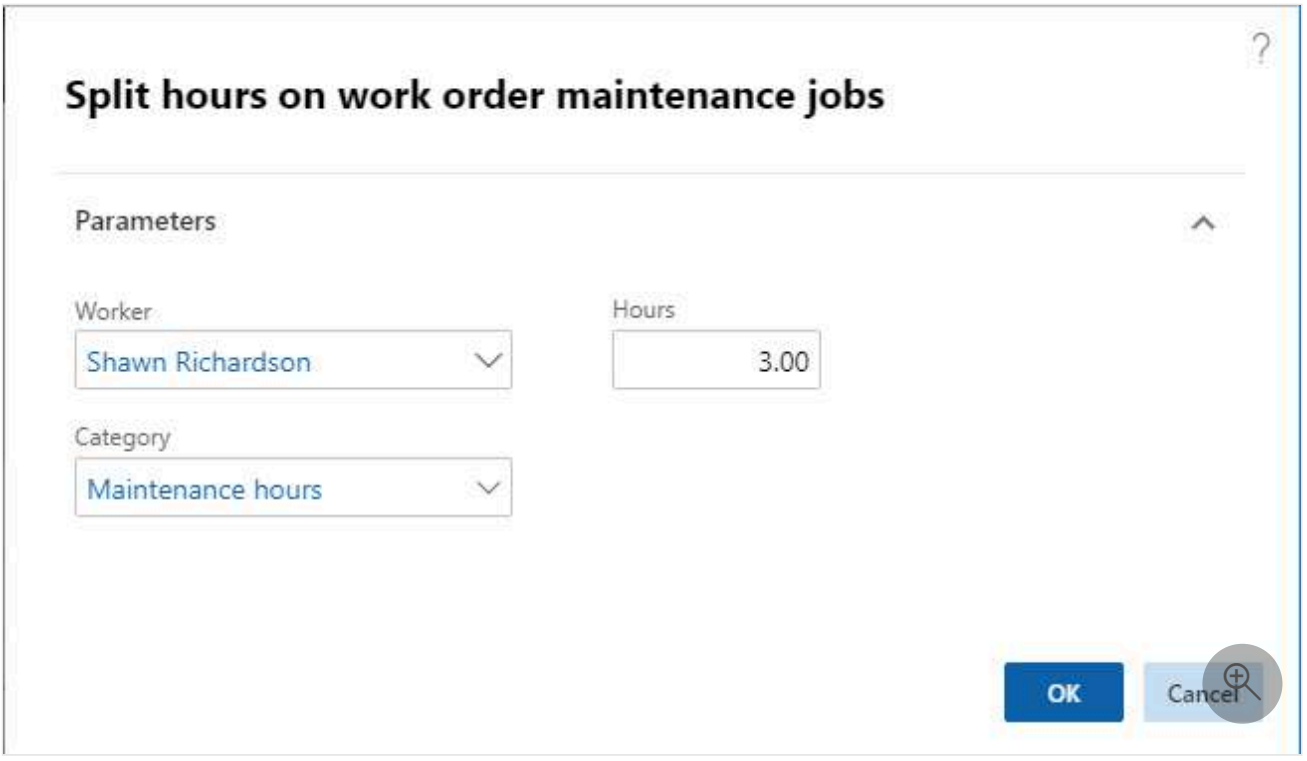
The following screenshot shows an example of hour and item registrations on a work order in **Work order journals**.



Split hours on work orders with several work order jobs

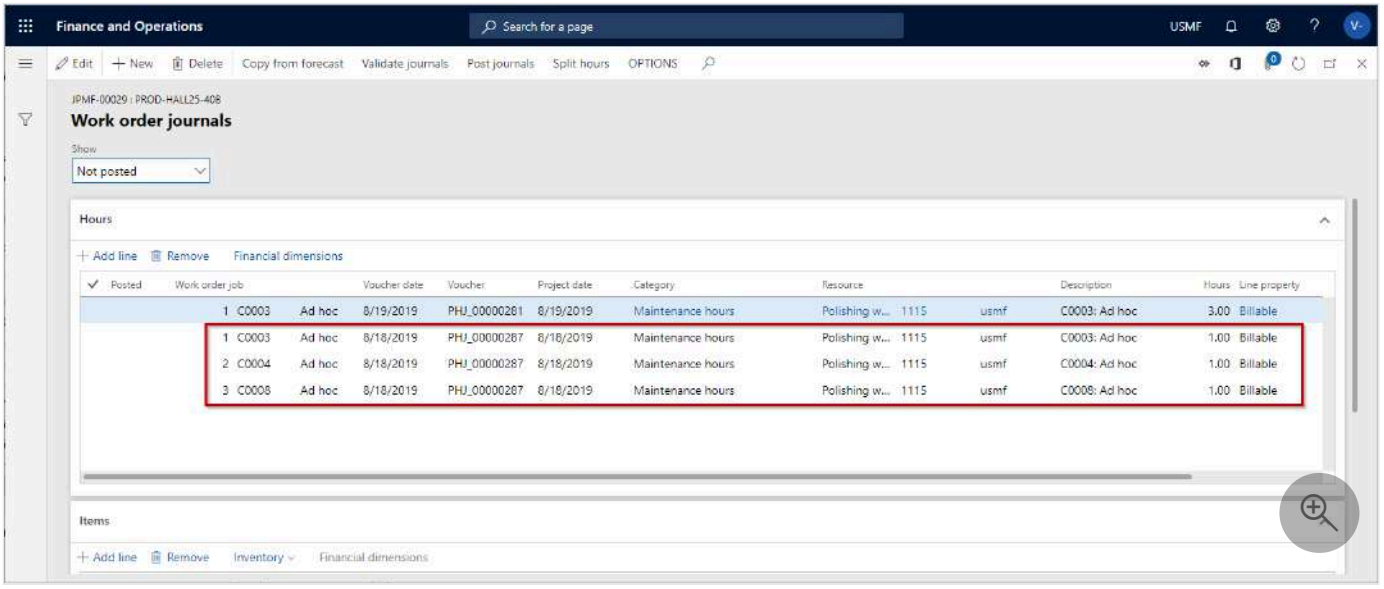
If a work order contains several work order jobs, use the **Split hours** functionality to register work hours. You can distribute one hour registration line evenly across each work order job.

1. Select **Asset management** > **Work orders** > **All Work orders** or **Active work orders**.
2. Select the work order and select **Journals**.
3. Select the hour registration line you want to split, and select **Split hours**.
4. In the **Split hours on work order maintenance jobs** dialog, the name of the worker who is signed in automatically appears in the **Worker** field. If required, select another worker.
5. Select a category for the hour registration in the **Category** field.
6. Enter the number of work hours to split in the **Hours** field.



7. Select **OK**.

Example: The following screenshot shows journal lines for a work order containing three work order jobs. The first line, which contains three work hours, is split, and one work hour is registered on each work order job. After the three hour registration lines are created, you decide what to do with the original hour registration line (the first line in the example). You can keep it as-is or delete it.



Financial dimensions on consumption registrations

When you make consumption registrations, the system adds financial dimensions related to the different registration types to the registrations in a specific sequence.

- *Hour and Expense registrations:* First, the system adds financial dimensions from the journal header, if any. Next, it adds financial dimensions from the related work order project. Finally, it adds financial dimensions from the resource (worker).
- *Item registrations:* First, the system adds financial dimensions from the related work order project. Next, it adds financial dimensions from the site. Finally, it adds financial dimensions from the item.

> **Important**
>
> If the dimension link feature is active (on **Inventory management** > **Setup** > **Posting** > **Dimension link**) and a financial dimension is linked to the inventory site, the linked dimension values from the site take precedence on item registrations. In this case, the values from the dimension attributes override the values that came from the related work order project.

> **Note**
>
> For all three registration types, the system validates the financial dimension combination and blanks invalid combinations.

Create consumption reports

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you've created and posted consumption registrations on work orders in Asset Management, two reports are available to display consumption details.

Asset consumption report

When you have posted consumption on work orders, you can print an asset consumption report. The report displays hours, hour costs, item costs, and expenses posted on assets.

1. Click **Asset management** > **Reports** > **Assets** > **Asset consumption**.
2. In the **Asset consumption** dialog, select the parameters and detail level you want to see by selecting **Yes** on the relevant toggle buttons, and inserting a functional location level in the **Show** section.
    - You can use the **Levels** field to indicate how detailed you want the asset lines to be regarding functional locations.

      For example, if you enter the number "1" in the field, and you have a multi-level functional location structure, all assets for a functional location will be shown on the top level, and therefore a line may be added up from functional locations located at a lower level.

      If you enter the number "0" in the **Levels** field, you will see a detailed result showing all assets on all the functional location levels to which they are related.
    - Select **Yes** on the **Sum on all sub assets** toggle button to see sums for each sub asset in the report.
3. Select a date interval in the **Dates** section.
4. On the **Destination** FastTab, select if you want to display the report on screen, print it, or save it as a file or email.

5. If required, you can select specific assets to be displayed in the report. On the **Records to include** FastTab, click **Filter**, and add the assets you want to include in the report.
6. Click **OK** to generate the report.

Work order consumption report

When you have posted consumption on work orders, you can print a work order consumption report. The report displays hours, hour costs, item costs, and expenses posted on work orders.

1. Click **Asset management** > **Reports** > **Work orders** > **Work order consumption**.
2. In the **Work order consumption** dialog, select the parameters you want to include in the report by selecting **Yes** on the relevant toggle buttons in the **Show** section.
3. Select a date interval in the **Dates** section.
4. On the **Destination** FastTab, select if you want to display the report on screen, print it, or save it as a file or email.
5. If required, you can select specific work orders to be displayed in the report. On the **Records to include** FastTab, click **Filter**, and add the work orders you want to include in the report.
6. Click **OK** to generate the report.

> **Note**
>
> You can also generate a work order report, which contains more work order details.

Warranty agreements

Article • 06/03/2022

In Asset Management, you can set up warranty terms that can be connected to an asset or an asset type. Warranty terms are created for a specific period. Warranty can be set up to provide full coverage or partial coverage, and you can set up terms that are related to hours, expenses, and items.

The first step is to create any vendor warranty agreements that you have for your equipment. You then attach warranty agreements to assets or asset types. Vendor warranty agreements are used only for informational purposes. If vendor warranty is set up on an asset, you can see the warranty coverage period on the asset.

Create a warranty agreement

A warranty agreement can include several agreement lines to cover the warranty for work hours, expenses, and items.

1. Select **Asset management** > **Setup** > **Assets** > **Warranty**.
2. Select **New** to create a product.
3. In the **Warranty** field, enter a warranty ID.
4. In the **Name** field, enter a description.

   On the **Details** FastTab, the **Assets** field shows the number of active assets that use the warranty agreement.

5. On the **Warranty lines** FastTab, follow these steps to add lines that should be included in a warranty agreement:
   a. Select **Add line** to add a new condition to the warranty. A sequential line number is automatically entered in the **Line** field.
   b. In the **Period** field, select the type of warranty period.
   c. In the **Interval** field, enter a number. This field defines the number of periods that the warranty should be valid for.
   d. In the **Percent** field, enter the coverage percentage for the warranty line. The percentage indicates how much is covered by your company.

Warranties on assets and asset types

Article • 06/15/2022

This article explains how to set up warranties on assets and asset types in Asset Management.

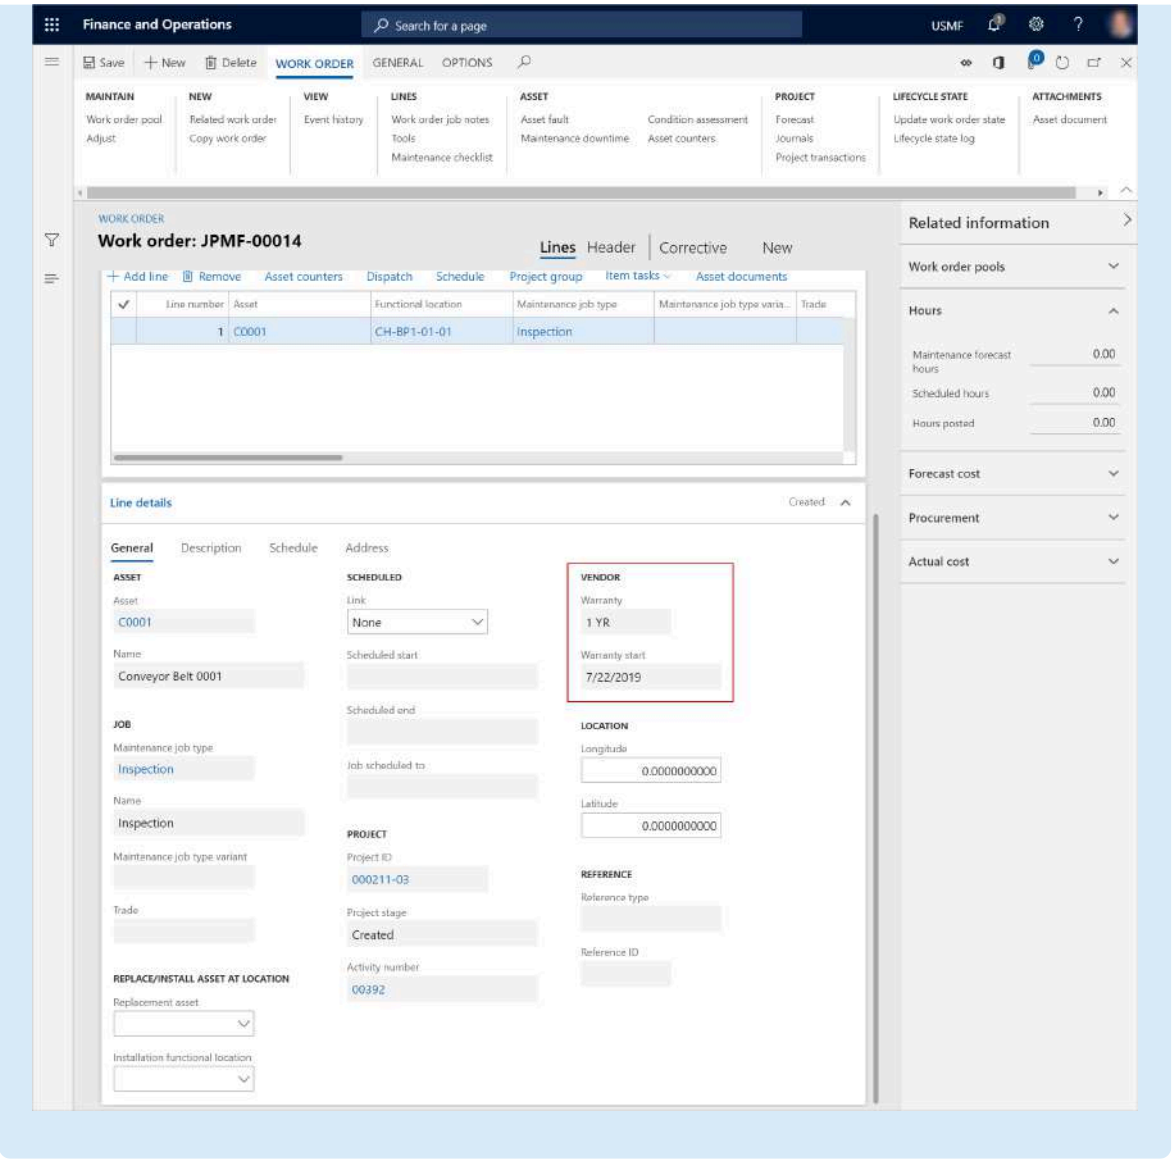
Set up a warranty on an asset type

1. Select **Asset management** > **Setup** > **Asset types** > **Asset types**.
2. In the left pane, select the asset type to attach a vendor warranty agreement to, and then select **Asset type defaults**.
3. On the **General** FastTab, in the **Vendor warranty** field, select the agreement.

Set up a warranty on an asset

1. Select **Asset management** > **Assets** > **All assets**.
2. Select the asset, and then select **Edit**.
3. On the **Vendor** FastTab, in the **Vendor warranty** section, in the **Warranty** field, select the warranty agreement.
4. In the **Warranty start** and **Warranty end** fields, select the start and end dates.

> **Important**
>
> If a date is selected in the **Warranty start** field on a work order, the warranty becomes valid for the work order on that date. When you create a work order, the **Warranty start** field is automatically set to the date of creation. However, you can change the date so that it corresponds to, for example, the start date of a warranty agreement.



> **Note**
>
> When you create a work order for an asset that is covered by a vendor warranty, if the work order has an expected start date during the warranty period, you receive a notification about the warranty agreement. You can then cancel the work order, as you require.

Create maintenance budgets

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Maintenance budgets are used to provide an overview of expected costs for preventive maintenance. Budget lines are calculated based on maintenance schedule lines that have an expected start date during the budget period.

Maintenance budgets are based on the cost types that are used in Asset Management: **Preventive**, **Corrective**, and **Investment**. Budget costs for investment maintenance are included for active assets that have a replacement date during the budget period and a related replacement value. Budget costs for corrective maintenance are included if a past corrective date is included in the budget calculation. In that case, corrective costs from an earlier period are calculated for the same future period that you calculate the maintenance budget for.

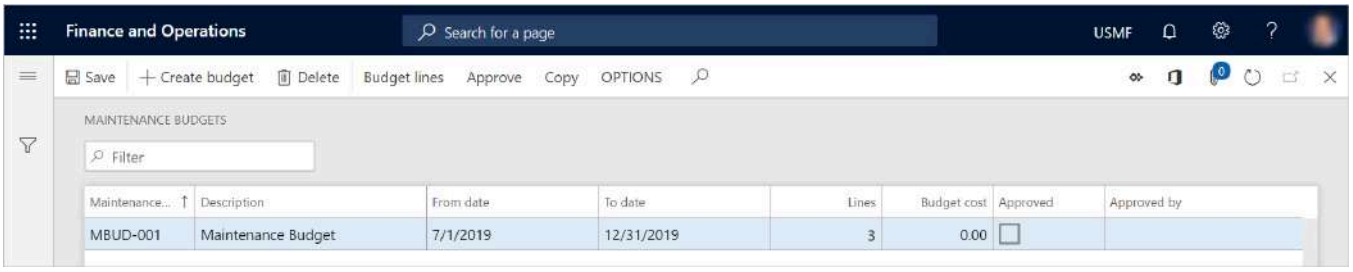
Create a maintenance budget

1. Select **Asset management** > **Inquiries** > **Maintenance budget** > **Budget**.
2. Select **Create budget**.
3. In the **Maintenance budget** field, enter a budget ID.
4. In the **Description** field, enter a description.
5. On the **Period** FastTab, in the **From date** and **To date** fields, enter the start and end dates of the budget period.
6. To include corrective budget costs that are calculated on the basis of actual costs from a previous period, in the **Corrective from date** field, enter the start date of the period that those costs should be included from.
7. Depending on the level of detail that is required in the budget, set the relevant options on the five **Group by** FastTabs.
8. Select **OK**.

9. Select **Budget lines** to open **Maintenance budget lines** page, where you can view all the budget lines that have been created for the period.

10. To approve the budget, select it on the **Maintenance budgets** page, and then select **Approve**. Then, in the **Approve budget** dialog box, select **OK**. Your name is entered in the **Approved by** field on the **Maintenance budgets** page.

> **Note**
>
> After you've approved a maintenance budget, you can't recalculate or adjust the related lines on the **Maintenance budget lines** page unless you first remove the approval. To remove the approval of a maintenance budget, select it on the **Maintenance budgets** page, and then select **Approve**. Then, in the **Approve budget** dialog box, select **OK**.



You can also create a new maintenance budget by copying an existing budget. On the **Maintenance budgets** page, select the budget to copy, and then select **Copy**. This approach is useful if, for example, you've created a budget for one month and want to copy it to other months.

> **Note**
>
> The maintenance budget calculates only budget costs based on maintenance schedule lines. To calculate actual costs for the same period, you can do that calculation on the **Asset cost control** page.

Last updated on 05/07/2025

Update maintenance budgets

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The **Maintenance budget lines** page shows all the budget lines that have been created for the budget that is selected on the **Maintenance budgets** page. (Learn more in Create maintenance budgets.) You can recalculate and adjust maintenance budget lines until the maintenance budget is approved. After the budget period has passed, and costs have been posted in Asset Management, you can also update the budget lines with actual costs.

Recalculate a maintenance budget

You can recalculate a maintenance budget on the **Maintenance budget lines** page. When you recalculate a maintenance budget, the existing budget lines are deleted, and a new calculation is done.

1. On the **Maintenance budget lines** page, select **Recalculate**.
2. In the **Recalculate budget** dialog box, make the required changes for the new calculation, and then select **OK**.

New budget lines are created according to the values that you set.

Adjust budget lines

Instead of recalculating the whole maintenance budget, you can adjust selected lines that are related to budget costs.

1. On the **Maintenance budget lines** page, select the lines to update the budget cost for.
2. Select **Adjust**.
3. To add an amount to the selected lines, select the **Add cost** check box, and then enter the value in the **Add value** field.
4. To multiply the budget cost on the selected budget lines by a factor, select the **Multiply cost** check box, and enter the factor in the **Multiply value** field.

For example, if you enter **1.2** in the **Multiply value** field, you increase the budget cost on the selected lines by 20 percent. If you enter **0.7**, you reduce the budget cost on the selected lines by 30 percent.

5. Select **OK**.

The selected budget lines are updated according to the values that you set in step 3 or 4.

Update actual costs

After the dates on the budget lines have passed, and actual costs have been posted in Asset Management, you can update the actual costs on the maintenance budget.

1. On the **Maintenance budget lines** page, select **Update cost**.
2. In the **Calculate actual cost** dialog box, select **OK**.

The **Actual cost** fields on the budget lines are updated if actual costs have been posted. New budget lines might be generated if new asset types have been created since you created the budget, and if those asset types have been used on assets that work orders have been created for and related costs have been posted for. New budget lines show only actual costs, because no budget costs were calculated for them.

> ⓘ **Note**
>
> To see an overview of actual costs divided into preventive, corrective, and investment costs, you can do a calculation for the same period on the **Asset cost control** page.

Manually add budget lines

On the **Maintenance budget lines** page, you can manually add a new budget line by selecting **New** and then making selections on the line. Here are some examples of situations where this approach might be useful:

- You know that refurbishment of some assets is currently in the planning phase, but related jobs haven't yet been created in Asset Management. However, you want budget costs for those jobs to be included in the maintenance budget.
- New assets or asset types have been created since you made the maintenance budget, but maintenance plans haven't yet been set up on those assets or asset types. However, you want budget costs for those asset types to be included in the maintenance budget.

Cost and date control

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

In Asset Management, you can calculate costs to get an overview of actual costs compared to budget costs on assets, functional locations, and work orders. Actual costs are based on posted transactions.

You can also make a date calculation if you want to compare scheduled start and end dates to actual start and end dates on work orders.

Cost control for assets, functional locations, and work orders

The calculations made for assets, functional locations, and work orders are almost identical. The only difference is that for assets and functional locations, you can also include sub assets and sub locations in your calculation. The date is the transaction date when the registration was recorded.

1. Click **Asset management** > **Inquiries** > **Assets** > **Asset cost control** or **Functional location cost control**, or **Asset management** > **Inquiries** > **Work orders** > **Work order cost control**.
2. In the **Asset cost control** / **Functional location cost control** / **Work order cost control** dialog, select a time range to be calculated.
3. If required, select a financial dimension set to be included in the calculation.
4. Select "Yes" on the **Skip zero** toggle button if you don't want to show results with a cost of zero.
5. You can use the **Level** field to indicate how detailed you want the cost control lines to be regarding functional locations.

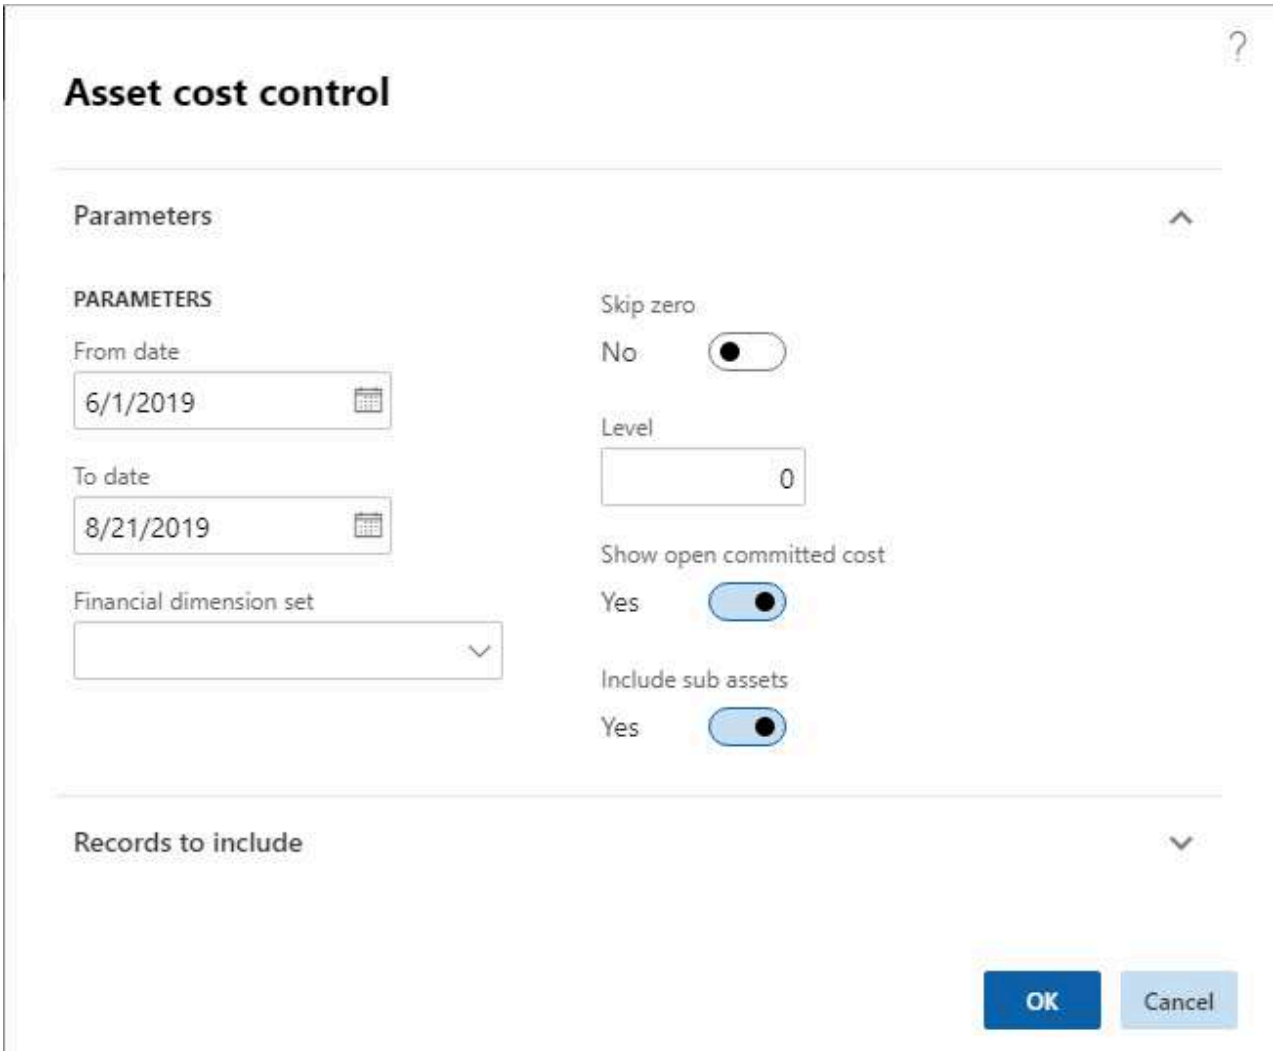
   For example, if you insert the number "1" in the field, and you have a multi-level functional location hierarchy, all cost control lines for a functional location will be shown

on the top level, and therefore the hours on a line may be added up from functional locations located at a lower level.

If you insert the number "0" in the **Level** field, you will see a detailed result showing all cost control lines on all the functional location level to which they are related.

6. Select "Yes" on the **Show open committed cost** toggle button if you want to include that column in the calculation.
7. Select "Yes" on the **Include sub assets** toggle button to show costs related to sub assets as separate lines.
8. If you want to limit the search, you can select specific assets / functional locations / work orders on the **Records to include** FastTab.
9. Click **OK** to start the calculation.

   The figure below shows an example of the **Asset cost control** dialog.

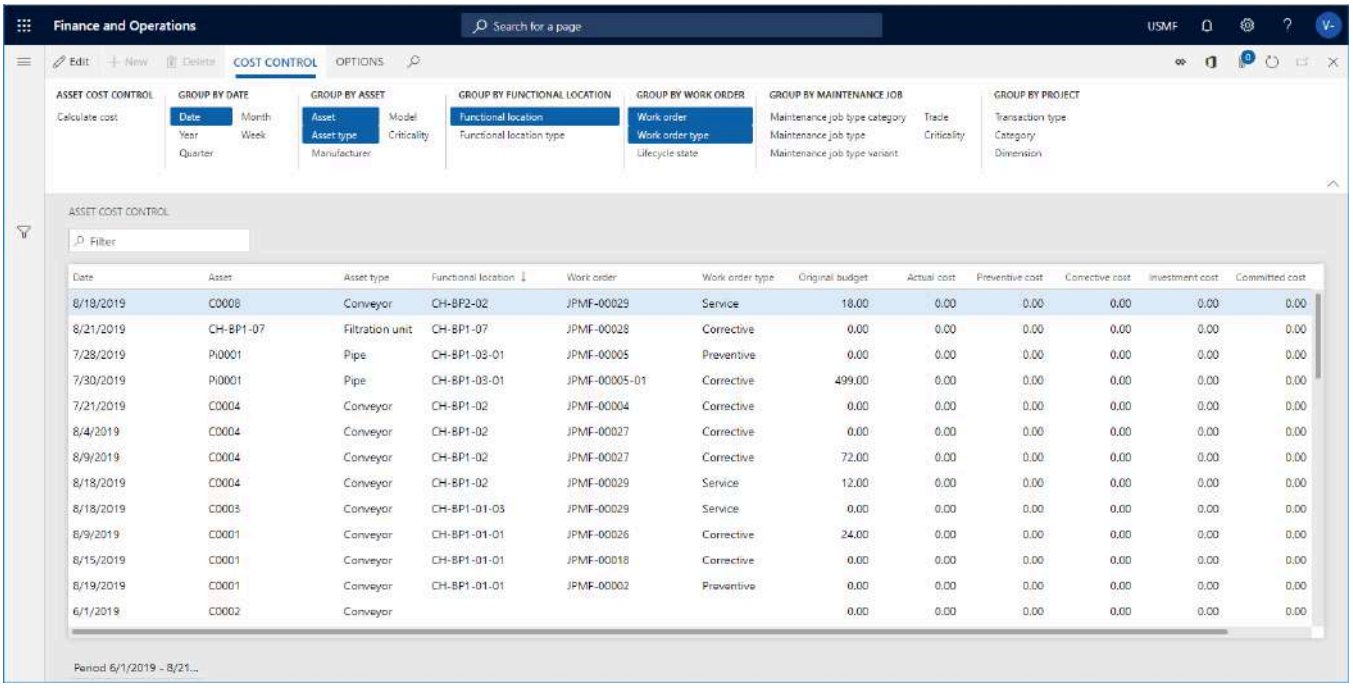


10. On the **Asset cost control** page, click the **Group by** buttons to show the required detail level of the calculation. The selected **Group by** buttons are highlighted. Click on a button to activate or deactivate it.

Example of calculation results in asset cost control

The screenshot below shows an example of calculation results in **Asset cost control**.

- The **Original budget** field shows budget costs from the work order forecast.
- The **Committed cost** field shows the total amount of expenses that a legal entity has committed itself to pay.
- The **Open committed cost** field shows commitments to pay for items, hours, and services you have ordered or received but not yet paid for.
- The **Actual cost** field shows related costs after all consumption registrations have been posted.



Another way of making a cost calculation is to multi-select assets in **All assets** or **Active assets**. Then, you click the **Cost control** button on the **General** tab. In the **Asset cost control** dialog, the selected assets are automatically inserted in the **Asset** field on the **Records to include** FastTab. Click **OK**, and a cost calculation for the selected assets is shown. The same procedure can be done for functional locations in **All functional locations** or **Active functional locations**, and for work orders in **All work orders** or **Active work orders**.

Work order date control

Use this page to get an overview of expected start and end dates compared to actual start and end dates on work orders.

1. Click **Asset management** > **Inquiries** > **Work orders** > **Work order date control**.

2. Click **Calculate**.

3. Select a functional location in the **Functional location** field.
4. Insert the range for which you want to make the calculation in the **From date** and **To date** fields. All work orders with expected start date within the range will be included.
5. Click **OK**.
6. Click the **Group by** buttons to show the required detail level of the calculation. The selected **Group by** buttons are highlighted. Click on a button to activate or deactivate it.

Example of calculation results in work order date control

The screenshot below shows an example of calculation results in **Work order date control**.

- The **Avg. start delay** field shows the difference in days between scheduled start date for a work order compared to actual start date. If, for example, the actual start date was two days before the scheduled start date, "-2" will be displayed in this field.
- The **Avg. end delay** field shows the difference in days between scheduled end date for a work order compared to actual end date. If, for example, the actual end date was three days after the scheduled end date, "3" will be displayed in this field.
- The **Occurrences** fields show the number of times deviations occur in relation to scheduled and actual start date, and scheduled and actual end date on the work order.

Work hour control

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

In Asset Management, you can calculate hours to get an overview of actual hours compared to budget hours on assets, functional locations, or work orders. Actual hours are based on posted transactions.

Work hour control for assets, functional locations, and work orders

The calculations made for assets, functional locations, and work orders are almost identical. Only difference is that for assets and functional locations, you can also include sub assets and sub locations in your calculation. The date is the transaction date when the registration was recorded.

1. Click **Asset management** > **Inquiries** > **Assets** > **Asset hour control** or **Functional location hour control**, or **Asset management** > **Inquiries** > **Work orders** > **Work order hour control**.

2. In the **Asset hour control** dialog, .

3. In the **Asset hour control** / **Functional location hour control** / **Work order hour control** dialog, select a period to be calculated in the **From date** and **To date** fields.

4. If required, select a **Financial dimension set** to be included in the calculation.

5. Select "Yes" on the **Skip zero** toggle button if you don't want to show results containing zero hours.

6. You can use the **Level** field to indicate how detailed you want the hour control lines to be regarding functional locations.

   For example, if you insert the number "1" in the field, and you have a multi-level functional location hierarchy, all hour control lines for a functional location will be shown on the top level, and therefore the hours on a line may be added up from functional locations located at a lower level.

If you insert the number "0" in the **Level** field, you will see a detailed result showing all hour control lines on all the functional location levels to which they are related.

7. Select "Yes" on the **Include sub assets** toggle button to show costs related to sub assets as separate lines.

8. If you want to limit the search, you can select specific assets / functional locations / work orders on the **Records to include** FastTab.

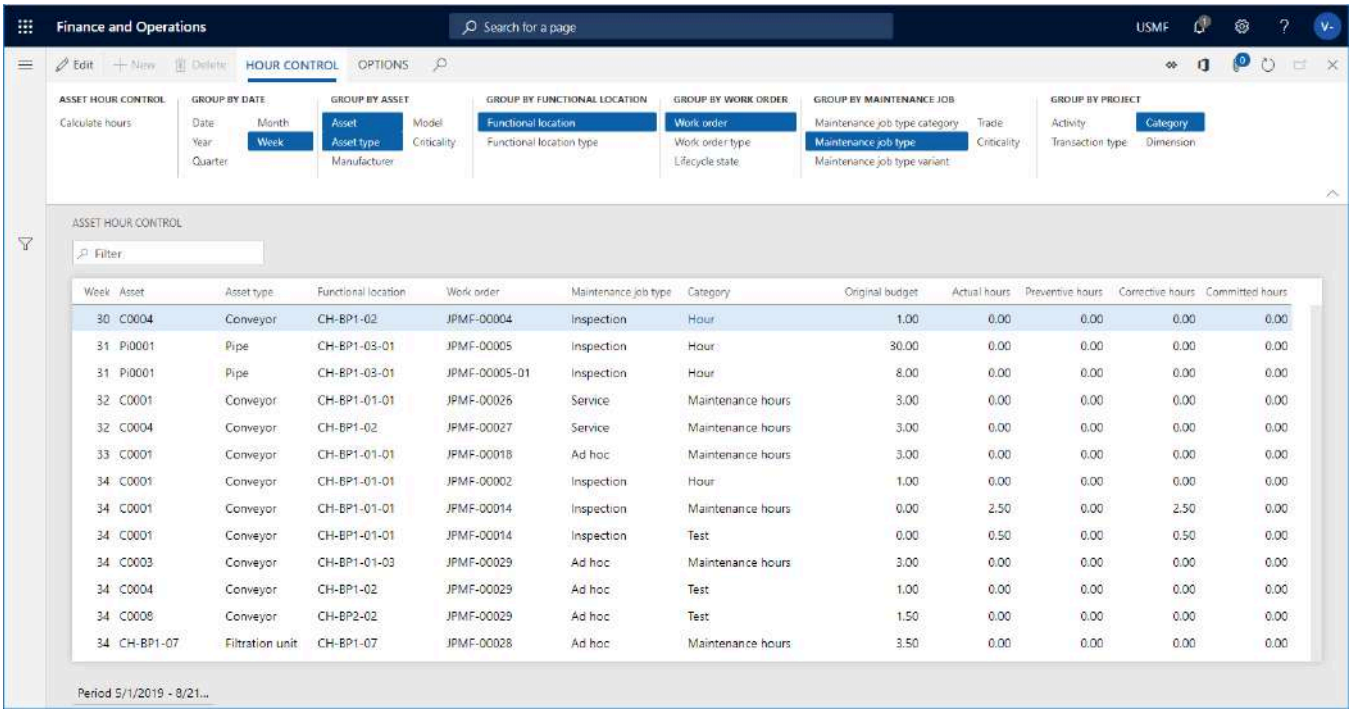
9. Click **OK** to start the calculation.

10. On the **Asset hour control** page, click the **Group by** buttons to show the required detail level of the calculation. The selected **Group by** buttons are highlighted. Click on a button to activate or deactivate it.

Example

The screenshot below shows an example of an **Asset hour control** calculation.

- The **Original budget** field shows budget hours from the work order forecast.
- The **Actual hours** field shows posted hours on work orders.
- The **Committed hours** field shows total amount of hours that your company is committed to in relation to work orders.



Another way of making an hour calculation is to multi-select assets in **All assets** or **Active assets**. Then you click the **Hour control** button on the **General** FastTab. The selected assets are automatically inserted in the **Asset** field on the **Records to include** FastTab. Click **OK** in the **Asset hour control** dialog, and the calculation for the selected assets is shown. The same

procedure can be done for functional locations in **All functional locations** or **Active functional locations**, and for work orders in **All work orders** or **Active work orders**.

Asset fault cost control

Article • 06/03/2022

In Asset Management, you can calculate costs on asset fault registrations to get an overview of actual costs compared to budget costs. Actual costs are based on posted transactions. The date is the fault date on which the symptom was recorded.

1. Click **Asset management** > **Inquiries** > **Asset fault** > **Asset fault cost control**.
2. In the **Asset fault cost control** dialog, select a financial dimension set to be included in the calculation, if required.
3. Select "Yes" on the **Skip zero** toggle button if you don't want to show results with a cost of zero.
4. You can use the **Level** field to indicate how detailed you want the cost control lines to be regarding functional locations.

   For example, if you insert the number "1" in the field, and you have a multi-level functional location structure, all asset fault cost control lines for a functional location will be shown on the top level, and therefore the hours on a line may be added up from functional locations located at a lower level.

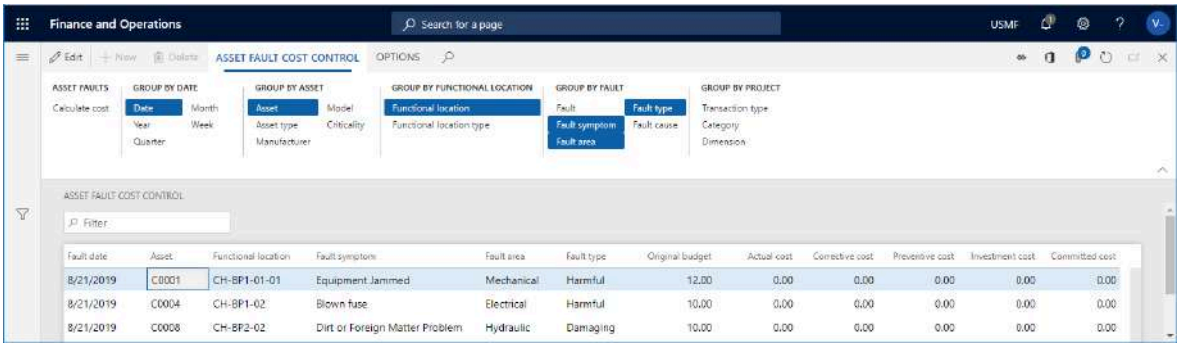
   If you insert the number "0" in the **Level** field, you will see a detailed result showing all asset fault cost control lines on all the functional location levels to which they are related.
5. If you want to limit the search, you can select specific assets, fault dates, and fault causes on the **Records to include** FastTab.
6. Click **OK** to start the calculation.
7. Click the **Group by** buttons to show the required detail level of the calculation. The selected **Group by** buttons are highlighted. Click on a button to activate or deactivate it.

Example

This example shows an asset fault cost control calculation.

- The **Original budget** field shows budget costs from the work order forecast.
- The **Actual cost** field shows posted costs on work orders.

- The **Committed cost** field shows total costs that your company is committed to in relation to work orders.



For information about how to set up faults, see the Fault management article.

Asset fault analysis

Article • 06/03/2022

In Asset Management, you can analyze asset fault registrations to get an overview of the total number of faults registered during a specific period. Fault registrations can be analyzed from different perspectives, for example with focus on assets, asset types, functional locations, fault symptoms, or fault types.

1. Click **Asset management** > **Inquiries** > **Asset fault** > **Asset fault analysis**.
2. In the **Asset fault analysis calculation** dialog, you can use the **Level** field to indicate how detailed you want the asset fault lines to be regarding functional locations.

   For example, if you insert the number "1" in the field, and you have a multi-level functional location structure, all asset fault lines for a functional location will be shown on the top level, and therefore the hours on a line may be added up from functional locations located at a lower level.

   If you insert the number "0" in the **Level** field, you will see a detailed result showing all asset fault lines on all the functional location level to which they are related.
3. If you want to limit the search, you can select specific assets, fault dates, fault causes, and fault remedies on the **Records to include** FastTab.
4. Click **OK** to start the calculation.
5. On the **Asset fault analysis** tab, click one or more **Group by** buttons to display the detail level you want to see. Activated buttons are highlighted. Activate or deactivate buttons by clicking on them.
6. Click **Update calculations** to show your selections on the screen.

> ⓘ **Note**
>
> Every time you activate or deactivate a **Group by** button, remember to click the **Update calculations** button. This is required because a large amount of data is processed as you are recalculating fault probability.

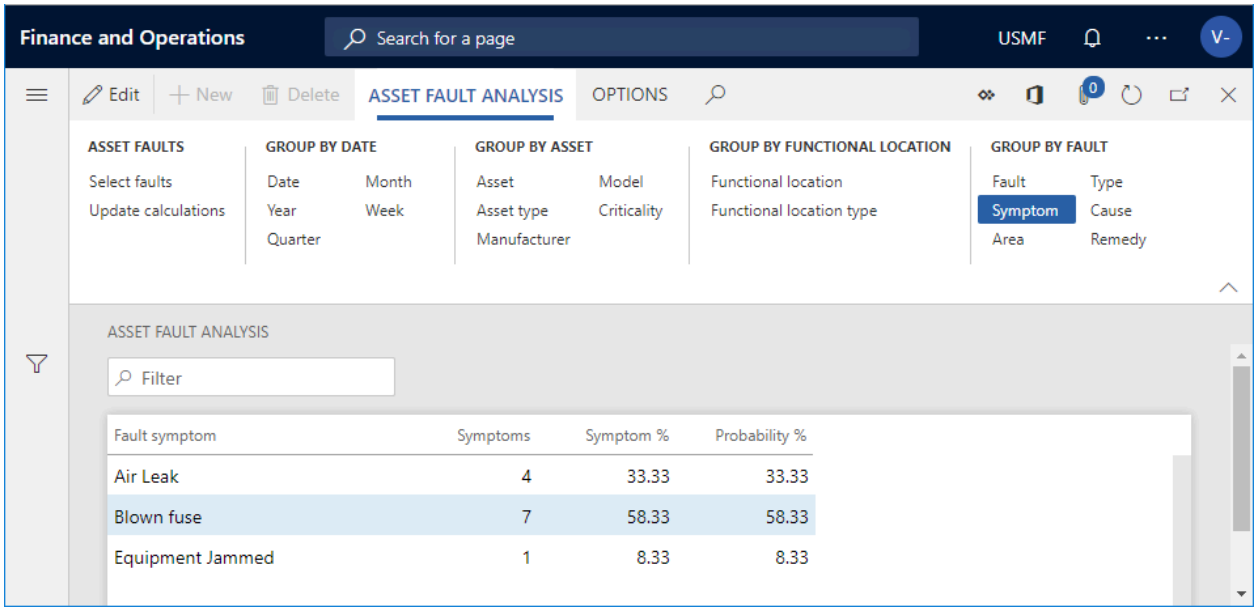
Examples

There are many ways to analyze fault registrations. This section has five examples of how different data selections can provide more insight and detail when analyzing asset fault registrations.

Group by symptoms

In the screenshot below, only the **Symptom** button is selected.

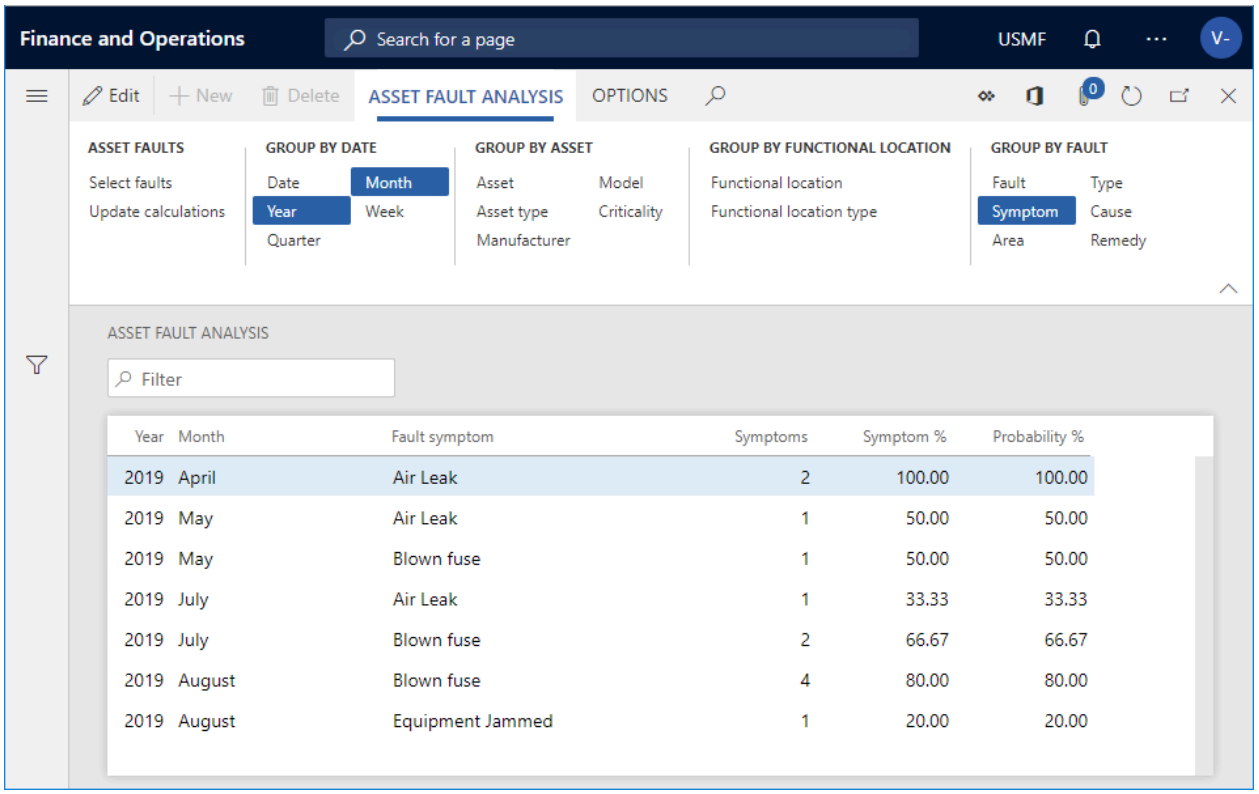
- Fault registrations have been made on three fault symptoms: "Air leak", "Blown fuse", and "Equipment jammed".
- In the **Probability %** column, all percentages add up to 100%. Probability is based on all **Symptom** registrations in this fault analysis.



Group by symptoms and time period

In the screenshot below, **Year** and **Month** are added to show how you can view fault registrations during a selected period.

- The fault symptoms are now shown as registrations per year/month.
- In the **Probability %** column, if you add all percentages for each month, they add up to 100%. Probability is based on the **Symptom** registrations in this fault analysis. If you have a large number of lines on an asset, but a large percentage stands out on a line, that would be an indication of a fault symptom to examine more closely to find a way to limit the number of registrations for that fault symptom.



Group by multiple symptoms and assets

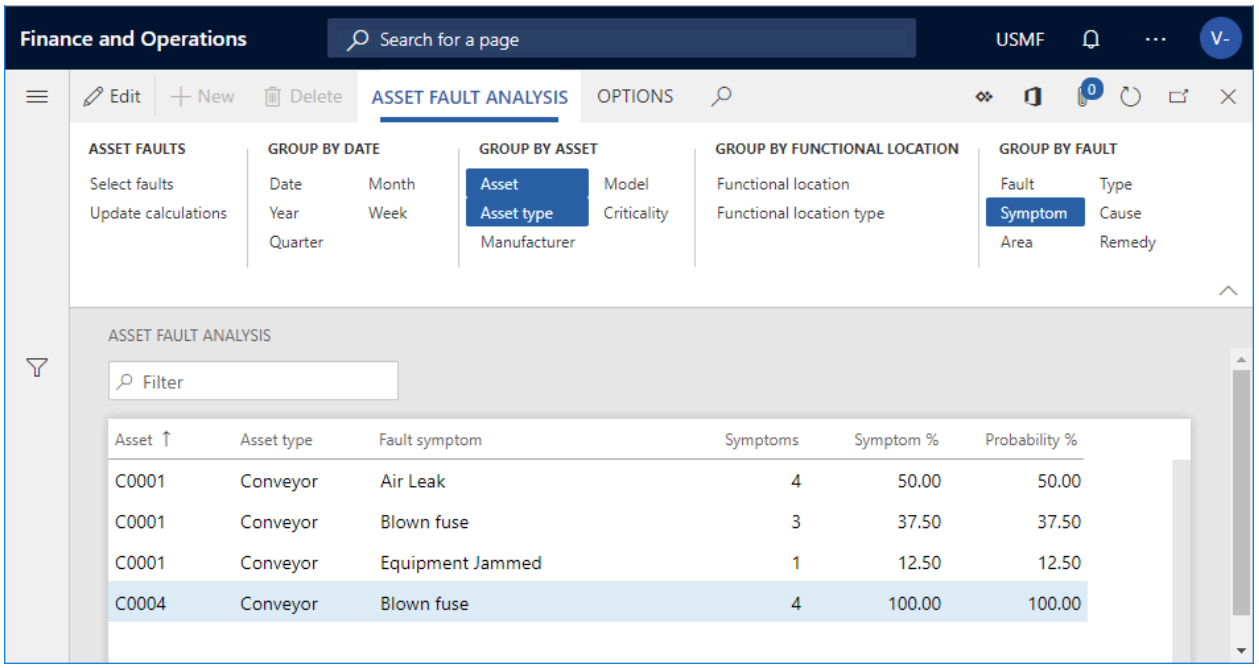
The combination of assets and an asset type is used as a basis for the calculations shown in the three screenshots below, which will increase in detail level.

Generally, the buttons in the **Group by date**, **Group by asset**, **Group by functional location** Action Pane groups, as well as the **Fault** button (Fault ID), contain periods or asset relations. The **Symptom**, **Area**, **Type**, **Cause**, and **Remedy** buttons are categorizations used in fault management to analyze asset fault registrations and pinpoint problem areas.

Group by symptom, asset, and asset type

In the screenshot below, **Asset** and **Asset type** were added to provide more detail regarding fault registrations.

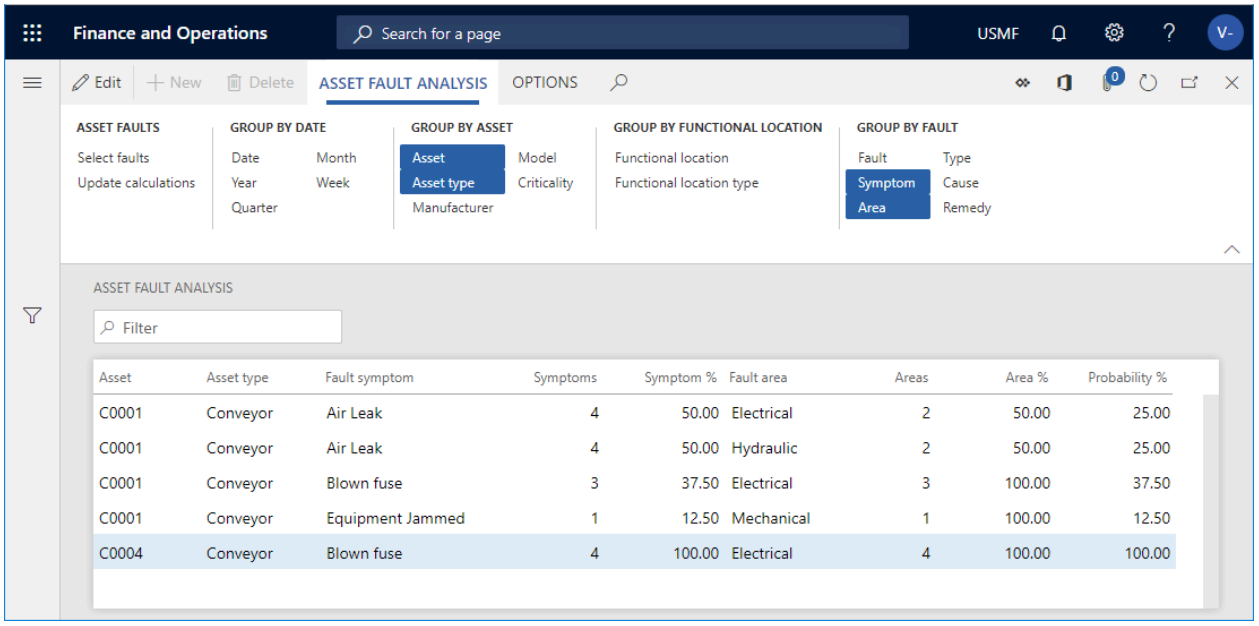
- The fault symptoms are now split up in **Asset** / **Asset type** / **Symptom** combinations.
- In the **Probability %** column, if you add all percentages for the combination of **Asset** / **Asset type** / **Symptom** respectively, they each add up to 100%. Probability is based on **Symptom** registrations in this fault analysis. If you have a large number of lines on an asset, but a large percentage stands out on a line, that would be an indication of a fault symptom to examine more closely to find a way to limit the number of registrations for that fault symptom.



Group by two symptoms, asset, and asset type

In the screenshot below, **Area** was added to **Symptom**, **Asset**, and **Asset type** to provide more detail regarding fault registrations.

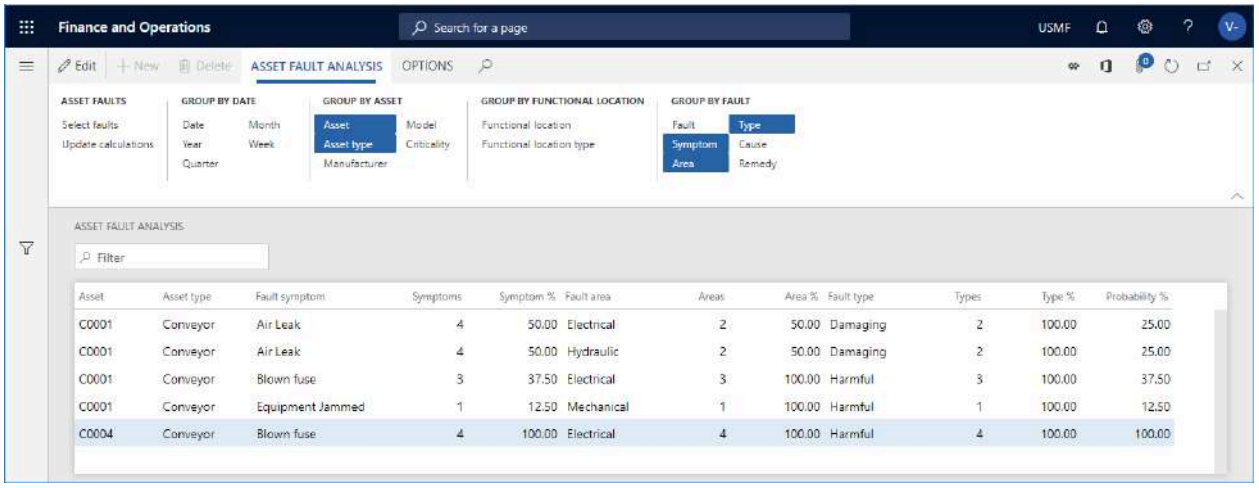
- In the **Probability %** column, if you add all percentages for the combination of **Asset** / **Asset type** / **Symptom** on an asset, they each add up to 100%. Probability is based on the combination of **Symptom** and **Area** in this fault analysis. If you have a large number of lines on an asset, but a large percentage stands out on a line, that would be an indication of a fault area to examine more closely to find a way to limit the number of registrations for that fault area.



Group by three symptom, asset, and asset type

In the screenshot below, **Type** was added, and the most detailed calculation in this example is shown.

- In the **Probability %** column, if you add all percentages for the combination of **Asset** / **Asset type** / **Symptom** on an asset, they each add up to 100%. Probability is based on the combination of **Symptom**, **Area**, and **Type** in this fault analysis. If you have a large number of lines on an asset, but a large percentage stands out on a line, that would be an indication of a fault type to examine more closely to find a way to limit the number of registrations on that fault type.



> **Note**
>
> For an overview of all fault registrations created on work orders and maintenance requests, click **Asset management** > **Inquiries** > **Asset fault** > **Asset faults**. On the **Asset faults** page, select an asset fault registration and expand the **Related information** pane to see information regarding the related work order or maintenance request.

Asset KPIs

Article • 06/03/2022

In Asset Management, you can calculate various Key Performance Indicators (KPIs) for assets and asset types. You use KPIs to get an overview of performance on assets in relation to, for example, uptime, downtime, repair time, and Mean Time Between Failure (MTBF).

1. Click **Asset management** > **Inquiries** > **Assets** > **Asset KPIs**.
2. In the **Calculate asset KPIs** dialog, you select the **Time scale** to be used in the calcualtion, and a period in the **From date** and **To date** fields.
3. On the **Records to include** FastTab, you can select specific assets and asset types to be included in the calculation, if required.
4. Click **OK** to start the calculation.
5. On the **Overview** FastTab, the results of the calculation are displayed in grid view. Each asset is displayed on a separate line.
6. On the **KPIs for selected line** FastTab, you see calculations for the asset selected on the **Overview** FastTab. The KPI values are categorized regarding **Time**, **Availability**, **Work orders**, **Maintenance**, **Faults**, **Maintenance downtime**, and **Cost**.

In the table below, you'll find a description of the fields on the **Asset KPIs** page.

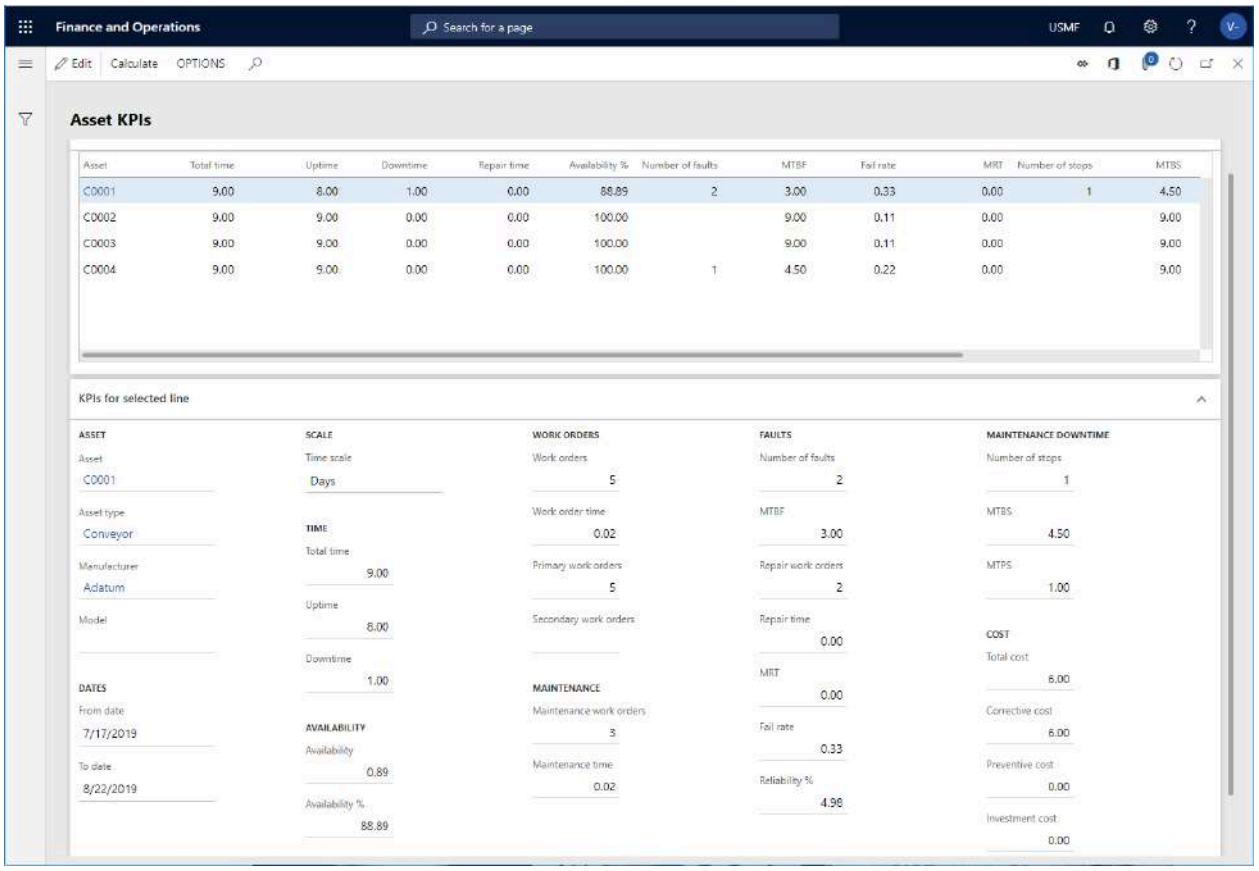
Expand table

Field	Description
Asset	Asset ID.
Total time	Total time set up in the calendar used in the calculation. If the asset is related to a resource, the related resource calendar is used. If the asset isn't related to a resource, the calendar selected in the **Standard calendar** field in **Asset management parameters** is used.
Uptime	Total time minus downtime.
Downtime	Maintenance downtime registrations made on the asset in the selected period.
Repair time	Total number of work hours consumed on repair work orders.
Availability %	Uptime divided by total time and multiplied by 100.

Field	Description
Number of faults	Number of fault causes registered on fault symptoms on the asset in the selected period.
MTBF	Mean Time Between Failure, which is total time divided by number of faults registered on the asset in the selected period. If number of faults is zero, MTBF is set to total time.
Fail rate	1 divided by MTBF.
MRT	Mean Repair Time, which is repair time divided by number of faults registered on the asset in the selected period. If number of faults is zero, MRT is set to repair time.
Number of stops	Number of maintenance downtime registrations created on the asset.
MTBS	Mean Time Between Stops, which is total time divided by number of maintenance downtime registrations. If number of maintenance downtime registrations is zero in the selected period, the MTBS value is set to total time.
Preventive cost	Costs posted on the asset related to cost type "Preventive" in the selected period. Cost types are set up on work order types.
Corrective cost	Costs posted on the asset related to cost type "Corrective" in the selected period. Cost types are set up on work order types.
Replacement value	Value defined on the asset as the replacement cost.
Asset type	Identification of the asset type selected on the asset.
Manufacturer	Identification of the manufacturer selected on the asset.
Model	Identification of the manufacturer model selected on the asset.
From date	Start date of the KPI calculation. If the asset was created after the start date selected for the calculation, the start date of the asset is shown in this field.
To date	End date of the KPI calculation. If the asset was registered as inactive before the end date selected for the calculation, the date from which the asset was no longer active is shown in this field.
Time scale	During calculation of the KPIs, you select a time scale to be used: Hours, Days, or Weeks.
Availability	Uptime divided by total time.
Work orders	Total number of work orders included in the KPI calculation.
Work order time	Total number of work hours consumed on the work orders.

Field	Description
Primary work orders	Number of primary work orders included in the KPI calculation.
Secondary work orders	Number of secondary work orders included in the KPI calculation.
Maintenance work orders	Number of maintenance work orders included in the KPI calculation. A maintenance work order is a work order with no related fault causes.
Maintenance time	Total number of work hours consumed on maintenance work orders.
Repair work orders	Number of repair work orders included in the KPI calculation. A repair work order is a work order with a related fault cause.
Reliability %	Calculation based on the expected exponential development in fault registrations on an asset meaning that, over time, the asset becomes less reliable due to wear and tear. The calculation of this KPI is based on MTBF and total time.
MTPS	Mean Time Production Stops, which is maintenance downtime divided by number of maintenance downtime registrations. If number of maintenance downtime registrations is zero in the selected period, the MTPS value is set to zero.
Total cost	Total costs posted on the asset in the selected period.
Investment cost	Costs posted on the asset related to cost type "Investment" in the selected period. Cost types are set up on work order types.

The figure below shows a screenshot of a KPI calculation for four assets.



- You can multi-select several assets in **All assets** and click the **Asset KPIs** button on the **General** tab. Then click **OK** in the **Calculate asset KPIs** dialog to calculate KPIs for the selected assets.
- Results from a KPI calculation may or may not include maintenance downtime registrations, depending on the setup and use of maintenance downtime reason codes.

Item where used

Article • 06/03/2022

You can make a calculation for a specific item to get an overview of where in Asset Management the item has been used. The results show the context in which the item has been used during its lifetime. The **Item where used** page can be opened from the main Asset Management menu, and it can also be accessed from the following pages:

- Asset BOMs
- Spare parts on asset type defaults
- Maintenance job type categories and maintenance job types, maintenance job type variants, maintenance job trades, and maintenance checklists
- Maintenance forecast
- Procurement
- Work order purchase

Make an item-where-used calculation

1. Click **Asset management** > **Inquiries** > **Item where used**, or select the **Item where used** button on one of the pages mentioned above.
2. In the **Item where used** dialog, select the item for which you want to make the calculation in the **Item number** field.
3. You can use the **Level** field to indicate how detailed you want the item lines to be regarding functional locations.

   For example, if you insert the number "1" in the field, and you have a multi-level functional location structure, all item lines for a functional location will be shown on the top level. Therefore, relation/quantity on a line may be added up from functional locations located at a lower level.

   If you insert the number "0" in the **Level** field, you will see a detailed result showing all item lines on all the functional location levels to which they are related.
4. In the **Include** section, select "Yes" on the toggle buttons that you want to include in the calculation.
5. Click **OK** to start the calculation.

6. On the **Item where used** tab, select the **Group by** buttons to show the required detail level of the calculation. The selected **Group by** buttons are highlighted. Click on a button to activate or deactivate it.

7. If you want to show dimensions related to the item, click **Display dimensions**, and select the dimensions to be shown.

Example

In the screenshot below, you see an example of an item-where-used calculation for item number "1000".

Maintenance status

Article • 06/03/2022

In Asset Management, you can make an overview calculation for a specific period for new, active, and completed maintenance requests, work orders, and maintenance downtime activities. You can also see the number of completed condition assessments for the same period. Use this calculation to get an overview of workload for incoming and completed maintenance requests and work orders.

Make a maintenance status calculation

1. Click **Asset management** > **Inquiries** > **Maintenance status**.
2. In the **Calculate status** dialog, select the time range that you want to make the calculation in the **From date** and **To date** fields.
3. You can use the **Level** field to indicate how detailed you want the maintenance lines to be regarding functional locations.

For example, if you insert the number "1" in the field, and you have a multi-level functional location structure, all maintenance lines for a functional location will be shown on the top level, and therefore the status on a line may be added up from functional locations located at a lower level.

If you insert the number "0" in the **Level** field, you see a detailed result showing all maintenance lines on all the functional location levels to which they are related.

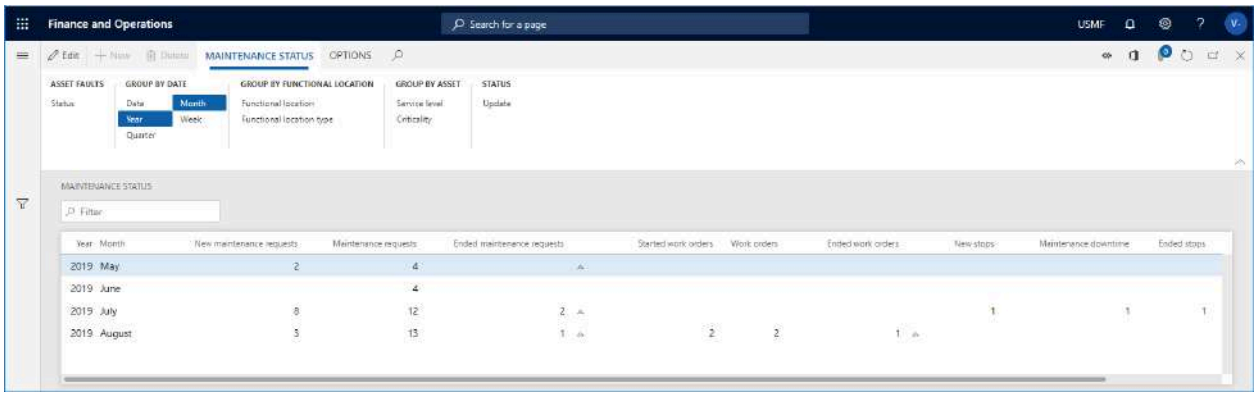
4. Click **OK** to start the calculation.
5. Click the **Group by** buttons to show the required detail level of the calculation. The selected **Group by** buttons are highlighted. Click on a button to activate or deactivate it.
6. Remember to click the **Update** button to update the calculation each time you make changes by activating or deactivating **Group by** buttons, or by making a calculation for a new period.
7. Click **Status** if you want to create a new maintenance status calculation.

> **Note**

The results shown in **Maintenance status** only include maintenance requests and work orders that have an actual start date and time. End date and time may be blank.

Example 1

In the screenshot below, the **Year** and **Month** buttons have been activated. With these **Group by** options selected, you get a general overview on a monthly basis of workload and throughput related to maintenance requests and work orders.



Example 2

In the screenshot below, information about functional locations has been added. Now it is possible to compare workload and throughput across functional locations, which may represent geographical locations, factories, or work areas.

Asset Management mobile app overview

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> The Asset Management mobile app is now provided on GitHub as an open-source sample at microsoft/scmsamples-EnterpriseAssetManagement. It provides the same functionality as the original app and is freely customizable. For timeline and transition guidance, see Asset Management mobile app open-source release.

The Asset Management mobile app provides the following capabilities for workers and organizations that use Asset Management for Microsoft Dynamics 365 Supply Chain Management:

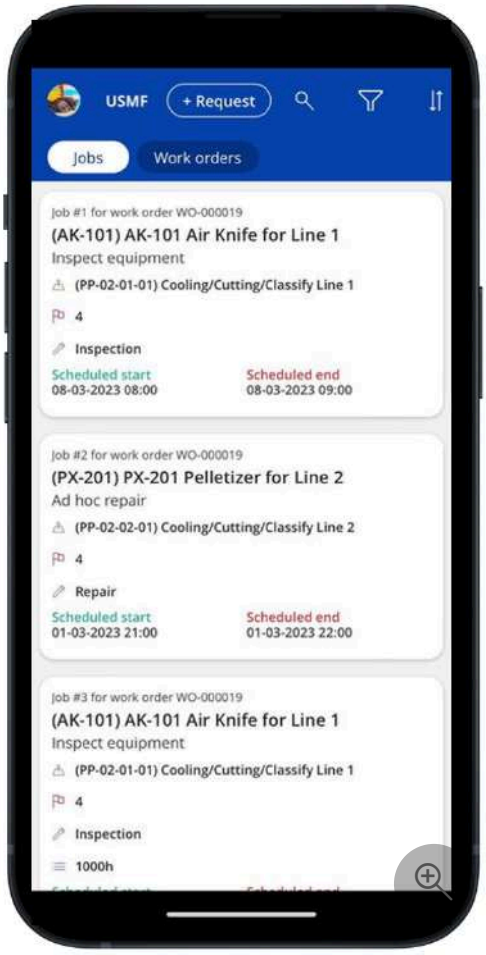
- **Manage work orders.** Maintenance workers use work orders as a daily to-do list that provides the information that they need to complete their planned maintenance tasks. In the app, workers can search for work orders that have been assigned to them. They then use the app to record their progress, so that the system can track labor, materials, and services for the work that's done. Workers can process work orders and perform tasks such as updating checklist items, registering time and materials, and viewing and adding notes.
- **Create maintenance requests.** Administrators can use the role-based security setup in Supply Chain Management to grant workers permission to create new maintenance requests. Workers who receive this permission will then be able to use the mobile app to proactively request maintenance of assets.
- **Create work orders.** Maintenance workers can create new work orders from scratch, or from existing work orders that need further work in the future.

To use the app, you must have a fully implemented setup of Asset Management in your Supply Chain Management environment.

The following video shows how the Asset Management mobile app supports various business roles in common asset management scenarios.

https://learn-video.azurefd.net/vod/player?id=0781126d-d706-42af-b4f5-e4f727a55e8e&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Fasset-management%2Fasset-management-mobile-app%2Fasset-management-mobile-app-overview

The following illustration shows an example of a list of jobs for a work order in the Asset Management mobile app.



> **Note**
>
> Use of the Asset Management mobile app is covered by the *Dynamics 365 Supply Chain Management* user licenses. Using the app for maintenance requests requires a *Dynamics 365 Team Members* license. Using the app for processing work orders requires a *Dynamics 365 Operations – Activity* license. Licensing terms are subject to change without notice. For complete and up-to-date licensing information, see the Dynamics 365 Licensing Guide.

Asset Management mobile app open-source release

> **Important**
>
> The Asset Management mobile app is now available on GitHub as an open-source sample at microsoft/scmsamples-EnterpriseAssetManagement. It provides the same functionality as the original app and is freely customizable. The existing app remains available for installation through Dynamics 365 apps in the Power Platform admin center until November 30, 2026, with critical fixes from Microsoft during this transition period. After that date, the app is no longer distributed through the admin center. Existing installations continue to work in customer tenants.

Until now, canvas-app customizations made in Power Apps Studio weren't preserved across official updates. Releasing the source code as open source removes that limitation: you can build from the source, customize it freely, and deploy under your own publisher without your changes being overwritten by Microsoft updates.

Open-source release timeline

The following table summarizes the key milestones in the open-source release of the Asset Management mobile app.

Expand table

Date	Milestone
June 1, 2026	Source code released as open source. The app enters a 6-month transition period during which it remains available for installation through the Power Platform admin center, with critical fixes from Microsoft.
November 30, 2026	End of the transition period. Microsoft maintenance concludes and the app is no longer distributed through the Power Platform admin center. Existing installations continue to function in customer tenants.

Guidance for existing installations

Continue using the installed app

Existing installations require no action. Microsoft delivers any critical fixes during the maintenance window through the same Power Platform admin center channel as previous versions. After November 30, 2026, the installed app continues to function in the customer tenant. Customers who plan to evolve the app beyond that date should follow the Build from the open-source code guidance.

Customize the app for in-tenant use

For additive customizations to the data model (such as adding new fields, tables, or security roles), use solution layering in the Power Apps maker portal. These customizations live in the customer tenant's unmanaged solution layer and are preserved when Microsoft delivers managed-solution updates during the maintenance window.

For customizations to the canvas app itself (such as screens, formulas, or UI changes), we recommend that you build from the open-source code so your changes persist. Customizations made directly in Power Apps Studio aren't preserved across Microsoft updates during the maintenance window.

Build from the open-source code

To customize the app and make it your own, build from the open-source code provided on GitHub at microsoft/scmsamples-EnterpriseAssetManagement. The source code is licensed under the MIT license, which permits free use, modification, and redistribution.

By default, builds from the open-source code use a Microsoft-branded sample publisher (`AssetManagementMobileSample`, display name "Microsoft Asset Management Mobile Sample") in Microsoft Dataverse. This publisher is distinct from the first-party Microsoft publisher used by in-market Dynamics 365 products. The default publisher is appropriate when you customize and run the app in your own organization's tenant. If you plan to distribute your custom build to other organizations, change the publisher and customization prefix to your own brand before building. The repository README documents this process.

After producing a custom build under your own publisher, transitioning an existing tenant requires that you delete the existing solutions (`msdyn_EnterpriseAssetManagementMobileV2` and `msdyn_EnterpriseAssetManagementMobileAnchor`) and import the custom-built solution. For details on deleting solutions, see Work with solutions in Power Apps.

Guidance for new installations

For Supply Chain Management customers who need field-level work order management, we recommend that you build a custom solution from the open-source code provided on GitHub at microsoft/scmsamples-EnterpriseAssetManagement. The MIT-licensed source can be customized freely and deployed under your own publisher to fit your needs. Alternatively, evaluate Microsoft AppSource for partner-built alternatives.

The existing app remains available for installation through the Power Platform admin center until November 30, 2026. For new deployments, build from the open-source code instead.

Support

For product issues during the maintenance window, use your existing Microsoft support agreements and Dynamics 365 support channels. After November 30, 2026, Microsoft doesn't provide product support for the app. Issues filed against the open-source repository aren't triaged.

Last updated on 06/01/2026

Onboard the Asset Management mobile app

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> The Asset Management mobile app is now provided on GitHub as an open-source sample at microsoft/scmsamples-EnterpriseAssetManagement. It provides the same functionality as the original app and is freely customizable. For timeline and transition guidance, see Asset Management mobile app open-source release.

This article describes how administrators can prepare your Microsoft Dynamics 365 Supply Chain Management and Dataverse environments to support the Asset Management mobile app. It also describes how to install the app on your mobile devices.

Prerequisites

Before you can start to onboard the Asset Management mobile app, you must meet the requirements that are outlined in this section.

System requirements

To run the latest Asset Management mobile app, you must be using Supply Chain Management version 10.0.36 or later.

Set up Dataverse for your Supply Chain Management environment

The mobile app uses Dataverse virtual tables that are connected to Supply Chain Management. Therefore, a Dataverse environment must be integrated with your Supply Chain Management

environment. If Dataverse isn't already set up for your environment, follow the instructions in Microsoft Power Platform integration with finance and operations apps.

When you create the Dataverse environment where you want to install the app, be sure to enable Dynamics 365 apps.

The Power Apps component framework feature must be enabled for your environment.

Licensing requirements

To gain access to the app, users must have the appropriate security roles assigned to them in Supply Chain Management. The roles that are available for each user in Supply Chain Management depend on the licenses assigned to them in Microsoft Entra ID. For details about which security roles grant access to which functionality in the Asset Management mobile app, see Configure users and workers in Supply Chain Management. For details about which licenses grant access to which security roles, see the Dynamics 365 Licensing Guide.

Install the mobile app in Dataverse

You must install the Asset Management mobile app in your Dataverse environment to enable users to access it when they sign in by using the Power Apps mobile app. The installation process also sets up the required user roles and other dependencies in Dataverse.

Follow these steps to install the Asset Management mobile app in Dataverse.

1. Sign in to Power Platform admin center.
2. On the left navigation pane, select **Resources** > **Dynamics 365 apps**.
3. Search for and select the app named *Dynamics 365 Asset Management Mobile Application*.
4. On the top toolbar, select **Install**.
5. Select the environment where you want to install the app, review the packages that will be installed, and select the **I agree to the terms of service** checkbox.
6. Select **Install**.

Grant access to the mobile app in Dataverse

After the mobile app solution is installed in your Dataverse environment, you must share it with your users. The Asset Management mobile app is a canvas app. To share it, follow the instructions in Share an app.

Each relevant user must be assigned a role that lets them work with the Dataverse Supply Chain Management virtual tables that the solution installs. The solution installs a role named *Asset Management Mobile Application User Role* that grants access privileges to all the required virtual tables. You can assign this role to a Dataverse group team. Any user who's a member of that team will then have the role too. Alternatively, you can assign the role directly to a user.

Each relevant user must also have the *Finance and Operations Basic User* role.

- To assign a role to a group team, follow the instructions in Manage the security roles of a team. We recommend that you use group teams if you must assign the role to multiple users. For information about how to manage team members, see Manage team members.
- To assign a role directly to a user, follow the instructions in Assign a security role to a user.

Configure users and workers in Supply Chain Management

Each user who will use the Asset Management mobile app must be set up as described in this section.

Set up user accounts to maintain assets and/or request maintenance

Each Supply Chain Management user who should be able to operate the Asset Management mobile app must have one or both of the following standard security roles:

- *Maintenance requester* – This role allows a Supply Chain Management user account to use the app to create maintenance requests.
- *Maintenance worker* – This role allows a Supply Chain Management user account to use the app to manage maintenance work orders.

Users who have the *System administrator* role can use the app both to create maintenance requests and to manage work orders.

Follow these steps to add the required security roles to a Supply Chain Management user and review that user's **Person** setting.

1. Sign in to your Supply Chain Management environment by using an administrator account.
2. Go to **System administration** > **Users** > **Users**.
3. Use the filter to find a user who should be able to use the app.

4. Open the details page for the selected user by selecting the hyperlink in the **User ID** column.
5. Review the value of the **Person** field to determine which person is assigned to the current user account. If a person is assigned, write down their name. If no person is assigned, you'll assign one in the next section.
6. On the **User's roles** FastTab, on the toolbar, select **Assign roles** to open the **Assign roles to user** dialog box.
7. In the **Role name** column, find and select the *Maintenance requester* and *Maintenance worker* roles.
8. Select **OK** to apply your settings and close the dialog box.

> ⓘ **Note**
>
> User role organization assignments aren't supported. If one or more organizations that differ from a selected user's default company have been assigned to any security role that's set for that user, app installation will fail.

For more information about how to set up roles and security in Supply Chain Management, see Security roles.

Set up a maintenance worker for each user

Follow these steps to confirm or create a maintenance worker for a selected user account.

1. Go to **Asset Management** > **Setup** > **Workers** > **Workers**.
2. Follow one of these steps, depending on whether a person was assigned to the user account that you set up in the previous section:
   - If a person was assigned, confirm that the same person is listed here as a maintenance worker. If they aren't, set up a maintenance worker for that person now. If you must set up a worker, follow the instructions in Maintenance workers and worker groups.
   - If no person was assigned, either select a maintenance worker in the list here, or add the person that you want to use as a maintenance worker by following the instructions in Maintenance workers and worker groups. Then go back to **System administration** > **Users** > **Users**, and open the user account that you're setting up. In the **Person** field, assign the maintenance worker that you just selected or added.

> ⊗ **Caution**

The **Person** setting for user accounts is permanent. You won't be able to edit it after you save your changes. Therefore, make sure that you select the correct person when you set up the user account.

Install and open the Asset Management mobile app

Follow these steps to install and use the Asset Management mobile app on a mobile device.

1. Install the Power Apps mobile app by following the instructions in Install the Power Apps mobile app.
2. Open the Power Apps mobile app, and sign in by using the same corporate account that you use to sign in to Supply Chain Management.
3. Use the **Search** field to search for *Asset Management V2*. Because it's a canvas app, you can add it to your favorites list in Power Apps by swiping left on it after you find it.
4. Open the Asset Management mobile app, and start to use it.

Clear the Power Apps cache on a mobile device after an update of the back-end setup

If the back-end setup is updated in Supply Chain Management after you install the Power Apps mobile app on a mobile device (for example, if the legal entity setup is changed), you might have to clear the cache in Power Apps to update the local setup data. Power Apps will then be able to reload the settings that otherwise might not take effect until the cache is cleared.

Follow these steps to clear the Power Apps cache on a mobile device.

1. Sign in to the Power Apps mobile app.
2. Select the image for your user account in the upper left of the page to open the settings menu.
3. Select **Clear cache** to open the **Clear cache** dialog box.
4. Select **Confirm**.

Manage work orders using the Asset Management mobile app

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> The Asset Management mobile app is now provided on GitHub as an open-source sample at microsoft/scmsamples-EnterpriseAssetManagement. It provides the same functionality as the original app and is freely customizable. For timeline and transition guidance, see Asset Management mobile app open-source release.

Maintenance workers can use the Asset Management mobile app to manage and process maintenance work orders. The app supports maintenance workers through the following main capabilities:

- It lists maintenance jobs and work orders that are assigned to a worker, including all information that the worker needs to process each job.
- Workers can register the time and spare parts that are consumed for each job.
- Workers can view and update the maintenance checklist that's associated with a job.

For more information about maintenance work orders in Supply Chain Management, see Introduction to work orders.

User requirements

To view and process work orders by using the Asset Management mobile app, you must meet the following requirements:

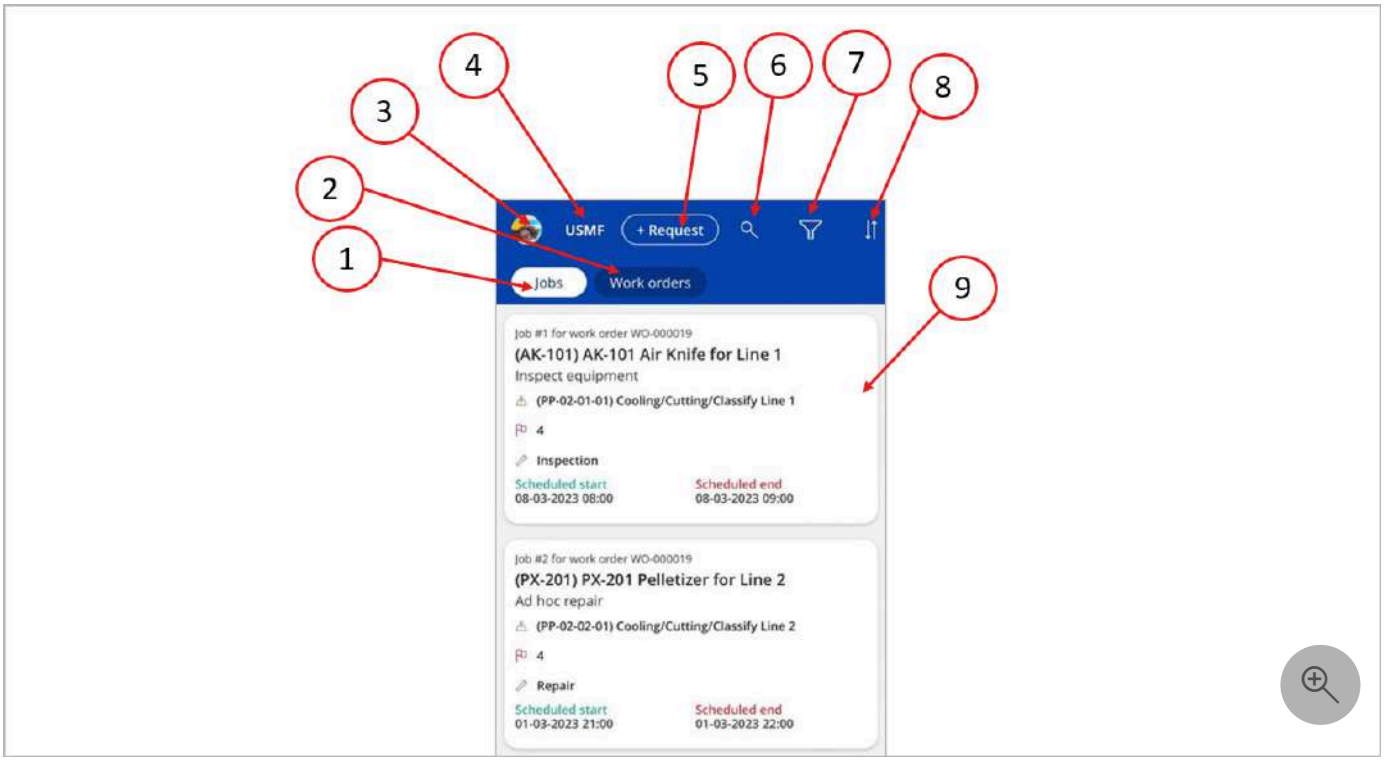
- Your user account in Supply Chain Management must be assigned the *Maintenance worker* security role. Learn more in Onboard the Asset Management mobile app.

- Your user account in Supply Chain Management must be associated with a human resources *Worker* record that's also set up as an Asset Management worker. Learn more in Onboard the Asset Management mobile app.
- You must sign in to Power Apps by using a domain account that matches a user account in Supply Chain Management that has the same Microsoft Entra ID username.

View the jobs and work orders assigned to you

When you open the Asset Maintenance mobile app and sign in as a user who has the *Maintenance worker* security role, the list of jobs and work orders is shown.

The following illustration highlights the different user interface (UI) elements for working with maintenance work orders.



The job and work order list includes the UI following elements. The numbers correspond to the numbers in the previous illustration.

1. **Jobs tab** – Select this tab to view the job list. The list shows only maintenance jobs that both are assigned to you and belong to a maintenance work order that's *Active*.

2. **Work orders tab** – Select this tab to view the work order list. The list shows only active work orders that have jobs that are assigned to you.

3. **User image** – Select this image to view information about the app, such as terms and conditions and the current version of the app.

4. **Legal entity identifier** – This label shows the legal entity (company) that you're currently working in. The lists show only jobs and work orders that are associated with this legal entity. If your Supply Chain Management user account is set up as an Asset Management worker in more than one legal entity, you can select this label to switch between legal entities.

5. **Request button** – If your Supply Chain Management user account is assigned the *Maintenance requester* security role, you can use this button to create a maintenance request. For more information about this functionality, see Maintenance requests.

6. **Search button** – When you select this button, a search field appears. There, you can enter text to search for the ID of the work order, asset, or functional location that you're looking for.

7. **Filter button** – Select this button to filter the jobs or work orders in the list, based on the following criteria:

    - *Today* – Show only jobs that are scheduled for today.
    - *This week* – Show only jobs that are scheduled to start during the current week.
    - *All time* – Show all jobs.

8. **Sort order button** – Select this button to specify how the list is sorted. You can sort by work order service level, scheduled start date, or work order ID.

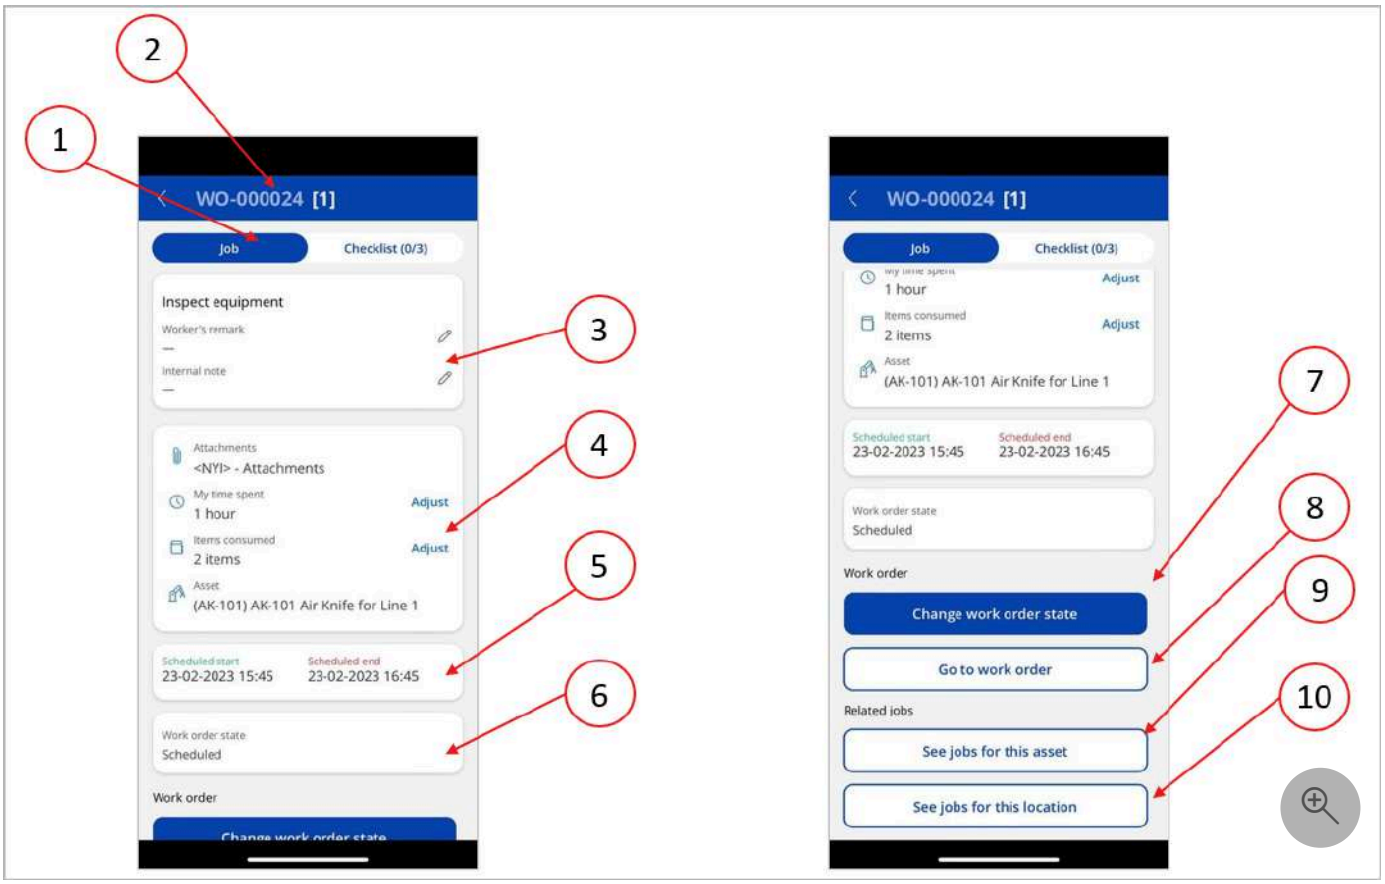
9. **Job or work order cards** – Each job or work order in the list is presented as a *card* that summarizes the item. Tap a card to open its details page, which provides more information about the selected job or work order.

Job details page

In the job lists, each job is presented as a *card* that shows summary information. Tap a card to open its details page, which provides more information about the selected job. The job details page provides access to both job information and the maintenance checklist.

Job information

To view the job information, select the **Jobs** tab at the top of the page. The following illustration highlights the different UI elements on the **Jobs** tab.



The **Jobs** tab of the job details page includes the following UI elements. The numbers correspond to the numbers in the previous illustration.

1. **Job and Checklist tabs** – Select a tab to switch between the job details and the checklist. The numbers in parentheses on the **Checklist** tab indicate the number of completed tasks and the total number of tasks on the checklist.

2. **Work order identifier** – This heading shows the ID of the work order that the current job belongs to. The number in square brackets indicates the total number of jobs in the work order.

3. **Job information** – This section shows the job description, and lets you view and edit a worker's remark and an internal note.

4. **Attachment, time spent, and materials consumed information** – This section lets you view and open documents that are attached to the job. You can also adjust the time that's spent and the materials that are consumed while you work on the job. In Supply Chain Management, the hours that are spent on a maintenance job are accounted for in a project journal. For more information about how materials and time are accounted for in journals, see Register consumption.

    - To adjust the number of hours that are spent working on the job, select **Adjust** next to the **My time spent** heading.

- To adjust the materials that are consumed while you work on the job, select **Adjust** next to the **Items consumed** heading. You can adjust quantities in the list of items that are expected to be consumed for the job. You can also add new items. When you add new items, you can select from lists of released products, items on the asset bill of materials (BOM), and spare parts for the current asset. When you select a product that will be consumed, you can specify storage dimensions (site, warehouse, and location) and tracking dimensions (batch and serial number) as required. Items that have product variants (such as configuration, color, and size) aren't listed.

5. **Scheduled start and end dates and times** – This section shows the dates and times when the current job was expected to be done.

6. **Work order state** – This section shows the current state of the work order.

7. **Change work order state button** – Select this button to change the state of the parent work order for the current job. You'll typically use this button to mark the work order as completed or to note a problem that prevents it from being completed.

8. **Go to work order button** – Select this button to open the work order that the current job belongs to.

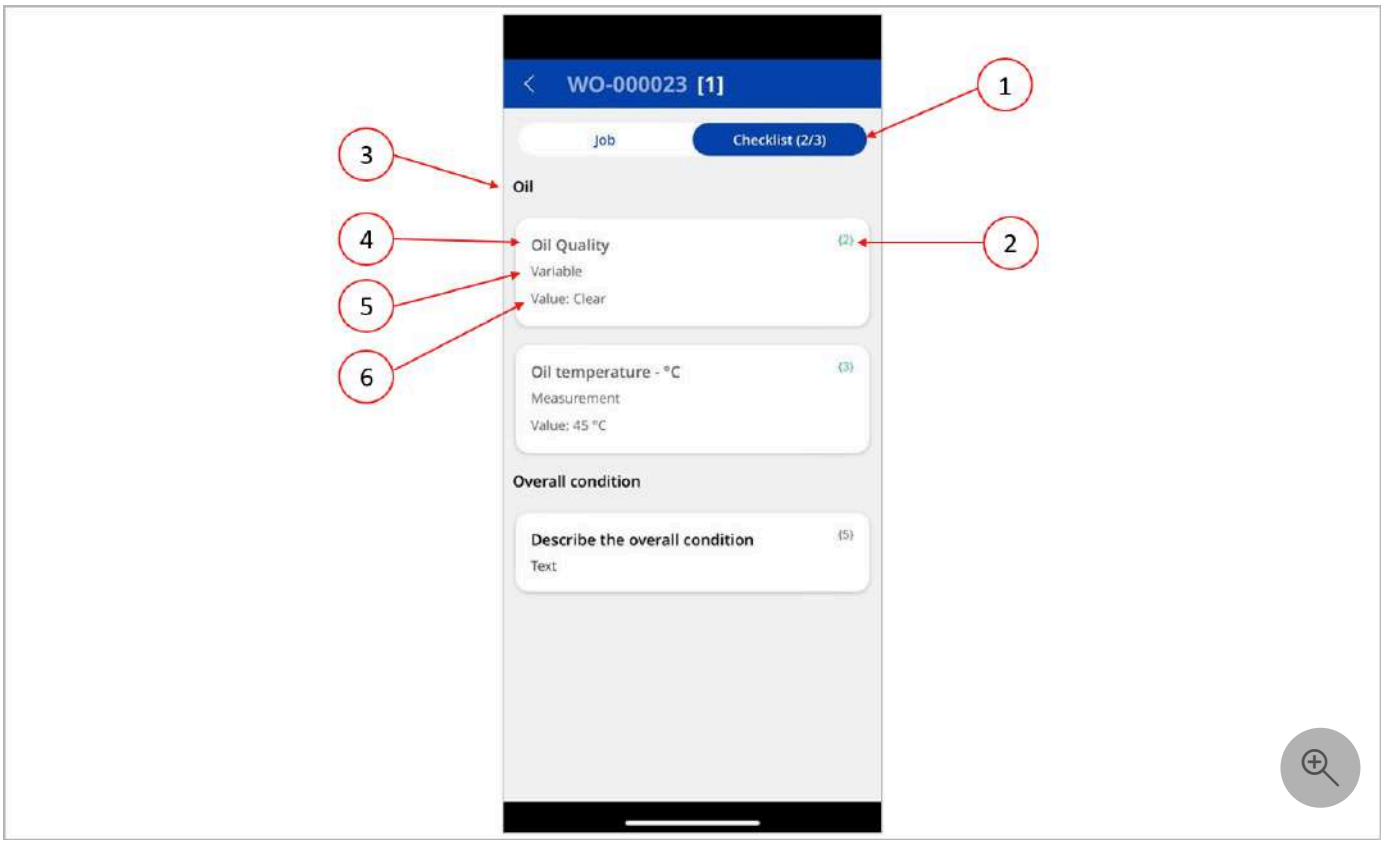
9. **See jobs for this asset button** – Select this button to view a list of all open maintenance jobs that are associated with the same asset as the current job. This list includes jobs that are assigned to you.

10. **See jobs for this location** – Select this button to view a list of all open maintenance jobs that are associated with the same location as the current job. This list includes jobs that are assigned to you.

Maintenance checklist

A maintenance checklist is a set of tasks that the maintenance worker must complete to close the maintenance job. For more information about how to define a checklist for a job, including how to use item types and create groups, see Maintenance checklists. For more information about how to set up default checklists that can be assigned to various maintenance jobs or asset types, see Maintenance job types, categories, variants, trades, and checklists.

To view the maintenance checklist, select the **Checklist** tab at the top of the page. The following illustration highlights the different UI elements on the **Checklist** tab.

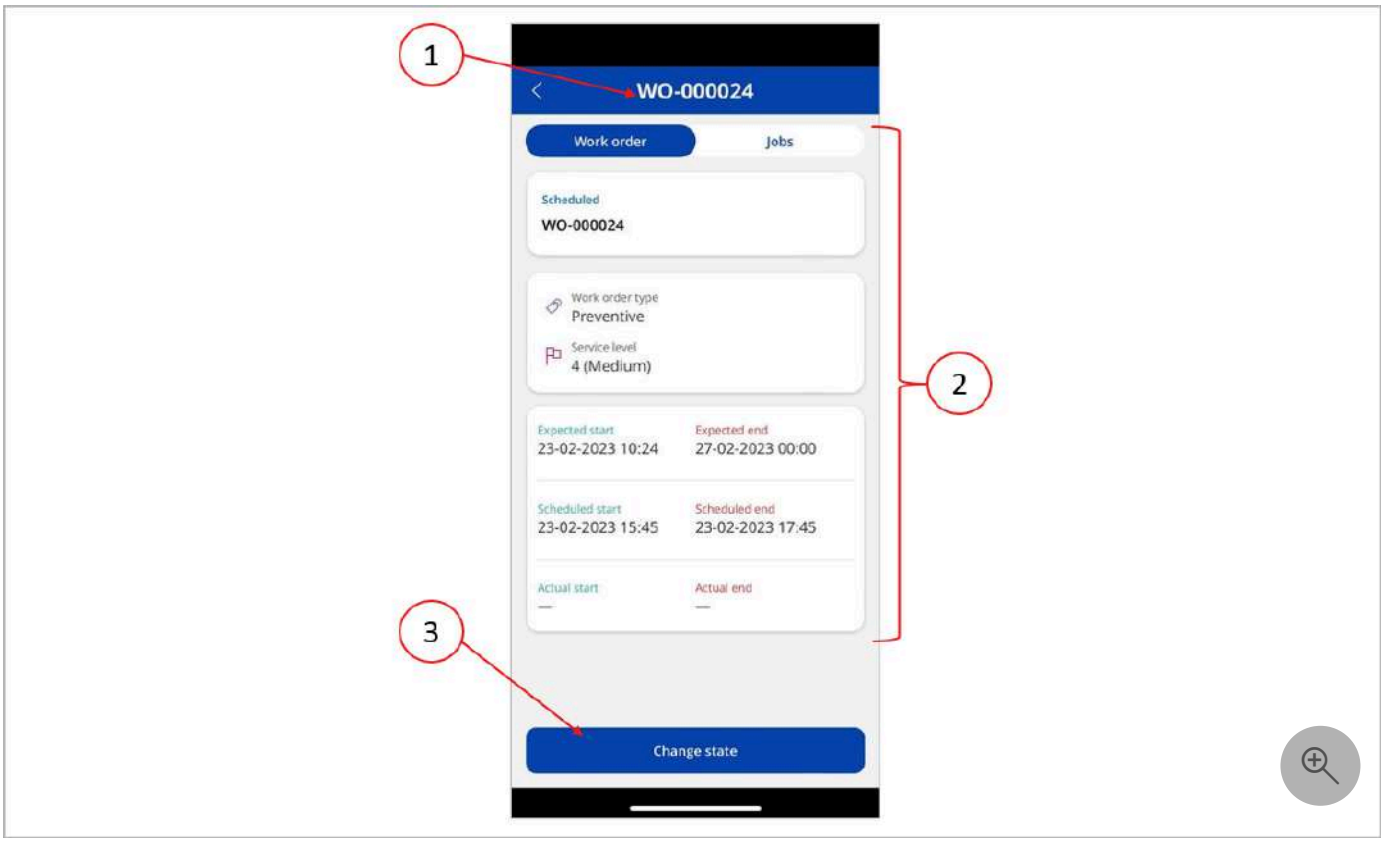


The **Checklist** tab of the job details page includes the following UI elements. The numbers correspond to the numbers in the previous illustration.

1. **Job and Checklist tabs** – Select a tab to switch between the job details and the checklist. The numbers in parentheses on the label of the **Checklist** tab indicate the number of completed items and the total number of items on the checklist.
2. **Checklist line number** – Each checklist item has a system-generated line number. You can use this number to refer to the checklist item when you communicate with other workers. The text color changes to green when the item is marked as completed by the worker.
3. **Group name** – Checklist items can be grouped under a heading. (You set up group names in Supply Chain Management by creating a checklist item of the *Header* type.)
4. **Checklist item title** – This text shows the title of the checklist item.
5. **Checklist item type** – This text shows the type of checklist item (*Variable*, *Text*, or *Measurement*).
6. **Value** – This field shows the value that has been entered for checklist items of the *Measurement* or *Variable* type. To enter these values, select the checklist item card.

Work order details page

The work order details page shows more information about a selected work order. To open it, select a card in the work order list. The following illustration highlights the different UI elements on a work order details page.



The work order details page includes the following UI elements. The numbers correspond to the numbers in the previous illustration.

1. **Work order and Jobs tabs** – Select a tab to switch between the work order details and the list of jobs that belong to the work order. The job list shows a list of job cards. Select a card to open the details page for that job.
2. **Work order information** – Information about the work order is shown on various cards.
3. **Change state button** – Select this button to change the lifecycle state of the work order. For more information about work order states, see Work order lifecycle states.

File maintenance requests using the Asset Management mobile app

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> The Asset Management mobile app is now provided on GitHub as an open-source sample at microsoft/scmsamples-EnterpriseAssetManagement. It provides the same functionality as the original app and is freely customizable. For timeline and transition guidance, see Asset Management mobile app open-source release.

You can use the Asset Management mobile app to file maintenance requests.

For more information about maintenance requests in Microsoft Dynamics 365 Supply Chain Management, see Maintenance requests.

User requirements

To submit maintenance requests from the Asset Management mobile app, you must meet the following requirements:

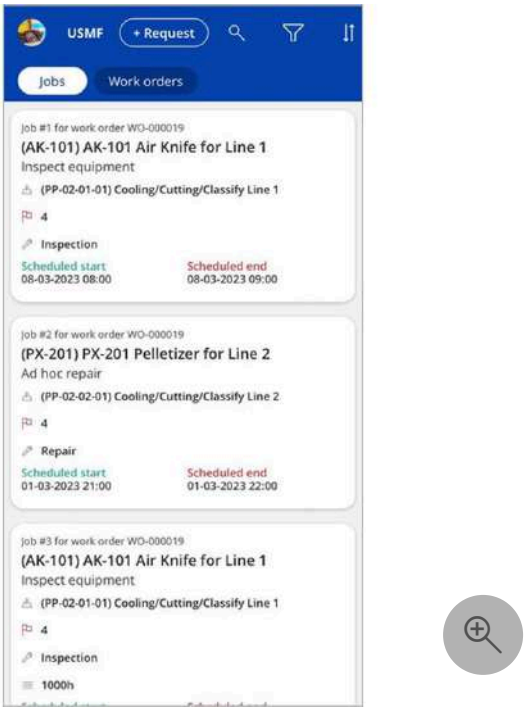
- You must sign in to Power Apps by using a domain account that matches a user account in Supply Chain Management that has the same Microsoft Entra ID username.
- Your user account in Supply Chain Management must be assigned the *Maintenance requester* security role.

For more information about how to set up roles and security in Supply Chain Management, see Security roles.

Identify the asset or functional location that you want to request maintenance for

The procedure for creating maintenance requests varies slightly, depending on the security roles that are assigned to your user account in Supply Chain Management. The following combinations are possible:

- If you have the *Maintenance requester* role but not the *Maintenance worker* role, the **Search** and **Scan** buttons are shown when you first open the app. Select one of these button to start to create a maintenance request as described later in this article.
- If you have both the *Maintenance requester* role and the *Maintenance worker* role, a list of jobs that are assigned to you is shown when you first open the app. To start to create a maintenance request, select **Request** at the top of the page to open a dialog box that includes the **Search** and **Scan** buttons.
- If you have the *System administrator* role, the app behaves as though you have both the *Maintenance requester* role and the *Maintenance worker* role.



Start page for users who have both the *Maintenance requester* role and the *Maintenance worker* role (or the *System administrator* role)

Start page for users who have the *Maintenance requester* role but not the *Maintenance worker* role

Search

Select **Search** to manually search for the asset or functional location that you want to create a maintenance request for. If you want to search for assets, select **Asset** under the search field. If you want to search for functional locations, select **Functional locations**. The system will search for assets and functional locations across all legal entities where the user's *Maintenance requester* security role is granted access in Supply Chain Management.

In the search field, enter the name or ID of the asset or functional location that you want to submit a maintenance request for. Then select an asset or functional location to continue.

The following illustration shows an example of search results for an asset.

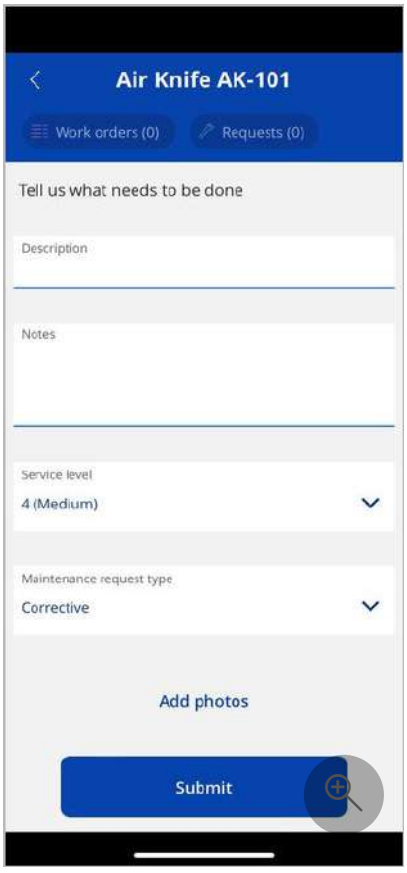
Scan

If your organization uses bar codes or QR codes to uniquely identify each asset, you can use the **Scan** button to identify the asset that you want to submit a maintenance request for. The bar code or QR must contain the ID of the asset or functional location.

When you scan the bar code or QR code on a tag, the system automatically searches for matching assets or functional locations, and then shows a list of results. Select an asset or functional location to continue.

Document the maintenance request

When you've identified the target asset or functional location, you're directed to a documentation page where you can add details about the maintenance request.



Before you file the request, look at the **Work orders** and **Requests** buttons at the top of the page to determine whether any open maintenance requests or work orders already exist for the selected item. If a button shows a value that's more than 0 (zero), select the button to view a list of relevant records and get more information.

Set the following fields as required:

- **Description** – Enter a description of the request.
- **Notes** – Add details about the request.
- **Service level** – Select a service level for the request. The service level is typically used to identify how critical the maintenance request is. For more information about how to set up service levels and set related default values, see Asset service levels.

- **Maintenance request type** – Select the request type. The request type is typically used to categorize the type of incident that's being reported. For more information about how to set up request types and set related default values, see Maintenance request types.

Add photos

You can use the camera on your mobile device to take photos that document the incident that you're filing. The photos will be attached to your maintenance request. If the maintenance request is later converted into a maintenance work order, the system will copy these photos to the work order.

To add photos, select **Add photos** at the bottom of the documentation page.

Submit the maintenance request

When you've finished filling in the documentation page, select **Submit** to create the maintenance request. You'll receive a confirmation message when the maintenance request is created in the system.

Asset Management mobile app FAQs and known issues

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> The Asset Management mobile app is now provided on GitHub as an open-source sample at microsoft/scmsamples-EnterpriseAssetManagement. It provides the same functionality as the original app and is freely customizable. For timeline and transition guidance, see Asset Management mobile app open-source release.

This article provides answers to several frequently asked questions (FAQs) about the Asset Management mobile app. It also describes a few known issues that affect the app and how to work around them.

What platforms and mobile devices are supported?

The Asset Management mobile app runs within the Power Apps mobile app. All platforms supported by the Power Apps mobile app can also run the Asset Management mobile app. For details, see System requirements, limits, and configuration values for Power Apps.

Why don't I see anything when I sign in to the app?

If you don't see any features in the app, you probably lack the permissions required to access them. Access to each feature is controlled by security roles assigned to your user account in Supply Chain Management. Learn more in Configure users and workers in Supply Chain Management

What versions of Supply Chain Management support the app?

The Asset Management mobile app requires Supply Chain Management version 10.0.36 or newer.

Can I customize and extend the app?

Yes — the source code is now available as an open-source sample on GitHub at microsoft/scmsamples-EnterpriseAssetManagement and can be customized freely. See Asset Management mobile app open-source release for guidance.

Does the app support offline mode?

No, the Asset Management mobile app doesn't currently support offline mode.

Is there multi-language support?

Yes, the Asset Management mobile app is available in all the same languages as Supply Chain Management, except for right-to-left (RTL) languages. We're awaiting RTL support from the canvas app platform and plan to add RTL support in a future release.

Where can I go to discuss the app with the community and submit suggestions to Microsoft?

The Asset Management community on Microsoft Viva Engage is a great place to go if you want to exchange tips, ask questions, or submit suggestions for improvement. Viva Engage community participants include Microsoft partners, customers, experts, and employees.

How can I diagnose "Error when trying to retrieve data from the network" issues?

If you see the error message "Error when trying to retrieve data from the network," follow these steps to diagnose and solve the issue:

1. Run the Asset Management app in a browser as described in Run an app in a web browser.
2. If you see the same error while running in a browser, set up your browser to capture a HAR file and then reload the tab where the app is running.
3. Use a tool such as the Google HAR analyzer to redact all secrets from the HAR file.

4. Contact Microsoft Support and share the redacted HAR file with them.
5. Microsoft Support will help you diagnose and solve the issue.

The content of the HAR file might reveal an error similar to the following example:

text

```
SecLib::CheckPrivilege failed. User: <EntraObjectID>, PrivilegeName:
prvReadRelationship, PrivilegeId: <PrivilegeID>, Required Depth: Basic,
BusinessUnitId: <BusinessUnitID>, MetadataCache Privileges Count: <CacheCount>, User
Privileges Count: <UserPrivilegeCount>
```

This error can occur because the *Asset Management app* role doesn't have the privileges required to read the `Relationship` table. Instead, that privilege is provided by the *Finance and Operations Basic User* role in Dataverse. To resolve this issue, add the *Finance and Operations Basic User* role to each user or team that's using the app.

When updating the app, how can I solve the error: "Could not delete solution ... because it has been modified"?

The update process fails with an error if it detects that the Asset Management mobile application canvas app has been customized. This helps prevent the updater from overwriting your customizations. To solve this issue, remove any customization layers by restoring the oldest version of the app. If the oldest version is over six months old, you'll need to manually delete the `msdyn_EnterpriseAssetManagementMobileV2` solution and then reinstall the app from *Dynamics 365 apps* or *Marketplace*.

Consider cloning the canvas app before removing your customizations, just in case you want to copy the customizations to the updated app.

> **Note**
>
> For canvas-app customizations that need to be preserved across official updates, use the open-source release rather than editing in Power Apps Studio.

Are there any known issues affecting the release of the Asset Management mobile app?

Yes, the Asset Management mobile app has a few known issues that we expect to correct in an upcoming release. The following subsections describe them.

Limited file-type support for attachments

The current release provides only limited support for viewing file attachments on the job details page. We plan to add support for more file types in the final release.

Supported attachment types:

- URL (link)
- PNG/JPEG/JPG/BMP/GIF (image)
- PDF (document)

Unsupported attachment types:

- Note
- All other file types

Last updated on 05/29/2026

Integrate Dynamics 365 Supply Chain Management (Asset management) with Dynamics 365 Guides

You can integrate the **Asset management** module in Microsoft Dynamics 365 Supply Chain Management with Dynamics 365 Guides to take advantage of mixed-reality guides in your day-to-day service and maintenance workflows. If a guide is associated with an Asset Management work order, a worker who opens the work order's maintenance checklist in the Supply Chain Management (Dynamics 365) mobile app sees that a guide is available. The worker can then find and open the guide in the Dynamics 365 Guides HoloLens app.

Prerequisites

Before you can attach guides to Asset management work orders, you must complete these prerequisites:

- Set up Dynamics 365 Supply Chain Management version 10.0.9 or later.
- Turn on dual-write for Supply Chain Management apps.
- Turn on the following configuration keys on the **License configuration** page:
  - Asset management > Asset management mixed reality
  - Mixed reality > Mixed reality guide
- Set up Dynamics 365 Guides version 200.0.0.96 or later.

Use Dynamics 365 Guides with Asset management

To associate a guide, you use a maintenance checklist line in Asset management. You can create the association through a maintenance checklist template, a maintenance job type, or a work order, because all three contain maintenance checklist lines. You can save time by using a template, because a template can be associated with all the maintenance job types that use it. For example, a guide that is associated with a maintenance job type is automatically associated with all work orders that specify that job type. On the other hand, a guide that is associated directly with a work order exists only for that work order.

Associate a guide with a maintenance checklist template

To associate a guide with a maintenance checklist template, follow these steps:

1. Create a guide by using the Dynamics 365 Guides PC and HoloLens apps. For information about how to create a guide, see the following articles:

    - Use the PC app to create a guide
    - Use the HoloLens app to place your holograms

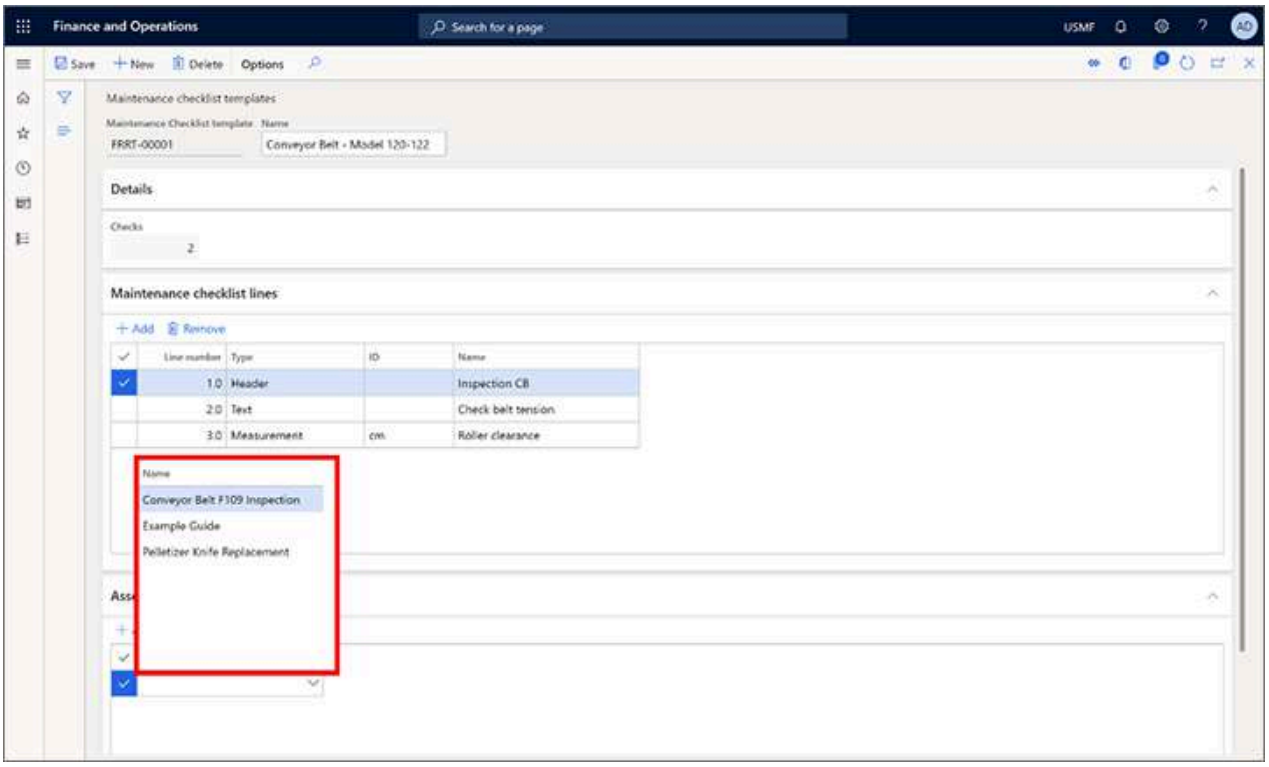
2. In Supply Chain Management, create a maintenance checklist template.

3. Associate the guide that you created with a maintenance checklist line in the new maintenance checklist template:

    a. On the **Maintenance checklist lines** FastTab, select the line that you want to associate the guide with.

    b. On the **Associated guides** FastTab, select **Add Guide**.

    c. In the **Name** field, select a guide, and then select **Save**.



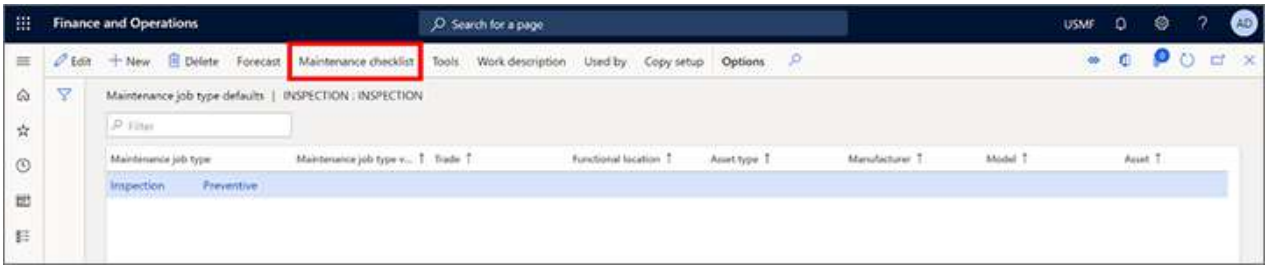
4. Associate the maintenance checklist template with a job type:

   a. Create a maintenance job type, or select an existing maintenance job type.

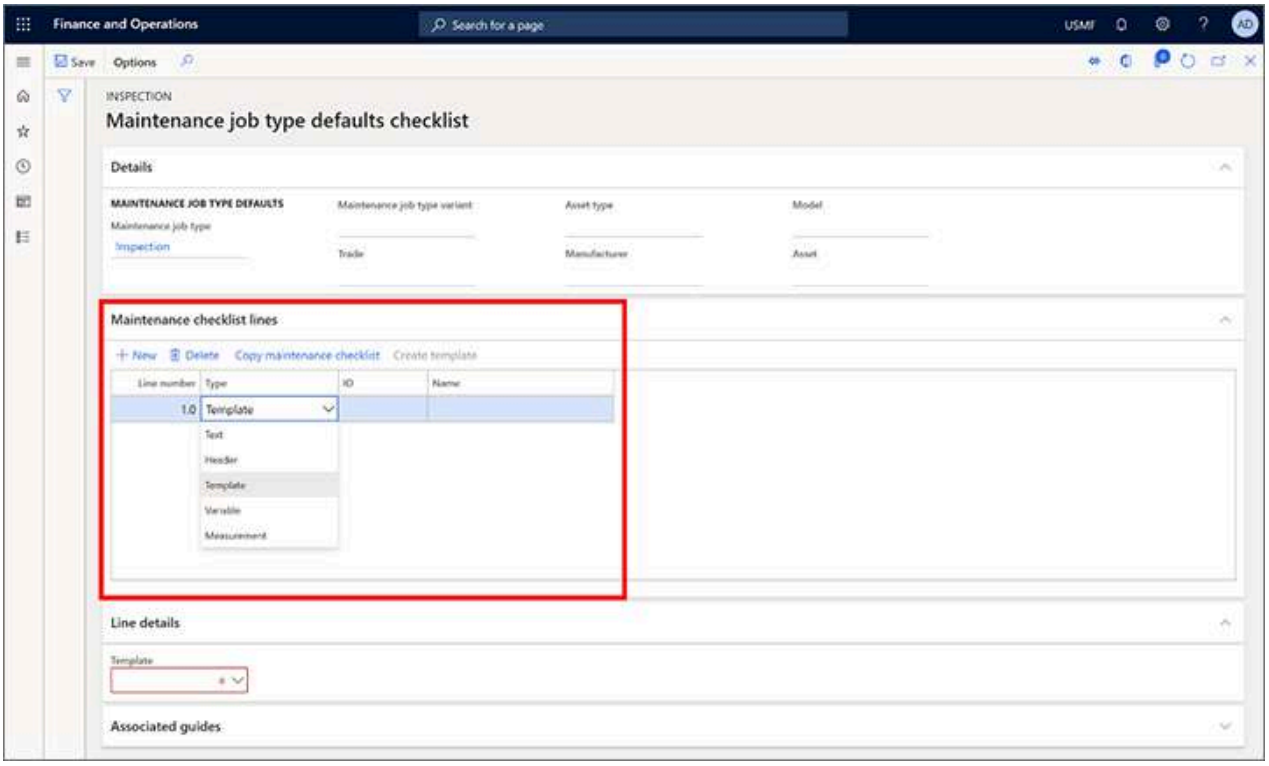
   b. On the Action Pane, select **Maintenance job type defaults**.

   c. Create a line, and then select **Save**.

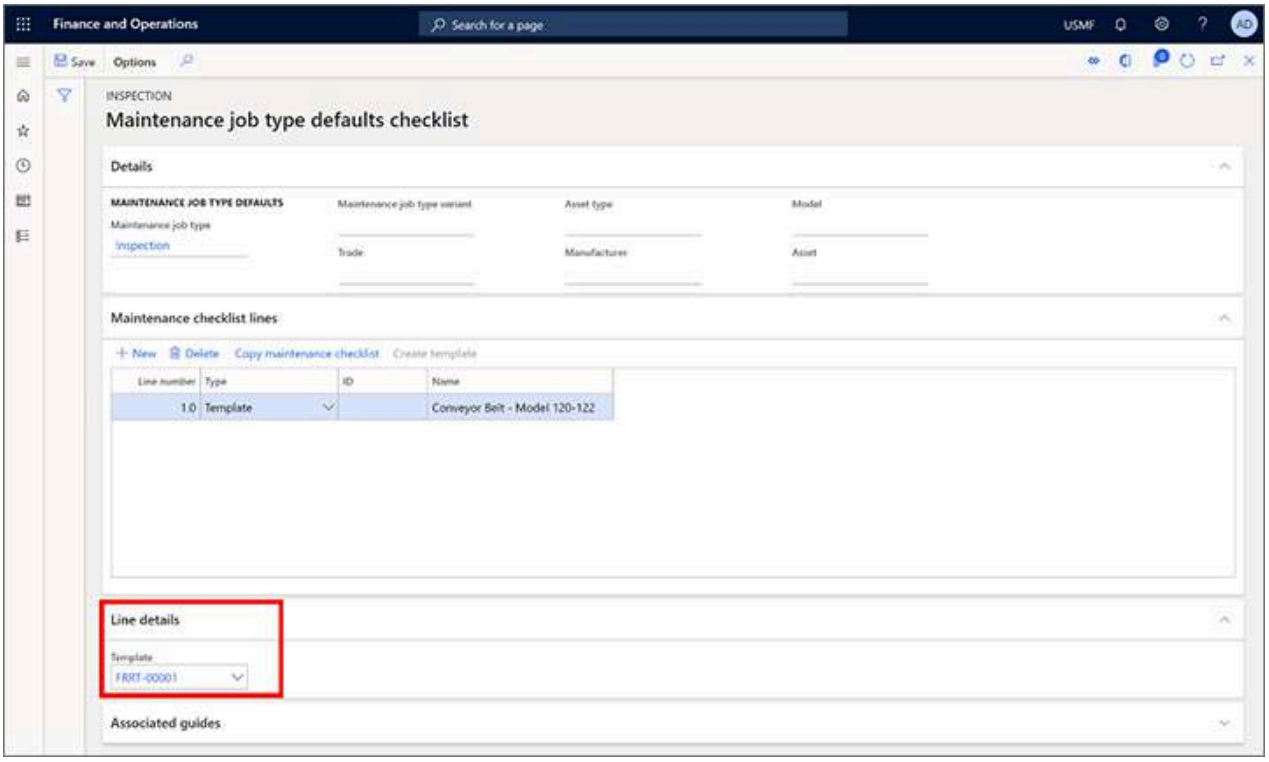
   d. On the Action Pane, select **Maintenance checklist**.



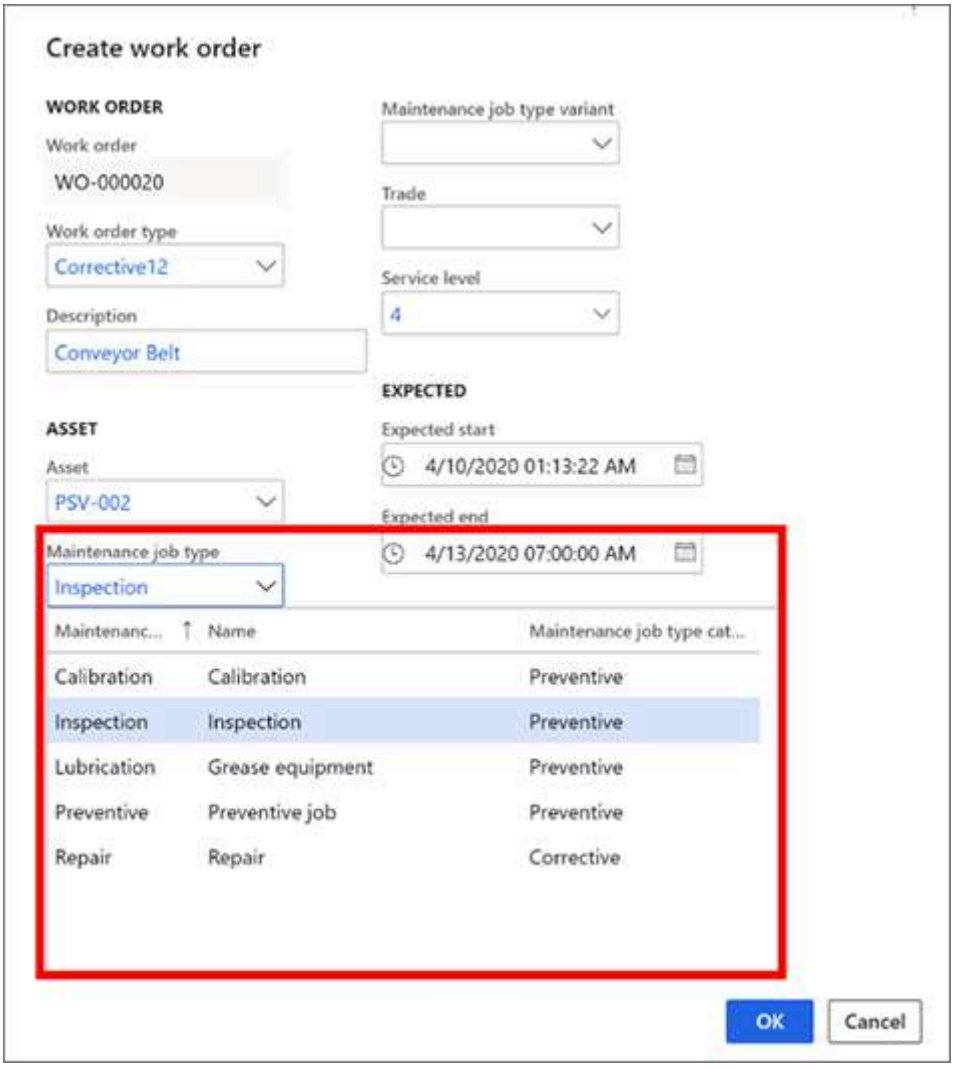
e. On the **Maintenance checklist lines** FastTab, add a line, and then change the value of the **Type** field to **Template**.



f. On the **Line details** FastTab, in the **Template** field, select the template that you associated the guide with, and then select **Save**.



5. Create a work order, and then select the maintenance job type that uses the maintenance checklist template that you associated the guide with. The guide is automatically associated with the work order.



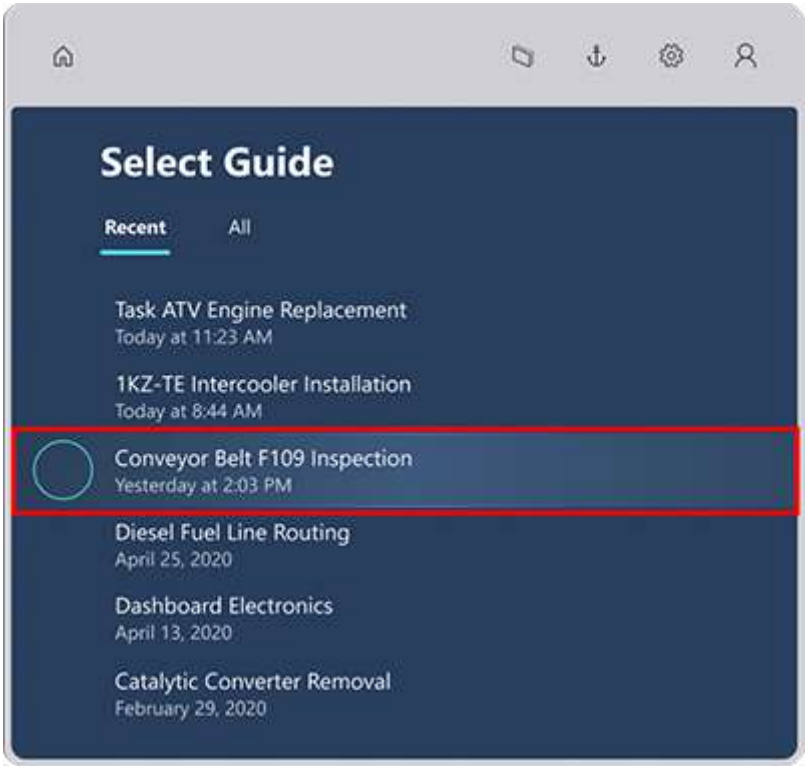
6. View the guide that is associated with the work order and workers:

   a. Open the Asset management mobile workspace to access the work order.

   b. Open the maintenance checklist for the work order.

   c. Select a checklist line to see the associated guide.

   d. Open the guide on HoloLens.



> **Note**

You can also associate a guide directly in the maintenance checklist of a work order or a job type.

Important

There is a known issue where, when you associate a maintenance checklist template with a default maintenance job type, the guide that is linked to the template doesn't appear on the **Associated guides** FastTab of the **Maintenance job type defaults** page. However, the guide will appear after that job type is applied to a work order on the **Associated guides** FastTab.

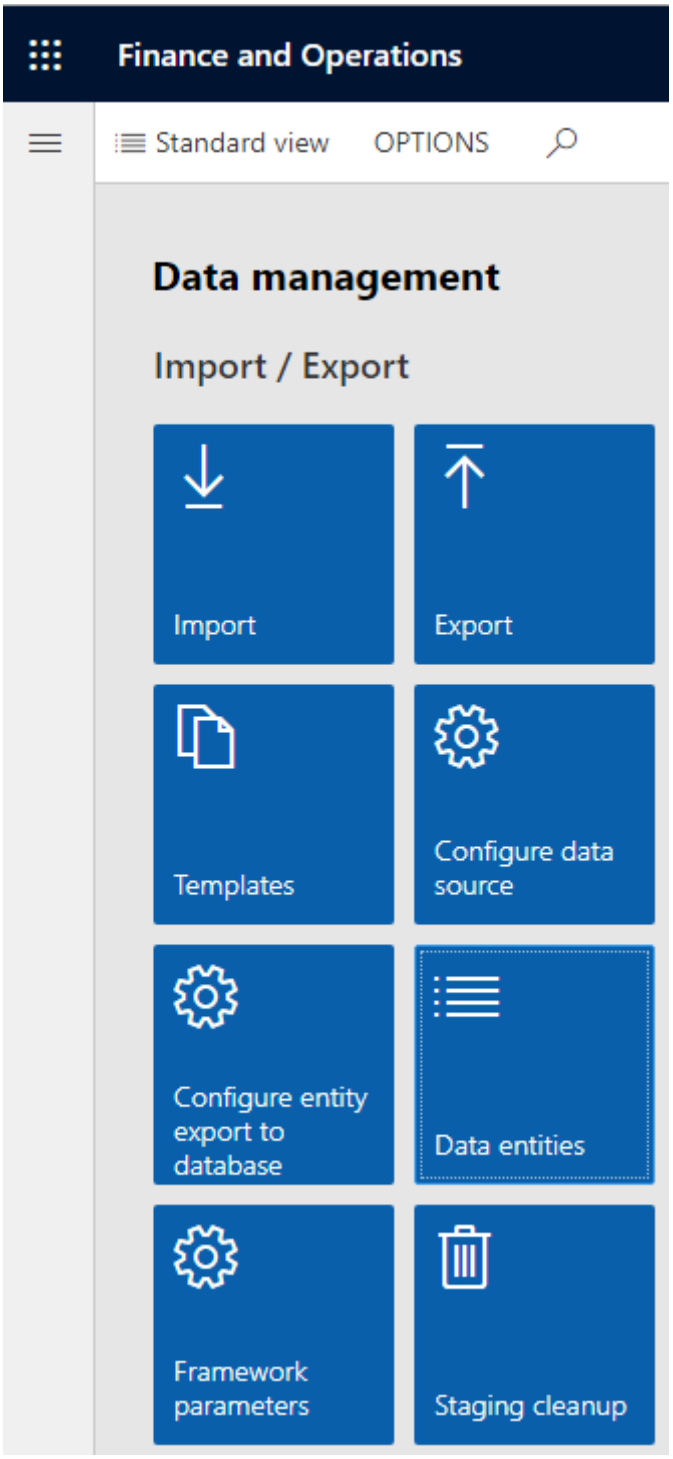
Target entities

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

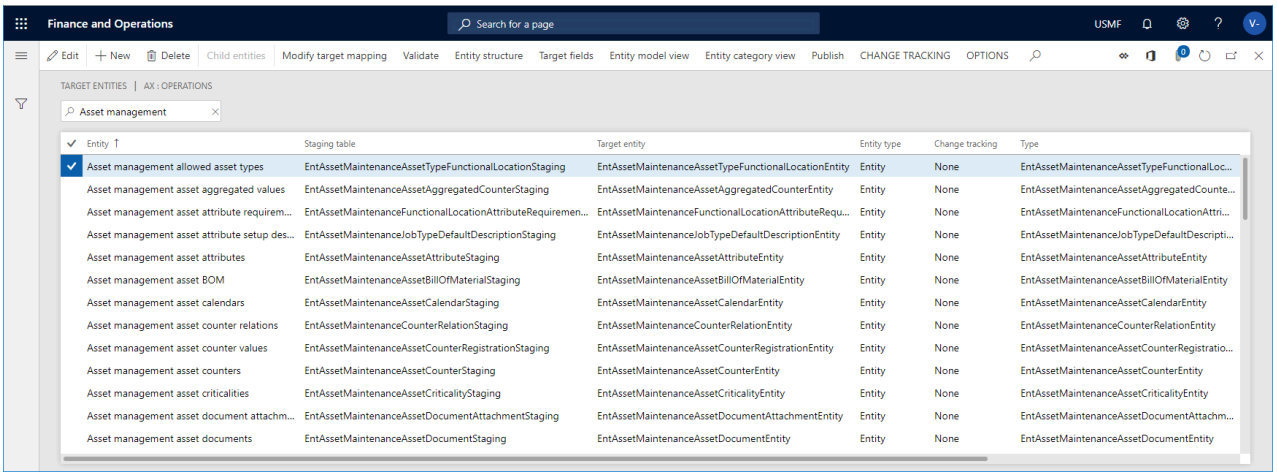
In the **Data management** workspace, you can get an overview of target entities, related entity types and staging tables related to the **Asset management** module.

1. Click the **Finance and operations** button in the upper-left corner of the screen, and click **Data management**.
2. In the **Import / Export** section, click **Data entities**.



3. On the **Target entities** page, search for "asset management" in the filter, and press Enter to see a list of the entities related to Asset management.

   The figure below shows some of the Asset management entities.



4. Select an entity and click **Modify target mapping**.

5. On the **Map staging to target** page, you see a list of the staging fields related to the selected entity. Click **Mapping visualization** to see a graphic overview of how staging data and target data are related.

   In the figure below, a visualization of the fields related to the asset types entity is shown.

Cost accounting terminology

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article defines the key terms that are used in Cost accounting.

Allocation base

The allocation base is used to measure and quantify activities, such as machine hours that are used, kilowatt hours that are consumed, or square footage that is occupied. It's used as basis for allocating costs to one or more cost objects

Cost accounting

Cost accounting lets you collect data from various sources, such as the general ledger, subledgers, budgets, and statistical information. You can then analyze, summarize, and evaluate cost data, so that management can make the best possible decisions for price updates, budgets, cost control, and so on. The source data that is used for cost analysis is treated independently in Cost accounting. Therefore, updates in Cost accounting don’t affect the source data. However, when you collect cost data from various sources, and especially when you import the main accounts from General ledger as cost elements, there's data redundancy, because the same data exists in both General ledger and Cost accounting. This redundancy is required, because you use financial management for external reporting and Cost accounting for internal reporting.

Cost accounting ledger

Defined by calendar, currency, and cost element dimension, it controls processes and policies for measuring costs.

Cost entry

Cost entries result from a transfer via data connectors from general ledger entries, cost allocations, and posted cost entries in cost journals.

Cost object

Any type of object that is selected for cost control. Costs or revenues are either directly posted on or allocated to cost objects. Some typical cost objects are:

- Products
- Projects
- Departments
- Cost centers

Management uses cost objects to quantify costs, but also to drive profitability analysis.

Cost element

Use cost elements as a function to track and categorize costs. There are two types of cost elements: primary and secondary.

Primary cost elements represent the cost flow from financial accounting to Cost accounting. The structure typically corresponds to the profit and loss account structure in the general ledger where a cost element can correspond to a main account. Not all main accounts must be represented as cost elements, depending on business requirements.

Secondary cost elements represent the internal cost flow because these costs are only used in Cost accounting. They're used in cost roll-up rules to aggregate costs into meaningful buckets used by overhead calculation.

Cost classification

Cost classification groups cost according to their shared characteristics. For example, costs can be grouped by elements, traceability, and behavior.

- **By elements** – Materials, labor, and expenses.
- **By traceability** – Direct costs and indirect costs. Direct costs are assigned directly to cost objects. Indirect costs aren't directly traceable to cost objects. Indirect costs are allocated to cost objects.
- **By behavior** – Fixed, variable, and semi-variable.

Cost behavior

Cost behavior classifies costs according to their behavior in relation to changes in key business activities. To control costs effectively, management must understand the cost behavior. There are three types of cost behavior pattern: fixed, variable, and semi-variable.

- **Fixed cost** - A fixed cost is a cost that doesn't vary in the short term, regardless of changes in activity level. For example, a fixed cost can be a basic operating expense of a business, such as rent, that isn't affected even if the activity level increases or decreases.
- **Variable cost** - A variable cost changes according to changes in activity level. For example, a specific direct materials cost is associated with each product that is sold. The more products that are sold, the more direct materials costs there are.
- **Semi-variable cost** - Semi-variable costs are partly fixed and partly variable costs. For example, an Internet access fee includes a standard monthly access fee and a broadband usage fee. The standard monthly access fee is a fixed cost, whereas the broadband usage fee is a variable cost.

Cost control unit

The cost control unit represents the cost structure. The structure determines how cost flows in a hierarchical order between cost object dimensions and their respective cost objects.

Cost distribution

Distribute cost from one cost object to one or more other cost objects by applying a relevant allocation base. Cost distribution and cost allocation differ in that cost distribution always occurs at the level of the primary cost element of the original cost and involves no reciprocal processing.

Cost allocation

Is used to allocate the balance of a cost object to other cost objects by applying an allocation base. Finance supports the reciprocal allocation method. In the reciprocal allocation method, the mutual services that auxiliary cost objects exchange is fully recognized. The system automatically determines the order to perform the allocations in and iterate over it. The balance of a cost object is allocated by a single allocation base. Allocations across cost object dimensions and their respective members are supported. The allocation order is controlled by the cost control unit.

Cost allocation policy

A cost allocation policy defines the amounts and quantities that you must allocate. Allocation rules include allocation source rules, which determine the costs that are allocated, and allocation target rules, which determine where the costs are allocated. For example, all costs for facility services are an allocation source that you can allocate to various departments in an organization (that is, to allocation targets).

Cost roll-up

The purpose of cost roll-up rules is to aggregate costs into meaningful buckets. The level of aggregation is user-defined and involves the assignment of a secondary cost element. If cost roll-up isn't used, every element of a cost is allocated from one cost object to another

Cost rate policy

Use the cost rate to calculate price per cost object. To understand the elements of the price, define cost rate policies. There are two types of cost rate: historical cost rate and planned cost rate. A historical cost rate is a calculated rate that is used as a multiplier for the allocation base of a cost object. The rate is calculated based on the cost allocations in the previous period. A planned rate is a user-defined rate.

Dimension hierarchy

There are two dimension hierarchies: categorization hierarchy and classification hierarchy. Use the dimension categorization hierarchy type for reporting purposes. It supports only the cost element dimensions. Use the dimension classification hierarchy type to define policies and for reporting purposes. It supports all dimensions, such as cost objects, cost elements, and statistical dimensions.

Data connector

Cost accounting supports integration of data from source systems via a set of data connectors. The following data connectors are available:

- Imported transactions (preconfigured)
- Dynamics 365 Finance (preconfigured)
- Dynamics AX (configuration required)

> **Note**
>
> The data connector Imported transactions are based on data entities.

Data provider

Most source systems can provide data that matches one or more data sources in Cost accounting. To align data from the source systems with the data source in Cost accounting, you need to configure a data provider. The following table lists the availability of data providers per data connector and data source.

Expand table

Data sources	Imported transactions data connector	Dynamics 365 Finance data connector	Dynamics AX data connector
Cost element dimension members	Yes	Yes	Yes
Cost object dimension members	Yes	Yes	Yes
Statistical dimension members	Yes	No	No
General ledger	Yes	Yes	Yes
Budget entries	Yes	Yes	Yes
Statistical measures	Yes	Yes	Yes

Formula

Formula allocation bases let you define advanced formulas to achieve the correct allocation basis. You can manually create formula allocation bases. You can use the following operators to define your formula.

Expand table

Symbols	Text
( )	Parentheses
<	Smaller than

Symbols	Text
>	Larger than
+	Addition
–	Subtraction
*	Multiplication

Traditional IF statements aren't supported. However, you can create statements and validate whether they're true.

Expand table

Statement Validation	Result
a > b	True
a > b	False

Overhead cost

Overhead costs refer to the ongoing expenses of operating a business. They're costs that you can't link directly to specific business activities. Here are some examples of overhead costs:

- Accounting fees
- Depreciations
- Insurance
- Interest
- Legal fees
- Taxes
- Utilities costs

Overhead rate

Define rates per cost object and cost element. Two types of rates exist: fiscal period and user-specified. The overhead calculation determines fiscal period rates. A user-specific rate is user-defined and can allocate cost between cost objects at a predetermined rate in the overhead calculation.

Published

If you set this field to Yes, a user assigned one of the following roles can view the report in the Cost control workspace:

- Cost accounting manager
- Cost accountant
- Cost accountant clerk
- Cost object controller

If you set this field to No, only users who are assigned one of the following roles can view the report in the Cost control workspace:

- Cost accounting manager
- Cost accountant
- Cost accountant clerk

Statistical dimension

A statistical dimension and its members are used to register and control nonmonetary entries in Cost accounting. Statistical dimension members can be used for two purposes:

- As an allocation base in policies such as cost distribution or cost allocation.
- For reporting of nonmonetary consumption.

A statistical dimension is the expression of a count or sum of an activity that can be used as the basis for allocations or rate calculations. It's either created manually or imported from source systems. Examples of statistical dimensions include the number of employees, the count of licensed software on each device, power consumption of each machine, or square meters for a cost center.

Statement

Statements are views for the managers who are responsible for controlling costs. Statements are defined by a cost controller, and they provide a quick overview of actual costs, budgeted costs, and deviations. A manager can drill further into details if necessary. To help ensure that managers view only data that they're accountable for, data that appears in the statements is subject to access rules.

Version

Use versions to simulate, view, and compare various outcomes. By default, you view all actual costs in one base version that's known as *actual*. For budgets and calculations, you can work with as many versions as you require. For example, you can import budget data into an original version and then revise the budget in a revised version. For calculations, you can create multiple versions. In these various versions, you can then create calculations by using different calculation rules that apply for cost allocation.

Fiscal calendars, fiscal years, and periods

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article discusses fiscal calendars, fiscal years, and periods, and how to use them for legal entities, fixed assets, and budgeting.

Fiscal calendars provide a framework for the financial activity of an organization. Each fiscal calendar contains one or more fiscal years, and each fiscal year contains multiple periods. Fiscal calendars can be based on a January 1 to December 31 calendar year, or on any dates that you select. For example, some organizations select a fiscal calendar that starts on July 1 of one year and ends on June 30 of the following year.

You can create unlimited fiscal calendars and fiscal years for a fiscal calendar. Each fiscal calendar is independent of your organization, and multiple legal entities in the organization can use it. For example, an organization has eight departments and each department is a separate legal entity. Five of them share the same fiscal calendar and three use different fiscal calendars. You can create one fiscal calendar for the five legal entities that share the same fiscal calendar, and then create separate fiscal calendars for the other legal entities.

Create fiscal calendars, fiscal years, and periods

You can create and delete fiscal calendars, fiscal years, and periods on the **Fiscal calendars** page. You can also divide existing periods and create closing periods that you can use to close a fiscal year.

A closing period is used to separate general ledger transactions that are generated when a fiscal year is closed. When the closing transactions are in one fiscal period, it's easier to create financial statements that either include or exclude different types of closing entries. If a fiscal year is divided into 12 fiscal periods, the closing period is usually the 13th period. However, a closing period can be created from any period that has a status of Open.

When you create a closing period, select a period that has a status of **Open** and that has the dates that you want to use. The new closing period copies the starting and ending dates from the existing period. The original period continues to exist. For example, you select Period 12, which is the last period in the fiscal year, and that has dates of August 1 through August 31. You enter a name for the closing period, such as **Close**. After you create the new closing period, you now have the original period and the closing period. Both have dates that start on August 1 and end on August 31.

Select fiscal calendars for ledgers, fixed assets, and budget cycles

Fiscal calendars are used with fixed asset depreciation, financial transactions, and budget cycles. When you create a fiscal calendar, you can use it for multiple purposes. You can select a fiscal calendar for a fixed asset book to make it a fixed asset calendar. You can select a fiscal calendar for a ledger to make it a ledger calendar. And you can select a fiscal calendar for a budget cycle to make it a budget calendar. You can use the same fiscal calendar for all of these.

Select a fiscal calendar for your legal entity

Select the fiscal calendar that you want to use for the ledger for your legal entity in the **Ledger** page. A fiscal calendar must be selected on the **Ledger** page for every legal entity. After a fiscal calendar is selected, you can set up period statuses and permissions on the **Ledger calendar** page for any of the periods that are part of a fiscal year.

Select a fiscal calendar for fixed assets

You can select a fiscal calendar for a fixed asset book, and that fiscal calendar will be used by the fixed assets that use the selected book. You can select from any fiscal calendar that is defined on the **Fiscal calendars** page.

Define budget cycle time spans

Budget cycles are the length of time during which a budget is used. Budget cycles can include part of a fiscal year or multiple fiscal years, such as a biennial budget cycle of two years or a triennial budget cycle of three years. The budget cycle time span defines the number of periods that are included in the budget cycle. To specify the budget cycle time span, use the **Budget cycle time spans** page.

Maintain periods for your organization

Use the **Ledger calendar** page to view the details of the fiscal calendar, fiscal years, and periods used by your organization. You can also change the status of the periods and select which users can post accounting transactions to periods. For example, at the start of a new period, you might want a group of users to finish posting financial transactions in the previous period, while other groups work only in the new period.

Ledger and subledger accounting overview

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

What is a ledger?

A *ledger* captures the collection of main accounts in a defined structure. It represents the general ledger for a legal entity, where all the financial transactions are summarized and posted. Therefore, it serves as the basis for the preparation of statutory finance reports (balance sheets and profit and loss statements). Each legal entity can have only one ledger. However, up to 10 posting layers can be used to track the deltas for additional accounting standards.

Set up a ledger

For each legal entity in Microsoft Dynamics 365 Finance, details about the ledger must be configured. To configure ledger settings, go to **General ledger** > **Ledger setup** > **Ledger**.

A ledger has the following main components:

- **Chart of accounts** – Determines the main accounts that are used for all accounting entries that are posted to the ledger.

  Account structures determine which financial dimensions are used with the main accounts. (Financial dimensions can be different for each main account or group of accounts.) Account structures also determine which combination of financial dimension values is valid when entries are posted to the ledger.

- **Calendar** – Defines the fiscal year and periods of the ledger.

- **Currency** – Defines the accounting currency, or home currency, of the ledger. The reporting currency is considered a second accounting currency and is optional. The exchange rate types determine which exchange rate tables are used for transaction entry.

Learn more about how to configure a ledger in Configure ledgers.

What is a subledger?

Most documents that are posted affect a *subledger* or a *module*. Examples of subledgers in Dynamics 365 finance and operations apps include Accounts payable, Accounts receivable, Inventory, Fixed assets, Tax, and Production. Each subledger captures the document details that are relevant to it. For example, when a customer invoice is posted, the customer's balance is captured in the **Accounts receivable** module, the tax codes and amounts are captured in the **Tax** module, and the cost of inventory that was sold is captured in the **Inventory/Costing** modules.

What are subledger journal account entries?

Each source document maintains the subledger journal account entries, which represent the detailed accounting entries of the document. The subledger journal account entries are ultimately transferred to the ledger.

The subledger journal account entries are created through accounting rules that are defined through the posting profile for each module. Posting profiles use the main accounts from the chart of accounts that is defined in the ledger setup.

To set up posting profiles in finance and operations apps, follow these steps:

- **Accounts payable:** Go to **Accounts payable** > **Setup** > **Vendor posting profile**.
- **Accounts receivable:** Go to **Accounts receivable** > **Setup** > **Customer posting profile**.
- **Inventory:** Go to **Inventory management** > **Setup** > **Posting** > **Posting**.
- **Production groups:** Go to **Production control** > **Setup** > **Production** > **Production groups**.

Additional posting profiles exist for other modules.

Learn more about posting profiles in Posting profiles overview.

Link between a subledger and a ledger

When a source document is posted, the subledger journal account entry captures the accounting impact of that document. This subledger accounting contains the affected ledger accounts and the corresponding debit and credit amounts. The ledger accounts in the subledger journal account entries are created by using the posting profiles for the main accounts and the financial dimensions from the document. The resulting ledger account (main account + financial dimension values) adheres to the chart of accounts and account structures that are defined in the ledger.

The total debit and credit amounts must be balanced. According to the requirements of the double-entry bookkeeping principle, every transaction that is posted to an account must have an equal and opposite entry in another account. For example, a product receipt for $100 in purchases results in a $100 debit to the Inventory account and an equivalent credit of $100 to the Purchase accrual account.

The balanced accounting entry in the subledger journal account entry is then transferred to the ledger, either in detail or summary, depending on the setup in General ledger parameters.

To view transactions that are posted to the main account, go to **General ledger** > **Inquiries and reports** > **Voucher transactions**. Alternatively, open the **Trial balance** list page by going to **General ledger** > **Inquiries and reports** > **Trial balance**. Drill down to the transaction details.

The voucher is used as the shared reference between the subledger document and the accounting entries in the ledger.

Example: Product receipt subledger and ledger postings

After a product receipt is posted for a purchase order, you can view the product receipt journal that was created during posting. From the **Product receipt** journal, select **Vouchers** to view the ledger accounting entry for the product receipt.

In the **Voucher transactions** view, select the **View subledger journal** tab to view the subledger details. Because summarization can occur during the transfer to the ledger, more account entries might be shown in the subledger journal account entry.

Financial dimensions

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Human Resources, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

Use financial dimensions to further categorize financial transactions. Financial dimension values become segments within the ledger account. Use them for further analysis, such as generating a profit and loss financial statement by a dimension or a trial balance by dimension.

Financial tags (tags) are an alternative to financial dimensions. An organization can create up to 20 user-defined financial tags and enter values for them on transactions. For more information, see Financial tags. To understand the differences between the two, see Differences between financial tags and financial dimensions.

This article explains the various types of financial dimensions and their key properties. For step-by-step creation instructions, see Define financial dimensions.

Financial dimension types

Use the **Financial dimensions** page to create financial dimensions that you can use as account segments for charts of accounts. Two types of financial dimensions exist: custom dimensions and entity-backed dimensions.

Custom dimensions

A custom dimension is a financial dimension that reflects your organization's specific business needs - for example, an internal cost center classification, fleet identifier, or expense purpose. Unlike entity-backed dimensions, you create and maintain custom dimension values manually on the **Financial dimension values** page. In addition, custom dimensions are always shared across legal entities.

Entity-backed dimensions

An entity-backed financial dimension is based on a system-defined entity that you select in the **Use values from** field. For entity-backed dimensions, the values are defined somewhere else in the system, such as in Customers or Stores entities. Some entity-backed dimensions are shared across legal entities, whereas other entity-backed dimensions are company-specific. Dimensions that are company-specific (also known as company-striped dimensions) are only visible when accessed as a user from the associated company.

For example, to create dimension values for projects, select **Projects**. This selection allows any value from the project table to be used as a dimension value directly. You create a dimension value for each project name. The **Financial dimension values** page shows the values for the entity. If those values are company-specific, the page also shows the company.

Entity-backed dimension values aren't available in the dimension framework until you use the value in a transaction, posting profile, journal, or similar context. A record that exists in the source entity (for example, a new customer) doesn't appear as a selectable dimension value until it's referenced in one of these areas.

If you want to rename or delete dimension values from entity-backed dimensions, make these changes from the source entity rather than from the **Financial dimension values** page. For more information, see Modifying and deleting financial dimensions.

Financial dimension values

After you create a financial dimension, use the **Financial dimension values** page to create, view, or assign additional properties to each financial dimension value.

For a custom financial dimension, use this page to create and edit dimension values. You can only enter or edit the **Dimension value** and **Description** fields for custom dimensions. Dimension values have a maximum length of 30 characters.

For an entity-backed financial dimension, you can't create dimension values from the **Financial dimension values** page. You also can't edit the dimension value and descriptions from within the

page. For example, let's say you created the Project financial dimension previously described. On the **Financial dimension values** page, you can't edit the project **Dimension value** or **Description**. This information is taken directly from the project setup. If a new project value is necessary, you must create it from the **Project** page.

To validate whether a ledger account or default dimension combination is structurally valid, use the **Dimension data validation** page. For more information, see Dimension data validation.

Legal entity overrides

All custom dimensions and some entity-backed dimensions, such as dimensions created from an operating unit, are global. When you use global values, all dimension values for that dimension are active for all legal entities that include that dimension in their account structure.

But, not all dimensions or main accounts are valid for all legal entities. Additionally, some might be relevant only for a specific period. In these cases, use the **Legal entity overrides** section to specify the companies that the dimension or main account should be suspended for, the owner, and the period when the dimension is active. The overrides at the shared level can't be more restrictive than the overrides at the legal entity level.

Example

Department has dimension values of 100, 200, and 300. USMF, USSI, and DEMF all use the Department dimension. DEMF is only permitted to use department 100 and 200. To restrict DEMF from using Department 300, create a legal entity override where you mark the dimension value as Suspended. USMF and USSI still have full access to departments 100, 200, and 300.

Financial dimensions as legal entities

You can use financial dimensions to represent legal entities. You don't need to create the legal entities in Dynamics 365 Finance. However, financial dimensions aren't designed to address the operational or business requirements of legal entities. The intercompany accounting functionality in Finance is designed to address only the accounting entries that each transaction creates.

Before you set up financial dimensions as legal entities, evaluate your business processes in the following areas to determine if this setup works for your organization:

- Inventory
- Sales and purchases between financial dimensions and legal entities
- Sales tax calculation and reporting

- Operational reporting

Here are some of the limitations:

- You can use sales tax functionality only with legal entities, not with financial dimensions.
- Some reports don't include financial dimensions. Therefore, to report by financial dimension, you might have to modify the reports.

Financial dimension service

> **Important**
>
> Starting September 11, 2026, Microsoft deprecates the Financial dimension service with the release of Dynamics 365 Finance version 10.0.49 and aligns future investment with Optimized Financial dimensions. The Financial dimension service was introduced as an optional performance optimization for specific journal import scenarios, mainly large general journal imports through the Data Management Framework where ledger account values are provided on journal lines. The service applies to a limited set of scenarios and isn't used for Customer, Vendor, Bank account types, or when derived dimensions are configured.

You can access the Financial dimension service add-in in your Microsoft Dynamics Lifecycle Services environment. It provides improved performance when you use the Data management framework to import a journal that has a large number of lines. To use the service, you must enable it on the **Financial dimension service parameters** page. Currently, the service works only on imported journals. In addition, it can currently process only general journals where the **Ledger** account type is set on the journal lines. Other account types on journal lines, such as **Customer**, **Vendor**, and **Bank**, aren't currently supported. This service isn't invoked when derived dimensions are set up in the system.

The Financial dimension service provides improved performance when you import journals by using a new service that runs in parallel to the data import. It runs only on the main account and financial dimension data in the journal, and it generates the dimension combinations that are specified in the ledger account string field on the journal lines. The processing converts this string into the structured data storage that the Financial dimension framework uses throughout the rest of the product for validation, summary reporting, and inquiries. For more information about summary reporting of financial dimension data, see Financial dimension sets.

For more information, see the following topics:

- Define financial dimensions
- Maintain financial dimension default templates

Financial dimensions and posting

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you plan and set up your chart of accounts, consider how the various components work together when you post a document or journal. These components include account structures, advanced rules, and balancing and fixed dimensions. This article explains what each component is and how the components work together.

Chart of accounts and financial dimension components

A rich, rule-based system defines valid combinations of main accounts and financial dimension values. This section gives a brief overview of the functionality of each component and explains where you can find the component.

Account structures

You need an account structure when you set up your ledger. You must define and activate at least one account structure, and you must assign it to the ledger. The account structure must include the main account. You can define the order of segments that works best for the business. After you define the main account, the system can determine the account structure that is used. By putting the main account first or near the front of a structure, you can help limit the values and also help the system apply the last known valid value as a default value. You can include up to 10 additional financial dimensions in the account structure. The account structure defines which dimension values are valid in combination with other values. It also defines whether you must enter dimension values.

Advanced rules

Advanced rules are an optional component when you set up the chart of accounts. You can add as many advanced rules as you want to an account structure. Use advanced rules to handle

scenarios where you must track extra financial dimensions when specific criteria are met. For example, if you use a Travel expense account, you might want to track extra information, such as the event that the employee is traveling for. If there are multiple advanced rules, the system applies them in alphabetical order, based on the names of the rules. The segments that a rule adds can be applied only after the segments of the account structure.

Balancing dimension

You can optionally define a balancing financial dimension. On the **Ledger** page, you can define the financial dimension that should be balanced. Then, whenever you post transactions to that financial dimension, the system automatically creates and posts entries to make the financial dimension balanced.

Default and fixed financial dimensions on the main account

Default dimensions come from various places, such as master records (for example, customer or vendor records), document headers, and the main account. This article focuses on default dimensions on the main account by legal entity. You can define whether a main account has a **Not fixed** or **Fixed** value for each financial dimension that is used across all account structures for the ledger. If a financial dimension is **Not fixed**, it uses a default value, but you can overwrite that value. This behavior applies to all default values in the system, even default values that come from master records. If you set a financial dimension to a **Fixed** value, the system always applies that value, regardless of whether it came from somewhere as a default value or the user entered it.

> ⓘ **Note**
>
> A related concept is derived dimensions. Derived dimensions let the value of one financial dimension automatically set the values of other dimensions, based on rules that you define. By default, derived values are applied only when the target dimensions are blank, but you can enable the **Replace existing dimension values with derived values** option to overwrite values that are already populated. For more information, see Derived dimensions.

Order in which the system applies default dimensions during posting

You might have questions about the order that the various components run in. It's very important that you understand the order that the system applies default dimensions, because this behavior

affects the approach that you take to set up.

> **Note**
>
> This information applies only to the application of default dimensions in the application. If you import data by using Microsoft Excel or the Data Management Framework, the behavior differs.

Example 1

Account structure

Expand table

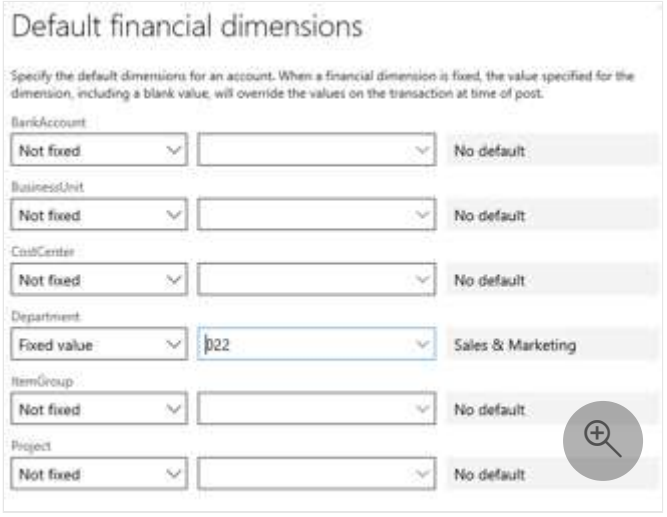
Main account	Business unit	Department	Cost center
All values are allowed	All values are allowed	All values are allowed	All values are allowed

Main account

Expand table

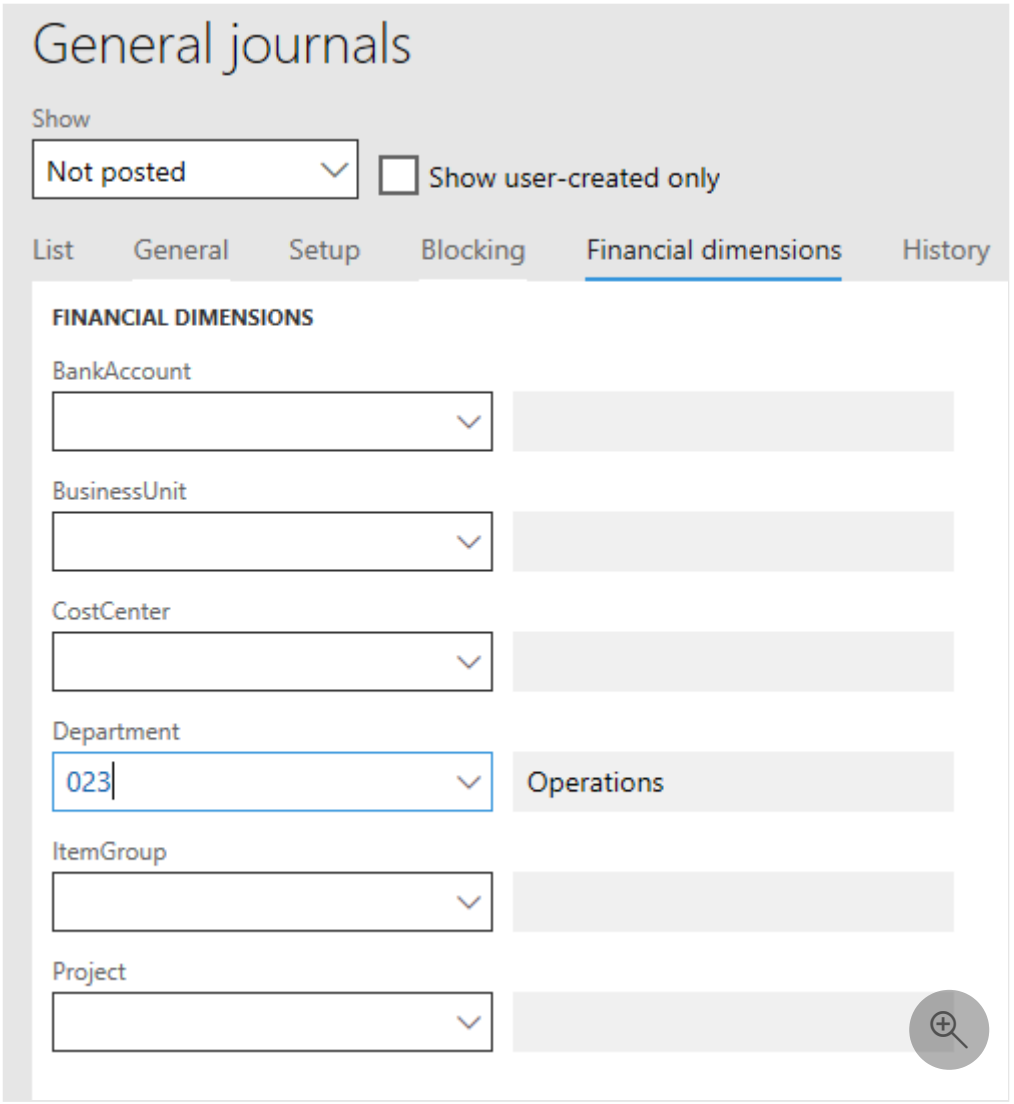
Main account	Name	Legal entity	Department
401100	Product Sales	USMF	Fixed – 022 Sales and Marketing department

The following illustration shows the fixed default dimension that is set on main account 401100.

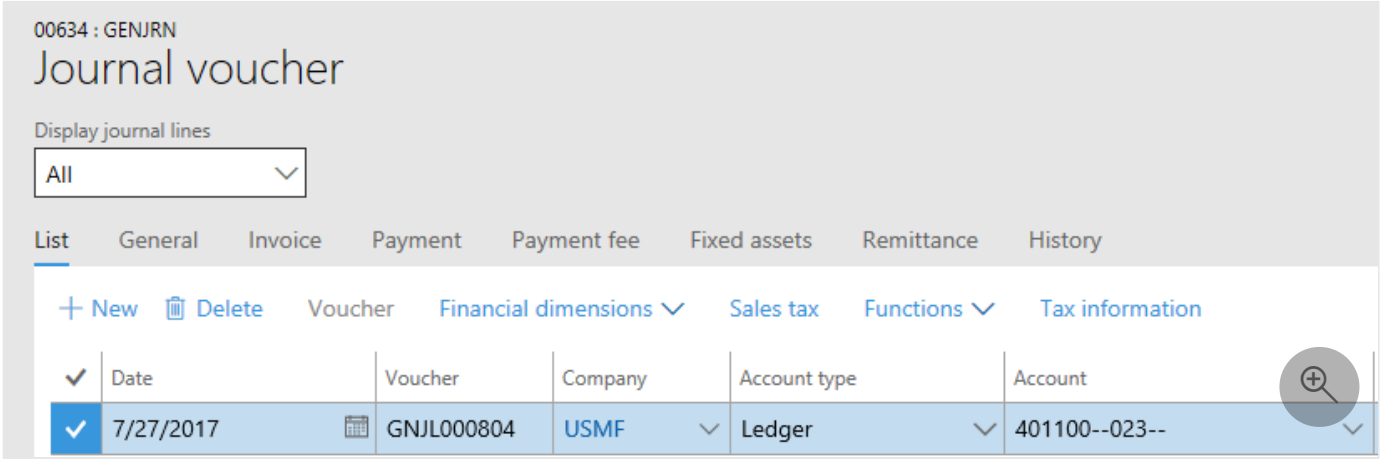


For this basic example, you enter a general journal where the Department dimension is set to use the default value **023** (Operations). You enter and post a ledger account. The following illustration

shows the default financial dimension on the general ledger header.

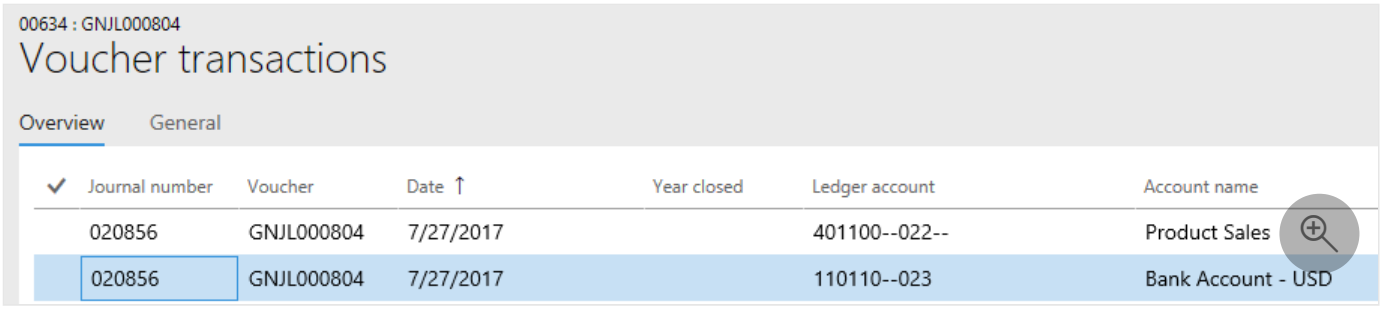


The default dimension on the journal header causes department 023 to be applied by default on the sales account line. The following illustration shows the general journal line, where the **023** default dimension value from the header is applied.



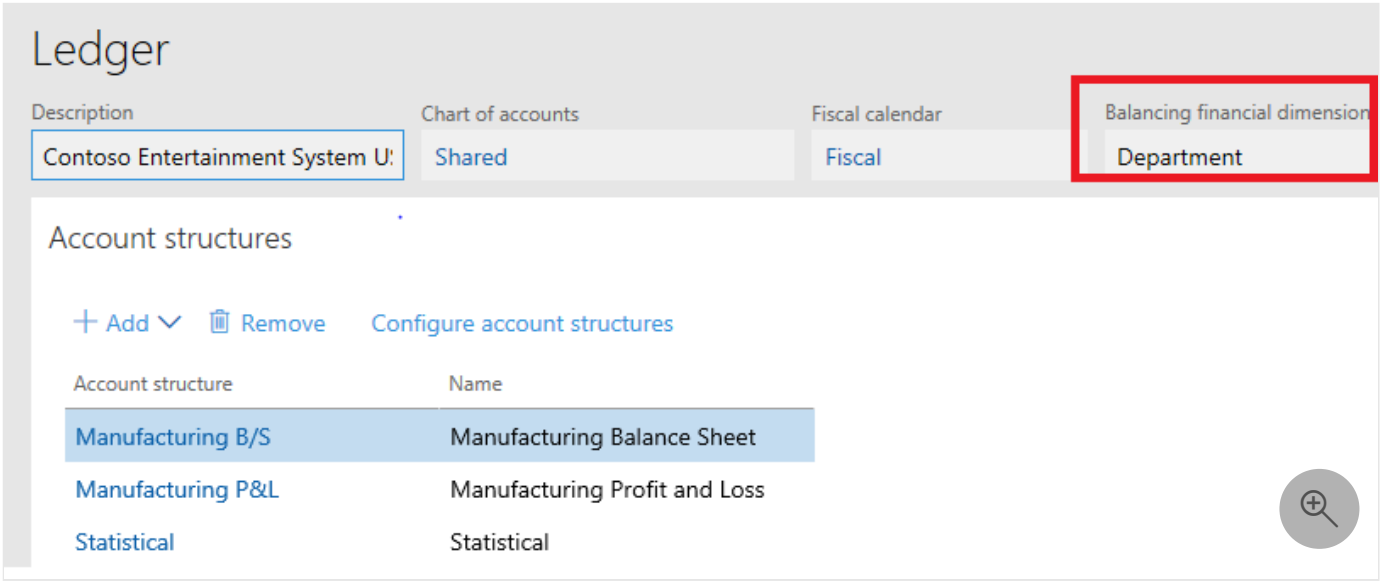
However, when you post the line, the fixed dimension is applied, and the line is posted to department 022. The following illustration shows the posted voucher, where the fixed dimension

is applied for the sales account.

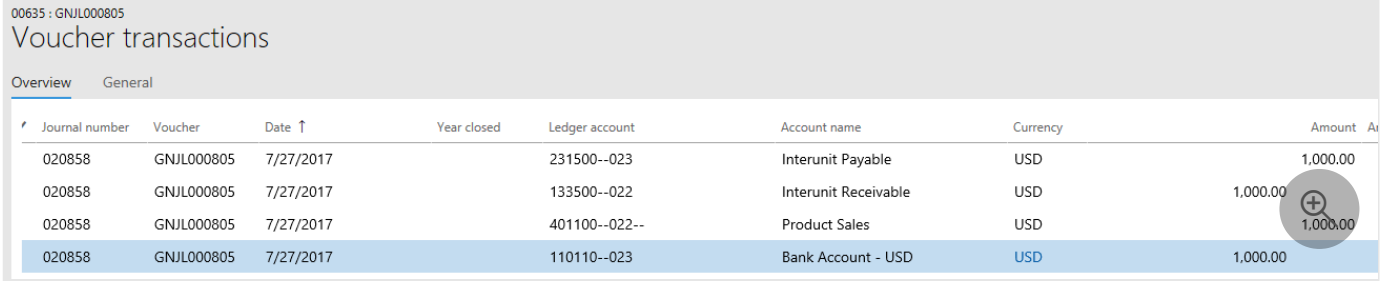


Example 2

This example uses the same setup as the first example. However, you add a second component and use the Department dimension as a balancing dimension. In the following illustration, **Department** is the balancing financial dimension for the USMF ledger.



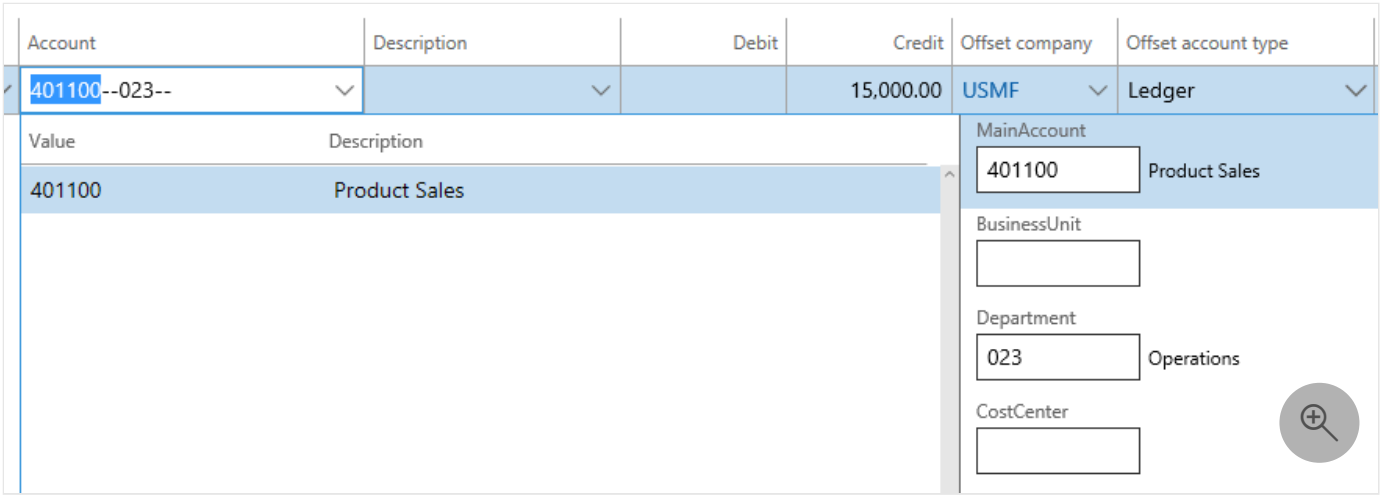
When you use the same journal header setup and post the same transaction, the fixed dimension is applied first. Then the balancing logic is applied to help guarantee that every department has a balanced entry. The following illustration shows voucher transactions that include the balancing entry after the fixed dimension is applied.



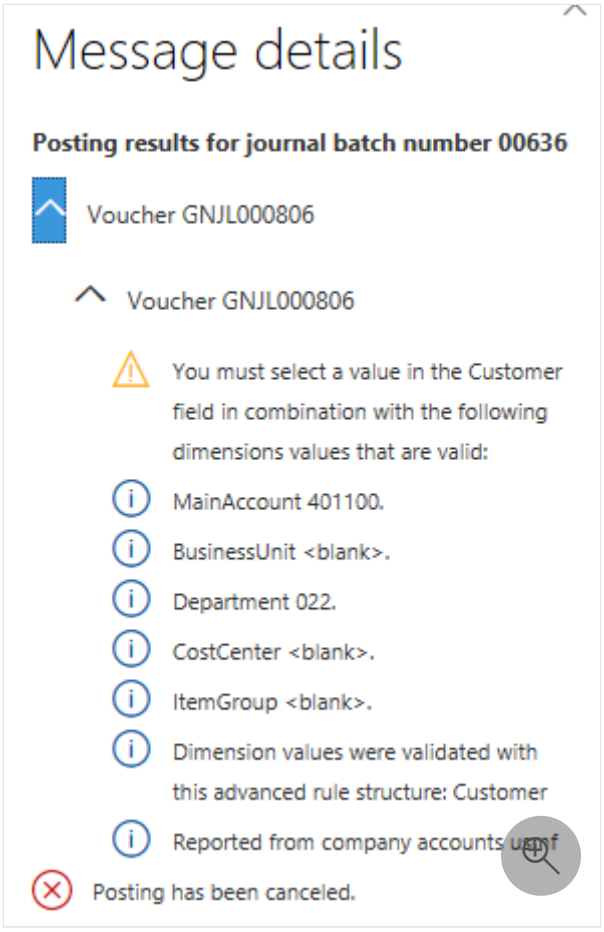
Example 3

In this example, you add an advanced rule. The advanced rule specifies that if sales account 401100 and department 022 (Sales and Marketing) are used, the system should track an additional segment that is named Customer.

This example is important because of the order. The account structure is determined after the main account is entered. If you refer to the account structure setup, the system can determine that the main account, business unit, department, and cost center are relevant. At this point, the advanced rule isn't triggered, because fixed dimensions aren't applied until default dimensions are applied for the journal voucher during posting. In the following illustration, the Customer segment isn't present, because the criteria for the advanced rule aren't met.



The posting isn't successful, because the fixed dimension was applied at the end of the process. Dimension validation determines that the Customer segment is required if the main account is 401100 and the department is 022. Posting can't occur because of the validation error. The following illustration shows the message that appears after dimension validation determines that Customer is a required segment.



In this example, you must overwrite the default value so that the advanced rule is triggered and you can enter the Customer segment. However, this solution isn't always possible, and some users aren't even aware of the posting rules. Therefore, it's important that you understand the order that default dimensions are applied in when you set up your chart of accounts.

To achieve what you want in this example, you can change the configuration in several ways. For example, you can create a new account structure for sales accounts and include the Customer segment in the structure. You can also add more rows in an existing account structure, and specify the main account and valid department values. Then, in the additional customer structure, you might find it useful to have a separate account structure of sales accounts where the Customer segment is present.

Additional resources

Some of the following resources refer to an earlier version. However, much of the information about the application of default dimensions and many of the concepts are the same in the earlier version, so the references are still valid.

Balanced journals for interunit accounting

Plan your chart of accounts

Add financial dimensions to the CFO workspace

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

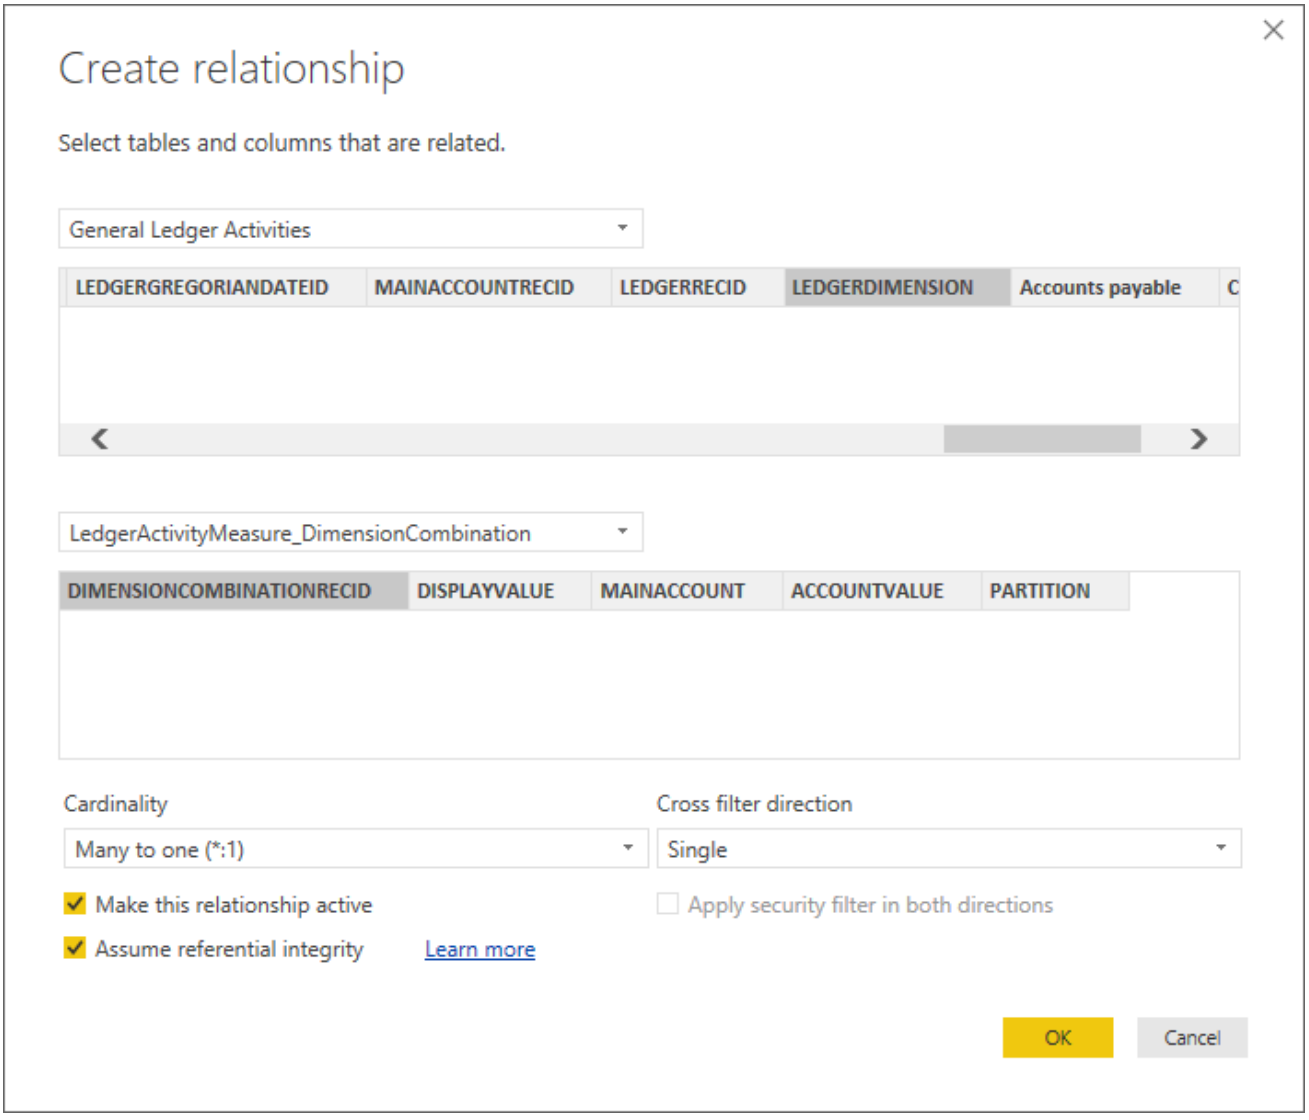
This article explains how to add financial dimensions to the Chief Financial Officer (CFO) workspace, so that they can be used for the ledger and budget reports. The CFO workspace has an **Overview** tab and a **Financial** tab. The reports on these two tabs are backed by two measures: LedgerActivityMeasure and BudgetActivityMeasure. There's a relation between those two measures and the DimensionCombinationEntity entity. Therefore, you can select dimensions.

1. In Microsoft Dynamics 365 Finance, on the **Entity Store** page, update the **LedgerActivityMeasure** and the **BudgetActivityMeasure** measures.
2. In Microsoft Visual Studio, open Application Explorer, and search for **LedgerCFO**.
3. Under **Resources**, open **LedgerCFOWorkspacePBIX**.
4. When the resource opens in Microsoft Power BI Desktop, select **Get Data**, select **SQL Server database**, and then select **Connect**.
5. Enter the server name, and enter **AxDW** as the database. Select **DirectQuery**, and then select **OK**.
6. Search for and select **LedgerActivityMeasure_DimensionCombination**, and then select **Load**.

   > **Tip**
   >
   > In the **Fields** list, rename the table **Financial dimensions**, so that it's easy to identify.

7. Select **Manage Relationships**, and then select **New**.

8. In the first field, select **General Ledger Activities**, and then select **LedgerDimension**.
9. In the second field, select **LedgerActivityMeasure_DimensionCombination** (or **Financial dimensions** if you renamed the table). Select the **DimensionCombinationRECID** header.
10. In the **Cardinality** field, select **Many to One**.
11. Change the **Cross filter direction** value to **Single**.
12. Select both **Make this relationship active** and **Assume referential integrity**, select **OK**, and then select **Close**.



13. In the **Fields** list, you see the table and the available financial dimensions. Drag the financial dimensions that you want to the report-level filters.
14. Save your changes.
15. In the Application Object Tree (AOT), right-click your project, and then select **Synchronize**.
16. Build your project, and then open the application to view the results.

Last updated on 06/24/2026

Creating, modifying, and deleting account structures

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article walks through the process of creating, activating, and deleting account structures. The steps use the USMF demo data company.

Creating account structures

1. Go to **General ledger** > **Chart of accounts** > **Structures** > **Configure account structures**.
2. On the **Action pane**, click **New** to open the drop dialog.
3. In the **Account structure** field, enter a name to describe the purpose of the account structure.
4. In the **Description** field, enter a description to specify the purpose of the account structure.
5. Click **Create**.
6. In the **Segments and allowed values**, click **Add segment**.
7. In the dimensions list, select the dimension to add to the account structure.
8. At the end of the list, click **Add segment**.
9. Repeat step 6 to 9 as needed.
10. In the **Allowed value details** section, select the segment to edit the allowed values. For example, click the **Main Account** field.
11. In the **Operator** field, select an option, such as is between and includes.
12. In the **Value** field, type a value. For example, 600000.
13. In the **through** field, type a value. For example, 699999.
14. In the **Allowed value details** section, click **Apply**.
15. Repeat step 10 to 15 as needed.
16. In the **Allowed value details** section, click **Add new criteria**.
17. In the **Operator** field, select an option, such as is between and includes.

18. In the **Value** field, type a value. For example, 033.
19. In the **through** field, type a value. For example, 034.
20. Click **Apply**.
21. In the grid, select the segment to edit the allowed values. For example, Cost Center.
22. In the **CostCenter** field, type a value. For example, 007..021.
23. In the **Segments and allowed values**, click **Add**.
24. In the **MainAccount** field, type a value. For example, 600000..699999
25. In the grid, select the segment to edit the allowed values. For example, Department.
26. In the **Department** field, type a value. For example, 032.
27. In the **CostCenter** field, type a value. For example, 086.
28. On the **Action pane**, click **Validate**.
29. On the **Action pane**, click **Activate**.
30. Click **Activate**.

Activating account structures

When you're satisfied with your new setup or a change to an account structure, you must activate it before it takes effect. During activation, the system validates the structure and then synchronizes all unposted transactions to match the new structure. Posted transactions aren't affected by account structure changes.

> ⓘ **Note**
>
> Account structure activation is not the same as dimension activation. Account structure activation synchronizes unposted transactions to match your updated structure and runs as a batch job during normal operations. It can't be performed in maintenance mode.

The activation process runs as a batch job. Depending on the volume of unposted transactions, activation can take anywhere from a few seconds to several hours. While activation is running, the structure is marked as **Activating** on the **Account structures** page.

> ⓘ **Important**
>
> Don't cancel a running activation. Canceling resets the process, and resubmitting starts the work over from the beginning — it doesn't resume from where it left off.

Monitoring activation status

When you activate an account structure, the system validates the structure and marks it as active. Unposted transaction processing then continues in the background, with multiple transaction updates running at the same time.

To monitor activation progress:

1. On the **Account structures** page, select **View activation status** above the grid, or select **View** on the Action Pane and then **Activation status**.
2. A dialog box appears showing the individual tasks running as part of the activation process, along with each task's status and completion time.

For more information, see Account structure activation.

Account structure activation failure

If an activation fails, the structure reverts to **Draft** status. The error is typically not displayed on the account structure form itself — check the **batch job error log** for the specific error message.

The most common reasons for activation failure are overlapping criteria, either within the structure or across other structures on the same ledger. For more information, see Account structures overview.

Modifying an existing account structure

In many cases, modifying an existing account structure is preferable to deleting it and creating a new one. Modification avoids the overhead of reassigning the structure across legal entities and reconfiguring dependent processes.

Modification is suitable for scenarios such as:

- **Broadening a range** — For example, changing from 1000-2000 to 1000-3000.
- **Restricting a range** — For example, specifying a **Department** segment range of 012-014.
- **Subdividing a main account range** — For example, splitting a **BalanceSheet** structure with range 1000-3000 into two structures: **BalanceSheet_Small** with range 1000-2000 and **BalanceSheet_Large** with range 2000-3000.
- **Adding or removing dimensions** — For example, adding a new segment or removing one that is no longer needed.

To modify an account structure:

1. Go to **General ledger** > **Chart of accounts** > **Structures** > **Configure account structures** and select the desired structure.
2. Select **Edit** on the Action Pane. The system creates a draft copy while keeping the original active for ongoing transactions.
3. Make your changes — update criteria, add or remove segments, or adjust ranges as needed.
4. Select **Validate** to check your changes.
5. Select **Activate** to apply your changes and wait for successful activation.

Deleting account structures

If an account structure is no longer needed and has no blocking unposted transactions, it can be deleted. Before deleting, consider whether modifying the structure would better serve your needs.

Resolving blocking transactions

You can't delete an account structure if unposted transactions reference it. To find and resolve these transactions:

1. Navigate to the journal which has the transactions (e.g. **General ledger** > **Journal entries** > **General journals**).
2. Filter by **Show** > **Not posted**.
3. Select a journal and select **Lines** on the Action Pane to view its transactions.
4. Transactions that reference the account structure can be removed with the **Delete** button or updated to reference a different ledger account or offset account.

Deleting the structure

After all blocking transactions are resolved:

1. Go to **General ledger** > **Chart of accounts** > **Structures** > **Configure account structures**.
2. Select the account structure you want to delete.
3. Select **Delete** on the Action Pane.

If you can't locate the blocking transactions, contact Microsoft Support for assistance.

Budgeting overview

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Almost every company that uses Financials functionality in Microsoft Dynamics 365 Finance needs to create reports of budget versus actuals. This article explains the minimum configuration that you need to create budgets in finance and operations or load them from a third-party program.

Overview

You maintain the approved budget for a legal entity in a document known as a *budget register entry*. The lines in a budget register entry document are known as *budget account* entries. They contain financial dimension information, dates, and the amounts of the approved budget. The budget register entry document integrates with basic financial reports and inquiry pages where ledger actual amounts are compared to budget amounts.

You can create budget register entries in several ways:

- Manually enter the document information on the **Budget register entries** page.
- Use the Microsoft Excel template that you can open by selecting the **Open in Excel** button on the **Budget register entries** page.
- Use the **Budget Account Entries** data entity in Data management to import budget register entries. Consider using this method and turning on the **Set based processing** parameter when you must import many budget account entries.
- If the company uses Budget planning functionality to prepare budget data, you can use the **Generate budget register entry** periodic process.

The budget register entry is considered completed when you update the budget balances. On the **Budget register entries** page, select **Update budget balances** for a selected budget register entry or multiple entries. After you update the budget balances, the status of the budget register entry changes to **Completed**. You can't reopen a completed budget register entry for edits.

Therefore, if you must adjust the budget data, you must create a new budget register entry instead of correcting data in the completed budget register entry.

Configuration

When you configure budgeting, start on the **Budgeting parameters** page. On this page, you must define the budget journal, the number sequence for budget register entries, and the default behavior in the workspaces.

On the **Budgeting parameters** page, the following fields are available:

- **Allocation key** – This field determines how the amount for a budget account entry is allocated in a cash flow forecast.
- **Use rules for budget transfers** – Select this option to enable budget transfers.
- **Display legacy budget analysis inquiry** – Select this option to show the legacy budget analysis inquiry.
- **Default account structure** – Select this checkbox to automatically populate the account structure in the budget register, based on the main account. This checkbox is available if the **Default the account structure in the budget register entry** feature is enabled in Feature management.
- **Budget journal** – Select a journal name for budget appropriations. This field is available if the **Enable budget appropriation** field is selected on the **General Ledger parameters** page.

Next, if policies govern the approval of budget register entries based on budget type (for example, transfers or revisions), create budget register entry workflows on the **Budgeting workflows** page. If there are scenarios where transfers might be allowed without workflow approval, you can define budget transfer rules to support those scenarios.

On the **Budgeting dimensions** page, select the financial dimensions that are used for budgeting, based on the dimensions that are used in the chart of accounts. You can select all financial dimensions or a subset of them for budgeting.

Define a *budget model* that corresponds to all or some of the budgets. You can use a single budget model for all budget register entries. Alternatively, you can create separate models that are based on the budget type, the geographical location, or some other way that a budget can be classified.

> ⓘ **Note**

If you use budget control, you can associate only one budget model with a specific budget cycle time span.

Create *budget codes* that identify the type of budget transactions to record and any related workflow. Budget codes can support the following budget types:

- Original budget
- Transfer
- Revision
- Encumbrance
- Preencumbrance
- Carry-forward budget

Budget codes provide an audit trail of approved budget modifications throughout the course of the budget cycle. If you associate a workflow with a budget code, the workflow is enabled for all budget register entries that use that budget code, and workflow steps must be completed before the budget register entry can reach the **Completed** stage.

You can also optionally set up *budget transfer rules*. To use budget transfer rules, select **Use rules for budget transfers** on the **Budget parameters** page. When budget transfer rules are used, if a user creates a document by using a budget code of the **Transfer** type, budget balances aren't updated if the budget transfer rules are violated. For example, you can allow budget transfer documents where the expense budget is transferred between the main accounts for the Sales and Marketing department, but can prohibit budget from being transferred from or to that department unless workflow approval is granted for that type of budget account entry.

Functionality that was introduced in Microsoft Dynamics 365 Finance version 10.0.7 (January 2020) adds capability and flexibility for budget register entries. To enable these enhancements, go to the **Feature management** workspace and select **Budget register entries for quantity only** and/or **Budget register entries defaulting of amount type**.

The **Budget register entries for quantity** only feature lets you post a budget register entry with quantity-only amounts. For example, you could post a budget entry with a quantity of 32 and a price of zero, which results in an amount of zero. You can then use this quantity within the context of a financial report to determine a price per quantity. No inquiries or reports were updated as part of this feature; the feature just enables you to post an amount of zero.

The **Budget register entries defaulting of amount type** feature allows the default amount type within a budget register entry to be an amount type other than expense. The budget register

entry line now defaults to expense when the main account type is expense; it defaults to revenue when the main account type is revenue; and it defaults to expense for all other account types.

Using workspaces and inquiry pages to track budget vs. actuals

The budget manager can review the current state of a budget in the **Ledger budgets and forecasts** workspace. The **Expense over budget** and **Revenue under budget** tabs provide a quick view of the financial dimension combinations where budget targets aren't being met or are approaching the threshold. You can personalize the budget threshold percentage and financial dimension sets that are used on those tabs by clicking **Configure my workspace**. You can select **Unit managers** to see the workers who are responsible for specific financial dimension combinations that are selected on those tabs. For example, if you see that the expense budget of the Operations department is going over the budget threshold, you can easily find and contact the Operations department manager to discuss the issue.

> **Note**
>
> The **Department manager** field on the **Organization Units** page determines which managers support specific financial dimension combinations. Select **See more** at the bottom of the tab to open the **Budget vs actuals** inquiry page for more details about budget amounts versus actual amounts.

The **Actual vs budget** inquiry page lets you drill into the details of the budget versus actual amounts. Select a line on the inquiry page, and then select **Period balances** to see budget and actual amounts spread across fiscal periods. The **Budget account entries** page provides drill-through to the details of the budget amount in budget register entries. The **General journal entries** page opens the ledger transactions that are included in the calculated **Actuals** amount.

A company that's using Budget planning functionality can create and use *budget forecasts* in the **Ledger budgets and forecasts** workspace.

Create dimensions and import dimension members

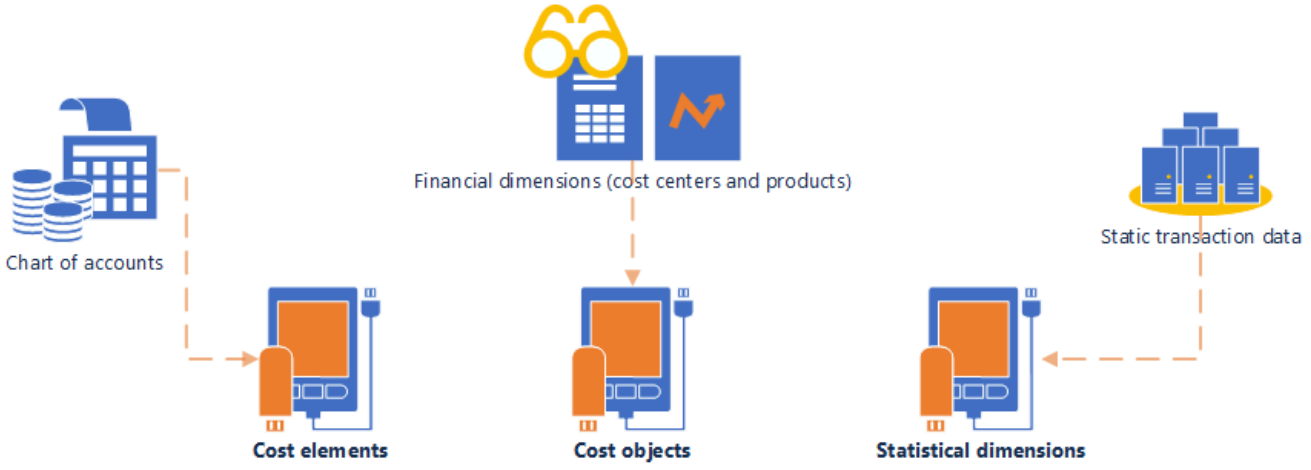
> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Cost accounting is an independent module that requires data from other modules. Categorize this data into the following categories:

- Cost elements
- Cost objects
- Statistical dimensions

A **Cost element** corresponds to a cost-relevant item in the chart of accounts. A **Cost object** corresponds to any type of financial dimension, such as products, cost centers, and projects that you want to estimate, allocate costs to, or measure directly. A **Statistical dimension** and its members are used to register nonmonetary entries. Statistical dimension members can be used as an allocation base in cost distribution and allocation

The following diagram illustrates the dimensions that are used in Cost accounting.



After you import the data into Cost accounting, use it to build various perspectives that provide insights to managers at all levels of the organization. The following articles provide information

about creating dimensions and importing dimension members.

- Cost element dimensions
- Create cost elements
- Cost object dimensions
- Map cost element dimension members to a common set of dimension members
- Map a cost element dimension
- Statistical dimension members and statistical measure provider templates

Cost element dimensions

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

As a core pillar in cost accounting, use cost element dimensions to categorize and track where costs flow.

A cost element corresponds to a cost-relevant item in the chart of accounts. It can be any type of element at the lowest level in a business where costs can flow. The concept of cost elements includes ledger accounts and all cost-relevant resources. Currently, Cost accounting supports ledger accounts.

Two types of cost elements

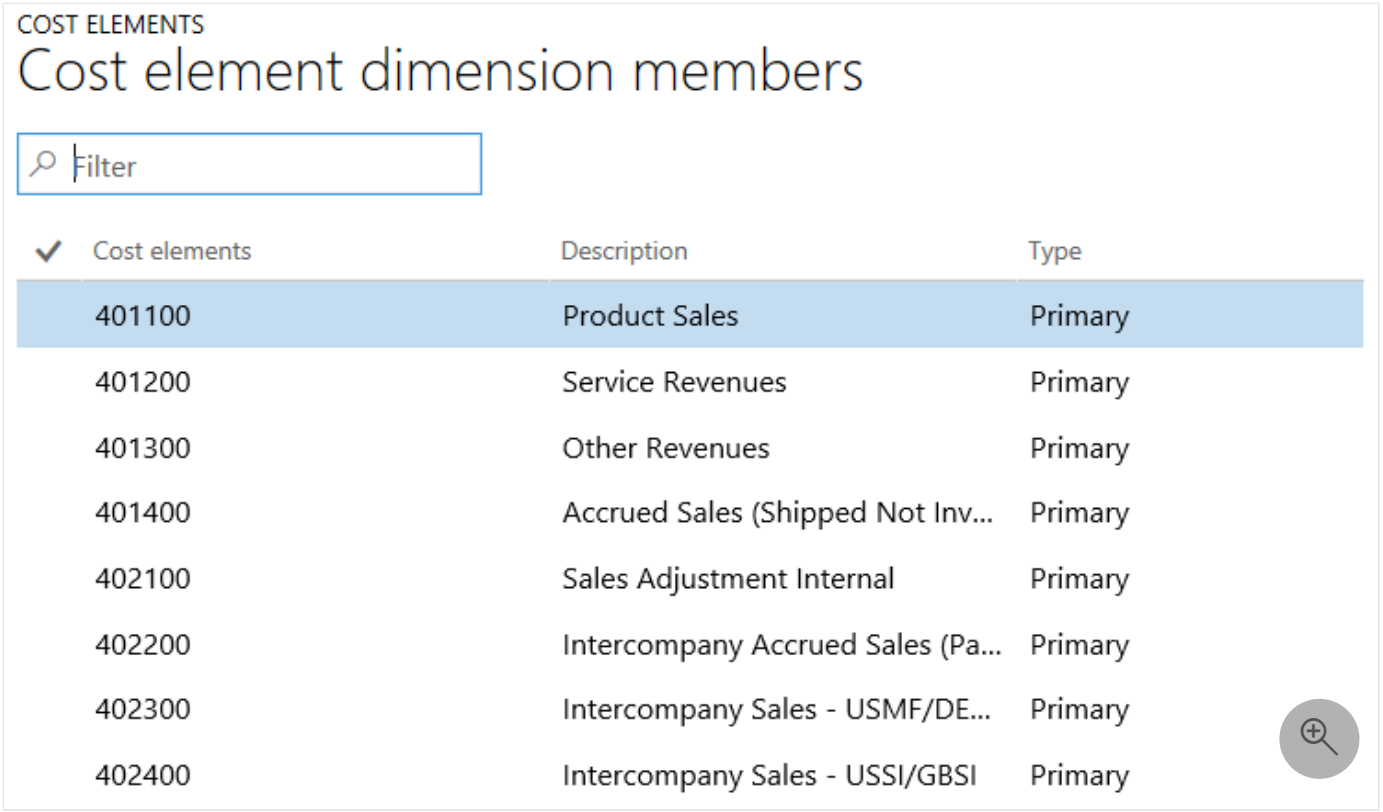
There are two types of cost elements: primary cost elements and secondary cost elements. The following table describes the difference between the two types.

Expand table

Primary cost elements	Secondary cost elements
The primary cost elements represent the flow of costs from financial accounting to cost accounting. The cost element structure corresponds to the profit and loss account structure in the general ledger, where a cost element can correspond to a main account. Not all main accounts need to be represented as cost elements depending on the business needs. Examples of primary cost elements include: • Costs of goods sold (COGs) • Indirect material costs • Personnel costs • Energy costs	The secondary cost elements represent the flow of costs internally because these costs are created and used only in Cost accounting. Use them to ensure that you can trace the source of costs. Use these cost elements in cost allocations and overhead calculations. Examples of secondary cost elements include: • Production costs • Production, material, and marketing overheads

Cost element dimensions and cost element dimension members

Cost elements are *cost element dimensions*. The individual dimension values are *cost element dimension members*. For example, you have a US chart of accounts structure (COA) that serves as the base for your statutory reporting. Use this COA as the cost element dimension. The accounts, which are primary cost elements, appear as the cost element dimension members in Cost accounting. The following screenshot shows an example of Main Accounts as the cost element dimension with its actual main accounts as the cost element dimension members.



Import cost element dimension members through data connectors

To simplify the setup of cost element dimension members in Cost accounting, use data connectors that are either prebuilt or custom built to retrieve the primary cost elements from one or more source systems.

Implementation considerations

Because cost elements represent the lowest level of cost details, make sure you include all the cost elements required for managerial reporting when you implement the cost elements structure. It can be a challenge to find an appropriate number of cost elements for cost control.

Having thousands of cost elements can make it difficult to control each cost element. As an alternative, group cost elements and manage cost control at an aggregated level.

Create cost elements

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

There are several ways to create cost elements in Cost accounting. This procedure shows how to create cost elements by importing main accounts via a data connector. The USMF demo company was used to create this procedure. This procedure is for a Cost accounting feature that was added in Dynamics 365 for Operations, version 1611.

Create new cost elements

1. Go to **Cost accounting** > **Dimensions** > **Cost element dimensions**.
2. Click **New**.
3. In the **Name** field, type a value.
4. In the **Data connector for dimension members** field, enter or select a value.
5. In the **Description** field, type a value.
6. Click **Save**.

Configure the data connector

1. Click **Configure dimension member provider**.
2. In the **Chart of accounts** field, enter or select a value.
    - Select **Shared** to use the shared chart of accounts.
3. Click **New**.
4. In the list, mark the selected row.
    - You can apply filters to accounts to meet your criteria.
5. In the **From main account** field, enter or select a value.
6. In the **To main account** field, enter or select a value.
7. Click **OK**.

Import main accounts

1. Click **Import dimension members**.
    - Main accounts will be imported into Cost accounting and used as cost elements.
2. Click **OK**.

View the imported accounts as cost elements

1. Click **View dimension members**.
    - View the imported ledger accounts as cost elements in your business that costs can flow to.

Cost object dimensions

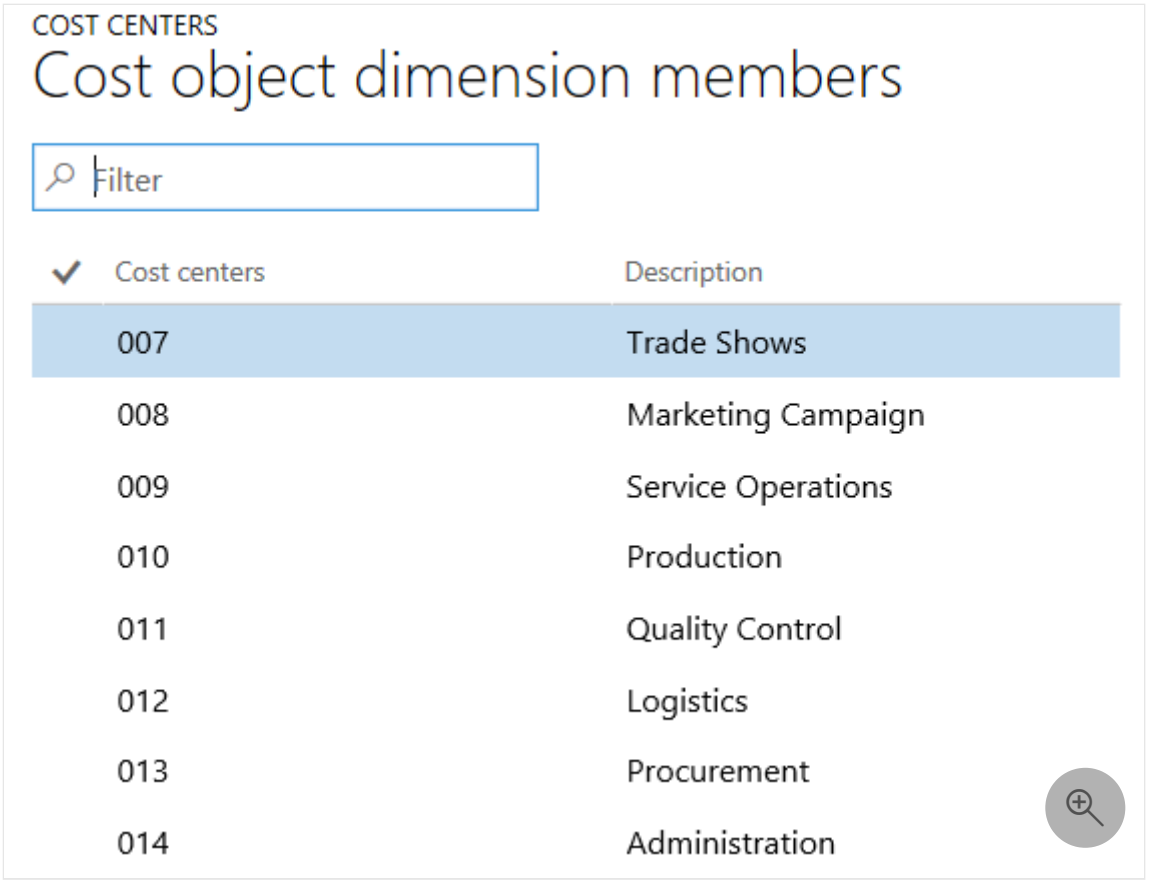
> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you analyze costs, use cost element dimensions to determine where costs flow. Use cost object dimensions to determine where you should assign costs. This article provides information about cost object dimensions.

A cost object can be any type of object that you want to estimate, allocate costs to, or measure directly. Typical cost objects include products, projects, resources, departments, cost centers, and geographical regions. Management uses cost objects to quantify costs and also to drive profitability analysis.

Cost object dimensions and cost object dimension members

Cost objects are known as *cost object dimensions*. After you decide which entity the cost object dimension should refer to, specify the individual dimension values or import them into Cost accounting from other source systems. These individual dimension values are known as *cost object dimension members*. For example, you want to use the financial dimension that is named Cost center as the cost object dimension. To see how costs flow to the individual cost centers, you must import the cost object dimension members. In this case, the cost object dimension members are the actual cost centers, such as Sales, Production, Administration, and Geographic locations. The following screenshot shows an example of Cost Centers as the cost object dimension with its actual cost centers as cost object dimension members.



Import cost object dimension members through data connectors

To make the import of cost object dimension members easier, use data connectors to retrieve the values from the entities that you want to use as cost object dimensions. You can use either the prebuilt data connectors or custom data connectors that you build.

Create cost objects

Article • 03/28/2023

This procedure shows how to create cost objects by importing the cost center financial dimension into Cost accounting via a data connector. The USMF demo company was used to create this procedure.

Create new cost objects

1. Go to **Cost accounting** > **Dimensions** > **Cost object dimensions**.
2. Click **New**.
3. In the **Name** field, type a value.
4. In the **Data connector for dimension members** field, enter or select a value.
5. In the **Description** field, type a value.
6. Click **Save**.

Configure the data connector

1. Click **Configure dimension member provider**.

    - Select **CostCenter** to import the CostCenter dimension into Cost accounting.

2. In the **Dimension name** field, select Cost center.
3. Click **OK**.

Import cost centers

1. Click **Import dimension members**.
2. Click **OK**.

View the imported cost centers

1. Click **View dimension members**.

Map cost element dimension members to a common set of dimension members

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

By mapping different cost element dimension members to a common set of cost element dimension members, you merge data into a common format for analysis purposes.

If you're a global company and comply with statutory accounting requirements, you might use multiple charts of accounts. When you import cost element dimension members from different charts of accounts, you can end up with a mix of accounts. However, these accounts might actually have the same nature, and you might want to analyze and allocate costs for them by using a common format.

Map cost element dimension members to a common format

The following example shows how you, as a cost controller, can create a new cost element dimension in Cost accounting that maps cost element dimension members from the US chart of accounts structure and the French chart of accounts structure to a common set of cost element dimension members. You can then use the common set of cost element dimension members to analyze cost data from the two legal entities in a cost accounting ledger.

Expand table

Source: US chart of accounts	Source: French chart of accounts	New common set of cost element dimension members
Imported cost element dimension members from the US chart of accounts	Imported cost element dimension members from the French chart of accounts	Mapping of US and French cost element dimension members to a common set

Source: US chart of accounts	Source: French chart of accounts	New common set of cost element dimension members
5001: Sales	5001: Sales and advertising	5000: Sales and advertising
5030: Advertising	6390: Stock purchase*	7000: Cleaning expenses
7001: Cleaning expenses	7001: Travel expense	7001: Travel expenses

*The Stock purchase French cost element dimension member isn't mapped.

Currency conversion

The various charts of accounts that you use might be set up to use different currencies. In this case, be sure to specify a currency conversion, so that cost data is processed by using the correct currency, as defined in the cost accounting ledger where the cost element dimension members are used. In the preceding example, if US dollars (USD) are used in the cost accounting ledger, you must create a currency conversion from USD to euros (EUR) to process transactions for the mapped cost element dimension members.

Update mappings at any time

You can update the mapping definitions for a cost element dimension at any time. Because mappings aren't date-effective, changes apply the next time you process cost transactions or run cost calculations.

Last updated on 05/27/2026

Map a cost element dimension

Article • 03/28/2023

A cost controller can use this procedure to map a cost element dimension to a cost element dimension in the MXMF legal entity. This recording uses the USP2 demo data company.

1. Go to **Cost accounting** > **Dimensions** > **Cost element dimensions**.
2. In the list, find and select the desired record.
    - For this example, select **Cost elements**.
3. Click **Dimension mappings**.
4. Click **Configure mappings** from this dimension.
5. Click **New**.
6. In the **To dimension** field, enter or select a value.
    - For this example, select MXMF Cost elements.
7. Click **New**.
8. In the list, mark the selected row.
9. In the **From dimension member** field, enter or select a value.
    - For this example, select dimension member 606400 Telephone & Fax Expense.
10. In the **To dimension member** field, enter or select a value.
    - For this example, select dimension member 6001004 Telefono.
11. Click **Save**.

Dimension hierarchy

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

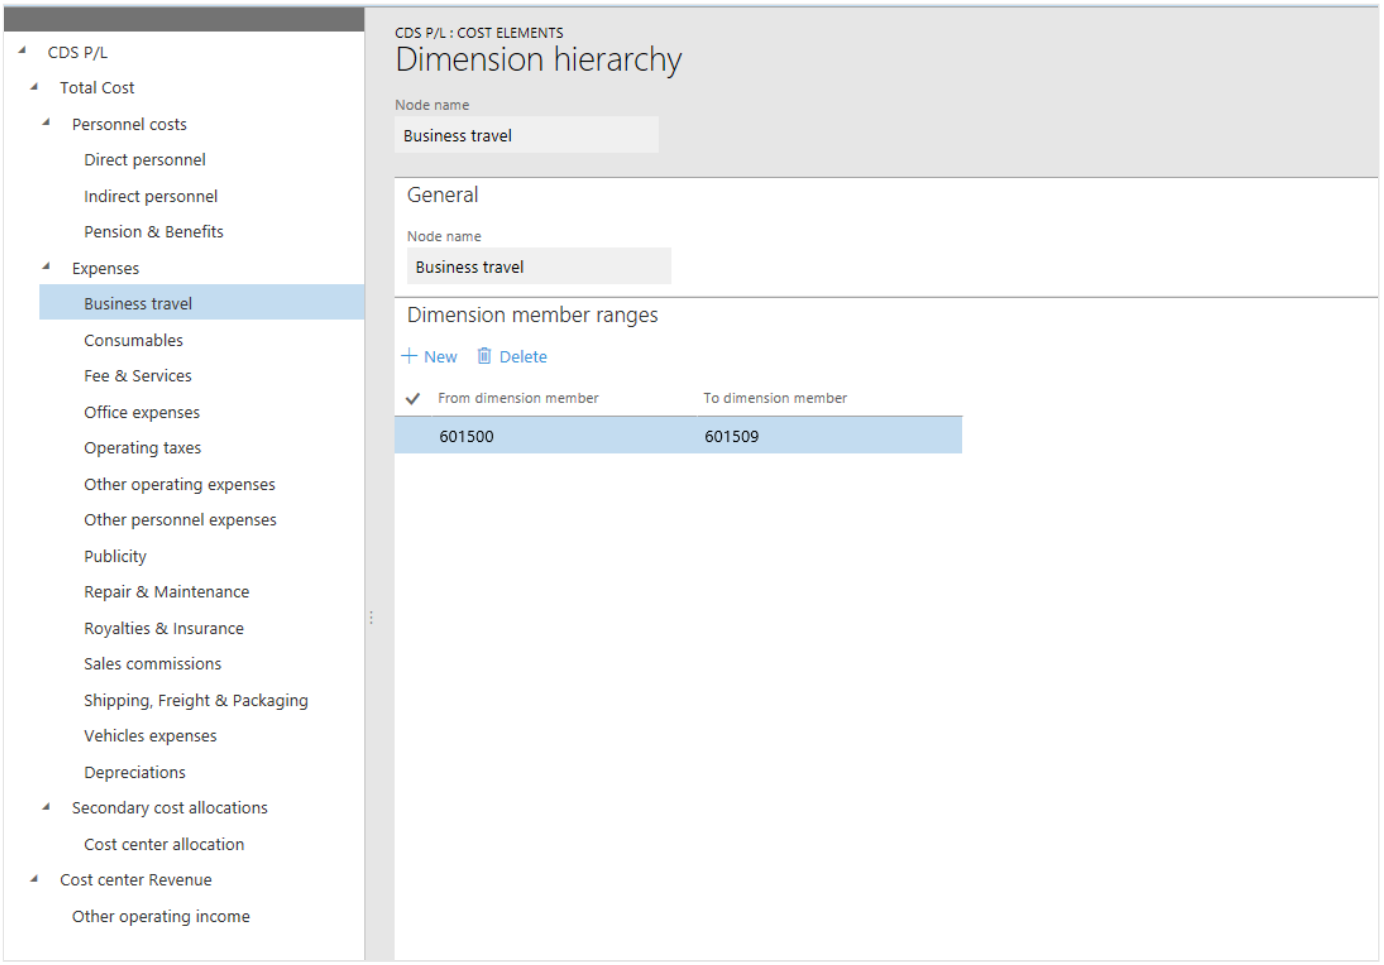
This article provides information about dimension hierarchies. Use a dimension hierarchy to define the reporting structure, cost policies, and security setup in Cost accounting.

Overview

Cost accounting uses dimension hierarchies in various places. A dimension hierarchy lets you define the following information:

- The reporting structure that fits into the organization's requirements
- Cost policies
- The security setup

Here's an example of a dimension hierarchy.



You can create a dimension hierarchy for the following types of dimensions:

- Cost element dimensions
- Cost object dimensions
- Statistical dimensions

> **Note**
>
> - You can create multiple dimension hierarchies for the same dimension if you need different perspectives.
> - You can associate a dimension hierarchy with only one dimension.
> - A dimension hierarchy can have unlimited levels in its structure. All the levels appear in the **Cost control** workspace. When you use Microsoft Excel or Microsoft Power BI for reporting purposes, only the first 15 levels of the dimension hierarchy are exported. This limitation exists because both Excel and Power BI require a fixed schema.
> - A dimension hierarchy isn't date-effective. Therefore, any change to a dimension hierarchy is immediately saved to the record, and you can't compare the before date and after date.

Dimension hierarchy type

When you create a new dimension hierarchy, you must select a hierarchy type. Go to **Cost accounting** > **Dimensions** > **Dimension hierarchies**. Select **New**, and choose a dimension hierarchy type. You can select either **Dimension categorization hierarchy** or **Dimension classification hierarchy**.

Dimension categorization hierarchy

Use the **Dimension categorization hierarchy** type for reporting. It supports only the cost element dimensions. When you select this type, the following rules apply:

- You can associate a dimension member more than once in the hierarchy structure.
- You can put a cost element dimension member in different nodes by assigning a cost behavior to the leaf node.

Dimension classification hierarchy

Use the **Dimension classification hierarchy** type for defining rules and reporting purposes. It supports all dimensions, such as cost objects, cost elements, and statistical dimensions. When you select this type, you can associate a dimension member only once in the hierarchy structure.

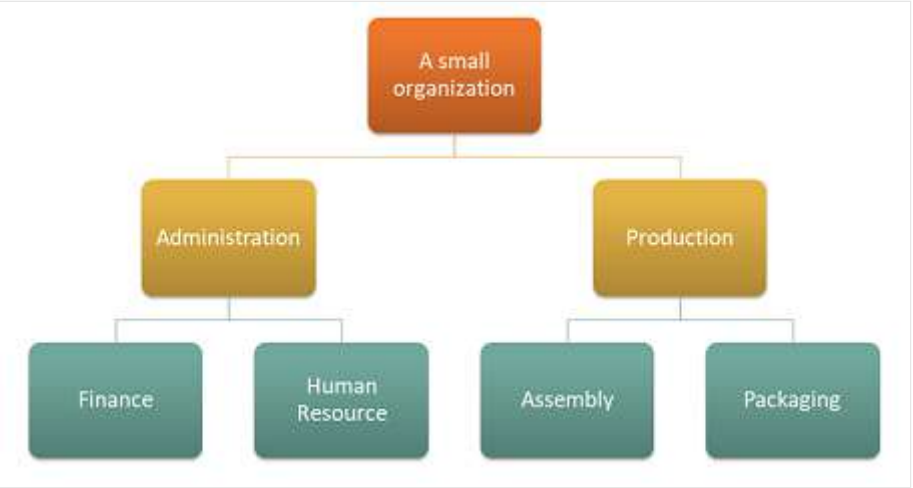
Create and maintain a dimension hierarchy

Create a dimension hierarchy as a tree structure that has node and leaf node relationships.

- A node can have 1:*n* subnodes.
- A node can't have both subnodes and leaf nodes assigned to it.
- You can assign a leaf node only at the lowest level in the hierarchy.

Example

A small company has the following organization structure, where Finance and Human resources are departments under Admin, and Assembly and Packaging are departments under Production.



A cost object dimension represents all the cost centers in the organization.

- Cost object dimension
  - Cost centers

Set up the cost object dimension that represents all the cost centers as shown in the following table.

Expand table

Cost centers	Description
CC001	HR
CC002	Finance
CC003	Tax
CC007	AR/AP
CC005	Assembly
CC006	Packaging

A cost element dimension represents all the cost elements in the organization.

- Cost element dimension
  - Cost elements

Set up the cost element dimension that represents all the cost elements as shown in the following table.

Expand table

Cost elements	Description
10001	Electricity
10010	Cleaning
10011	Heating
40001	COGS

Set up a dimension hierarchy that meets the organizational reporting requirements as shown in the following table.

Dimension hierarchy details

Expand table

Dimension hierarchy name	Dimension	Dimension hierarchy type name	Access list hierarchy
Organization	Cost centers	Dimension classification hierarchy	No

Set up the dimension hierarchy for reporting as shown in the following table.

Dimension member ranges

Expand table

Nodes	From dimension member	To dimension member
Organization		
Admin		
Finance	CC002	CC003
	CC007	CC007
HR	CC001	CC001
Production		
Packaging	CC005	CC005
Assembly	CC006	CC006

Set up a dimension hierarchy that meets the policy requirement as shown in the following table.

Dimension hierarchy details

Expand table

Dimension hierarchy name	Dimension	Dimension hierarchy type name
Cost behavior	Cost elements	Dimension classification hierarchy

Set up the dimension hierarchy for the policy as shown in the following table.

Dimension member ranges

Expand table

Nodes	From dimension member	To dimension member
Cost behavior		
Fixed cost	10001	10011
Variable cost	40001	40010

> **Note**
>
> Under **Dimension member ranges**, a node can contain one-to-many dimension member ranges. You can insert dimension member IDs that don't yet exist as dimension members. This approach makes the hierarchy resilient for the future.

Copy a hierarchy

You can copy a current dimension hierarchy as the starting point for a new dimension hierarchy. This approach is useful if you want to compare the previous dimension hierarchy to the new dimension hierarchy.

Rearrange nodes in a hierarchy

You can move a node up and down within its current level in the structure. Use this method to rearrange the order of nodes for reporting in the **Cost control** workspace.

To move a node to a new location in the hierarchy, select the target node. Use one of two options to move a node:

- **Move below** – Move the selected node from its current position in the hierarchy, and insert it **under** the selected target node.

- **Move after** – Move the selected node from its current position in the hierarchy, and insert it **after** the selected target node at its level of the hierarchy.

> ⓘ **Note**
>
> The order of the nodes isn't maintained when you export data to Excel or Power BI, because those tools use an alphanumeric sort order by default. You should manually rearrange the order.

Define dimension hierarchies for reporting

Dimension hierarchies are important for reporting. They let you define the specific structure that fits into the individual organization. The aggregations that you perform at the node level of the dimension hierarchy let stakeholders at any level of the organization see data at any level.

You can find dimension hierarchies in the following reporting tools. This approach helps guarantee consistency in the reporting structure.

- **Cost control** workspace (Client):
  - Controlled by configuration.
- **Cost control** workspace (Mobile application):
  - Controlled by configuration.
- Excel
  - Provides the option to select specific dimension hierarchies per export definition:
    - One cost element dimension hierarchy (mandatory)
    - One cost object dimension hierarchy (optional)
    - One statistical dimension hierarchy (optional)
- Power BI:
  - All dimension hierarchies are available.

If you create reports by using Excel or Power BI, you can export only the first 15 levels of the dimension hierarchies. This limitation exists because Excel and Power BI require a fixed schema. If a hierarchy has more than 15 levels, the extra levels aren't exported. The normalized table contains a record for each dimension member in the hierarchy. Therefore, automated aggregation occurs. This behavior helps guarantee that the balances at any of the 15 available levels in the hierarchy are still correct.

The following example shows what a dimension hierarchy might look like in the reporting structure.

Expand table

Cost object dimension hierarchy – Level 1	Cost object dimension hierarchy – Level 2	Cost object dimension hierarchy – Level 3	Cost object dimension hierarchy – Level 4	Cost object dimension hierarchy – Level 15
Organization	Admin	Finance	CC002	
Organization	Admin	Finance	CC003	
Organization	Admin	Finance	CC007	
Organization	Admin	HR	CC001	
Organization	Production	Packaging	CC005	
Organization	Production	Assembly	CC006	

Update the dimension hierarchies that you use for reporting

Over time, you need to update the dimension hierarchies that you use in the previously mentioned reporting tools. You can update dimension hierarchies by refreshing the client.

- **Cost control** workspace (Client)
- **Cost control** workspace (Mobile application)

Updates to dimension hierarchies are picked up every 24 hours by a precached job. After the exported data is updated, the updated dimension hierarchies are available in the following tools:

- Excel
- Power BI

> **Note**
>
> To manually trigger an update of the dimension hierarchy cache, create a new export to Excel for the dimension hierarchy or hierarchies that you need to update.

Define dimension hierarchies for cost policies

Cost accounting consists of multiple policies where you define detailed rules. You must define one or more dimension hierarchies for the following policies:

- Cost behavior
- Cost distribution
- Cost allocation
- Cost rollup

Dimension hierarchies make it easy to create rules. To avoid having to create rules for every dimension member, you can take advantage of the aggregations of dimension members that are provided by dimension hierarchy levels. If you have overlapping rules, you must define specific rules that the system will consider when it does the overhead calculation.

Example: Define a cost behavior policy

Create a new cost behavior policy and assign the appropriate dimension hierarchies to the policy, as shown in the following table.

Cost behavior policy

Expand table

Policy name	Cost element dimension hierarchy	Cost object dimension hierarchy	Accounting currency
Cost behavior	Cost behavior	Organization	USD

Rules

Expand table

Cost element dimension hierarchy node	Cost object dimension hierarchy node	Fixed percentage	Fixed amount	Valid from	Valid to
Fixed cost	Organization	100.00	0.00	1/1/2025	Never
10001	Organization	0.00	150.00	1/1/2025	Never
10001 (*)	Finance	50.00	1/1/2025	Never	
Cost behavior or Variable cost (**)	Organization	0.00	0.00	1/1/2025	Never

* The variable cost node isn't required. If a cost isn't classified as a fixed cost, it must be a variable cost.

** A detailed rule is created for the combination of cost element member 10001 and all cost object members that are aggregated under the Finance hierarchy level (CC002, CC003, CC007).

The preceding rules show the flexibility that dimension hierarchies provide. By defining high-level rules, you can help minimize maintenance. You can then define detailed rules to fit into a specific business objective.

If the dimension hierarchies that are used in rules are updated, the system automatically brings the updates forward.

If a level of granularity in the rules is no longer required, you can expire the rule.

For example, a specific cost behavior rule for the Finance cost object dimension hierarchy node is no longer required. In this case, select **Expire rule** to expire the rule.

Expand table

Cost element dimension hierarchy node	Cost object dimension hierarchy node	Fixed percentage	Fixed amount	Valid from	Valid to
Fixed cost	Organization	100.00	0.00	1/1/2025	Never
10001	Organization	0.00	150.00	1/1/2025	Never
10001	Finance		50.00	1/1/2025	20/1/2025
Cost behavior or Variable cost	Organization	0.00	0.00	1/1/2025	Never

Any overhead calculation that runs after January 20, 2025, no longer considers this rule.

> **Note**
>
> The **Valid from** and **Valid to** fields are date-effective and time-effective. You can expire the rule and run a new overhead calculation on the same day.

Define dimension hierarchies for security setup

Cost accounting data should be made available to all managers who are responsible for a reporting unit. In Cost accounting terminology, a reporting unit is represented as a cost object or a set of cost objects.

Potentially, all managers are able to access highly sensitive business data, such revenues and margins. Therefore, it's important that you set up security, so that managers see only the data that's relevant to them. To help control data security, you define dimension hierarchies.

- The use of dimension hierarchies applies only when the dimension value that is selected in the dimension hierarchy reference is a cost object dimension.
- You can enable only one dimension hierarchy per cost object dimension in the access list hierarchy.

Dimension hierarchy details

Expand table

Dimension hierarchy name	Dimension	Dimension hierarchy type name	Access list hierarchy
Organization	Cost centers	Dimension classification hierarchy	**Yes**

A new **Users** FastTab is available in the hierarchy designer. Here, you can insert one or more user IDs at each node in the hierarchy.

Users and dimension member ranges

Expand table

Nodes	User ID	From dimension member	To dimension member
Organization	Benjamin, Claire		
Admin	April		
Finance	Alicia	CC002	CC003
		CC007	CC007
HR	Arnie	CC001	CC001
Production	David		
Packaging	Ellen	CC005	CC005
Assembly	Chris	CC006	CC006

> **Note**
>
> Cost accountants should be assigned to the top level of the hierarchy, so that they can see all entries in Cost accounting.

To enable the access list hierarchy and its security settings, go to **Cost accounting** > **Setup** > **Parameters** > **General**. Select the **Enable view access for cost object dimension members** parameter.

The settings for the access list hierarchy control the data that is shown in the following areas:

- **Cost control** workspace (Client):
  - Data in pages that are used to drill through scenarios
- **Cost control** workspace (Mobile application):
  - Balances in cards
- Power BI:
  - Data that is shown in Power BI visualizations
  - Data Power BI visualizations that are embedded in the Dynamics 365 Finance client

> **Note**
>
> - Before the access list hierarchy can affect data in Power BI, access list hierarchy and row-level security in Power BI must be paired. For more information, see Set up security for Cost accounting content pack.
> - The access list hierarchy doesn't help secure the export of data to Excel. Therefore, that reporting tool should be used only by cost accountants and managers who must have full access to view the data.

Create an organization report hierarchy

Use this procedure to create a report hierarchy for organization reporting. The purpose of this recording is to guide you through the dimension hierarchy so that you can continue until the whole organization reporting structure is created. This recording uses the USP2 demo data company.

1. Go to **Cost accounting** > **Dimensions** > **Dimension hierarchies**.
2. Select **New**.
3. In the **HierarchyTypeComboBox** field, select **Dimension classification hierarchy**.
    - The **Dimension classification hierarchy** type defines rules and supports reporting for all dimensions, such as cost objects, cost elements, and statistical dimensions.
4. Select **Create**.
5. In the **Dimension hierarchy name** field, enter **Oganization USP2**.
6. In the **Dimension** field, enter or select a value.
    - Select **Cost centers**.
7. Select **Save**.
8. Select **View hierarchy**.
9. Select **New**.
10. In the **Node name** field, enter **CEO**.
11. Select **Save**.
12. Select **New**.
13. In the **Node name** field, enter **CEO cost centers**.
14. Select **Save**.
15. Select **New**.
16. In the **Node name** field, enter **Region East**.
17. Select **Save**.
18. Select **New**.
19. In the list, select the row.
20. In the **From dimension member** field, enter or select a value.
    - Select the dimension member that corresponds to the node.
21. Select **Save**.

22. In the tree, select **Oganization USP2\CEO\CEO cost centers**.
23. Select **New**.
24. In the **Node name** field, enter **Region West**.
25. Select **Save**.
26. Select **New**.
27. In the list, select the row.
28. In the **From dimension member** field, enter or select a value.

    - Select the dimension member that corresponds to the node.

29. Select **Save**.
30. In the tree, select **Oganization USP2\CEO**.
31. Select **New**.
32. In the **Node name** field, enter **CFO cost centers**.
33. Select **Save**.
34. Select **New**.
35. In the **Node name** field, enter **Marketing campa**.
36. In the **Node name** field, enter **Marketing campaign**.
37. Select **Save**.
38. Select **New**.
39. In the list, select the row.
40. In the **From dimension member** field, enter or select a value.

    - Select the dimension member that corresponds to the node.

41. Select **Save**.
42. In the tree, select **Organization USP2\CEO\CFO cost centers**.
43. Select **New**.
44. In the **Node name** field, enter **Trade shows**.
45. Select **Save**.
46. Select **New**.
47. In the list, select the row.
48. In the **From dimension member** field, enter or select a value.

    - Select the dimension member that corresponds to the node.

49. Click **Save**.
50. In the tree, select `Oganization USP2\CEO`.
51. In the **Node name** field, type `CIO cost centers`.
52. Click **Save**.

53. Click **New**.
54. In the **Node name** field, type `Call centers`.
55. Click **Save**.
56. Click **New**.
57. In the list, mark the selected row.
58. In the **From dimension member** field, enter or select a value.
    - Select the dimension member that corresponds to the node.
59. Click **Save**.

Access rights for cost object controllers

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The **Cost control** workspace is a central point where managers can view the performance of their cost objects. This workspace lets managers consume Cost accounting data even though they aren't cost accountants. For security reasons, managers should only see the Cost accounting data that relates to the specific cost objects that they're responsible for.

Cost accounting has four unique roles.

Expand table

Role name	License
Cost accounting manager	Activity
Cost accountant	Operations
Cost accountant clerk	Operations
Cost object controller	Team members

This article explains how to assign the **Cost object controller** role to a manager.

When you assign the **Cost object controller** role to a manager, the manager can perform the following tasks:

- Access the **Cost control** workspace (in the client).
  - Drill through and have view access to the pages that support the drill-through experience.
- Access the **Cost control** workspace (in the mobile application).

> **Note**

The **Cost object controller** role doesn't control which cost objects the user can access and view data for. Row-level security is provided via dimension hierarchies and the Access list hierarchy.

Grant access rights

The following example shows what a dimension hierarchy can look like.

Dimension hierarchy details

Expand table

Dimension hierarchy name	Dimension	Dimension hierarchy type name	Access list hierarchy
Organization	Cost centers	Dimension classification hierarchy	**Yes**

Use the **Users** FastTab in the hierarchy designer to add one or more user IDs on each node.

Expand table

Nodes	Users	From dimension member	To dimension member
Organization	Benjamin, Claire		
Admin	April		
Finance	Alicia	CC002	CC003
		CC007	CC007
HR	Arnie	CC001	CC001
Production	David		
Packaging	Ellen	CC005	CC005
Assembly	Chris	CC006	CC006

Note

Assign cost accountants to the top level of the hierarchy, so they can see all entries in Cost accounting.

Before you can apply the Access list hierarchy and its security settings, set the **Enable view access for cost object dimension members** option to **Yes** on the **General** tab of the **Cost accounting parameters** page (**Cost accounting** > **Setup** > **Parameters**).

Use the settings for the Access list hierarchy to control the data that is shown in the following areas:

- **Cost control** workspace (in the client):
  - Data on the pages that are used for drill-through
- **Cost control** workspace (in the mobile application):
  - Balances in cards
- Microsoft Power BI:
  - Data that is shown in Power BI visualizations
  - Data in Power BI visualizations that are embedded in the Dynamics 365 Finance client

> **Important**
>
> - Before the Access list hierarchy can affect data in Power BI, you must pair the Access list hierarchy with row-level security in Power BI. For more information, see Set up security for Cost accounting content pack.
> - This article shows the prerequisites that must be in place before you can use the **Cost control** workspace.

Additional resources

- Cost control workspace
- Dimension hierarchy
- Set up security for Cost accounting content pack

Configure access rights for a cost object controller

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use this procedure to configure access rights for a cost object controller. This recording uses the USP2 demo data company.

Assign the cost object controller role

1. Go to **System administration** > **Users** > **Users**.
2. Use the Quick Filter to find records. For example, filter on the **User name** field with a value of 'alicia'.
3. In the list, click the link in the selected row.
4. Click **Assign roles**.
5. In the list, find and select the desired record.
6. Click **OK**.

Enable access list security

1. Go to **Cost accounting** > **Dimensions** > **Dimension hierarchies**.
2. In the list, find and select the desired record.

    - Select **Organization**.

3. Click **Edit**.
4. Select **Yes** in the **Access list hierarchy** field.
5. Click **View hierarchy**.

Assign access rights to user

1. Click **New**.
2. In the list, mark the selected row.
3. In the **User ID** field, enter or select a value.

- Select **Admin**.

4. In the tree, select 'Organization\CEO\CFO\FIM'.
5. Click **New**.
6. In the list, mark the selected row.
7. In the **User ID** field, enter or select a value.

    - Select Alicia.

8. Click **Save**.

Enable access rights in Cost accounting

1. Go to **Cost accounting** > **Setup** > **Parameters**.
2. Click the **General** tab.
3. Select **Yes** in the **Enable view access for cost object dimension members** field.
4. Click **Save**.
5. Close the page.
6. Go to **Cost accounting** > **Setup** > **Cost control workspace configuration**.
7. Click **Edit**.
8. Select **Yes** in the **Published** field.

    - If you select **Yes**, a user who is assigned one of the following four roles can see the reports in the **Cost control** workspace: cost accounting manager, cost accountant, cost accountant clerk, and cost object controller. If you select No, only a user who is assigned one of the following roles can see the reports: cost accounting manager, cost accountant, and cost accountant clerk.

9. Click **Save**.

Last updated on 10/02/2025

Define cost control units

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure shows how to define cost control units in the cost accounting ledger. You select the cost object dimension for which you want to control costs in the ledger. The cost object dimension members are transformed into cost objects of the cost control units. The demo data company used to create this procedure is USP2.

1. Go to **Cost accounting** > **Ledger setup** > **Cost accounting ledgers**.
2. In the list, find and select the desired record.
3. Click **Control units**.
4. Click **New**.
5. In the **Name** field, type a value.
6. In the **Dimension** field, enter or select a value.
7. Click **Save**.
8. Click **New**.
9. In the **Name** field, type a value.
10. In the **Dimension** field, enter or select a value.
11. Click **Save**.

Last updated on 10/02/2025

Create a cost accounting ledger

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

A cost accounting ledger represents the overall reporting unit. It is defined by a cost element dimension, statistical dimension, fiscal calendar, and currency. It is agnostic to the concept of legal entities. A legal entity and its data can be associated with many cost accounting ledgers. This recording uses the USP2 demo data company.

1. Go to **Cost accounting** > **Ledger setup** > **Cost accounting ledgers**.
2. Click **New**.
3. In the **Name** field, type a value.
4. In the **Cost element dimension** field, enter or select a value.
5. In the **Fiscal calendar** field, enter or select a value.
6. In the **Accounting currency** field, enter or select a value.
7. In the **Exchange rate type** field, enter or select a value.
8. In the **Statistical dimension** field, enter or select a value.
9. Click **Save**.

Last updated on 10/02/2025

Provider templates for statistical dimension members and measure providers

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use a statistical dimension and its members to register and control nonmonetary entries in Cost accounting. Use statistical dimension members for two purposes:

- As an allocation base in policies such as cost distribution or cost allocation
- For reporting of nonmonetary consumption

Statistical dimension

A statistical dimension has a unique name and a set of unique dimension members. Assign the statistical dimension to a Cost accounting ledger ID. This relationship ties all corresponding statistical dimension members to the Cost accounting ledger. Therefore, you create all statistical entries in the context of the Cost accounting ledger.

> **Note**
>
> You can assign a statistical dimension to more than one Cost accounting ledger.

Here's an example of a statistical dimension.

Expand table

Name	Data connector for dimension members
Shared Statistical elements	Imported dimension members

Here's an example of a statistical dimension that you assigned to a Cost accounting ledger.

Expand table

Name	Accounting currency	Exchange rate type	Fiscal calendar	Cost element dimension	Statistical dimension
Managerial accounting	USD	Constant currency	Fiscal period	Shared Cost elements	Shared Statistical elements

Statistical dimension members

A statistical dimension member represents an entity that you want to register nonmonetary measures for. Use these measures as an allocation base or just to report nonmonetary values.

Create statistical dimension members manually. Alternatively, import them from a file by using the Data management import/export tool.

A statistical dimension member automatically becomes a predefined allocation base. Use it as an allocation base in policies or as input in other types of allocation bases.

Here are some examples of typical statistical dimension members.

Expand table

Statistical dimension name	Statistical elements	Description	Unit
Shared Statistical elements	FTE	Full time employees	Ea.
Shared Statistical elements	Electricity	Electricity consumption	kWh
Shared Statistical elements	Pack CC	Packaging Cost center	Hrs.

Statistical measure provider template

Statistical measures can come from many kinds of sources. Dynamics 365 Finance is a great source for extracting statistical measures. Use a statistical measure provider template to easily configure the statistical measures you want to extract.

The definition of a statistical measure provider template is generic and can be reused in multiple statistical dimension members.

> **Note**
>
> You can use all tables that contain financial dimensions as sources for statistical measures.

Example: Count of employees per cost center

The count of employees per cost center is a statistical measure that you can use for various purposes that provide managerial insight:

- A statistical reporting measure by cost center
- An allocation base for various types of expenses
- Internal cost rates by cost center:
  - Cost by employee
  - Revenue by employee

The HcmEmployment table holds a list of all employees in the instance. This table is a global table. Therefore, the records aren't related to a specific data area ID.

Here's an example of employees in the HcmEmployment table.

Expand table

Name	Cost center	Description	Worker type
Employee 1	CC001	HR	Employee
Employee 2	CC002	FI	Employee
Employee 3	CC002	FI	Employee
Employee 4	CC003	IT	Employee
Employee 5	CC003	IT	Employee
Employee 6	CC002	FI	Contractor

When you create a **Statistical measure provider template** record, decide which function to use:

- **Count** – A count of records per cost object is transferred.
- **Sum** – A sum for records per cost object is transferred. (The **Sum** field and **Date** field are required.)

Using the Count function

For example, set up a statistical measure provider template as follows.

Expand table

Name	Function	Source table	Sum field	Date field
FTEs	Count	HcmEmployment	Not applicable	Not applicable

You can also add one or more ranges to narrow the measures from the source table.

In this example, if you want a count of all full-time employees (FTEs), add a range in the **Worker type** field. In the **Criteria** field, select **Employee** to limit the output range as follows.

Ranges

Expand table

Source table	Field	Criteria
HcmEmployment	Worker type	Employee

Before you can get statistical measures into Cost accounting, you must establish the relation between the statistical measure provider template and the statistical dimension member. Create this relation per Cost accounting ledger and version. The relation consists of a data connector and a data provider. You can have several data connectors and data providers per statistical dimension member.

> **Note**
>
> In this example, you create a relation only for the **Actual version**.

Go to **Cost accounting ledger** > **Actual version** > **Manage** > **Statistical measures** to establish the relation. For this scenario, select the **Dynamics 365 Finance – Statistical measures** data connector, because you want to extract data from Finance.

Data source

Expand table

Name	Data connector	Statistical dimension member
FTEs D365FO	Dynamics 365 Finance – Statistical measures	FTEs

Data provider configuration

Expand table

Statistical template name
FTEs

After the source data for the statistical measure is processed, Cost accounting creates the following statistical entries.

Journal

Expand table

Journal	Journal type	Fiscal calendar period	Year	Period	Version	Data connector source entries
00001	Statistical entry transfer journal	Fiscal	2017	Period 1	CA ledger USMF	FTEs

Statistical entry transfer journal entries

Expand table

Accounting date	Magnitude	Statistical element	Description	Cost center
31-01-2017	1.00	FTEs	Full time employees	CC001
31-01-2017	2.00	FTEs	Full time employees	CC002
31-01-2017	2.00	FTEs	Full time employees	CC003

Statistical entries

Expand table

Cost object	Description	Accounting date	Statistical dimension member	Description	Magnitude
CC001	HR	31-01-2017	FTEs	Full time employees	1.00
CC002	FI	31-01-2017	FTEs	Full time employees	2.00
CC003	IT	31-01-2017	FTEs	Full time employees	2.00

If you assign the FTEs predefined dimension member allocation basis as an allocation base in a cost distribution rule, the cost distributes by using the following allocation factor.

Expand table

Cost object	Description	Magnitude	Allocation factor
CC001	HR	1.00	(1/5) × Amount
CC002	FI	2.00	(2/5) × Amount
CC003	IT	2.00	(2/5) × Amount

Using the Sum function

A production cost center, CC010 (Packaging), is responsible for packaging the products before they're shipped to customers. Add the direct labor cost to the products through the bill of materials (BOM) and route. You must also allocate the indirect cost of running the cost center to the produced products. Often, the best statistical measure for such an allocation is the number of registered production hours per product within the given period.

The ProdRouteTrans table holds all production labor transactions per legal entity DataAreadID.

Here's an example of the ProdRouteTrans table.

Expand table

Reference	Number	Operation	Type	Time	Physical date	Product group (Financial dimension)	Legal entity
Production order	P0001	Packaging	Time	8.00	01-01-2017	Orange juice B2B	USMF
Production order	P0001	Packaging	Time	8.00	02-01-2017	Orange juice B2B	USMF
Production order	P0002	Packaging	Time	4.00	03-01-2017	Orange juice Consumer	USMF
Production order	P0003	Packaging	Time	4.00	03-01-2017	Orange juice Consumer	USMF
Production order	P0004	Reconst.	Time	10.00	03-01-2017	Orange juice Consumer	USMF

When you create a **Statistical measure provider template** record, decide which function to use:

- **Count** – A count of records per cost object is transferred.
- **Sum** – A sum for records per cost object is transferred. (The **Sum** field and **Date** field are required.)

The statistical measure provider template can be set up as follows.

Expand table

Name	Function	Source table	Sum field	Date field
Pack CC	Sum	ProdRouteTrans	Hours	Physical date

You can also add ranges to narrow the measures from the source table.

In this example, if you want only the sum of hours that relate to the CC010 Packaging cost center, add a range in the **Operation** field. In the **Criteria** field, select **Packaging** to limit the output range.

Ranges

Expand table

Source table	Field	Criteria
ProdRouteTrans	Operation	Packaging

Before you can get statistical measures into Cost accounting, you must establish the relation between the statistical measure provider template and the statistical dimension member. Create this relation per Cost accounting ledger and version. The relation consists of a data connector and a data provider. You can have several data connectors and data providers per statistical dimension member.

> **Note**
>
> In this example, you create a relation only for the **Actual version**.

Go to **Cost accounting ledger** > **Actual version** > **Manage** > **Statistical measures** to establish the relation. For this scenario, select the **Dynamics 365 Finance – Statistical measures** data connector, because you want to extract data from Finance.

Data source

Expand table

Name	Data connector	Statistical dimension member
Pack CC D365FO	Dynamics 365 Finance – Statistical measures	Pack CC

The system recognizes that ProdRouteTrans is a table where each record belongs to a separate legal entity. Therefore, you're asked to select the legal entity that transactions should be imported from.

Data provider configuration

Expand table

Statistical template name	Legal entity
Pack CC	USMF

After the source data for the statistical measure is processed, the following statistical entries are created in Cost accounting.

Journal

Expand table

Journal	Journal type	Fiscal calendar period	Year	Period	Version	Data connector source entries
00002	Statistical entry transfer journal	Fiscal	2017	Period 1	CA ledger USMF	Pack CC

Statistical entry transfer journal entries

Expand table

Accounting date	Magnitude	Statistical element	Description	Product group
31-01-2017	16.00	Pack CC	Packaging Cost center	Orange juice B2B
31-01-2017	8.00	Pack CC	Packaging Cost center	Orange juice Consumer

Statistical entries

Expand table

Cost object	Accounting date	Statistical dimension member	Description	Magnitude
Orange juice B2B	31-01-2017	Pack CC	Packaging Cost center	16.00
Orange juice Consumer	31-01-2017	Pack CC	Packaging Cost center	8.00

If you assign the Pack CC predefined dimension member allocation basis as an allocation base in a cost distribution rule, the system distributes the cost by using the following allocation factor.

Expand table

Cost object	Magnitude	Allocation factor
Orange juice B2B	16.00	(16 ÷ 24) × Amount
Orange juice Consumer	8.00	(8 ÷ 24) × Amount

Imported statistical measures

You can import statistical measures into Cost accounting by using the Data management import/export tool.

The data entity that is used for the import is named **Imported statistical measures**.

> **Note**
>
> This data entity is designed to allow a maximum of five unique dimension values per entry.

You can record the consumption of electricity in Microsoft Excel by using the predefined format of the data entity. Here's an example.

Expand table

Accounting date	Dimension member name1	Dimension member name2	Dimension member name5	Magnitude	Source identifier
31-01-2017				2,450.00	Electricity
31-01-2017				4,100.00	Electricity
31-01-2017	CC003			15,000.00	Electricity

When you've imported your data via Data management, the data is stored in a Cost accounting staging table. Therefore, the imported data can be used in multiple Cost accounting ledgers. A reload of data isn't required.

To import the data, go to **Imported data** > **Data entity** > **Imported statistical measures**.

Expand table

Source identifier	Accounting date	Magnitude	Dimension member name1	Dimension member name2	Dimension member name5
Electricity	31-01-2017	2,450.00	CC001		
Electricity	31-01-2017	4,100.00	CC002		
Electricity	31-01-2017	15,000.00	CC003		

Before you can get statistical measures into Cost accounting, you must establish the relation between the source identifier and the statistical dimension member. This relation is created per Cost accounting ledger and version. The relation consists of a data connector and a data provider. You can have several data connectors and data providers per statistical dimension member.

> **Note**
>
> In this example, you create a relation only for the **Actual version**.

Go to **Cost accounting ledger** > **Actual version** > **Manage** > **Statistical measures** to establish the relation. For this scenario, select the **Imported statistical measures** data connector, because you imported data from a third-party system into Cost accounting via Excel.

Data source

Expand table

Name	Data connector	Statistical dimension member
Electricity	Imported statistical measures	Electricity

Data provider configuration

Expand table

Import source identifier	Function	Dimension1	Dimension2	Dimension5
Electricity	Sum	Cost centers		

> **Note**
>
> When you define the data provider configuration, you must specify which cost object dimensions to match against the imported transactions. After the system processes the source data for the statistical measure, it creates the following statistical entries in Cost accounting.

Journal

Expand table

Journal	Journal type	Fiscal calendar period	Year	Perid	Version	Data connector source entries
00002	Statistical entry transfer journal	Fiscal	2017	Period 1	CA ledger USMF	Electricity

Statistical entry transfer journal entries

Expand table

Accounting date	Magnitude	Cost element	Description	Cost center
31-01-2017	2,450.00	Electricity	Electricity consumption	CC001
31-01-2017	4,100.00	Electricity	Electricity consumption	CC002
31-01-2017	15,000.00	Electricity	Electricity consumption	CC003

Statistical entries

Expand table

Cost object	Description	Accounting date	Statistical dimension member	Description	Magnitude
CC001	HR	31-01-2017	Electricity	Electricity consumption	2,450.00
CC002	FI	31-01-2017	Electricity	Electricity	4,100.00

Cost object	Description	Accounting date	Statistical dimension member	Description	Magnitude
				consumption	
CC003	IT	31-01-2017	Electricity	Electricity consumption	15,000.00

If you assign the Electricity predefined dimension member allocation basis as an allocation base in a cost distribution rule, the system distributes the cost by using the following allocation factor.

Expand table

Cost object	Description	Magnitude	Allocation factor
CC001	HR	2,450.00	(2,450 ÷ 21,550) × Amount
CC002	FI	4,100.00	(4,100 ÷ 21,550) × Amount
CC003	IT	15,000.00	(15,000 ÷ 21,550) × Amount

Additional resources

Allocation bases

Last updated on 05/27/2026

Allocation bases

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

An allocation base is the basis on which Cost accounting allocates overhead costs. An allocation base can be a quantity, such as machine hours that are used, kilowatt hours (kWh) that are consumed, or square footage that is occupied. Allocation bases are mostly used to assign overhead costs to inventory that is produced. For example, an IT department allocates its expenses according to the number of computers that each department uses.

Cost accounting has three types of allocation bases:

- Predefined dimension member allocation bases
- Hierarchy allocation bases
- Formula allocation bases

Predefined dimension member allocation bases

The system automatically creates predefined dimension member allocation bases when you create a dimension member of one of the following types:

- Statistical dimension members
- Cost element dimension members

> **Note**
>
> The predefined dimension member allocation bases that are based on a cost element dimension member consider only the values from the data source provider, such as the general ledger or budget.

Example 1: Use a cost element dimension member as the allocation base

This example shows how to create a cost allocation rule to allocate cost element 10002 (Employee insurance) to the balance that is recorded on cost element 10001 (Salaries). The allocation rule is based on the ratio of each department's salaries to total salaries.

In the general ledger, the chart of accounts is defined as follows.

Expand table

Chart of accounts	Main account	Description	Main account type
Shared	10001	Salaries	Expense
Shared	10002	Employee insurance	Expense

Define a cost element dimension, and configure the data connector. After you import the data, Cost accounting creates the following entries.

Cost element dimension members

Expand table

Cost element dimension name	Cost element	Description	Type
Cost elements	10001	Salaries	Primary
Cost elements	10002	Employee insurance	Primary

Predefined dimension member allocation bases

Expand table

Name	Description	Cost element dimension
10001	Salaries	Cost elements
10002	Employee insurance	Cost elements

In the general ledger, you post the following entries:

- The entries that show the Salaries main account come from the Payroll system and are posted to cost centers.
- You manually post the expense for employee insurance to a default cost center.

Expand table

Accounting date	Cost center	Description	Main account	Description	Amount in accounting currency
03-01-2017	CC001	HR	10001	Salaries	2,000.00
03-01-2017	CC002	FI	10001	Salaries	5,000.00
03-01-2017	CC003	IT	10001	Salaries	3,000.00
03-01-2017	CC099	Default cost center	10002	Employee insurance	1,000.00

After the general ledger source data is processed, Cost accounting creates the following entries.

Cost entries

Expand table

Cost object	Description	Cost element	Description	Cost behavior	Amount	Accounting date
CC001	HR	10001	Salaries	Unclassified	2,000.00	03-01-2017
CC002	FI	10001	Salaries	Unclassified	5,000.00	03-01-2017
CC003	IT	10001	Salaries	Unclassified	3,000.00	03-01-2017
CC099	Default cost center	10002	Employee insurance	Unclassified	1,000.00	03-01-2017

In this simplified example, you create a cost allocation rule to allocate cost element 10002 (Employee insurance) relative to the balance that is recorded on cost element 10001 (Salaries).

Cost distribution rule

Expand table

Cost object dimension hierarchy node	Cost element dimension hierarchy node	Cost behavior	Allocation base
CC099	10002	Unclassified	10001

Perform overhead calculation

After you apply cost element 10001 (Salaries) as the allocation base, the result of the overhead calculation is as follows.

Expand table

Cost object	Description	Magnitude	Allocation factor	Amount
CC001	HR	2,000	(2,000 ÷ 10,000) × 1,000.00	200.00
CC002	FI	5,000	(5,000 ÷ 10,000) × 1,000.00	500.00
CC003	IT	3,000	(3,000 ÷ 10,000) × 1,000.00	300.00

Journal

Expand table

Journal	Journal type	Fiscal calendar period	Year	Period	Version
00001	Cost distribution calculation journal	Fiscal	2017	Period 1	Overhead calculation / 01-02-2017 11:51:00 PM / Ledger /2017 / Period 1

Cost object balance journal entries

Expand table

Accounting date	Cost object	Description	Cost element	Description	Cost behavior	Amount
31-01-2017	CC099	Default cost center	10002	Employee insurance	Unclassified	1,000.00

Cost entries

Expand table

Cost object	Description	Cost element	Description	Cost behavior	Amount	Accounting date
CC099	Default cost center	10002	Employee insurance	Unclassified	-1,000.00	31-01-2017
CC001	HR	10002	Employee insurance	Unclassified	200.00	31-01-2017

Cost object	Description	Cost element	Description	Cost behavior	Amount	Accounting date
CC002	FI	10002	Employee insurance	Unclassified	500.00	31-01-2017
CC099	IT	10002	Employee insurance	Unclassified	300.00	31-01-2017

Example 2: Use a statistical dimension member as the allocation base

You can use statistical dimension members as allocation bases to define policies or report nonmonetary consumption by cost objects. You can manually create statistical dimension members or import them from a file by using the Data management import/export tool.

Statistical dimension members

Expand table

Statistical dimension name	Statistical element	Description	Unit
Statistical elements	FTE	Full time employees	Ea
Statistical elements	Electricity	Electricity consumption	kWh

When a statistical dimension member is saved, a corresponding record is created in the predefined dimension member allocation bases.

Predefined dimension member allocation bases

Expand table

Name	Description	Statistical element dimension
FTE	Full time employees	Statistical elements
Electricity	Electricity consumption	Statistical elements

Statistical measures can come from various sources:

- Electricity consumption can be measured by meters that are installed in different areas of the company.

- Tables hold statistical measures. For example, the HcmEmployment table holds a list of all employees and the cost centers that they work for.

Expand table

Name	Cost center	Description	Worker type
Employee A	CC001	HR	Employee
Employee B	CC002	FI	Employee
Employee C	CC002	FI	Employee
Employee D	CC003	IT	Employee
Employee F	CC003	IT	Employee

> **Note**
>
> You can use all the tables that contain financial dimensions as sources for statistical measures.

Cost accounting supports a collection of statistical measures by using the following data connections:

- Data management import/export tool
- Statistical measures

To pull statistical measures from the system, a statistical measure provider template is required. For more information, see Statistical measure provider template. (Will add a link once this article is written.)

Statistical measure provider templates

Expand table

Name	Function	Source table	Sum field	Date field
FTE's	Count	HcmEmployment	Not applicable	Not applicable

After the system processes the statistical measure source data, it creates the following entries in Cost accounting.

Statistical entries

Expand table

Cost object	Description	Accounting date	Statistical dimension member	Description	Magnitude
CC001	HR	31-01-2017	FTE's	Full time employees	1.00
CC002	FI	31-01-2017	FTE's	Full time employees	2.00
CC003	IT	31-01-2017	FTE's	Full time employees	2.00

Here is an example of a cost distribution rule if the FTE's predefined dimension member allocation basis is assigned as the allocation base in it.

Expand table

Cost object	Description	Magnitude	Allocation factor
CC001	HR	1.00	(1/5) × Amount
CC002	FI	2.00	(2/5) × Amount
CC003	IT	2.00	(2/5) × Amount

Use the **Imported statistical measures** data entity to import statistical measures into Cost accounting. You can also use the Data management import/export tool. In Excel, the consumption of electricity is recorded as follows.

Expand table

Accounting date	Dimension member	Magnitude	Source identifier
31-01-2017	CC001	2,450.00	Electricity
31-01-2017	CC002	4,100.00	Electricity
31-01-2017	CC003	15,000.00	Electricity

After the system processes the statistical measure source data, it creates the following entries in Cost accounting.

Statistical entries

Expand table

Cost object	Name	Accounting date	Statistical dimension member	Description	Magnitude
CC001	HR	31-01-2017	Electricity	Electricity consumption	2,450.00
CC002	FI	31-01-2017	Electricity	Electricity consumption	4,100.00
CC003	IT	31-01-2017	Electricity	Electricity consumption	15,000.00

Here's an example of a cost distribution rule if you assign the **Electricity** predefined dimension member allocation basis as the allocation base.

Expand table

Cost object	Description	Magnitude	Allocation factor
CC001	HR	2,450.00	(2,450 ÷ 21,550) × Amount
CC002	FI	4,100.00	(4,100 ÷ 21,550) × Amount
CC003	IT	15,000.00	(15,000 ÷ 21,550) × Amount

Hierarchy allocation bases

Cost accountants can manually create hierarchy allocation bases by applying a cost object dimension hierarchy node to an existing allocation base. By using this method, you can limit the range of the original predefined dimension member allocation basis. You can use one predefined dimension member allocation basis to create several hierarchy allocation bases. You can maintain ranges in the cost object dimension hierarchy that you associate with the hierarchy allocation bases.

Example: Hierarchy allocation bases that are based on full-time employees in the organization

Here's an example of a cost object dimension hierarchy that you can create to describe a simplified organization.

Expand table

Hierarchy name	Node level 0	Node level 1	Node level 2	Dimension members
Organization	CEO	CFO	FICO	CC001
Organization	CEO	CFO	HR	CC002
Organization	CEO	CIO	IT	CC003

The FTE's predefined dimension member allocation basis that was created in the previous section holds the following entries.

Statistical entries

Expand table

Cost object	Description	Accounting date	Statistical dimension member	Description	Magnitude
CC001	HR	31-01-2017	FTE's	Full time employees	1.00
CC002	FI	31-01-2017	FTE's	Full time employees	2.00
CC003	IT	31-01-2017	FTE's	Full time employees	2.00

A cost must be distributed between cost centers that report to the organization's chief financial officer (CFO). It's acknowledged that the correct allocation ratio is the number of full-time employees (FTEs) by cost center.

Hierarchy allocation bases

Expand table

Name	Allocation base	Cost object dimension hierarchy	Cost object dimension hierarchy node
Number of FTEs in CFO	FTE's	Organization	CFO

A Preview function lets you validate the hierarchy allocation basis that you create, based on statistical entries in the system.

Allocation base details

Expand table

Cost object	Description	Magnitude
CC001	HR	1.00
CC002	FI	2.00

Here's an example of a cost distribution rule if the Number of FTEs in CFO hierarchy allocation basis is assigned as the allocation base in it.

Expand table

Cost object	Description	Magnitude	Allocation factor
CC001	HR	1.00	(1/3) × Amount
CC002	FI	2.00	(2/3) × Amount

Formula allocation bases

Formula allocation bases let you define advanced formulas to achieve the correct allocation basis. You can manually create formula allocation bases.

When you create a formula allocation base, you select which statistical dimension and cost element dimension should be the basis for the formula. You can use all allocation bases that come from the previously selected dimensions in a formula allocation base.

> **Note**
>
> You can use previously defined formula allocation bases to define a new formula allocation base.

In formula allocation base factors, you create an alias and associate it with either an allocation base or a constant. Use the aliases to define the formula.

To define your formula, use the following operators.

Expand table

Symbols	Text
( )	Parentheses

Symbols	Text
<	Smaller than
>	Larger than
+	Addition
–	Subtraction
*	Multiplication

Traditional **IF** statements aren't supported. However, you can create statements and validate whether they're true.

Expand table

Statement	Validation	Result
a > b	True	1
a > b	False	0

Example 1: A simple formula

Electricity bills often consist of two parts:

- A fixed fee for being connected to the grid
- A cost that is associated with consumption per kWh

The Electricity predefined dimension member allocation basis already defined holds these values.

Statistical entries

Expand table

Cost object	Name	Accounting date	Statistical dimension member	Description	Magnitude
CC001	HR	31-01-2017	Electricity	Electricity consumption	2,450.00
CC002	FI	31-01-2017	Electricity	Electricity consumption	4,100.00
CC003	IT	31-01-2017	Electricity	Electricity consumption	15,000.00

If you need to spread the fixed fee evenly over cost objects that consume electricity, you have two options for allocating the costs:

- Create a new predefined allocation base, Electricity fixed, and then apply a statistical measure of 1.00 for each cost object that consumed electricity.
- Create a formula allocation base, Electricity fixed, that takes advantage of the Electricity predefined allocation base that's already defined in the system. The benefit of this option is that you only need to load data into Cost accounting for one Electricity statistical dimension member.

Formula allocation base

Expand table

Name	Cost element dimension	Statistical dimension	Formula
Electricity fixed		Statistical elements	

Before you can fill the **Formula** field, you must specify the alias that should be used in the formula.

Formula allocation base factors

Expand table

Alias	Constant	Allocation base
a		Electricity
b	0.01	

Note that 0 (zero) isn't supported as a constant.

Formula allocation base

Expand table

Name	Cost element dimension	Statistical dimension	Formula
Electricity fixed		Statistical elements	a > b

A Preview function lets you validate the formula allocation base that you created, based on statistical entries in the system.

Allocation base details

Expand table

Cost object	Description	Formula	Magnitude
CC001	HR	2,450.00 > 0.01	1.00
CC002	FI	4,100.00 > 0.01	1.00
CC003	IT	15,000.00 > 0.01	1.00

Here's an example of a cost distribution rule if you assign the Electricity formula allocation base as the allocation base in it.

Cost object magnitude allocation factor

Expand table

Cost object	Name	Magnitude	Allocation factor
CC001	HR	1.00	(1/3) × Amount
CC002	FI	1.00	(1/3) × Amount
CC003	IT	1.00	(1/3) × Amount

Example 2: An advanced formula

For this example, the cost of electricity shouldn't just follow the actual electricity that is consumed in kWh. Management wants to incorporate an incentive for lowering electricity usage.

Expand table

Rule	Rate
a <= 10,000.00 kWh	0.75
a > 10,000.00 kWh	1.15

Create a new formula allocation base named **Electricity usage**.

Formula allocation base

Expand table

Name	Cost element dimension	Statistical dimension	Formula
Electricity usage		Statistical elements	

Before you can fill the **Formula** field, you must specify the alias that should be used in the formula.

Formula allocation base factors

Expand table

Alias	Constant	Allocation base
a		Electricity
b	10,000.00	
c	0.75	
d	1.15	

Formula allocation base

Expand table

Name	Cost element dimension	Statistical dimension	Formula
Electricity fixed		Statistical elements	((a > b) × ((b × c) + (a – b) × d)) + ((a <= b] × a × c)

A Preview function lets you validate the formula allocation base that you created, based on statistical entries in the system.

Allocation base details

Expand table

Cost object	Name	Formula	Magnitude
CC001	HR	((2,450.00 > 10.000.00) × ((10,000.00 × 0.75) + (2,450.00 – 10,000.00) × 1.15)) + ((2,450.00 <= 10,000.00) × 2,450.00 × 0.75)	1,837.50
CC002	FI	((4,100.00 > 10.000.00) × ((10,000.00 × 0.75) + (4,100.00 – 10,000.00) × 1.15)) + ((4,100.00 <= 10,000.00) × 4,100.00 × 0.75)	3,075.00

Cost object	Name	Formula	Magnitude
CC003	IT	((15,000.00 > 10.000.00) × ((10,000.00 × 0.75) + (15,000.00 – 10,000.00) × 1.15)) + ((15,000.00 <= 10,000.00) × 15,000.00 × 0.75)	1,3250.00

Here's a closer look at the formula for CC003 (IT):

((15,000.00 > 10,000.00) × ((10,000.00 × 0.75) + (15,000.00 – 10,000.00) × 1.15)) + ((15,000.00 <= 10,000.00) × 15,000.00 × 0.75) = 13,250.00

(1 × (7,500.00 + 5,000.00 × 1.15)) + (0 × 15,000.00 × 0.75)

1 × 7,500.00 + 5,750.00 + 0

Here's an example of a cost distribution rule if you assign the **Electricity fixed** formula allocation base as the allocation base.

Expand table

Cost object	Description	Magnitude	Allocation factor
CC001	HR	1,837.50	(1,837.50 ÷ 18,162.50) × Amount
CC002	FI	3,075.00	(3,075.00 ÷ 18,162.50) × Amount
CC003	IT	13,250.00	(13,250.00 ÷ 18,162.50) × Amount

Create and assign a cost allocation policy to a cost control unit

Article • 05/09/2022

Use this procedure to create and assign a cost allocation policy and the corresponding rules to a cost control unit. This recording uses the USP2 demo data company.

Create a policy

1. Go to **Cost accounting** > **Policies** > **Cost allocation policies**.
2. Click **New**.
3. In the **Policy name** field, type a value.
4. In the **Cost object dimension hierarchy** field, enter or select a value.

    - Select Organization.

5. In the **Statistical dimension** field, enter or select a value.
6. Click **Save**.

Create allocation rules

1. Click **New**.
2. In the list, mark the selected row.
3. In the **Cost object dimension hierarchy node** field, enter or select a value.
4. In the **Cost behavior** field, select 'Total'.
5. In the **Allocation base** field, enter or select a value.
6. Click **New**.
7. In the list, mark the selected row.
8. In the **Cost object dimension hierarchy node** field, enter or select a value.
9. In the **Cost behavior** field, select 'Total'.
10. In the **Allocation base** field, enter or select a value.
11. Click **New**.
12. In the list, mark the selected row.
13. In the **Cost object dimension hierarchy node** field, enter or select a value.
14. In the **Cost behavior** field, select 'Total'.
15. In the **Allocation base** field, enter or select a value.

    - Continue until you've created all the rules.

16. Click **Save**.

Assign the policy to a cost control unit

1. Click **Policy assignments for cost control unit**.
2. Click **New**.
3. In the list, mark the selected row.
4. In the **Valid from accounting date** field, enter a date.

    - The rules are date-effective. A user or the system can expire the rules if a newer version is created.

5. In the **Cost control unit** field, enter or select a value.
6. Click **Save**.

Create and assign a cost behavior policy to a cost control unit

Article • 05/09/2022

Cost behavior is the classification of costs as either fixed or variable. A policy and the corresponding rules have to be assigned to a cost control unit for the policy to become effective. Use this procedure to create a policy and then assign the policy to a cost control unit.

Create a cost behavior hierarchy

1. Go to **Cost accounting** > **Dimensions** > **Dimension hierarchies**.
2. Click **New**.
3. Click **Create**.
4. In the **Dimension hierarchy name** field, type 'Cost behavior hierarchy'.
5. In the **Dimension** field, enter or select a value.

    - Select Cost elements.

6. Click **Save**.
7. Click **View hierarchy**.
8. Click **New**.
9. In the **Node name** field, type a value.

    - Enter Fixed cost.

10. In the tree, select 'Cost behavior hierarchy'.
11. Click **New**.
12. In the **Node name** field, type a value.

    - Enter Variable cost.

13. Click **Save**.
14. In the tree, select 'Cost behavior hierarchy\Fixed cost'.
15. Click **New**.
16. In the list, mark the selected row.
17. In the **From dimension member** field, enter or select a value.

    - The range of dimension members can contain gaps, but the members can't overlap.

18. In the **To dimension member** field, enter or select a value.
    - The range of dimension members can contain gaps, but the members can't overlap.
19. In the tree, select 'Cost behavior hierarchy\\Variable cost'.
20. Click **New**.
21. In the list, mark the selected row.
22. In the **From dimension member** field, enter or select a value.
    - The range of dimension members can contain gaps, but the members can't overlap.
23. In the **To dimension member** field, enter or select a value.
    - The range of dimension members can contain gaps, but the members can't overlap.
24. Click **Save**.

Create the policy and rules

1. Go to **Cost accounting** > **Policies** > **Cost behavior policies**.
2. Click **New**.
3. In the **Policy name** field, type a value.
4. In the **Cost element dimension hierarchy** field, enter or select a value.
    - Select the policy hierarchy that you just created.
5. In the **Cost object dimension hierarchy** field, enter or select a value.
    - Select Organization.
6. Click **Save**.
7. Click **New**.
8. In the list, mark the selected row.
9. In the **Cost element dimension hierarchy node** field, enter or select a value.
    - Expand the hierarchy to select Variable cost.
10. In the **Cost object dimension hierarchy node** field, enter or select a value.
    - By default, the variable percentage is 100 percent.
11. Click **Policy assignments for cost control unit**.

12. Click **New**.
13. In the list, mark the selected row.
14. In the **Valid from accounting date** field, enter a date.

    - The rules are date-effective, and a user or the system can expire a rule if a newer version is created.

15. In the **Cost control unit** field, enter or select a value.
16. Click **Save**.

Create and assign a cost distribution policy to a cost control unit

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Cost distribution rules are used to distribute costs that have been financially counted on a collective cost center. The cost accountant makes sure that the cost is distributed to the cost centers, based on the selected allocation base. A policy and the corresponding rules are assigned to a cost control unit. This task guide uses an example to show how to create a cost distribution policy and the corresponding rules.

Create a policy

1. Go to **Cost accounting** > **Policies** > **Cost distribution policies**.
2. Click **New**.
3. In the **Policy name** field, type a value.
4. In the **Description** field, type a value.
5. In the **Cost object dimension hierarchy** field, enter or select a value.
    - Select **Organization**.
6. In the **Cost element dimension hierarchy** field, enter or select a value.
    - Select **CDS P/L**.
7. In the **Statistical dimension** field, enter or select a value.
    - Select Statistical elements.
8. Click **Save**.

Create rules for the policy

1. Click **New**.
2. In the list, mark the selected row.
3. In the **Cost object dimension hierarchy node** field, enter or select a value.

- Expand the hierarchy to select 094.

4. In the **Cost element dimension hierarchy node** field, enter or select a value.
    - Select **Other operating expenses** and then select 605110 Cleaning.
5. In the **Cost behavior** field, select an option.
    - Select **Fixed cost**.
6. In the **Allocation base** field, enter or select a value.
7. Click **New**.
8. In the list, mark the selected row.
9. In the **Cost object dimension hierarchy node** field, enter or select a value.
    - Expand the hierarchy to select 094.
10. In the **Cost element dimension hierarchy node** field, enter or select a value.
    - Select **Other operating expenses** and then select 605150 Rent.
11. In the **Cost behavior** field, select an option.
    - Select **Fixed cost**.
12. In the **Allocation base** field, enter or select a value.
13. Click **Save**.

Assign rules to a cost control unit

1. Click **Policy assignments** for cost control unit.
2. Click **New**.
3. In the list, mark the selected row.
4. In the **Valid from accounting date** field, enter a date.
    - Select September 1 in the valid fiscal year.
5. In the **Cost control unit** field, enter or select a value.
6. Click **Save**.

Create a cost rollup policy

Article • 03/28/2023

This procedure shows how to create a cost rollup policy and create rules for the policy. The demo data used to create this procedure is USP2.

Create a policy

1. Go to **Cost accounting** > **Policies** > **Cost rollup policies**.
2. Click **New**.
3. In the **Policy name** field, type a value.
4. In the **Description** field, type a value.
5. In the **Cost object dimension hierarchy** field, enter or select a value.
    - Select Cost rollup CC.
6. In the **Cost element dimension hierarchy** field, enter or select a value.
    - Select Cost rollup CC.
7. Click **Save**.

Create rules for the cost rollup policy

1. Click **New**.
2. In the list, mark the selected row.
3. In the **Cost object dimension hierarchy node** field, enter or select a value.
    - Select 007.
4. In the **Cost element dimension hierarchy node** field, enter or select a value.
    - Select Cost rollup CE.
5. In the **Secondary cost element** field, enter or select a value.
    - For this example, map the secondary cost element CC-007 to the cost center.
6. Click **New**.
7. In the list, mark the selected row.
8. In the **Cost object dimension hierarchy node** field, enter or select a value.
    - Select 008.

9. In the **Cost element dimension hierarchy node** field, enter or select a value.
    - Select Cost rollup CE.
10. In the **Secondary cost element** field, enter or select a value.
    - For this example, map the secondary cost element CC-008 to the cost center.
11. Click **New**.
12. In the list, mark the selected row.
13. In the **Cost object dimension hierarchy node** field, enter or select a value.
    - Select 009.
14. In the **Cost element dimension hierarchy node** field, enter or select a value.
    - Select Cost rollup CE.
15. In the **Secondary cost element** field, enter or select a value.
    - For this example, map the secondary cost element CC-009 to the cost center.
    - Continue until all cost centers are mapped to their corresponding secondary cost elements.
16. Click **Save**.

Manage a data source for the cost accounting ledger

Use this procedure to manage the general ledger data source for a cost accounting ledger. Before you complete this task, make sure that you complete the "Create a cost accounting ledger" and "Define cost control units" task guides. This recording uses the USP2 demo data company.

1. Go to **Cost accounting** > **Ledger setup** > **Cost accounting ledgers**.
2. In the list, find and select the desired record.
3. Select **Actual versions**.
4. On the Action Pane, select **Manage**.
5. Select **General ledger**.
6. Select **New**.
7. In the **Name** field, type a value.
8. In the **Data provider** field, enter or select a value.
    - For this example, select **Dynamics 365 Finance - General ledger entries**.
9. In the **Cost element dimension** field, enter or select a value.
    - For this example, select **Cost elements**.
10. Select **Save**.
11. Select **Configure data provider**.
12. In the **Legal entity** field, enter or select a value.
    - For this example, select **USP2**.
13. Select **New**.
14. In the **Posting layer** field, select **Current**.
15. Select **OK**.

Process and trace source data

Article • 03/27/2023

All data processing is run by jobs. For each job and data provider, a journal is created to document that the process has been run, and that the entries were processed in the current job. Use this procedure to set up a data source and then trace the origin of a specific cost entry. This recording uses the USP2 demo data company USP2. Before you complete this task, make sure that you play the following task guides: "Create a cost accounting ledger," "Define cost control units," and "Manage data source for the cost accounting ledger."

1. Go to **Cost accounting** > **Ledger setup** > **Cost accounting ledgers**.
2. In the list, find and select the desired record.
    - Select the cost accounting ledger that you created earlier.
3. Click **Actual versions**.
4. On the Action Pane, click **Source data processing**.
5. Click **General ledger entry transfer journals**.
6. In the list, find and select the desired record.
7. Click **Journal entries**.
8. In the list, mark the selected row.
9. Click **Cost entries**.
10. Click **Source entry**.
11. On the Action Pane, click **Source data processing**.
12. Click **General ledger**.
13. In the **Fiscal calendar period** field, enter or select a value.
    - For this example, select Fiscal 2017 Period 9.
14. Click **OK**.

Overhead calculation

This article describes the typical processes for calculating and allocating overhead costs.

Term definition

Overhead costs are the costs that you incur to run a business but can't directly attribute to any specific business activity, product, or service. Overhead costs provide critical support for the generation of profit-making activities. Here are some examples of overhead costs:

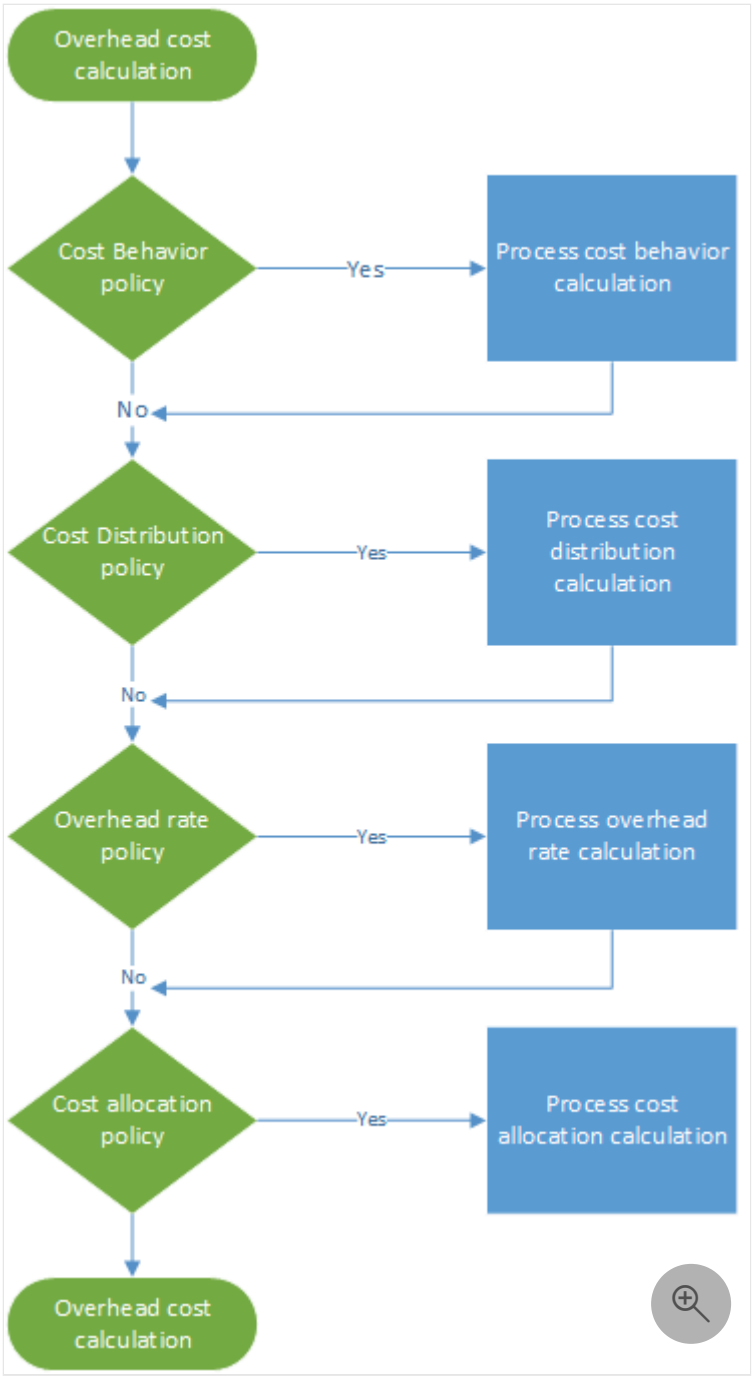
- Rent
- Electricity
- Administrative salaries

Overhead calculation overview

Overhead calculation runs the cost accounting policies in the correct order. You can run overhead calculation multiple times for the same fiscal period if you change cost accounting policies or detect specific errors. Each run of the overhead calculation is stored and receives a unique version ID that lets you compare the calculations in various versions. The cost entries that the overhead calculation generates receive an accounting date. This accounting date matches the end date of the fiscal period that is used in the calculation. The unique version ID consists of the following elements:

- Version type
- Date and time
- Cost accounting ledger
- Fiscal year
- Fiscal period

You run overhead calculation independently of the version. Therefore, you can calculate the Budget version before the Actual version. Overhead calculation consists of four steps, as shown in the following illustration. In each step, the process creates a journal header that has journal entries. This journal header keeps the input data for each calculation step. The process applies policies and rules to each journal line, and generates cost entries as output. Therefore, you always have full traceability.



Calculate and allocate the electricity overhead cost

In Financial accounting, some costs, such as electricity, are registered as a lump sum. Therefore, detailed managerial insight isn't provided for Cost accounting. In Cost accounting, to provide correct managerial insight across all organizational units and levels, costs must flow through the organizational units. This flow must be based on either an accurate record of the consumption or a fair assessment. In the general ledger, an electricity cost can be posted as shown in the following table.

Expand table

Accounting date	Cost center	Main account	Amount in the accounting currency
January 3, 2023	CC099 - Default cost center	10001 - Electricity	10,000.00

Step 1: Process the cost behavior calculation

By default, when you import cost entries from the source data, they receive the **Unclassified** cost behavior classification in Cost accounting. By applying cost behavior policy rules, you can reclassify cost entries as either **Fixed cost** or **Variable cost**.

Define the cost behavior rule

In some cases, part of the cost is a fixed fee, and the remaining cost is based on consumption. Electricity bills often match this definition. After you pay a specific fixed fee, you pay for consumption per kilowatt hour (Kwh). For example, if the fixed cost fee is 1,000.00, here's how you define the cost behavior rule:

- Fixed amount 1,000.00
  - 0 <= 1,000.00 = Fixed
  - 1000,01 < N = Variable

Journal

Expand table

Journal	Journal type	Fiscal calendar period	Version

Expand table

Accounting date	Cost object	Cost element	Cost behavior	Amount
January 3, 2023	CC099 - Default cost center	10001 - Electricity	Unclassified	10,000.00

Cost entries

Expand table

Cost object	Cost element	Cost behavior	Amount	Accounting date
CC099 - Default cost center	10001 - Electricity	Unclassified	10,000.00	January 3, 2023
CC099 - Default cost center	10001 - Electricity	Unclassified	-10,000.00	January 31, 2023
CC099 - Default cost center	10001 - Electricity	Fixed cost	1,000.00	January 31, 2023
CC099 - Default cost center	10001 - Electricity	Variable cost	9,000.00	January 31, 2023

For more information, see Create and assign a cost behavior policy to a cost control unit.

Step 2: Process the cost distribution calculation

Use cost distribution to redistribute costs from one cost object to one or more other cost objects by applying a relevant allocation base. Cost distribution and cost allocation differ in that cost distribution always occurs at the level of the primary cost element of the original cost.

Define the cost distribution rule

In financial accounting, register electricity costs as a lump sum. In cost accounting, this approach isn't detailed enough. Distribute the variable cost to the individual cost objects on a fair basis. The most logical allocation basis is the consumption of electricity (Kwh). Create a statistical dimension member named **Electricity**, and record electricity consumption. By default, all statistical dimension members become available as allocation bases.

Expand table

Cost object	Kwh
CC001 - HR	1,000
CC002 - Finance	6,000
CC003 - Assembly	0

The following table shows the result when you apply electricity consumption as an allocation base for variable costs.

Expand table

Cost object	Magnitude	Allocation factor	Amount
CC001 - HR	1,000	(1,000 ÷ 7,000) × 9,000.00	1,285.71

Cost object	Magnitude	Allocation factor	Amount
CC002 - Finance	6,000	(6,000 ÷ 7,000) × 9,000.00	7,714.29
CC003 - Assembly	0	(0 ÷ 7,000) × 9,000.00	0.00

Distribute the fixed cost evenly to the individual cost objects that consume electricity. To achieve this result, use the Electricity statistical dimension member in a formula allocation base: (Electricity > 0.00). The following table shows the result when you apply electricity consumption as an allocation base for variable costs.

Expand table

Cost object	Formula	Magnitude	Allocation factor	Amount
CC001 - HR	(1,000 > 0.00)	1	(1 ÷ 2) × 1,000.00	500.00
CC002 - Finance	(6,000 > 0.00)	1	(1 ÷ 2) × 1,000.00	500.00
CC003 - Assembly	(0 > 0.00)	0	(0 ÷ 2) × 1,000.00	0.00

Journal

Expand table

Journal	Journal type	Fiscal calendar period	Version
00002	Cost distribution calculation journal	Fiscal - 2023 Period 1	Overhead calculation / 01-02-2023 11:51:00 PM / Ledger /2023 / Period 1

CC001 - HR	10001 - Electricity	Fixed cost	500.00	January 31, 2023
CC002 - Finance	10001 - Electricity	Fixed cost	500.00	January 31, 2023
CC099 - Default cost center	10001 - Electricity	Variable cost	-9,000.00	January 31, 2023
CC001 - HR	10001 - Electricity	Variable cost	1,285.71	January 31, 2023
CC002 - Finance	10001 - Electricity	Variable cost	7,714.29	January 31, 2023

For more information, see Create and assign a cost distribution policy to a cost control unit.

Step 3: Process the overhead rate calculation

Use the overhead rate to charge one or more specific cost objects. The charge is based on a predetermined cost rate and the magnitude from the assigned allocation base.

Define the overhead rate

Cost object CC001 HR contributes to a set of internal projects. Create a statistical dimension member named **HR projects** to measure the consumed magnitude.

Expand table

Cost object	Hours
Proj 1 - Project 1	3
Proj 2 - Project 2	1

Define a predetermined cost rate for the cost projects contribution.

Expand table

Cost object	Cost element	Cost behavior	Units	Rate
CC001 - HR	10001	Variable cost	1	10

The following table shows the result when the HR projects are applied as an allocation base.

Expand table

Cost object	Magnitude	Cost element	Allocation factor	Amount
Proj 1 - Project 1	3	10001	(3 ÷ 1) × 10.00	30.00
Proj 2 - Project 2	1	10001	(1 ÷ 1) × 10.00	10.00

Journal

Expand table

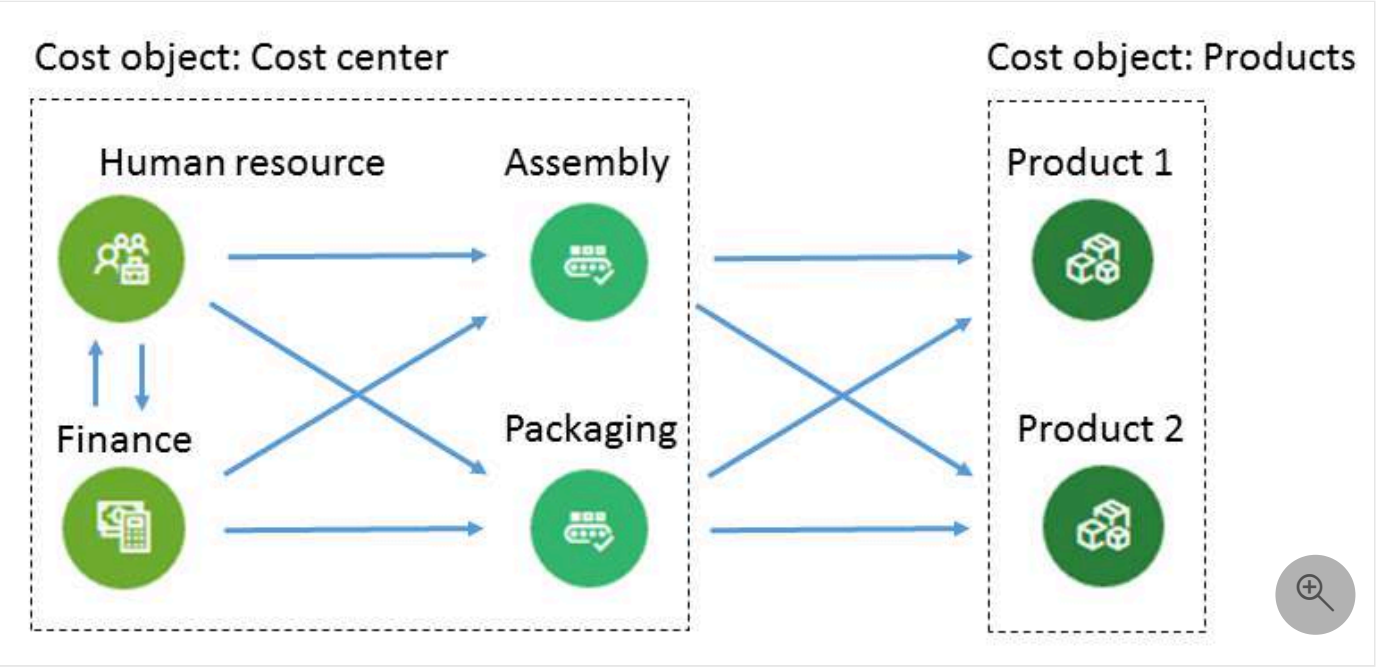
CC001 - HR	10001	Electricity - Variable cost	-10.00	January 31, 2023
Proj 2 - Internal Proj 2	10001 - Electricity	Variable cost	10.00	January 31, 2023

For more information, see Perform overhead calculation.

Step 4: Process the cost allocation calculation

Allocation is used to allocate the balance of a cost object to other cost objects by applying an allocation base. Finance supports the reciprocal allocation method. In the reciprocal allocation

method, the mutual services that auxiliary cost objects exchange are fully recognized. The system automatically determines the correct order to perform the allocations in. The balance of a cost object is allocated by a single allocation base. Allocations across cost objects dimensions and their respective members are supported. The allocation order is controlled by the cost control unit.



Define the cost allocation

Here's a simple example that explains how you can trace the flow of cost. Cost object CC001 HR contributes to several cost objects. You create a statistical dimension member named HR services to measure the consumed magnitude.

Expand table

Cost object	HR services
CC002 - Finance	35
CC003 - Assembly	55
CC004 - Packaging	10

Cost object CC002 Finance contributes to several cost objects. You create a statistical dimension member named Finance services to measure the consumed magnitude.

Expand table

Cost object	Finance services
CC003 - Assembly	65
CC004 - Packaging	35

Cost object CC003 Assembly contributes to several cost objects. You create a statistical dimension member named Assembly services to measure the consumed magnitude.

Expand table

Cost object	Assembly services (hours)
Prod 1 - Product 1	60
Prod 2 - Product 2	20

Cost object CC004 Packaging contributes to several cost objects. You create a statistical dimension member named Packaging services to measure the consumed magnitude.

Expand table

Cost object	Packaging services (hours)
Prod 1 - Product 1	80
Prod 2 - Product 2	15

> **Note**
>
> Statistical measures such as the production hours that a product consumes can be derived from source data. For more information, see Statistical measure provider template. The following table shows the result when the HR services are applied as an allocation base for total cost (fixed cost and variable cost).

Expand table

Cost object	Magnitude	Allocation factor	Amount	Cost behavior
CC002 - Finance	35	(35 ÷ 100) × 500.00	175.00	Fixed cost
CC003 - Assembly	55	(55 ÷ 100) × 500.00	275.00	Fixed cost
CC004 - Packaging	10	(10 ÷ 100) × 500.00	50.00	Fixed cost

Cost object	Magnitude	Allocation factor	Amount	Cost behavior
CC002 - Finance	35	(35 ÷ 100) × 1,245.71	436.00	Variable cost
CC003 - Assembly	55	(55 ÷ 100) × 1,245.71	685.14	Variable cost
CC004 - Packaging	10	(10 ÷ 100) × 1,245.71	124.57	Variable cost

The following table shows the result when the Finance services are applied as an allocation base for total cost (fixed cost and variable cost).

Expand table

Cost object	Magnitude	Allocation factor	Amount	Cost behavior
CC003 - Assembly	65	(65 ÷ 100) × (500.00 + 175.00)	438.75	Fixed cost
CC004 - Packaging	35	(35 ÷ 100) × (500.00 + 175.00)	236.25	Fixed cost
CC003 - Assembly	65	(65 ÷ 100) × (7,714.29 + 436.00)	5,297.69	Variable cost
CC004 - Packaging	35	(35 ÷ 100) × (7,714.29 + 436.00)	2,852.60	Variable cost

The following table shows the result when the Assembly services are applied as an allocation base for total cost (fixed cost and variable cost).

Expand table

Cost object	Magnitude	Allocation factor	Amount	Cost behavior
Prod 1 - Product 1	60	(60 ÷ 80) × (275.00 + 438.75)	535.31	Fixed cost
Prod 2 - Product 2	20	(20 ÷ 80) × (275.00 + 438.75)	178.44	Fixed cost
Prod 1 - Product 1	60	(60 ÷ 80) × (5,297.69 + 685.14)	4,487.12	Variable cost
Prod 2 - Product 2	20	(20 ÷ 80) × (5,297.69 + 685.14)	1,495.71	Variable cost

The following table shows the result when the Packaging services are applied as an allocation base for total cost (fixed cost and variable cost).

Expand table

Cost object	Magnitude	Allocation factor	Amount	Cost behavior
Prod 1 - Product 1	80	(80 ÷ 95) × (50.00 + 236.25)	241.05	Fixed cost

Cost object	Magnitude	Allocation factor	Amount	Cost behavior
Prod 2 - Product 2	15	(15 ÷ 95) × (50.00 + 236.25)	45.20	Fixed cost
Prod 1 - Product 1	80	(80 ÷ 95) × (2,852.60 + 124.57)	2,507.09	Variable cost
Prod 2 - Product 2	15	(15 ÷ 95) × (2,852.60 + 124.57)	470.08	Variable cost

Conclusion

In financial accounting, you post a cost of 10,000.00 for electricity to a dummy cost center ID. This posting alerts cost accountants that they need to allocate this cost. In cost accounting, costs flow across organizational units and levels based on the policies and rules that you apply. Each cost associates with an allocation base that provides the best assessment for the allocation of costs.

Expand table

Cost element	Cost object CC099	Cost object CC001	Cost object CC002	Cost object CC003	Cost object CC004	Cost object Proj 1	Cost object Proj 2	Cost object Prod 1	Cost object Prod 2	Total
10001 Electricity	0.00	0.00	0.00	0.00		30.00	10.00	7,770.57	2,189.43	10,000.00
Unclassified	0.00									
Fixed cost	0.00	0.00	0.00	0.00	0.00			776.36	223.64	1,000.00
Variable cost	000	0.00	0.00	0.00	0.00	30.00	10.00	6,994.21	1,965.79	9,000.00

> **Note**
>
> This article shows how a primary cost element, 10001 Electricity, flows through the cost objects. Therefore, you allocate this overhead cost to the lowest level in the organization. In other words, the cost objects at the lowest level bear the cost. If you require a visual flow of the cost between the cost objects, you can use the cost roll-up policy rules to visualize the flow of the cost. For more information, see Cost rollup policy and overhead calculation.

Cost accounting helps you understand how costs flow to the products and services that an organization delivers. To achieve cost transparency, you need to allocate costs between cost objects using an appropriate allocation basis. By default, the system allocates costs for the primary cost element. This default allocation works well in some situations, but it has a few implications that you should consider.

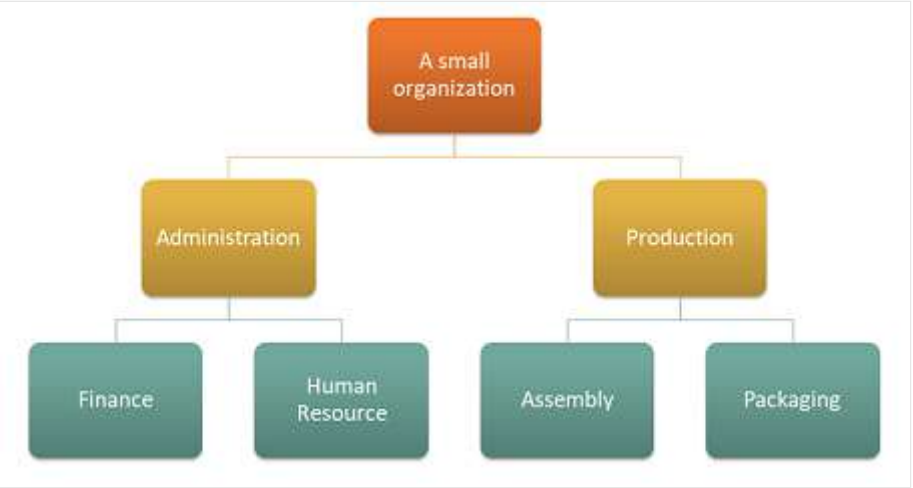
- After overhead calculation, auxiliary cost objects have a zero balance for the primary cost element.
- The volume of cost entries generated by overhead calculation can be very high.
- You can't track the cost flow between cost objects.

To avoid these implications, use Cost accounting to configure cost allocation to fit your organization's managerial reporting requirements. This article discusses how you can determine the correct level of secondary cost elements and create cost rollup rules that fit organization reporting and cost traceability.

> **Note**
>
> You can change configurations if reporting requirements change.

Example of cost rollup policy setup

Imagine that an organization has the following structure with four cost centers.



Cost object dimension

Expand table

Cost centers	Description
CC001	HR
CC002	Finance
CC003	Assembly
CC004	Packaging

Cost element dimension

Expand table

Cost elements	Description	Type
1001	Electricity	Primary
1002	Salaries	Primary
1003	Advertising	Primary

You can set up a dimension hierarchy that fulfills the organizational reporting requirements as follows.

Dimension hierarchy details

Expand table

After processing the general ledger entries, the cost entry balance by cost object looks like this.

Expand table

	Cost object				Total
Cost element	**CC001**	**CC002**	**CC003**	*CC004**	
1001 Electricity	100.00	200.00	6,000.00	2,000.00	**8,300.00**
1002 Salaries	10,000.00	10,000.00	8,000.00	6,500.00	**34,500.00**
1003 Advertising	0.00	4,000.00	0.00	0.00	**4,000.00**
	10.100,00	14.200,00	14.000,00	8.500,00	**46.800,00**

Statistical dimension

Expand table

Statistical elements	**Description**
SE-1	HR services
SE-2	Finance services

Cost object CC001 HR contributes HR services to several cost objects.

The following table shows how HR services are consumed by the distribution of magnitude.

Expand table

Cost object	**Description**	**HR services**
CC002	Finance	35
CC003	Assembly	55
CC004	Packaging	10

Cost object CC002 Finance contributes to several cost objects.

The following table shows how finance services are consumed by the distribution of magnitude.

Expand table

Cost object	Description	Finance services
CC003	Assembly	65
CC004	Packaging	35

Set up cost allocation policies as follows.

Expand table

Policy name	Description	Cost object dimension hierarchy	Statistical dimension	Cost element dimension
2017	Cost allocation	Organization	Statistical elements	Cost elements

Set up cost allocation rules as follows.

Expand table

Cost object dimension hierarchy node	Cost behavior	Allocation base
CC001	Total	**HR services**
CC002	Total	**Financial services**

How cost flows between cost centers

If you want to learn how cost flows between the cost centers in the organization, you can create cost elements of the type **Secondary** for each cost center. These cost elements will then be used to transfer balances between the cost centers during the overhead calculation.

Set up cost element dimension members as follows.

Expand table

Cost elements	Type	
1001	Electricity	Primary
1002	Salaries	Primary
1003	Advertising	Primary
SC-CC001	**HR**	**Secondary**

Cost elements	Type	
SC-CC002	Finance	Secondary
SC-CC003	Assembly	Secondary
SC-CC004	Packaging	Secondary

Update the dimension hierarchy **Profit & Loss statement** with the new dimension members so that the dimension hierarchy contains the correct data for defining reporting and policies.

Nodes	From dimension member	To dimension member
Profit & Loss statement		
Primary cost	10001	10003
Secondary cost	**SC-CC001**	**SC-CC004**

Create a **Cost rollup policy** where you map each cost center to a corresponding cost element of the type **Secondary**.

Cost rollup polices

Expand table

Policy name	Description	Cost object dimension hierarchy	Cost element dimension hierarchy
2017	Cost flow	Organization	Profit & Loss statement

Cost rollup rules

Expand table

Cost object dimension hierarchy node	Cost element dimension hierarchy node	Secondary cost element
CC001	Profit & Loss statement	**SC-CC001**
CC002	Profit & Loss statement	**SC-CC002**
CC003	Profit & Loss statement	**SC-CC003**
CC004	Profit & Loss statement	**SC-CC004**

Perform overhead calculation

Journal

Expand table

Journal	Journal type	Fiscal calendar period	Year	Period	Version
00002	Cost allocation journal	Fiscal	2017	Period 1	Overhead calculation / 01-02-2017 11:51:00 PM / Ledger /2017 / Period 1

The system applies the **Cost rollup policy** when it creates the **Cost object balance journal entries**.

Cost object balance journal entries

Expand table

Accounting date	Cost object	Description	Cost element	Description	Amount
31-01-2017	CC001	HR	SC-CC001	HR	10,100.00
31-01-2017	CC002	Finance	SC-CC002	Finance	17,735.00
31-01-2017	CC003	Assembly	SC-CC003	Assembly	31,082.75
31-01-2017	CC004	Packaging	SC-CC004	Packaging	15,717.25

> **Note**

The system creates the journal entries based on the rules in the **Cost rollup policy** if a policy exists. The balance displayed is the balance of the overhead calculation.

The **Cost object cost balance journal entry details** page that you access from the journal entries displays how the balance is obtained.

Example: The journal entry for Cost object CC002 Finance

Cost object cost balance journal entry details

Expand table

Cost element dimension member	Description	Amount
1001	Electricity	200.00
1002	Salaries	10,000.00
1003	Advertising	4,000.00
SC-CC001	HR	3,535.00

Cost entries generated by the Overhead calculation

Expand table

Cost object	Description	Cost element	Description	Amount	Accounting date
CC001	HR	SC-CC001	HR	-10,100.00	31-01-2017
CC002	Finance	SC-CC001	HR	3,535.00	31-01-2017
CC003	Assembly	SC-CC001	HR	5,555.00	31-01-2017
CC004	Packaging	SC-CC001	HR	1,010.00	31-01-2017
CC002	Finance	SC-CC002	Finance	-17,735.00	31-01-2017
CC003	Assembly	SC-CC002	Finance	11,527.75	31-01-2017
CC004	Packaging	SC-CC002	Finance	6,207.25	31-01-2017

After the **Overhead calculation** finishes, you can report the results by using tools such as Microsoft SharePoint Workspace, Excel, or Power BI.

View reporting in Excel

The dimension hierarchies allow you to view data at different aggregation levels.

Here's an example of Power Pivot reporting in Excel.

Expand table

Profit & Loss statement	Cost object				Total
	CC001	**CC002**	**CC003**	CC004**	
Primary cost	**10,100.00**	**14,200.00**	**14,000.00**	**8,500.0**	**46,800.00**
1001	100.00	200.00	6,000.00	2,000.00	**8,300.00**
1002	10,000.00	10,000.00	8,000.00	6,500.00	**34,500.00**
1003	0.00	4,000.00	0.00	0.00	**4,000.00**
Secondary cost	**-10,100.00**	**-14,200.00**	**17,082.75**	**7,217.25**	**0.00**
SC-CC001	-10,100.00	3,535.00	5,555.00	1,010.00	**0.00**
SC-CC002	0.00	-17,735.00	11,527.75	6,207.25	**0.00**
SC-CC003	0.00	0.00	0.00	0.00	0.00
SC-CC004	0.00	0.00	0.00	0.00	0.00
Total	**0.00**	**0.00**	**31,082.75**	**15,717.25**	**46,800.00**

By using **Cost rollup policy** and **Cost elements of the type secondary**, you can keep the primary cost per cost object for internal reporting as the primary cost that remains after **Overhead calculation**.

If you perform the same example without creating the **Cost rollup policy**, the reporting result is as shown in the following table. The cost flows correctly but the traceability and insight into how cost flows between the cost centers are lost.

Expand table

Profit & Loss statement	Cost object				Total
	CC001	**CC002**	**CC003**	**CC004**	
Primary cost	**0.00**	**0.00**	**31,082.75**	**15,717.25**	**46,800.00**
1001	0.00	0.00	6,207.75	2,092.25	**8,300.00**
1002	0.00	0.00	22,275.00	12,225.00	**34,500.00**

Profit & Loss statement	Cost object				Total
1003	0.00	0.00	2,600.00	1,400.00	**4,000.00**
Secondary cost	**0.00**	**0.00**	**0.00**	**0.00**	**0.00**
SC-CC001	0.00	0.00	0.00	0.00	**0.00**
SC-CC002	0.00	0.00	0.00	0.00	**0.00**
SC-CC003	0.00	0.00	0.00	0.00	0.00
SC-CC004	0.00	0.00	0.00	0.00	0.00
Total	**0.00**	**0.00**	**31,082.75**	**15,717.25**	**46,800.00**

Depending on the reporting and traceability requirements in your organization, you can determine the correct level of secondary cost elements and create cost rollup rules that fit your needs.

The clear separation between **Cost allocation** and **Cost rollup policies** provides the flexibility to make continuous updates without affecting each other.

Cost control workspace

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The **Cost control** workspace is a central point where managers who are responsible for controlling a cost object or a set of cost objects within a dimension or across dimensions (for example, cost centers and product groups) can access reports. Cost accountants fully manage the reports in the workspace, so the layout and data used for reporting are consistent across the whole organization.

Cost control workspace configuration

Cost accountants can define as many report configurations as they require for the desired data composition or layout. A report configuration consists of six sections, each of which contributes to either the selection of the targeted data composition or the layout.

To configure a cost control workspace, select **Cost accounting** > **Setup** > **Cost control workspace configuration**.

General

On the **General** FastTab, create a unique report layout. The name of the report is a unique identifier that users recognize in the **Cost control** workspace. You can also specify whether to share the report or keep it internal for cost accountants.

Expand table

Field	Description
Name	Enter a unique name for the layout.
Description	Enter a detailed description.

Field	Description
Published	If you set this field to **Yes**, a user assigned one of the following roles can see the report in the **Cost control** workspace: • Cost accounting manager • Cost accountant • Cost accountant clerk • Cost object controller If you set this field to **No**, only users assigned one of the following roles can see the report in the **Cost control** workspace: • Cost accounting manager • Cost accountant • Cost accountant clerk

Data filtering

On the **Data filtering** FastTab, you define the data foundation for the report. Users of this report see values on the report after the system processes the source data.

Expand table

Field	Description
Cost accounting ledger	The **Cost accounting ledger** that the report is based on. The value comes from the **Cost control unit** field.
Cost control unit	The value that you select determines the cost accounting ledger and cost objects that this report is based on.
Statistical dimension hierarchy, Cost element dimension hierarchy	A **Cost control** workspace configuration record can report either nonmonetary or monetary values, but not in the same layout. Select a value in the **Cost element dimension hierarchy** field to report monetary values. Select a value in the **Statistical dimension hierarchy** field to report nonmonetary values. The dimension hierarchy record that you select determines the structure of the reporting and aggregation levels.**NOTE:** To view nonmonetary and monetary values side by side, you can export data to Microsoft Excel for the Microsoft Power BI content pack.
Cost object dimension hierarchy	Select the dimension hierarchy of the cost object dimension that suits the purpose of the reporting that you're defining.
Budget original version	Select the budget version ID that acts as the original budget in the context of this report.

Field	Description
Budget revised version	Select the budget version ID that acts as the revised budget in the context of this report.

Assign calculation records

The overhead calculation performs several calculation steps on the source data, such as cost behavior classification, cost distribution, and cost allocation. You can perform multiple overhead calculations for the same fiscal period in case missing source data is discovered or rules must be updated. Each overhead calculation is saved with a unique ID. The cost accountant selects a specific overhead calculation ID. Users of the report, such as managers, see the results of the overhead calculation in the **Cost control** workspace.

Expand table

Field	Description
Fiscal calendar period	Select the fiscal calendar period to assign an overhead calculation ID to.**NOTE:** The fiscal periods that are listed in the field come from the fiscal calendar that is associated with the cost accounting ledger.
Actual version	Select the appropriate overhead calculation ID.
Budget version	Select the appropriate overhead calculation ID.
Revised budget version	Select the appropriate overhead calculation ID.

Fiscal periods per column

On the **Fiscal periods per column** FastTab, the cost accountant decides which fiscal period shows in the report layout.

The values in the selected columns multiply by the selected values on the **Fiscal periods per column** FastTab.

Expand table

Field	Description
Current period	The balance of the current fiscal period shows.**NOTE:** By default, the session date determines the current period. In the **Cost control** workspace, you can select a specific fiscal period. The selected value then represents the current period.
Previous period	The balance of the previous fiscal period shows. The following formula is used: Current fiscal period – 1**NOTE:** By default, the session date determines the previous period. In the **Cost control** workspace, you can select a specific fiscal period as the current period. The system recalculates **Previous period** accordingly.
Year to date	The value for the year to date shows. The following formula is used: YearToDate (Current fiscal period)**NOTE:** By default, the session date determines the current period. In the **Cost control** workspace, you can select a specific fiscal period. The selected value then represents the current period, and the **Year to date** value updates accordingly.
Year to date average	The average for the year to date shows. The following formula is used: (YearToDate [Current fiscal period]) ÷ (Count [Current fiscal period]) **Example** - **Statistical dimension member:** Full time employees - **Current date:** 3-21-2017 - **Period:** Fiscal period 1, Fiscal period 2, Fiscal period 3 - **Magnitude:** 10, 10, 12 In this case, **Year to date average** = (10 + 10 + 12) ÷ 3 = 10.67 The **Year to date average** value can be calculated for cost element dimension members and statistical dimension members. **NOTE:** By default, the session date determines the current period. In the **Cost control** workspace, you can select a specific fiscal period. The selected value then represents the current period, and the **Year to date** and **Year to date average** values update accordingly.

Columns to display for costs

On the **Columns to display for costs** FastTab, the cost accountant decides which columns the report layout should contain. There are three categories: Fixed cost, Variable cost, and Unclassified cost.

Expand table

Field	Description
Fixed cost	This column type shows the fixed cost, based on the selected overhead calculation ID.**NOTE:** This column type shows a balance only when you select an overhead calculation ID for the fiscal period.

Field	Description
Variable cost	This column type shows the variable cost, based on the selected overhead calculation ID.**NOTE:** This column type shows a balance only when you select an overhead calculation ID for the fiscal period.
Fixed + variable cost	This column type shows the fixed cost and variable cost, based on the selected overhead calculation ID.**NOTE:** This column type shows a balance only when you select an overhead calculation ID for the fiscal period.
Total cost	This column type shows the total cost (unclassified cost, fixed cost, and variable cost).**NOTE:** The column type always shows the balance.
Unclassified cost	This column type shows the unclassified cost.**NOTE:** You can use this column to validate whether all costs are correctly classified by the overhead calculation, or whether the cost behavior rules must be adjusted.

Columns to display for budgeted costs

On the **Columns to display for budgeted costs** FastTab, the cost accountant decides which columns to show for the selected budget versions. You can make individual selections for the original and revised budget.

> **Note**
>
> Because the following fields behave in the same manner for original budget and revised budget, the descriptions apply to both the original budget and the revised budget.

Expand table

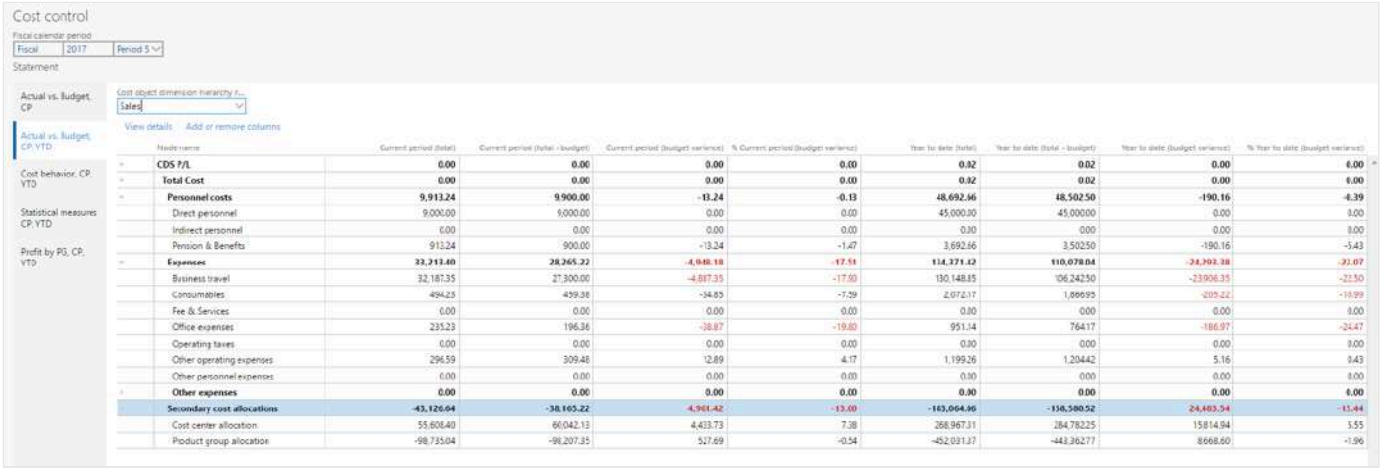
Field	Description
Budget	Shows budget balances per the selected columns.**NOTE:** The balances are based on the budget versions that you select on the **Data filtering** FastTab.
Budget variance	Calculates and shows the difference between budget and actual. The following formula is used: Budget balance – Actual balance
Budget variance in %	Calculates and shows the difference in percentage between budget and actual. The following formula is used: (Budget balance – Actual balance) ÷ Budget balance

Field	Description
Variance period threshold	Sets a threshold for the variance in monetary amount for the current period. If the threshold is exceeded, the line is highlighted in red in the **Cost control** workspace.**NOTE:** This field applies only to the cost elements that represent expenditures.
Variance year threshold	Sets a threshold for the variance in monetary amount for the year. If the threshold is exceeded, the line is highlighted in red in the **Cost control** workspace.
Variance threshold %	Sets a threshold for the variance in percentage. If the threshold is exceeded, the line is highlighted in red in the **Cost control** workspace.**NOTE:** The same percentage threshold applies to the current period and year.

Cost control workspace

The **Cost control** workspace is designed as a web report. Therefore, you can grant access to all managers who are responsible for a cost object as described in Define access rights for cost object controllers.

The list of reports that are available for users, such as managers, is controlled by the setting of the **Published** option on the **Cost control workspace configurations** page.



A manager can select the fiscal calendar period to view. The session date determines the default current period.

The values in the fiscal calendar period are determined by the report name and the fiscal calendar that you select for the cost accounting ledger that is associated with the report name on the **Cost control workspace configurations** page.

In the cost object dimension hierarchy, users can select the aggregation level at which balances should be shown. By enabling access-level security, you control the permissions, so that users can select only the hierarchy levels that they have access to. Therefore, they can see only the aggregated balances that they have access to.

Use the Cost control workspace

Add or remove columns

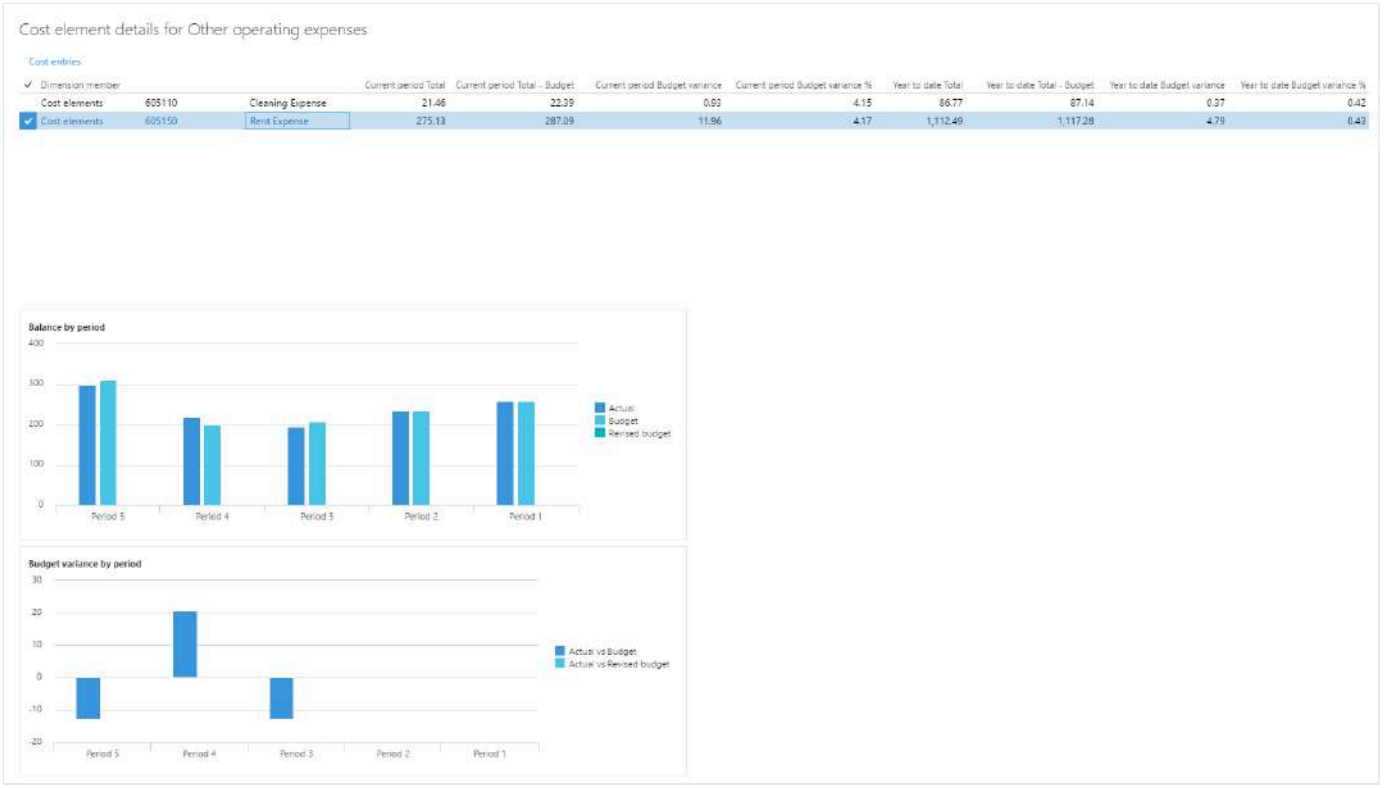
Users can customize the columns on a report to fit their requirements.

View details

You can view the details behind the balances that appear in the workspace. If you select a cost element dimension hierarchy node and then select **View details**, the **Cost element details** dialog box shows detailed information for the node.

A grid shows each cost element that is associated with the cost element dimension hierarchy node, and its values. The columns that appear in the grid match the workspace settings.

Two charts show a summary of actual versus budget and budget variance by period.



Select **Cost entries** to drill down into the entry details as required.

For example, rent is an expenditure that you distribute to cost centers. If you want to understand the rent cost that your cost center must carry, drill down to see how rent is calculated.

If you select **Allocation base** on the **Cost entries** page, a dialog box appears. You can then assign the allocation base to the rule and view the corresponding statistical measures that are registered for the period.

In the following example, the allocation base is of the **Formula allocation base** type, and the formula is shown. The factors that define the formula are listed. Additionally, a grid shows the calculation that is done per cost object.

Configure cost control workspace parameters

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use this procedure to configure the Cost control workspace so that managers at various levels in an organization can gain insight into their cost objects, such as cost centers and product groups. The USP2 demo company was used to create this recording.

1. Go to **Cost accounting** > **Setup** > **Cost control workspace configuration**.
2. Click **New**.
3. In the **Name** field, type a value.
4. In the **Description** field, type a value.
5. Select **Yes** in the **Published** field.

    - If you set this option to **Yes**, users who are assigned one of these roles can see the report in the **Cost control workspace**: cost accounting manager, cost accountant, cost accountant clerk, or cost object controller. If you set this option to **No**, only users who are assigned one of these roles can see the report in the **Cost control workspace**: cost accounting manager, cost accountant, or cost accountant clerk.

6. Expand the **Data filtering** section.
7. In the **Cost control unit** field, enter or select a value.
8. In the **Budget original version** field, enter or select a value.
9. In the **Cost element dimension hierarchy** field, enter or select a value.
10. In the **Cost object dimension hierarchy** field, enter or select a value.
11. Expand the **Assign calculation records** section.
12. Click **New**.
13. In the list, mark the selected row.
14. In the **Fiscal calendar period** field, enter or select a value.
15. In the **Actual version** field, enter or select a value.
16. Expand the **Fiscal periods per column** section.
17. Select **Yes** in the **Current period** field.
18. Expand the **Columns** to display for costs section.
19. Select **Yes** in the **Fixed cost** field.

20. Select **Yes** in the **Variable cost** field.
21. Select **Yes** in the **Total cost** field.
22. Click **Save**.
23. Close the page.
24. Go to **Cost accounting** > **Workspaces** > **Cost control**.
25. Select a statement to see fixed, variable, total, and unclassified costs for the selected fiscal periods.
26. In the **Fiscal calendar period** field, enter or select a value.
27. In the **Cost object dimension hierarchy node** field, enter or select a value.

    - After you've selected a **Cost object dimension hierarchy**, expand the **Cost element dimension hierarchy** to see the desired cost values. For example, you can expand the hierarchy to Manufacturing overhead to see the value.

Set up security for the Cost accounting analysis Power BI content

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how you can propagate the access-level security in Cost accounting to row-level security in Microsoft Power BI. This functionality helps guarantee that users see only Power BI data that they're granted access to.

Overview

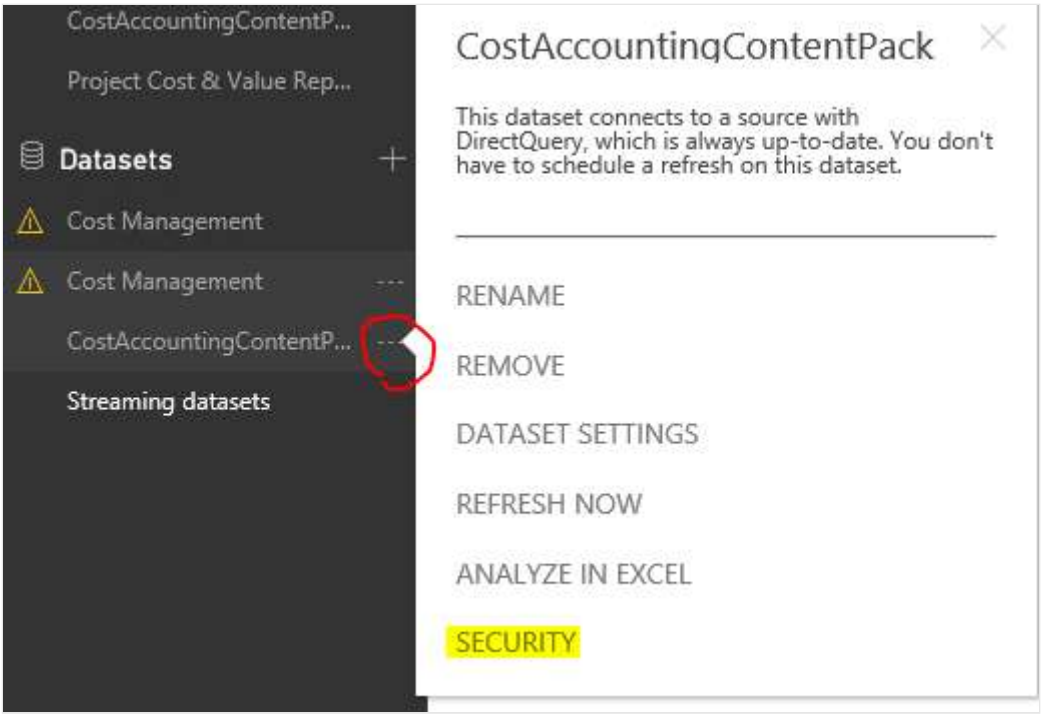
The **Cost accounting analysis** Microsoft Power BI content uses Power BI row-level security to limit a user's access. Set up security based on the access-level organizational hierarchy in the Cost accounting parameters. For more information about the **Cost accounting analysis** Power BI content, see Cost accounting analysis Power BI content.

Setup

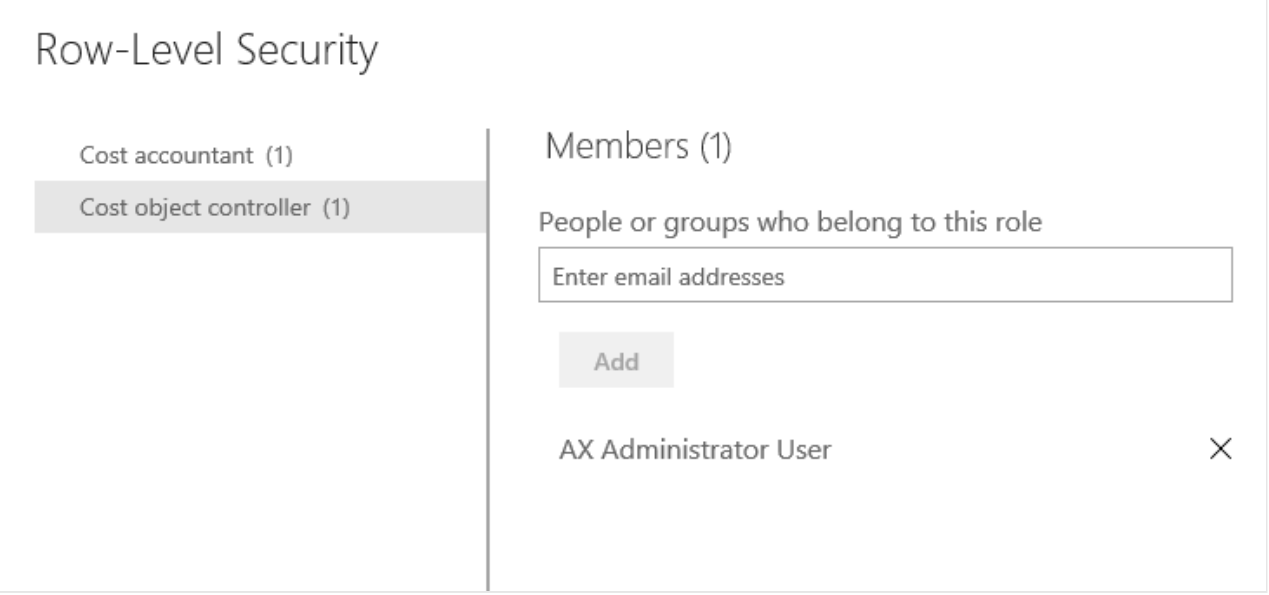
To propagate access-level security to Power BI, the owner of the Power BI content must follow these steps:

> **Note**
>
> The user who publishes the **Cost accounting analysis** Power BI content automatically becomes the owner. Only an owner can set up security in Power BI. Additionally, until an owner adds other users on PowerBI.com, no one except the owner can see any data in the **Cost accounting analysis** Power BI content.

1. Publish the definition file to Power BI.
2. Sign in to PowerBI.com.
3. Find the dataset for the **Cost accounting analysis** Power BI content.
4. Open the security page.



5. The **Cost object controller** role is already created. Add other members who are part of the Cost accounting access-level organizational hierarchy.



Users who are added to the **Cost object controller** role see only the data that they're allowed to see, according to the definition in the Cost accounting access-level organizational hierarchy.

> ⓘ **Note**
>
> Row-level security applies to tiles and reports that are embedded from Power BI.

Updating security

If you make updates to access-level security in Cost accounting, and you want Power BI to reflect those updates, you must update the entity store for the **Cost accounting analysis** Power BI content. After you complete the entity store update, you must update the artifacts on PowerBI.com. For more information about how to do an entity store update, see Power BI integration with Entity store. The owner of the **Cost accounting analysis** Power BI content must also do an entity store update if new users are granted access to the organizational hierarchy. Additionally, the owner must add the new users to the **Cost object controller** role on PowerBI.com, so that row-level security is applied for them.

Disabling security

This article assumes that your organization wants to restrict data access. If you disable the security parameters when you run Cost accounting, the owner must add users to the **Cost accountant** role in Power BI instead. If you change security from an enabled state to a disabled state, remove users from the **Cost object controller** role. And vice versa if you re-enable security. Users can belong to both roles. Joint access is the union of both roles. For the **Cost accounting analysis** Power BI content, users who have joint access have unrestricted data access. If your goal is to apply restricted access, assign users only to the **Cost object controller** role. These row-level security updates take effect immediately. Affected users should refresh their browsers.

Additional resources

To learn more about Power BI row-level security, see Manage security on your model in Power BI .

Cost accounting analysis Power BI content

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes what the **Cost accounting analysis** Microsoft Power BI content includes. It explains how to access the Power BI reports, and provides information about the data model and entities that were used to build the content.

Overview

The **Cost accounting analysis** Power BI content is intended for cost controllers or anyone who's responsible for performing cost control of an organization. It includes the key metrics, such as cost, magnitude, and cost rate by actual cost, budget cost, and flexible budget cost. It uses transaction data from the **Cost accounting** module and provides an aggregate view of costs for the whole organization in one reporting currency. Managers can filter the data by cost objects to perform cost control of their organizational units, even if the organization has several legal entities.

Because the **Cost accounting analysis** content highlights variances between the actual costs and budgeted costs, it notifies managers about positive and negative trends for their operational units. Managers can drill down to the cost element hierarchies or individual cost elements. In this way, managers can gain detailed insight into how cost variances occurred, and then take effective action.

The **Cost accounting analysis** content lets cost accountants analyze how cost flows through the cost objects of the whole organization.

To learn more about Cost accounting, see Cost accounting home page.

By defining access-level security in Cost accounting and combining it with row-level security in Power BI, you can grant all cost object owners access to the **Cost accounting analysis** Power BI content. All data in the visualizations is then filtered based on the access level that's controlled in Cost accounting. To learn more about access-level security and row-level security, see Set up security for the Cost accounting analysis Power BI content.

Accessing the Power BI content

You can find the **Cost accounting analysis** Power BI content in the Shared assets library in Microsoft Dynamics Lifecycle Services (LCS). For more information about how to download the content and implement it in your organization, see Power BI content in LCS from Microsoft and your partners.

Be sure to download the **Cost accounting analysis** content that applies to the version of Microsoft Dynamics 365 that you're using.

> **Note**
>
> KB 4011327 is a prerequisite for this Power BI content. After you sign in to LCS, you can access the KB at https://fix.lcs.dynamics.com/issue/results/?q=kb4011327.

Metrics included in the Power BI content

The content includes a set of report pages. Each page consists of a set of metrics that the report visualizes as charts, tiles, and tables. The following table provides an overview of the visualizations in the **Cost accounting analysis** Power BI content.

Expand table

Report page	Chart	Tile
Cost control by fiscal period	Actual cost and Budget cost by Cost element hierarchy level	Actual cost vs Budget cost
	Budget variance by Cost element hierarchy level	Actual cost rate vs Budget cost rate
	Top 10 Budget variance in percentage by Cost element	Actual magnitude vs Budget magnitude
Cost control by Year to date	Actual cost and Budget cost by Calendar Year Period	Actual cost vs Budget cost
	Budget variance by Calendar Year Period	Actual cost rate vs Budget cost rate
	Top 10 Budget variance in percentage by Cost element	Actual magnitude vs Budget magnitude
Cost rate by fiscal year	Actual cost rate by Cost behavior	Actual cost rate vs Budget cost rate

Report page	Chart	Tile
	Actual cost rate, Budget cost rate variance, Budget cost rate percentage, and Budget cost rate by Cost element hierarchy level	Actual magnitude vs Budget magnitude
	Budget variance by Cost element hierarchy level	
	Top 10 Budget variance in percentage by Cost element	
Flexible budget by fiscal period	Actual cost, Budget cost, and Flexible budget cost by Cost element hierarchy level	Actual magnitude vs Budget magnitude
	Budget variance and Flexible budget variance by Cost element hierarchy level	Actual cost vs Flexible budget cost
	Actual cost, Budget cost, and Flexible cost by Cost behavior and Cost element hierarchy level	Actual cost rate vs Flexible budget cost rate
Cost statement by fiscal period	Actual cost by Cost element hierarchy level and Cost object dimension member name	
	Actual cost by Cost object dimension member name and Cost element dimension member name	

Understanding the data model and entities

The report pages in the **Cost accounting analysis** Power BI content use the following data. This data is represented as aggregate measurements staged in the Entity store. The Entity store is a Microsoft SQL Server database that's optimized for analytics. For more information, see Power BI integration with Entity store.

The content uses the following key aggregate measurements.

Expand table

Entity	Key aggregate measurement	Data source for Dynamics 365	Field	Description
Cost accounting entries	SUM(Amount)	CAMDATAAggregatedCostEntry	Amount	The amount in the Cost accounting ledger currency.
Statistical entries	SUM(Magnitude)	CAMDATAAggregatedStatisctialEntry	Magnitude	

The following table shows how the key aggregate measurements are used to create several calculated measures in the content's dataset.

Expand table

Measure	How the measure is calculated
Actual cost	CALCULATE('Cost accounting entries'[Measure], 'Transaction versions'[ISSOURCEVERSIONBUDGET_VALUE] = 0)
Budget cost	CALCULATE('Cost accounting entries'[Measure], 'Transaction versions'[ISSOURCEVERSIONBUDGET_VALUE] = 1)
Budget cost variance	[Budget cost] - [Actual cost]
Budget variance percentage	IF([Budget cost] = 0, blank(), [Budget variance] / [Budget cost])

Cost management home page

Cost management (video) helps you work with the valuation and accounting of raw materials, semi-finished goods, finished goods, and work-in-progress assets. It's the process of defining, managing, and reporting Inventory accounting and Manufacturing accounting.

You can define cost policies in the following areas:

- Predetermined cost
- Inventory accounting
- Manufacturing accounting
- Indirect cost accounting
- Ledger integration

For example, you can define which inventory valuation methods, such as FIFO, Weighted average, Standard cost, or Moving average that you want to apply to products in the Item model group in Inventory accounting.

You can access Inventory accounting and Manufacturing accounting from the **Cost administration** and **Cost analysis** workspaces. These workspaces provide a comprehensive overview of the current status, key performance indicators (KPIs), and detection of deviation.

> **Tip**
>
> Are you new to inventory costing? Check out the following resources:
>
> - Glossary of terms in Dynamics 365 business processes
> - Define service costing overview and relation to other business processes
> - Business process for product costing and how it relates to other processes with Dynamics 365

Manufacturing accounting lets you handle Job order costing in production orders and batch orders, as well as Backflush costing in lean manufacturing.

The Cost management Power BI content provides managerial insight into inventory and work-in-progress (WIP) inventory, and how cost flows through them by category over time. The information can also be used as a detailed supplement to the financial statement.

This article answers some frequently asked questions about inventory costing in Microsoft Dynamics 365 Supply Chain Management.

Inventory closing, adjustments, recalculation, pre-closing, and reverse

Why is inventory closing required?

The inventory close process matches and settles inventory issue transactions (resulting from sales, production order issue, transfer journals, and other transactions) to their receipt transactions (such as purchase, counting journals, production receipts, and other transactions). The process uses the inventory valuation method that you define in the item's *item model group* and considers the item's active financial *product*, *storage*, and *tracking* dimensions.

You perform inventory closing for periodic inventory valuation methods (FIFO, LIFO, weighted average, and other methods). It ensures that the financial statements (income statement, balance sheet, trial balance, and other statements) reflect appropriate inventory values and cost of goods sold (COGS) based on all receipts and issues up to the period end.

You should run inventory closing regularly for a specific period. Once you close the inventory for that period, you can't post any transactions in that period.

The frequency of inventory close runs varies by company. However, transaction volume should determine how often you decide to run inventory close. In general, most companies run inventory closing as part of their month-end closing and reconciliation procedures, and before any audit activities.

To balance out the transactional load, run inventory closing regularly, once inventory transactions are finalized for a period, typically at a monthly frequency.

You must run inventory closing if you plan to change the valuation model in *item model group* of an item from periodic to perpetual, or if you plan to archive old inventory transactions.

Why is inventory recalculation required?

If you need to adjust inventory and the general ledger during a month or other inventory period, run inventory recalculation instead of inventory close. Inventory recalculation adjusts the inventory transactions according to the applicable valuation method but doesn't settle inventory transactions. Like inventory closing, you can only run inventory recalculation for periodic inventory valuation methods.

During inventory recalculation, the system adjusts on-hand and inventory transactions. These tasks affect any ledger account that's linked to the original inventory transaction.

Inventory recalculation doesn't close any period, unlike inventory closing. You can still post transactions in the period for which you already ran inventory recalculation.

The frequency of inventory recalculation runs depends on your business requirements. You can run recalculations daily, weekly, or monthly to adjust the on-hand and inventory transactions and reflect the accurate cost of the items based on their valuation method. However, running inventory recalculation is an optional procedure and not a prerequisite to inventory closing. Run inventory closing monthly. Once you run closing, the system automatically cancels all the recalculations you ran for dates after the closing date. Running many recalculations or running scheduled recalculations has a performance impact.

What are the differences between inventory closing and inventory recalculation?

These are the key differences between inventory closing and inventory recalculation:

- Inventory closing matches and settles transactions, whereas inventory recalculation adjusts transactions.
- Inventory closing closes the period for which you run it, so you can't post any further transactions in that period. Inventory recalculation doesn't restrict inventory postings for any period.
- You must run inventory closing before making any modifications in an item's *item model group* and before archiving old transactions. Besides, you should regularly run inventory closing at periodic intervals to reduce the system load for high transactional volume. Inventory recalculation isn't a mandatory process.

Is it mandatory to run inventory closing or recalculation?

You must run inventory closing before making any modifications in an item's *item model group* and before archiving old inventory transactions. Besides, you should regularly run inventory closing at periodic intervals to reduce the system load for high transactional volume. Inventory

closing closes the settled inventory transactions, thereby excluding the closed transactions from further inventory processes. Inventory recalculation isn't a mandatory process. You can run it according to your business requirements—either daily, weekly, or monthly—to adjust the inventory transactions for reporting the accurate cost of the items based on the valuation method. Run inventory closing monthly for best performance.

What is inventory pre-closing?

Pre-closing replaces the *activate closing of non-financial transfer* functionality that was available in older versions of Supply Chain Management. Pre-closing finalizes non-financial transfers; this finalization allows the inventory closing process to safely ignore them, since closing and recalculation only affect financial transactions. *Non-financial transfers* are inventory transactions that have no effect on inventory costing, like inventory movement journal between two warehouses in the same site if warehouse isn't a financial dimension. You can explicitly run pre-closing if required as per the business requirements. Moreover, the closing and recalculation procedure always implicitly runs pre-closing for the non-financial transfers (among the transfer orders) against which markings are present.

What is inventory reversal? How is it different from canceling a closing?

If you need to revert the settlements or adjustments made by a closing or recalculation voucher, select the respective voucher and then select **Reverse**. This action posts equal but opposite settlements or adjustments in the ledger, balancing the changes made by the respective closing or recalculation voucher.

Use inventory reversal when you need to post any transaction in an already closed inventory period. In that case, the closing voucher is reversed, which opens the period and allows you to post transactions.

Inventory reversal and cancellation refer to the same operation and can be used interchangeably.

What is inventory revaluation?

For perpetual valuation models like moving average or standard cost, use inventory revaluation to revalue the on-hand inventory. Inventory revaluation works similarly to inventory recalculation. Use inventory revaluation to adjust the recorded value of inventory items to reflect changes in cost, market conditions, accounting corrections, or policy updates. This adjustment can either increase (appreciate) or decrease (depreciate) the value of inventory on hand in the system and general ledger.

What is the typical duration required to complete the inventory closing and recalculation process, and what factors impact the run time?

The duration required to complete the inventory closing and recalculation process can vary widely depending on several factors. It can range from a few minutes to several hours for most environments. Overall run time depends on:

- Volume of inventory transactions (issues versus receipts)
- Type of inventory transactions (source documents)
- Length of the period
- Number of items and inventory dimensions (site, warehouse, location, and so on)
- Real-time resource utilization and availability
- Parallel processes being run at the same time, number of active sessions, and so on

Because the closing process can run from few minutes to several hours, schedule the process during off-peak hours to avoid any business disruptions.

Why does my inventory closing or recalculation take so long? Can I speed it up?

As discussed previously, there's no fixed duration for inventory closing or recalculation. The overall run depends on the count of open or unsettled transactions, the nature of source documents, resource availability, parallel processing, parallel user sessions, and other factors. The following recommendations help you analyze the closing process:

- **Track progress of the run** – You can always track the progress of the closing or recalculation voucher from the **Closing and adjustment** page. Select the specific voucher and go to *Progress details*. You can find the bundles that have completed running and the ones that are still pending.

- **Run inventory closing regularly** – If you have a high volume of transactions and don't run inventory closing regularly at periodic intervals, you might experience performance issues as the count of open or unsettled transactions gradually increases in the system. Hence, run inventory closing regularly (preferably at monthly intervals) for customers with a high volume of transactions for better performance. You can check the time stamp for the most recent closing run. You can view this information from the **Closing and adjustment** page by filtering the **Type** as *Closing*. If you didn't run closing recently and have items that use any periodic valuation methods in your inventory, proceed with closing the inventory for the period nearest to your recalculation period.

- **Count of issue and receipt transactions** – During the adjustment process, issue transactions are adjusted with the receipt transactions. A large difference in the count of issue transactions and receipt transactions can impact the overall performance because the system might not find the required number of receipts to settle the large quantity of issues.

- **Circularity in inventory transactions** – Overall run time largely depends on your inventory transactions and the nature of your source documents. BOM journals are one of the source documents that consume a considerable amount of time in calculating the cost of the final product when the BOM structure is quite complicated, with lots of depth, consumption of scrap products, circular links in production and consumption, and other factors. If you have inventory transactions that pertain to any BOM journal, you can perform a basic BOM circularity check and eliminate any circular link. BOM circularity doesn't throw errors in the closing or recalculation process because the process has a specific design to handle such scenarios. However, BOM circularity increases the overall run time to a large extent. The same situation applies to transfer order circularity. Consider the scenario when there's a transfer from site 1 to site 2 and then again from site 2 to site 1. To improve performance, reduce and eliminate the possibility of any such circularity in BOM journals or transfer orders. For more information about BOM circularity check strategies, refer to the other FAQs in this article.

- **Review inventory performance parameters** – You can configure a few parameters to control the performance of closing and recalculation. Here's how to optimize these parameters:

  Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters** and open the **Inventory accounting** tab. In the **Closing** section, make the following settings:
  - **Extra Batch Helpers** – Set the number of extra threads to spawn based on thread pool availability to aid the running of the respective batch job. The default value for this parameter is *8*. You can increase this value based on the availability of your system resources. Learn more in batch capacity.
  - **Number of items per bundle** – Set the maximum number of items to keep in a bundle. The default value is *40*. An item is always present in a single bundle, and a single thread or task always processes a bundle. If your transactions have many items and a relatively comparable number of transactions per item, keep this value at *40*. If your inventory transactions don't have many items or instead have a large number of transactions for only a few items, set this value to *10*. Modify these values before starting the closing or recalculation process, not during the run.

  In the **Closing** or **Recalculation** dialog, make the following settings:

- **Maximum number of iterations allowed per item** – Pertains to cost calculations for circular links and is a trade-off between performance and accuracy. It determines the number of iterations for which the closing or recalculation process runs. Every iteration adjusts the cost of the item involved in the circular BOM. Hence, the more iterations, the better the cost accuracy for those items in the circular BOM. But you can't practically run this process infinitely, so the default iteration value is *100*. If your business transactions don't have many circular inventory transactions, or if you're fine with some approximate cost adjustments, consider reducing this value to reduce the overall run time.
- **Minimum amount allowed to be expensed** – Determines the minimum adjustment amount to be expensed while processing inventory transactions in every iteration. This parameter is again a tradeoff, like the previous one, but instead, performance is reversely proportional to the value. A lower value contributes to poorer performance but more accurate results. The default value is *1.00* in the accounting currency. Most companies don't modify this value, but it's up to your business requirements to determine an optimized value.

To improve the closing or recalculation performance, eliminate any circular links from your inventory transactions.

If you feel that the operation is running for an unusual amount of time, contact Microsoft Support or your partner to monitor the real-time run status and resource utilization.

How do I check circularity in BOM journals?

To check circularity in BOM journals, go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters** > **Bill of materials**. Enter the required values in **Level of circularity** and **Circularity check strategy**. The **Circularity check strategy** option works in conjunction with the **Level of circularity** option, so start by looking at the **Level of circularity** setting.

The **Level of circularity** setting determines when the system checks for circularity in BOM structures. A circular BOM exists when an item is defined as a component of itself within a BOM structure. A BOM is considered circular regardless of whether it's a first-level component or a lower-level component in the BOM structure that is referenced. Set it to one of the following values:

- *Line* – The circularity check occurs when you save the BOM line. This setting prevents you from adding a BOM line when the component item causes BOM circularity.
- *Never* – The system doesn't check for circularity. You can manually check for circularity errors by using the **Check** function on the **BOM line** page. If circularity exists, the error is also reported when you perform cost rollup and planning calculations.

- *BOM* – The circularity check occurs when you do any of the following activities: close the **Bills of materials** page, use the **Check** function on the **Bills of materials** page, or associate a BOM with a BOM version.

The controls that prevent a circular BOM don't apply to a production BOM or a production order. You can manually add a component or consume a component that creates BOM circularity. When the component consumption reflects BOM circularity, the inventory closing process might not calculate a sensible cost for a manufactured item that has an inventory valuation method using actual cost. In such an occurrence, the use of a manufacturing indirect cost of the surcharge type can also cause problems in inventory closing, because the calculated cost can grow exponentially.

For the **Circularity check** field, choose one of the following values:

- *Optimize for low complexity* – Requests data from storage as it's needed for the circularity check. For single-level or simple BOM structures, performance is better when you select this option.
- *Optimize for high complexity* – The system caches the BOM structure and all its dependencies before processing the circularity check. When processing a BOM with many lines, it might take a moment for the processing to start since it's loading the information into cache. However, the *Optimize for high complexity* option can significantly improve overall performance of the circularity check. This improvement is especially true if you're running a task that performs a circularity check on multiple BOMs or if you're doing a consistency check on the bill of materials.

You can use the following SQL query to fetch the items with circular links directly from the database. You could also convert this query to an X++ script and run it.

SQL

```
select p.itemid, c.itemid, p.REFERENCECATEGORY, c.REFERENCECATEGORY, c.REFERENCEID,
p.REFERENCEID, *
from INVENTTRANSORIGINASSEMBLYCOMPONENT a, INVENTTRANSORIGIN p, INVENTTRANSORIGIN c
where a.ASSEMBLYINVENTTRANSORIGIN=p.RECID
  and a.COMPONENTINVENTTRANSORIGIN=c.RECID
  and p.ITEMID=c.ITEMID
  and p.DATAAREAID=c.DATAAREAID
  and p.DATAAREAID = 'abc';
```

What are the best practices for running inventory closings and recalculations?

Here are some best practices for running inventory closings and recalculations:

- Run inventory closings and recalculations during off-peak business hours when the overall system load is lower. This schedule increases the availability of resources.
- Always run inventory closings, recalculations, and resume calculations as batch processes for better performance and error tracing.
- Verify the inventory closing parameters to ensure they fit your business operations.
- If you have a high transactional volume for a period that might prolong the closing run, divide the period into smaller time intervals and close those periods consecutively.
- If recalculation takes a long time, check when you last ran closing. You can view this information on the **Closing and adjustment** page by filtering the **Type** as *Closing*. If you didn't run closing recently and your inventory includes items that use periodic valuation methods, run inventory closing for the period nearest to your recalculation period. Closing the inventory closes the transactions and reduces the scope and volume for further inventory operations.

How can I analyze the issue and receipt transactions as part of the inventory closing and recalculation process?

Inventory closings and recalculations settle and adjust issue transactions to receipt transactions. If there aren't enough receipt transactions, the process temporarily stores many issue transactions in memory during the adjustment process. Run inventory closings or recalculations when the number of issue and receipt transactions is comparable. The inventory value report can provide a summarized view of issue versus receipt transactions.

You can also get this information directly from the database by running the following SQL query, which you could also convert to an X++ script.

SQL

```
select ITEMID, STATUSISSUE, count(*) countOfOpenTrans
from InventTrans
where PARTITION = 5637144576
  and DATAAREAID = 'abc'
  and STATUSISSUE <= 1
  and STATUSRECEIPT <= 1
  and VALUEOPEN = 1
  and DATEFINANCIAL <= 'closing_trans_date'
group by ITEMID, STATUSISSUE
order by ITEMID, STATUSISSUE, countOfOpenTrans desc;
```

What are the best practices for running inventory reversals?

Here are some best practices for running inventory reversals:

- Run inventory reversals during off-peak business hours to make better use of system resources.
- Always run inventory reversals one at a time. Running multiple reversals at the same time might lead to errors (such as *duplicate reverse is not allowed*) or even ledger data corruption.
- If your reversal run is very slow, check the number of batch helpers you're using. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters** and open the **Inventory accounting** tab. The **Extra batch helpers** field in the **Closing** section decides the number of parallel threads to use for the reversal task, based on thread pool availability. The recommended and default number of extra batch helpers is *8*. If your reversal run is very slow, consider increasing this value based on the real-time system resources availability.

Why did my inventory closing or recalculation end in an error? What should I do?

Several issues can cause inventory closings, recalculations, or reversals to end in an error. To find the exact error message, check the **Batch jobs** page for the related batch job and the **Closing and adjustment** page after you select the specific voucher, then view *log* details. If you can't fix these issues, contact Microsoft Support or your partner.

Possible reasons for errors include:

- **Over utilization of system resources** – Because these operations consume a considerable amount of resources, try running these operations during off-peak business hours and minimizing other parallel and background processes and user sessions. Also check whether the closing parameters match your business requirements and resource availability. For more information, see the other sections of this article.

- **SQL deadlock or availability issues** – Most of the SQL issues are transient. Retry the operation after selecting the specific voucher and selecting **Resume Calculation**. If the issue persists, check for the exact error from the **Batch jobs** or **Closing and adjustment** page and share them with your partner.

- **Business data corruption and inconsistencies such as rounding or currency issues** – Run a consistency check for the relevant item. Go to **System administration** > **Periodic tasks** > **Database** > **Consistency check**. In the **Consistency check** dialog, set **Module** to *Inventory management*, and set **Check/Fix** to *Check* or *Fix error* (depending or your business requirements). Then expand the **Item** tree and select the checkboxes for **Inventory transactions** and **On-hand**. Then open the **More** menu (three dots) and select *Dialog*. Use the dialog to filter for the exact item you want to check. If required, you can run the check as a batch process in the background. You can view the final check/fix logs

from the batch job logs or in the notification panel. If the consistency check doesn't highlight or fix any issues, use the **Potential conflicts - inventory and general ledger** and **Inventory value report storage** reports to drill down further into the discrepancies and inventory postings respectively.

- **Incorrect business practices**
- **Configuration issues like ledger, account, project, or warehouse setup**

When should I use the on-hand inventory adjustment on the Closing and adjustments page?

You can run the on-hand inventory adjustment only after you complete an inventory close. Typically, you run it for the date after the last close. The on-hand adjustment can adjust only inventory that's still on hand as of the date when you run the adjustment.

When should I use the inventory transaction adjustment on the Closing and adjustments page?

Use the inventory transaction adjustment before you run an inventory close. Typically, use it to correct an incorrect receipt. You can't post the inventory transaction adjustment after you run an inventory close and settle the transaction.

Are purchase order returns treated like other issues during the inventory close?

Yes. A purchase order receipt is an issue that the heuristic model you select for the item settles to a receipt. If you use a periodic costing model, you can use marking to override the heuristic cost.

What happens to sales order returns during the inventory close?

When you run the inventory close, the system treats a sales order return as a receipt into inventory. The system settles issues against the inventory based on the heuristic model that you select for the item.

What cost price is used on a sales order return?

When you create a return that relates to a sales order, the system copies the value of the **Unit price** field from the original sales order. The system sets the **Return cost price** field on the return to the adjusted cost price from the original inventory transaction for the sales order line that you're returning. If you set the **Value open** option for the related inventory transaction to *Yes*, the inventory close can update the issue cost on the original sales order. The **Return cost price** field isn't updated in this scenario. However, when you post a return order packing slip, the system checks the cost price and uses the updated cost on the return inventory transaction.

For a return of a standard cost item that relates to a sales order, the system uses the standard cost from the time of the original sales order, even if a new standard cost is active for the item.

When you create a return that doesn't relate to a sales order, the system sets the **Return cost price** field to the active item price for the item in the site that you're creating the return order for. If you don't have an active cost price in a costing version for the item, the value is 0. If you leave the value as 0, you receive a warning that states that the return lot ID or return cost price isn't specified.

Why are my inventory transactions posted at a different cost price?

Issue transactions are always posted at the running average cost. Receipt transactions are posted at the cost specified during posting the document line, or the latest activated cost price.

The system estimates this running average cost price for an item by using the following formula:

Estimated price = (Physical amount + Financial amount) ÷ (Physical quantity + Financial quantity)

If the **Include physical value** option isn't selected for an item in its item model group, the system uses 0 for both the physical amount and the physical quantity.

Learn more in Running average cost price

Why is item cost inflated?

The running average cost can be inflated when you price several inventory issue transactions that don't have enough receipt transactions. This issue can occur when you enable both **Include physical value** and **Physical negative inventory** for the item model group. If you disable **Include physical value** but still see this issue, make sure that you have also disabled **Physical negative inventory** for the item model group.

Learn more in Avoiding pricing amplification.

Why does the cost change after running inventory closing or recalculation?

Inventory closing or recalculation adjusts on-hand inventory and inventory transactions. After these operations, a cost adjustment or settlement modifies the resulting cost of the inventory transactions.

Why does the system reopen and adjust already closed inventory transactions?

This behavior is by design and might occur for items that use *Weighted average (date)* as the valuation model.

When the system settles or adjusts inventory through inventory closing or recalculation, it creates a summarized transaction for all issues and receipts separately. These summarized transactions settle or adjust issues to receipts. If you post a manual adjustment to any inventory transaction involved in previous summarized transactions and then run a new closing or recalculation, the system reopens and resettles or readjusts all inventory transactions that make up the summarized transaction.

I'm getting abnormal inventory costs reported for an item. How can I use the system to check or fix the issue?

Run a consistency check for the relevant item by following these steps:

1. Go to **System administration** > **Periodic tasks** > **Database** > **Consistency check**.
2. In the **Consistency check** dialog, set **Module** to *Inventory management*, and set **Check/Fix** to *Check* or *Fix error* (depending on your business requirements).
3. Expand the **Item** tree and select the checkboxes for **Inventory transactions** and **On-hand**.
4. Open the **More** menu (three dots) and select **Dialog**.
5. Use the dialog to filter for the exact item you want to check. If required, you can run the check as a batch process in the background.
6. View the final check or fix logs from the batch job logs or in the notification panel. If the consistency check doesn't highlight or fix any issues, use the *Potential conflicts - inventory and general ledger* and *Inventory value report storage* reports to drill down further into the discrepancies and inventory postings.

Once this process is completed and if the valuation method for that item is periodic, execute closing or recalculation to adjust the valuation and on-hand inventory as per the valuation

method.

Why does my ledger trial balance differ from the inventory value after I run closing, recalculation, or reverse?

Normally, you resolve this issue by rebuilding the trial balance for the corresponding main accounts from **General Ledger** > **Inquiries and reports** > **Trial Balance**.

Verify whether the inventory closing, recalculation, or reverse execution completed successfully and whether voucher postings are present. Cross check the status of batch job with the voucher execution status. Check the logs in the Closing and Adjustment form for the corresponding voucher. Once verified, rebuild the trial balance for the specific account where you observe the differences.

If the issue persists, then there's probably an inconsistency between the general ledger and inventory postings. Try generating a potential conflicts report to trace the items causing conflicts.

Next, generate an inventory value report for those specific items to trace the inconsistent inventory transactions. Run a consistency check for those items for on-hand inventory and inventory transactions to check whether it resolves the data inconsistencies. If the consistency check fix makes any changes to the inventory postings, execute inventory closing again and rebuild the trial balances to check whether the balance matches.

If these steps don't resolve the issue, contact Microsoft Support or your partner.

Costing sheet and indirect costs

Which costing models support the costing sheet?

Although organizations that use standard costing typically use the costing sheet, you can use it with any costing model that's available in Supply Chain Management.

Can I have multiple costing sheets for various parts of my organization?

No. You can have only one costing sheet per legal entity.

Can I have different costing sheets for each site?

No, you can't have a different costing sheet for each site. You can create only one costing sheet for each legal entity. However, you can configure total nodes, cost groups, or indirect cost nodes per site. This configuration is a manual process, and you must maintain the hierarchy and item assignments on the costing sheet when organizational or operational changes occur. If a single item is produced or purchased in more than one site, there's no mechanism that lets you treat the item differently on the costing sheet for each site. All indirect cost codes have a rate or surcharge that is defined in your costing version. The costs that you define are always site specific.

Can I deactivate and activate versions of the costing sheet?

Although the system doesn't keep detailed version history for the costing sheet, you can make changes to the costing sheet and then, when you're ready, save and validate it. There's no mechanism that lets you go back to an older version of the costing sheet or view the changes that you made to the costing sheet. If you start changes and don't want them to take effect, you can close the page without saving and validating the changes. You're prompted to discard the changes.

Can I create indirect costs for each item?

On your costing sheet, you can create indirect cost codes where the **Node type** field is set to *Surcharge*, *Rate*, or *Output unit based*. You can then define the rate or surcharge so that it's specific to an item number. On the **Rate** or **Surcharge** FastTab, add a row to the grid. Set the **Valid for** field to *Table* and the **Relation** field to the specific item number.

Can I create an indirect cost that isn't related to a specific item?

Yes. You can create an indirect cost code where the **Node type** field is set to *Output unit based*. You can then set the **Subtype** field to *Quantity*, *Weight*, or *Volume* to specify the quantity, weight, or volume of the item that you're producing. The rate that you specify on the **Rate** FastTab is applied to the subtype that you selected. For example, you set the **Subtype** field to *Quantity* and the **Rate** field to *1.00 USD*, and then create a production or batch order for a quantity of 10. In this case, the indirect cost that is added to the finished good is 10.00 USD.

Can I use the costing sheet to split my production costs by hours and materials?

Yes. You can create **Total** nodes on your costing sheet to separate the costs by any grouping that you choose. For example, you can create one **Total** node that is named *Hours* and another

that is named *Materials*. Under the **Hours** node, add each code group that is related to your hours. Under the **Materials** node, add each cost group that is related to your materials.

Dimension groups

Can I manage cost at the batch or serial number level?

Yes, if you're using a periodic costing model such as FIFO, LIFO, LIFO date, weighted average, or weighted average date, you can enable the **Financial inventory** option for the **Batch** or **Serial number** dimension in the tracking dimension group to track costs at a detailed level.

Can I manage costs at the location level?

No, you can't enable the **Financial inventory** option for the **Location** dimension in the storage dimension group. If your organization must track costs at a more detailed level, consider whether you can create virtual warehouses, and then select the **Financial inventory** option for the **Warehouse** dimension in your storage dimension group.

Should I enable the Use warehouse management processes option for the storage dimension group?

If you think that you might want to use the warehouse management processes (WMS) features in the future, you should enable the **Use warehouse management processes** option. After you save a storage dimension group, you can no longer change the setting of the **Use warehouse management processes** option for it. If you decide to use warehouse management processes later, you'll have to create a new warehouse where the option is enabled. There's no automated process that you can use to move all the inventory from one warehouse to another warehouse, or to copy related configurations to a new warehouse.

Can I enable the Use warehouse management processes for the storage dimension group even if I'm not planning to use warehouse management processes (WMS)?

Yes, even if you don't plan to use the warehouse management processes (WMS) features, you can enable the **Use warehouse management processes** option for the storage dimension group. To create and process transactions, you need to complete the minimum configuration, such as reservation hierarchies and unit sequence groups. However, the settings for WMS are generally ignored when you manually process picking lists, packing slips, and product receipts (for example, on the sales order and purchase order pages).

When should I enable the Physical inventory option for a storage or tracking dimension group?

Enable the **Physical inventory** option for storage and tracking dimension groups when you need to keep detailed inventory records based on that dimension. Typically, any dimension that's active is also physically tracked. Therefore, the system tracks any receipt, issue, or movement of the inventory by the selected dimension. If a dimension isn't mandatory (for example, the license plate), you can enable the **Blank receipt allowed** and **Blank issue allowed** options to let users receive, issue, or move inventory even when the dimension isn't specified.

When should I enable the Financial inventory option for a storage or tracking dimension group?

Enable the **Financial inventory** option for storage and tracking dimension groups when you need to keep detailed financial records based on that dimension. The **Site** dimensions are always financially tracked, whereas other dimensions are optional for financial tracking. If you use a periodic costing model such as FIFO, LIFO, or weighted average, enabling the **Financial inventory** option for a dimension indicates that you make settlements only in cases where the receipt and issue have the same dimension values. For example, if you enable the **Financial inventory** option for the **Warehouse** dimension, you have a different cost in each warehouse, and receipts and issues from different warehouses can't be settled.

Can I make changes to a product, storage, or tracking dimension group after transactions exist?

After you create an item model group, you can change the setting of the **Coverage plan by dimension**, **For purchase prices**, and **For sales prices** fields if you select the **Active** checkbox for a dimension in the item model group. You can't make any other changes. For example, you can't enable or disable the **Active**, **Blank issue allowed**, **Blank receipt allowed**, **Physical inventory**, and **Financial inventory** options.

Can I change the product, storage, or tracking dimension group for a released product?

If the on-hand inventory for a product is 0 (zero), and you set the **Value open** option to *No* for all the inventory transactions, you can change the storage and tracking dimension groups on the released production page. You can't change the product dimension group after the record is created.

Item model groups

When should I enable the Stocked product option?

Enable the **Stocked product** option for any item that you want to track in your inventory. When you enable this option, the system keeps detailed inventory transactions that track the receipt and issue of the item. Typically, you enable this option for any tangible item that you keep in your warehouse. You should also enable this option if you plan to add a non-tangible item such as a service item to your bills of materials (BOMs) or formulas. If you don't enable the **Stocked product** option, the system doesn't track any inventory transactions in the inventory subledger, and the cost of the items is typically expensed into your general ledger. For example, you might use this option for shop supplies or services that aren't included in your BOMs or formulas.

When should I enable the Post physical inventory option?

Typically, you enable the **Post physical inventory** option when you also enable the **Stocked product** option. When you enable this option, the system tracks the physical update to the item on the inventory transaction. Use this option in coordination with parameters in Accounts payable, Accounts receivable, and Production control that specify that the physical update should create a voucher. You typically enable this option when you want the ledger to be updated whenever you physically update the inventory. If Supply Chain Management isn't your system of record for financials, you might want to disable this option.

When should I enable the post Financial inventory option?

Typically, you enable the **Post financial inventory** option when you also enable the **Stocked product** option. Use this option in coordination with parameters in Accounts payable, Accounts receivable, and Production control that specify that the financial update should create a voucher. You typically enable this option when you want the ledger to be updated whenever you financially update the inventory (for example, by invoicing sales orders and purchase orders, or ending a production order). If Supply Chain Management isn't your system of record for financials, you might want to disable this option.

When should I enable the Post to Deferred Revenue Account on Sales Delivery option?

Use the **Post to Deferred Revenue Account on Sales Delivery** option to indicate whether you want to recognize revenue in the general ledger when you post a packing slip for a sales order. Use this option when there's a long delay between the packing slip and invoice on a sales

order, or when it's not possible to invoice all sales orders in the period. Typically, disable this option if you post your sales order invoices immediately after you post the packing slip. In this way, you avoid generating extra general ledger postings that are immediately reversed when you invoice a sales order.

When should I enable the Accrue liability on product receipt option?

In most organizations, enable the **Accrue liability on product receipt** option for all item model groups, regardless of whether you have a stocked product or a not-stocked product. Use this option to post an accrual to the general ledger, based on product receipt price. Because there's typically a delay between posting of the product receipt for a purchase order and posting of the invoice, most organizations must recognize the liability on the balance sheet to comply with local regulations such as Generally Accepted Accounting Practices (GAAP). If Supply Chain Management isn't your system of record for financials, you might want to disable this option. If your organization uses procurement categories on purchase orders, you can control the accrual requirement by enabling the **Accrue purchase expense on receipt** option for the category policy rule on the **Purchasing policies** page.

How can I prevent a user from posting a purchase order product receipt if a receipt registration isn't yet posted?

You can prevent a user from posting a purchase order product receipt if a purchase order registration isn't yet posted by enabling the **Registration requirements** option for the item model group. Use this option in organizations that use a two-step receiving process, or in scenarios where you must register a batch or serial number, for example, on the items that you're receiving. The **Registration requirement** option applies to *all* inventory receipts for an item, not just to purchase orders. For example, it applies to an inventory journal that has a positive quantity and a production order report as finished journal.

How can I prevent a user from posting a purchase order invoice if a product receipt isn't yet posted?

You can prevent a user from posting a purchase order product invoice if a purchase order product receipt isn't yet posted by enabling the **Receiving requirements** option for the item model group. Use this option in organizations that require that receipts be physically recognized in the general ledger for accruals. The **Receiving requirement** option applies to *all* inventory receipts for an item, not just to purchase orders. For example, it applies to an inventory journal that has a positive quantity and a production order report as finished journal. If your organization uses procurement categories on purchase orders, you can control the

requirement for a receipt by enabling the **Receiving requirements** option for the category policy rule on the **Purchasing policies** page.

How can I prevent a user from posting a sales order packing slip if a sales order picking list isn't yet posted?

You can prevent a user from posting a sales order packing slip or invoice if a sales order picking list isn't yet posted by enabling the **Picking requirements** option for the item model group. Use this option in organizations that perform a physical picking process in the warehouse (for example, by using the warehouse mobile device to do picking). The **Picking requirement** option applies to *all* inventory issues for an item, not just to sales orders. For example, it applies to an inventory journal that has a negative quantity and a production order picking list journal.

How can I prevent a user from posting a sales order invoice if the sales order packing slip isn't yet posted?

You can prevent a user from posting a sales order invoice if a sales order packing slip isn't yet posted by enabling the **Deduction requirements** option for the item model group. Use this option in organizations that perform a physical packing process in the warehouse (for example, by using the Warehouse Management mobile app to do packing or by generating a document that will be included with the items that are shipped). The **Deduction requirement** option applies to *all* inventory issues for an item, not just to sales orders. For example, it applies to an inventory journal that has a negative quantity and a production order picking list journal.

Can I prevent items that are registered from being sold?

When you register an item in your inventory in Supply Chain Management, the quantity is physically available to be issued in the system. If items that you registered but didn't yet receive shouldn't be available to be issued to sales orders or production orders, for example, consider using the inventory status, inventory blocking, quality orders, quarantine orders, or reservations features to manage the business process.

Production costing

Can I use one costing model for raw materials and a different costing model for finished goods?

Yes, you can use different costing models for each item. It's common for manufacturers to use a periodic costing model for raw materials and standard cost for semi-finished and finished goods.

How can I drive overhead off machine costs?

To drive overhead off your machine costs, you must create resources and resource groups for each machine, according to your business requirements. You can assign each resource or resource group to cost categories to control the cost of the machine. You can link each cost category to a cost group, and use each cost group as the basis for calculating indirect costs on the costing sheet.

How do I recognize costs related to energy consumption (for example, water, energy, or gas consumption) on the costing sheet?

You can generally recognize costs related to energy consumption in one of two ways:

- Create a line in your BOM or formula. Typically, you create this line as a service item, and you can specify the unit of measure that you're consuming in relationship to the quantity you're producing. In this way, the user can consume a different amount during the production process. You can automatically consume the items based on the value that you select in the **Flushing principle** field.
- Create an indirect cost on your costing sheet. Typically, you use this approach to allocate the total cost of your energy consumption across your production process. You can use the cost group and the absorption basis to scale the consumption based on materials or labor in your route, for example.

Select the best option based on your reporting, reconciliation, and operational requirements.

Can I capture resource details in the BOM or formula?

You can capture resource details only in a route operation. Although you can create a service item to represent a resource and assign a cost to increase the cost calculation for a finished good, we don't typically recommend this approach. Instead, create a simple route that has one line to track the resource costs, and configure the operation so that it's automatically consumed at either the start or the end of the production order.

Can I view the calculation details if I manually enter the cost?

No. If you manually enter the price on the **Item price** page, the **View calculation details** and **Report calculation details** buttons aren't available. If you select the **Cost rollup by cost group** button for a cost price that you manually enter, a summarized line is shown, and all costs roll up to the finished good item.

Does the system calculate variances on a production order when I manually enter the cost?

Yes, the system calculates variances when you manually enter a standard cost. However, when you manually enter a standard cost instead of calculating it, all material, route, and indirect cost consumptions in the production order are considered a substitution variance. If there are additional variances, such as consumption of extra materials or labor, the system also records them as variances from the production BOM. Therefore, always run a calculation for items that have a BOM, route, or indirect costs.

How can I carry the variances from a subproduction order to the parent production order?

When you use a periodic costing model such as FIFO, LIFO, or weighted average, the costs from a subproduction are recognized in the heuristic model that you select for the items. If you require actual costing, use the marking principle to indicate which subproduction is issued to a parent production order. Alternatively, use the **Financial inventory** option for the **Batch** or **Serial number** dimension in the tracking dimension group.

How does the flushing principle affect consumption?

The flushing principle on a BOM, formula, or route line controls the timing and technique that the system uses to consume the item or labor. If you select *Start*, the system automatically consumes the item or labor when you start the production order. If you select *Finish*, the system automatically consumes the item or labor when you report the production order as finished. If you select *Manual*, a user must manually pick materials or record the time in a job or route card journal. BOMs and formulas also have an *Available on location* option. If you select this option, the system automatically consumes the items after it transfers them to the production floor location.

How should I run cost calculations if I have multilevel BOMs or formulas?

In general, start at the lowest level of your BOMs or formulas for the calculation. To make filtering easier when you mass-run cost calculations, use calculation groups to help segregate

products. Run the *Recalculate BOM levels* periodic job before you start to mass-run cost calculations. Each organization should consider the mix of products and define a strategy that meets the specific needs of your product and BOM or formula structures.

Transfer order costing

Is there a way to allocate freight to a transfer order cost?

Add charges to a transfer order to add costs. The charges code defines the debit and credit for the charge that you're adding. First, create charges codes in the **Inventory management** module. To add a charge to a transfer order, select **Charges** on the transfer order line that you want to add a charge to.

Variances

Can I treat variances differently, based on the site or warehouse?

There's no option to configure variance accounts by site. When you use standard costing for a released product, you can select the main account that is used for standard cost variance postings on the **Posting** page. You can select to configure the accounts for one item, a group of items, or all items. You can also configure one cost group, a group of cost groups, or all cost groups.

Can I separate variances that are the result of currency exchange rates from other types of variances?

If a variance results from a currency exchange rate difference between the purchase order price and the standard cost for an item, you can't separate the exchange rate difference from other variances.

Reporting

How many inventory value report configurations can I create and use?

You can create unlimited inventory value report configurations. Evaluate your specific reporting requirements and create the number of configurations that you need to meet those requirements. You need at least one inventory value report configuration to run the report or the report storage option.

Can I use the inventory value report to analyze the cost of an item in each warehouse?

Yes. You can enable the **View** or **Total** option for each **Warehouse** dimension in the inventory value report configuration. However, the report shows values only for dimensions where the **Financial inventory** option is enabled for the storage dimension group. For other dimensions, it shows blank columns. Learn more in Inventory value report examples and logic.

How can I view the inventory quantity as of a specific date with the weighted average?

You can use the **Inventory aging** report, which includes an **Average unit cost** column that shows the value of inventory as of a specific date. Learn more in Inventory aging report examples and logic.

How can I view which receipt transactions are settled against an issue transaction?

You can view the settlements for an inventory transaction by selecting **Settlements** or **Cost explorer** on the **Inventory** tab on the Action Pane of the **Inventory transaction** or **Inventory transaction details** page. If you select a receipt to view the issues that are related to the transaction, the cost explorer doesn't show the details. Details are shown only if you select an issue transaction.

How does the inventory value report show items that have a positive physical quantity and a negative financial value?

The inventory value report separates the physical and financial amounts and quantities into their own columns. The values that are shown on the report are as of the date range that you selected when you ran the report. The level of summarization that is shown depends on the settings that you selected. If an item has transactions that are physically received and financially issued, the quantities and values are summed independently. If you select to view the detail level as transactions, rows for each receipt and issue are shown separately, and the

physical and financial quantities and amounts, respectively, are shown. Learn more in Inventory value report examples and logic.

What is the impact of storage and tracking dimension groups on the inventory value report?

If you enable the **Financial value** option for a dimension in a storage or tracking dimension group, you can select the **View** or **Total** option for the dimension in the inventory value report configuration. If you select the **View** or **Total** option for a dimension where the **Financial value** option isn't selected, the column is blank in the report output. If you enable the **Financial value** option for a dimension in a storage or tracking dimension group, and you don't select the **View** or **Total** option on the inventory value report configuration, the system summarizes the values for the selected dimensions where they're financially tracked.

Can I customize the Power BI embedded reports for costing?

Yes, users who have the correct security permissions can update the report design canvas for any Power BI embedded report in Supply Chain Management. Learn more in Customize embedded reports in analytical workspaces.

Where can I view the variance analysis statement?

You can access the variance analysis statement by going to **Cost management** > **Inquiries and reports** > **Inventory accounting – analysis reports** or **Cost management** > **Inquiries and reports** > **Manufacturing accounting – analysis reports**. Both options open the same report, and the report has the same behavior.

Item prices and default costs

Can I maintain the cost for each product variant?

Yes. You can enable the **Use cost price by variant** option on the **Manage cost** FastTab of the **Released product** page to enable pricing by product variant. (This option is available only for product masters.) Then, on the **Item price** page (which you can open from either the **Costing version** page or the **Released product** page), you can select **Dimensions display** to specify whether you want to show the **Configuration**, **Size**, **Color**, or **Style** dimension. To save the setup and use the selected dimensions every time that you open the page, enable the **Save setup** option, and then select **OK**. You can enter the dimensions only for items where the dimensions are active in the product dimension group.

Can I maintain the cost for each warehouse?

No, you can't maintain the item price by warehouse. However, you can maintain trade agreements for purchase prices or sales prices by warehouse. First, select the **For purchase prices** or **For sales prices** option for the dimension on the **Storage dimension group** page. Then, when you create the trade agreement journal and open the lines for the dimensions, select **Inventory** > **Display dimensions** to select which dimension should be shown in the grid. To save the setup and use the selected dimensions every time that you open the page, enable the **Save setup** option, and then select **OK**. You can enter the dimensions only for items where the dimensions are active in the product dimension group.

What are price charges?

Price charges provide a way to add a fixed amount to the unit price of the item price or trade agreement. When you enter an amount in the **Price charges** field, you can also enter a value in the **Charges quantity** field. The price charges are amortized over the charges quantity that you specify. Enable the **Incl. in unit price** option if you want to include the price charges in the unit price for the item. This option is always enabled for a standard cost.

How should I configure prices for items that are procured in multiple currencies?

If you enter a default price in the **Purchase price** field on the **Released product** page, the system assumes the price is in the accounting currency of the ledger for the legal entity that you're in. Likewise, if you enter a purchase price in a costing version where the **Price type** field is set to *Purchase*, you assume the price is in the accounting currency of your legal entity. When you create a purchase order for a vendor that has a different currency, the system automatically converts the currency from the accounting currency amount to the transaction currency by using the exchange rate that you specify in the **Accounting currency exchange rate type** field in your ledger.

When you create a trade agreement journal, you can specify the currency that you're expressing the price in on each line. You can create trade agreements for multiple currencies, specific vendors, and many other combinations of factors. If you create a purchase order where a trade agreement exists for the currency that you selected, the system uses the trade agreement that has the matching currency. When you post transactions such as product receipts or invoices, the amount is converted to the ledger's accounting currency by using the accounting currency exchange rate that you specify in the ledger.

How should I configure costs for items that are procured in multiple currencies?

You can't configure costs in more than one currency. The cost that you specify for the item price or default costs that you enter in the **Price** field on the **Manage cost** FastTab of the **Released product** page are always expressed in the accounting currency of the ledger for the legal entity that you select.

If your organization uses standard costing, you should define a strategy for defining the costs when there are multiple currencies. You should also define a process for regularly updating the cost to help reduce the number of variances that are posted.

Can I use the Profit setting on the Cost group page to calculate sales prices?

Yes, you can use the **Profit** setting on the **Cost group** page to add a percentage when sales prices are calculated by using a cost calculation. Learn more in BOM calculations.

Marking

How does marking affect periodic costing models?

If you use a periodic costing model such as FIFO, LIFO, or weighted average, and you mark a receipt transaction against an issue transaction, the inventory close process ignores the heuristic model of the item. Instead, the system uses the actual cost of the receipt for the cost of the issue.

What happens during the inventory close when I use marking?

When you mark receipts and issues, the inventory close settles the marked transactions together. When marking is used to create the settlement, the **Principle** field on the **Settlement** page is set to *Marking*. If you mark a transaction before physically or financially updating it, the issue uses the marked receipt's cost instead of the running average cost. If you mark the transactions after the financial update, the inventory close and adjustment process adjusts the issue cost so that it matches the receipt cost.

Can I manually mark transactions when I use standard costing or moving average?

No, you can't manually mark receipts or issues when you use standard costing or moving average. If transactions (for example, direct delivery or intercompany orders) are automatically marked, the marking record remains and acts as a hard reservation. However, when you use standard costing or moving average, the marking of records has no effect on the cost of the items.

How does marking affect the profit and loss statement?

When you mark an issue transaction against a receipt, the cost for the issue matches the selected receipt. When you physically and financially post the issue, the posting affects the **Cost of goods sold, delivered** and **Cost of goods sold, invoiced** accounts that you specify in the inventory posting profile. If you mark a transaction after the physical or financial update, the *Inventory close and adjustment* process creates an adjustment that has a matching voucher that adjusts the **Cost of goods sold, invoiced** account and offsets to the account that you specify for **Cost of units, invoiced** (inventory).

How does marking affect master planning?

The **Standard update** tab on the **Master planning parameters** page includes a field named **Update marking**. The option that you select is used when you firm a planned order that master planning generates. The following options are available:

- *No* – The system doesn't perform any marking.
- *Standard* – The system marks receipts against issues according to the pegging. A requirement order is marked against a fulfillment order. If some quantity remains on the fulfillment, the fulfillment order isn't marked.
- *Extended* – The system marks both the requirement orders and fulfillment orders, regardless of whether any quantity remains open on the fulfillment order.

Negative inventory

When should I allow physical negative inventory?

In general, don't allow physical negative inventory, because you can't have less than zero of a tangible item in your warehouse. However, some industries and business scenarios require physical negative inventory. For example, retailers might not want to prevent the sale of an item that a customer brings to the register, even when the system indicates that no items are available. Process manufacturers provide another example. For these manufacturers, the amount that is consumed can exceed what is recommended in the formula. Alternatively, the

consumption might be estimated instead of precise, so that the consumption exceeds the amount in a specific location, such as a tank.

Whenever possible, evaluate your business process and try to improve it to ensure that inventory can't be negative. If you must allow negative inventory, establish a clear business process for correcting the negative inventory, because it can adversely affect costing.

When should I allow financial negative inventory?

In general, allow financial negative inventory. (In most cases, the system doesn't process purchase order invoices before you can ship the items.) Enable this option when you have specific business processes that require the sales price to reflect the final cost of a purchase order. For example, this requirement might apply in a make-to-order industry or in specific regions where it's dictated by law.

What happens to the cost of my issues when the inventory is negative?

When the inventory for your item is negative, and you issue more items than you physically have, the system uses the default item price to calculate the running average if you use a periodic costing model such as FIFO, LIFO, or weighted average. If you don't specify a default price for the item, the system issues the inventory with a value of zero. This behavior can cause future calculations of your running average or moving average to be inaccurate.

Can I prevent items from being picked, packed, or sold on sales orders and production orders if there isn't enough on-hand inventory?

Yes. Disable the **Physical negative** option for the item model group to prevent items from being picked, packed, or sold on sales orders and production orders.

Can I prevent items from being invoiced on a sales order if no purchase orders have been invoiced for the same item?

Yes. Disable the **Financial negative** option for the item model group to prevent items from being invoiced on a sales order if no purchase orders are invoiced for the same item.

How does negative inventory affect financial ratios such as gross profit margin?

When you allow your inventory to go negative, the inventory value in your balance sheet and the cost of goods sold in your profit and loss statement can be understated, especially if you don't configure a default price for your items. Therefore, financial reporting and ratios such as gross profit margins can be overstated, because the cost is incorrect. If you use a periodic costing model such as FIFO, LIFO, or weighted average, you can adjust the value of the issues when you run the inventory close and adjustment process after the negative inventory quantities are corrected. However, if you use moving average, there's no way to revalue the individual transactions.

How do I correct negative inventory?

Frequently monitor and correct negative inventory when your organization or business requirements dictate that you allow your inventory to go negative. You can correct the inventory values by performing a cycle count, posting an adjustment, or posting a movement journal. If you must recognize the unexpected gains in inventory in a specific general ledger account, plan to use a movement journal. Otherwise, when you use the cycle counting or inventory adjustment process, the system posts the inventory adjustment to the **Inventory receipt** account and offsets to the **Inventory expenditure, profit** accounts that you specify on the inventory posting profile.

Do I have to create a new item if my inventory goes negative and I use moving average?

No. If your organization allows inventory to go physically negative, and you're using moving average as your inventory model, the system uses the fallback cost sequence that you assign on the **Inventory and warehouse management parameters** page to determine how the system assigns cost to your issues. In general, avoid allowing your inventory to go physically negative. For more information, see the other questions in the Negative inventory section of this article.

Not-stocked products

Can I post sales order picking lists for not-stocked products?

When you generate a picking list for a sales order that includes items in an item model group that isn't stocked, you don't see any lines for those not-stocked items. You can't use the Warehouse Management mobile app to process not-stocked items.

When you generate a packing slip for a sales order that includes items in an item model group that isn't stocked, set the **Quantity** field to *Picked quantity and not stocked products* to include

the not-stocked items in the document generation. If you select *All*, only stocked items are included in the packing slip.

Should I use a not-stocked product or a category (sales category or procurement category)?

The choice between a not-stocked product and a category depends on your specific business requirements. Not-stocked products generally offer more control over default values, such as quantities and prices on purchase orders and sales orders. Therefore, use not-stocked products in scenarios where you purchase or sell the same product or service more than once. Categories are useful in scenarios where the price, items, descriptions, and so on are inconsistent from transaction to transaction. You can also use categories on any product to help classify the type of product that you're selling or purchasing.

Service items

What is the difference between a service item and a not-stocked product?

A service item is a product type. When you create a newly released product, you can set the **Product type** field to either *Item* or *Service*. Typically, select *Item* to indicate that the item is tangible, and select *Service* to indicate that the item is intangible.

Any released product, regardless of whether it's an item or service product, can be stocked or not-stocked. The stocked or not-stocked setting is controlled by the item model group that you select for the released product. When you select an item group that isn't stocked, the system doesn't create inventory transactions for the related sales order or purchase order, for example.

Can I include not-stocked items in a BOM?

No, you can't include a released product that is linked to an item model group where the **Stocked** option is disabled in a BOM or formula. It doesn't matter whether the **Product type** field is set to *Item* or *Service*. You can only include stocked items on BOM or formula lines.

Costing model–specific questions

Which costing model should I use?

The costing model you select depends on your business requirements. Before you select a costing model to use in Supply Chain Management, validate that your local regulations allow the model. We recommend that you validate your selection with a certified accountant in your region.

Can I use more than one costing model in my organization?

Yes. You can select as many item model groups or costing models as you need in Supply Chain Management.

Can I use more than one costing model for each item?

No. You can select only one costing model for each released product. The item model group controls this behavior. If you need to use more than one costing model to report on inventory values, consider using the Global Inventory Accounting add-in.

When I use manufacturing execution, which costing methodology should I use?

The costing model you select depends on your business requirements. There's no specific advantage or disadvantage to using any costing model when your organization also uses manufacturing execution.

When is FEFO used?

First expired, first out (FEFO) isn't a costing methodology. Instead, it's a reservation technique that's often used in manufacturing organizations. You can enable FEFO reservations for an item model group by enabling the **FEFO date-controlled** option and then selecting a value in the **Pick criteria** field.

Are there performance benefits to selecting one costing model over another?

In general, the costing model that you select for an item has minimal impact on the overall performance of the system. However, the inventory costing model that you select might affect the amount of time required to run the inventory close or recalculation process. For example, if you use standard cost or moving average, the inventory close process has minimal impact on the system, because it doesn't update each inventory transaction and create settlements. However, a periodic costing model such as FIFO, LIFO, or weighted average can increase the amount of time required to complete the inventory close process. Specifically, the close

process can be longer when you enter a high number in the **Maximum number of iterations allowed per item** field or a low number in the **Minimum amount allowed** field for the *Close inventory* process.

When should I use the Fixed receipt price option?

When you select the **Fixed receipt price** checkbox on the **Item model group** page for an item, the system uses the receipt price as the standard cost for the inventory receipt. If there's a difference between the purchase price and the default item cost price that you configure for a product, the system posts the difference to the **Fixed receipt price profit** or **Fixed receipt price loss** account, and offsets it to the **Fixed receipt price offset** account. You specify all these accounts on the **Posting** page.

Select the **Fixed receipt price** checkbox when you use a periodic costing model such as FIFO, LIFO, or weighted average, and you want to track a purchase price variance in the ledger if the price of a receipt differs from the default item cost.

Moving average

Is moving average the same as a floating average?

The terms moving average, floating average, and running average are often used synonymously. Of these terms, moving average is the only official costing model that's available in Supply Chain Management. Although running average isn't an official costing model, it's the technique that is used when you use a periodic costing model such as FIFO, LIFO, or weighted average. The term floating average isn't used in Supply Chain Management and might have different connotations in other systems.

How can I accommodate the difference between the product receipt price and invoice price when I use moving average?

When you use moving average, the physical cost (receipt price) is used to calculate the moving average for all issue transactions. If there's a difference between the physical cost (receipt price) and the financial cost (invoice price), the system automatically posts the difference to the main account that you specify for the **Price difference for moving average** posting type on the **Inventory** tab of the **Inventory posting profile** page.

Where is the price difference for moving average presented in the general ledger?

When there's a price difference between the posting of a physical update and a financial update for a receipt, the system posts the difference to the main account that you specify for the **Price difference for moving average** posting type on the **Inventory** tab of the **Inventory posting profile** page. Learn more in Moving average.

When I use moving average, what happens if there's an issue before the receipt?

Typically, there might be an issue before the receipt either because you allow physical negative inventory for the item model group or because the issue is backdated. Learn more in the Negative inventory section of this article.

If you backdate transactions, carefully consider your business process and operations to determine whether there's a way to avoid this scenario. If you backdate a transaction for an item that uses moving average, the system assigns the current moving average to the transaction. Later issues aren't adjusted. Learn more about moving average with backdated transactions in Moving average.

Standard costing

What is the difference between standard costing and fixed receipt price?

Standard costing requires that you define an item price and activate the cost in a costing version. The system uses that cost for all receipts and issues. The system records variances for the receipts to inventory in the general ledger by using the standard cost variance accounts that you specify on the **Standard cost** tab of the **Inventory posting profile** page.

However, when you use fixed receipt price, only the cost for receipts is fixed. The system uses the cost that you specify on the **Manage costs** FastTab of the **Released product** page. Differences between the default cost and the purchase order price cause the purchase price variance to be posted to the fixed receipt price profit and loss accounts. Issues don't use fixed receipt price. Instead, issues are valued at the running average at the time of posting (unless you use marking), and they're revalued to the heuristic model that you select when you run the inventory close.

Can I use FEFO reservations with standard costing?

Yes, you can use FEFO reservations on an item model group when you select standard costing. FEFO reservations control the reservation logic that's used for the physical handling of the

items, whereas standard costing controls the physical and financial cost for an item.

Can I upload pending prices?

Yes, you can use the Excel add-in or the Data Management Framework to upload a pending price. Use the following entities:

- Pending item prices (V2)
- Pending route cost category unit costs
- Costing sheet node calculation factors (V2)

How often can I update the standard cost for an item?

You can activate a new standard cost as often as you want. If you activate a new cost for an item on the same day that you activated the last cost, the system uses the most recent activated cost on new transactions or updates (such as updates to existing transactions).

Can I deactivate or delete an activated cost?

No, you can't deactivate or delete an activated cost. If you incorrectly activate a cost, you can activate a new cost that has the correct cost.

Are calculation groups used with standard costing?

You can use calculation groups with any item, regardless of the item model group that you choose. The cost rollup or cost calculation process uses the calculation groups to determine the settings for the items that you're running the calculation for. Learn more about calculation groups in BOM calculations groups.

When should I use a planned costing version?

Costing versions can have a type of *Standard cost* or *Planned cost*. Use the *Standard cost* type for costs that are active in the system and that you post in transactions. Use the *Planned cost* type for running simulations on costs. This type doesn't affect the cost of transactions.

Can I transfer the total cost from one entity to another entity as the selling cost?

There's no automated way to copy costs from one company to another. Additionally, there's no automated way to copy costs from a purchase price to a sales price. If your organization must

complete one of these tasks, consider whether you can use the Data Management Framework to export the data out of your costing version and upload it into a different company, either as a sales price in the costing version or as a trade agreement. You might need to manually manipulate the files.

What's the best way to copy planned costs to a standard costing version?

Use the **Copy** button on the **Costing versions** page to copy item prices, cost category prices, or indirect costs from one costing version to another.

Last updated on 11/26/2025

Prerequisites for standard costs

This article describes the basic steps for using standard costs. Subsequent steps depend on the company's operations. For example, the steps differ for a non-manufacturing environment, a manufacturing environment that doesn't use routings, and a manufacturing environment that uses routings.

To set up standard costs, follow these steps:

1. Create an item model group for standard costs.

   Use the **Item model groups** page to create a new group for standard costs, and assign an inventory model of *Standard cost*. The identifier for the item model group should be meaningful, such as *Std Cost*. Select the check boxes to indicate that the group should allow financial negative inventory, and that it should post physical inventory and financial inventory. This standard cost group is assigned to items.

2. Define ledger accounts that are related to standard cost variances.

   Use the **Chart of accounts** page to define ledger accounts that are related to standard cost variances. These ledger accounts must be defined before they can be assigned on the **Posting** page. The ledger accounts can reflect item groups and cost groups.

3. Assign ledger accounts to item postings that are related to standard cost variances.

   Use the **Posting** page to assign the ledger accounts that are related to standard cost variances. You can specify a variance's ledger account by item (or item group) and by cost group (or cost group type), or you can specify that the ledger account applies to all items and all cost groups. These options correspond to cost relations for tables, groups, and all.

   Before you define the item posting rules, use the **Transaction combinations** page to enable cost relations (for tables, groups, and all).

4. Define inventory parameters that are related to standard costs.

   a. Use the **Inventory accounting** tab on the **Inventory accounting policies setup** > **Parameters** page to define two cost control parameters that are related to standard costs.

- In the **Cost breakdown** field, select *None* or *Sub ledger*. If you select *Sub ledger*, the cost breakdown is an *active* cost breakdown. An active cost breakdown is critical for calculating, retaining, and viewing cost group segmentation across a multilevel product structure for standard cost items. When the cost breakdown is active, you can report and analyze inventory, work in process (WIP), and cost of goods sold (COGS) per cost group in a single-level, multilevel, or total format. When the cost breakdown is active, if you activate a manufactured item's cost, the cost group segmentation is stored in the item's cost record.

- If you select *None*, cost group segmentation won't be maintained for standard cost items. In other words, a manufactured item's standard cost is calculated as a single amount, without cost group segmentation. The cost contributions of manufactured components are aggregated into the single amount.

b. In the **Variances to standard** field, select *Summarized* or *Per cost group*. If you select *Per cost group*, you can identify purchase price variances and production variances by cost group. You can also identify the four types of production variances: the lot size, quantity, price, and substitution variances. If you select *Summarized*, you can't identify variances by cost group, and you can't identify the four types of production variances. You can just view a summarized production variance.

   The policy about variance to standard works independently of the cost breakdown policy. In other words, you can select a cost breakdown policy of *None* and select variances per cost group, so that production variances by cost group will still be captured.

5. Create costing versions for standard costs.

   Use the **Costing version setup** page to create one or more costing versions for standard costs. Each costing version must be designated by a costing type of *Standard cost* and must allow content to include cost data.

6. Prepare an existing customer to use standard costs.

   Customers who want to change their existing items to a standard cost inventory model must use the **Standard cost conversions** page.

This article provides a process overview to help you set up and run a standard cost conversion. Complete the steps after you complete the prerequisites for a standard cost conversion.

Use the **Standard cost conversions** page to convert the inventory model for a batch of selected items from an actual costing approach to a standard costing approach. The conversion process involves a prerequisite inventory close, several steps during a transition period, which is defined by a transition start date and a planned conversion date, and then the conversion and an associated inventory close.

- Inventory close before the transition period – An inventory close is a prerequisite step because it settles an item's open transactions by using the old valuation method. During the transition period, you can enter and post backdated transactions, such as invoices, so that you can close the previous period. The inventory close date must be one day before the transition start date to ensure a clean break from the old valuation method.
- Conversion steps during the transition period – Use the **Standard cost conversions** page to create a conversion record that also contains the user-defined identifier for a new costing version. You identify the items that require conversion, and then enter the items' pending standard costs in the new costing version. You perform a check of the selected items to identify issues that might prevent conversion, resolve the issues, and then perform another check. After the items pass the checks, you change the status of the conversion record to *Ready*. On the planned conversion date, you perform the conversion and optionally include an inventory close. An item's inventory movements during the transition period are posted and valued according to the old inventory model. Then, after the conversion is successfully completed, the inventory movements are revalued to standard cost.
- Inventory close before the conversion – You can include the inventory close as part of the conversion on the planned conversion date, or you can perform it as a separate step before the conversion.

After the conversion process is successfully completed, the inventory model for each item is based on standard cost, and the item's standard cost is enabled. Subsequent inventory transactions are valued at the item's standard cost. In addition, the system converts the item's physical inventory transactions for receipts and issues to standard cost based on the conversion date. The system also converts the item's financial on-hand inventory to standard cost, and posts the difference in value as an inventory revaluation. Any transactions that occur after the conversion are valued at the item's standard cost. You can't enter backdated transactions before the conversion date, because an inventory close must be performed one day before the conversion date. A conversion can be performed only if an inventory close was performed one day earlier. You can't cancel this inventory close.

Step 1: Define a standard cost conversion record and the associated costing version

Use the **Standard cost conversions** page to create a conversion record. You can create a new conversion record only when existing conversion records have been completed. The duration of the planned transition period is defined by the transition start date and the planned conversion date. A planned transition period can be as short as one day. A planned transition period helps to ensure that the conversion process has enough time to complete all its steps. An inventory close must be performed on a date that is one day before the transition start date, to help ensure that settlements are completed before you start the conversion process. To make sure that the transition start date and inventory close date are correctly aligned, you can either change the transition start date to one day after an existing inventory close or perform an inventory close. When you enter a conversion record, also enter a user-defined identifier for a new costing version that contains the standard costs for converted items. The costing version is generated automatically when you save the conversion record.

Step 2: Review and change the new costing version for the conversion record

The new costing version is dedicated to the conversion record, as the *Conversion* costing type indicates. The dedicated costing version is similar to a costing version for standard costs and contains the item cost records for items that are associated with the conversion record. The dedicated costing version for a conversion record has the following settings, which you should review and modify on the various tabs as required:

- **Costing type:** Set this field to *Standard cost*.

- **Version:** The identifier reflects the information entered on the conversion record for the costing version ID.
- **Name:** By default, the name is blank. You can optionally enter a name.
- **Block:** Set this field to *No*. You can enter cost records into the costing version until you change the status of the conversion record to *Ready*. A status of *Ready* indicates that the selected items are checked, and that changes to cost records aren't permitted.
- **Block activation:** Set this field to *Yes*. You can't manually activate a pending cost record in the dedicated costing version. Activation occurs when you perform the conversion.
- **From date:** The from date reflects the planned conversion date that is entered on the conversion record.
- **Site:** Leave this field blank, so that cost records can be entered for any site.
- **Allow price type field group:** Set this field to *Yes*, so that only cost price records can be entered.
- **Fallback principle:** Set this field to *None*. Change the fallback principle to *Active* if you require cost information that is activated in other costing versions. For example, cost information about components, cost categories, and indirect costs might be required in order to calculate the costs of manufactured items.
- **Fallback costing version:** Leave this field blank.

You can maintain item cost information in the dedicated costing version only from the **Standard cost conversions** page. You can't use the **Costing version setup** page or the **Costing version maintenance** page to calculate costs for the costing version during conversion. However, you can use these pages to maintain the dedicated costing version after you complete the conversion process.

Step 3: Identify the items to convert to standard cost

Use the **Standard cost conversions** page to identify the individual items that you want to convert to standard cost. You can add multiple items by using the **Add items to standard cost conversion** page. In general, include all manufactured items in a single conversion record to help ensure that costs are calculated correctly.

Step 4: Enter or calculate the pending standard cost for each item that is being converted

Use the **Item price** page to enter pending standard costs in the dedicated costing version for purchased items and transfer items. Cost records are site-specific, and an item's pending costs must be entered for every site. Use the **Item price** page to calculate pending standard costs for

manufactured items. Calculate a manufactured item's pending costs for every manufacturing site, unless the site represents a transfer site. In this case, enter the pending costs manually. Some items might have color, size, or configuration product dimensions. On the **Standard cost conversions** page, the **Use cost price by variant** check box shows the standard cost for every combination of product dimensions. When this check box is cleared, you must enter only a pending cost for the item.

Step 5: Check and resolve any issues for the items that are being converted

Use the **Standard cost conversion checks** report to identify issues for the items that are converted. If an item doesn't have any issues, its status in the conversion record changes to *Checked*. If an item has issues, resolve the issues and then run the report again until the item's status changes to *Checked*. If you can't resolve an item's issues in a timely manner, you can optionally delete the item from the conversion record and then convert the item later.

Step 6: Change the status of the conversion record to Ready

When the status of the conversion record is changed to *Ready*, the system performs a final check before it runs a standard cost conversion. The status is changed to *Ready* only if the following conditions are met:

- Every item in the conversion record has a status of *Checked*.
- An inventory close was performed on a date that is one day before the transition start date. To make sure that the transition start date and inventory close date are correctly aligned, you can either change the transition start date to one day after an existing inventory close or perform an inventory close.

Step 7: Back up the database before conversion

The backup lets you restore the database if errors are encountered during the conversion.

Step 8: Perform the conversion when the conversion record has a Ready status

The conversion process requires that an inventory close be performed on a date that is one day before the planned conversion date. This requirement helps ensure that back-dated transactions

can't be entered during the transition period. If an inventory close isn't yet performed, you're asked if you want to perform it as part of the conversion process. The conversion process handles one item at a time. It starts with the lowest items in a product structure, based on the item's low-level code. When an item is successfully converted, its status in the conversion record changes to *Converted*. If the conversion process is interrupted, any items that aren't successfully converted still have a status of *Checked*. Successful completion of the conversion process has the following effects:

- The status of the conversion record changes from *Ready* to *Completed*, and the status of each selected item changes from *Checked* to *Converted*.
- The item model group for converted items changes so that it reflects a new group that has a standard cost inventory model.
- The standard costs for the converted items are enabled in the dedicated costing version.
- The costing type of the costing version changes from *Conversion* to *Standard cost*, and the costing version is now like other costing versions for standard costs.

Step 9: Validate and reconcile the inventory values for the converted items

The **Variance analysis statement** report lets you analyze revaluation variance and the **Inventory value** report lets you view inventory value on a specific date.

- Analyze revaluation variances. Use the **Variance analysis statement** report to view inventory revaluation variances for the converted items. You can also use the **Standard cost transactions** page to view the inventory revaluation transactions for the converted items that have inventory.
- Analyze the inventory value before the transition start date. Use the **Inventory value** report to view inventory values for the converted items. For the To date for the report, use a date that is one day before the transition start date.
- Analyze the inventory value before the conversion date. Use the **Inventory value** report to view inventory values for the converted items. As the To date for the report, use a date that reflects one day before the conversion date.
- Analyze the inventory value on the conversion date. Use the **Inventory value** report to view inventory values as of the conversion date. Both the From date and the To date for the report should match the conversion date. The report selection criteria should reflect the converted items.
- Analyze back-dated inventory movements. Use the **Inventory value** report to view back-dated inventory movements that were entered after the conversion. The "From date and the

To date for the report should correspond to the transition start date and the conversion date, minus one day. The report selection criteria should reflect the converted items. The report shows inventory movements that were made at standard cost during the transition period.

Prerequisites for a standard cost conversion

This article discusses tasks to perform before you run a standard cost conversion.

Before you run a standard cost conversion, follow these steps:

1. Define an **item model group** for standard costs. Use the Item model groups page to create an item model group that uses a standard cost inventory model. When setting up a standard cost conversion, you assign this item model group to the items that are being converted.

2. Assign a **cost group** to each item.

    - The cost group that is assigned to a purchased item can act as the basis for assigning ledger accounts that are related to standard costs. This can include assigning ledger accounts for purchase price variances. In a manufacturing environment, the cost group that is assigned to purchased components also provides cost segmentation in the calculated costs of a manufactured item.
    - The cost group that is assigned to a manufactured item can act as the basis for assigning ledger accounts that are related to standard costs, such as assigning ledger accounts for production variances.

3. Assign a *standard order quantity* to a manufactured item when it has constant costs. The standard order quantity for a manufactured item acts as an accounting lot size for amortizing, or prorating, constant costs. These can include setup times in routing operations or a constant component quantity in a bill of material (BOM).

4. Assign *general ledger accounts* that are related to standard costs, especially the revaluation variance. Use the **Posting** page (**Inventory management** > **Setup**) to assign general ledger accounts that are related to standard costs. As a minimum for the standard cost conversion process, you must assign the account for the revaluation variance for all items and all cost groups. Use the **Chart of accounts** page to define the general ledger accounts that will be needed for standard costs. Use the **Transaction combinations** page to enable cost relations (for tables, groups, and all) before you define the item posting rules.

5. Define the inventory parameters that are related to standard costs. Use the **Number sequences** tab on the **Inventory and warehouse management parameters** page to assign a number sequence to revaluation vouchers. A revaluation voucher is generated when the

standard cost conversion creates a change of an item's inventory value. Use the **Inventory and warehouse management parameters** page to define Cost Control parameters (on the **Inventory accounting** tab) to define two parameters that are related to standard costs.

- Use the **Cost breakdown** field to select No or subledger. The selection of subledger is termed an active cost breakdown. An active cost breakdown is very important for calculating, retaining, and viewing cost group segmentation across a multilevel product structure for standard cost items. When the cost breakdown is active, you can report and analyze the following in a single level, multi-level, or total format:
  - Inventory
  - Work in process (WIP)
  - Cost of goods sold (COGS) per cost group

  An active cost breakdown means that if you enable a manufactured item's cost, the result is stored in the cost group segmentation in the item's cost record. If you put no value in the **Cost breakdown** field, the cost group segmentation isn't maintained for standard cost items. That is, a manufactured item's standard cost is calculated and maintained as a single amount without cost group segmentation, and the cost contributions of manufactured components are aggregated into the single amount.

- Use the **Variances to standard** field to select summarized or per cost group. The selection of per cost group enables you to identify purchase price variances and production variances by cost group. This also enables you to identify the four types of production variances (the lot size, quantity, price, and substitution variances). If you select summarized, you can't identify variances by cost group, and you can't identify the four types of production variances. You can only view a summarized production variance. The policy about variance to standard is independent of the cost breakdown policy. That is, you can select a cost breakdown policy of none, and select variances per cost group, so that production variances by cost group is still captured.

Manage standard cost updates

Updates to standard cost data can be managed by using two different approaches—the one-version approach or the two-version approach.

The one-version approach uses a single costing version that contains all cost records. These records include the original costs and all cost updates.

The two-version approach uses one version that contains records of the original costs and a second version that contains records of all cost updates. A primary advantage of the two-version approach is the clear delineation and tracking of cost updates in a separate costing version, without affecting the original costing version. The two-version approach can be used to identify multiple incremental updates, where each incremental update has a separate costing version that contains the incremental cost records.

Example

The following example illustrates how the one-version and two-version approaches can be used for updating standard costs in a manufacturing environment. For example, updates that reflect new items or error corrections. Assume that a single costing version represents the standard costs for the current year. The identifier for this version is 2020-STD. Version 2020-STD contains the current active costs for all items. Additionally, it contains all routing-related cost categories and overhead calculation formulas that were known at the start of the year 2020. 2020-STD is the original costing version.

- **One-version approach to cost data updates** – In the one-version approach, the original costing version 2020-STD contains all cost records. Cost updates are recorded in 2020-STD and set to a status of Pending. The pending costs can be manually entered for new purchased items, or they can be calculated for a manufactured item to reflect corrections. When the one-version approach is used, the bill of material (BOM) calculations don't require a fallback data source because all active costs are contained in the costing version. After the pending costs become active, the original costing version 2020-STD will again contain all the current active costs.
- **Two-version approach to cost data updates** – The two-version approach requires an additional costing version that contains only the cost updates. The identifier for this version is 2020-STD-CHANGES. Cost updates are recorded in 2020-STD-CHANGES and are set to a status of Pending. With the two-version approach, the BOM calculations of pending costs

for manufactured items require a fallback data source. This is because the additional costing version 2020-STD-CHANGES contains only a subset of cost data. The fallback can be expressed as the active costs or as the costing version 2020-STD, because both identify the source of cost data when it isn't included in 2020-STD-CHANGES. After the pending costs become active, the costing version 2020-STD-CHANGES will contain the current active costs that reflect the updates, whereas the original costing version 2020-STD won't be affected. When the two-version approach is used, blocking policies for the original costing version should be set up to prevent updates. Identical blocking policies should be set up for the additional costing version, except for the specified from-date and the selective use of blocking policies to allow for updates. The specified from-date should be updated with each batch of changes to reflect the scheduled activation date.

This example used one additional costing version for managing updates throughout the year 2020. More than one additional costing version can be used, such as a separate version for each batch of updates. When more than one additional costing is used, the fallback must be expressed as the active costs, because the active costs are spread over multiple costing versions.

Financial dimensions for the standard cost revaluation

Activating a new standard price will typically revaluate the on-hand inventory value by standard cost revaluation transactions. Usually, the financial dimensions of the item are then posted on the transactions. However, if you would like to control whether and how the financial dimensions are posted, use feature management to turn on the feature named *Options of defaulting financial dimensions for inventory standard cost revaluation*. After enabling this feature, go to **Cost management** > **Inventory accounting policies setup** > **Parameters** and set the new **Origin of financial dimension** drop-down list to one of the following values:

- *None* – No financial dimensions are posted on the revaluation transactions. If your account structure includes a required financial dimension, the revaluation process will still run, but it will create accounting entries that have no financial dimensions. In this case, users will receive a warning message first, so they can cancel the revaluation if necessary.
- *Table* – The financial dimensions of the item are posted on the revaluation transactions. This is the default setting and is consistent with the original system behavior without turning on the feature *Options of defaulting financial dimensions for inventory standard cost revaluation*.
- *Posting* – The financial dimensions of the transaction that is being revalued are posted on the revaluation transactions. By default, the financial dimensions from the original transaction's inventory account will be used for both the inventory account and the revaluation account.

Restrictions on costing versions for standard costs

This article describes the restrictions that apply to a costing version for standard costs.

The following restrictions help guarantee adherence to standard costing principles:

- Charges must be included in an item's cost. The charges for a manufactured item represent the amortized constant costs in the bill of materials (BOM) and route information. Therefore, the charges must be included in the unit cost. The charges for a purchased item are also included in the item's unit cost.
- Calculation of standard costs for manufactured items must be based on the cost records in a costing version for standard costs. Alternative sources of cost data can be used only with a costing version for planned costs, such as purchase price trade agreements for purchased items. Alternative sources of cost data are defined by the BOM calculation group.
- BOM calculations must be performed in a single-level explosion mode.

The item cost data for standard costs can be copied to another costing version that contains standard costs or planned costs. However, the item cost data for planned costs can't be copied to a cost version that contains standard costs, because the restrictions that are listed earlier in this article don't apply to planned costs.

Information used in BOM calculations with standard costs

Article • 02/11/2025

Bills of material (BOM) calculations use data from several sources to calculate the standard costs of a manufactured item. The sources include information about items, bills routings, indirect cost calculation formulas, and the costing version.

The purchased item information that is used in a standard cost BOM calculation includes the following:

- Cost – A purchased item's costs are maintained as site-specific cost records in a costing version for standard costs. Each cost record has an effective date, and the BOM calculation date determines which cost record will be used. For example, a BOM calculation with a future calculation date might use a cost record with a pending status and a future effective date.
- Cost group – The cost group that is assigned to a purchased item provides the basis for cost segmentation in the calculated costs of a manufactured item.
- Warning conditions that are embedded in the item's BOM calculation group enable the BOM calculation to identify potential problems. This can be when the purchased item has a zero cost, a zero quantity in a BOM, or an out-of-date cost record. The applicable warning conditions can be overridden when initiating a BOM calculation.

The manufactured item information that is used in a standard cost BOM calculation includes the following:

- Standard order quantity for inventory – The item's standard order quantity for inventory, acts as the default accounting lot size for amortizing constant costs in a BOM calculation. The accounting lot size will also reflect the order quantity multiple if it's specified.
- Warning conditions that are embedded in the item's BOM calculation group enable the BOM calculation to identify potential problems. One example could be that the manufactured item doesn't have a BOM or route. The applicable warning conditions can be overridden when initiating a BOM calculation.

The bill of material information that is used in a standard cost BOM calculation includes the following:

- BOM version – The BOM version that is assigned to the manufactured item has effective from and to dates, and a status for approved and active. The bill version

can be company-wide or site-specific, and it can optionally reflect quantity breakpoints.

- BOM line item quantity − A component typically has a variable quantity required, but it can be a constant. The component quantity is typically expressed for producing one parent item, but it could be expressed per 100 or per 1000 to handle decimal precision issues. The component quantity can also be calculated based on measurements.
- BOM line item scrap − A component can have a variable or constant quantity for planned scrap.
- BOM line item valid dates − A component can have valid from and to dates.
- BOM line item type of production − The costing lot size for amortizing constant costs reflect the BOM calculation quantity and a make-to-order explosion mode, because the BOM calculation assumes that the manufactured component will be produced to the exact quantity instead of its standard order quantity.
- Sub-BOM for a manufactured component − A manufactured component can optionally have a specified BOM version, which would be used instead of the item's current active BOM version in a BOM calculation.
- Sub-route for a manufactured component − A manufactured component can optionally have a specified route version, which would be used instead of the item's current active route version in a BOM calculation.
- Operation number and the impact of operation scrap percentages − The operation number links a component to a specific operation, and operations can have a scrap percentage. The linkage enables BOM calculations to account for scrap percentages and cumulative scrap percentages across multiple operations on the component's required quantity.
- Ignore BOM line item in cost calculations − A component can be ignored for BOM calculation purposes.

The operations resource information that is used in a standard cost BOM calculation includes:

- Hourly costs − The hourly costs that are associated with an operations resource are expressed as cost categories that are assigned to set up time and run time. These cost categories should be identified for resource groups and operations resources. The hourly costs that are associated with a cost category can be site-specific or company-wide.
- Per unit costs − Some manufacturing environments assign operations resource costs per unit of output, which would be expressed as a different cost category for quantity. For example, the quantity-related costs can reflect piece rates for labor, or a paint manufacturer might assign operations resource costs per gallon of output.

- Overriding operations resource information on routing operations − The resource information about cost categories will be inherited by operations, where it can be overridden. BOM calculations use the cost category information that is specified on the routing operations.
- Cost group for a cost category − The cost group that is assigned to a cost category provides cost segmentation in the calculated costs of a manufactured item. For example, different cost groups might be used to segment the calculated costs that are associated with machines and labor or with setup and run time.

The route information that is used in a standard cost BOM calculation includes:

- Route version − The route version that is assigned to the manufactured item has effective from and to dates, and a status for approved and active. The route version must be site-specific, and it can optionally reflect quantity breakpoints.
- Routing operation time − The time can be specified for runtime and setup time. The hourly time is typically expressed for producing one parent item, but it might be expressed per 100 or per 1000 to handle decimal precision issues.
- Routing operation time for secondary resources − A secondary resource has the same operation number as the primary resource, and the same routing operation time. For example, an operation might require a machine as the primary resource and labor and tools as secondary resources.
- Routing operation scrap percentage − BOM calculations account for scrap percentages and cumulative scrap percentages across multiple operations. This applies to the required time for routing operations and the required quantity for components that are linked to operation numbers.
- Cost categories for a routing operation − Operations resource information about cost categories will be inherited by operations, where it can be overridden. BOM calculations use the cost category information that is specified on the routing operations.

The manufacturing overhead information that is used in a standard cost BOM calculation includes:

- Surcharge − A surcharge calculation formula reflects a percentage of value, such as 100 percent, that is tied to a specific cost group, such as labor.
- Rate − A rate calculation formula reflects an amount per unit, such as USD 10.00 per hour, that is tied to a specific cost group, such as labor.
- Time-based versus material-based overhead − The manufacturing overhead can be tied to routing operations or material components.

The costing version information that is used in a standard cost BOM calculation includes:

- Costing type – The costing version must contain standard costs. Several restrictions apply to BOM calculations that use standard costs. For example, these restrictions specify that miscellaneous charges must be included in unit costs and that the BOM calculation explosion mode must be single level.
- Mandated fallback principle – The costing version can mandate the use of a fallback principle, such as using a specified costing version or the active cost records. The mandated fallback principle typically applies to a costing version that represents the incremental updates in a two-version approach for cost updates.
- Blocking flag for pending costs – A blocking flag can prevent BOM calculations of the pending cost for manufactured items.
- Specified from-date – The specified from-date acts as the default calculation date for all BOM calculations that involve the costing version.
- Specified site – A specified site limits BOM calculations to the single site.
- Content of the costing version must include costs – The content must include costs. It can optionally include sales prices in order to calculate suggested sales prices for manufactured items.

Several sources of information can be specified when initiating a BOM calculation. This includes the site, the calculation date, and the costing version.

Update standard costs in a manufacturing environment

This article provides guidance about how to update standard costs in a manufacturing environment.

Updates can reflect new items, cost categories, or indirect cost calculation formulas. They can also reflect corrections and cost changes. The type of update affects the steps that you must complete to update standard costs, as illustrated in the following cases:

- Enter expected standard cost changes for purchased items, and then change the status of the item cost records to **Active** on the appropriate date. However, don't recalculate the costs of manufactured items that use the purchased items.
- Enter standard costs for a new purchased item, but don't recalculate the costs of manufactured items that have a bill of materials (BOM) version that contains the new purchased item as a component.
- Correct or change the cost of a purchased item, or change the cost group that is assigned to a purchased item, and calculate the cost for all manufactured items that have a BOM version that contains the purchased item as a component.
- Change the cost for a cost category, and calculate the cost for all manufactured items that have a route version that contains routing operations that use the cost category.
- Change the cost categories that are assigned to routing operations or the cost group that is assigned to cost categories. Then calculate the cost for all manufactured items that have a route version that contains routing operations that use the cost category.
- Change an indirect cost calculation formula, and calculate the cost for all manufactured items that are affected by the change.
- Change or add a manufacturing site for a manufactured item, and calculate the item's manufactured cost for the site.
- Calculate, or recalculate, the cost for a manufactured item, and recalculate the cost for all manufactured items that have a BOM version that contains the manufactured item as a component.
- Calculate costs for a new manufactured item, based on its defined, approved, and active BOM and route information.

Each case requires careful consideration about how to update standard costs.

Last updated on 11/26/2025

Update standard costs for a new manufactured item

This article provides guidance for updating standard costs for a new manufactured item.

The following guidelines assume that you use a two-version approach to update standard costs. In this approach, one costing version contains the standard costs that were originally defined for the frozen period, and the second costing version contains the incremental updates that pertain to the new manufactured items. The incremental updates are entered as cost records in the second costing version, and eventually they're enabled. The two-version approach requires that you define a second costing version. Here are the guidelines for defining this costing version:

- Assign a costing type of **Standard cost**.
- Assign a significant identifier that indicates the contents of the costing version, such as **2016-UPDATES**.
- In the **Allow price types** field group, make sure that **Cost price** is set to **Yes**.
- Allow cost records to be entered for all sites (that is, leave the **Site** field blank). If you enter a site, cost records can be entered only for that site.
- Use a fallback principle of **Active**.

To add new manufacturing items throughout the frozen period, follow these steps:

1. Use the **Costing version setup** page to enable cost records to be entered into the second costing version that contains the incremental updates. Prevent the activation of pending costs, where activation is allowed after pending costs have been completely and accurately defined. Indicate a blank from-date as a policy in the costing version, and then enter the from-date when you enter each cost record. The from-date should represent a date before the new items are purchased or manufactured.
2. Use the **Item price** page to enter cost records for new purchased items. For each cost record, enter the costing version that contains incremental updates, and use a from-date that comes before the expected manufacturing date for new manufactured items.
3. Calculate the cost of new manufactured items by using the **Calculation** page. Open the **Calculation** page from the **Costing version maintenance** page, and then select the costing version that contains the incremental updates. Use the selection criteria to specify the new manufactured item and any one of its manufactured components. In a multilevel product structure, you might also have to specify any parent item that contains the new manufactured items as a component. Enter a from-date for the bill of materials (BOM)

calculation that corresponds to the start of manufacturing for the new manufactured items. The from-date should be in the effective dates for the item's BOM version and route version. **Note:** A missing cost record can indicate a new manufactured item. BOM calculations can be limited to items that have missing costs.

4. Verify the completeness and accuracy of the calculated costs for new manufactured items. Use the **Complete** page to review the calculated costs for each item cost record, and also review any Action center warning messages. Alternatively, use the **Calculation** page to review the calculated costs.
5. Use the **Costing version setup** page to change the blocking flag to allow activation of the pending cost records in the second costing version.
6. Use the **Activate prices** page (which you open from the **Costing version maintenance** page) to enable all pending cost records in the second costing version. You can also enable the pending cost records for individual items by clicking the **Activate** button on the **Item price** page.
7. Use the **Costing version setup** page to change the blocking flags in the second costing version to prevent additional data maintenance. The blocking policies prevent the entry of new pending costs and the activation of pending costs.

Update standard costs in a non-manufacturing environment

This article provides guidance for updating standard costs in a non-manufacturing environment.

The following guidelines assume that you use a two-version approach to update standard cost. In this approach, one costing version contains the standard costs that were originally defined for the frozen period, and the second costing version contains the incremental updates. Each update is entered as a cost record that is enclosed in the second costing version, and eventually it's enabled. An alternative, one-version approach uses the set of standard costs that was originally defined. The two-version approach requires that you define a second costing version. Here are the guidelines for defining this costing version:

- Assign a costing type of **Standard costs**.
- Assign a meaningful identifier that indicates the contents of the costing version, such as *2025-UPDATES*.
- Make sure that the content includes cost records.
- Allow cost records to be entered for all sites. If you specify a site, cost records can be entered only for that site.
- Indicate a fallback principle of *None*. The fallback principle applies only to cost calculations for manufactured items.

To correct, adjust, or update standard costs for new items, follow these steps:

1. Use the **Costing version setup** page to enable cost data to be entered into the second costing version. Optionally, prevent the activation of pending costs, so that activation will be allowed after pending costs have been completely and accurately defined. You can also optionally enter a date in the **From date** field. As a general guideline, use the date when you intend to enable the incremental updates. Alternatively, leave the **From date** field blank for the costing version, and then enter a date in the **From date** field for each cost record.
2. Use the **Item price** page to enter updates as item cost records that are enclosed in the second costing version.
3. Use the **Item prices** report to verify the completeness and accuracy of the item cost records that are enclosed in the second costing version.
4. Use the **Costing version maintenance** page to change the blocking flag to allow activation of the pending cost records that are enclosed in the second costing version.

5. Use the **Activate prices** page (which you open from the **Costing version maintenance** page) to activate all pending item cost records that are enclosed in the second costing version. You can also activate the pending cost records for individual items by clicking the **Activate pending price** button on the **Item price** page.
6. To prevent additional data maintenance, use the **Costing version setup** page to change the blocking flags that are enclosed in the second costing version. The blocking policies will prevent the entry of new pending costs and the activation of pending costs.

Prepare to maintain standard costs for manufactured items

This article describes the steps for preparing to maintain costs for manufactured items. The steps for manufactured items differ slightly from the steps for purchased items.

Policies that are assigned to manufactured items can affect the cost calculations for the parent manufactured items. To prepare to maintain costs for manufactured items, follow these steps:

1. Assign an item model group to the manufactured item.

   The item model group identifies that standard costs will be used.

2. Assign an item group to the manufactured item.

   The item group contains ledger accounts that apply to the manufactured item. The ledger accounts for a manufactured item that has a standard cost inventory model include several production variances, the cost change variance, and the inventory cost revaluation.

3. Assign the inventory unit of measure to the item.

   The item's costs are always expressed in the item's inventory unit of measure.

4. Don't assign a cost group to the manufactured item unless the item will be treated as a purchased item.

5. Assign a bill of materials (BOM) calculation group to the manufactured item.

   The item's BOM calculation group defines warning conditions that apply. In that way, when a BOM calculation is done, warning messages can be generated about possible sources of calculation errors. For example, a warning message can identify when an active BOM or route doesn't exist. The BOM calculation group contains a stop explosion policy that indicates when a manufactured item should be treated as a purchased item.

6. If the manufactured item has constant costs, assign a standard order quantity to it.

   The standard order quantity is an accounting lot size for amortizing constant costs. Examples of constant costs include setup times in routing operations and a constant component quantity in the BOM.

7. Define the BOM for the manufactured item.

   One or more BOM versions can be defined for the manufactured item. Verify that the versions that you want have been marked as approved and active, and that they have the effective dates that you want. The BOM version can be company-wide or site-specific.

8. Define the routing for the manufactured item.

   One or more route versions can be defined for the manufactured item. Verify that the versions that you want have been marked as approved and active, and that they have the effective dates that you want. The route version must be site-specific.

If you want to use routing information for costing purposes, additional preparation steps are required. For example, the cost categories that are assigned to routing operations must be correct and completed.

This article provides information about costing versions, how to maintain them, and the types of data that you can include in them.

A costing version can serve one or more purposes, depending on the data that the costing version contains. The primary purpose of a costing version is to contain cost records about items, cost categories, and calculation formulas for indirect costs. A costing version can contain a set of standard cost records or a set of planned cost records that are based on the costing type that is assigned to the costing version.

Costing versions for standard or planned costs

Standard costs

A costing version can support a standard cost inventory model for items, where the costing version contains a set of standard cost records about items and manufacturing processes. Cost data about manufacturing processes is expressed in terms of the cost categories for routing operations and the calculation formulas for manufacturing overheads.

Planned costs

A costing version can contain a set of planned cost records about items and manufacturing processes. A costing version that contains planned costs is often used to support cost calculation simulations, such as simulations of the effect that cost changes to purchased materials or manufacturing processes have on the calculated costs of manufactured items. The item cost records for planned costs can also be used to support an actual cost inventory model by providing the initial values for item costs. These values include the calculation of planned costs for manufactured items.

Entering costs

Data maintenance for cost records in a costing version involves entering costs for purchased items and for items that are transferred between sites. Additional data maintenance for manufacturers involves entering costs for cost categories that are associated with routing operations, entering calculation formulas for the indirect costs that reflect manufacturing overhead, and calculating costs for manufactured items.

The item cost data in a costing version consists of one or more cost records for each item. When an item cost record is first entered, it has *Pending* status and an intended effective date. When you activate the item cost record, the status is updated to *Active*, and the effective date is updated to the activation date. Different item cost records can reflect different sites, effective dates, or statuses. When you calculate costs for manufactured items for a future date, the bill of materials (BOM) calculation uses cost records that have the relevant effective date, regardless of whether the status is *Pending* or *Active*. An item's current active cost record is used to estimate production order costs and to value inventory transactions under a standard costing inventory model. The maintenance of cost records for cost categories and indirect cost calculation formulas resembles the maintenance of item cost records.

Two blocking policies for a costing version determine whether pending costs can be maintained and whether the pending cost can be activated. Use the blocking policies to permit data maintenance, and then use them to prevent data maintenance for cost records in a costing version. The following blocking policies can prevent pending costs from being updated or modified until they are finalized:

- *Block* – Prevents pending costs from being edited in or added to a cost version.
- *Block activation* – Prevents pending costs from being activated.

A costing version can also contain data about item sales prices or purchase prices for BOM calculation purposes.

Item sales prices for BOM calculations

The main reason for including data about sales prices is to retain a manufactured item’s calculated sales price. The calculated sales price can then be analyzed to determine how components, routing operations, and overhead contribute to the cost and sales price.

A secondary reason for including data about sales prices is to define the sales price records for component items. These records can then be used to calculate the sales price of manufactured

items. You first define the sales price model that is embedded in a BOM calculation group, and assign the BOM calculation group to purchased items. Then, when you perform BOM calculations that use planned costs, you select the cost price model of the BOM calculation group.

Otherwise, the sales price records for items are used only as reference information, regardless of whether the records are manually entered or calculated. By activating an item's sales price record, you can update the item's base sales price. However, the base sales price isn't site-specific and can be manually overridden. The item's base sales price is used as a default sales price on sales orders and sales quotations.

Item purchase prices for BOM calculations

The main reason for enabling purchase price data is to define purchase price records for component items to calculate the costs of manufactured items. Enter the item purchase price records manually.

To enable purchase price content, you first define a BOM calculation group that contains a cost price model for the item's purchase price, and assign the BOM calculation group to purchased items. You then use a cost price model for the BOM calculation group when you perform BOM calculations that use planned costs to calculate the sales price of manufactured items.

The purchase price records for items are also used as reference information. By changing the status of an item's purchase price record from *Pending* to *Active*, you can update the item's base purchase price. However, the base purchase price isn't site-specific and can be manually overridden. The item's base purchase price is used as a default purchase price on purchase orders.

Costing sheets

Setting up the costing sheet involves two objectives. As the first objective, you define the format for displaying cost of goods sold information about a manufactured item or production order. The formatted display is termed a costing sheet. As the second objective, you define the basis for calculating indirect costs. The costing sheet setup builds on the cost group feature for displaying information and for the indirect cost calculation formulas. The two objectives of costing sheet setup are described in this article.

The following table lists the out-of-box security roles that can access costing sheets, including the level of access granted to each role by the default settings.

Expand table

Role	Access
Accounting manager	Edit
Inventory accountant clerk	View
Inventory accountant	View

A costing sheet is the formatted display of information about the cost of goods that are sold for a manufactured item or a production order. When you set up a costing sheet, you define the format for the information and also define the basis for calculating indirect costs. The costing sheet setup builds on the cost group features for displaying information and for the formulas that are used to calculated indirect cost. Here's more information about the two objectives of costing sheet setup:

- **Define the format for the costing sheet.** The user-defined format for a costing sheet identifies the segmentation of costs that contain a manufactured item's cost of goods sold. For example, the information about an item's cost of goods sold can be segmented into material, labor, and overhead, based on cost groups. These cost groups are assigned to items, cost categories for routing operations, and indirect cost calculation formulas. The format for the costing sheet typically requires intermediate totals when multiple cost groups are defined. For example, multiple cost groups that are related to material can be aggregated. The definition of a costing sheet format is optional, but a costing sheet format must be defined if indirect costs will be calculated.

- **Define the basis for calculating indirect costs.** Indirect costs reflect manufacturing overhead that is associated with the production of a manufactured item. An indirect cost calculation formula can be expressed as either a surcharge or a rate. A surcharge represents a percentage of value, whereas a rate represents an amount per hour for a routing operation. A cost group defines the basis for the calculation formula, such as a 100-percent surcharge for a labor cost group or a USD 50.00 hourly rate for a machine cost group. If you want to define a calculation formula and its cost group basis, the costing sheet setup requires that you identify the cost group that represents the overhead, and select whether a surcharge or rate approach is used.

Each calculation formula must be entered as a cost record. The cost record consists of a specified costing version, a surcharge percentage or a rate amount, the cost group basis, a status, and an effective date. When a cost record is first entered, it has *Pending* status and an effective date. When you activate the cost record, the status is updated to so that the record is the current active record, and the effective date is updated to the activation date. The cost record can also specify a site for a site-specific calculation formula. Alternatively, you can leave the **Site** field blank to indicate that the calculation formula is a company-wide formula. The cost record can optionally consist of a specified item or item group when the calculation formula is marked as a per-item formula.

The current active cost records for indirect cost calculation formulas are used to estimate production order costs. They're also used to calculate actual costs that are related to actual consumption of time and material. Pending cost records are used in bill of materials (BOM) calculations for a future date.

Two blocking policies for a costing version determine whether pending costs can be maintained, and whether the pending cost can be started. Use the blocking policies to permit data maintenance, and then to prevent data maintenance for the cost data in a costing version.

After you define the costing sheet format and calculations for indirect costs, you must perform a separate step to validate and save the information. The costing sheet represents a company-wide format for consistently displaying information about the costs of goods sold.

The costing sheet is displayed as part of the **Calculate item cost** page. The costing sheet can be displayed for a manufactured item's calculated cost record on the **Item price** page or for an order-specific calculation record on the **BOM calculation results** page. It can also be displayed as part of the **Price calculation** page for a production order.

Related information

- The white paper BOM calculation by using a costing sheet describes how to set up a costing sheet that includes material and manufacturing, and how the setup affects the BOM calculation results. To better explain the articles, it provides concrete scenarios and data that demonstrates the effect of the various settings and configurations.

Simulate cost changes by using a costing version for planned costs

This article explains how you can simulate the effects of cost changes on a manufactured item's calculated costs by using a separate costing version for planned costs.

You can simulate the effects of cost changes on the calculated costs of a manufactured item by using a separate costing version for planned costs. Use this separate costing version to enter pending cost records that reflect incremental cost changes, and to calculate the cost impact on manufactured items. Because the Active costs fallback principle will be used in the bill of materials (BOM) calculations, only the incremental cost changes must be entered.

Guidelines for defining the simulation costing version

Use the following guidelines when you define the costing version for simulations:

- Assign a costing type of *Planned costs*.
- Assign a meaningful identifier for the costing version, such as *Simulation*.
- Make sure that the content includes cost records.
- Allow the entry of cost records. Don't block the entry of pending costs.
- Allow the entry of cost records for all sites. If you specify a site, you'll limit the entry of cost records to that site.
- Prevent the activation of pending costs. Only pending costs must be entered for cost records in the simulation costing version.
- Don't enter a "from" date. A calculation date will be entered for each BOM calculation that uses the simulation costing version.
- Specify a fallback principle of *Current active*. The fallback principle enables incremental cost changes to be entered for simulation purposes but uses the current active costs as the source for all other cost records. We assume that all current active costs exist for all other cost records.
- Specify a cost price model of *Version cost price*, but don't restrict calculations. For example, the simulations can also use the *BOM calculation group* cost price model to indicate the source of cost contribution data for purchased items.
- Specify an explosion mode of *Multilevel*, but don't restrict calculations. The simulations can use other explosion modes.

Costing versions

The following scenarios illustrate how the simulation costing version is used to simulate the impact of cost changes. Before you enter a simulated cost change, delete the pending cost records in the simulation costing version, so that you have a clean starting point. Use the **Item price** page to view and delete the pending cost records that are related to item prices and cost category prices.

- Simulate the cost change for a purchased item. For example, the cost change might reflect an expected increase or decrease in the cost of critical purchased materials. To define the different cost for a purchased item, use the **Item price** page to enter a pending cost record in the simulation costing version.
- Simulate the cost change for a cost category. For example, the cost change might reflect an expected increase or decrease in labor rates, or in the hourly rates for operations resources. To define the different cost for a cost category, use the **Cost category price** page to enter a pending cost record in the simulation costing version.
- Simulate the cost change in an indirect cost calculation formula. For example, the cost change might reflect an expected increase or decrease in manufacturing overhead. To define the change in an indirect cost calculation formula, use the **Costing sheet setup** page to enter a pending cost record in the simulation of costing version, and to validate and save the change.

After you enter the simulated cost changes, calculate the costs for manufactured items that are affected by the cost changes. Use the **Calculation** page for the simulation costing version, and identify the selected manufactured items that will be affected by the cost changes. The BOM calculations apply to all manufactured items unless you select specific items. Alternatively, you can use the BOM calculation option for where-used updates. View the item cost records in the simulation costing version to analyze how the simulated cost changes affected the costs of the selected manufactured items. Use the **Item price** page and the **Calculate item cost** page to view and analyze the costs.

Compare item prices storage report

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to run a **Compare item prices storage** report and make the output available digitally, either as an interactive page in Dynamics 365 Supply Chain Management, or as an exported document in any of several formats.

When you view the report in your browser, columns and aggregate balances are dynamically adjusted, depending on your configured layout. You can sort the results, filter them, drill down into the data, and more.

Report results are stored in the **Compare item prices** data entity, which lets you filter and export the results to a format such as CSV or Microsoft Excel.

The **Compare item prices storage** report is helpful in cases where the output contains many lines. For example, the output will contain many lines if you have more than 40,000 items holding a pending item price in the costing version.

Generate a Compare item prices storage report

Follow these steps to generate and store a **Compare item prices storage** report:

1. Go to **Cost management** > **Inquiries and reports** > **Predetermined cost reports** > **Compare item prices storage**.

2. Select **New** to open the **Compare item prices** pane. Set the following options to define which prices to compare in your report:

    - On the **Parameters** FastTab, give the report a unique **Name** and use the fields in the **Pending prices to compare** and **Prices used for comparison** sections to define which prices and dates to compare.
    - On the **Records to include** FastTab, set up filters and constraints to define which data to include in the report.
    - On the **Run in the background** FastTab, set up how, when, and the frequency at which you want to generate the report.

> **Note**
>
> This report is always executed as part of a batch job.

3. Select **OK** to apply your settings and close the pane.
4. After the batch job is completed, it will be listed on the **Compare item prices storage** page. You might need to refresh the page to see the report.

Explore the Compare item prices storage report

After generating a report, you can view and explore it at any time as follows:

1. Go to **Cost management** > **Inquiries and reports** > **Predetermined cost reports** > **Compare item prices storage**.
2. Select a report from the list.
3. Do one of the following:
   - Select **Overview** to get an overview of your report results.
   - Select **View details** to get a more detailed view of your report
4. After the selected view opens, you can do the following:
   - Select almost any column heading to sort or filter the table by values in that column, just as with most standard forms in Supply Chain Management. Note, you can't sort or filter the **Net change price %** column because it's a calculated field.
   - Select **Dimension display** to open a pane where you can choose which dimension column to include on the form. Set **Save setup** to *Yes* if you'd like to save these settings so they'll be preserved the next time you open the report. Select **OK** to apply your settings and close.
   - Select any row in the form and then select **View details** to see more information about the selected item. You'll be able to drill down into the data from here.
   - Select any row in the form and then select **View comparison chart** to see an interactive graphical representation of your results as they relate to your selected item. You can explore these results by selecting various graphical elements in the chart and chart legend.
   - Select any row in the form and then select **View calculation details** to see more information about calculations related to the selected item. You'll be able to drill down into the data from here.

Export the Compare item prices storage report

Each report that you generate is stored in the **Compare item prices** data entity. You can use the standard data management features of Supply Chain Management to export data from this entity to any supported data format, including CSV or Microsoft Excel.

The following is an example of how to export a **Compare item prices storage** report:

1. Go to **System administration** > **Workspaces** > **Data management**.
2. Select the **Export** button in the **Data management** section.
3. The **Export** page opens, which you'll use to set up your export job. Start by giving your job a **Group name**.
4. In the **Selected entities** section, select **Add entity** to open a dialog box where you can set the following options:
    - **Entity name** - Select **Compare item prices**.
    - **Target data format** - Choose the format that you want to export to.
5. Select **Add** to add the new row and then select **Close** to close the dialog box.
6. Usually you'll export one report at a time. To do this, set up a **Filter** for the row you just added to the **Inquiry** pane. This will let you define which reports from the **Compare item prices** entity that you want to include in your export. Set the following filter options to export a single report:
    - On the **Range** tab, select **Add** to add a new row.
    - Set **Table** to *Compare item prices*.
    - Set **Derived table** to *Compare item prices*.
    - Set **Field** to the field that you want to filter by. Usually you'll use *Execution name* or *Execution time*.
    - Set **Criteria** to the value from your selected field that you want to look for (either the name of the report or the time the report was generated).
    - If necessary, add more rows to the **Range** table until you have uniquely identified the report that you're looking for.
7. Select **OK** to save your settings and close.
8. Select **Save** to save your export setup.
9. Open the **Export options** tab and select **Export now** to generate the export file.

10. The **Execution summary** page opens, where you can see the status of your export job and a list of entities that were exported. Select the **Compare item prices** entity listed in the **Entity processing status** area and then select **Download file** to download the data exported from that entity.

For more information about how to use data management to export data, see Data import and export jobs overview.

Last updated on 10/03/2025

Running average cost price

The inventory close process settles issue transactions to receipt transactions, based on the inventory valuation method that is selected in the item's item model group. However, before inventory close is run, the system calculates a running average cost price that is typically used when issue transactions are posted.

The system estimates this running average cost price for an item by using the following formula:

Estimated price = (Physical amount + Financial amount) ÷ (Physical quantity + Financial quantity)

Default item cost

The default item cost for a released product can be configured in one of two ways on the **Released product details** page:

- Create a standard cost by selecting **Item price** in the **Set up** group on the **Manage costs** tab of the Action Pane. If you use this method, you must use a standard cost costing version, and the cost must be activated.
- Define a default item cost price for a released product by entering a value in the **Price** field on the **Manage costs** FastTab.

In addition to entering or creating a price, you can select the **Use latest cost price** checkbox on the **Manage costs** FastTab of the **Released product details** page. In this case, the system automatically updates the **Price** field when you post a financial update. For example, if you post a purchase order invoice, the field is set to the purchase price from that invoice.

If you have a cost price in an active costing version, and you enter a price on the **Manage costs** FastTab, the system uses the price from the active costing version before it uses the price that is defined on the **Manage costs** FastTab.

Using the running average cost price

The following table shows when the system posts inventory transactions by using the running average cost price, and when it uses the cost price that is defined on the item master record instead.

Expand table

Condition	The system uses the estimated running average cost price	The system uses the default item cost price
Both the numerator* and denominator** are positive.	Yes	No
The numerator*, denominator**, or both are negative.	No	Yes
The denominator** is 0 (zero).	No	Yes

* Numerator = (Physical amount + Financial amount)

** Denominator = (Physical quantity + Financial quantity)

> **Note**
>
> If the **Include physical value** option isn't selected for an item, the system uses 0 (zero) for both the physical amount and the physical quantity. For information about this option, see Options for including physical value in cost calculations.

Avoiding pricing amplification

On rare occasions, the system prices several issues before it has enough receipts to base the price on. This scenario can cause estimates of the running average cost price to be overly inflated. However, there are steps that you can take to avoid pricing amplification, or to reduce its impact when it does occur.

Scenario: The following transactions occur for an item where the **Include physical value** option is selected:

1. You financially receive a quantity of 100 at USD 100.00.
2. You financially issue a quantity of 200.
3. You physically receive a quantity of 101 at USD 202.00.

When you examine the estimated running average cost price for the item, you expect a cost price of USD 1.51. Instead, you find an estimated running average of USD 102.00, which is based on the following formula:

Estimated price = [202 + (-100)] ÷ [101 + (-100)] = 102 ÷ 1 = 102

This pricing amplification occurs because, when 200 items are financially issued in step 2, the system must price 100 of the items before it has any corresponding receipts. This situation causes

negative inventory. The system then estimates a unit price of USD 1.00, as you might expect. However, when the corresponding 100 receipts arrive, they are at a unit price of USD 2.00 each.

> **Note**
>
> Although the issues create negative inventory, inventory is positive when the issue price is calculated. Therefore, the running average cost price is used instead of the price on the item master. At this point, the system has an inventory value offset of USD 100.00. Although that offset was built up over 100 pieces, where there was a unit offset of USD 1.00 each, you now have only one piece in inventory. Therefore, the offset of USD 100.00 is allocated to this one piece. The result is the overly inflated estimated cost price.
>
> For comparison, notice that if steps 2 and 3 are reversed in the scenario, 200 items will be issued at a unit price of USD 1.51, and one piece will remain at a unit price of USD 1.51. Because this pricing amplification scenario can occur when negative inventory is involved, it's difficult to avoid in the following cases:
>
> - You must estimate issue prices on the on-hand value and quantity.
> - You must adjust the on-hand value and quantity on issues and receipts.
> - Your business model allows you to send out, or price, more pieces than you have.
> - You must accept any receipt value and quantity that are submitted to you.

However, if your business model allows for the following practices, they can help you avoid the negative quantities that make the pricing amplification scenario possible:

- If you select the **Include physical value** option for an item, clear the **Physical negative inventory** checkbox on the **Item model groups** page.
- If you do **not** select the **Include physical value** option for an item, clear the **Financial negative inventory** option on the **Item model groups** page.

Additionally, consider that the maximum offset in your physical inventory value is limited by the number of physical transactions, and the difference between physical and financial prices. If all physical transactions are eventually updated financially, the physical value can't rise to extreme levels. The amplification effect decreases significantly when the accumulated offset is spread out over several on-hand pieces instead of just one.

Avoid a zero cost price on issues

When the **Include physical value** option isn't selected on the **Item model group** page, an issue from inventory can have a zero cost price if there are no financially updated receipts in inventory. To help avoid this scenario, consider the following options:

- Select the **Include physical value** option on the **Item model group** page. This option prevents a zero cost price on an issue, provided that the receipt is physically updated. If you don't allow negative physical inventory, issues calculate the running average from the physically updated transactions.
- Create a default item cost price by activating a costing version that has a standard cost, or enter the price on the **Manage costs** FastTab of the **Released product details** page. This option is best when the **Include physical value** option isn't selected on the **Item model group** page, because the system will always have a fallback price to use.
- Select the **Use latest cost price** option on the **Manage costs** FastTab of the **Released product details** page. This option keeps the **Price** field up to date each time that you financially update a receipt. If you select this option, but you don't enter a default price or activate a cost in a standard costing version, you can still have a zero cost on an issue.

If you have issue transactions that have zero cost, the *Inventory close and adjustment* process will correct the cost price by creating an adjustment after the receipts are financially updated. Keep in mind that the financial period when this update occurs might differ from the financial period when the items were physically received or issued.

Track running average cost per inventory dimension

An inventory dimension group is attached to every inventory item. Therefore, the running average cost price of an item is calculated based on the selected inventory dimensions that are being tracked financially.

There are three types of inventory dimensions: product, storage, and tracking. Product dimensions include configuration, size, and color. Product dimensions are always tracked financially. Storage and tracking dimensions include site, warehouse, location, inventory status, license plate, batch number, and serial number. You can decide which storage and tracking dimensions are tracked financially.

Example 1

If the storage dimension group that is attached to the item is financially tracked by warehouse, the running average cost price is calculated per warehouse. The following purchase orders have been invoiced:

- A purchase order for a quantity of 2 at a cost price of USD 10.00 has been invoiced for warehouse GW.
- A purchase order for a quantity of 3 at a cost price of USD 12.00 has been invoiced for warehouse GW.
- A purchase order for a quantity of 5 at a cost price of USD 15.00 has been invoiced for warehouse MW.

The running average cost price for warehouse GW is USD 11.20, and the running average cost price for warehouse MW is USD 15.00. A sales order invoice is posted for warehouse GW. The value of the inventory and the cost of goods sold (before inventory close is run and without marking) is USD 11.20. Another sales order is posted for warehouse MW. The value of the inventory and the cost of goods sold (before inventory close is run and without marking) is USD 15.00.

Example 2

If the storage dimension group that is attached to the item is financially tracked by warehouse, and the tracking dimension group is financially tracked by batch number, the running average

cost price is calculated for each batch. The following purchase orders have been invoiced:

- A purchase order for a quantity of 2 at a cost price of USD 10.00 has been invoiced for warehouse GW and batch AAA.
- A purchase order for a quantity of 3 at a cost price of USD 12.00 has been invoiced for warehouse GW and batch AAA.
- A purchase order for a quantity of 2 at a cost price of USD 15.00 has been invoiced for warehouse GW and batch BBB.

The running average cost price for warehouse GW and batch AAA is USD 11.20, and the running average cost price for warehouse GW and batch BBB is USD 15.00.

> **Note**
>
> We recommend that you always view the cost price for all financial dimensions that are being tracked.

FIFO with physical value and marking

07/21/2025

First in, first out (FIFO) is an inventory management and valuation method where inventory that is produced or acquired first is sold, used, or disposed of first. During the inventory close process in Microsoft Dynamics 365 Supply Chain Management, the system creates settlements where the first receipt is matched against the first issue, and so on.

The settlements and matching principle are based on the financial date of the inventory transactions. A preliminary assessment of the settlements and adjustments can be performed by running the inventory recalculation process.

You can override the FIFO principle by marking inventory transactions so that a specific item receipt is settled against a specific issue. A periodic inventory close is required when you use the FIFO inventory model to create settlements and adjust the value of issues according to the FIFO principle. Until you run the inventory close process, issue transactions are valued at the running average when the physical and financial updates occurred. Unless you're using marking, the running average is calculated when the physical or financial update is performed. The following examples show the effect of using FIFO in three configurations:

- FIFO without the **Include physical value** option
- FIFO with the **Include physical value** option
- FIFO with marking

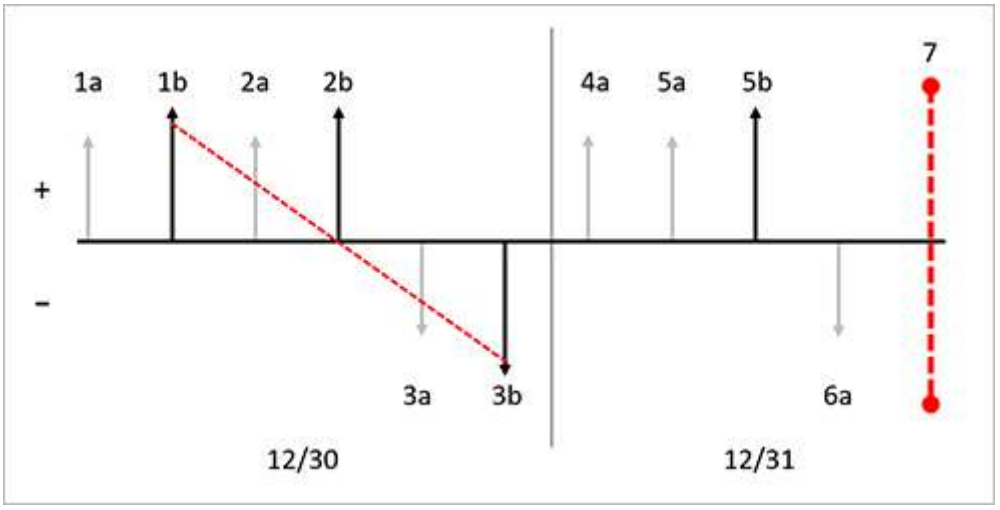
FIFO without the Include physical value option

In this example, the **Include physical value** checkbox is cleared on the item model group for the released product. The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.

- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions)
- 7. Inventory close is performed. Based on the FIFO method, the first financially updated issue is settled against the first financially updated receipt, and so on. In this example, one settlement is created between 1b and 3b. An adjustment of USD –6.00 will be made to 3b, and the resulting final cost will be USD 10.00.

The new running average cost price reflects the average of the financially updated transactions. The following illustration shows the effects of the FIFO inventory model on this series of transactions when the **Include physical value** option isn't used.



Key to the diagram

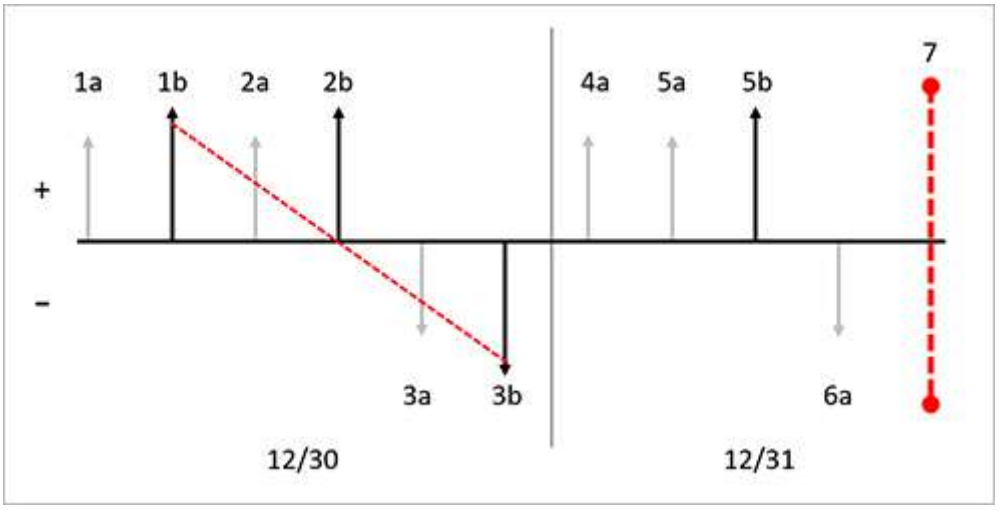
- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the timeline.
- Issues out of inventory are represented by vertical arrows below the timeline.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

FIFO with the Include physical value option

If the **Include physical value** checkbox is selected for an item on the **Item model group** page, the system uses both physical and financial receipt transactions to calculate the running

average cost price. Where applicable, the system also adjusts the physically updated issue transaction. Inventory close that uses the FIFO inventory model makes settlements only to transactions that are financially updated. The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.67 (running average of physically and financially posted transactions).
- 7. Inventory close is performed. Based on the FIFO method, the first financially updated issue is settled against the first financially updated receipt, and so on. In this example, one settlement is created between 1b and 3b. An adjustment of USD –6.00 will be made to 3b, and the resulting final cost will be USD 10.00. Additionally, transaction 6a will be adjusted to the receipt transaction cost of 2b. The system won't settle these transactions because the receipt is updated physically but not financially. Instead, only an adjustment of USD -1.67 will be posted to the physical issue transaction, and the resulting adjusted cost will be USD 22.00.



Notice that the result of running the inventory close process is the same, regardless of whether you select the **Include physical value** option on the **Item model group** page. The **Include physical value** option affects only the running average.

Key to the diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the timeline.
- Issues out of inventory are represented by vertical arrows below the timeline.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

FIFO with marking

Marking is a process that lets you link, or mark, an issue transaction to a receipt transaction. Marking can occur either before or after a transaction is posted. You can use marking when you want to be sure of the exact cost of inventory when the transaction is posted or the inventory close is performed.

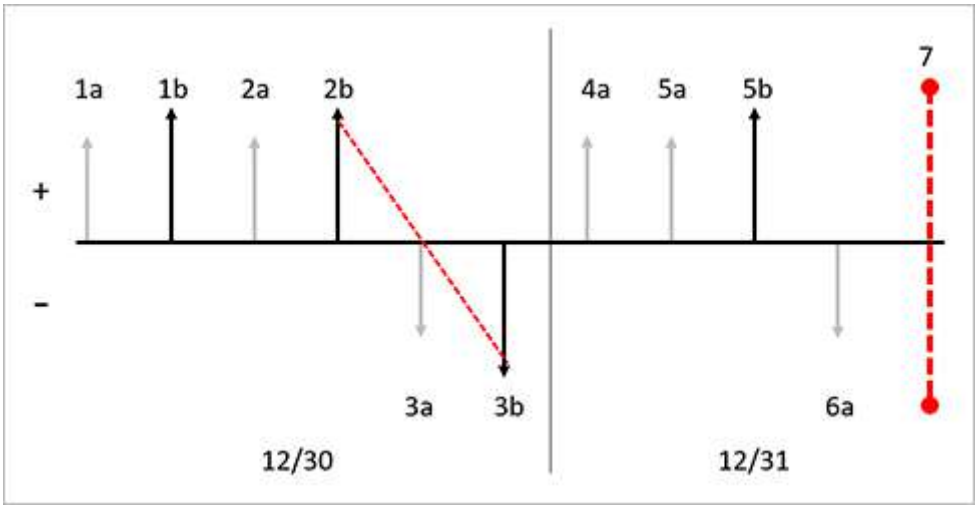
For example, the Customer Service department accepted a rush order from an important customer. Because this order is a rush order, you must pay more for this item to fulfill your customer's request. You must make sure that the cost of the inventory item is reflected in the margin, or cost of goods sold (COGS), for the sales order invoice. When the purchase order is posted, the inventory is received at a cost of USD 120.00. If the sales order document is marked to the purchase order before the packing slip or invoice is posted, the COGS will be USD 120.00, not the current running average cost for the item. If the sales order packing slip or invoice is posted before the marking occurs, the COGS is posted at the running average cost price. Before inventory close is performed, these two transactions can still be marked to each other.

When a receipt transaction is marked to an issue transaction, the valuation method that is defined in the item model group is disregarded, and the system settles these transactions to each other. You can manually mark a transaction against a sales order line on the **Sales order details** page by selecting **Inventory** > **Marking** on the **Sales order lines** FastTab. You can view the open receipt transactions on the **Marking** page. You can match or mark an issue transaction to an open receipt transaction for an inventoried item from a posted inventory adjustment journal. The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.

- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3c. Inventory financial issue for 3b is marked to inventory financial issue for 2b.
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions)
- 7. Inventory close is performed. Based on the marking principle that uses the FIFO method, the marked transactions are settled against each other. In this example, 3b is settled against 2b, and an adjustment for USD 6.00 is posted to 3b to bring the value to USD 22.00. In this example, no additional settlements are made, because the close creates settlements only for financially updated transactions.

The following illustration shows the effects of the FIFO inventory model on this series of transactions when marking between issues and receipts is used.



Key to the diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the timeline.
- Issues out of inventory are represented by vertical arrows below the timeline.
- Each new receipt or issue transaction is designated by a new label.

- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements and markings that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

LIFO date with physical value and marking

07/21/2025

Last in, first out date (LIFO date) is an inventory management and valuation method where inventory that was produced or acquired last is sold, used, or disposed of first. During the inventory close process in Microsoft Dynamics 365 Supply Chain Management, the system creates settlements where the last receipt is matched against the first issue for each given date starting with the oldest date first, and so on. When you use the last in, first out date (LIFO date) inventory model, if there's no receipt before the issue, the issue is settled against any receipts that occur after the date of the issue. The settlements and matching principle are based on the financial date of the inventory transactions. When there are several issues on the same date, they're settled in the order of last issue, last receipt. A preliminary assessment of the settlements and adjustments can be performed by running the inventory recalculation process.

You can override the LIFO date principle by marking inventory transactions so that a specific item receipt is settled against a specific issue. A periodic inventory close is required when you use the LIFO date inventory model to create settlements and adjust the value of issues according to the LIFO principle. Until you run the inventory close process, issue transactions are valued at the running average when the physical and financial updates occurred. Unless you're using marking, the running average is calculated when the physical or financial update is performed.

We recommend a periodic inventory closing when you use the LIFO date inventory model.

The following examples show the effect of using LIFO date in three configurations:

- LIFO date without the **Include physical value** option
- LIFO date with the **Include physical value** option
- LIFO date with marking

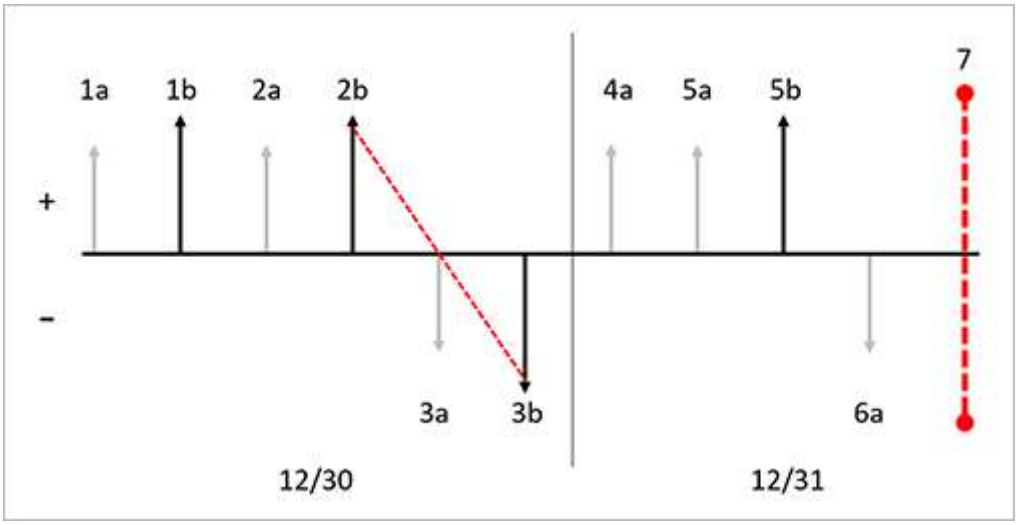
LIFO date without the Include physical value option

In this example, the item model group isn't marked to include physical value. The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.

- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions)
- 7. Inventory close is performed. Based on the LIFO date method, the first financially updated issue is settled against the last financially updated receipt starting on the first date, and so on. In this example, one settlement is created between 3b and 2b. An adjustment of USD 6.00 is made to 3b, and the resulting final cost is USD 22.00.

The following illustration shows the effects of the LIFO date inventory model when the **Include physical value** option isn't used.



Key to the diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.

- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

LIFO date with the Include physical value option

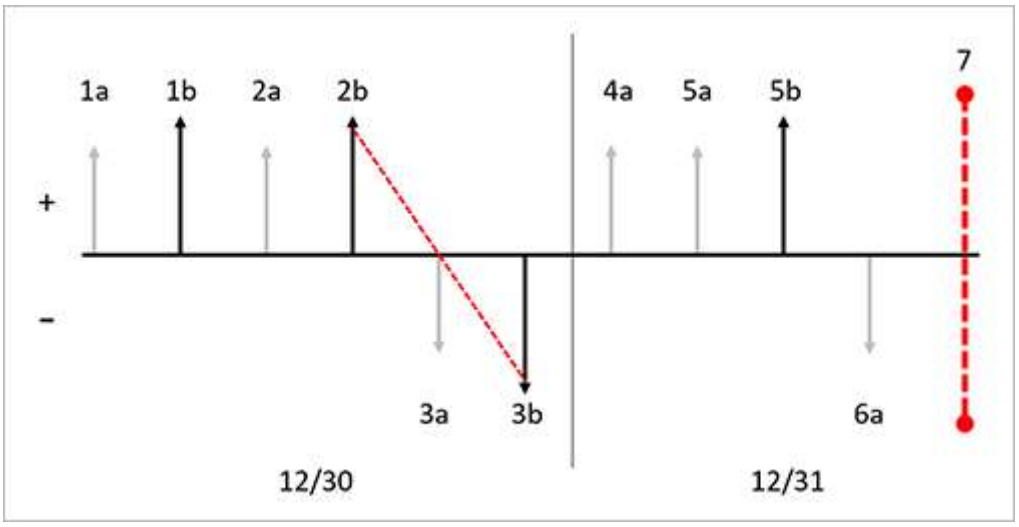
If the **Include physical value** checkbox is selected for an item on the **Item model groups** page, the system uses both physical and financial receipt transactions to calculate the running average cost price. Where applicable, the system also adjusts the physically updated issue transaction. When the **Include physical value** checkbox is cleared, inventory close that uses the LIFO date inventory model makes settlements only to transactions that are financially updated.

In this example, the item model group is marked to include physical value.

The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.67 (running average of physically and financially posted transactions).
- 7. Inventory close is performed. Based on the LIFO date method, the first financially updated issue is settled against the last financially updated receipt for each date starting on the first date, and so on. In this example, one settlement is created between 2b and 3b. An adjustment of USD 6.00 is made to 3b, and the resulting final cost is USD 22.00. Additionally, transaction 6a is adjusted to the receipt transaction cost of 5b. The system doesn't settle these transactions because the receipt is updated physically but not financially. Instead, only an adjustment of USD 6.33 is posted to the physical issue transaction, and the resulting adjusted cost is USD 30.00.

The following illustration shows the effects of the LIFO inventory model when the **Include physical value** option is used.



Key to the diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

LIFO date with marking

Marking is a process that lets you link, or mark, an issue transaction to a receipt transaction. Marking can occur either before or after a transaction is posted. You can use marking when you want to be sure of the exact cost of inventory when the transaction is posted or the inventory close is performed. For example, the Customer Service department accepted a rush order from an important customer. Because this order is a rush order, you must pay more for the item to fulfill the customer's request.

You must make sure that the cost of the inventory item is reflected in the margin, or cost of goods sold (COGS), for the sales order invoice. When the purchase order is posted, the inventory is received at a cost of USD 120.00. If this sales order document is marked to the purchase order before the packing slip or invoice is posted, the COGS will be USD 120.00, not

the current running average cost for the item. If the sales order packing slip or invoice is posted before the marking occurs, the COGS will be posted at the running average cost price.

Before inventory close is performed, these two transactions can still be marked to each other.

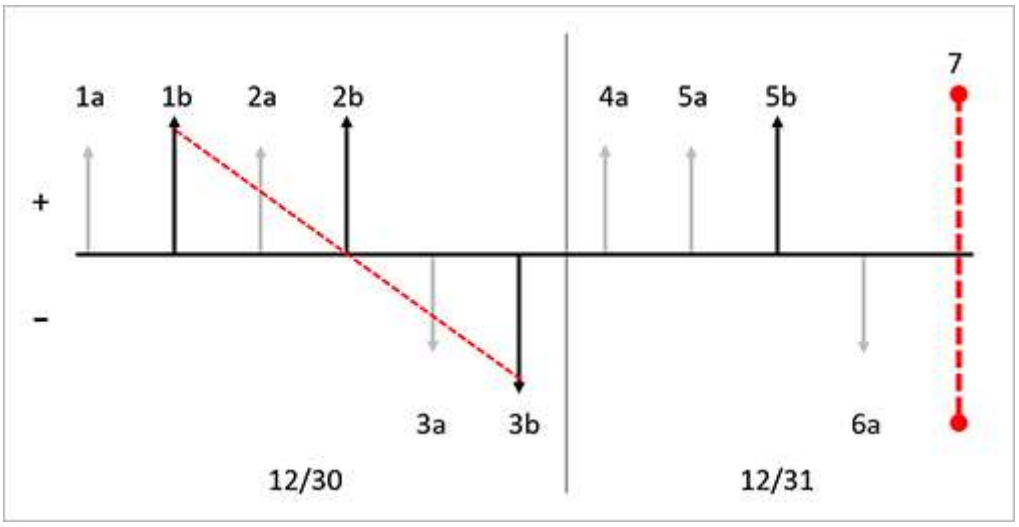
You can mark an issue transaction to a receipt before the transaction is posted. You can do this marking from a sales order line on the **Sales order details** page by selecting **Inventory** > **Marking** on the **Sales order lines** FastTab. You can view the open receipt transactions on the **Marking** page.

You can also mark an issue transaction to a receipt after the transaction is posted. You can match or mark an issue transaction for an open receipt transaction for an inventoried item from a posted inventory adjustment journal.

The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3c. Inventory financial issue for 3b is marked to inventory financial issue for 1b.
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions)
- 7. Inventory close is performed. Based on the marking principle that uses the LIFO date method, the marked transactions are settled against each other. In this example, 3b is settled against 1b, and an adjustment for USD -6.00 is posted to 3b to bring the value to USD 10.00. In this example, no additional settlements are made, because the close creates settlements only for financially updated transactions.

The following illustration shows the effects of the LIFO date inventory model when marking between issues and receipts is used.



Key to the diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements and markings that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

LIFO with physical value and marking

Article • 02/11/2025

Last in, first out (LIFO) is an inventory management and valuation method where inventory that was produced or acquired last is sold, used, or disposed of first. During the inventory close process in Microsoft Dynamics 365 Supply Chain Management, the system creates settlements where the last receipt is matched against the first issue, and so on. The settlements and matching principle are based on the financial date of the inventory transactions. A preliminary assessment of the settlements and adjustments can be performed by running the inventory recalculation process.

You can override the LIFO principle by marking inventory transactions so that a specific item receipt is settled against a specific issue. A periodic inventory close is required when you use the LIFO inventory model to create settlements and adjust the value of issues according to the LIFO principle. Until you run the inventory close process, issue transactions are valued at the running average when the physical and financial updates occurred. Unless you're using marking, the running average is calculated when the physical or financial update is performed.

The following examples show the effect of using LIFO in three configurations:

- LIFO without the **Include physical value** option
- LIFO with the **Include physical value** option
- LIFO with marking

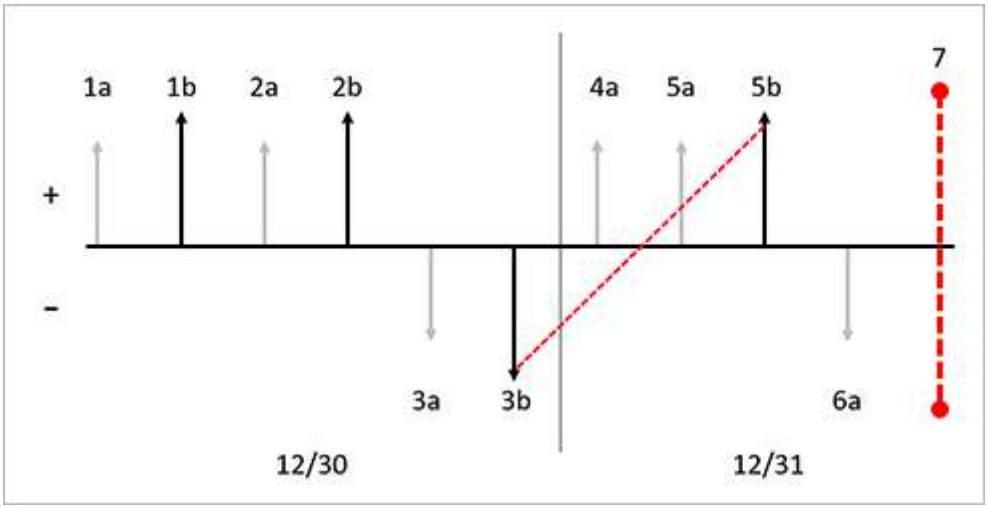
LIFO without the Include physical value option

In this example, the **Include physical value** checkbox is cleared on the item model group for the released product. The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.

- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions)
- 7. Inventory close is performed. Based on the LIFO method, the first financially updated issue is settled against the last financially updated receipt, and so on. In this example, one settlement is created between 5b and 3b. An adjustment of USD 14.00 is made to 3b, and the resulting final cost is USD 30.00.

The following illustration shows the effects of the first in, first out (FIFO) inventory model on this series of transactions when the **Include physical value** option isn't used.



Key to the diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

LIFO with the Include physical value option

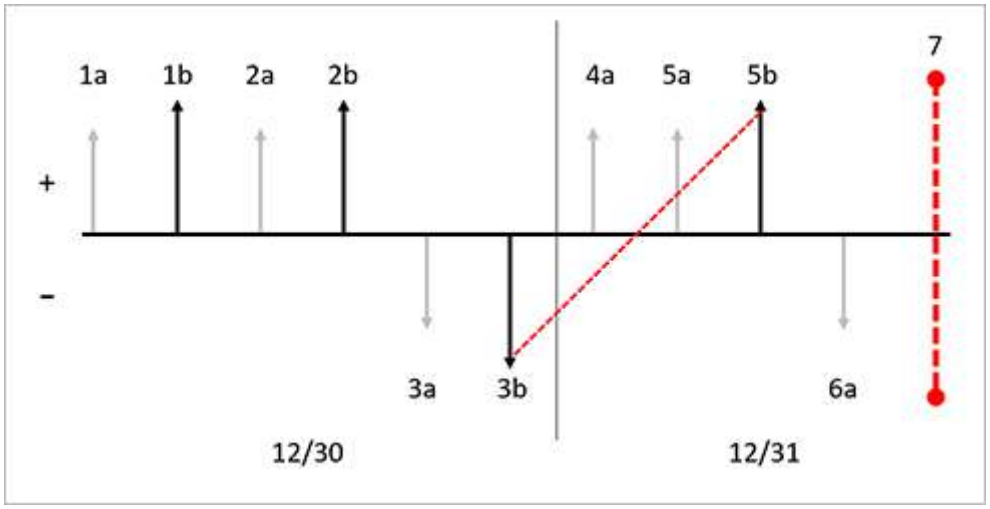
If the **Include physical value** checkbox is selected for an item on the **Item model groups** page, the system uses both physical and financial receipt transactions to calculate the running average cost price. Where applicable, the system also adjusts the physically

updated issue transaction. When the **Include physical value** checkbox is cleared, inventory close that uses the LIFO inventory model makes settlements only to transactions that are financially updated.

The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.67 (running average of physically and financially posted transactions).
- 7. Inventory close is performed. Based on the LIFO method, the first financially updated issue is settled against the last financially updated receipt, and so on. In this example, one settlement is created between 3b and 5b. An adjustment of USD 14.00 is made to 3b, and the resulting final cost is USD 30.00. Additionally, transaction 6a is adjusted to the receipt transaction cost of 4a. The system won't settle these transactions, because the receipt is updated physically but not financially. Instead, only an adjustment of USD 1.33 is posted to the physical issue transaction, and the resulting adjusted cost will be USD 25.00.

The following illustration shows the effects of the LIFO inventory model on this series of transactions when the **Include physical value** option is used.



Key to the diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

LIFO with marking

Marking is a process that lets you link, or mark, an issue transaction to a receipt transaction. Marking can occur either before or after a transaction is posted. You can use marking when you want to be sure of the exact cost of inventory when the transaction is posted or the inventory close is performed. For example, the Customer Service department accepted a rush order from an important customer. Because this order is a rush order, you must pay more for the item to fulfill the customer's request.

You must make sure that the cost of the inventory item is reflected in the margin, or cost of goods sold (COGS), for the sales order invoice. When the purchase order is posted, the inventory is received at a cost of USD 120.00. If this sales order document is marked to the purchase order before the packing slip or invoice is posted, the COGS is USD 120.00, not the current running average cost for the item. If the sales order packing slip or invoice is posted before the marking occurs, the COGS is posted at the running average cost price.

Before inventory close is performed, these two transactions can still be marked to each other.

You can mark an issue transaction to a receipt before the transaction is posted. You can do this marking from a sales order line on the **Sales order details** page by selecting **Inventory** > **Marking** on the **Sales order lines** FastTab. You can view the open receipt transactions on the **Marking** page.

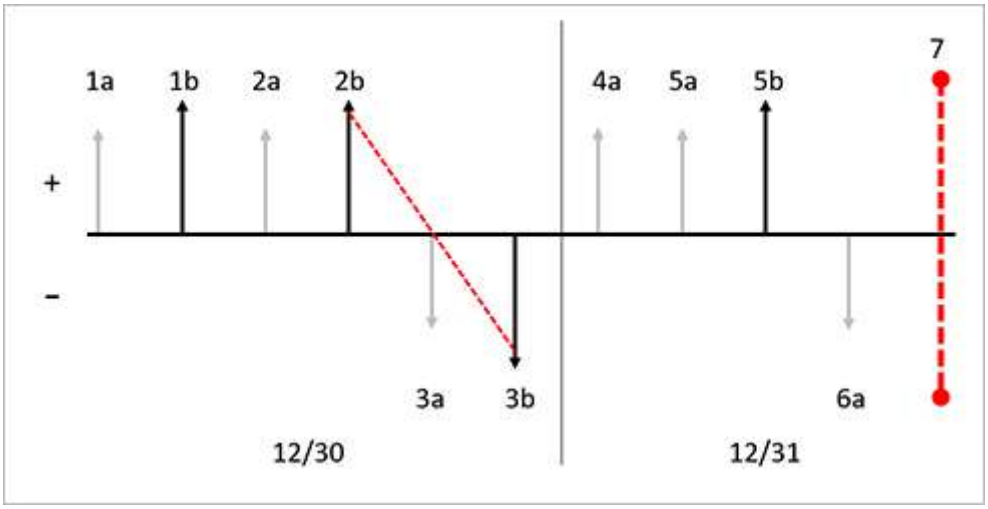
You can also mark an issue transaction to a receipt after the transaction is posted. You can match or mark an issue transaction for an open receipt transaction for an inventoried item from a posted inventory adjustment journal.

The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3c. Inventory financial issue for 3b is marked to inventory financial issue for 2b.
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions)
- 7. Inventory close is performed. Based on the marking principle that uses the LIFO method, the marked transactions are settled against each other. In this example, 3b is settled against 2b, and an adjustment for USD 6.00 is posted to 3b to bring the value to USD 22.00. In this example, no additional settlements are made, because the close creates settlements only for financially updated transactions.

The new running average cost price reflects the average of the financially and physically updated transactions, USD 17.50.

The following illustration shows the effects of the LIFO inventory model on this series of transactions when marking between issues and receipts is used.



Key to diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements and markings that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average with physical value and marking

07/21/2025

Weighted average is an inventory model based on an average that results from the multiplication of each component (item transaction) by a factor (cost price) reflecting its importance (quantity). Another way to say this is that weighted average is an inventory model that assigns the cost of issue transactions based on the mean value of all inventory received during the period, plus any on-hand inventory from the previous period.

When you run an inventory closing using the weighted average inventory model, there are two ways a settlement can be created. Typically, all receipts are settled against a virtual issue, which holds the total received quantity and value. This virtual issue has a corresponding virtual receipt from which the issues are settled. In this manner, all issues get the same average cost. The virtual issue and receipt can be seen as a virtual transfer, which is named the *weighted average inventory closing transfer*. This settlement method is called a *weighted average summarized settlement*. If there's only one receipt, all issues can be settled from it and the virtual transfer won't be created. This settlement method is referred to as a *direct settlement*. Any inventory that is on hand after the inventory close is performed is valued at the weighted average from the previous period and included in the weighted average calculation in the next period.

You can override the weighted average principle by marking inventory transactions so that a specific item receipt is settled against a specific issue. A periodic inventory close is required when you use the weighted average inventory model to create settlements and adjust the value of issues according to the weighted average principle. Until you run the inventory close process, issue transactions are valued at the running average when the physical and financial updates occurred. Unless you're using marking, the running average is calculated when the physical or financial update is performed.

The weighted average inventory costing method is calculated by the following formula:

- Weighted average = ([Q1 × P1] + [Q2 × P2] + [Q*n* × P*n*]) ÷ (Q1 + Q2 + Q*n*)

Q = quantity of the transaction
P = price of the transaction

Settlements are inventory close postings that adjust the issues to the correct weighted average as of the closing date. The following examples illustrate the effect of using weighted average with five different configurations:

- Weighted average direct settlement without the **Include physical value** option

- Weighted average summarized settlement without the **Include physical value** option
- Weighted average direct settlement with the **Include physical value** option
- Weighted average summarized settlement with the **Include physical value** option
- Weighted average with marking

Weighted average direct settlement without Include physical value

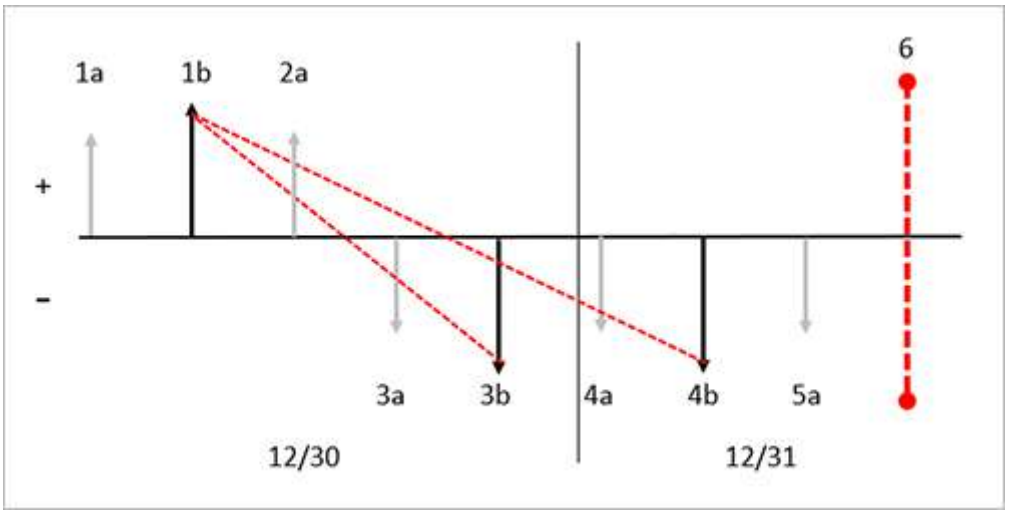
The direct settlement principle creates settlements directly between receipts and issues without creating additional inventory transactions. The system uses this direct settlement principle in the following situations:

- One receipt and one or more issues were posted in the period.
- Only issues were posted in the period and the inventory contains on-hand items from a previous closing.

In this example, the **Include physical value** checkbox is cleared on the **Item model group** for the released product. The illustration that follows shows these transactions:

- 1a. Inventory physical receipt for a quantity of 10 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 10 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 10 at a cost of USD 20.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 10.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 10.00 (running average of financially posted transactions).
- 4a. Inventory physical issue for a quantity of 1 at a cost of USD 10.00 each (running average of financially posted transactions).
- 4b. Inventory financial issue for a quantity of 1 at a cost of USD 10.00 each (running average of financially posted transactions).
- 5a. Inventory physical issue for a quantity of 1 at a cost of USD 10.00 each (running average of financially posted transactions).
- 6. Inventory close is performed. Based on the weighted average method, the system uses the direct settlement method because only one receipt is financially updated in the period. In this example, one settlement is created between 1b and 3b, and another between 1b and 4b. No adjustment is made because the running average is the same as the weighted average.

The following diagram illustrates this series of transactions with the effects of choosing the weighted average inventory model and the direct settlement principle without the **Include physical value** option.



Key to diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average summarized settlement without the Include physical value option

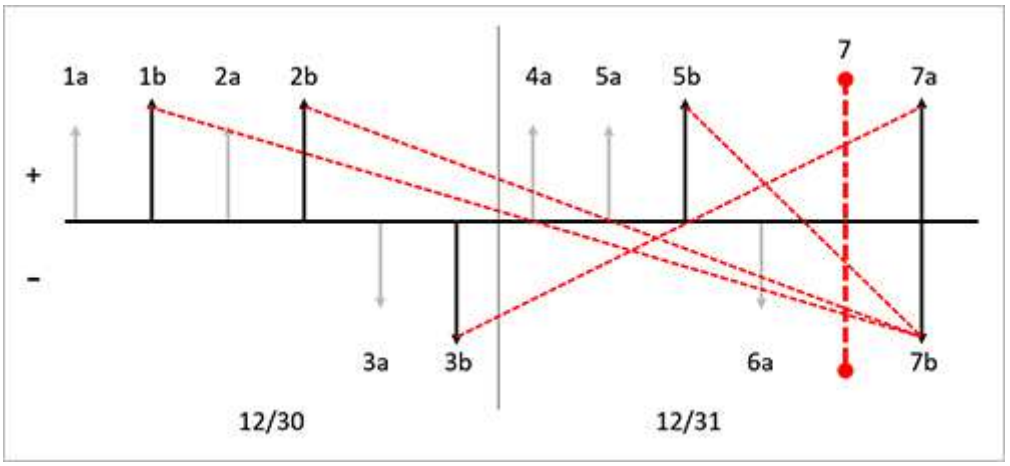
When there are multiple receipts in a period, weighted average uses the summarized settlement principle where all receipts within in a closing period are summarized into a transaction called *weighted average inventory closing*. All the receipts for the period will be settled against the issue of the newly created inventory transaction. All issues for the period will be settled against the receipt of the new inventory transaction. If there's remaining on-hand inventory after the inventory close, the on-hand inventory value is included in the receipt transaction of the weighted average inventory closing transactions.

The following transactions are illustrated in the graphic that follows:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.

- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions).
- 7. Inventory close is performed.
- 7a. Weighted average inventory close transaction financial issue is created to sum the settlements of all the inventory financial receipts.
    - Transaction 1b is settled for a quantity of 1 with an amount settled of USD 10.00.
    - Transaction 2b is settled for a quantity of 1 with an amount settled of USD 22.00.
    - Transaction 5b is settled for a quantity of 1 with an amount settled of USD 30.00.
    - Transaction 7a. is created for a quantity of 3 with an amount settled of USD 62.00. This transaction offsets the sum of the three receipt transactions that are financially updated in the period.
- 7b. Weighted average inventory close transaction financial receipt is created as the offset to financially posted issues.
    - Transaction 3b is settled for a quantity of 1 with an amount settled of USD 20.67. This transaction is adjusted by USD 4.67 to bring the original value of USD 16.00 to 20.67, which is the weighted average of financially posted transactions for the period.
    - Transaction 7b. is created for a quantity of 1 with an amount settled of USD 20.67 to offset 3b. This transaction offsets the sum of the one issue transaction that is financially updated in the period.

The following diagram illustrates this series of transactions with the effects of choosing the weighted average inventory model and the summarized settlement principle without the **Include physical value** option.



Key to diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average direct settlement with the Include physical value option

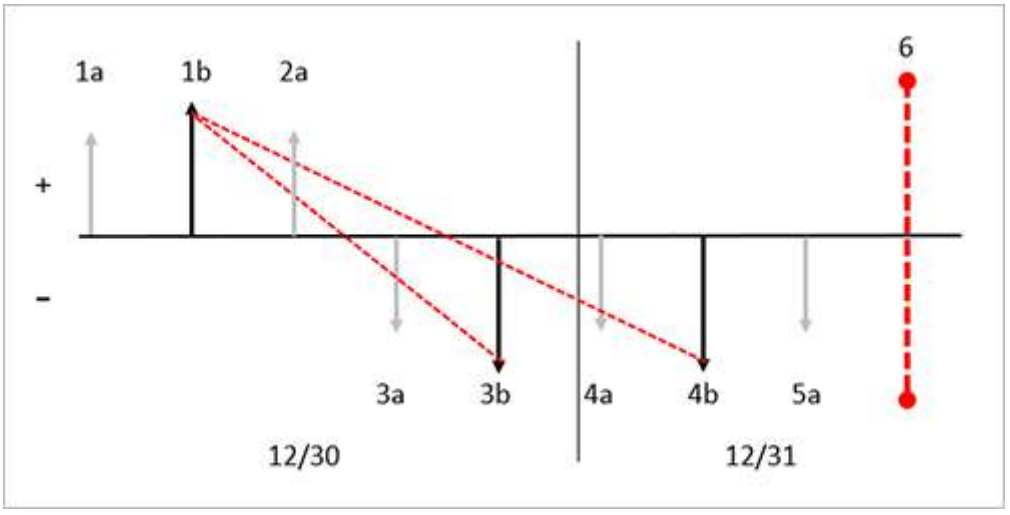
The parameter **Include physical value** works differently with the weighted average inventory model than in earlier versions of the product. When you select the **Include physical value** option for an item in the **Item model group** form, the system uses physically updated receipts when calculating the estimated issue cost price, or running average. Issues are posted based on this estimated cost price during the period. During the inventory close, financially updated receipts are only considered in the weighted average calculation.

The following transactions are illustrated in the graphic that follows:

- 1a. Inventory physical receipt for a quantity of 10 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 10 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 10 at a cost of USD 20.00 each.

- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 15.00 (running average of physically and financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 15.00 (running average of physically and financially posted transactions).
- 4a. Inventory physical issue for a quantity of 1 at a cost of USD 15.00 each (running average of physically and financially posted transactions).
- 4b. Inventory financial issue for a quantity of 1 at a cost of USD 15.00 each (running average of physically and financially posted transactions).
- 5a. Inventory physical issue for a quantity of 1 at a cost of USD 15.00 each (running average of physically and financially posted transactions).
- 6. Inventory close is performed. Based on the weighted average method, the system uses the direct settlement method because only one receipt is financially updated in the period. In this example, one settlement is created between 1b and 3b, and another between 1b and 4b. Transaction 3b and 4b are each adjusted by USD -5.00 to bring the value to USD 10.00.

The following diagram illustrates this series of transactions with the effects of choosing the weighted average inventory model and the direct settlement principle with the **Include physical value** option.



Key to diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.

- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average summarized settlement with the Include physical value option

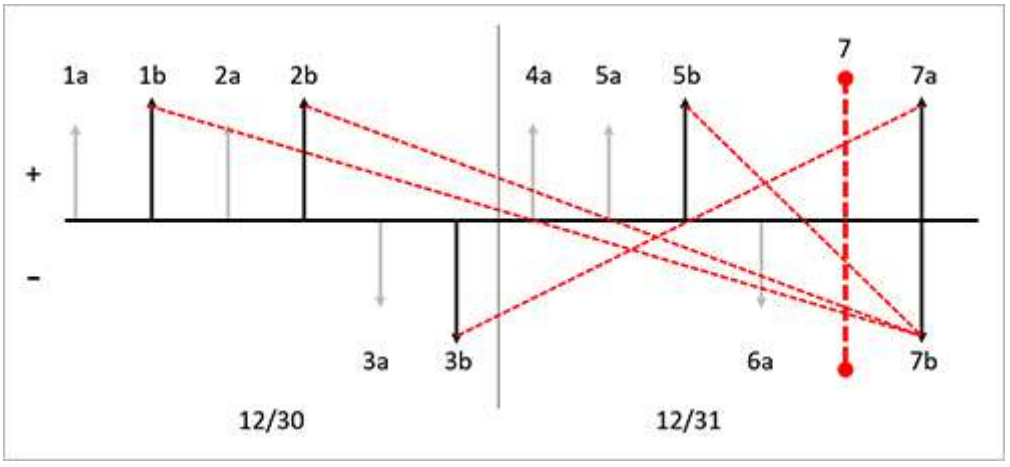
The **Include physical value** parameter works differently with weighted average than in earlier versions. Select the **Include physical value** checkbox for an item on the **Item model group** page. Then the system uses physically updated receipts in the calculation of estimated cost price, or running average. Issues are posted based on this estimated cost price during the period. During the inventory close, financially updated receipts are only considered in the weighted average calculation. We recommend a monthly inventory close when you use the weighted average inventory model. In this weighted average summarized settlement example, the inventory model is marked to include physical value.

The following transactions are illustrated in the graphic that follows:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.67 (running average of physically and financially posted transactions).
- 7. Inventory close is performed.
- 7a. Weighted average inventory close transaction financial issue is created to sum the settlements of all the inventory financial receipts.
    - Transaction 1b is settled for a quantity of 1 with an amount settled of USD 10.00.
    - Transaction 2b is settled for a quantity of 1 with an amount settled of USD 22.00.
    - Transaction 5b is settled for a quantity of 1 with an amount settled of USD 30.00.
    - Transaction 7a. is created for a quantity of 3 with an amount settled of USD 62.00.

- 7b. Weighted average inventory close transaction financial receipt is created as the offset the financially closed issue transactions.
    - Transaction 3b is settled for a quantity of 1 with an amount settled of USD 20.67. This transaction is adjusted by USD 4.67 to bring the original value of USD 16.00 to 20.67, which is the weighted average of financially posted transactions for the period.
    - Transaction 7b. is created for a quantity of 1 with an amount settled of USD 20.67 to offset 3b.

The following diagram illustrates this series of transactions with the effects of choosing the weighted average inventory model and the summarized settlement principle without the **Include physical value** option.



Key to diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average with marking

Marking is a process that lets you link, or mark, an issue transaction to a receipt transaction. Marking can occur either before or after a transaction is posted. You can use marking when you

want to make sure of the exact cost of the inventory when the transaction is posted or when the inventory close is performed.

For example, your Customer Service department accepted a rush order from an important customer. Because this is a rush order, you'll have to pay more for this item to service your customer's request. You must be certain the cost of this inventory item is reflected in the margin, or cost of goods sold (COGS), for this sales order invoice.

When the purchase order is posted, the inventory is received at a cost of USD 120.00. For example, this sales order document is marked to the purchase order before the packing slip or invoice is posted. Then COGS will be USD 120.00 instead of the current running average cost for the item. If the sales order packing slip or invoice is posted before the marking occurs, the COGS will be posted at the running average cost price.

Before inventory close is performed, these two transactions can still be marked to each other.

A receipt transaction is marked to an issue transaction. Then, the valuation method selected for the item's item model group will be disregarded and the system will settle these transactions to each other.

You can mark an issue transaction to a receipt before the transaction is posted. You can do this from a sales order line on the **Sales order details** page. The open receipt transactions are shown on the **Marking** page.

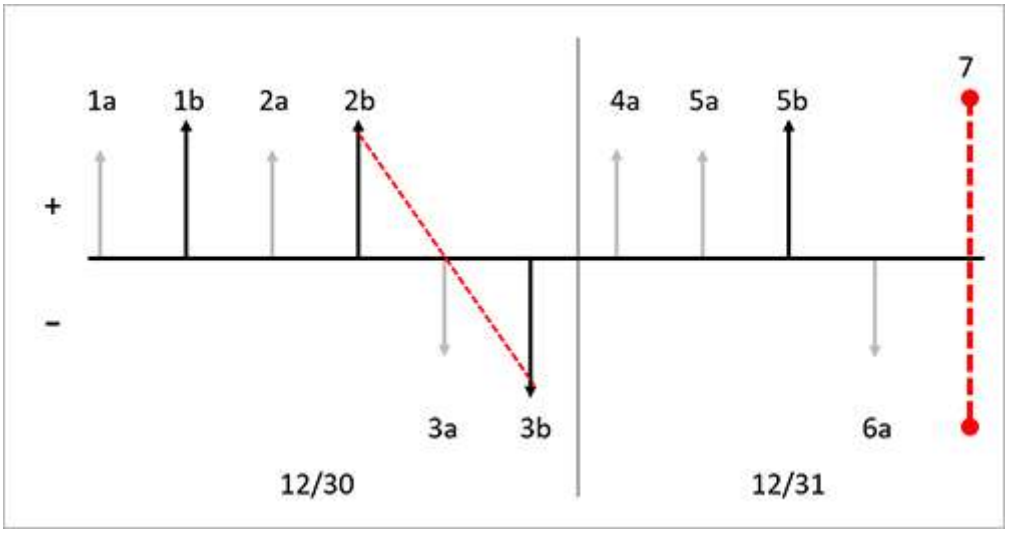
You can mark an issue transaction to a receipt after the transaction has been posted. You can match or mark an issue transaction for an open receipt transaction for an inventoried item from a posted inventory adjustment journal.

The following transactions are illustrated in the graphic that follows:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3c. Inventory financial issue for 3b is marked to inventory financial issue for 2b.
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions).

- 7. Inventory close is performed. Based on the marking principle that uses the weighted average method, the marked transactions are settled against each other. In this example, 3b is settled against 2b, and an adjustment for USD 6.00 is posted to 3b to bring the value to USD 22.00. In this example, no additional settlements are made because the close creates settlements only for financially updated transactions.

The following diagram illustrates this series of transactions with the effects of choosing the weighted average inventory model with marking.



Key to diagram

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Each date in the diagram is separated by a thin black vertical line. The date is noted at the bottom of the diagram.
- Inventory closings are represented by a red vertical dashed line.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average date with Include physical value and marking

Article • 01/24/2025

Weighted average date is an inventory model that is based on an average that is calculated by multiplying each component (item transaction) by a factor (cost price) that reflects its importance (quantity) on each day in the period. In other words, this inventory model assigns the cost of issue transactions based on the mean value of all inventory that is received each day, plus any on-hand inventory from the previous day.

When you run an inventory closing by using the weighted average date inventory model, two methods can be used to create a settlement. Typically, all receipts are settled against a virtual issue that holds the total received quantity and value. This virtual issue has a corresponding virtual receipt that the issues are settled from. In this way, all issues get the same average cost each day. The virtual issue and the virtual receipt can be considered a virtual transfer. This virtual transfer is referred to as *weighted average inventory closing transfer*. Therefore, this settlement method is known as a *weighted average summarized settlement*. If there's only one receipt, all issues can be settled from it, and no virtual transfer is created. This settlement method is referred to as *direct settlement*. Any inventory that is on hand after the inventory close is performed is valued at the weighted average from the last day of the previous period and included in the weighted average date calculation in the next period.

You can override the weighted average date principle by marking inventory transactions so that a specific item receipt is settled against a specific issue. A periodic inventory close is required when you use the weighted average date inventory model to create settlements and adjust the value of issues according to the weighted average date principle. Until you run the inventory close, issue transactions are valued at the running average when the physical and financial updates occurred. Unless you're using marking, the running average is calculated when the physical or financial update is performed.

The weighted average date inventory costing method is calculated by using the following formula each day:

$$Cost = [(Q_b \times P_b) + \sum_n (Q_n \times P_n)] \div (Q_b + \sum_n Q_n)$$

- Q = Quantity of the transaction
- P = Price of the transaction

In other words, the weighted average cost equals the beginning quantity times the beginning price, plus the sum of each receipt quantity times its receipt price, all divided

by the beginning quantity plus the sum of the receipt quantities.

During inventory close, the calculation is performed every day during the closing period.

> **Note**
>
> For more information about settlements, see Inventory close.

The following examples show the effect of using weighted average date with five configurations:

- Weighted average date direct settlement when the **Include physical value** option isn't used
- Weighted average date summarized settlement when the **Include physical value** option isn't used
- Weighted average date direct settlement when the **Include physical value** option is used
- Weighted average date summarized settlement when the **Include physical value** option is used
- Weighted average date when marking is used

Weighted average date direct settlement when the Include physical value option isn't used

The direct settlement principle creates settlements directly between receipts and issues, without creating additional inventory transactions. The system uses this direct settlement principle in the following situations:

- One receipt and one or more issues have been posted in the period.
- Only issues have been posted in the period, and the inventory contains on-hand items from a previous closing.

In this example, the **Include physical value** checkbox is cleared on the **Item model group** page for the released product. The diagram that follows shows these transactions:

Day 1:

- 1a. Inventory physical receipt for a quantity of 10 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 10 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 10 at a cost of USD 20.00 each.

- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 10.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 10.00 (running average of financially posted transactions).

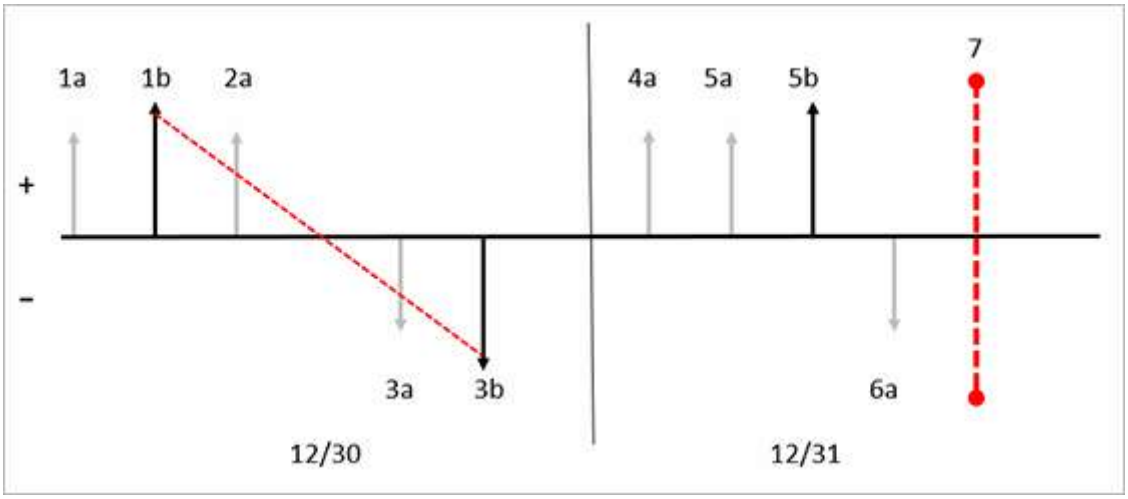
Day 2:

- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory financial issue for a quantity of 1 at a cost of USD 20.00 each (running average of financially posted transactions).

Day 3:

- 7. Inventory close is performed. Based on the weighted average date method, the system uses the direct settlement method for December 30 (12/30) because only one receipt is financially updated on 12/30. In this example, one settlement is created between transactions 1b and 3b. An adjustment of USD 10.00 is made to bring the value of transaction 3b up to 20.00. No adjustment or settlement is made on December 31 (12/31) because there are no financially updated issues on 12/31.

The following diagram shows this series of transactions and the effects of using the weighted average inventory model and the direct settlement principle without the **Include physical value** option.



Key to the diagram:

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.

- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Dates are separated by thin black vertical lines. The dates are noted at the bottom of the diagram.
- Inventory closings are represented by red vertical dashed lines.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average date summarized settlement when the Include physical value option isn't used

When there are multiple receipts in a period, weighted average date uses the summarized settlement principle, where all receipts in a single day are summarized into a transaction that is named *weighted average inventory closing*. All the receipts for the day will be settled against the issue of the newly created inventory transaction. All issues for the day will be settled against the receipt of the new inventory transaction. If any on-hand inventory value remains after the inventory close, the on-hand inventory value is included in the receipt transaction of the weighted average inventory closing transactions.

The diagram that follows shows these transactions:

Day 1:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).

Day 2:

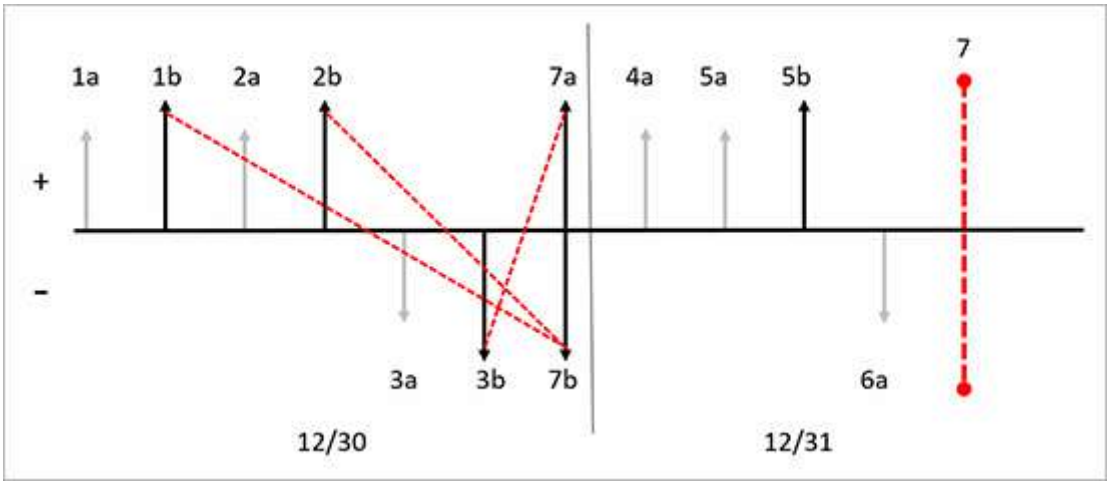
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.

- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions).

Day 3:

- 7. Inventory close is performed.
- 7a. Weighted average inventory close transaction financial issue is created to sum the settlements of all the inventory financial receipts.
  - Transaction 1b is settled for a quantity of 1 with a settled amount of USD 10.00.
  - Transaction 2b is settled for a quantity of 1 with a settled amount of USD 22.00.
  - Transaction 7a is created for a quantity of 2 with a settled amount of USD 32.00. This transaction offsets the sum of the two receipt transactions that are financially updated in the period.
- 7b. Weighted average inventory close transaction financial receipt is created as the offset for financially posted issues.
  - Transaction 3b is settled for a quantity of 1 with a settled amount of USD 16.00. This transaction isn't adjusted because it's the weighted average of financially posted transactions on December 1 (12/1).
  - Transaction 7b is created for a quantity of 2 with a financial amount of USD 32.00 and a settled amount of USD 16.00 to offset transaction 3b. This transaction offsets the sum of the one issue transaction that is financially updated in the period. The transaction remains open because there's still one on hand.

The following diagram shows this series of transactions and the effects of using the weighted average inventory model and the summarized settlement principle, but without using the **Include physical value** option.



Key to the diagram:

- Inventory transactions are represented by vertical arrows.

- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Dates are separated by thin black vertical lines. The dates are noted at the bottom of the diagram.
- Inventory closings are represented by red vertical dashed lines.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average date direct settlement when the Include physical value option is used

In the current version of the product, the **Include physical value** option works differently with the weighted average date inventory model than it worked in earlier versions. When you select the **Include physical value** checkbox for an item on the **Item model group** page, the system will use physically updated receipts when it calculates the estimated issue cost price, or running average. Issues will be posted based on this estimated cost price during the period. During the inventory close, only financially updated receipts will be considered in the weighted average calculation.

The diagram that follows shows these transactions:

Day 1:

- 1a. Inventory physical receipt for a quantity of 10 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 10 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 10 at a cost of USD 20.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 15.00 (running average of physically and financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 15.00 (running average of physically and financially posted transactions).

Day 2:

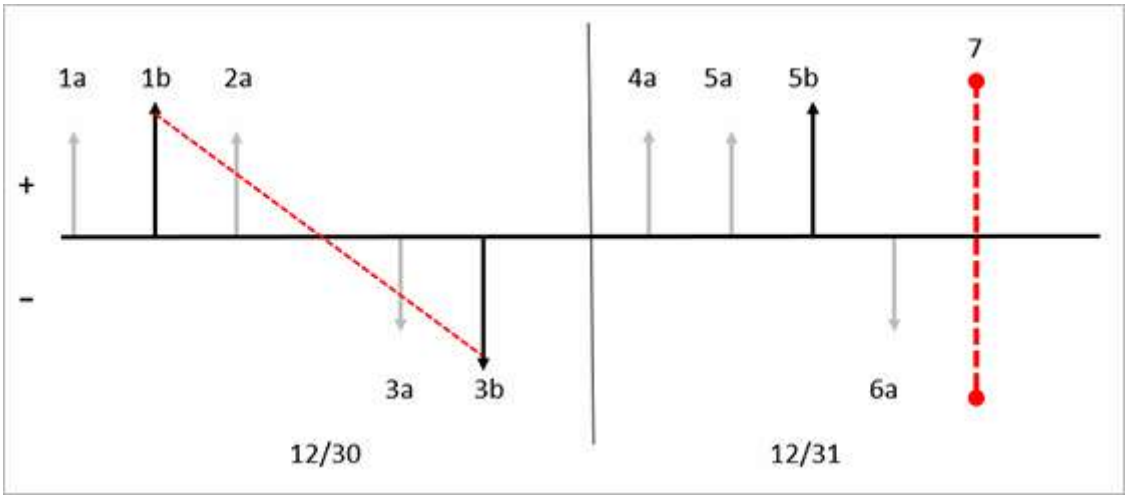
- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.

- 6a. Inventory physical issue for a quantity of 1 at a cost of USD 21.25 each (running average of physically and financially posted transactions).

Day 3:

- 7. Inventory close is performed. Based on the weighted average date method, the system uses the direct settlement method for December 30 (12/30) because only one receipt is financially updated on 12/30. In this example, one settlement is created between transactions 1b and 3b. No adjustment is made to the issue on 12/30. Additionally, no adjustment or settlement is made on December 31 (12/31) because there are no financially updated issues on 12/31.

The following diagram shows this series of transactions and the effects of using the weighted average inventory model and the direct settlement principle with the **Include physical value** option.



Key to the diagram:

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Dates are separated by thin black vertical lines. The dates are noted at the bottom of the diagram.
- Inventory closings are represented by red vertical dashed lines.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average date summarized settlement when the Include physical value option is used

In the current version of the product, the **Include physical value** option works differently with weighted average than it worked in earlier versions. When you select the **Include physical value** checkbox for an item on the **Item model group** page, the system will use physically updated receipts when it calculates the estimated cost price, or running average. Issues will be posted based on this estimated cost price during the period. During the inventory close, only financially updated receipts will be considered in the weighted average calculation. We recommend that you perform a monthly inventory close when you use the weighted average inventory model. In this example of weighted average date summarized settlement, the inventory model is marked to include physical value.

The diagram that follows shows these transactions:

Day 1:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.
- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of physically and financially posted transactions).

Day 2:

- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.67 (running average of physically and financially posted transactions).

Day 3:

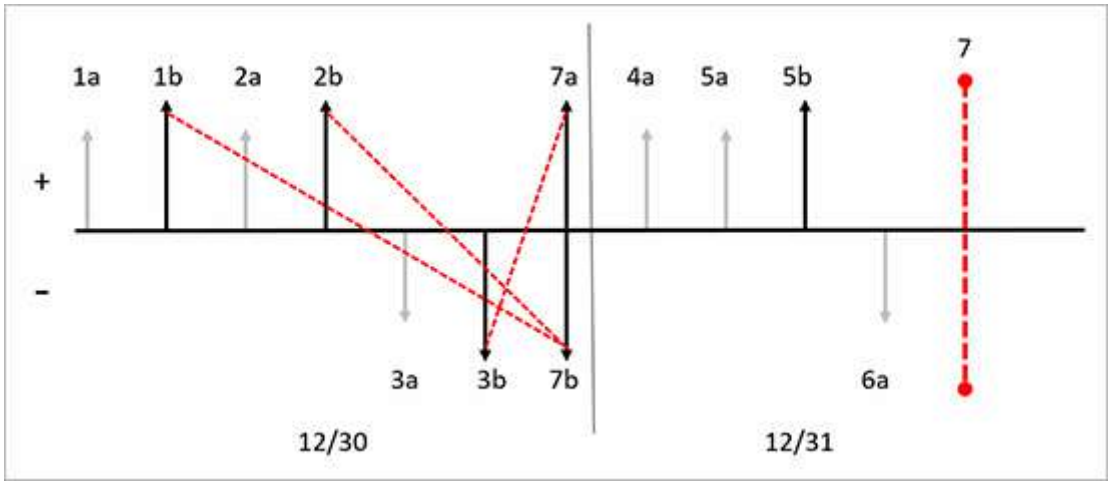
- 7. Inventory close is performed.

- 7a. Weighted average inventory close transaction financial issue is created to sum the settlements of all the inventory financial receipts.
  - Transaction 1b is settled for a quantity of 1 with a settled amount of USD 10.00.
  - Transaction 2b is settled for a quantity of 1 with a settled amount of USD 22.00.

    - Transaction 7a is created for a quantity of 2 with a settled amount of USD 32.00. This transaction offsets the sum of the two receipt transactions that are financially updated in the period.

- 7b. Weighted average inventory close transaction financial receipt is created as the offset for financially posted issues.
    - Transaction 3b is settled for a quantity of 1 with a settled amount of USD 16.00. This transaction isn't adjusted because it's the weighted average of financially posted transactions on December 1 (12/1).
    - Transaction 7b is created for a quantity of 2 with a financial amount of USD 32.00 and a settled amount of USD 16.00 to offset transaction 3b. This transaction offsets the sum of the one issue transaction that is financially updated in the period. The transaction remains open because there's still one on hand.

The following diagram shows this series of transactions and the effects of using the weighted average inventory model and the summarized settlement principle without the **Include physical value** option.



Key to the diagram:

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.
- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Dates are separated by thin black vertical lines. The dates are noted at the bottom of the diagram.
- Inventory closings are represented by red vertical dashed lines.

- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Weighted average date when marking is used

Marking is a process that lets you link, or mark, an issue transaction to a receipt transaction. Marking can occur either before or after a transaction is posted. You can use marking when you want to make sure of the exact cost of the inventory when the transaction is posted or the inventory close is performed.

For example, your Customer Service department accepted a rush order from an important customer. Because it's a rush order, you'll have to pay more for this item to service your customer's request. You must be sure that the cost of this inventory item is reflected in the margin, or cost of goods sold (COGS), for this sales order invoice.

When the purchase order is posted, the inventory is received at a cost of USD 120.00. If the sales order document is marked to the purchase order before the packing slip or invoice is posted, COGS will be USD 120.00 instead of the current running average cost for the item. If the marking occurs after sales order packing slip or invoice is posted, the COGS will be posted at the running average cost price.

Before inventory close is performed, these two transactions can still be marked to each other.

If a receipt transaction is marked to an issue transaction, the valuation method that is selected for the item's item model group will be disregarded, and the system will settle these transactions to each other.

You can mark an issue transaction to a receipt before the transaction is posted. You can do this marking from a sales order line on the **Sales order details** page. The open receipt transactions are shown on the **Marking** page.

You can also mark an issue transaction to a receipt after the transaction is posted. You can match or mark an issue transaction for an open receipt transaction for an inventoried item from a posted inventory adjustment journal.

The diagram that follows shows these transactions:

Day 1:

- 1a. Inventory physical receipt for a quantity of 1 at a cost of USD 10.00 each.
- 1b. Inventory financial receipt for a quantity of 1 at a cost of USD 10.00 each.
- 2a. Inventory physical receipt for a quantity of 1 at a cost of USD 20.00 each.
- 2b. Inventory financial receipt for a quantity of 1 at a cost of USD 22.00 each.

- 3a. Inventory physical issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3b. Inventory financial issue for a quantity of 1 at a cost price of USD 16.00 (running average of financially posted transactions).
- 3c. Inventory financial issue for transaction 3b is marked to inventory financial issue for transaction 2b.

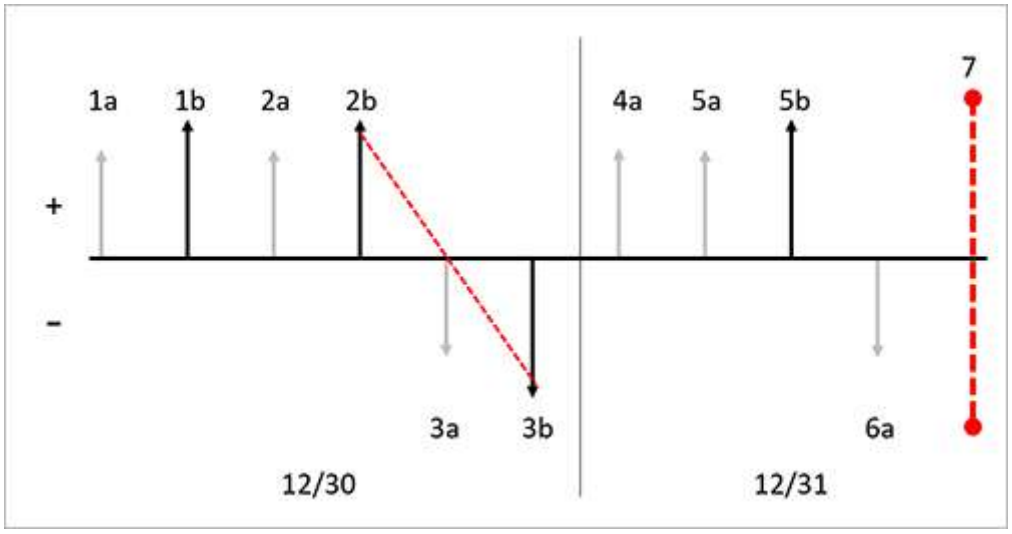
Day 2:

- 4a. Inventory physical receipt for a quantity of 1 at a cost of USD 25.00 each.
- 5a. Inventory physical receipt for a quantity of 1 at a cost of USD 30.00 each.
- 5b. Inventory financial receipt for a quantity of 1 at a cost of USD 30.00 each.
- 6a. Inventory physical issue for a quantity of 1 at a cost price of USD 23.00 (running average of financially posted transactions).

Day 3:

- 7. Inventory close is performed. Based on the marking principle that uses the weighted average method, the marked transactions are settled against each other. In this example, transaction 3b is settled against transaction 2b, and an adjustment for USD 6.00 is posted to transaction 3b to bring the value to USD 22.00. In this example, no additional settlements are made because the close creates settlements only for financially updated transactions.

The following diagram shows this series of transactions and the effects of using the weighted average inventory model with marking.



Key to the diagram:

- Inventory transactions are represented by vertical arrows.
- Physical transactions are represented by shorter light gray arrows.
- Financial transactions are represented by longer black arrows.

- Receipts into inventory are represented by vertical arrows above the axis.
- Issues out of inventory are represented by vertical arrows below the axis.
- Each new receipt or issue transaction is designated by a new label.
- Each vertical arrow is labeled with a sequential identifier, such as *1a*. The identifiers indicate the order of inventory transaction postings in the timeline.
- Dates are separated by thin black vertical lines. The dates are noted at the bottom of the diagram.
- Inventory closings are represented by red vertical dashed lines.
- Settlements that are performed by inventory close are represented by red diagonal dashed arrows that go from a receipt to an issue.

Moving average is a perpetual costing method based on the average principle, where the costs on inventory issues don't change when the purchase cost does. The difference is capitalized and is based on a proportional calculation. The amount that remains is expensed.

When you use moving average, inventory settlements and inventory marking aren't supported. Inventory close doesn't affect products that have moving average as the inventory model group, and it doesn't generate any settlements between the transactions.

The following are prerequisites when you use moving average cost as a costing method.

1. On the **Item model groups** page, set up an item model group that has **Moving average** selected in the **Inventory model** field.

   > **Note**
   >
   > By default, when **Moving average** is selected, the **Post physical inventory** and **Post financial inventory** fields are also selected.

2. On the **Posting** page, assign accounts to the **Price difference for moving average**. You use the **Price difference for moving average** account when cost has to be proportionally expensed. This occurs in following two scenarios:

   - There's a difference in cost between a purchase receipt and the purchase invoice because there's a difference between the original inventory quantity and the current on-hand quantity.
   - The transactions bring the inventory from negative to zero, and there's a difference between the transaction cost and the current moving average cost.

3. On the **Posting** page, assign accounts to the **Cost revaluation for moving average** accounts on the **Inventory** tab. You use the **Cost revaluation for moving average** account when you want to adjust the moving average cost for a product to a new unit price.

4. On the **Released products** page, assign the moving average item model group to the product.

   > ⓘ **Note**
   >
   > The inventory close process only closes the accounting period. It doesn't affect products that have moving average assigned to them as an item model group.

Convert to the moving average costing method

You can convert products to use the moving average inventory valuation method. You usually do this type of conversion at the end of the year, after the last month of the current year is closed, by using the product's current costing model. You can change your inventory costing method from a costing method that is based on average cost or standard cost to a method that is based on moving average.

If you're changing your costing method from a standard costing method to a moving average method, you have to complete the following tasks:

1. Make adjustments to get inventory quantities and values down to 0 (zero).
2. After the inventory value and quantity are 0 (zero), change the item model group to moving average.
3. Make adjustments to get the quantity and value back into inventory.

You can't change your inventory costing method from a moving average method to a First in, First out (FIFO) method, a Last in, First out (LIFO) method, or a weighted average method.

> ⓘ **Note**
>
> Converting from standard cost to moving weighted average is a manual process.

The following examples illustrate the effect of using the moving average costing method. There are four configurations:

- Purchase order and proportionally expensed cost difference

- Moving average product and inventory adjustment
- Moving average with production
- Moving average with a backdated transaction

Purchase order and proportionally expensed cost difference

With moving average, the purchase receipt determines the product's cost. When the purchase invoice is posted, if there's a difference in cost between the purchase receipt and the purchase invoice, the difference is proportionally adjusted to the current products in stock, and any remaining amount is expensed.

In this example, a purchase order is created and received at one cost, and the purchase invoice is posted with a different cost.

1. Create a purchase order for a quantity of 2 and a unit price of 10.00.
2. Create a purchase receipt of the product.
3. Create a sales order for a quantity of 1 and a unit price of 10.00.
4. Create a purchase invoice for a quantity of 2 and a unit price of 12.00.

The difference in unit price, 2.00, is posted to the Price difference for moving average account when the purchase invoice is posted. The reason is that two products were purchased for a cost of 20.00. One of the products was sold for a unit price of 10.00. The purchase invoice was posted at a unit price of 12.00 with a quantity of 2. The unit price of the product can't be posted at 14.00.

Moving average product and inventory adjustment

If you need to adjust the moving average cost of a product, inventory adjustments are allowed as of today's date. You can't backdate an inventory adjustment to correct the moving average cost of a product. You can't have the cost flow through subsequent transactions.

In this example, the moving average cost is adjusted for a product.

1. Select the product that you want to adjust the moving average cost for.

> **Note**

The **Revaluation for moving average** page examines the inventory available for a product. The product selected has a posted quantity of 1, a posted a value of 12.00, a posted unit cost of 12.00, and a unit cost of 12.00.

2. Update the **Unit cost** field to 16.00. The system calculates the remaining fields.

3. The adjustment is posted.

> **Note**
>
> You can only adjust the moving average cost as of today's date.

On the **Settlements for voucher** page, you can see an adjustment of 4.00 posted to the Cost revaluation for moving average account.

Moving average with production

Moving average supports produced items. If you plan to use moving average in a production environment, select **Use estimated cost price** on the **Production control parameters** page. This means that the cost price that is calculated during estimation is used instead of the actual bill of material (BOM) calculation cost price.

Moving average with a backdated transaction

Backdated transactions are assigned the current moving average cost, and the product's physical quantity is updated, but the product's moving average cost isn't affected. In this moving average example, a backdated transaction for a moving average product is posted.

1. Create an inventory adjustment for the moving average product for a quantity of 1 and a cost of 20.00.
2. The inventory transaction history for the product resembles the following:

    - An inventory transaction of 1, a cost of 16.00, a posting date of January 15, and a transaction date of January 15.
    - An inventory adjustment of 1, a cost of 20.00, a posting date of January 1, and a transaction date of January 15.

3. Post the adjustment.

On the **Inventory transactions** page, you can see that 4.00 is expensed as the current moving average for the product is 16.00. You can post in the past, but the difference in cost is expensed, so the moving average cost isn't affected.

Negative inventory balances

Transactions are handled differently depending on whether the new on-hand quantity after the transaction is negative, zero, or positive.

New balance is negative or zero

If the new on-hand quantity is negative or zero, the transaction is costed at the current average costs. If there's a difference between the purchase price and the current average costs, it's posted to **Price difference for moving average**.

New balance is positive

If the new on-hand quantity is positive after the transaction, the transaction is split into two parts and costed differently, as summarized in the following table.

Expand table

Part	Description
Quantity from negative to zero	Inventory uses the current moving average cost of the item rather than the transaction cost for that portion of the receipt quantity that increases the on-hand balance from negative to zero. The difference between the transaction cost and the current moving average cost is posted to **Price difference for moving average**.
Quantity from zero to positive	Inventory uses the transaction cost for that portion of the receipt quantity that increases the on-hand balance from zero to positive.

Inventory value report

In this moving average example, the inventory value report is printed to support the current moving average calculation for a product. The Inventory value report can print the transactions in chronological order, together with the cost to support the moving average cost calculation of a product. The report displays the moving average cost for the product. In the **Inventory value reports** dialog box, a date interval allows you to select the **Transaction time** or the **Posting date** to sort the report by. The **Posting date** option is how the report is traditionally printed. The

Transaction time option is the actual date that the transaction is reported and the moving average cost for the product is updated. You can print the Inventory value report by using the **Transaction time sorting** option if you want to see the moving average cost calculation over time. The following table displays the transactions for the product that the report covers when using the **Transaction time sorting** option.

Expand table

Transaction time	Date	Transaction type	Quantity	Amount	Average unit cost
	October 1	Beginning balance	0	0.00	0.00
October 8	September 28	Backdated receipt	1	16.00	16.00
October 3	October 3	Purchase receipt	2	20.00	12.00
October 5	October 5	Sales order	-1	-10.00	13.00
October 7	October 7	Purchase invoice		2.00	14.00
October 8	October 8	Moving average revaluation		4.00	16.00
	October 31	Total	2	32.00	16.00

Note

You can't reconcile the general ledger with inventory by using the **Transaction time sorting** option. The report must be printed by using the **Posting date** option.

As of the release of the Inventory value report storage report in Supply Chain Management version 10.0.29, the older Inventory value report no longer supports transaction-level calculations. As a result, the **Average unit cost** is hidden by default for the older report. However, an extension point is provided that makes it possible to customize the system to add support for calculating cost prices on a transaction level and to make the **Average unit cost** field visible in the Inventory value report.

Last updated on 06/22/2026

Moving average fallback cost sequence

One way that you can calculate the cost of your inventory is by using a *moving average*. Up to three cost values can be associated with each inventory item:

- **Last issue** – The last issue cost that was assigned before inventory went negative
- **Active cost** – The latest cost that was activated in a costing version
- **Item price** – The cost that is specified for the released product

To determine which of these cost values should be used in moving average calculations, the system uses a *fallback cost sequence* to establish the order of preference for the values. If the preferred cost value isn't available, the system uses the next-preferred value, and so on.

To select the fallback cost sequence for moving average calculations, follow these steps:

1. Go to **Cost management** > **Inventory accounting policies setup** > **Parameters**.
2. On the **Inventory accounting** tab, in the **Moving average** section, set the **Fallback cost sequence** field to one of the following values:
    - *Last issue – Active cost – Item price* – This is the default sequence.
    - *Active cost – Last issue*
    - *Active cost – Item price* – Organizations might experience performance issues if they use business processes where inventory regularly goes negative and, at the same time, the transaction volume is high. This setting can help mitigate those performance issues.

Physical and financial updates

This article provides an overview of which types of transactions increase or decrease inventory quantities.

You can physically update and financially update inventory transactions in Dynamics 365 Supply Chain Management. Some types of physical and financial transactions increase inventory quantities, whereas others decrease the quantity.

Physical increases

When a physical transaction is posted, the status of the transaction record is *Received*. The following transactions are considered physical increases:

- Purchase order receipt
- Sales order packing slip return
- Reporting a production order as finished
- By-product on a production order picking list

Financial increases

When a financial receipt transaction is posted, the status of the transaction record that increases the quantity is *Purchased*. The following transactions are considered financial increases:

- Vendor invoice
- Sales order invoice for a return
- Production order costing
- Positive quantity inventory journals, such as movement, profit and loss, counting, bill of materials, and transfer

Transactions that increase quantity

Transactions that increase quantity are posted at the running average cost price. The calculated running average cost price is based on the cost of each of these transactions for each inventory dimension that is tracked financially. For information about running average cost prices, see Running average cost price.

Transactions that decrease quantity

The calculated running average cost price is used when a transaction that decreases quantity is posted, regardless of the inventory model associated with that inventory. The transaction that decreases quantity shouldn't marked to another transaction before it's posted. If the physical on-hand inventory becomes negative, the inventory cost defined for the item on the **Item** page is used.

> ⓘ **Note**
>
> If multisite functionality is enabled, this cost is the inventory cost defined for a site on the **Default order settings** page.

Physical issues vs. financial issues

When a physical issue transaction is posted, the status of the transaction record is *Deducted*. The following transactions are considered physical issues:

- Production order picking list journal
- Sales order packing slip
- Purchase order packing slip return

When a financial transaction is posted, the status of the transaction record is *Sold*. The following transactions are considered financial issues:

- Ending a production order
- Sales order invoice
- Vendor invoice return
- Negative quantity inventory journals, such as movement, profit and loss, counting, bill of materials, and transfer

Transactions that decrease quantity are posted at the running average cost price. Therefore, you need to run the inventory close procedure to settle issue transactions to receipt transactions, based on the inventory model assigned to each item.

Options for including physical value in cost calculations

Supply Chain Management provides two options for including physical value in cost calculations:

- Include physical value
- Include physical value in weighted average recalculation

You can also choose not to include physical value in cost calculations.

This article explains these options and how to set them up.

Include physical value

You can choose whether the system should consider physically updated transactions when calculating the average cost price for items belonging to a given item model group. To set this option, follow these steps:

1. Go to **Cost management** > **Inventory accounting policies setup** > **Item model groups**.
2. On the list pane, select the item model group that you want to configure (or create a new one).
3. Expand the **Costing method & cost recognition** FastTab.
4. Set the **Include physical value** check box to one of the following values:

    - *Selected* – Both physically updated transactions and financially updated transactions are used to calculate the running average cost price.
    - *Cleared* – Only financially updated transactions are used to calculate the running average cost price.

The check box has slightly different effects, depending on the inventory model that you use.

- If you select the **Include physical value** check box when using the *FIFO* (first in, first out), *LIFO* (last in, first out), or *LIFO date* inventory model, inventory close also makes adjustments to physically updated transactions.
- If you don't select the **Include physical value** check box when using the *FIFO* (first in, first out), *LIFO* (last in, first out), or *LIFO date* inventory model, inventory close makes settlements only to financially updated transactions.

- When you use the *weighted average* or *weighted average date* inventory model, inventory close settles only financially updated transactions, regardless of whether you select the **Include physical value** check box.

Include physical value example 1

The **Include physical value** check box is selected and you receive the following purchase orders:

- A purchase order for a quantity of 2 and a cost price of USD 10.00 that has been packing slip–updated.
- A purchase order for a quantity of 3 and a cost price of USD 12.00 that has been invoice-updated.

In this case, the running average cost price is USD 11.20 = (2x10+3x12)/(2+3), because both physically updated transactions and financially updated transactions are used to calculate the cost price.

Include physical value example 2

The **Include physical value** check box isn't selected, and the cost price on the item setup is USD 10.00.

- You receive a purchase order for a quantity of 20 and a cost price of USD 12.00 that has been packing slip–updated.

When a sales order is posted, the posted cost amount is USD 10.00, because the running average cost price doesn't include physically posted transactions.

> **Note**
>
> For comparison, if you select the **Include physical value** check box for this item, when a sales order is posted, the posted cost amount will be USD 12.00.

Include physical value in weighted average recalculation

This feature lets you choose whether to include physically updated transactions that haven't yet been financially updated when recalculating weighted average.

> **Important**
>
> This capability is only available during recalculation and isn't used during inventory close. If you would like to check the results including physical value after inventory closing, you should run a new recalculation.

Prerequisites

To use the feature described in this section, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.41 or later.
- The feature named *Recalculation for Weighted Average Cost including Physical Transaction* must be turned on in feature management.

Choose whether to include physical value in weighted average recalculation

To choose whether the system should include physically updated transactions that haven't yet been financially updated when recalculating weighted average, follow these steps:

1. Go to **Cost management** > **Inventory accounting policies setup** > **Item model groups**.
2. On the list pane, select the item model group that you want to configure (or create a new one).
3. Expand the **Costing method & cost recognition** FastTab.
4. Set the **Include physical value in weighted average recalculation** check box to one of the following values:

    - *Selected* – Both physically updated transactions and financially updated transactions are used to calculate the running average cost price.
    - *Cleared* – Only financially updated transactions are used to calculate the running average cost price.

> **Note**
>
> - This check box is only visible for item model groups where **Inventory model** is set to *Weighted avg.* or *Weighted avg. date*.

- This option is only available during recalculation and isn't used during inventory close. To ensure accurate results, we recommend that you perform the recalculation immediately after inventory closing.

Last updated on 03/25/2026

Fixed receipt price

Fixed receipt price is an option that you can select on an item model group when you use an inventory model other than *Standard cost* or *Moving weighted average*. In early versions of Microsoft Dynamics AX, this option was named **Standard cost**. It was renamed **Fixed receipt price** when the new standard cost inventory model was introduced in Dynamics AX 2012. This article explains how you can configure and use fixed receipt prices in Dynamics 365 Supply Chain Management.

About fixed receipt prices

When you select the **Fixed receipt price** checkbox on the **Item model group** page for an item, the system uses the receipt price as a standard cost for the inventory receipt. If the purchase price and the default item cost price that is configured for a product differ, the difference is posted to the **Fixed receipt price profit** or **Fixed receipt price loss** account and offset to the **Fixed receipt price offset** account that you specify on the **Inventory posting profile** page.

Because the **Fixed receipt price** option is used with different inventory models (such as first in, first out (FIFO); last in, first out (LIFO); and weighted average), the *Inventory close and adjustment* process will still create settlements and adjustments according to the inventory principle that you select on the **Item model group** page. However, adjustments are made only to issues from inventory.

For example, you've configured a product with an item model group where the **Inventory model** field is set to *FIFO* and the **Fixed receipt price** option is selected. When you receive inventory through a purchase order, the inventory value is set to the value of the item's default cost price at the time of product receipt. When you invoice the purchase order, if the invoice price is different, the system posts the default cost price on the released product to the inventory account. It posts the difference to the fixed receipt price profit or loss account. Later, when you sell or consume the product, the system uses the running average for the item at the time when the sales order invoice was posted (unless you use marking).

When you run the *Inventory close and adjustment* process, the system creates a settlement with the first issue against the first receipt. The difference between the receipt price that was used on the receipt and the running average that was used on the issue is posted in a new voucher.

Enable fixed receipt prices

To enable fixed receipt prices for an item, follow these steps:

1. Go to **Inventory management** > **Setup** > **Inventory** > **Item model groups**.
2. Create a new item model group, or select an existing model group.
3. On the **Costing method & cost recognition** FastTab, select the **Fixed receipt price** checkbox.

   > ⓘ **Note**
   >
   > You can't select the **Fixed receipt price** checkbox if the **Inventory model** field is set to *Standard cost* or *Moving average*.

4. Close the page.

After you enable the **Fixed receipt price** option, you must update your inventory posting profile by following these steps.

1. Go to **Inventory management** > **Setup** > **Posting** > **Posting**.
2. On the **Purchase order** tab, in the **Select** column, select **Fixed receipt price profit**.
3. On the Action Pane, select **New** to add a row to the grid.
4. Set up the new row so that it applies to the item model group that you enabled fixed receipt pricing for, and specify the main account that is used to record fixed receipt price profits for purchase orders. Configure other settings as you require.
5. In the **Select** column, select **Fixed receipt price loss**. Add a new row that applies to the item model group that you enabled fixed receipt pricing for, and specify the main account that is used to record fixed receipt price losses for purchase orders. Configure other settings as you require.
6. In the **Select** column, select **Fixed receipt price offset**. Add a new row that applies to the item model group that you enabled fixed receipt pricing for, and specify the main account that is used to record fixed receipt price offsets for purchase orders. Configure other settings as you require.
7. On the **Inventory** tab, in the **Select** column, select **Fixed receipt price profit**. Add a new row that applies to the item model group that you enabled fixed receipt pricing for, and specify the main account that is used to record fixed receipt price profits for inventory. Configure other settings as you require.
8. In the **Select** column, select **Fixed receipt price loss**. Add a new row that applies to the item model group that you enabled fixed receipt pricing for, and specify the main account that is

used to record fixed receipt price losses for inventory. Configure other settings as you require.

> **Note**
>
> We usually recommend that the **Fixed receipt price profit** and **Fixed receipt price loss** fields use the same main account for both purchase orders and inventory.

> **Important**
>
> When you change the value in the **Price** field on the **Manage costs** FastTab of the **Released products** page, the system doesn't automatically revalue the inventory that is on hand. As a manual workaround, open the **Closing and adjustment** page, and select **Adjustment** > **On-hand** on the Action Pane. Then select the items that are on hand, and adjust them to the current price. One clear advantage of using the standard cost inventory model is that it causes the system to automatically revalue the on-hand inventory.

Post to charge account accounting principle

07/10/2025

The *post to charge account* accounting principle lets you account for and more easily reconcile any differences that occur in the unit price between a physical posting and financial posting, indirect costs on purchased items, or charges on a purchase order.

Two configurations for Accounts payable charges codes on the **Charges code** page (**Accounts payable** > **Charges setup** > **Charges code**) can cause a purchase order to affect the valuation of inventory assets:

- For charges codes where the **Debit type** field is set to *Item* and the **Credit type** field is set to *Ledger account*, the ledger account that is selected as the absorption account acts as a stock variation account.
- For charges codes where the **Debit type** field is set to *Item* and the **Credit type** field is set to *Customer/Vendor*, the charge will be accounted as material cost, and the stock variation account of the item will be used.

European special accounting rule

In Europe, the *post to charge account* accounting principle is often used to incorporate a special accounting rule. For example, one of the following methods is typically used to account for inventory changes:

- **Cost of sales method** – The standard inventory posting profile configuration supports this method. The *post to charge account* accounting principle isn't required.
- **Nature of expense method** – Smaller organizations often use this method. It typically involves the following steps:

    1. Goods or services are fully expensed at the time of receipt.
    2. At the end of the period, a cycle count is performed.
    3. A manual adjustment for the quantity and value is posted into inventory. (The offset account is a stock variation account that offsets the expense that was posted in step 1. Therefore, you see the variation in the stock value only on this account.)

The *post to charge account* principle lets you fully automate the two postings. In this way, you can eliminate a manual period-end closing adjustment posting.

Enable the post to charge account accounting principle

To enable the *post to charge account* accounting principle, follow these steps.

1. Go to **Accounts payable** > **Setup** > **Accounts payable parameters**.
2. On the **Invoice** tab, on the **Invoice** FastTab, set the **Post to charge account in ledger** option to *Yes*.
3. Close the page.

Prerequisites and recommended parameters for the post to charge account accounting principle

If you plan to account for purchase charges and stock variations, the following prerequisites must be in place:

- On the **Invoice** tab of the **Accounts payable parameters** page (**Accounts payable** > **Setup** > **Accounts payable parameters**), the **Post to charge account in ledger** option must be set to *Yes*.

- On the **Item model groups** page (**Cost management** > **Inventory accounting policies setup** > **Item model groups**), all the following options must be set to *Yes* for every relevant model group that contains items that are included on a purchase order:
  - Post physical inventory
  - Post financial inventory
  - Accrue liability on product receipt

- On the **Delivery** tab of the **Procurement and sourcing parameters** page (**Procurement and sourcing** > **Setup** > **Procurement and sourcing parameters**), the **Generate charges on product receipt** option must be set to *Yes*.

- On the **Inventory accounting** tab of the **Inventory and warehouse management parameters** page (**Inventory management** > **Setup** > **Inventory and warehouse management parameters**), the **Post packing slip in ledger** option must be set to *Yes*.

- On the **Purchase order** tab of the **Posting** page (**Inventory management** > **Setup** > **Posting** > **Posting**), main accounts that apply to every relevant item must be specified for each of the following posting types:
  - Purchase expenditure, un-invoiced
  - Purchase expenditure for product
  - Stock variation

Example scenario 1: Change in unit cost price

This example scenario has the following prerequisites:

- First in, first out (FIFO) costing model

The following procedure provides an example that shows what happens when you change the unit cost price on a purchase order.

1. Create a purchase order for a quantity of 1 of an item that has a unit price of 100.00.
2. Confirm the purchase order.
3. Post the product receipt for the purchase order.
4. Validate the voucher on the product receipt. The following table shows a sample voucher.

Expand table

Posting type	Main account	Main account name	Account type	Debit/Credit?	Clearing account	Physical/Financial?	Amount
Purchase, stock variation	600170	Stock variation materials	Expense	Credit	No	Physical	-100.00
Cost of purchased materials received	140100	Materials Inventory	Asset	Debit	Yes	Physical	100.00
Purchase expenditure, un-invoiced	600180	Material Receipts	Expense	Debit	Yes	Physical	100.00
Purchase, accrual	200140	Accrued Purchases	Liability	Credit	Yes	Physical	-100.00

5. Post the invoice for the purchase order that has an updated unit price of 110.00.
6. Validate the voucher on the invoice. The following table shows a sample voucher.

Expand table

Posting type	Main account	Main account name	Account type	Debit/Credit?	Clearing account	Physical/Financial?	Amount
Purchase, stock variation	600170	Stock variation materials	Expense	Credit	No	Financial	-10.00
Cost of purchased materials received	140100	Materials Inventory	Asset	Debit	Yes	Financial	-100.00

Posting type	Main account	Main account name	Account type	Debit/Credit?	Clearing account	Physical/Financial?	Amount
Purchase expenditure, un-invoiced	600180	Material Receipts	Expense	Debit	Yes	Financial	-100.00
Purchase, accrual	200140	Accrued Purchases	Liability	Credit	Yes	Financial	100.00
Cost of purchased materials invoiced	140100	Materials Inventory	Asset	Debit	No	Financial	110.00
Purchase expenditure for product	600180	Materials Receipt	Expense	Credit	No	Financial	110.00
Vendor balance	211000	Accounts Payable Trade	Liability	Credit	No	Financial	-110.00

Example 2: Charges and indirect costs on the purchase order

This example scenario has the following prerequisites:

- FIFO costing model
- **Charges code 1:** Debit item and credit ledger account for 10%
- **Charges code 2:** Debit item and credit customer/vendor for 10.00 proportional
- **Indirect cost:** 2.00% added to the purchase price

The following procedure provides an example that shows what happens when you include charges and indirect costs on a purchase order.

1. Create a purchase order for a quantity of 1 of an item that has a unit price of 100.00.
2. Add one charges code for 10 percent that debits the item and credits the ledger.
3. Add one charges code for 10.00 that debits the item and credits the customer/vendor.
4. Allocate the charges to the purchase order lines.
5. Confirm the purchase order.
6. Post the product receipt for the purchase order.

7. Validate the voucher on the product receipt. The following table shows a sample voucher.

Expand table

Posting type	Main account	Main account name	Account type	Debit/ Credit?	Clearing account	Physical or Financial	Amount
Purchase, stock variation	600170	Stock variation materials	Expense	Credit	No	Physical	-110.00
Estimated indirect cost absorbed	600520	Absorbed Indirect Costs	Expense	Credit	Yes	Physical	-2.40
Purchase freight	600120	Freight/ Transportation Costs	Expense	Credit	No	Physical	-10.00
Cost of purchased materials received	140100	Materials Inventory	Asset	Debit	Yes	Physical	122.40
Purchase expenditure, un-invoiced	600180	Material Receipts	Expense	Debit	Yes	Physical	110.00
Purchase, accrual	200140	Accrued Purchases	Liability	Credit	Yes	Physical	-110.00

8. Post the invoice for the purchase order.

9. Validate the voucher on the invoice. The following table shows a sample voucher.

Expand table

Posting type	Main account	Main account name	Account type	Debit/Credit?	Clearing account	Physical/Financial?	Amount
Purchase, stock variation	600170	Stock variation materials	Expense	Credit	No	Financial	0.00
Estimated indirect cost absorbed	600520	Absorbed Indirect Costs	Expense	Debit	Yes	Financial	2.40
Indirect cost absorbed	600520	Absorbed Indirect Costs	Expense	Debit	No	Financial	-2.40

Posting type	Main account	Main account name	Account type	Debit/Credit?	Clearing account	Physical/Financial?	Amount
Cost of purchased materials received	140100	Materials Inventory	Asset	Credit	Yes	Financial	-110.00
Purchase expenditure, un-invoiced	600180	Material Receipts	Expense	Credit	Yes	Financial	-110.00
Purchase, accrual	200140	Accrued Purchases	Liability	Debit	Yes	Financial	110.00
Cost of purchased materials invoiced	140100	Materials Inventory	Asset	Debit	No	Financial	110.00
Purchase expenditure for product	600180	Materials Receipt	Expense	Credit	No	Financial	110.00
Vendor balance	211000	Accounts Payable Trade	Liability	Credit	No	Financial	-110.00

Cost objects

This article provides information about costs objects, and explains how costs and quantities are accumulated. A cost object is an entity that costs and quantities are accumulated for. A cost object entity can be either a product or product variants, such as variants for style and color.

The **Cost objects** page lists all cost objects that are registered on a product. The cost objects are defined by data from the following sources:

- Product
- Product dimension group
- Storage dimension group
- Tracking dimension group

A cost object represents a cost element of the *Direct material* type only. A cost object and an inventory object differ in the way that a cost object is defined by the inventory dimensions that are selected for financial inventory.

For example, suppose you have an item with following configuration:

- **Site:** Physical inventory = Yes, Financial inventory = Yes
- **Warehouse:** Physical inventory = Yes, Financial inventory = No
- **Batch No.:** Physical inventory = Yes, Financial inventory = No

For this example, the following table shows what is a cost object and what is an inventory object.

Expand table

Object type	Item number	Site	Warehouse	Batch No.
Cost object	x	x		
Inventory object	x	x	x	x

Accumulation of costs and quantities

- The value in the **Value** field is a sum of the following values:
  - Physical cost amount
  - Financial cost amount
  - Adjustments

- The value in the **Quantity** field is a sum of the following values:
  - Received
  - Deducted
  - Posted quantity
- The **Average unit cost** field is a calculated field. The value is calculated by dividing the **Value** value by the **Quantity** value.

> **Note**
>
> The **Include physical value** parameter has no effect on the preceding calculations.

View cost object balance

Follow these steps to view your cost object balance. This procedure is intended for the cost controller.

1. Go to **Cost management** > **Workspaces** > **Cost administration**.
2. On the Action Pane, select **Released products**.
3. Find and select the product you're looking for. If necessary, you can use the **Filter** field to help find it.
4. On the Action Pane, open the **Manage costs** tab and select **Cost objects**.
5. Find and select the cost object you're looking for.
6. On the Action Pane, select **Physical quantity**.
7. If you'd like to change the set of dimensions displayed, select **Dimensions display** from the Action Pane and then use the dialog to choose which dimensions to show. The **Physical quantity** grid shows a row for each unique combination of displayed dimensions, so if you show fewer dimensions, you'll probably see fewer rows, but the total quantity for all rows remains the same.

View inventory statement and KPI by cost object

Follow these steps to view inventory statement and key performance indicators (KPIs) by cost object. This procedure is intended for the cost controller.

1. Go to **Cost management** > **Workspaces** > **Cost administration**.
2. On the Action Pane, select **Released products**.
3. Find and select the product you're looking for. If necessary, you can use the **Filter** field to help find it.
4. On the Action Pane, open the **Manage costs** tab and select **Cost objects**.
5. Find and select the cost object you're looking for.
6. On the Action Pane, select **Inventory statement and KPIs**.
7. Use the **From date** and **To date** fields to specify the date range you're looking for.

Last updated on 11/26/2025

Cost entries

This article provides information about cost entries and when they're created. A cost entry is a record that registers the quantity and cost of a given event.

Cost entries are aggregations of inventory transactions that are recorded on active financial inventory dimensions.

Examples

Example 1: No cost entries are created

A transfer journal event is registered. The event transfers one piece of item A from location A to location B. The Location inventory dimension isn't considered part of the cost object. Therefore, the event creates two inventory transactions and no cost entries.

Example 2: Cost entries are created

A transfer journal event is registered. The event transfers one piece of item A from site 1 to site 2. The Site inventory dimension is considered part of the cost object. Therefore, the event creates two inventory transactions and two cost entries.

Example 3: One cost entry is created

A product receipt event is registered for a purchase order. The event registers 100 pieces of item A at a unit cost of 10.00 U.S. dollars (USD). Because item A uses a serial number to track the purpose of inventory management, a unique serial number is created for each item that is received. Therefore, the event creates 100 inventory transactions and one cost entry.

Cost entries page

The new **Cost entries** page lets you view and control registrations of quantities and costs. This page complements the **Inventory transaction** and **Inventory settlement** pages. Records are registered in chronological order for an event. Therefore, you can quickly find and control the accumulated costs of a specific event or all events that are related to a document. Here's an example:

- A product receipt event is registered for item A. One hundred pieces are received at a unit cost of 10.00 USD.
- A few days after the invoice event is registered, the cost increases to 11.00 USD. Therefore, the total amount is 1,100 USD. A second voucher is created to account for the difference of 100 USD.
- A few days later, a miscellaneous charge of 15.00 USD to cover the transportation cost is registered on the purchase order.

Expand table

Voucher	Date	Reference	Number	Lot ID	Quantity	Amount
00001	01-01-2015	Purchase order	100001	0000101	100.00	1000.00
00002	20-01-2015	Purchase order	100001	0000101		100.00
00003	31-01-2015	Adjustment	100001	0000101		15.00

The **Cost entries** page enables filtering by document ID and document date.

> **Note**
>
> Cost entries are available only for cost objects or released products.

Cost groups

Cost groups provide the basis for segmenting and analyzing cost contributions in a manufactured item's calculated cost, such as the cost contributions for material, labor, and overhead. Cost group segmentation has several synonyms within manufacturing environments, such as cost breakdown, cost decomposition, or cost classification.

Cost group segmentation has several synonyms within manufacturing environments, such as cost breakdown, cost decomposition, or cost classification. Cost group segmentation can serve several purposes. Here are some examples:

- It can segment costs for different types of material, such as ingredients and packaging material for a canned goods product, based on the cost groups that are assigned to items.
- It can segment costs for different types of operations resources, such as different types of labor or machines, based on the cost groups that are assigned to cost categories that are related to operations resources and routing operations.
- It can segment costs for setup time and run time in routing operations, based on the cost groups that are assigned to cost categories that are related to the routing operations.
- It can segment costs for different types of overhead, such as labor-related and machine-related overhead, based on cost groups that are assigned to indirect costs in the costing sheet setup.
- It can act as the basis for calculating various types of manufacturing overhead in the costing sheet setup. This overhead can include different types of overhead that are related to routing information about operations resources, or information about setup time and run time. Manufacturing overhead can also be related to cost contributions of component material, reflecting a lean manufacturing philosophy that eliminates the need for routing information.

Cost group segmentation applies to a manufactured item's calculated cost, regardless of whether that cost was based on standard costs or planned costs. The **Summary** page displays this segmentation by cost group, by level, or by both cost group and level.

The ability to retain cost group segmentation across multiple levels in a product structure is known as *splitting*. Splitting applies only to manufactured items that use a standard cost inventory model. If splitting isn't used, the cost of a manufactured component is treated as a material cost contribution. The inventory parameter for cost breakdown by subledger indicates that cost group segmentation will be retained across multiple levels in standard cost calculations.

By contrast, if a policy has no levels, cost group segmentation applies only to a single-level calculation. For example, the **Cost rollup by cost group** page displays the cost group segmentation across multiple levels for standard cost items.

Cost group segmentation can also apply to variances for a standard cost item. A second inventory parameter defines whether variances are identified by cost group or just summarized.

A cost group can be assigned a cost group type and a behavior for supplemental segmentation purposes.

- **Cost group type** – Each cost group must be assigned a cost group type to indicate that the cost group applies to direct material, direct manufacturing, or direct outsourcing, or to designate it as indirect or undefined. A cost group that is designated as direct material can be assigned to items. A direct manufacturing cost group can be assigned to cost categories. A direct outsourcing cost group can be assigned to a product type of service, so that you can classify costs that are associated with the service purchase to subcontracting activities. An indirect cost group can be assigned to indirect costs for surcharges or rates. A cost group that is designated as undefined can be assigned to items, cost categories, or indirect costs. The assignment of a cost group type serves several purposes. First, it constrains the ability to assign a cost group and to view a list of applicable cost groups. Second, it provides supplemental segmentation for reporting purposes. Third, it can be used to assign ledger accounts for variances.
- **Behavior** – Each cost group can optionally be assigned a behavior to indicate that the cost group applies to fixed costs or variable costs. A cost group that has a null value for behavior is treated as a variable cost. The assignment of a behavior serves only a reporting purpose. For example, costs can be displayed with segmentation of fixed and variable costs on the costing sheet and on the **Cost rollup by cost group** page. If you assign a profit setting percentage to each cost group, the bill of materials (BOM) calculation provides a suggested sales price, based on a cost-plus-markup approach.

Inventory object values

This article provides information about how the values of an inventory object are calculated.

A new functionality that is named **physical quantity** lets you see the values of a specific inventory object.

A cost object represents the entity level where inventory accounting is performed. For more information about cost objects, see Cost objects.

To see the values of a specific inventory object, click **Physical quantity** on the **Cost object** page. Here is how the value of an inventory object is calculated:

Inventory object.Value = Cost object.Average unit cost × Inventory object.Quantity

The following example shows how the values of an inventory object and a cost object are calculated. Two product receipt events are registered on item A:

- Product receipt 1: Quantity = 100 pcs., Amount = $1,000.00, Site = 1, Warehouse =11, Batch No. = B1
- Product receipt 2: Quantity = 50 pcs., Amount = $800.00, Site = 1, Warehouse =11, Batch No. = B2

The following table shows the calculation result for a cost object. You can view the result on the **Cost object** page.

Expand table

Object type	Item number	Site	Quantity	Inventory unit	Value	Average unit cost
Cost object	A	1	150	Pcs.	$1800.00	$12.00

The following table shows the calculation result for an inventory object. You can view the result by clicking **Physical quantity** on the **Cost object** page.

Expand table

Object type	Item number	Site	Warehouse	Batch No.	Quantity	Inventory unit	Value	Average unit cost
Inventory object	A	1	11	B1	100	Pcs.	$1200.00	$12.00
Inventory object	A	1	11	B2	50	Pcs.	$600.00	$12.00

Inventory close

As part of the process to settle issue transactions with receipt transactions, you can also choose to have the general ledger updated to reflect the adjustments that have been made.

The inventory close process settles issue transactions to receipt transactions, based on the inventory valuation method that is selected in the item's item model group. As part of the settlement process, you can specify that the general ledger should be updated, so that it reflects the adjustments that have been made. However, until inventory close or recalculation has been run, issue transactions are posted at the calculated running average cost price.

After inventory close, you can no longer post in periods that are before the inventory closing date that you set, unless you reverse a completed inventory close process. For example, if inventory close is run for the period that ends on January 31, you can't post transactions that have a date that is earlier than January 31.

Items in inventory are assigned to one of two inventory types: item or service. Inventory close performs the same functions for both types. However, for service items, inventory close still settles issues to receipts.

How often the inventory close process is run varies by company. However, transaction volume should help determine how often you decide to run inventory close. In general, most companies run inventory close as part of their month-end close and reconciliation procedures.

Inventory recalculation and the general ledger

If adjustments to inventory and the general ledger are required during a month or other inventory period, you can run inventory recalculation instead of inventory close. Inventory recalculation makes adjustments but doesn't make settlements to inventory transactions.

During inventory recalculation, on-hand inventory is adjusted, inventory transactions are adjusted, and inventory recalculations and inventory closes are run. These tasks affect any ledger account that is linked to the original inventory transaction.

Example

When you create a purchase order from a sales order, the general ledger accounts that are used for the original sales order are updated. Even if the ledger accounts for the item group that is

assigned to the item were changed after the sales order was posted, and an inventory recalculation created an adjustment amount, the adjustment amount is posted to the original ledger accounts. The adjusted amount isn't posted to the new ledger accounts that are assigned to the item.

After the update is completed, you can review the ledger voucher that is posted because of one of these tasks.

1. On the **Closing and adjustment** page, on the **Overview** tab, select the update to review.
2. Select **Details**, and then select **Voucher**.

Effects of the inventory close process on the general ledger

Several of the tasks that you can perform on the **Closing and adjustment** page cause an update to general ledger. For example, the general ledger is updated when you make inventory on-hand adjustments, make inventory transaction adjustments, run inventory recalculation, and run inventory close.

The ledger accounts that are updated because of these tasks are linked to the original inventory transaction. For example, if a sales order is settled to a purchase order, the general ledger accounts that were used for the original sales order are adjusted. This behavior occurs even if the ledger accounts for the item group that is assigned to the item have changed since the sales order was posted. After inventory close creates a settlement amount, the settlement amount is still posted to the original ledger accounts, not to the new ledger accounts that are assigned to the item. The general ledger might also be updated if you reverse an inventory close.

> ⓘ **Note**
>
> - Inventory close is a required step in the month-end closing procedure for all inventory models except moving average. You'll be warned if you try to close a financial period without first performing the inventory close as of the period end date.
> - Before you run the closing procedure, you can view a list of items that can't be settled during the update.
> - We recommend that you run inventory close during off-peak hours, to distribute computing resources more evenly.

The inventory close log

After the inventory close process has been completed, a message in the message center might inform you that a unit cost price might be incorrect because a transaction couldn't be fully settled.

Before this message is shown, the system reports the item number and the affected transaction. The message informs you that the cost amount that is used for this transaction wasn't updated because of the inventory close. This message appears when a transaction of the issue type can't be settled.

During the inventory close process, the system checks each financial dimension to see whether there are more issues than receipts up to the specified closing date. This type of imbalance can occur when an inventory transaction from a purchase order isn't fully posted financially, either because the vendor invoice hasn't been received, or because bill of materials (BOM) components that are included in a production on a higher level aren't financially posted. (The subproduction isn't cost-calculated.) In this case, the subsequent close won't adjust all issues to the correct cost price, because not enough receipt information is available.

For each run of the closing procedure, the system indicates whether a log that contains the warnings is stored and can be viewed.

If you receive many warnings in the message, we recommend that you perform the following actions:

- Update receipts financially.
- Advance the closing date.
- Reevaluate the business procedures.

In some circumstances, you might not be able to do anything about the warnings. For example, if marking is used, and the marked purchase order has a financial date that is after the closing date, the closing date can't be changed.

Reversing a completed inventory close

Occasionally, you might have to reverse a completed inventory close to return settlements to the state that they had before adjustments were made. When you reverse a completed inventory close, inventory is reopened to enable posting in the period that the inventory close covers. Related changes might also be made in the general ledger. After you've finished making adjustments, you can run inventory close again for the period that you're working with.

> ⓘ **Note**

Only the last inventory period that was closed can be reopened. To reverse an earlier inventory close, you must reverse each subsequent inventory close one at a time, starting with the most recent close.

Adjust on-hand inventory cost values

Use the **Adjustment of on-hand inventory** page to adjust the cost value of the on-hand inventory quantities after running an inventory close process. To open the **Adjustment of on-hand inventory** page, start on the **Closing and adjustment** page, select the record of a completed inventory close process, and then select **Adjustment** > **On-hand**.

For example, suppose you have the following transactions in February:

- February 1: An inventory financial receipt for a quantity of 2 at a cost of USD 10.00
- February 5: An inventory financial receipt for a quantity of 1 at a cost of USD 13.00
- February 19: An inventory financial issue for a quantity of 1 at a running average cost of USD 11.00

This item was set up with the first in, first out (FIFO) inventory model, and inventory close was performed as of February 28. The financial issue transaction of USD 11.00 is settled against the financial receipt that is dated February 1, and an adjustment of USD 1.00 is made. The following inventory receipts then contain open inventory quantities:

- February 1: A quantity of 1 at a cost of USD 10.00
- February 5: A quantity of 1 at a cost of USD 13.00

To set the cost of these two items to USD 15.00, use the on-hand adjustment option to adjust the open on-hand quantities as of the last inventory close period.

> **Note**
>
> The posting date of the on-hand adjustment transaction is the date of the last inventory close. You can't modify this date.

Inventory value reports

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Inventory value reports provide details about your inventory physical and financial quantities and amounts. You can view the reports in many different ways. For example, you can show totals or transactions, or filter by items or a time range. You can view cost of goods sold (COGS) values or work in process (WIP) values, and set other options.

Inventory value reports let you perform the following tasks:

- Reconcile the general ledger and inventory.
- Consult on-hand inventory and values for a specific period.
- Create report configurations that are tailored to a specific purpose.
- Save report configurations so that you can use them multiple times.
- Add ranges to filter data when you run a report.

Types of inventory value report

There are two types of inventory value report: **Inventory value** (the standard report) and **Inventory value report storage**.

Standard inventory value report

The standard **Inventory value** report is a simple report that lets you select the information that is included and then shows that information on the screen. It doesn't save the results. It also doesn't provide interactive features for filtering, drilling down, browsing, or exporting. For these reasons, use the **Inventory value report storage** report instead in most cases.

Inventory value report storage report

The **Inventory value report storage** report provides output either as an interactive page in Microsoft Dynamics 365 Supply Chain Management or as an exported document in one of several formats.

When you view the report in your browser, columns and aggregate balances dynamically adjust, depending on the layout that you configure. You can sort the results, filter them, drill down into the data, and more.

Report results are stored in the **Inventory value** data entity. Therefore, you can filter and export the results to a format such as comma-separated values (CSV) or Microsoft Excel format.

The **Inventory value report storage** report is helpful when the output contains many lines. For example, you have 50,000 items, and 300 stores are created as warehouses. In this case, if you request inventory ending balances by item, site, and warehouse, the output contains many lines.

> ⓘ **Note**
>
> The **Inventory value report storage** report doesn't include subtotals that are defined in the report layout. It also doesn't include general ledger balances, even if those balances are defined in the report layout. Reconciliation to the general ledger must be done by using trial balances. However, the standard **Inventory value** report does include these subtotals and balances.

Define inventory value report configurations

Use the **Inventory value reports** page to set up the content that is included in the different types of inventory value report. You can define any number of report types. Each time that you generate either type of inventory value report, select a report type.

1. Go to **Cost management** > **Inventory accounting policies setup** > **Inventory value reports**.
2. Follow one of these steps:
    - To edit an existing report, select it in the list pane, and then select **Edit** on the Action Pane.
    - To create a new report, select **New** on the Action Pane.
3. In the header of the new or selected report, set the following fields:

- **ID** – Enter a short identifier for the report. This value must be unique among all inventory value report configurations. You can't edit it after you save a new configuration.
- **Name** – Enter a descriptive name for the report.

4. If you're creating a new report configuration, select **Save** on the Action Pane to make the remaining fields available.

5. On the **General** FastTab, set the following fields:

    - **Date interval** – Select a predefined date interval. You can override this date interval when you run the report.
    - **Range** – Select either *Posting date* or *Transaction Time*, depending on the date and time that should be used when retrieving records for the report.
    - **Dimension set** – Select the set of dimensions to run the data for. (The dimensions are defined in the general ledger.) For example, you might run the data for *Main account* or for *Main account* + *Business unit*. The dimension set that you select must have no more than two dimensions. For more information, see Financial dimension sets.

6. On the **Columns** FastTab, set the following fields. These fields control the columns that your report includes and the types of data that those columns contain.

    - **Inventory** – Set this option to *Yes* to show the inventory values. You can then reconcile those values with the general ledger account balances.

    - **WIP** – Set this option to *Yes* to show the WIP values. You can then reconcile those values with WIP account balances in the general ledger. When you set this option to *Yes*, the report shows only the physical quantities and amounts of inventory that have WIP status. Production orders that have WIP status are picked or reported as finished, but they aren't ended.

    - **Deferred COGS** – Set this option to *Yes* to display a column that shows the physical quantities and amounts of inventory for deferred COGS. Deferred COGS is shown by using physical quantities and amounts, because it offsets packing slip quantities and amounts.

    - **COGS** – Set this option to *Yes* to display a column that shows the financial quantities and amounts for COGS. COGS is shown by using financial quantities and amounts, because it offsets the invoice quantities and amounts.

- **Profit and loss** – Set this option to *Yes* to display a column that shows the financial amount that was posted to the profit and loss accounts for inventory.

- **Print cumulative account values for comparison** – Set this option to *Yes* to display a column that shows the general ledger account balance. In this way, you don't have to check the trial balance. This option works only with the standard **Inventory value** report, not with the **Inventory value report storage** report. After you set this option to *Yes*, use the following fields to specify each general ledger account that you want to list, depending on the **Financial position** options that you enabled.

  > ⓘ **Note**
  >
  > If you select a *total* account for any of these fields, both the amount of each inventory account that is included in the total account and the amount of the total account are shown.

  - **Inventory account** – Specify the general ledger account to show inventory information for. (Both the **Inventory** option and the **Print cumulative account values for comparison** option must be set to *Yes*.)
  - **WIP account** – Specify the general ledger account to show WIP information for. (Both the **WIP** option and the **Print cumulative account values for comparison** option must be set to *Yes*.)
  - **Deferred COGS account** – Specify the general ledger account to show deferred COGS information for. (Both the **Deferred COGS** option and the **Print cumulative account values for comparison** option must be set to *Yes*.)
  - **COGS account** – Specify the general ledger account to show COGS information for. (Both the **COGS** option and the **Print cumulative account values for comparison** option must be set to *Yes*.)

- **Summarize physical and financial values** – Set this option to *Yes* to display a column that shows the total inventory quantity and inventory amount (a summary of both physical and financial inventory values). If this option is set to *No*, the report shows both physical and financial inventory values.

- **Include not posted to ledger** Set this option to *Yes* to display a column that shows the transactions that were never posted to the general ledger. Transactions for the following types of items might not be posted to the general ledger:
  - Received and not yet invoiced items when the **Post physical inventory** option is cleared for the relevant item model group.

    - Received and not yet invoiced items when the **Post product receipt in ledger** option is cleared on the **Product receipt** FastTab on the **General** tab of the **Accounts payable parameters** page (**Accounts payable** > **Setup** > **Accounts payable parameters**).

- **Calculate average unit cost** – Set this option to *Yes* to display a column that shows the average unit cost. The average unit cost is the total amount divided by the total quantity.

- **Total quantity and value** – Set this option to *Yes* to display columns that show the total quantity of physical inventory (and financial quantities) and the total amount of physical inventory (and financial amounts). You can set this option to *Yes* only if the **Summarize physical and financial values** option is set to *No*.

- **Inventory dimensions** – In this grid, select the **View** checkbox for each dimension that you want to show on the report. Only dimensions where the **Financial inventory** option is enabled show values on the report. Other dimensions show only blank columns. For the dimensions that you select to show, you can select the **Total** checkbox to include totals too.

- **Resource ID** – Set the **View** option to *Yes* to display a column that identifies the item for each row. Set the **Total** option to *Yes* to include totals too. Depending on the type of item that is listed in each row, the column shows one of the following types of information:
    - **Material** – The column shows the `ItemID` field value for the relevant material record.
    - **Labor** – The column shows the `WorkCenterID` field value for the relevant labor record.
    - **Indirect cost** – The column shows the `CodeID` field value for the relevant cost record.

  If the **View** option is set to *No* for both the **Resource ID** field and the **Resource Group** field, you see only a total inventory value that is based on the inventory dimensions that you selected.

- **Resource Group** – Set the **View** option to *Yes* to display a column that identifies the resource group for each row. Set the **Total** option to *Yes* to include totals too. Depending on the type of item that is listed in each row, the column shows one of the following types of information:

- **Material** – The column shows the `ItemGroup` field value for the relevant material record.
- **Labor** – The column shows the `WorkcenterGroup` field value for the relevant labor record.
- **Indirect cost** – The column shows the `CostGroup` field value for the relevant cost record. (The `CostGroupType` value must be *Indirect*.)

If the **View** option is set to *No* for both the **Resource ID** field and the **Resource Group** field, you see only a total inventory value that is based on the inventory dimensions that you selected.

7. On the **Rows** FastTab, set the following fields. These fields let you add corresponding WIP-related subsections to the report or remove them.

- **Material** – Set this option to *Yes* to show information about materials. *Material* is a default resource type because you must include materials in all report configurations to create reliable output.
- **Labor** – Set this option to *Yes* to show labor costs of WIP.
- **Indirect cost** – Set this option to *Yes* to show indirect costs of WIP.
- **Direct outsourcing** – Set this option to *Yes* to show direct outsourcing costs of WIP. This information is useful for subcontracting.
- **Detail Level** – Select a view option for the report:
- *Transactions* – View all relevant transactions on the report. You might experience performance issues when you view reports that include a large volume of transactions. Therefore, if you want to use this view option, use the **Inventory value report storage** report.
- *Totals* – View the total result.
- **Include beginning balance** – Set this option to *Yes* to show the beginning balance. This option is available only when the **Detail level** field is set to *Transactions*.

Generate an Inventory value report storage report

Follow these steps to generate and store an **Inventory value report storage** report.

1. Go to **Cost management** > **Inquiries and reports** > **Inventory value report storage**.

2. On the Action Pane, select **New**.

3. In the **Inventory value** dialog box, on the **Parameters** FastTab, set the following fields:

    - **Name** – Enter a unique name for the report.
    - **Large item volume** – To use the large-volume report generation feature, set this option to *Yes*. Only enable this option when generating reports for a significantly large number of items (for example, 50,000 or more) because this option takes longer to run than the standard-volume option. Learn more in Generate an inventory value report storage report for a large number of items.
    - **ID** – Select the inventory value report configuration to use for the report. The configuration establishes options for the columns and rows that the report includes.
    - **Date interval** – Use the fields in this section to define which records are included on the report. To define the date interval, select either a preset range (relative to the report generation date) in the **Date interval code** field, or specific dates in the **From date** and **To date** fields.

4. On the **Records to include** FastTab, set up filters and constraints to define which data is included on the report. Select **Filter** to open a standard query editor dialog, where you can define selection criteria, sorting criteria, and joins. The fields work just as they do for other types of queries in Supply Chain Management. All these filters apply to the inventory transactions but not to the general ledger balance. Keep this behavior in mind when you set up your filters. Otherwise, you might see a discrepancy between inventory and the general ledger.

5. On the **Run in the background** FastTab, specify how, when, and how often the report is generated. The fields work just as they do for other types of background jobs in Supply Chain Management.

    > ⓘ **Note**
    >
    > This report is always run as part of a batch job.

6. Select **OK** to apply your settings and close the dialog box.

After the batch job completes, the report is listed on the **Inventory value report storage** page. You might have to refresh the page to see the report.

> ⓘ **Important**

In the selected inventory value report configuration, you might get an incorrect beginning balance if you select the same date in both the **From date** field and the **To date** field, and if you also set the **Include beginning balance** option to *Yes*.

Explore an Inventory value report storage report

After you generate a report, you can view and explore it at any time by following these steps.

1. Go to **Cost management** > **Inquiries and reports** > **Inventory value report storage**.
2. Select a report in the list. The page shows the details of the inventory value report configuration that was used to generate the selected report.
3. On the Action Pane, select **View details** to show the report content.
4. Explore the report by following any of these steps:
    - As with most standard pages in Supply Chain Management, select almost any column heading to sort or filter the grid by the values in that column.
    - Use the **Filter** field to filter the report by any value in any of several available columns.
    - Use the view menu (above the **Filter** field) to save and load your favorite combinations of sort and filter options.

Export an Inventory value report storage report

Every report that you generate is stored in the **Inventory value** data entity. You can use the standard data management features of Supply Chain Management to export data from this entity to any supported data format, such as CSV or Excel format.

The following example shows how to export an **Inventory value report storage** report.

1. Go to **System administration** > **Workspaces** > **Data management**.
2. In the **Import / Export** section, select the **Export** tile.
3. On the **Export** page, enter a **Group name** for the job.
4. On the **Selected entities** FastTab, select **Add entity**.
5. In the **Add entity** drop-down dialog, set the following fields:
    - **Entity name** – Select *Inventory value report storage*.

- **Target data format** – Select the format to export data to.

6. Select **Add** to add the new row, and then select **Close** to close the dialog box.

7. Usually, you export one report at a time. To export a single report, select the button in the **Filter** column for the row that you just added to **Selected entities** FastTab. Then use the query designer to set up the following filter:

   - **Table** – Select *Inventory value report storage*.
   - **Field** – Select *Execution name*.
   - **Criteria** – Enter the name of the report that you want to export.

8. On the Action Pane, select **Save**.

9. On the Action Pane, open the **Export options** tab and select **Export now**.

10. The **Execution summary** page opens. Here you can view the status of your export job and a list of the entities that were exported. In the **Entity processing status** section, select the **Inventory value** entity in the list, and then select **Download file** to download the data that was exported from that entity.

For more information about how to use data management to export data, see Data import and export jobs overview.

Delete stored inventory value reports

As the number of stored inventory value reports increases, they can take up too much space in your database. This situation can affect system performance and cause higher data-storage costs. To avoid these issues, clean up the reports by deleting older reports.

> **Important**
>
> Before you delete any previously generated inventory value reports, export the reports and store them externally. You might not be able to regenerate the reports later. This limitation exists because when you generate an inventory value report, the system works backwards from today and processes each inventory transaction record in reverse order as it goes. If you try to look too far back when you generate a report, the volume of transactions to process might become so large that the system times out before it can finish generating the report. The distance into the past that you can generate new reports for depends on the number of inventory transactions that you have in your system for the relevant time span.

Delete one report at a time

Follow these steps to delete one stored report at a time.

1. Export the report that you plan to delete, and store it in an external location for future reference.
2. Go to **Cost management** > **Inquiries and reports** > **Inventory value report storage**.
3. In the list pane, select the report to delete.
4. On the Action Pane, select **Delete**.
5. A warning message reminds you to back up generated reports. Select **Yes** if you're ready to proceed with the deletion.

Delete several reports at the same time

Follow these steps to delete several stored reports at the same time.

1. Export all the reports that you plan to delete, and store them in an external location for future reference.
2. Go to **Cost management** > **Inventory accounting** > **Clean up** > **Inventory value report data clean up**.
3. In the **Inventory value report data clean up** dialog box, in the **Delete inventory value report executed before** field, select the date before which all inventory value reports should be deleted.
4. On the **Records to include** FastTab, set additional filter conditions to limit the set of reports that are deleted. Select **Filter** to open a standard query editor where you can define the properties of the reports to delete.
5. On the **Run in the background** FastTab, specify how, when, and how often the reports should be deleted. The fields work just as they do for other types of background jobs in Supply Chain Management. However, you typically run this job manually each time that it's required.
6. Select **OK** to delete the specified reports.

Generate a standard Inventory value report

Use the following procedure to generate a standard **Inventory value** report.

1. Go to **Cost management** > **Inquiries and reports** > **Inventory accounting - status reports** > **Inventory value**.

2. In the **Inventory value report** dialog box, on the **Parameters** FastTab, set the following fields:

    - **Name** – Enter a unique name for the report.
    - **ID** – Select the inventory value report configuration to use for the report. The configuration establishes options for the columns and rows that the report includes.
    - **Date interval** – Use the fields in this section to define which records are included on the report. To define the date interval, select either a preset range (relative to the report generation date) in the **Date interval code** field, or specific dates in the **From date** and **To date** fields.

3. On the **Records to include** FastTab, set up filters and constraints to define which data is included on the report. Select **Filter** to open a standard query editor dialog, where you can define selection criteria, sorting criteria, and joins. The fields work just as they do for other types of queries in Supply Chain Management.

4. On the **Run in the background** FastTab, specify how, when, and how often the report is generated. The fields work just as they do for other types of background jobs in Supply Chain Management.

5. Select **OK** to apply your settings and close the dialog box. The report appears.

Reading inventory value reports

This section provides guidance on how to read and understand an inventory value report.

Supply Chain Management supports the following two important concepts that are related to inventory status:

- **Financial updated** – This concept indicates that the inventory transactions are already invoiced. For production orders, it indicates the end of a production order.
- **Physical updated** – This concept indicates that the inventory transactions aren't yet invoiced, but they're received or shipped. For production orders, it indicates that material is picked or the production order is reported as finished.

When you understand these two concepts, it should be easy to understand the following columns in the report output:

- **Inventory: Financial Quantity** – The quantity that is financially updated.
- **Inventory: Financial Amount** – The amount value of inventory that is financially updated.
- **Inventory: Physical Quantity Posted** – The quantity that is physically updated.

- **Inventory: Physical Amount Posted** – The amount value of inventory that is physically updated.
- **Inventory: Physical Quantity Not Posted** – The quantity that has inventory transactions but isn't posted to the general ledger. For example, you have an item model group where the **Post physical inventory** and **Post financial inventory** options are cleared, and you have an item that is linked to that group. You then create a purchase order, receive it, and invoice it. At this point, if you review the inventory value report for the item, you see that the quantity and the value on the purchase order are shown in the **Inventory: Physical Quantity Not Posted** and **Inventory: Physical Amount Not Posted** columns.
- **Inventory: Physical Amount Not Posted** – You can set up your reports so that they show unposted amounts. However, if you're using the report for inventory reconciliation, don't use this value. Otherwise, the amount isn't posted to the general ledger.
- **Inventory: Quantity** – The total quantity of all the quantity columns on the report.
- **Inventory: Amount** – The total quantity of all the amount columns on the report. When you do inventory reconciliation, don't use this column if your report includes the **Inventory: Physical Amount Not Posted** column. In this case, you must exclude the **Inventory: Physical Amount Not Posted** amount from the total amount.
- **Average unit cost** – The total amount divided by the total quantity.

Typically, you use an inventory value report to view the inventory value and quantity. However, sometimes the report doesn't show all the relevant inventory dimensions. If you don't see the dimensions that you expect, validate the following settings:

- Review the item storage and tracking dimension groups. Only dimensions where the **Financial inventory** option is enabled can be shown on the report.
- Go to **Cost management** > **Inventory accounting policies setup** > **Inventory value reports**, select the report configuration that you used to generate the report, and make sure that the required inventory dimensions are selected in the **View** column.

For example, you have an item that has the item number *A0001*. In the storage dimensions group, only the site is enabled for financial inventory. The site and warehouse are both enabled for physical inventory. In the tracking dimension group, the batch number is enabled for physical inventory but not for financial inventory. You then use a report configuration where site, warehouse, and batch number are all selected. When you view the report, you see a value only for the site. The columns for the warehouse and batch number are blank. As this example shows, inventory value reports can show only inventory dimensions that are enabled for financial inventory.

Generate an inventory value report storage report for a large number of items

This feature helps you handle extensive datasets while maintaining control over the process of generating **Inventory value report storage** reports. It ensures smooth and uninterrupted operation. It improves performance by dividing large datasets into manageable bundles. The system processes each bundle sequentially, which prevents timeout errors. You can also pause and resume the process to support incremental report generation.

Prerequisites

To use this feature, your system must meet the following requirements:

- You're running Microsoft Dynamics 365 Supply Chain Management version 10.0.44 or later.
- The feature named *Large Volume Historical Inventory Value Report Generation* is turned on in feature management.

Configure the large-volume option

To configure this feature, follow these steps:

1. Go to **Cost management** > **Inventory accounting policies setup** > **Parameters**.
2. In the **Inventory value report storage** field group, set the **Number of items per bundle** field to the number of items that you want to process in one bundle when generating large-volume reports. For example, if you often deal with reports that cover 800,000 items, a bundle size of 30,000 might be appropriate.

> **Important**
>
> Proper configuration of the bundle size is crucial for balancing performance and reliability. If the bundle size is too small, the system takes longer to process the report. If the bundle size is too large, the system might time out before it can finish processing the report. Start with a bundle size of 30,000 items and adjust it as needed based on your experience.

Use the large-volume option when generating a report

When you generate a report, choose whether to use standard-volume processing or large-volume processing.

> **Important**
>
> Use the large-volume option only when generating reports for a significantly large number of items (for example, 50,000 or more) because it takes longer to run than the standard-volume option.

To generate a large-volume historical inventory value report, follow these steps:

1. Go to **Cost management** > **Inquiries and reports** > **Inventory value report storage**.
2. On the Action Pane, select **New**.
3. In the **Inventory value** dialog, expand the **Parameters** FastTab and set **Large item volume** to *Yes*.
4. Fill out the rest of the dialog as described in Generate an Inventory value report storage report.
5. Select **OK** to start the batch job.

When the batch job finishes, the report appears on the **Inventory value report storage** page. Refresh the page if needed to view the newly generated report.

Pause and resume functionality

To pause and resume report generation:

1. Go to **Cost management** > **Inquiries and reports** > **Inventory value report storage**.
2. Select the report in progress from the list. The page displays the report configuration details.
3. Select one of the following buttons on the Action Pane:

    - **Pause** – Temporarily stop generating a running report.
    - **Resume** – Resume a paused process. The system picks up from where it left off.

Inventory value report examples and logic

Inventory value reports provide details about your inventory physical and financial quantities and amounts. This article provides some examples of results that are presented on each type of inventory value report.

For more information about how to generate and use each type of inventory value report, see Inventory value reports.

Sample data that is used in these examples

The examples in this article are based on the sample inventory transaction data that is described in this section.

Storage dimension setup

The example system contains the following setup of storage dimensions.

Expand table

Name	Active	Physical inventory	Financial inventory
Site	Yes	Yes	Yes
Warehouse	Yes	Yes	No

Inventory model

For the example system, the inventory model for the released products is *FIFO*, and the **Cost price** field for the inventory model is set to *Include physical value*.

Inventory transactions

The example system contains the following inventory transactions for a released product that has the item number *B0001*.

Expand table

Reference	Site	Warehouse	Receipt	Issue	Physical date	Financial date	Quantity	Cost amount	Physical cost amount
Purchase order	1	11	Purchased		March 15	March 15	10	1,000	1,000
Purchase order	2	21	Purchased		March 15	March 15	10	2,000	2,000
Purchase order	1	11	Received		April 15		5		375
Transfer order	1	11		Sold	May 2	May 2	-5	-458.33	-458.33

Reference	Site	Warehouse	Receipt	Issue	Physical date	Financial date	Quantity	Cost amount	Physical cost amount
Transfer order	1	12	Purchased		May 2	May 2	5	458.33	458.33
Sales order	1	12		Sold	May 3	May 3	-1	-91.67	-91.67

Inventory value report configuration

The example system includes an inventory value report configuration that has the following settings:

- **Range:** *Posting date*
- **Inventory:** *Yes*
- **Calculate average unit cost:** *Yes*
- **Total quantity and value:** *Yes*
- **Site, View:** *Selected*
- **Resource ID, View:** *Yes*
- **Level:** *Totals*

Inventory value report example 1

The following table and illustrations show the results when you use the sample data and report configuration described earlier in this article.

Expand table

Resource type	Resource	Site	Reference	Inventory: Financial quantity	Inventory: Financial amount	Inventory: Physical quantity posted	Inventory: Physical amount posted	Inventory: Quantity	Inventory: Amount	Avera unit cost
Material	B0001	1	Ending balance	9.00	908.33	5.00	375.00	14.00	1,283.33	91.67
Material	B0001	2	Ending balance	10.00	2,000.00	0.00	0.00	10.00	2,000.00	200.0

Inventory aging report storage

In Microsoft Dynamics 365 Supply Chain Management, you can run an *inventory aging report storage* report and make the output available as a form and a chart. In the form, columns and aggregate balances dynamically adjust based on the configured layout. The chart provides a visual overview that supports filtering and lets you drill down into details. Additionally, a data entity named *Inventory aging report* lets you export the results of an *inventory aging report storage* report run to a format such as a Microsoft Excel file or a PDF file.

This method of running an inventory aging report is helpful when the output contains many lines. For example, the output contains many lines if you have 50,000 items and 300 stores that are created as warehouses, and you request inventory aging by item, site, and warehouse.

Set up and generate reports

To set up and generate *inventory aging report storage* reports, follow these steps:

1. Go to **Cost management** > **Inquiries and reports** > **Inventory aging report storage**.

2. Select **New**. The **Inventory aging** dialog opens.

3. On the **Parameters** FastTab, make the following settings:

    - **Name** – Enter a unique name for the report.
    - **As of date** – Select the date to base the values of the report on. Leave blank to use the date on which the report runs, which is useful if you choose to set up a repeating schedule.
    - **View** – Choose which fields to include in your report. Tooltips are provided for each of them, so you can hover your mouse pointer for more information. Select one of the following values for each field:
        - *No* – Don't include the field in the report.
        - *View* – Include the field in the report.
        - *Total* – Display the field as a subtotal (subtotals aren't shown in the online reports).
    - **Unit of aging period** – Choose how you want to define your aging periods. Select one of the following values:
        - *Days* – Specify each period as a number of days previous to the **As of date**.
        - *Dates* – Select a specific calendar date for each period.

    - *Date intervals* – Select from a list of predefined date intervals related to the **As of date**.
  - **Aging periods** – You can specify up to four aging periods using the unit you selected for **Unit of aging period**

4. If you want to limit the records included in your report, expand the **Records to include** FastTab and add the filters you require, just as you might do for other batch jobs in Supply Chain Management.

5. On the **Run in the background** FastTab, set up batch, scheduling, and recurrence options as you require, just as you might do for other batch jobs in Supply Chain Management. The report always runs in a batch job.

6. Select **OK** to run and/or schedule the report.

7. After the batch job completes, the output appears on the **Inventory aging report storage** page. If you set up a recurring report, then a new report is added to the list each time the report runs.

View a report

To view an inventory aging report storage, follow these steps:

1. Go to **Cost management** > **Inquiries and reports** > **Inventory aging report storage**.
2. On the list pane, select the report that you want to view.
3. On the Action Pane, select one of the following actions:

   - **View details** – View the report as a form that has a traditional grid layout.
   - **View chart** – View the report as an aggregated chart.

> ⓘ **Note**
>
> The views don't include the subtotals that are defined in the report layout.

Export a report

Every report that you generate is stored in the *Inventory value report storage* data entity. You can use the standard data management features of Supply Chain Management to export data from this entity to any supported data format, such as CSV or Excel format.

The following example shows how to export an inventory aging report storage report.

1. Go to **System administration** > **Workspaces** > **Data management**.
2. In the **Import / Export** section, select the **Export** tile.
3. On the **Export** page, enter a **Group name** for the job.
4. On the **Selected entities** FastTab, select **Add entity**.
5. In the **Add entity** drop-down dialog, set the following fields:
    - **Entity name** – Select *Inventory aging report storage*.
    - **Target data format** – Select the format to export data to.
6. Select **Add** to add the new row, then select **Close** to close the dialog box.
7. Usually, you export one report at a time. To export a single report, select the button in the **Filter** column for the row that you just added to **Selected entities** FastTab. Then use the query designer to set up the following filter:
    - **Table** – Select *Inventory aging report storage*.
    - **Field** – Select *Execution name*.
    - **Criteria** – Enter the name of the report that you want to export.
8. On the Action Pane, select **Save**.
9. On the Action Pane, open the **Export options** tab and select **Export now**.
10. The **Execution summary** page opens. Here you can view the status of your export job and a list of the entities that were exported. In the **Entity processing status** section, select the *Inventory aging report storage* entity in the list. Then select **Download file** to download the data that was exported from that entity.

For more information about how to use data management to export data, see Data import and export jobs overview

Inventory aging report examples and logic

This article presents some examples that show how to interpret the results of an **Inventory aging** report. This report categorizes on-hand quantity and inventory values for a selected item or item group into several period buckets. This article also shows the internal logic of the report.

The examples in this article show results that are presented on a standard **Inventory aging** report. However, in general, we recommend that you use the Inventory aging report storage version of this report, especially when you have many items and warehouses that must be processed. Inventory aging report storage saves each report that you generate, shows the results as an interactive page and a chart, and lets you export any saved report.

Sample data that is used in these examples

The examples in this article are based on the sample inventory transaction data that is described in this section.

Storage dimension setup

The example system contains the following setup of storage dimensions.

Expand table

Name	Active	Physical inventory	Financial inventory
Site	Yes	Yes	Yes
Warehouse	Yes	Yes	No

Inventory model

For the example system, the inventory model for the released products is *FIFO*, and the **Cost price** setting for the inventory model is *Include physical value*.

Inventory transactions

The example system contains the following inventory transactions for a released product that has the item number *1000*.

Expand table

Reference	Site	Warehouse	Receipt	Issue	Physical date	Financial date	Quantity	Cost amount	Physical cost amount
Purchase order	1	11	Purchased		March 15	March 15	10	1,000	1,000
Purchase order	2	21	Purchased		March 15	March 15	10	2,000	2,000
Purchase order	1	11	Received		April 15		5		375
Transfer order	1	11		Sold	May 2	May 2	-5	-458.33	-458.33
Transfer order	1	12	Purchased		May 2	May 2	5	458.33	458.33
Sales	1	12		Sold	May 3	May 3	-1	-91.67	-91.67

Reference	Site	Warehouse	Receipt	Issue	Physical date	Financial date	Quantity	Cost amount	Physical cost amount
order									

How quantities and amounts in each period bucket are calculated

By using the sample data that is described in the previous sections, you can run an **Inventory aging** report that has the following settings:

- **As of date:** *May 9, 2020*
- **Site:** *View*
- **Warehouse:** *No*
- **Item number:** *Total*
- **Aging period:** Set this field to generate monthly buckets.

In this case, the content of the report that is generated will resemble the following example.

Expand table

Item number	Site	On-hand quantity	On-hand value	Inventory value quantity	Inventory value	Average unit cost	P1:Quantity (5/8/2020 - 5/1/2020)	P1:Amount (5/8/2020 - 5/1/2020)	P2:Quantity (4/30/2020 - 4/1/2020)	P2:Amount (4/30/2020 - 4/1/2020)	P3:Q (3/3 - 3/1
1000	1	14	1,283.33	14	1,283.33	91.67			5.00	458.33	9.00
1000	2	10	2,000.00	10	2,000.00	200.00					10.0
1000 Totals		**24.00**	**3,283.33**						**5.00**	**458.33**	**19**

Note the following details in this example report:

- The **Inventory value quantity**, **Inventory value**, and **Average unit cost** values that are shown on the report are values for the financial inventory dimension (**Site**, in this case).

  For example, for site 1, the report shows the following information:
  - The **Inventory value quantity** value is *14* (= 10 + 5 – 5 + 5 – 1).
  - The **Inventory value** value is *1,283.33* (= 1,000 + 375 – 458.33 + 458.33 – 91.67).
  - The **Average unit cost** value is *91.67*.
  - The **On-hand value** value and the **Amount** value in each period bucket are calculated by using the **Average unit cost** value.

- The report determines the on-hand quantity for each period bucket by summarizing the total received inventory quantity for each period bucket. It then applies the first in, first out (FIFO) principle to deduct the total issued quantity, regardless of the inventory model that the items use.

If you run the same report again, but this time you set both the **Site** and **Warehouse** fields to *View*, the new report will resemble the following example.

Expand table

Item number	Site	Warehouse	On-hand quantity	On-hand value	Inventory value quantity	Inventory value	Average unit cost	P1:Quantity (5/8/2020 - 5/1/2020)	P1:Amount (5/8/2020 - 5/1/2020)	P2:Quantity (4/30/2020 - 4/1/2020)	P2:A (4/3 - 4/1/
1000	1	11	10	916.67	14	1,283.33	91.67			5.00	458.3
1000	1	12	4	366.67	14	1,283.33	91.67	4.00	366.67		
1000	2		10	2,000.00	10	2,000.00	200.00				

Item number	Site	Warehouse	On-hand quantity	On-hand value	Inventory value quantity	Inventory value	Average unit cost	P1:Quantity (5/8/2020 - 5/1/2020)	P1:Amount (5/8/2020 - 5/1/2020)	P2:Quantity (4/30/2020 - 4/1/2020)	P2:A (4/3 - 4/1/
1000 Totals			**24.00**	**3,283.33**				**4.00**	**366.67**	**5.00**	**458.**

This time, site 1 is split into two rows, one for warehouse 11 and one for warehouse 12. However, the **Inventory value quantity**, **Inventory value**, and **Average unit cost** values are the same, because **Warehouse** isn't a financial inventory dimension.

Additionally, notice that the quantity distribution of site 1 is different. In the first report that you ran, the system ignored the transfer order that occurred in the same site and deducted the quantity of the sales invoice from the **3/31/2020 - 3/1/2020** period bucket in site 1. However, in the new report, the system deducts the quantity of the sales invoice from the **5/8/2020 - 5/1/2020** period bucket in warehouse 12.

Effects of inventory closing

If you run the inventory closing for May and then run the previous report again, but you set the **As of date** field to *May 31, 2020*, you will notice the following results:

- The **Inventory value** and **Average unit cost** values are updated.
- The **On-hand value** value and all the **Amount** values in every period bucket are updated accordingly.

The new report will resemble the following example.

Expand table

Item number	Site	Warehouse	On-hand quantity	On-hand value	Inventory value quantity	Inventory value	Average unit cost	P1:Quantity (5/31/2020 - 5/1/2020)	P1:Amount (5/31/2020 - 5/1/2020)	P2:Quantity (4/30/2020 - 4/1/2020)	P2:A (4/3 - 4/1/
1000	1	11	10	910.70	14	1,275.00	91.07	0.00		5.00	455.3
1000	1	12	4	364.29	14	1,275.00	91.07	4.00	364.29		
1000	2		10	2,000.00	10	2,000.00	200.00				
1000 Totals			**24.00**	**3,275.00**				**4.00**	**364.29**	**5.00**	**455.3**

BOM calculations

07/21/2025

The cost roll-up and sales price calculations are known as bill of materials (BOM) calculations, and you initiate them from the Calculations page. This article provides information about BOM calculations.

The cost roll-up and sales price calculations are known as bill of materials (BOM) calculations, and you initiate them from the **Calculations** page. You use the **Calculations** page to perform the following tasks:

- Calculate the cost of a manufactured item, and generate an associated item cost record within a costing version.
- Calculate the sales price of a manufactured item, and generate an associated item sales price record within a costing version.

The way that you use the **Calculations** page varies slightly, depending on how you initiate the BOM calculations. The way that you use the **Calculations** page also depends on whether the BOM calculations involve a costing version for standard costs or planned costs, and on several policies that are defined in the costing version that is used in the BOM calculations. A variation of the **Calculations** page is used in the context of a sales order, sales quotation, or service order line item. These calculations are known as order-specific BOM calculations. An order-specific BOM calculation doesn't generate an item cost record within a costing version. Instead, it generates a calculation record that appears on the **BOM calculation details** page. The calculation record includes a calculated cost and a calculated sales price. The **Calculations** page can be opened for a single manufactured item or for a costing version.

- To calculate costs for a single manufactured item, you initiate BOM calculations from the **Item price** page. The **Calculations** page inherits the item identifier. The costing version, BOM version, route version, calculation quantity, calculation date, and site must be specified.
    - By default, the BOM version and route version are set to the active versions for the item, site, date, and calculation quantity. However, you can override the default values with approved versions.
    - By default, the calculation quantity is set to the item's standard order quantity. However, you can override the default value.
    - The calculation date or site can be mandated by the costing version, or user-specified values can be set when the date or site isn't mandated in the costing version. A future calculation date determines how pending cost records are used. BOM calculations use a pending cost record that has the nearest from-date that is on or before the calculation date.

- To calculate costs for all manufactured items or selected items, or to update items on a where-used basis, you initiate BOM calculations from the **Costing version setup** page or the **Costing version maintenance** page. The **Calculations** page inherits the costing version.
    - For the calculations, it's assumed that the active BOM version and route version are used for a manufactured item (and for the related site, date, and quantity), unless a manufactured component has a specified sub-BOM or subroute.
    - For the calculations, it's assumed that the standard order quantity is used for manufactured items. The standard order quantity provides the basis for calculating component quantities, determining the relevant BOM versions and route versions (when you use quantity-sensitive BOMs and routes), and amortizing constant costs. However, when a manufactured component has a BOM line type of *Production* or *Vendor*, or when you use a make-to-order explosion mode for the BOM calculations, this assumption doesn't apply, because quantities reflect the specified calculation quantity.
    - The calculation date or site can be mandated by the costing version, or user-specified values can be set when the date or site isn't mandated in the costing version.

Other variations in BOM calculations reflect the costing type and restrictions of the costing version:

- BOM calculations that use standard costs must be restricted by costing version policies, because the restrictions help guarantee that standard costing principles are used. Standard costing principles require the enforcement of restrictions about the use of standard costs for purchased items, a single-level explosion mode, and the inclusion of miscellaneous charges in unit costs.
- BOM calculations that use planned costs don't have to follow standard costing principles. These BOM calculations can use different explosion modes, alternative sources of cost data for purchased items, and optional enforcement of restrictions within the costing version.

BOM calculations that use standard costs

Policies within the costing version (for standard costs) can mandate enforcement of five BOM calculation policies. The *Recording restriction* option in the costing version mandates one of these policies, where miscellaneous charges must be included in the unit price. Miscellaneous charges for purchased items can be entered manually, whereas miscellaneous charges for manufactured items reflect the calculated amortization of constant costs. The *Calculation restriction* option in the costing version mandates the other four BOM calculation policies:

- The source of cost contributions for purchased items must be based on standard costs. In other words, BOM calculations must use the item cost records within the specified costing version, or within the fallback that contains standard costs.
- To help guarantee accurate and consistent calculation of standard costs, the explosion mode must be single-level.
- To help guarantee consistent results when the sales price of the items is calculated, the profit setting must be mandated. The profit setting can be used, and the item sales price records can be generated, only if the costing version allows for content of sales prices.
- The fallback principle must be mandated, and can be set to *None*, *Active* (for active cost records), or *Costing version* (for a specified costing version).

BOM calculations that use planned costs

Policies within the costing version (for planned costs) can optionally mandate enforcement of five BOM calculation policies. Alternatively, the policies can just provide default values. The *Recording restriction* option in the costing version determines whether the BOM calculation policy about miscellaneous charges will be mandated or act as a default value. Miscellaneous charges can optionally be included in the unit price. The *Calculation restriction* option in the costing version determines whether the other four BOM calculation policies will be mandated or act as default values:

- The source of cost contributions for a purchased item can be the item cost records within a costing version. Alternatively, the source can be defined by the BOM calculation group that is assigned to the item. For example, the BOM calculation group can define purchase price trade agreements as the source of cost contribution data.
- The explosion mode can be single-level, multilevel, or make-to-order, or it can be based on the BOM line item. The explosion mode for the BOM line type replicates the cost calculation logic for production order estimates.
- The profit setting can be mandated, or it can be a default value. The profit setting can be used, and the item sales price records can be generated, only if the costing version allows for content of sales prices.
- The fallback principle can be mandated, or it can be a default value. The fallback principle can be set to *None*, *Active* (for active cost records), or *Costing version* (for a specified costing version).

BOM calculations generate warning messages and other types of messages. Several BOM calculation policies determine the types of messages. The warning conditions are defined in the BOM calculation group that is assigned to items. However, you can override these warning conditions when you initiate a BOM calculation. When the fallback principle is used, it's often helpful if the fallback is shown as an information message. When you're trying to update

calculated costs for items that have missing cost records, it's also helpful if the information message identifies items that weren't updated.

BOM calculations that use the fallback principle

The following situations illustrate two uses of the fallback principle:

- **Two-version approach to standard cost updates** - A costing version can contain the incremental changes to standard costs, such as pending cost records that represent new items or cost changes. In this situation, the fallback principle can identify the use of the active standard costs that are contained in other costing versions.
- **Simulation of the effect of cost changes by using planned costs** - A costing version for planned costs can contain incremental changes for simulation purposes. This costing version will include pending cost records that represent the simulated cost changes to items, cost categories, and calculation formulas for indirect cost. In this situation, the fallback principle can identify the use of the active standard costs that are contained in other costing versions.

BOM calculation of a suggested sales price

When you use a cost-plus-markup approach, the calculated sales price for an item reflects the set of profit-setting percentages that is specified for the BOM calculation, and the costs that are associated with the item's component items, routing operations, and applicable manufacturing overheads. The markup reflects profit-setting percentages that are assigned to cost groups, and the cost groups that are assigned to items, cost categories for routing operations, and the indirect cost calculation formulas for manufacturing overheads. The sets of profit-setting percentages are labeled *Standard*, *Profit 1*, *Profit 2*, and *Profit 3*. Within the Profit 1 set, for example, a profit-setting percentage of 50 percent can be defined for a cost group that is assigned to purchased material, and a profit-setting percentage of 80 percent can be defined for a cost group that is assigned to cost categories for routing operations. The context of the BOM calculation determines how the results of a calculated sales price are handled:

- **BOM calculation for an item and specified costing version** - The BOM calculation generates a pending sales price record within the costing version. This sales price record provides the starting point for viewing the calculation details (for example, on the **Calculate item cost** page). The sales price record acts mainly as reference information and isn't used as the basis for a sales price on sales orders.
- **Order-specific BOM calculation** - A variation of the **BOM calculation** page is used in the context of a sales order, sales quotation, or service order line item. An order-specific BOM calculation doesn't generate a record within a costing version. Instead, it generates a calculation record that appears on the **BOM calculation results** page. This calculation

record provides the starting point for viewing the calculation details (for example, on the **Calculate item cost** page). Information about a selected calculation record can be transferred to the originating line item. For example, the calculated sales price can be transferred to a sales order line item.

Order-specific BOM calculations

An order-specific BOM calculation represents a variation of a BOM calculation for a manufactured item. The order-specific BOM calculation is performed in the context of a sales order, sales quotation, or service order line item. An order-specific BOM calculation generates a calculation record that appears on the **BOM calculation results** page. The calculation record includes a calculated weight, a calculated cost that is based on active cost records, and a calculated sales price. The calculation record that each order-specific BOM calculation for an item generates on the **BOM calculation results** page is uniquely identified by a calculation number. The results of a calculation record can be optionally transferred to the originating line item. An order-specific BOM calculation differs from a BOM calculation for a manufactured item in two ways:

- An order-specific BOM calculation doesn't generate an item cost record within a costing version. Therefore, the BOM calculation policies aren't applied when an item cost record is created, or when a cost record is overwritten.
- An order-specific BOM calculation always uses the active cost records for components, cost categories, and indirect cost calculation formulas.

BOM calculation groups

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides information about calculation groups for bills of materials (BOMs) and how to set them up. To run a BOM calculation, you must either set up calculation groups and assign them to individual items, or set a default calculation group. The calculation settings from the calculation group are then used as default values on the BOM calculation page at the time of BOM calculation.

You must set a default calculation group on the **Inventory and warehouse management parameters** page, or set a product-specific calculation group on the **Released product details** page. The system first looks for the calculation group setup on the **Released product details** page. If it doesn't find a calculation group there, it looks on the **Inventory and warehouse management parameters** page. If the system can't find a calculation group, the user receives an error message during calculation. A calculation group contains policies for the cost price model, the sales price model, and the warnings checklist. The calculation settings from the calculation group are used as default values on the **BOM calculation** page at the time of BOM calculation.

Purposes of BOM calculation groups

Assign a BOM calculation group to items for several reasons:

- By setting the **Cost price model** field, you indicate the source of a purchased component's cost contribution data during the calculation of the planned cost of a manufactured item. Some manufacturers calculate planned costs by using the purchase price trade agreements for purchased components or another basis, such as the purchase price records in a costing version.
- By setting the **Sales price model** field, you indicate how the item's data is used to calculate a suggested sales price. You can specify either the item sales price or the cost group. Some manufacturers want to calculate a suggested sales price for manufactured items. The

calculated sales price can reflect a rolled-price approach that is based on the component's sales price record. Alternatively, the calculated sales price can reflect a cost-plus-markup approach that is based on the component's cost and applicable profit percentage, which is associated with the item's cost group.

- By using the **Stop explosion** field, you indicate that a manufactured item should be treated as a purchased item for cost roll-up purposes during BOM calculation. Typical scenarios include a purchased item that is occasionally manufactured or a manufactured item that is now being purchased. The item is first designated as a manufactured item to define BOM and route information, and to support production orders for the item. However, the **Stop explosion** flag prevents cost calculations from using the item's BOM and route. Instead, the BOM calculation uses the item's specified costs.

Calculation groups

Define calculation groups under **Predetermined cost policies setup** in Cost management. Calculation groups assigned to items let you specify how the cost or sales price of components, as outlined by the calculation group, is sourced for the calculation. On the **Calculation groups** page, you can define a cost price model, an alternative cost price model, a sales price model, and warnings.

Cost price model

There are four options for the **Cost price model** field:

- *Item cost price* – The cost price from the **Released product** table is used, or the combination of item dimensions is used as the cost price.
- *Item purchase price* – The purchase price from the **Cost price** field on the **Purchase** tab of the **Released product list** page is used.
- *Trade agreements* – You can configure trade agreements for specific combinations of items and vendors, or for specific sites. Then, when you select the *Trade agreements* option here, the trade agreement that you created for the purchase price together with the item and site is used.
- *Inventory price* – The current inventory value for the item is used to calculate the unit cost in the BOM calculation. A unit cost price is calculated only if the posted quantity and the physical quantity are more than 0 (zero).

Alternative cost price

The **Alternate cost price** field has the same options as the **Cost price model** field. However, this field is used only when a price can't be found in the primary cost price model.

Sales price model

For the **Sales prices** field, choose from two options for calculation:

- **Cost group** – When you select this option, the sales price is calculated based on the cost price and the profit setting percentage from the cost group.
- **Item sales price** – When you select this option, the sales price on the **Sell** FastTab from the Released product table is used.

Stop explosion

Use the **Stop explosion** check box to indicate when a manufactured item should be treated as a purchase item. Typically, you leave the **Stop explosion** check box cleared. By selecting this check box, you indicate that a manufactured item must be treated as a purchase component instead of a manufactured component for the purpose of BOM calculations. Depending on the site, the item's cost can still be calculated by using BOM calculations. Explosion of planned purchase orders and production orders stops at the BOM whose components are associated with the calculation group that the **Stop explosion** check box is selected for. Master scheduling generates the planned orders on the BOM itself, not on the items that are included in the BOM. By selecting this check box, you specify that a cost isn't added into the BOM calculation for items that have this calculation group.

Warnings

On the **Warnings** FastTab, select the options for any warning messages that users should receive when they do BOM calculations.

For example, if you select the **No BOM** check box, the user receives a warning if no active BOM version is found for one of the components or the parent item that the BOM calculation is run for. If you select the **No route** check box, the user receives a warning if no active route version is found. If you're using resources on your routes and operations, you can instruct the system to check for those resources. Then, if a resource isn't found on every line in the active route, the user receives a warning.

You can also verify and check for consumption. Consumption is the quantity in a particular route. Typically, it represents the amount of time that is required to perform a specific operation for a

production process. You can check whether an item has no cost price. If there's no active cost price for an item, no cost is added into the BOM calculation.

You can also check and verify the age of the cost price. For example, enter *60* to indicate that the unit cost price must be reevaluated after 60 days. If this limit is reached, the system generates a warning. For example, a cost price was entered for an item in January of this year. If it's now August, which is more than 60 days after the cost price was entered, the user receives a warning when the BOM calculation is run. You can enter a percentage in the **Minimum contribution margin** field. This value indicates the point at which the minimum contribution margin isn't being met. If the contribution margin for a particular component isn't met, the user receives a warning. Therefore, this field helps guarantee that you don't undercut the costs and the additional carrying costs that might be required for your items.

Default setup in Inventory and warehouse management parameters

Because calculation groups are required to run calculations, set up a default calculation group in the Inventory management parameters. This setup enables companies to have a standard cost group and profit setting for all items. If a particular item has special calculation requirements, assign a different calculation group to that item. Typically, you set calculation groups on BOM component items instead of BOM items. However, when warning messages are shown, you can apply calculation groups. A calculation group that you assign to items overrides the default value that you set up in the Inventory management parameters.

Set up the default parameter at **Cost management** > **Inventory accounting policies setup** > **Parameters** > **Inventory accounting** > **Calculation group**. By setting up a default configuration group, you can also configure the warning conditions that prompt users during the BOM calculation process, if the selected components might cause calculation errors.

View warning messages on the Complete page

A BOM calculation generates warning messages. You can view the warnings about a selected item. For example, in Sales and marketing, create a new sales order for item D0001. Then, on the sales order line, on the **Update line** menu, select **Calculate Based on BOM/Formula** to view the calculation details and warnings. You can also view BOM calculation results on the **Complete** page. For the warning messages, only two warning conditions apply to manufactured items, whereas four warning conditions apply to any item:

- Identify when a manufactured item doesn't have an active BOM.

- Identify when a manufactured item doesn't have an active route.
- Identify when the item on a BOM line has a quantity of 0 (zero).
- Identify when the item on a BOM line has a cost of 0 (zero), or when it doesn't have a cost record.
- Identify when the item on a BOM line has an out-of-date cost. The warning reflects a comparison of the calculation date to the specified days for a maximum age of cost.
- Identify when the item on a BOM line has a profitability percentage that is less than you want.

You can define multiple BOM calculation groups, depending on your requirements for variations in warning messages. For example, one BOM calculation group that has warning conditions about an active BOM, a component quantity of 0 (zero), and component cost of 0 (zero) might be enough. When you start a BOM calculation, you can override the warning conditions that are associated with the BOM calculation group. You can also add or remove warning conditions. For example, if the current situation doesn't involve routing data, you can remove the warning condition about an active route.

Time and attendance includes a **Calculation groups** page, but that page has no relationship to BOM calculation groups. In Time and attendance, workers can be assigned to calculation groups that reflect the grouping of workers who are associated with the same supervisor or manager. Calculation of worker registrations can be done either automatically or manually by a supervisor or manager.

Cost calculation level

The bill of materials (BOM) level that is named **Cost calculation level** excludes production orders and batch orders from its calculations. The system uses this level when it runs cost calculations in costing versions. In processes such as recalculation and inventory close, the system uses the **Costing level** BOM level instead.

Example scenario

The following simple scenario shows the differences between the **Cost calculation level** BOM level and the **Costing level** BOM level.

You have three products: A, B, and C. Product C is the component of product B, and product B is the component of product A.

- **Costing level** assigns the following BOM levels:
  - **Product A:** 0
  - **Product B:** 1
  - **Product C:** 2

- **Cost calculation level** assigns the following BOM levels:
  - **Product A:** 0
  - **Product B:** 1
  - **Product C:** 2

A production order for product C is then created, and product A is added to the production order BOM. After the order is estimated, BOM levels are updated in the following way:

- **Costing level** assigns the following BOM levels:
  - **Product B:** 1
  - **Product C:** 2
  - **Product A:** 3

- **Cost calculation level** assigns the following BOM levels:
  - **Product A:** 0
  - **Product B:** 1
  - **Product C:** 2

This behavior ensures that changes to production order BOMs don't affect subsequent cost calculations.

Backflush costing

Article • 01/31/2025

This article introduces the concept of backflush costing that is used for Lean manufacturing.

Costing for Lean manufacturing enables the production flow to use the cost accumulation method that is known as backflush costing. In the backflush costing method, the direct materials that are consumed are accumulated in the production flow's work in progress (WIP) cost account. The standard cost inventory model group is used. The products that are received from the production flow are deducted from WIP at their standard cost. The main difference between backflush costing and standard cost is that, for backflush costing, variances aren't calculated per kanban or finished product. Instead, variances are calculated per production flow over a period. This method introduces a truly lean concept for reporting material consumption. Dedicated picked quantities of material aren't reported to a kanban or production order. Instead, full batches or handling units are staged to the production flow. After the batches or handling units are registered as empty, they're declared consumed. Advanced consumption might be used, depending on the configuration of the production flow. Before advanced consumption can be used, organizations must allow themselves to make material vanish in the WIP of the production flow. The periodic backflush costing determines the effective value of WIP to the end of the period. This determination is based on the kanban handling units and the kanban job status. Deviations between the effective values and the actual WIP values per cost group and item are accounted and shown as variances.

Configuring backflush costing

To enable costing, you must complete the following setup:

- **Set up WIP accounts for the production group and production flow.** The WIP accounts for the production flow are specified in the production group. The backflush costing production flow calculates variances as the difference in the WIP value before and after backflush costing is run for each production flow. Therefore, we recommend that you create a WIP account for every production flow.
- **Assign a cost category to the resource group.** You must assign a cost category to the run-time category of the work cell. To determine variances by activity, you should create a cost category for every work cell. The cost categories for setup and quantity aren't considered in costing for lean manufacturing. The WIP accounts per resource group are ignored in backflush costing. For subcontracted activities, no

cost category is required. The cost group that is assigned to the active service is used instead.

- **Assign cost groups.** To enable segmentation of the cost contribution in a production flow, you must assign cost groups by cost group type:
  - *Direct material cost group* – Direct material requires a cost group that identifies the material category for costing. This cost group enables an aggregated view of cost, WIP, and variances by direct material.
  - *Direct manufacturing cost group* – The direct manufacturing cost group captures the direct cost contribution of operational resources to the production flow. This cost group enables an aggregated view of cost, WIP, and variances by direct manufacturing cost.
  - *Indirect cost group* – The indirect cost group is required in order to calculate the indirect cost contribution to the production flow. This cost group enables an aggregated view of cost, WIP, and variances by indirect cost.
  - *Direct outsourcing cost group* – The cost group for the services enables an aggregated view of assigned cost and WIP, and determines the cost variances of the subcontracted services.
  - *Cost group for a finished product* – Finished products require a cost group that identifies the product category for costing. This cost group enables an aggregated view of cost, WIP, and variances by product category. The standard cost for products is calculated by using the cost calculation that is based on the bill of materials (BOM), and either the production flow and kanban rules or the route.

Costing sheet

The costing sheet models the cost structure for the company and is built by the cost groups to classify the cost. The costing sheet has various forms. It shows cost information according to the structure that is designed in it. In the costing sheet, you also define the formula that is used to calculate the indirect cost. The calculation formula can be based on quantities, weight, volume, or value.

- **Define a costing version.** In the costing version, the company defines how the cost should be maintained. A costing version can contain a set of standard cost records or a set of planned cost records, depending on the costing type that is assigned to the costing version. The costing version that is used for costing for Lean manufacturing must be based on standard cost.
- **Assign an inventory model group for released products.** All products that are related to the production flow must be assigned to an inventory model group that uses the *Standard cost* inventory model group. Standard cost is maintained per site

and activation date. For product masters, the inventory model group can be selected if the cost is maintained per variant or product master.

- **By definition, subcontracted services are non-inventoried services.** Subcontracted activities have no inventory model group. To cost a subcontracted activity correctly, you must make sure that the service activity belongs to an inventory model group where the inventory policy is set to *Stocked product = False*.

For output products, cost calculation that is based on the production flow requires that a standard cost be maintained for the services that are related to subcontracted activities. The cost group that is assigned to the services is used to determine the cost variances of the subcontracted activity.

Cost calculation for Lean manufacturing

For products that are supplied out of a production flow, the BOM calculation must be based on either a route version or a production flow. The BOM calculation calculates the cost of a product and the related breakdown to the resources and material that are required in order to build the product. The deduction from the WIP account for the production flow is done by using the breakdown of a product by item and cost group.

Calculation that is based on the production flow

Lean manufacturing for Dynamics 365 Supply Chain Management is independent of routes. The cost calculation for products that are supplied from a production flow can be based on the production flow itself. Before the calculation can be done, a kanban rule must be created that supplies the product out of the production flow. If a product can be supplied from multiple production flows at the same site on the calculation date, you can select the production flow for the BOM calculation. On the **Default production flow** page, you can configure a default production flow for each item. If multiple kanban rules exist for the same product in the same production flow that is active on the calculation date, the calculation selects the first kanban rule that is active for the calculation.

Calculation that is based on the route

Calculation that is based on a route is as valid as calculation that is based on a production flow. However, calculation that is based on a route doesn't use the costing for Lean manufacturing functionality. The route should use resource requirements for resource groups. To avoid systematic variances, it should also use the same work cells, or at least the same cost categories. Again, you should avoid cost categories for setup

and quantity. They don't help calculate the cost in a more granular breakdown than Lean manufacturing cost backflushing. To determine which option (production flow or route) you should use to calculate the cost, consider the results of the cost breakdown. The version that comes closer to reality and produces fewer variances overall is the better option. In a Lean manufacturing environment where a product is supplied by a single production flow and a single kanban rule, the calculation that is based on the production flow is probably more accurate. For a product that can be supplied by Lean manufacturing and production orders on the same site, or that can have multiple production flows or multiple kanban rules in the same flow, a calculation might be more accurate if it's based on a route version that is built specifically for the cost calculation, not for the production. The production flow calculation must be used to calculate products that involve subcontracting. The cost models for subcontracting via production orders and subcontracting in Lean manufacturing are using two different approaches. Lean manufacturing introduces a new cost group type, *Direct outsourcing*, to calculate subcontracted services.

Material consumption

When material is consumed from inventory to WIP, the cost of material is added to WIP at its actual standard cost for a cost group. This operation occurs under the following conditions:

- Kanban issues are posted for kanban picking lines that update inventory.
- Transfer jobs are completed that update inventory on pick but not receipt (Transfer of material from inventory to WIP).

Receiving products from the production flow

Products are received from the production flow under the following conditions:

- Process jobs are completed that have **Update inventory on receipt** set to *Yes*.
- Transfer jobs are completed that update inventory on receipt, but that have **Update inventory on pick set** to *No* (Transfer from WIP to inventory). This option lets you receive any products out of a production flow independently of the BOM and route configuration. The process just follows the physical flows. This option is especially suitable for receiving by-products, co-products, or scrap out of a production flow, and for correcting the cost balance of the production flow WIP accordingly.

Products that are received from the production flow are deducted from WIP.

Products in WIP

The WIP model of Lean manufacturing lets you use the kanban handling unit status to manage the material, semi-finished products, and finished products that are part of WIP.

- **Assigned** - The kanban can have consumed material that is accounted in WIP.
- **Received** - If the kanban refers to a last activity where **Update inventory on receipt** is set to *No*, it represents a full handling unit of a product or a semi-finished product that isn't registered to inventory.

Material in WIP isn't visible in inventory on-hand overviews. However, it's visible in the kanban quantity overviews.

Consuming products in WIP

Products in WIP are consumed when the corresponding kanban handling units are emptied. A kanban empty signal doesn't produce an active costing transaction but will take effect when the next backflush costing is run. Emptied kanban handling units are no longer accounted as on-hand and therefore calculated as consumed within the period.

Automatic empty registration

Scheduled or event kanbans can be set to automatic empty registration in the kanban rule:

- **When handling units are received** - By default, for scheduled kanbans, the material is declared as consumed when the last job of the kanban is completed. For fixed quantity kanbans, this option is recommended only for single-bin kanbans, because it returns the card to the source of demand whenever a kanban is received at the final destination.
- **When source requirement is registered** - This option is available only for event kanbans and is the default option for them. In connection to WIP, this option is useful for keeping WIP clean, because kanbans for components in WIP are automatically emptied, and therefore consumed from WIP, when the parent kanban is prepared.

In conclusion, kanban handling units can be assigned (= in process), received (=full), or emptied. There's no partial emptying. Therefore, to enable accurate registration of consumption, it's important that you limit the product quantities of a kanban so that they're less than the consumption per period. Products that are moved to the shop floor

in large batches that cover days or weeks of demand shouldn't be consumed to WIP. Instead, these products should be kept in inventory.

Backflush costing steps

You should run backflush costing to periodically value the WIP and produce an end-of-period status that calculates the variances of material, labor, and indirect costs. The calculated variances are posted to the variance accounts. In the backflush costing process, all production flows of the legal entity are used in the same batch run. When backflush costing is run in a batch, the processing might be multi-threaded by production flow. The backflush period is defined by an end date. You can't post new transactions to a date when a backflush costing calculation has been run. You should never run backflush costing for the current date before the day is actually over. Backflush costing performs the following steps.

1. Determine the unused quantities in the production flow as of the period's end date. After the backflush costing is run, you can view the unused quantities on the date of the costing run in the **Unused quantities** dialog box.

2. Calculate the production flow's net realized usage over the period.

3. Clear the WIP from the realized resource consumption and products.

4. Calculate production variances to standard cost for the period.

   For consumed components for the period:

   - Financially update the net realized quantities of material that the production flow consumed over the period. The system processes in first in, first out (FIFO) order on the individual inventory transactions as to financially update the physically updated transactions for the production flow, until the net realized quantities for the period are reached.
   - Transactions are financially split to map the exact consumed quantities.
   - Unused quantities in the production flow WIP remain in physically updated status.

   For production completed quantities of the period:

   - Financially update the inventory transactions for the completed quantities for the period.

   For the conversion cost:

- The applied conversion cost transactions (route transactions) that were recorded for the period are financially updated.
- All direct manufacturing cost is financially updated. All kanban process jobs that are completed during the period are accumulated.
- All indirect cost calculated for the consumed material within the period is calculated and deducted from WIP. The remaining indirect cost is posted as a variance.

5. Calculate the production variances to standard cost. The variance is calculated per cost group.

Common sources of production variances

This article explains various typical sources of each type of production variance.

Here are some typical sources of a *lot size* variance:

- The good quantity for a production order differs from the calculation quantity that is used in the standard cost calculation. The quantity provides the basis for amortizing constant costs.
- The value of constant costs on the production order differs from the constant costs that are used in the standard cost calculation. The constant costs on the production order can differ for several reasons. For example, the constant costs might reflect the following factors:
  - Manual changes to the production bill of materials (BOM) or route
  - The selection of a different BOM version or route version when you create the production order
  - Planned engineering changes to the BOM version or route version that is assigned to the item

Here are some typical sources of a *production price* variance:

- The cost category (and cost category price) for the reported consumption of a routing operation differs from the cost category that is used in standard cost calculation.
- The active cost for the cost category price differs from the cost category price that is used in standard cost calculation.

Here are some typical sources of a *production quantity* variance:

- You over-issue or under-issue a material component.
- You over-report or under-report the time for a routing operation.
- You over-receive or under-receive the good quantity of the parent item, relative to the order quantity. However, you issue components and report operations completely, based on the order quantity for the production order.

Here are some typical sources of a *production substitution* variance:

- You issue a material component that isn't on the production BOM.
- You manually add a component to the production BOM and report that component as consumed.
- You report an item as consumed but don't manually add it to the production BOM.

- You manually add an operation to the production route and report that operation as consumed.
- When you create the production order, you select a BOM version that differs from the BOM version that is used in the standard cost calculation.
- When you create the production order, you select a route version that differs from the route version that is used in the standard cost calculation.

Cost categories used in production routing

This article provides information about cost categories that apply to manufacturing environments that use routing.

Cost categories apply to manufacturing environments that use routing. They're assigned to operations resources and routing operations to define hourly costs and to segment cost contributions in a manufactured item’s calculated costs. The cost groups assigned to cost categories classify manufacturing cost contributions based on the operation resources and the type of activity, such as setup time and run time. The specificity of cost group assignments enables manufacturing overhead to be calculated based on routing information.

> **Note**
>
> In manufacturing environments, cost categories are known by several other names, such as labor rate codes or machine rate codes.

Each cost category has associated cost records and an assigned cost group. Different cost categories are required for different production purposes.

- Assign different hourly costs, depending on the operations resource. For example, the costs can differ for various types of labor skills, machines, or manufacturing cells.
- Assign different hourly costs for the setup time or run time that is associated with a routing operation.
- Assign operations resource costs based on the output quantity instead of hourly costs, such as the piece rates for paying labor.
- Provide cost group segmentation of cost contributions to a manufactured item’s calculated cost. For example, you can segment labor and machine costs.
- Provide the cost group basis for overhead calculation formulas, such as formulas for labor-related and machine-related overhead, or overhead that is related to setup and run time.

A cost category can be assigned to the setup time, the process time, and the quantity for a routing operation. When, for example, costs or cost group segmentation differs between the setup time and the process time, different cost categories should be defined and assigned to the setup time and the process time. The selective use of cost categories for setup time, process time, and quantity is determined by the route group that is assigned to an operation. The assignment

of cost categories to time and quantity can be mandated by company-wide policies that are defined on the **Production control parameters** page.

Each cost category has associated costs that are based on the definition of cost records in a costing version. Use the **Cost category price** page to define the cost records for a specified costing version and site. When the cost record for a cost category is first entered, it has a status of *Pending* and an intended effective date. When you activate the cost record, the status is updated to *Current active*, and the effective date is updated to the activation date. Different cost records might reflect different sites, effective dates, or statuses. Bills of materials (BOM) calculations for a future or historical date use cost records that have the relevant effective date. The current active cost record can be used to estimate production order costs and to value reported time against a production order.

The cost record for a cost category can be site-specific or company-wide. To make a cost record site-specific, assign a site to it. Otherwise, a blank value indicates that the cost record applies to all sites in the company. Because costs can differ between sites, for example, the cost records must be defined as site-specific.

A routing operation generally inherits the cost categories that are assigned to the operations resource or master operation. When a production order is created, the routing operations in the production route reflect the selected route version. You can override the cost categories that are assigned to the operations in the production route.

Some types of production work can apply to project time estimates and reporting. In this case, a cost category is required for production and project purposes. You must define additional project-related information when a cost category is flagged for use in projects.

Cost categories used in Production control and Project management accounting

Some types of production work can apply to project time estimates and reporting. This article provides information about the cost categories that you must define for these types of production work for production and project purposes.

Some types of production work can apply to project time estimates and reporting. In this case, a cost category is required for production and project purposes. When a cost category is used in production and projects, additional project-related information must be defined. For example, the hourly costs that are associated with projects can differ from the hourly costs that are associated with production. You can use the **Cost categories** page to define a cost category that is used in Production control and Project management accounting.

> **Note**
>
> Cost accounting has a **Project categories** page, but this page has no relationship to the functionality that is described in this article. When you use a cost category in projects, the **Cost categories** page has additional tabs that show additional project-related information. This information includes the category group, a line property, and ledger accounts that are assigned to the cost category.

- The cost category must be assigned to a category group that supports a transaction type of **Hours**.
- The line property indicates default information about how reported time can be charged to a project.
- Typically, the ledger accounts that are related to costs and sales are defined for the category group that is assigned to the cost category. However, specific accounts can be defined for an individual cost category.

Additional buttons on the **Cost categories** page let you access project-related information about a selected cost category. For example, you can view project-related transactions, define employees or projects, define hourly costs and sales prices, and view reports.

Display charges for a manufactured item

The constant costs of a manufactured item reflect the operation setup times and the components that have a constant quantity or a constant scrap amount.

The calculated amount of an item's charges can be displayed with the item's unit costs. However, the charges are sometimes displayed as separate fields, and they aren't included in the item's unit costs. When the charges appear as separate fields, one field displays the total charge amount, and another field displays the costing lot size that is used to amortize the amount. The **Item price** page, for example, displays the charges as two separate fields. However, the **Complete** page displays the item's total cost per unit, and the amortized costs are included in the unit costs.

The charges for a manufactured item are always included in the item's unit cost for standard cost purposes. They can optionally be included for planned cost purposes. A policy in the costing version enforces the inclusion of charges in the cost of a manufactured item. When you activate an item's cost record, you update the charges for the item's base cost information, which is displayed on the **Item price** page. The charges are displayed as two separate fields, and they aren't included in the item's unit cost. Each activation updates the item's base cost information, even if the activation reflects different sites. Therefore, you should view the base cost information as reference information.

Production order cost analysis

This article provides information about the cost analysis that you can do for completed and current production orders. You can analyze the estimated costs and actual costs by using the **Price calculation** page or the **Cost estimates and costings** report. You can view information about the estimated and actual costs (and quantity) for each component item, the routing operation, and the indirect cost.

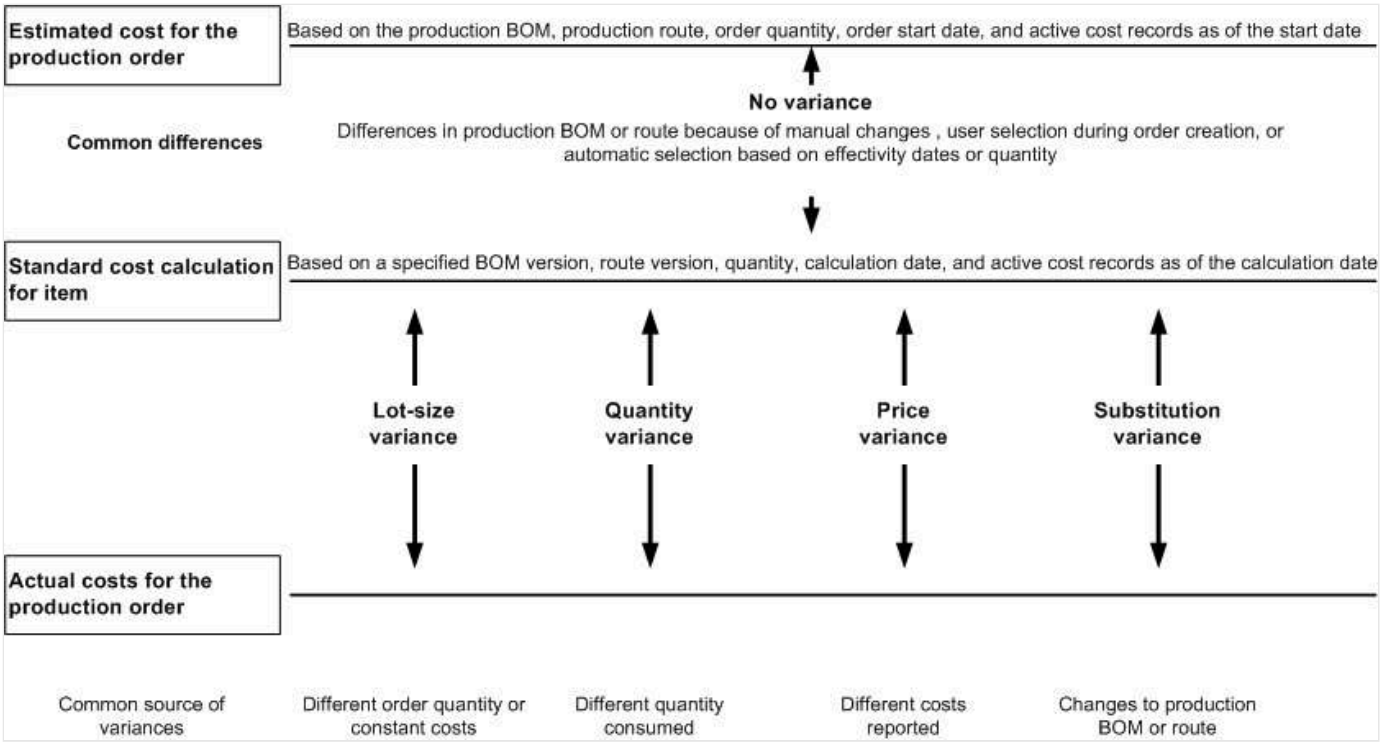
The actual costs for a production order are based on the reported consumption of material and routing operations. You can access detailed transactions about the reported consumption of material, routing operations, and indirect costs for a production order on the **Production posting** page.

Variance analysis for a completed production order

The variances reflect a comparison of the reported production activities and the calculation of standard costs for the production item. The variances don't reflect a comparison to the production order's estimated costs. The production activities that are reported include the consumption of material and routing operations, together with the associated indirect costs, and the quantity that is reported as finished. The following four types of variance are calculated:

- Lot size variance
- Production quantity variance
- Production price variance
- Production substitution variance

The following diagram shows the four variances that account for the difference between a production order's actual costs and the calculated costs within the item's cost record when the production order is ended.



You can analyze the production variances by using the **Variance** page or the **Production variance** report. Use the display options to view detailed variances by item and operations resource, or by cost group. The policy for cost breakdown in the inventory parameters determines whether the variances are tracked by cost group. You can also use the **single**, **multi**, and **total** display options to view summarized variances. The information about detailed variances can help you understand the source of each variance. To predict variances before you end a production order, analyze the detailed information that the **Cost estimates and costings** report provides.

Cost analysis for current production orders

Separate reports provide information about each type of transaction. Use these reports to analyze costs for reported production activities. Information is displayed only for current production orders that have a status of *Started* or *Reported as finished*.

- **Materials in process** – This report lists the picking list transactions that are reported against the current production orders as of a specified transaction date. The report indicates the quantity of a component that's issued and the cost amount for each transaction. Use the selection criteria for a single component item. For example, you can print information about the component's issued quantity against applicable production orders. The issued quantity isn't updated by the quantities reported as finished for the parent item. Therefore, the actual quantity of raw materials in process might be overstated.
- **Work in process** – This report lists route transactions (or job transactions) reported against the current production orders as of a specified transaction date. The report indicates the hours, amount, and quantity (both good quantity and error quantity) that are reported for

each transaction. It also includes information such as the operation number, operation ID, and operations resource. Additionally, this report shows the total time and amount for all transactions against the production order, and the quantity reported as finished.

- **Indirect costs in process** – This report lists the indirect costs incurred against production orders. This data is based on reported consumption of routing operations and components as of a specified transaction date. The report indicates the type of indirect cost (surcharge or rate), the costing sheet code for the indirect cost, and the cost amount for each transaction. This report doesn't provide information about the route card or pick list transaction that generated the indirect cost.

Production order cost estimation

This article provides information about production cost estimation. Production cost estimation provides the projected material and capacity consumption costs of producing an item in the planned production order quantity.

After you create a production order, you must estimate production costs. The purpose is to estimate item and route consumption for the production process, because these estimates are used as the basis for subsequent scheduling and production processes.

Production cost estimation

Estimates of production costs are based on the following information:

- The quantity on the production order
- The components on the production bills of materials (BOMs)
- The routing operations in the production route
- The indirect costs that apply to the components and operations
- The active cost data as of the calculation date

If there's a phantom line item on the production BOMs, the calculations reflect the phantom's components and route operations. You can use the estimation task to recalculate estimated costs so that they reflect updated information. For example, the updated information might be changes to the quantity on the production order, the components on the production BOMs, the routing operations in the production route, the indirect costs that apply to these components and operations, or the active cost data as of the recalculation date. The calculations of estimated cost also suggest a sales price for the production item, based on a cost-plus-markup approach. The calculations of estimated cost can optionally apply to reference orders that reflect other production orders that are linked to the production order.

View the estimated costs

After you run estimation, you can view the results on the **Price calculation** page. The estimation calculates the following values:

- **Production cost** – The production cost is the top line of the estimate. It shows the complete cost of running the production order and the total sales price for the production. It's the sum of all the cost lines on the estimate.

- **Route or resource costs** – Route or resource costs are the costs for the production operations. They include the cost of elements such as setup time, run time, and overhead.
- **Material costs** – Material costs are the costs and prices of the BOM components that are required in order to produce the item. These costs were previously established and entered into the system.

Other uses of cost estimation

A cost estimate also provides the following information:

- Meaningful price quotations
- Estimates of the profitability of the order
- Estimates of raw material usage
- Comparisons of cost information from previous productions
- Budget and forecasting information
- Estimates of the production size that is required in order to maintain a particular cost

View current WIP status on a production order

This procedure shows how to view a work in progress (WIP) statement for a production order. This procedure is intended for the cost controller.

1. Go to **Cost management** > **Workspaces** > **Cost administration**.
2. On the Action Pane, select **Production orders**.
3. Find and select the production order you're looking for. If necessary, you can use the **Filter** field to help find it.
4. On the Action Pane, open the **Manage costs** tab and select **Production WIP statement**.
5. Use the **From date** and **To date** fields to specify the date range you're looking for.

Last updated on 11/26/2025

Compare active, estimated, and realized costs on a production order

This procedure shows how to view reasons for high production variance for a production order. The demo data company used to create this procedure is USMF. This procedure is intended for the cost controller.

1. Select **Cost administration**.
2. In the **Date** field, enter or select a value. (This procedure uses the fiscal year 2012. You can set **From date** to *January 1, 2012* and **To date** to *December 31, 2012*.)
3. Open the **High production variances** tab.
4. Select the relevant link in the **Production** field. (If you're working with USMF sample data, select *P000116*).
5. On the Action Pane, select **Manage costs**.
6. Select **View cost comparison**.
7. Select **Close**.

Production posting

This article provides information about different types of postings in the production process.

Production posting activities follow production processes that are described in the sections below.

Material consumption

Materials are registered as consumed during production when the production picking list journal is posted. This process generates issue transactions that deduct the on-hand inventory. In the production parameters, you can specify whether the value of raw materials that are in progress (work in process [WIP]) should be posted in the ledger. The value of raw materials that are in progress (WIP) is then posted to a dedicated Picking list account and a dedicated Picking list offset account.

Time consumption

The time that workers spend on production jobs is recorded in the Route card journal or the Job card journal. When these journals are posted, ledger posting to a dedicated account for resources that are in progress (WIP) is processed. This posting represents the value of the time that is spent on the production order. After the production order is registered as ended, the WIP accounts are settled.

Reporting finished goods and error quantities

When a production order is reported as finished, the quantity of the finished goods that have been completed is updated in Inventory management through the Report as finished journal. If you're using WIP accounting, which can be set up in the production parameters, a ledger journal is made to reduce the WIP accounts and increase the inventory of the finished goods. The journal uses the standard cost that is defined for the product.

Ending the production order

Before a production order is ended, actual costs are calculated for the quantity that was produced. All estimated costs of material, labor, and overhead are reversed and replaced with actual costs. The overall cost of the finished item is debited from the inventory Receipt account

and credited to the inventory Issues account. If you select the **End job** check box when you run the cost calculation, the status of the production order is changed to *Ended*. This status prevents any additional costs from being unintentionally posted to a completed production order. You can specify that the value of error quantities that are reported during reporting as finished should be allocated to the good quantities that are reported as finished. Alternatively, you can specify that the value of error quantities should be posted to a dedicated scrap account.

Controlling the level of ledger posting

In the **Production control parameters**, you can use the **Ledger posting** field to set the level of ledger posting for production processes. The following values are available:

- *Item and resource* – Use the ledger accounts that are set up on the item groups for raw materials and finished goods. WIP for time consumption is taken from resource or resource group from the route operations.
- *Item and category* – Use the ledger accounts that are set up on the item groups for raw materials and finished goods. WIP for time consumption is taken from the cost categories that are associated with the route operations.
- *Production groups* – Use the ledger accounts that are set up on the production groups for both material and time consumption. The production groups are associated with the released products and copied to the production orders when those orders are created. The posting on the production orders will then follow the production groups that are associated with the production order.

> **Note**
>
> If the standard method for calculating the cost of the finished item was used, the final transactions reflect this fact. If actual costs and the costs that are calculated by using the standard method differ, the difference is posted to the account that shows profit or loss.

Set up products that can be produced or procured

Products can be sourced in various ways. They can be produced (manufactured) or procured (purchased). This article describes some typical points to consider when you configure products to support multi-sourcing.

Multi-sourcing is typically used for a purchased item that is occasionally manufactured, or when an item that was primarily a manufactured item is changed so that it's now primarily a purchased item. The item is first designated as a manufactured item, so that bill of materials (BOM) and route information can be defined, and to support production orders for the item. The production type should be set to *BOM* (or, for process manufacturing, *Formula* or *Co-Product*).

When you use standard cost, the item cost record can be calculated for the manufactured item. However, the item cost record might not match the standard cost that you want for purchasing purposes. In this case, the standard cost must be manually entered and activated for the item cost record. For the cost calculation, consider using a special BOM and route that represent the supply mix of the product over the course of a fiscal period, to minimize the variances over time. Additionally, a manufactured item at one site can be transferred to another site. Therefore, the item's cost must be manually entered and activated for the site that the item is transferred to. When you use the manufactured item as a component in higher-level products, the component's costs should be treated as a purchased item. This guideline applies, regardless of whether the component’s costs were calculated or manually entered. In other words, a BOM calculation should treat the item's costs as a purchased component instead of using the item's BOM and route information to calculate costs.

To prevent the calculation from occurring, select the **Stop explosion** flag that is embedded in the BOM calculation group that is assigned to the item. To prevent master scheduling calculations from exploding requirements through the item, set the explosion fence to 0 (zero) days in item coverage or in the coverage group. The master scheduling calculation will then treat the item as a purchased item and won't perform more calculations for the item's BOM and route information.

Total cost allocation method

Article • 01/28/2025

Total cost allocation (TCA) is a method of calculating the cost between the main formula item for a batch order and the co-products that are defined for the formula. This method is dynamic. It calculates the cost as a weighted average between the quantities that are reported as finished for the formula item and the co-products. When TCA is used, you don't have to review cost allocations for every batch order. If TCA isn't used, the formula calculation uses existing functionality.

Using TCA for co-products

Here are some of the guidelines for using TCA for co-products:

- If you set **Total Cost Allocation** to *Yes* for a formula version, co-products must have a cost price that is more than 0 (zero). The value can be retrieved from the active cost version for the same site, or for the first site for a formula that isn't site-specific. This condition is validated when the formula is approved.
  - You don’t need to manually enter cost allocation percentages for co-products. Instead, the system automatically creates the cost allocation percentage as the average of active cost prices of co-products.
  - You don’t need to enter standard cost for non-standard cost items that are co-products. There are two types of costing versions in the system: standard cost and planned cost
  - If an item isn’t valuated by the standard cost valuation method, we recommend you use an active cost price in the planned cost version. This price is used for cost estimation, for example, bill of material (BOM) calculation, production cost estimation, and fallback price in the inventory valuation process.

- If you set **Total Cost Allocation** to *Yes* for the formula version and the following conditions are true, the method of cost allocation is **TCA**, and the percentage of cost allocation is unchanged:
  - You added co-products.
  - You used a different method of cost allocation for the co-products.

- If you set **Total Cost Allocation** to *No* for the formula version and the following conditions are true, the method of cost allocation is changed to **Manual**, and the percentage of cost allocation is unchanged:
  - You added co-products.
  - The percentage of cost allocation is more than 0 (zero).

- Before you can successfully perform a formula calculation, you must estimate the percentages of cost allocation. You can complete this step either manually or by using the **Estimate cost** option on the **Co-products** page. The **Estimate cost** option is available only when **Total Cost Allocation** is set to *Yes* for the formula version. You can view the expected allocation if the batch order quantities that are reported as finished match quantities that appear on the formula.

- When a batch order is created manually or a planned batch order is firmed, the value of the **Total Cost Allocation** slider for the formula version is copied to the batch order. However, you can change this setting on the batch order. If **Total Cost Allocation** is set to *No* for the formula version and then changed to *Yes* for the batch order, the method of cost allocation for each line previously set to *Manual* is changed to *TCA*. A cost allocation of *None* is unchanged. If **Total Cost Allocation** is set to *Yes* for the formula version and then changed to *No* for the batch order, the method of cost allocation for each co-product of the *Production* type is changed to *Manual*. Any estimated percentage of cost allocation is unchanged.

- The **Co-product cost allocation** page shows the calculated cost allocation percentage. You can open this page from the **Batch order** page. This information is useful when the products and quantities that are reported differ from the scheduled or started quantities on the batch order. When the cost is complete, these new percentage allocations from TCA are shown on the **Co-product cost allocation** page.

Calculating the burden for byproducts

The **By-product cost allocation** field on the **Co-products** page is an enumerator field that is used only for by-products. For co-products, the value of this field is always *None*. For by-product lines, this field determines how the cost amount for the by-product line is added to the total cost of the production. The following options are available:

- *None* — No amount is added to the total cost of the production for this by-product line.
- *Percent* — The cost amount is calculated as a percentage of the total cost of raw materials that are consumed in the production. The percentage that is used for the calculation is entered in the field.
- *Per series* — The cost amount is calculated as an amount per standard batch size of the production order. This amount is independent of the reported quantity in the production. The amount that is used for the calculation is entered in the field.
- *Per quantity* — The cost amount is calculated as an amount per reported quantity of the formula item in the production. The amount that is used for the calculation

is entered in the field.

Amortize constant costs for a manufactured item

A manufactured item's constant costs reflect the operation setup times and the components that have a constant quantity or a constant scrap amount.

The concept of a costing lot size is used to amortize these constant costs in the calculated cost of a manufactured item. This concept has several synonyms, one of which is accounting lot size. The concept of amortizing constant costs also has several synonyms, one of which is proportional constant costs.

The quantity of a costing lot size for a manufactured item is used in a bill of material (BOM) calculation. The quantity depends on how you initiate and perform the BOM calculation, as illustrated by the following:

- Default calculation quantity in an item's BOM calculation – The item's standard order quantity for inventory acts as the costing lot size, but the default value might be a greater quantity to reflect the item's order quantity multiple. The item's standard order quantity and multiple can be defined within its default order settings or site-specific order settings.
- Specified calculation quantity in an item's BOM calculation – The specified calculation quantity acts as the costing lot size for the item. The calculation quantity initially uses the item's standard order quantity, but the default value can be manually overridden. The specified calculation quantity represents the costing lot size for the specified item, and for manufactured components that have a BOM line type of production. This is because it is assumed that the component will be produced to the exact quantity. The costing lot size for other manufactured components that have a BOM line type of item will reflect their standard order quantity.
- Specified make-to-order calculation quantity in an item's BOM calculation – The specified calculation quantity acts as the costing lot size for the item and its manufactured components when BOM calculations use a make-to-order explosion mode. It is assumed that the manufactured components will be produced to the exact quantity, just like a manufactured component that has a BOM line type of production.
- Specified calculation quantity in an order-specific BOM calculation – An order-specific BOM calculation can be performed for a line item on a sales order, sales quotation, or service order. The specified calculation quantity uses the quantity on the originating line item, but

the default quantity can be overridden. You can select whether the order-specific BOM calculation uses a make-to-order or multilevel explosion mode.

The calculated amount of a manufactured item's amortized constant costs is termed charges.

Cost management Power BI content

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Overview

The **Cost management** Microsoft Power BI content is intended for inventory accountants or individuals in the organization who are responsible for or interested in the status of inventory or work in progress (WIP), or who are responsible for or interested in analyzing standard cost variances.

This Power BI content provides a categorized format that helps you monitor the performance of inventories and visualize how cost flows through them. You can gain managerial insights such as the turnover ratio, number of days that inventory is on hand, accuracy, and "ABC classification" at your preferred aggregated level (company, item, item group, or site). The information that is made available can also be used as a detailed supplement to the financial statement.

The Power BI content is built on the **CostObjectStatementCacheMonthly** aggregated measurement, which has the **CostObjectStatementCache** table as its primary data source. This table is managed by the Data set cache framework. By default, the table is updated every 24 hours, but you can change the update frequency or enable manual updates in the configuration of the data set cache. Manual updates can be run in either the **Cost administration** workspace or the **Cost analysis** workspace.

After every update of the **CostObjectStatementCache** table, the **CostObjectStatementCacheMonthly** aggregated measurement must be updated before data in the Power BI visualizations is updated.

Accessing the Power BI content

The **Cost management** Power BI content is shown in the **Cost administration** and **Cost analysis** workspaces.

The **Cost administration** workspace contains the following tabs:

- **Overview** – This tab shows application data.
- **Inventory accounting status** – This tab shows Power BI content.
- **Manufacturing accounting status** – This tab shows Power BI content.

The **Cost analysis** workspace contains the following tabs:

- **Overview** – This tab shows application data.
- **Inventory accounting analysis** – This tab shows Power BI content.
- **Manufacturing accounting analysis** – This tab shows Power BI content.
- **Std. cost variance analysis** – This tab shows Power BI content.

Report pages that are included in the Power BI content

The **Cost management** Power BI content includes a set of report pages that consist of a set of metrics. These metrics are visualized as charts, tiles, and tables.

The following tables provide an overview of the visualizations in the **Cost management** Power BI content.

Understanding the data model and entities

Data from the application is used to fill the report pages in the **Cost management** Power BI content. This data is represented as aggregate measurements that are staged in the entity store, which is a Microsoft SQL Server database that is optimized for analytics. For more information, see Power BI integration with Entity store.

The key aggregate measurements of the following objects are used as the basis of the Power BI content.

Expand table

Object	Key aggregate measurements	Data source for finance and operations	Field
CostObjectStatementCacheMonthly	Amount	CostObjectStatementCache	Amount
CostObjectStatementCacheMonthly	Quantity	CostObjectStatementCache	Qty
CostInventoryAccountingKPIGoal	AnnualInventoryTurn	CostInventoryAccountingKPIGoal	AnnualInventoryTurn
CostInventoryAccountingKPIGoal	InventoryAccuracy	CostInventoryAccountingKPIGoal	InventoryAccuracy

The following table shows the key calculated measurements in the Power BI content.

Expand table

Measure	Calculation
Beginning balance	Beginning balance = [Ending balance]-[Net change]
Beginning balance qty.	Beginning balance qty. = [Ending balance qty.]-[Net change qty.]
Ending balance	Ending balance = (CALCULATE(SUM([Amount]), FILTER(ALL(FiscalCalendar) ,FiscalCalendar[MONTHSTARTDATE] <= MAX(FiscalCalendar[MONTHSTARTDATE]))))
Ending balance qty.	Ending balance qty. = CALCULATE(SUM([QTY]), FILTER(ALL(FiscalCalendar),FiscalCalendar[MONTHSTARTDATE] <= MAX(FiscalCalendar[MONTHSTARTDATE])))
Net change	Net change = SUM([AMOUNT])
Net change qty.	Net change qty. = SUM([QTY])
Inventory turnover ratio by amount	Inventory turnover ratio by amount = if(OR([Inventory average balance] <= 0, [Inventory sold or consumed issues] >= 0), 0, ABS([Inventory sold or consumed issues])/[Inventory average balance])
Inventory average balance	Inventory average balance = (([Ending balance] + [Beginning balance]) / 2)
Days inventory on-hand	Days inventory onhand = 365 / CostObjectStatementEntries[Inventory turnover ratio by amount]
Inventory accuracy	Inventory accuracy by amount = IF([Ending balance] <= 0, IF(OR([Inventory counted amount] <> 0, [Ending balance] < 0), 0, 1), MAX(0, ([Ending balance] - ABS([Inventory counted amount]))/[Ending balance]))

The following key dimensions are used as filters to slice the aggregate measurements, so that you can achieve greater granularity and gain deeper analytical insights.

Expand table

Entity	Examples of attributes
Products	Product number, Product name, Unit, Item groups
Category hierarchies (Assigned to role Cost management)	Category hierarchy, Category level
Legal entities	Legal entity names
Fiscal calendars	Fiscal calendar, Year, Quarter, Period, Month
Site	ID, Name, Address, State, Country/Region

- Tech Talk: Reporting options (video)
- finance and operations: Power BI Analytics & Reporting Services blog (blog)

Analytical workspaces

Workspaces can use rich infographics and visuals that Microsoft Power BI supports. These infographics and visuals include many controls that third parties provide. Therefore, workspaces can provide a highly visual, interactive experience for users.

Users can interact with data by clicking or touching visuals on the page. They can see cause and effect, and do simple what-if operations without leaving the workspace. Thanks to stunning, interactive visuals, your users have fun exploring data and discovering hidden trends.

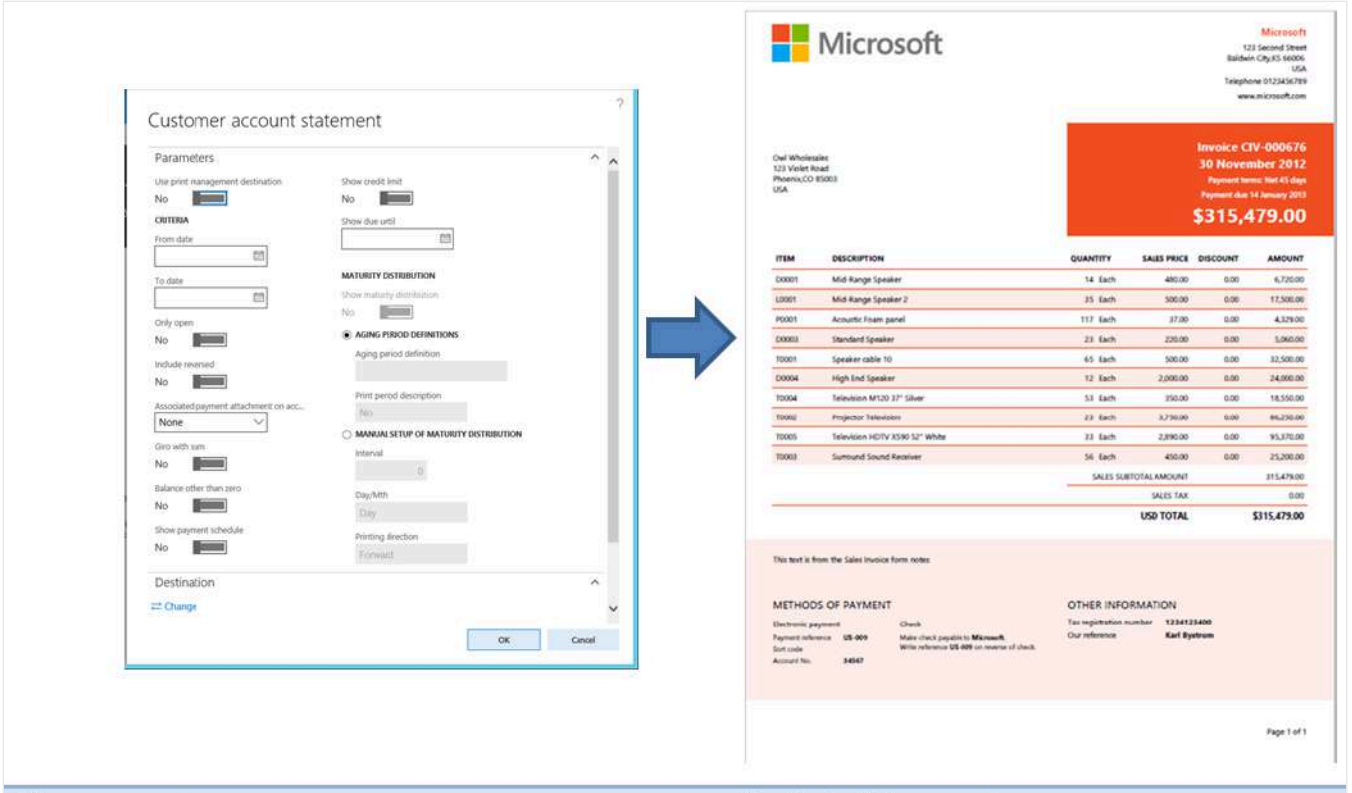
- Embedded Power BI in workspaces
- Power BI Embedded integration
- Add analytics to workspaces by using Power BI Embedded
- Help secure analytical workspaces and reports by using Power BI Embedded
- Power BI content home page

Business documents and printing

Reporting solutions often capture and communicate the details of business transactions. Therefore, a reporting solution must produce physical manifestations of business data by using existing devices, such as network printers. Examples of business documents include sales invoices, customer statements, and checks.



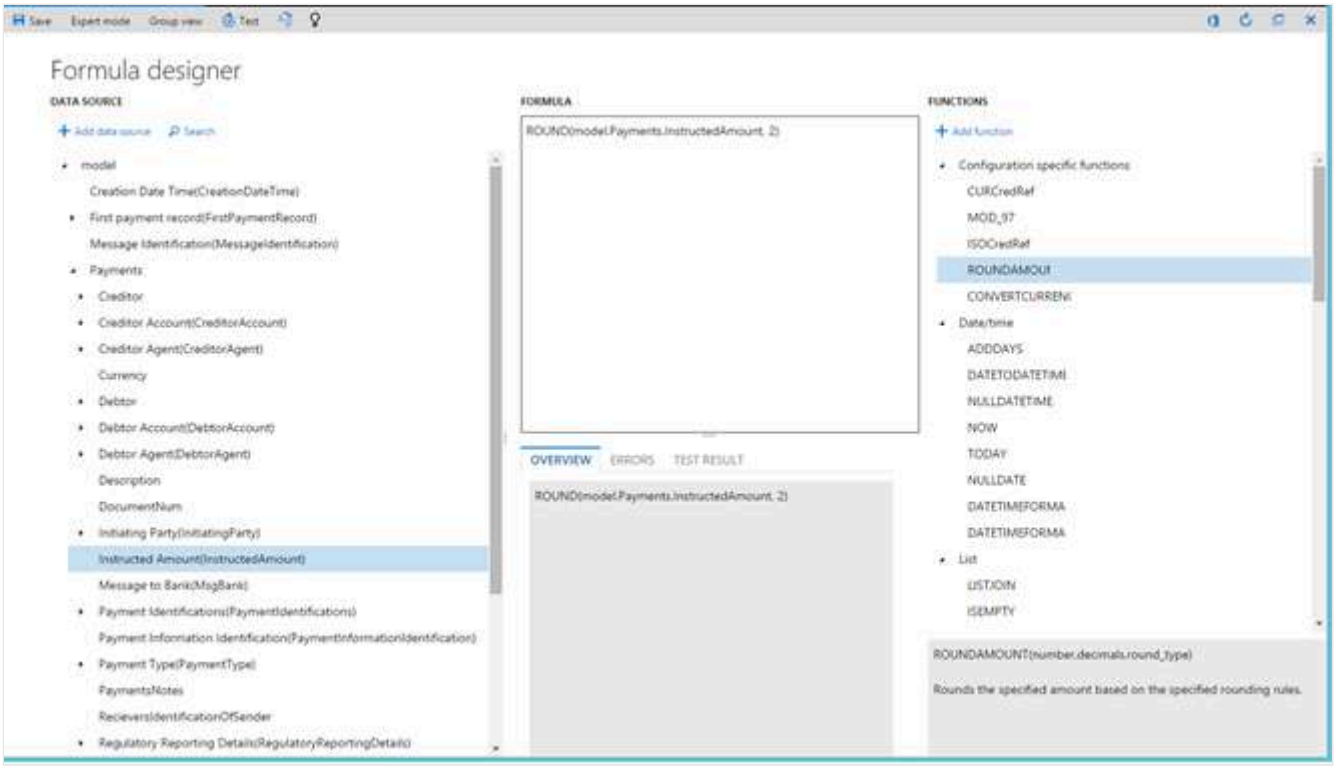
User parameters	Paginated document

Learn more in the following articles:

- Document Reporting Services
- Document printing overview
- Install the Document Routing Agent to enable network printing

Electronic reporting

Electronic reporting (ER) is the tool that you use to configure electronic document formats that comply with the legal requirements of various countries or regions. You can use electronic reporting for financial auditing, tax reporting, and electronic invoicing.

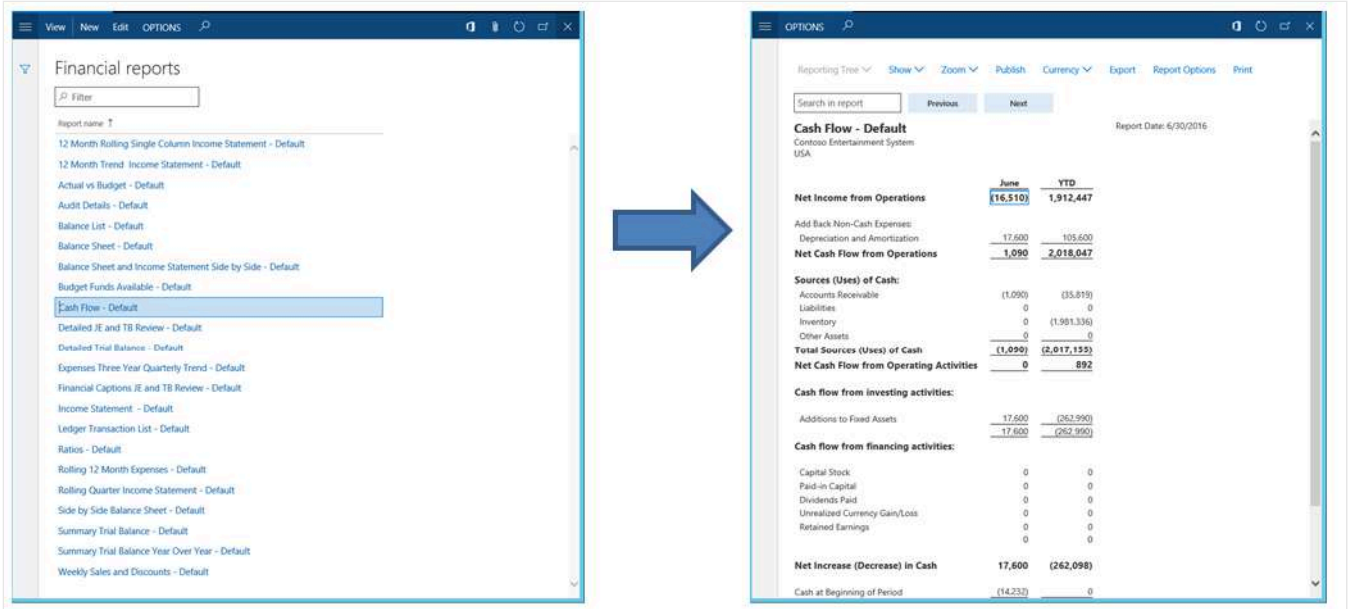


Learn more in the following articles:

- Electronic reporting (ER) overview
- Manage the Electronic reporting (ER) configuration lifecycle
- Create Electronic reporting (ER) configurations

Financial reporting

Standard financial reports use the default main account categories. Use the report designer to create or modify traditional financial statements, such as income statements and balance sheets. You can then share the results with other members of your organization. Examples of financial reporting include balance sheets, cash flow, and summary trial balance year over year.



Standard templates (GL > Inquiries > Fiancial reports)	Interactive financial reports

Information access and reporting

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains the various reporting options available as part of the platform.

Why information access is important

Information access is an essential part of an ERP solution. It represents a significant portion of the user engagement with the system. Consider the numerous methods of capturing information related to daily activities and the level of investments required to manage the data. Employees depend on logical interpretations of massive amounts of data to stay on top of their daily tasks. Out of the box, the platform provides a collection of reporting solutions to address the various information access needs of an ERP solution. In an increasingly competitive environment, mergers and acquisitions seem to occur as often as the change in seasons. More than ever before, businesses today are finding ways to expand their global reach to attract more customers. To be successful, they must adapt legacy solutions used to communicate with customers and prepare for the enforcement of regional regulatory requirements associated with new markets. Beyond the primitive functions provided by Microsoft Azure – compute, networking, storage, and authentication – the platform provides tools to manage resources for organizations that span in size from small businesses to global enterprise conglomerates. These tools are designed with flexibility in mind, to accommodate a dynamic world of business.

What is a "report" in the application?

A *report* is a structured presentation of data. Under ideal circumstances, reports present data in such a way that it allows the user to make informed decisions. The application supports a broad spectrum of information access scenarios: cross company all-up financial reporting; analytical dashboards and tiles; electronically transferable funds; customer sales invoices; checks and tax documents; and many more. Examples of integrated report scenarios that involve the consumption of business data include:

- **Native controls** including list pages, grid controls, and chart visualizations.
- **Dashboards and workspaces** containing predefined and personalized views.
- **Financial reporting** providing all-up views across legal entities.

- **Structured documents** distributed internally to employees or externally to customers and vendors.

Although each of these scenarios at its core involves the presentation of structured business data, the process of accessing these reports and how the results are then consumed varies greatly. Flexibility in the user tooling is essential for scenarios that involve data exploration. By contrast, layout precision is required for compliance with most regulatory documents. Given the diversity of information access scenarios, it's understandable that not all reports are created equal. This article is intended to help familiarize you with the various reporting options available as part of the platform.

Common myths of reporting

To become a proficient *report maker*, it's often useful to let go of past inhibitions. The following section seeks to rebuke three common myths about reporting.

- **Myth #1: Operational reports require "real-time" data** To the contrary, relatively few reporting scenarios require *real-time* results. And, in the grand scheme of things, taking a critical stance on a request for *real-time* views is recommended given the high development costs and potential heavy burden these solutions may incur on production environments.
- **Myth #2: The best tool is the one the developer is most comfortable using** Consider a customer request for a report that allows them to monitor company's assets. In the past, a developer would build a static report displaying a list of inventory items with complex calculations relying entirely on the user to provide filters to sufficiently reduce the result set. This solution might function perfectly in developer environments with a reduced data set. However, this approach can unnecessarily consume significant amounts of compute resources when utilized in production.
- **Myth #3: Developers are good at creating visually compelling designs** In reality, developers are often the worst offenders when it comes to producing elegant design layouts that appeal to the customer's aesthetic preferences. When it comes to analytical reports, you're better off empowering users to both explore the data directly and share personalized views.

Understanding report requirements

The best reporting solutions are designed with the expertise, daily functions, and information access needs of the target user in mind. The platform offers several tools designed to meet the functional requirements that are common across various reporting experiences. Selecting the right tool that most effectively addresses the *need* requires a clear understanding of the customer experience. You can drastically increase your chances of delivering a complete and

robust solution that fully satisfies customer requirements by simply asking the right questions. Here are some leading questions to ask when evaluating customer requirements for reporting solutions:

- **Get to know the user**
  - What is the proficiency of the target persona? Are they familiar with analytical tools like Microsoft Excel?
  - Does the user require a guided parameter experience to refine the dataset?
  - How frequently is the report accessed?

- **Familiarize yourself with the data**
  - Are they looking for transactional, analytical, and predictive information?
  - Does the shape of the data change and if so, how often?
  - Does the report include data from external sources?

- **Determine how the results are used**
  - Are you going to explore the data to gain insights?
  - How are the results shared with others?
  - Is there a fixed document structure for the target output?

It's understandable that customers *want* a solution that aligns with the existing processes they're comfortable using. However, you can learn a lot through these leading questions used to discover what the customer actually *needs* to be successful in their task. Delight your customers by providing them with solutions that empower them to be more productive.

Reporting experiences

Applications support information access scenarios that break down into five distinct reporting experiences. Specialized tools meet the complex and diverse reporting needs of various functions throughout the organization.

- **Operational views** – Designed to address the specific needs of a given business persona.
- **Business documents** – Static documents used to capture and exchange processed business data.
- **Analytical tools and visualizations** – Personalized presentations of logical calculations that allow the user to explore their data.
- **Electronic reporting** – Tool used to configure formats for electronic documents.
- **Financial reporting** – Designed to provide in-depth accounting management tools based on standard views of financial activities across legal entities.

Scorecard

Use the following table as a guide when choosing the right tool for your reporting solution.

Expand table

MAKER	Operational views	Business documents	Analytical tools & visualizations	Electronic reporting	Financial reporting
Persona	Developer	Developer	Power user	Power user	Power user
Authoring tool	Visual Studio	Visual Studio	PowerBI.com PowerBI app	Excel	Management Reporter Designer
Time to market	Weeks	Weeks	Hours	Hours	Hours
Data sources	Entity DB OLTP	OLTP	Entity DB Azure Catalog	OLTP	OLTP
Effort	Days	Days	Minutes	Hours	Hours

Expand table

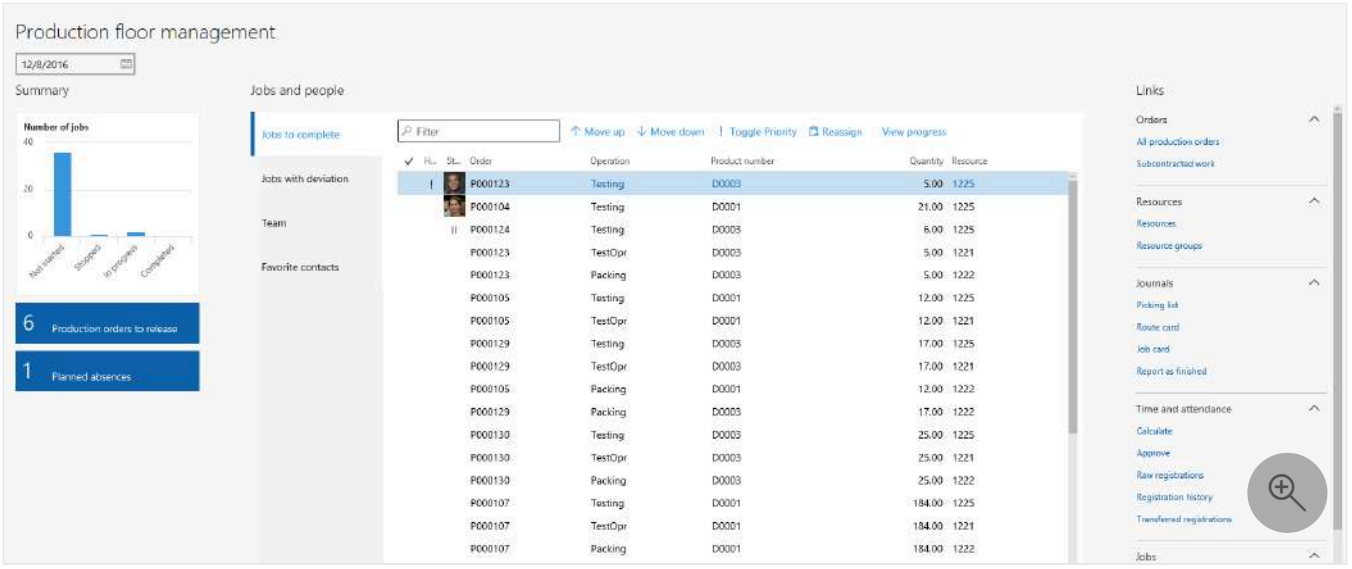
VIEWER	Operational views	Business views	Analytical tools & visualizations	Electronic reporting	Financial reporting
Target	Organization	Back Office	Power user	Power user	Finance officers
Data accuracy	Near real-time	Real-time	Near real-time	Real-time	Cached views
Personalization	Medium-Modeled	None	High - Free form designer	Low - Expressions	Medium - Modeled
Sharing	None	PDF export 0365 export Email	Dashboards Reports Tiles	Excel export	Excel export
Printing	Screen captures	Local printer Network devices	Screen captures	Excel	Local printer
Automation	Autorefresh	Batch integration	Scheduled refresh	Batch jobs	None
Scenarios	Monitoring	Transactions	Exploratory	Transactions	Accounting

> **Note**

"Near real-time" denotes processed data that's slightly slower than real-time.

Operational views

Operational views play an essential role in the daily work of most employees. As important as a brush is to a painter, operational views empower people to be productive. These views contain logical presentations of data to help users discover patterns, highlight anomalies, and act on the most important tasks. Targeted experiences satisfy the unique information access requirements for a given persona. These views provide actionable controls that help maximize efficiency for common user actions. For more information about constructing custom operational workspaces, see Build operational workspaces. Example applications of operational views include controller operations, production floor management, and customer collections monitoring.



What are the characteristics and capabilities?

- A fully integrated experience with responsive visualizations that understand user context and selections.
- Views that users can personalize to meet their unique and changing needs.
- Actionable controls that let users efficiently transact and monitor activities.
- A combination of analytical data that answers general questions and transactional views that provide access to record details.

What distinguishes "operational views" from other types of visualizations?

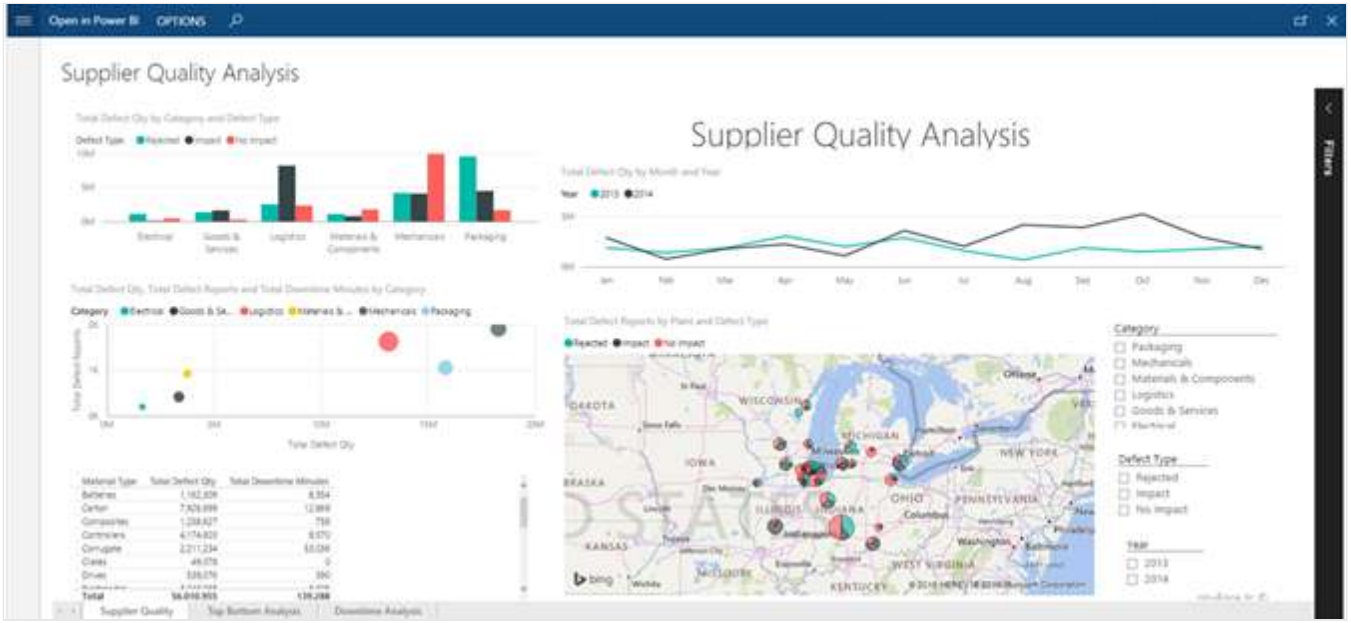
- General purpose tools designed for use at all levels of the organization.
- Predefined views based on common information access requirements associated with specific roles within the organization.
- Highly responsive to user interactions and changes made to the transactional database.

What should you consider when selecting this tool?

- The platform allows users to embed Power BI tiles and links to reports directly in workspaces.
- Users can introduce personalized workspaces to create their own custom operational views.
- Form data sources now support aggregate queries for analytical views using native controls.

Analytical tools and visualizations

Embedded visuals based on analytical data let users navigate between aggregate views and transactional details. Power BI service integration delivers world-class analytical tools with built-in support for accessing data. These tools empower "citizen developers" to author the reports they need and share the reports with others within the organization. Use the Power BI content packs available in Lifecycle Services to get started. For more information, see Features and services available through Power BI integration. Example applications of analytical tools and visualizations include customer sales per quarter, total revenue by region, and inventory turn-over.



What are the characteristics and capabilities?

- Near real-time results that provide macro level insights based on micro level activities.
- Common applications include charts, KPIs, and more complex visuals.
- Offer a deep exploratory experience with interactive controls that provide drill-through navigations.

What distinguishes "analytical tools and visualizations" from other types of reports?

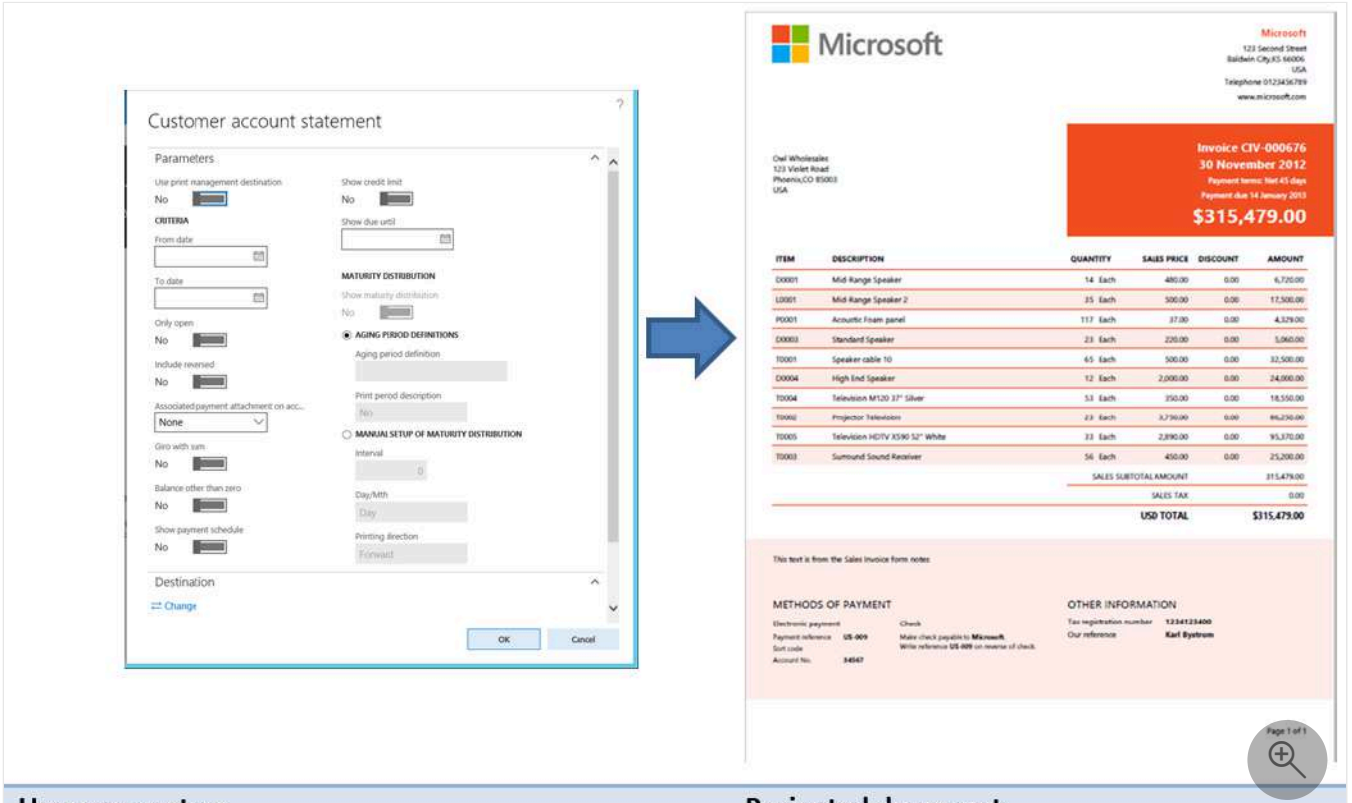
- Highly graphical nature, these presentations help you find the hidden meaning behind the data.
- Free form web designer that supports rich visualizations with built-in user interactions.
- Utilized by power users to explore data and gain insight through analysis.
- Personal nature by allowing the user to choose which information to include.
- Built-in sharing capabilities and user controlled access management.

What should you consider when selecting this tool?

- Developers are responsible for publishing data entities that Power BI can consume.
- Power users can produce mash-up views based on application data combined with external data sources.
- Visuals are highly responsive to user interactions and provide near real-time results when using Direct Query access to the data source.

Business documents

Use these reporting solutions to capture and communicate the details of business transactions. As such, you need a reporting solution that can produce physical manifestations of business data by using existing devices like network printers. For more information about the enhancements to the Document reporting service, see Document Reporting Services. Example applications of business documents include sales invoices, customer statements, and checks.



User parameters **Paginated document**

What are the characteristics and capabilities?

- Paginated documents that you print on paper or distribute through email.
- Heavy dependence on parameters to filter and produce the desired result set.
- Business documents capture a snapshot of customer and vendor activity that you can archive for future reference.
- Complex solutions that you develop in Visual Studio and deploy as part of the application.

What distinguishes "business documents" from other types of visualizations?

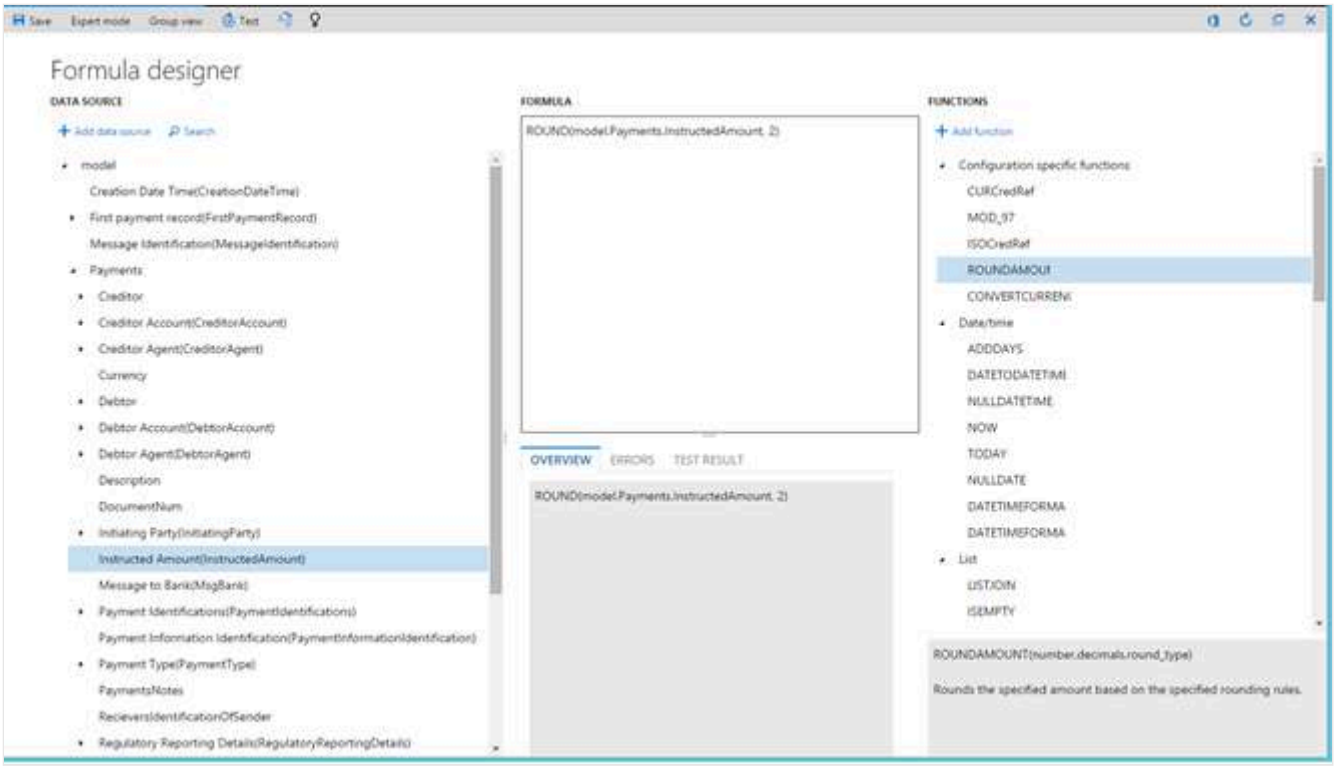
- Asynchronous data access and rendering solution designed to handle relatively large data sets.
- Dedicated reporting services that offer distributed resource utilization.
- Ideal solution for automated processes that involve bulk generation of business documents.
- Built-in support for document archive and data extraction via file export to PDF in addition to Word, Excel, and CSV.

What should you consider when selecting this tool?

- Use application suite reports as a starting point for custom solutions.
- Solutions that heavily depend on metadata changes and don't offer personalization.
- You must manage modifications to out-of-box solutions as a metadata change.

Electronic reporting

Electronic reporting (ER) is the tool to use to configure electronic document formats in accordance with the legal requirements of various countries and regions. For more information about the Electronic reporting tool, see Electronic reporting (ER) overview. Example applications of electronic reporting include financial auditing, tax reporting, and electronic invoicing.



What are the characteristics and capabilities?

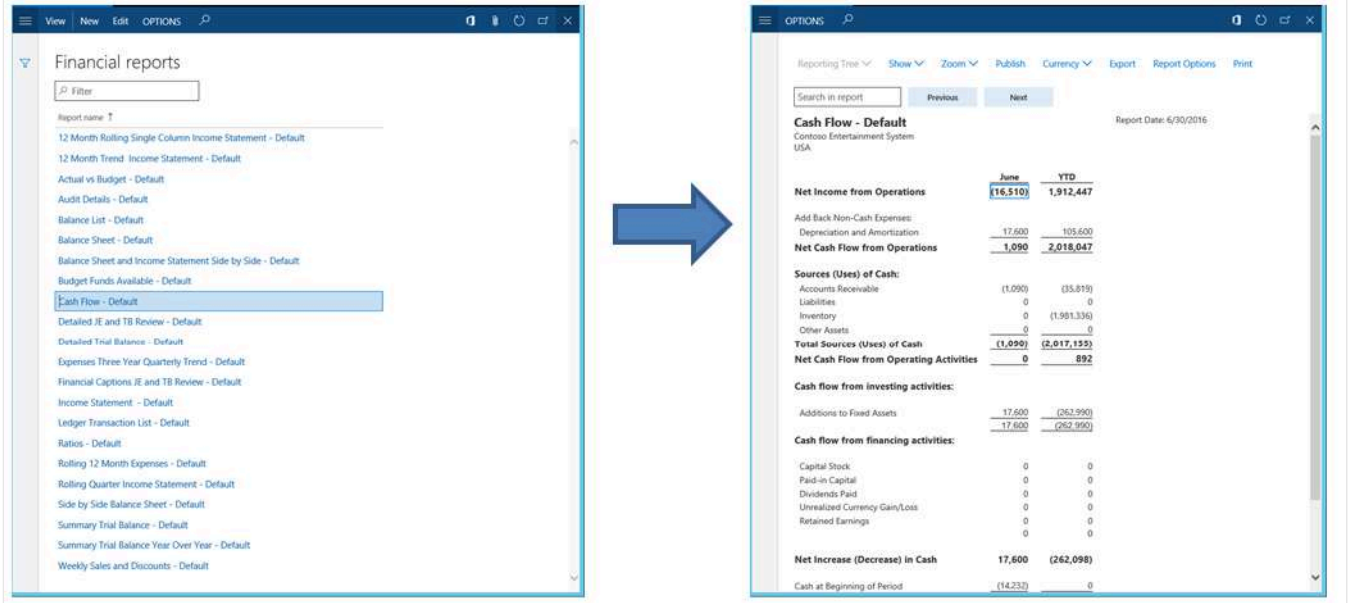
- Perfect tool for producing TEXT, XML, and OPENXML worksheet formats.
- Tooling is designed for business users familiar with Excel-based formulas.
- Highly adaptable to adhere to changes in regulatory requirements.
- Component versioning is available to manage draft definitions.

What distinguishes "electronic reports" from other types of visualizations?

- Designed for electronic submission to banks, governments, and other external entities.
- Use formulas to define data transformations into groups containing summary data and logical calculations.

Financial reporting

Standard financial reports use the default main account categories. Use the report designer to create or modify traditional financial statements, such as Income statement and Balance sheet, and share the results with other members of your organization. For detailed information about the Financial reporting tooling, see General ledger and Financial reporting overview. Example applications of financial reporting include balance sheets, cash flow, and summary trial balance year over year.



Standard templates (GL > Inquiries > Fiancial reports)	Interactive financial reports

What are the characteristics and capabilities?

- Built-in flexible financial reporting solution designed to handle complex organizational structures.
- Fully integrated with General ledger.
- Create custom financial reports using the default solutions as a starting point.
- Interactive reports with drill-down capabilities to navigate down to transaction details.

What distinguishes "financial reports" from other types of visualizations?

- User controls tailored for the specialized needs of financial reporting.
- Create roll-up reports containing data across companies or business units.
- Utilizes a financial data mart for optimized performance.

Features available through the Power BI integration

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Microsoft Power BI is a suite of business analytics tools that you can use to analyze data and share insights. By using Power BI tools, you can explore data and quickly create rich reports and dashboards. You and your colleagues can then use the reports interactively on many devices. The application uses Power BI for data exploration.

Data exploration through Power BI

There are various types of reporting.

Use chart controls to build embedded experiences that require visuals.

Microsoft SQL Server Reporting Services (SSRS) is an engine that's designed for pixel-perfect, formatted reports that often require printing. Use SSRS for document-style reports, such as invoices and purchase orders. Investments in SSRS integration focus on document generation and printing scenarios.

For all non-document reports or reports that don't require printing, use Power BI.

In the past, the terms *self-service reports* and *ad-hoc reports* referred to Power BI. Now, use the term *data exploration*. This change in terminology reflects a subtle shift in paradigms. Self-service reports were reports that users created. (Alternatively, a power user created the reports and shared them with other people. These people then continued to adjust the reports according to their requirements.) Often, users had to change the shape of a chart, add a new column, change the grouping, or just create a new view of data. Although you might think of the results as reports, users are just trying to understand the data by exploring it, pivoting it around columns, and changing the shape of charts. Technologies of the past didn't let users interactively explore large volumes of data. Therefore, users had to create "reports," or many views of the same data.

In Power BI, thanks to the in-memory database technologies in Microsoft SQL Server, a report is just the starting point for interactive data exploration. Charts in a Power BI report invite users to click them, visuals change shape interactively, and data can easily be filtered. Users can easily adjust existing reports and create their own views of the data. The reports can be shared, and teams can collaborate over data.

Therefore, although you might use the term *report* to refer to Power BI artifacts, think about the larger scenario that is involved. Your users are exploring data! Power BI is the tool of choice when you must address data exploration and visualization requirements.

For a detailed discussion of reporting concepts, see Information access and reporting.

Ready-made Power BI content

You can use ready-made Power BI reports right away. Two types of Power BI content are available:

- Power BI content that's available in Microsoft Dynamics Lifecycle Service
- Power BI content packs that are distributed in the PowerBI.com marketplace

Depending on your version, you can use one or both types of content.

Power BI content that's available in Lifecycle Services

Lifecycle Services is a service that can manage your environments. Microsoft operates Lifecycle Services. Developers create Power BI reports by using Entity store, and then distribute them in Lifecycle Services as implementation assets. In Lifecycle Services, you find not only content that Microsoft develops, but also content that independent software vendors (ISVs) and partners develop.

Microsoft continues to release Power BI content that's based on Entity store. For information, see the Roadmap.

Power BI content packs that are distributed in the PowerBI.com marketplace

Several Power BI content packs are available in the PowerBI.com marketplace. Although Microsoft continues to support these content packs until further notice, future investments in content packs are based on Entity store, and content is released via Lifecycle Services.

For more information about the content, see Power BI content.

Extending, creating, and distributing Power BI reports

Use the ready-made Power BI content as a first step. You can modify ready-made reports or extend them by using capabilities that are built into PowerBI.com. In addition to modifying ready-made reports, you can extend them by using Power BI authoring tools such as Power BI Desktop. You can also create new reports. You can use several approaches to create new Power BI reports.

Create high-volume, near-real-time "operational Power BI reports" by using Entity store

Entity store is an operational data store that's built specifically for Power BI integration. To create high-volume, near-real-time Power BI reports that use Entity store, a business analyst or a developer can use Power BI Desktop, which is the authoring tool for Power BI reports. Like other artifacts that developers create, you must distribute these reports to your users via Lifecycle Services.

Reports that you create by using Entity store take advantage of DirectQuery technology. This technology enables reports to be created over large volumes of data. Reports that are created by using DirectQuery technology don't cache data in the PowerBI.com service. Instead, data is always stored in application.

For an overview of Power BI integration with Entity store, see Power BI integration with Entity store.

If you're upgrading from Microsoft Dynamics AX 2012, you can upgrade cubes to aggregate measurements that use Entity store. You can then create Power BI reports by using Entity store. For more information, see Migrate upgraded AX 2012 R3 sales cubes to the entity store.

Create Power BI reports by using Excel

In addition to using the Power BI desktop authoring tool, you can use "Power tools" that are incorporated into Excel to create visualizations. Your organization might have many users who already use Excel every day. For a quick "one-off" report, Excel might be the best option for these users.

There are several scenarios where you can use Excel:

- Export data from a page in Dynamics 365 into Excel. You can then use the Power View add-in that is built into Excel to visualize the data. The Excel workbook can be used as a stand-alone visualization. In addition, you can import the report into the PowerBI.com service.
- Use the Power Query extension in Excel to combine the data in another worksheet (or data that is imported from OData endpoints) with external data. You can visualize the resulting data by using Power View.
- Use the PowerPivot extension in Excel to ingest a larger amount of data into Excel.

Consider using Export to Excel functionality for ad-hoc "one-off" reports. If you want to share the reports with a group of users, consider using Entity store to create them.

Sharing and using reports in PowerBI.com

PowerBI.com is a service that's offered by Microsoft. It lets you create dashboards and reports, and also enables collaboration with a group of users. Regardless of how you create your reports, you can share reports with users by uploading them into the PowerBI.com service. This process is also known as *publishing*.

After you upload your reports, your users can view, adjust, and explore them either on the web (when they're connected to the Internet at home or in the office) or by using apps on a device.

For more information about Power BI concepts, see the Power BI documentation.

Pin Power BI content to the client

You can use PowerBI.com on its own as a reporting and dashboard solution for your organization or business unit. However, users can also pin tiles and reports from their own PowerBI.com accounts to workspaces. Power BI content in Dynamics 365 provides contextual insights that are related to business operations.

You can pin two types of objects from PowerBI.com: tiles in PowerBI.com dashboards, and reports.

Before you can pin Power BI content, you must configure Power BI in your Dynamics 365 environment.

One-time configuration of PowerBI.com integration

Before you can pin tiles or reports, an administrator must configure integration with PowerBI.com in your environment. This configuration must be done only one time per environment. For instructions, see Configure Power BI integration for workspaces.

Pin PowerBI.com tiles

Power BI tiles that you pin to the Dynamics 365 client provide insightful visuals at a glance. They also let users open PowerBI.com for interactive analysis. For more information, see Configure Power BI integration for workspaces.

Pin PowerBI.com reports to workspaces

As a power user, a business analyst, or a developer, you can use Power BI desktop to create reports that use Entity store. These reports are rich and interactive, and your users can make changes without having to rely on another person.

Although the reports in PowerBI.com are powerful and interactive on their own, you can also pin them into workspaces. Your users can pin reports to workspaces themselves. For more information about how to pin reports to workspaces, see Pin Power BI reports to workspaces.

Last updated on 04/13/2026

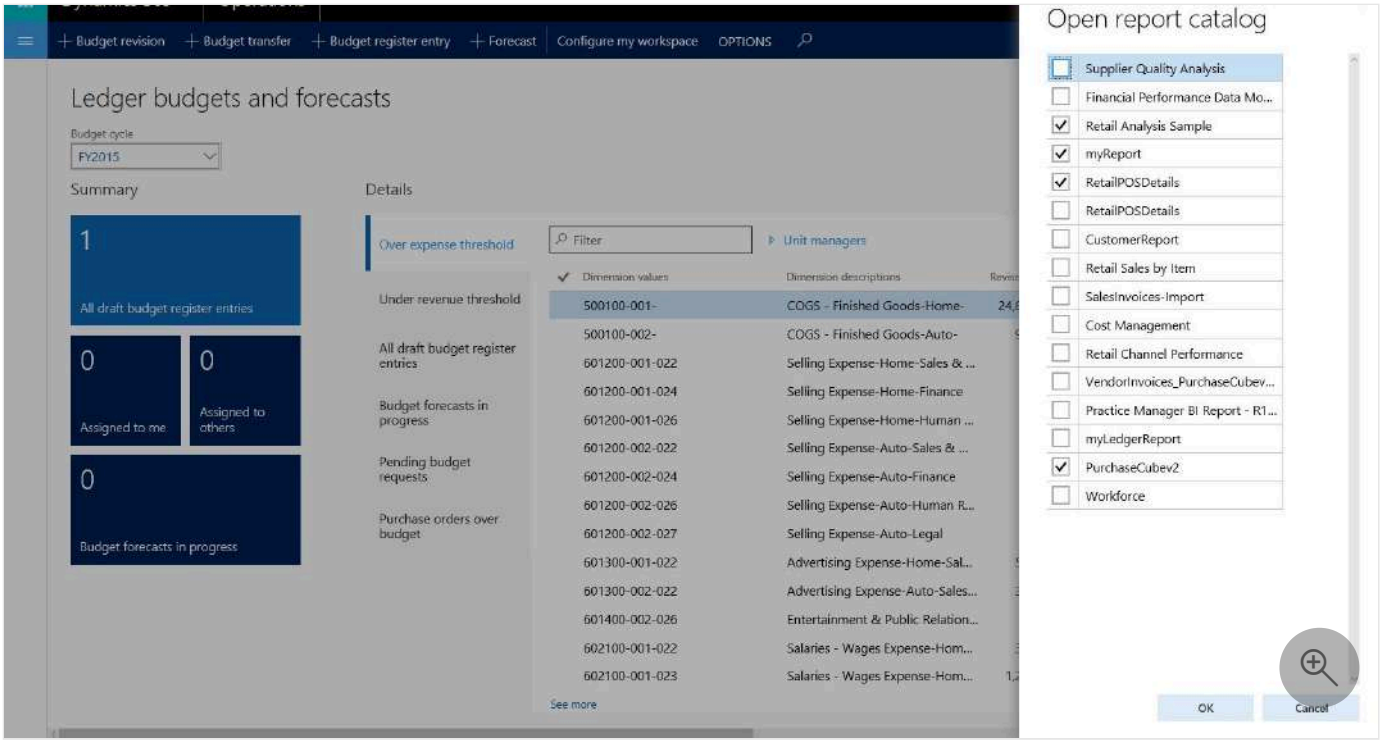
Pin Power BI content

Microsoft Dynamics 365 Finance uses Power BI for data exploration. This article explains how you can pin full-page Power BI reports to workspaces to give your users an interactive data exploration experience.

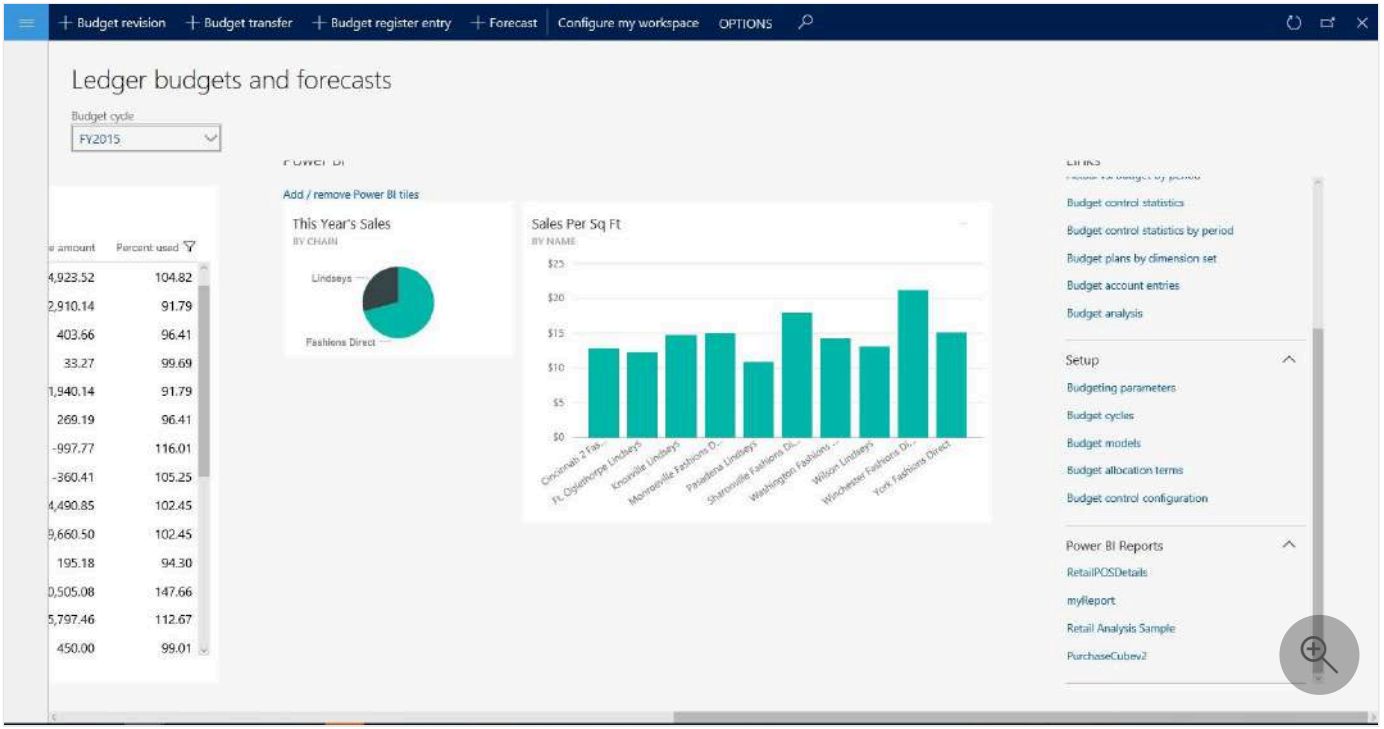
This article assumes that you're familiar with the feature that lets you pin Microsoft Power BI tiles to a workspace. For more information, see Features and services available through Power BI integration. If you're a developer who is creating a workspace, to let users pin Power BI tiles to the workspace, embed the Power BI tile control.

Pin Power BI reports to workspaces

Microsoft Dynamics AX platform update 1 (May 2016) introduced the capability to pin Power BI reports to workspaces. Power BI reports can be added to any workspace that contains a **Links** section. In other words, the reports can be added to most of the out-of-box workspaces that are included in the product. To enable Power BI reports and tiles, you must configure Power BI to work with the application. This one-time operation must be completed by an administrator of the environment. For instructions, see Configure Power BI integration for workspaces. After you've configured Power BI to work with the application, open the **Ledger budgets and forecasts** workspace in the client. In the workspace, select the **Options** tab. Notice that this tab contains buttons to open the (Power BI) tile catalog and the (Power BI) report catalog. Select **Open report catalog**. A dialog box that contains a list of reports appears. The list of reports comes from the reports that you have in your Power BI account. If you open PowerBI.com in a browser, you'll see that the same list of reports is used across your Power BI dashboards. Select some reports, as shown in the following illustration, and then select **OK** to continue.



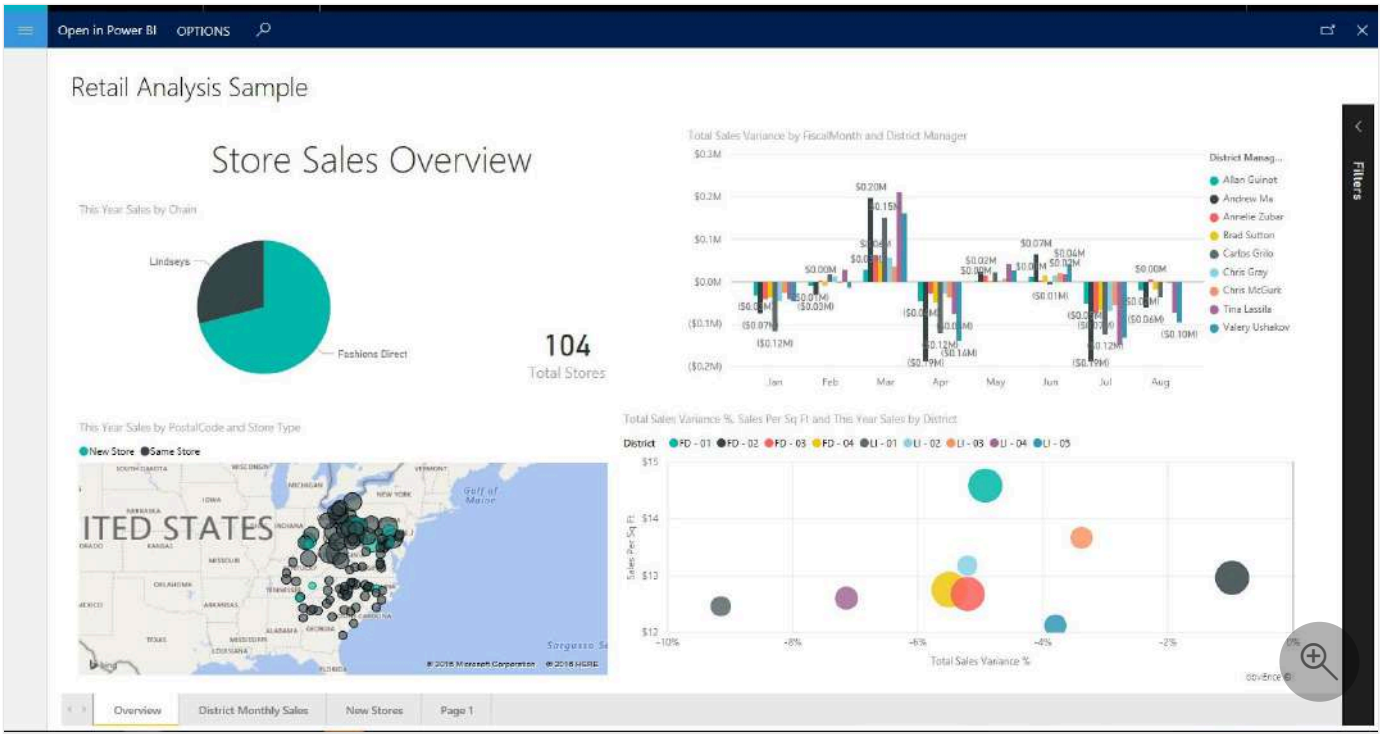
Next, scroll to the bottom of the **Links** section in the workspace. A new section for Power BI reports is added to your links.



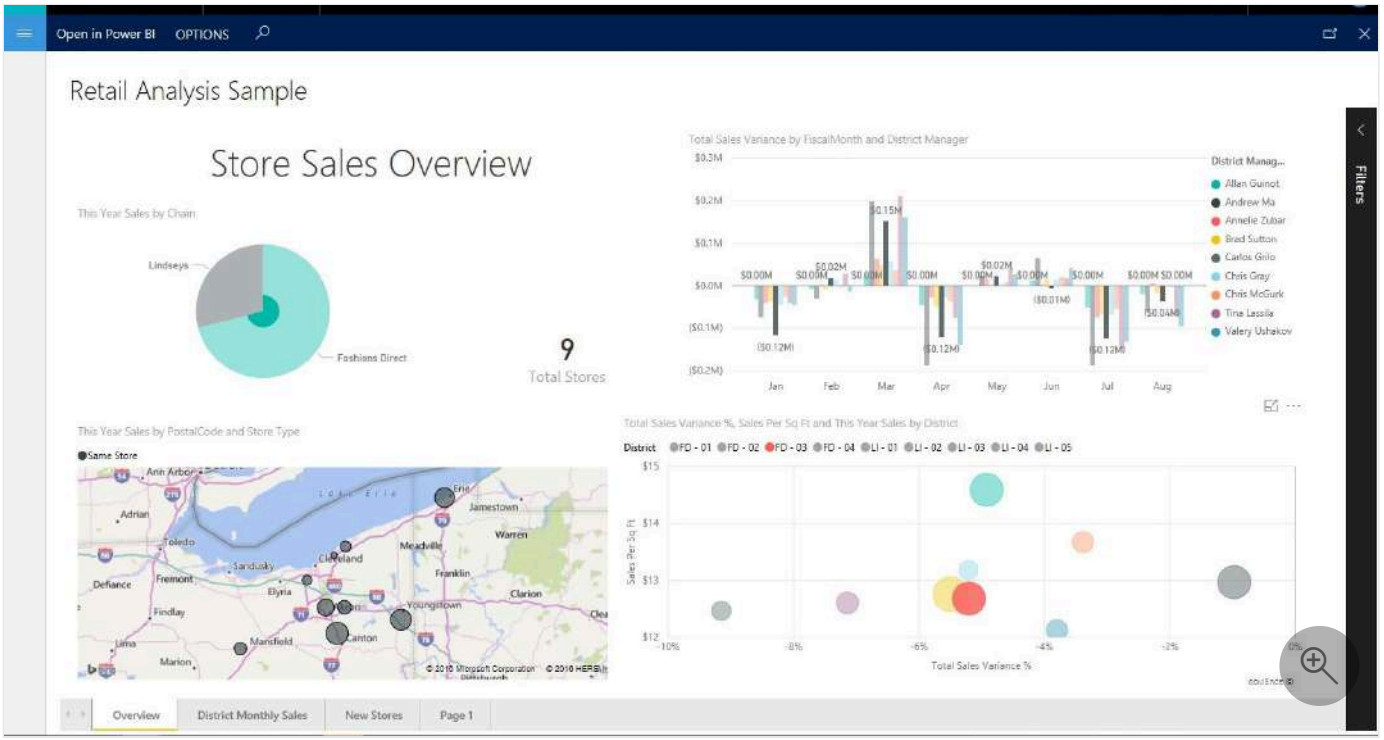
Full-page Power BI reports in the client

You can open and run Power BI reports in the client. The functionality resembles the functionality for running Microsoft SQL Server Reporting Services (SSRS) reports. To run a Power BI report, in the **Links** section, select the link for one of the Power BI reports. For this example, select the **Retail Analysis Sample** link. The Power BI report opens in the client in a full-page view, as shown

in the following illustration. This report is interactive. As you select regions of the report, the remaining visuals react to your selection.



You can filter the data on the report by using the filter pane. The following illustration shows the report after filters have been applied.



You can also open this report on PowerBI.com and make changes. You can then save the modified report as another copy that has a different name, and even pin the new report to the workspace.

Power BI in user-created workspaces

So far, you learned how to add Power BI tiles and reports to **developer-created** workspaces. Developer-created workspaces are workspaces that Microsoft (that is, they're built into the product), your independent software vendor (ISV) or partner, or in-house developers create. However, in Microsoft Dynamics AX platform update 1 (May 2016), users can create new workspaces by using the personalization capabilities of the client. To create a new workspace, on the home page (or the dashboard), right-click the tile for a workspace, and then select **Add a workspace**. A new workspace is created. New workspaces are named **My Workspace 1**, **My Workspace 2**, and so on. You can change the name later. Select the workspace that you created. You can now add Power BI tiles and reports by using the same options that we discussed earlier. The following illustration shows an example.

Select analytical workspaces from Power BI

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Analytical workspaces

The analytical workspaces that are bundled with the application suite offer users relevant insights into their business data. However, in some cases, it makes sense to replace standard reports with custom reports that are designed specifically for the users in your organization.

The tooling that PowerBI.com provides lets you produce analytical reports that contain mashup views that use data from external sources. In Platform update 26 for finance and operations, power users can replace the standard embedded reports with those that are hosted on PowerBI.com.

> **Important**
>
> The functionality that this article describes isn't a personalization. The customization of analytical workspaces applies to all users in the active legal entity.

Motivations for embedding PowerBI.com reports

Although standard reports deliver insights that are tailored for a given business persona, an organization can prefer a custom report in some cases. The application lets power users promote custom reports that are hosted on PowerBI.com and shared with members of the organization.

Here are some of the top motivations for selecting reports that are hosted on PowerBI.com:

- PowerBI.com reports support data mashups that use external data sources and can be accessed outside the application.
- The reports are appropriate for demonstrating custom solutions that are hosted on PowerBI.com and embedded in the application in one box deployments.
- Organizations that have Microsoft Power BI Premium services want to augment the standard reports.

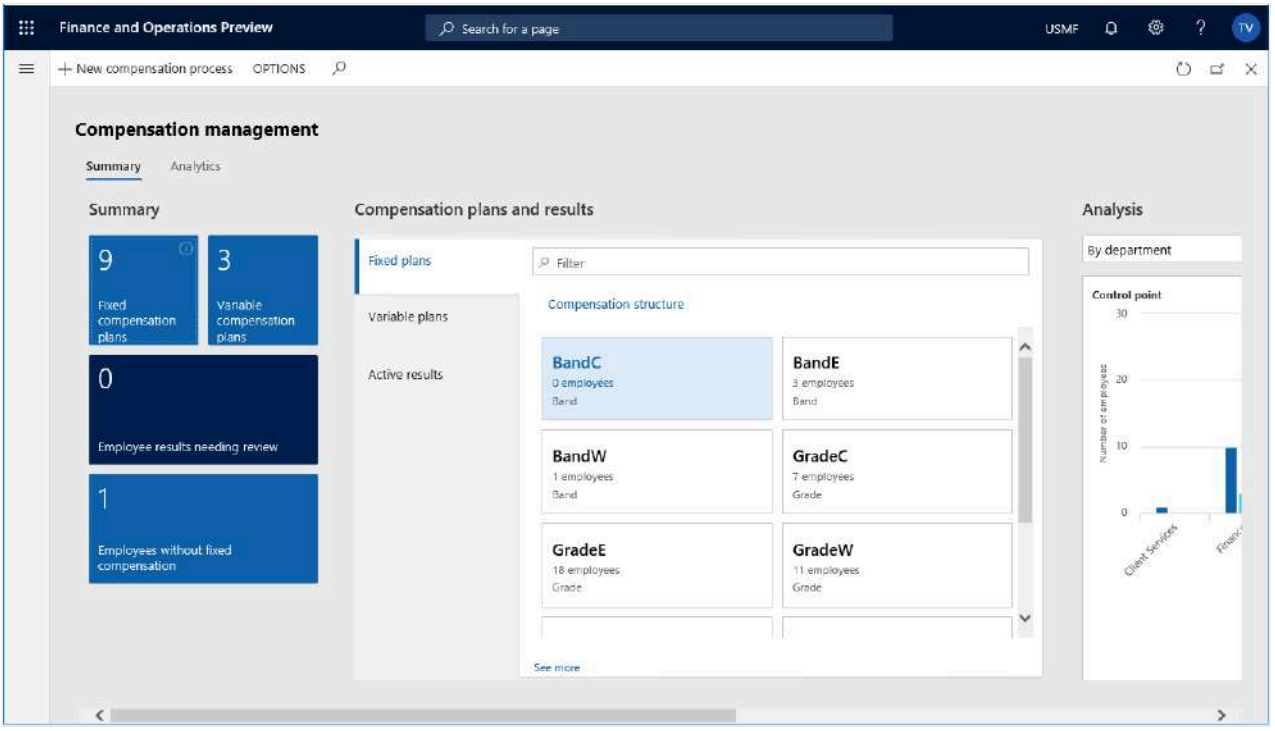
Embed a PowerBI.com report in an analytical workspace

https://learn-video.azurefd.net/vod/player?id=ecad8101-d1a3-4045-bf49-8703338f355a&locale=en-us&embedUrl=%2Fdynamics365%2Ffin-ops-core%2Fdev-itpro%2Fanalytics%2Fselect-analytical-workspace

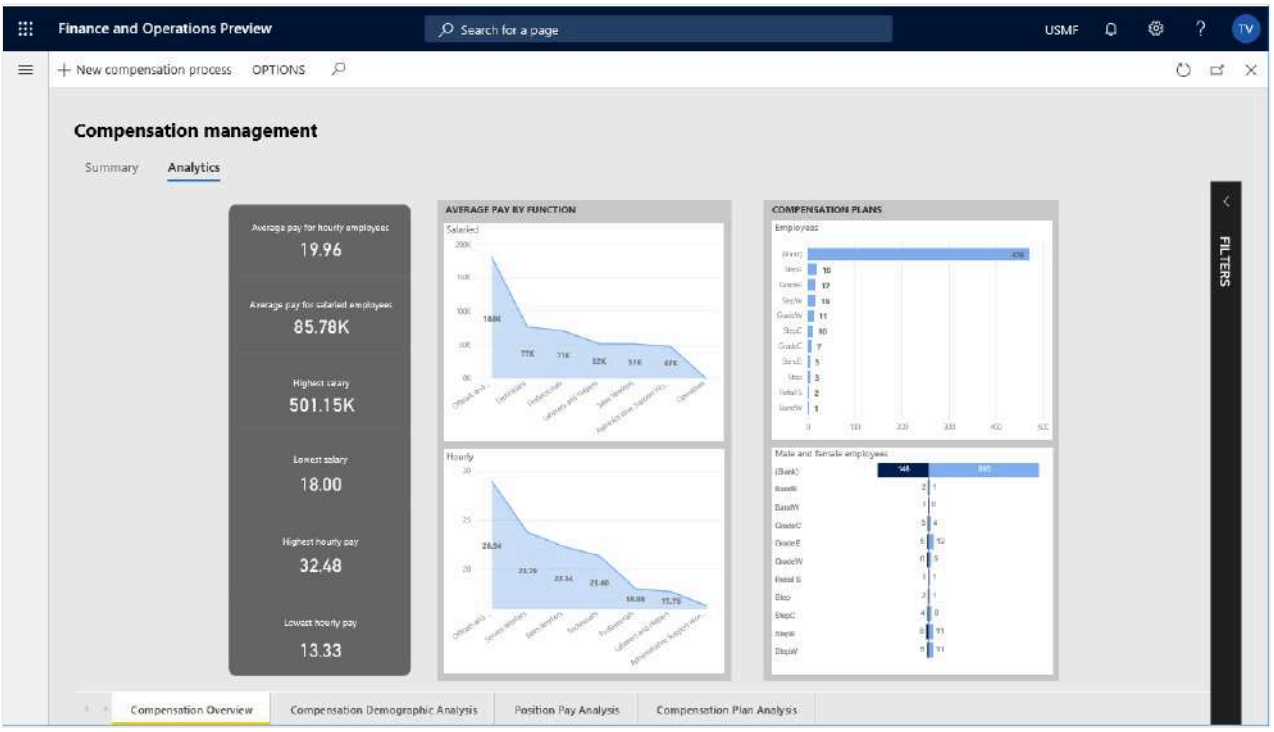
The How to embed PowerBI.com reports video (shown above) is included in the finance and operations playlist available on YouTube.

To replace the standard reports, you need to be a member of the System Report Editors security group. Members of this security group can access the options in application workspaces that let them customize the standard reports. This example shows how to replace the standard analytical report with a customized report that is hosted on PowerBI.com.

1. Sign in and open the application report that you want to customize. In this example, you'll replace the standard analytical report that is embedded in the **Compensation management** workspace.



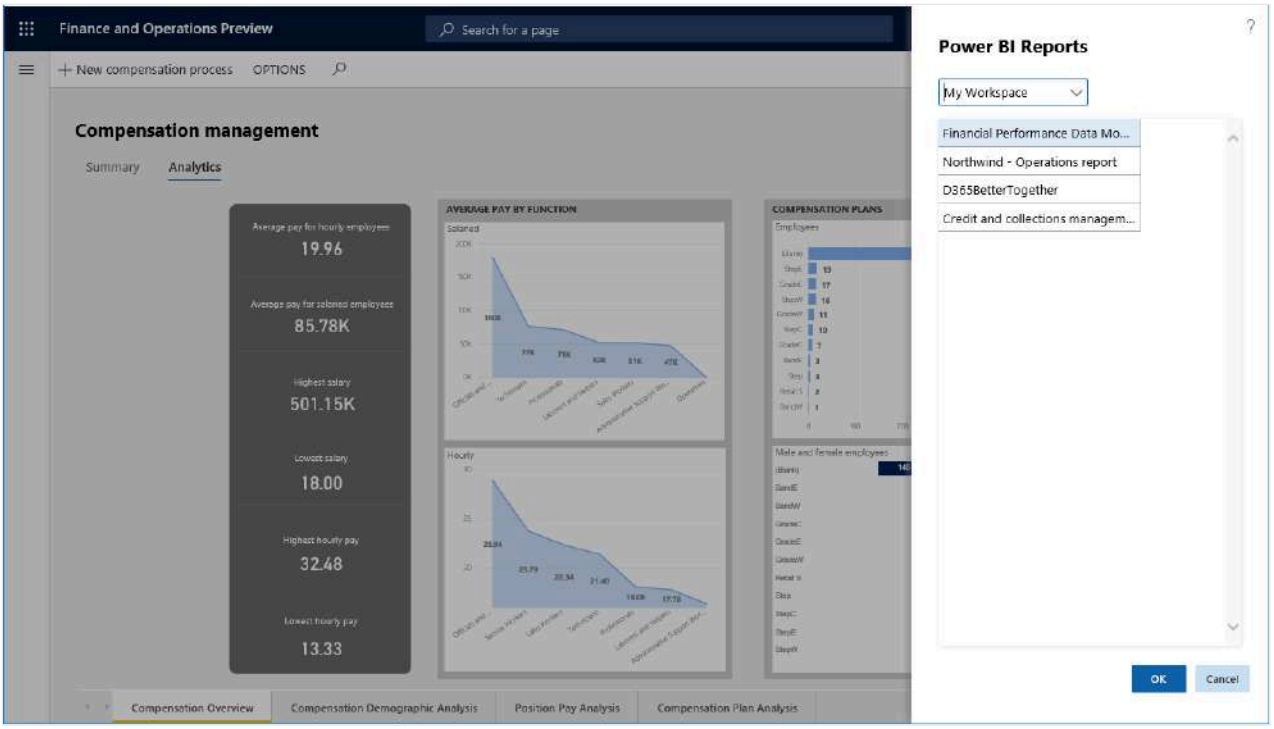
2. Select the **Analytics** tab to access the workspace's embedded analytical report.



By default, you see the standard analytical workspace solution that is included with your application. The reports in this solution are automatically deployed and configured for your environment during the provisioning process.

> **Note**
>
> The analytical workspaces require a hosted Power BI service that's available only for dedicated environments. For more information, see the blog post, Accessing Analytical Workspaces and Reports on 1-Box Environments.

3. On the Action Pane, on the **Options** tab, in the **Power BI** group, select **Select Analytics** to open the **Power BI Reports** dialog box.



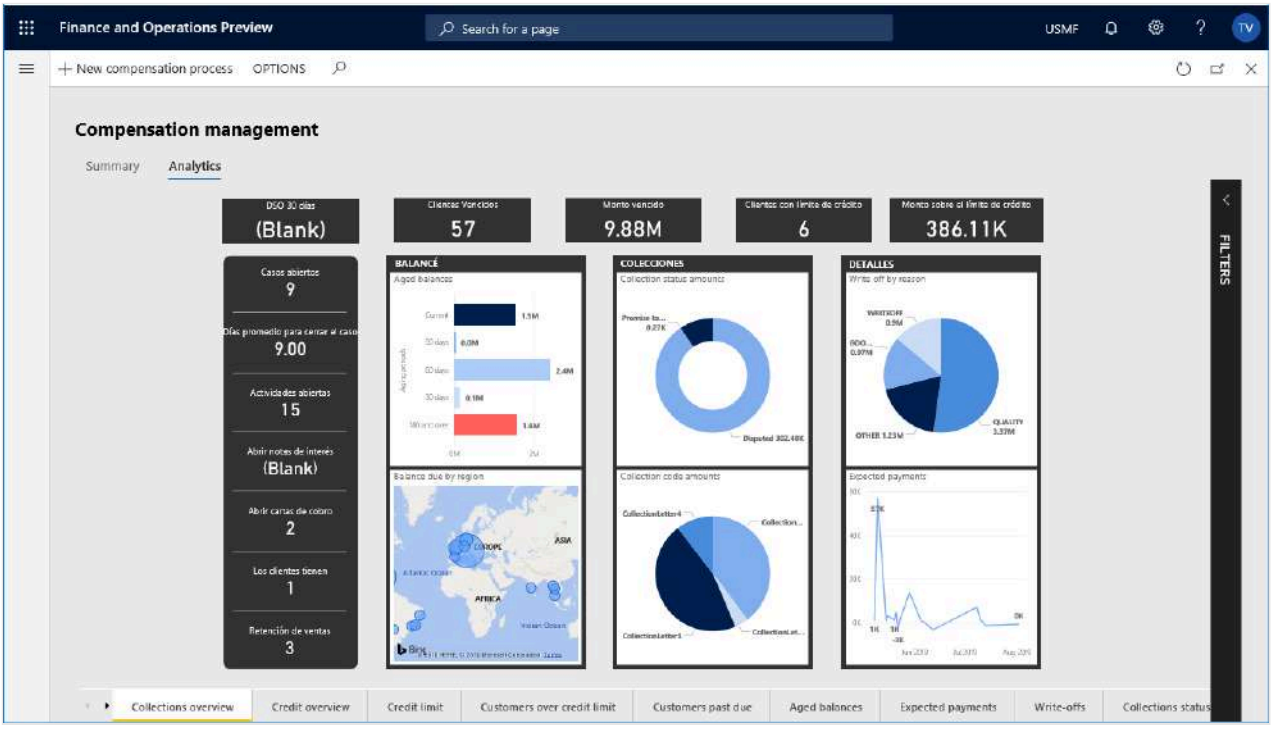
This dialog box lets you select among the reports that are shared on the PowerBI.com service. The reports are organized by workspace.

4. In the drop-down list, select the workspace that contains the report.

5. Select the report to embed in the application workspace, and then select **OK**.

6. To view the updates to the workspace, you need to reload the page. Either move away from the workspace and then return, or refresh your browser.

7. In the **Compensation management** workspace, select the **Analytics** tab to access the PowerBI.com report that is now embedded in the analytical workspace.



Revert to the standard solution

After a PowerBI.com report has been embedded in an application workspace, updates to the report are reflected immediately for users. However, to replace the report with another PowerBI.com solution, a power user needs to first revert to the standard application solution. Follow these steps to revert to the standard application solution.

1. On the Action Pane, on the **Options** tab, in the **Power BI** group, select **Restore Analytics**.

2. To view the updates to the workspace, you must reload the page. Either move away from the workspace and then return, or refresh your browser.

3. In the **Compensation management** workspace, select the **Analytics** tab to access the standard solution that is now embedded in the analytical workspace.

Cost management Power BI content

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Overview

The **Cost management** Microsoft Power BI content is intended for inventory accountants or individuals in the organization who are responsible for or interested in the status of inventory or work in progress (WIP), or who are responsible for or interested in analyzing standard cost variances.

This Power BI content provides a categorized format that helps you monitor the performance of inventories and visualize how cost flows through them. You can gain managerial insights such as the turnover ratio, number of days that inventory is on hand, accuracy, and "ABC classification" at your preferred aggregated level (company, item, item group, or site). The information that is made available can also be used as a detailed supplement to the financial statement.

The Power BI content is built on the **CostObjectStatementCacheMonthly** aggregated measurement, which has the **CostObjectStatementCache** table as its primary data source. This table is managed by the Data set cache framework. By default, the table is updated every 24 hours, but you can change the update frequency or enable manual updates in the configuration of the data set cache. Manual updates can be run in either the **Cost administration** workspace or the **Cost analysis** workspace.

After every update of the **CostObjectStatementCache** table, the **CostObjectStatementCacheMonthly** aggregated measurement must be updated before data in the Power BI visualizations is updated.

Accessing the Power BI content

The **Cost management** Power BI content is shown in the **Cost administration** and **Cost analysis** workspaces.

The **Cost administration** workspace contains the following tabs:

- **Overview** – This tab shows application data.
- **Inventory accounting status** – This tab shows Power BI content.
- **Manufacturing accounting status** – This tab shows Power BI content.

The **Cost analysis** workspace contains the following tabs:

- **Overview** – This tab shows application data.
- **Inventory accounting analysis** – This tab shows Power BI content.
- **Manufacturing accounting analysis** – This tab shows Power BI content.
- **Std. cost variance analysis** – This tab shows Power BI content.

Report pages that are included in the Power BI content

The **Cost management** Power BI content includes a set of report pages that consist of a set of metrics. These metrics are visualized as charts, tiles, and tables.

The following tables provide an overview of the visualizations in the **Cost management** Power BI content.

Inventory accounting status

Expand table

Report page	Visualization
Inventory overview	Beginning balance
	Net change
	Net change %
	Ending balance
	Inventory accuracy

Understanding the data model and entities

Data from the application is used to fill the report pages in the **Cost management** Power BI content. This data is represented as aggregate measurements that are staged in the entity store, which is a Microsoft SQL Server database that is optimized for analytics. For more information, see Power BI integration with Entity store.

The key aggregate measurements of the following objects are used as the basis of the Power BI content.

Expand table

Object	Key aggregate measurements	Data source for finance and operations	Field
CostObjectStatementCacheMonthly	Amount	CostObjectStatementCache	Amount
CostObjectStatementCacheMonthly	Quantity	CostObjectStatementCache	Qty
CostInventoryAccountingKPIGoal	AnnualInventoryTurn	CostInventoryAccountingKPIGoal	AnnualInventoryTurn
CostInventoryAccountingKPIGoal	InventoryAccuracy	CostInventoryAccountingKPIGoal	InventoryAccuracy

The following table shows the key calculated measurements in the Power BI content.

Expand table

Measure	Calculation
Beginning balance	Beginning balance = [Ending balance]-[Net change]
Beginning balance qty.	Beginning balance qty. = [Ending balance qty.]-[Net change qty.]
Ending balance	Ending balance = (CALCULATE(SUM([Amount]), FILTER(ALL(FiscalCalendar) ,FiscalCalendar[MONTHSTARTDATE] <= MAX(FiscalCalendar[MONTHSTARTDATE]))))
Ending balance qty.	Ending balance qty. = CALCULATE(SUM([QTY]), FILTER(ALL(FiscalCalendar),FiscalCalendar[MONTHSTARTDATE] <= MAX(FiscalCalendar[MONTHSTARTDATE])))
Net change	Net change = SUM([AMOUNT])
Net change qty.	Net change qty. = SUM([QTY])
Inventory turnover ratio by amount	Inventory turnover ratio by amount = if(OR([Inventory average balance] <= 0, [Inventory sold or consumed issues] >= 0), 0, ABS([Inventory sold or consumed issues])/[Inventory average balance])
Inventory average balance	Inventory average balance = (([Ending balance] + [Beginning balance]) / 2)
Days inventory on-hand	Days inventory onhand = 365 / CostObjectStatementEntries[Inventory turnover ratio by amount]
Inventory accuracy	Inventory accuracy by amount = IF([Ending balance] <= 0, IF(OR([Inventory counted amount] <> 0, [Ending balance] < 0), 0, 1), MAX(0, ([Ending balance] - ABS([Inventory counted amount]))/[Ending balance]))

The following key dimensions are used as filters to slice the aggregate measurements, so that you can achieve greater granularity and gain deeper analytical insights.

Expand table

Entity	Examples of attributes
Products	Product number, Product name, Unit, Item groups
Category hierarchies (Assigned to role Cost management)	Category hierarchy, Category level
Legal entities	Legal entity names
Fiscal calendars	Fiscal calendar, Year, Quarter, Period, Month
Site	ID, Name, Address, State, Country/Region

Learning Power BI content

This article describes the **Learning** Microsoft Power BI content.

Reports that are included in the Power BI content

The reports that are included in the **Learning** Power BI content have both charts and tables that contain additional information. The following table describes the reports.

Expand table

Report	Contents
Learning overview	Summary of other reports
Course analysis	Registration by location, attendee by status, courses by type per company, and course attendance by job
Registration analysis	Registration list
Course types	Course types by skill
Instructor analysis	Ratio of courses to instructors, number of instructors, courses by instructor, courses per instructor, and course agenda by instructor
Courses offered	List of courses
Courses design	Course agenda

You can filter the charts and tiles on these reports, and pin the charts and tiles to the dashboard. For more information about how to filter and pin in Power BI, see Create and Configure A Dashboard.

Understanding the data model and entities

The **Learning** Power BI content uses the following data to fill the reports. This table shows the entities that the content is based on.

Expand table

Entity	Contents	Relationships with other entities
Calendar Offset	Calendar offsets to slice reports	Course Agenda, Course Attendees
Company	Companies to filter reports by	Course Agenda, Course Attendees
Course	Course, description, instructor name, location, room, and status	Course Agenda, Course Attendees, Course Skill
Course Agenda	Agenda, course, and start and end times	Company, Calendar Offset, Date, Course
Course Attendees	Name, status, job, and registration date	Company, Calendar Offset, Date, Course, Demographics, Employment, Course, Employee Name, Employee Title, Job, Position
Course Skill	Skill, skill type, and level	Course
Date	Days, weeks, months, and years	Course Agenda, Course Attendees
Demographics	Date of birth, gender, ethnic origin, and marital status	Course Agenda, Course Attendees
Employment	Start date, end date, and transition date	Course Agenda, Course Attendees
Job	Function, type, and title	Course Agenda, Course Attendees
Position	Position, title, and full-time equivalent (FTE)	Course Agenda, Course Attendees
Employee Name	First name, last name, and full name	Course Attendees
Employee Title	Title and seniority date	Course Attendees

Production performance Power BI content

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes what is included in the **Production performance** Microsoft Power BI content. It explains how to access the Power BI reports, and provides information about the data model and entities that were used to build the content.

Overview

The **Production performance** Power BI content is for production managers or individuals in the organization who are responsible for production control.

The reports that are included let you use Power BI to monitor the performance of manufacturing operations with regard to timely execution, quality, and cost. The reports use transactional data from production orders and batch orders, and provide both an aggregate view of company-wide production metrics and a breakdown of metrics by product and resource.

The Power BI content highlights the organization's ability to complete production on time and in full. Future performance is projected based on the production plans. Comprehensive reports provide detailed insights into product defects that are caused by production, and also the defect rates for resources and operations.

This Power BI content also lets you analyze production variances. Production variances are calculated as the difference between estimated cost and realized cost. Production variances are calculated when production orders or batch orders reach **Ended** status.

The **Production performance** Power BI content includes data that originates from production orders and batch orders. The reports don't include data that is related to kanban productions.

Accessing the Power BI content

The **Production performance** Power BI content is shown on the **Production performance** page (**Production control** > **Inquiries and reports** > **Production performance analysis** > **Production performance**).

Metrics that are included in the Power BI content

The **Production performance** Power BI content includes a set of report pages. Each page consists of a set of metrics that are visualized as charts, tiles, and tables.

The following table provides an overview of the visualizations that are included.

Expand table

Report page	Charts	Tiles
Production performance	• Number of production by date • Number of productions by product and item group • Number of planned productions by date • Bottom 10 products by on-time & in-full	• Total orders • On-time & in full % • Incomplete % • Early % • Late %
Defects by product	• Defective rate (ppm) by date • Defective rate (ppm) by product and item group • Quantity produced by date • Top 10 products by effective rate	• Defective rate (ppm) • Defective quantity • Total quantity
Defects trend by product	Defect rate (ppm) by quantity produced	Defect rate (ppm)
Defects by resource	• Defect rate (ppm) by date • Defect rate (ppm) by resource and Site • Defect rate (ppm) by operation • Top 10 resources by defect rate	Defective quantity
Defects trend by resource	Defect rate (ppm) by quantity processed	
Production variances for job order costing	• Production variance by date and cost group type • Production variance by site and cost group type • Top 10 products with unfavorable production variance • Top 10 unfavorable production variance by resource	• Realized cost • Production variance • Production variance %

Understanding the data model and entities

The following data is used for the report pages in the **Production performance** Power BI content. This data is represented as aggregate measurements that are staged in the Entity store. The Entity store is

a Microsoft SQL Server database that is optimized for analytics. To learn more about the entity store, see Power BI integration with Entity store.

The following table shows the key aggregate measurements that are used as the basis of the Power BI content.

Expand table

Entity	Key aggregate measurements	Data source for finance and operations apps	Field
CostCalculation	CostAmount	ProdCalcTransExpanded	CostAmount
CostCalculation	CostMarkup	ProdCalcTransExpanded	CostMarkup
CostCalculation	ActualCostAmount	ProdCalcTransExpanded	RealCostAmount
CostCalculation	RealCostAdjustment	ProdCalcTransExpanded	RealCostAdjustment
RouteTransactions	ErrorQuantity	ProdRouteTransExpanded	QtyError
RouteTransactions	GoodQuantity	ProdRouteTransExpanded	QtyGood
ProductionOrder	DaysDelayed	ProdTableExpanded	DaysDelayed
ProductionOrder	LeadTime	ProdTableExpanded	LeadTime
ProductionOrder	PlannedLeadTime	ProdTableExpanded	PlannedLeadTime
ProductionOrder	ProductionOrderCount	ProdTableExpanded	
CoproductCostCalculation	CoproductCostAmount	PmfCoByProdCalcTransExpanded	CostAmount
CoproductCostCalculation	CoproductCostMarkup	PmfCoByProdCalcTransExpanded	CostMarkup
CoproductCostCalculation	CoproductRealCostAdjustment	PmfCoByProdCalcTransExpanded	RealCostAdjustment
CoproductCostCalculation	CoproductActualCostAmount	PmfCoByProdCalcTransExpanded	RealCostAmount

The following table shows how the key aggregate measurements are used to create several calculated measures in the content's dataset.

Expand table

Measure	How the measure is calculated
Production variance, %	SUM('Production variance'[Production variance]) / SUM('Production variance'[Estimated cost])
All planned orders	COUNTROWS('Planned production order')
Early	COUNTROWS(FILTER('Planned production order', 'Planned production order'[Scheduled end date] < 'Planned production order'[Requirement date]))

Measure	How the measure is calculated
Late	COUNTROWS(FILTER('Planned production order', 'Planned production order'[Scheduled end date] > 'Planned production order'[Requirement date]))
On-time	COUNTROWS(FILTER('Planned production order', 'Planned production order'[Scheduled end date] = 'Planned production order'[Requirement date]))
On-time %	IF ('Planned production order'[On-time] <> 0, 'Planned production order'[On-time], IF ('Planned production order'[All planned orders] <> 0, 0, BLANK())) / 'Planned production order'[All planned orders]
Completed	COUNTROWS(FILTER('Production order', 'Production order'[Is RAF'ed] = TRUE))
Defective rate (ppm)	IF('Production order'[Total quantity] = 0, BLANK(), (SUM('Production order'[Defective quantity]) / 'Production order'[Total quantity]) * 1000000)
Delayed production rate	'Production order'[Late #] / 'Production order'[Completed]
Early & in full	COUNTROWS(FILTER('Production order', 'Production order'[Is in full] = TRUE && 'Production order'[Is early] = TRUE))
Early #	COUNTROWS(FILTER('Production order', 'Production order'[Is early] = TRUE))
Early %	IFERROR(IF('Production order'[Early #] <> 0, 'Production order'[Early #], IF('Production order'[Total orders] = 0, BLANK(), 0)) / 'Production order'[Total orders], BLANK())
Incomplete	COUNTROWS(FILTER('Production order', 'Production order'[Is in full] = FALSE && 'Production order'[Is RAF'ed] = TRUE))
Incomplete %	IFERROR(IF('Production order'[Incomplete] <> 0, 'Production order'[Incomplete], IF('Production order'[Total orders] = 0, BLANK(), 0)) / 'Production order'[Total orders], BLANK())
Is delayed	'Production order'[Is RAF'ed] = TRUE && 'Production order'[Delayed value] = 1
Is early	'Production order'[Is RAF'ed] = TRUE && 'Production order'[Days delayed] < 0
Is in full	'Production order'[Good quantity] >= 'Production order'[Scheduled quantity]
Is RAF'ed	'Production order'[Production status value] = 5 || 'Production order'[Production status value] = 7
Late & in full	COUNTROWS(FILTER('Production order', 'Production order'[Is in full] = TRUE && 'Production order'[Is delayed] = TRUE))
Late #	COUNTROWS(FILTER('Production order', 'Production order'[Is delayed] = TRUE))

Warehouse performance Power BI content

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes what's included in the **Warehouse performance** Microsoft Power BI content. It explains how to access the Power BI reports, and provides information about the data model and entities that are used to build the content.

Overview

The **Warehouse performance** Power BI content was created so that warehouse and operations managers can monitor important inbound, outbound, and inventory metrics. It uses Warehouse management, product, and other transactional data from your system, and provides both an aggregate view of warehouse performance and a breakdown for vendors, product groups and products, and site and warehouses.

Warehouse managers can use the **Warehouse performance** Power BI content to measure the following three areas:

- **Inbound performance** – Measure how well a vendor is performing against customer requirements (in other words, measure delivery performance), and measure put-away performance, so that you can identify issues that involve workers or items over a period. It's important that you know whether vendors are delivering on time, early, or late, so that you can determine how vendor performance is affecting overall put-away performance. A vendor that delivers outside the dates that were agreed on can put extra pressure on the warehouse because of unexpected work, and can increase the average put-away time.
- **Shipping performance** – Measure whether your warehouse is shipping in full and on time to customers (in other words, measure outbound shipping and delivery performance), so that you can identify any issues that involve products, sites or warehouses, or dedicated customers. If you find that you're shipping late to specific areas or towns, you might have to pay more attention to transportation or account management.

- **Location inventory accuracy** – Inventory accuracy is important internal warehouse business intelligence (BI). It's very important that you determine how accurately you're counting in general. However, it's also important that you determine how accurate you are at storing items in the correct locations, and that you highlight discrepancy data, so that you can find better positions for items or initiate total counting on specific items. (Currently, the new item-based counting functionality is delivered as a hotfix.) If you're using this Power BI content to determine the correctness of on-hand inventory data per location, you can also identify theft in your shops. You can also determine whether any locations have on-hand quantities that differ from enterprise resource planning (ERP) data. Those locations might be too large, or they might be impossible to count. Alternatively, some of the physical positioning might be bad, so that it's difficult to keep a single type of item in sync with on-hand data.

Prerequisites

The **Warehouse performance** Power BI content only shows data for the dates defined on the **Date dimensions** page (**Organization administration** > **Setup** > **Calendars** > **Date dimensions**).

Accessing the Power BI content pack

The **Warehouse performance** Power BI content is shown on the **Warehouse performance** page (**Warehouse management** > **Inquiries and reports** > **Warehouse performance analysis** > **Warehouse performance**).

Metrics that are included in the Power BI content

The **Warehouse performance** Power BI content includes a report. This report consists of a set of metrics that are visualized as charts, tiles, and tables. The following table provides an overview of the visualizations in the **Warehouse performance** Power BI content.

Expand table

Report page	Charts	Description
Inbound Performance	Total put aways	The number of put-away work lines that are processed during a given time.
Inbound Performance	Put away average time	The average time, in hours, for all purchase order put-away lines that are processed, from registration of the items until the last put is

Report page	Charts	Description
		processed.
Inbound Performance	Received early	The number of purchase order lines that are received early.
Inbound Performance	Received on time	The number of purchase order lines that are received on time.
Inbound Performance	Received late	The number of purchase order lines that are received late.
Inbound Performance	On time by vendor	A view of the percentage of purchase order lines that are received from a vendor or vendor group early, on time, and late.
Inbound Performance	Dock to stock average put away (hours)	The average dock-to-stock put-away time in hours over time.
Inbound Performance	Average put away by worker	The average time, in hours, that a worker has been taking for put-away processing of purchase order lines.
Inbound Performance	Average put away hour by vendor	The average put-away time in hours by vendor or vendor group.
Inbound Performance	Average put away hour by product	The average put-away time in hours by item or item group.
Location inventory accuracy	Total count	The number of counting work lines that are processed for a given period.
Location inventory accuracy	Discrepancy rate	The total discrepancy rate as a percentage of all lines that are counted for a given period.
Location inventory accuracy	Count without discrepancy	Of the total number of counting work lines that are processed, the number of lines that are processed without any discrepancy.
Location inventory accuracy	Items counted over time	The percentage of items that are counted with and without discrepancy over time.
Location inventory accuracy	Item quantity discrepancy greater than %	A table view of counting lines that have discrepancies that exceed a specified percentage. The table includes information about locations, items, the average discrepancy, the total counting work lines that are counted, the number of counting lines that have discrepancies for the location, the average quantity that is counted, the expected total

Report page	Charts	Description
		quantity that will be counted, and the actual item quantity that is counted.
Location inventory accuracy	Item count by worker	The counting performance of workers. Performance is expressed as a percentage of counting work lines that have and don't have discrepancies.
Location inventory accuracy	Item count by site / warehouse	Counting performance by the number of processed counting work lines by site or warehouse that have and don't have discrepancies.
Location inventory accuracy	Discrepancy rate by product	The discrepancy rate for counting performance. The rate is expressed as a percentage of processed counting work lines by item or item group.
Shipping performance	Lines shipped	The total number of shipment lines that are shipped over a given period.
Shipping performance	Early	The percentage of shipment lines that are shipped early.
Shipping performance	On time	The percentage of shipment lines that are shipped on time.
Shipping performance	Late	The percentage of shipment lines that are shipped late.
Shipping performance	Shipments over time	The percentage of shipment lines that are shipped on time, early, or late over a given period. A trend line shows the trend for lines that are shipped on time.
Shipping performance	Shipped late by city	A map visualization of cities and areas that are affected by late shipments.
Shipping performance	Shipped by product	The percentage that is shipped early, on time, or late by item or item group.
Shipping performance	Shipped by customer	The percentage that is shipped early, on time, or late by customer or customer group.
Shipping performance	Shipped by site / warehouse	The percentage that is shipped early, on time, or late by site or warehouse.

Understanding the data model and calculations

The following data is used to fill the report pages in the **Warehouse performance** Power BI content. This data is represented as aggregate measurements that are staged in the Entity

store. The Entity store is a Microsoft SQL Server database that is optimized for analytics. For more information, see Power BI integration with Entity store.

The following key aggregate measurements are used as the basis of the content.

Expand table

Report page	Charts	Tables	Calculation descriptions
Inbound Performance	Total put aways	WHSWorkLine	The count of work lines where the work type is **put**.
Inbound Performance	Put away average time	WHSWorkLine	The sum of work lines max. time divided by the count of work lines max. time, where work lines max. time is the maximum gap between the work created date and the closed date.
Inbound Performance	Received early	WHSWorkLine	The count of work lines where the work created date is earlier than the delivery date that is used. If the delivery confirmed date isn't set, use the default delivery date.
Inbound Performance	Received on time	WHSWorkLine	The count of work lines where the work created date is equal to the delivery date that is used. If the delivery confirmed date isn't set, use the default delivery date.
Inbound Performance	Received late	WHSWorkLine	The count of work lines where the work created date is later than the delivery date that is used. If the delivery confirmed date isn't set, use the default delivery date.
Inbound Performance	On time by vendor	WHSWorkLine	Received early, Received on time, and Received late (see the descriptions earlier in this table).
Inbound Performance	Dock to stock average put away (hours)	WHSWorkLine	Put away average time (see the description earlier in this table).
Inbound Performance	Average put away by worker	WHSWorkLine	Put away average time (see the description earlier in this table).
Inbound Performance	Average put away hour by	WHSWorkLine	Put away average time (see the description earlier in this table).

Report page	Charts	Tables	Calculation descriptions
	vendor		
Inbound Performance	Average put away hour by product	WHSWorkLine	Put away average time (see the description earlier in this table).
Location inventory accuracy	Total count	WHSWorkLineCycleCount	Cycle counts where the absolute discrepancy quantity is equal to or more than 0 (zero).
Location inventory accuracy	Discrepancy rate	WHSWorkLineCycleCount	Cycle counts that have discrepancies, divided by the total count. A cycle count is considered to have discrepancies if the absolute discrepancy quantity is more than 0 (zero).
Location inventory accuracy	Count without discrepancy	WHSWorkLineCycleCount	Cycle counts where the absolute discrepancy quantity is more than 0 (zero).
Location inventory accuracy	Count with discrepancy	WHSWorkLineCycleCount	Cycle counts where the absolute discrepancy quantity is equal to 0 (zero).
Location inventory accuracy	Items counted over time	WHSWorkLineCycleCount	Count without discrepancy and Count with discrepancy (See the descriptions earlier in this table.)
Location inventory accuracy	Item quantity discrepancy greater than %	WHSWorkLineCycleCount	The average discrepancy is the absolute discrepancy quantity divided by the expected quantity where the absolute discrepancy quantity is more than 0 (zero). The average discrepancy quantity is the average absolute discrepancy quantity where the absolute discrepancy quantity is more than 0 (zero). Count with discrepancy, Total count, Expected quantity, and Counted quantity where the whole quantity is grouped by item and location (see the descriptions earlier in this table).
Location inventory accuracy	Item count by worker	WHSWorkLineCycleCount	Count without discrepancy and Count with discrepancy (see the descriptions earlier in this table).
Location inventory accuracy	Item count by site / warehouse	WHSWorkLineCycleCount	Count without discrepancy and Count with discrepancy (see the descriptions earlier in this table).

Report page	Charts	Tables	Calculation descriptions
Location inventory accuracy	Discrepancy rate by product	WHSWorkLineCycleCount	Discrepancy rate (see the description earlier in this table).
Shipping performance	Lines shipped	SalesLine	The count of sales lines where sales lines are shipped.
Shipping performance	Early	CustPackingSlipOnTimeStatus	Sales lines where the ship date status is **1 (Early)**. Early means that the ship date of the packing slip is earlier than the confirmed ship date of the sales line. If the confirmed ship date isn't set, use the requested ship date.
Shipping performance	On time	CustPackingSlipOnTimeStatus	Sales lines where the ship date status is **2 (On time)**. On time means that the ship date of the packing slip is equal to the confirmed ship date of the sales line. If the confirmed ship date isn't set, use the requested ship date.
Shipping performance	Late	CustPackingSlipOnTimeStatus	Sales lines where the ship date status is **3 (Late)**. Late means that the ship date of the packing slip is later than the confirmed ship date of the sales line. If the confirmed ship date isn't set, use the requested ship date.
Shipping performance	Shipments over time	SalesLine CustPackingSlipOnTimeStatus	Orders that are fully shipped, where the whole quantity of the sales line is shipped, plus Early, On time, and Late (see the descriptions earlier in this table).
Shipping performance	Shipped late by city	CustPackingSlipOnTimeStatus	Late (see the descriptions earlier in this table).
Shipping performance	Shipped by product	CustPackingSlipOnTimeStatus	Early, On time, and Late (see the descriptions earlier in this table).
Shipping performance	Shipped by customer	CustPackingSlipOnTimeStatus	Early, On time, and Late (see the descriptions earlier in this table).
Shipping performance	Shipped by site / warehouse	CustPackingSlipOnTimeStatus	Early, On time, and Late (see the descriptions earlier in this table).

Analyze warehouse material movement through process mining

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The Microsoft Power Automate Process Mining feature offers *task mining* and *process mining* capabilities to help you better understand your business processes, so that you can optimize them. Dynamics 365 Supply Chain Management offers a *Warehouse material movement analysis* template for the Power Automate Process Mining. Use this template to create processes that help warehouse and operations managers gain insights into the material flow in the warehouse. It helps find inefficiencies that you can remove to improve the performance of the warehouse.

The *Warehouse material movement analysis* template uses warehousing, product, and transactional data that's stored in your system. It lets you visualize and analyze material movements on the warehouse floor, based on closed warehouse work records. In process mining terminology, each warehouse work record corresponds to a *case*, and each pick or put work line corresponds to an *event*. Depending on your configuration, an *activity* can be any one of the following items:

- Warehouse location
- Warehouse location profile
- Warehouse zone

For more information about Power Automate Process Mining, see Overview of Power Automate Process Mining.

This article describes what's included in the *Warehouse material movement analysis* template, and explains how to deploy and access Power Automate Process Mining processes.

Prerequisites

The *Warehouse material movement analysis* template for Power Automate Process Mining has the following prerequisites:

- You're running Supply Chain Management version 10.0.35 or later.
- Your Supply Chain Management environment must be linked to a Dataverse environment.
- The user who deploys the process in Power Automate Process Mining must have the *Warehouse manager*, *Warehouse planner*, and/or *System administrator* role.
- The Supply Chain Manager user who deploys the process in Power Automate Process Mining must also be configured as a user in the linked Dataverse environment. To deploy the process, a user must have the *Environment maker* and/or *System administrator* role. After the process is deployed, it can be shared with other users. Those users automatically get the permissions required to use the process.

Deploy a new Power Automate Process Mining process based on the template

Set up as many processes as you need, each with a different name and filters. Follow these steps to deploy a *Warehouse material movement analysis* process.

1. Go to **Warehouse management** > **Setup** > **Process mining** > **Warehouse material movement process configuration**.

2. On the Action Pane, select **Deploy process** to open the deployment wizard.

3. Follow the on-screen instructions. Provide the following information:

    - **Process name** – Enter a name for the process. Include the legal entity (company) and other filter information in the name, so you can easily identify the process later.
    - **Company** – Select the legal entity that you want to use this process to analyze. Only warehouse work records in the selected legal entity are included in Power Automate Process Mining process.
    - **Number of months to load** – Specify the number of months to load at a time. This filter helps prevent excessive or irrelevant data from being loaded into Power Automate Process Mining. Only warehouse work records that were closed after the specified time threshold are included in Power Automate Process Mining process.
    - **Activity** – Specify which column Power Automate Process Mining should treat as an *activity*. To learn more about process mining terminology, see Glossary in Power Automate Process Mining.

> **Note**
>
> Try to limit the data by optimizing the **Number of months to load** filter value. Power Query Online includes several threshold checks. Therefore, if you try to load too much data, time-out or quota violation exceptions might occur, and the system might fail. Load less than 25 months of data into the *Warehouse material movement analysis* process and ensure that the total number of events in the process is less than 4 million.

When you complete the deployment wizard, the following actions occur:

- **Initial data is loaded.** The system loads 200 *cases* into the staging table. In the context of the *Warehouse material movement analysis* process template, each case corresponds to a single closed warehouse work record. Most likely, many more than 200 records meet the filtering criteria set in the deployment wizard. By loading only 200 cases, the system enhances performance and the user experience, so that you can access the visualization more quickly.
- **You're prompted to complete the deployment process.** Power Automate Process Mining user interface (UI) opens on a new tab in your browser. You might be asked to sign in. Power Automate Process Mining uses your credentials to read data from Supply Chain Management. Don't close the page right away. Otherwise, you interrupt the deployment. You don't have to do anything else on the page. Power Automate Process Mining lets you know when deployment is completed.

Refresh data in the staging table and Power Automate Process Mining

As mentioned earlier, after you deploy a new process, the system loads an initial set of 200 cases into the staging table and loads that data into Power Automate Process Mining. This behavior lets you get started quickly. However, to work with your full data set, you must refresh the staging table and Power Automate Process Mining. This section describes how to manually trigger this process.

> **Tip**
>
> Although it can be useful to refresh the data on demand from time to time, you probably want to set up each process so that it automatically refreshes its data on a regular basis. For

instructions, see the Configure the warehouse material movement process section of this article.

Follow these steps to manually refresh data in the staging table and Power Automate Process Mining.

1. Go to **Warehouse management** > **Setup** > **Process mining** > **Warehouse material movement process configuration**.
2. In the list pane, select the process to refresh the data for.
3. On the Action Pane, select **Refresh staging table**. The batch job that's responsible for refreshing the staging table runs every five minutes. The next time that it runs, it picks up the request to refresh the table. It then loads all the data that matches the filters specified during deployment.
4. On the **General** FastTab, the **Last staging table refresh** field is updated to indicate that the table is refreshed. However, the new data isn't available in Power Automate Process Mining until you refresh it there. Select **View process details** on the Action Pane, and then select **Refresh data** in Power Automate Process Mining.

A staging table cleanup batch job runs daily and removes any records from the staging table that no longer satisfy the filter criteria. For example, it removes any records that are now too old.

Configure warehouse material movement processes

After you deploy a process, you can configure it at any time by following these steps.

1. Go to **Warehouse management** > **Setup** > **Process mining** > **Warehouse material movement process configuration**.

2. In the list pane, select the process to refresh the data for.

3. On the **General** FastTab, set the following fields:

    - **Automatic refresh recurrence** – Select how often the system should update the data table (*None*, *Once per day*, or *Once per week*). Although this update refreshes data in the staging table, it doesn't automatically load that data into Power Automate Process Mining. To set Power Automate Process Mining to periodically load this data from the staging table, select **View process details** on the Action Pane. Then, in Power Automate Process Mining, select **Schedule refresh**, and select a refresh schedule. You can also manually refresh the data in Power Automate Process Mining by selecting **Refresh data** in Power Automate Process Mining.

- **Last staging table refresh** – This read-only field shows the date and time when the staging table was last refreshed.
- **Enforce offline hours** – Set this option to *Yes* to prevent the system from refreshing the staging table during the specified hours. This option can be useful if you want to avoid refreshing the table during peak hours.

4. On the **Process parameters** FastTab, review the following fields:

    - **Legal entity** – This read-only field shows the legal entity specified during deployment.
    - **Number of months to load** – This read-only field shows the number of months to load, as specified during deployment.
    - **Activity** – This read-only field shows the activity specified during deployment.

    The **Processing log** FastTab shows a history of data refresh and cleanup operations. This information can be useful during troubleshooting.

Access the warehouse material movement analysis process

You can access the warehouse material movement analysis process from both Supply Chain Management and Power Automate Process Mining UI.

To access the process from Supply Chain Management, follow these steps:

1. Go to **Warehouse management** > **Enquiries and reports** > **Warehouse performance analysis** > **Warehouse material movement analysis**.

2. In the **Process name** field, select the name of the process to view. The list includes only processes that meet both the following conditions:

    - The process is ready for analysis. (In other words, it has been deployed and analyzed in Power Automate Process Mining.)
    - The current user can access the process. (In other words, the current user created or shared the process.)

3. The Power BI report for your selected process opens. You can interact with the report to view the process and analyze it in various ways.

4. To view the selected process in Power Automate Process Mining, select **View process report** on the Action Pane. Power Automate Process Mining UI opens on a new tab in your browser.

5. To perform advanced process analysis, assess process behavior with business rules, detect rework, and build your own business metrics, select **Open Power Automate Process Mining** to open process in Power Automate Process Mining desktop app. For more information about its capabilities, see Power Automate Process Mining overview.

FAQ

Why don't I see all the events (work lines) and cases (work headers) that I expect in Power Automate Process Mining process?

Several reasons might prevent you from seeing all the events and cases that you expect. Check the following items:

- Confirm that the staging table is recently refreshed. Go to **Warehouse management** > **Setup** > **Process mining** > **Warehouse material movement process configuration**, and review the **Last staging table refresh** field on the **General** tab and the information on the **Processing log** FastTab.
- Confirm that the warehouse work that you expect to see in the process is closed. The warehouse work closed date and legal entity (company) should meet the process filtering criteria that are specified during process deployment. You can check these details on the **Warehouse material movement process configuration** page.
- Confirm that Power Automate Process Mining process is recently refreshed. For information about how to view refresh information, and how to set up schedules to automatically refresh the staging table and Power Automate Process Mining process, see the Configure the warehouse material movement process section of this article.

Why don't I see the process that I'm looking for on the Warehouse material movement analysis page?

Several reasons might prevent you from seeing a process on the **Warehouse material movement analysis** page. Check the following items:

- Confirm that you have access to the process. Usually, to view a process, you must have created it yourself, or the creator must share it with you. To confirm that you have access, sign in to Power Automate Process Mining in Power Automate by using the same user account, and determine whether you can access the process.
- Confirm that the process is deployed and ready for analysis. The **Warehouse material movement analysis** page shows only processes that are ready for analysis. If the process is

still being deployed, it might not yet appear on the page. To confirm that the process is ready for analysis, try to open the Power BI report for the process in Power Automate Process Mining UI.

Why do I receive an error during process deployment?

The system performs several checks while it's provisioning a process. Most failures occur either because the Supply Chain Management user account that's used isn't registered in Dataverse or because the account doesn't have the required privileges. If deployment takes a long time (about four hours), you're probably exceeding the threshold limits for Power Automate Process Mining integration. Consider changing the filters to reduce the number of events that are loaded into Power Automate Process Mining. You can typically lower the **Number of months to load** filter value.

Analytical Workspaces (using Power BI Embedded)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Dynamics finance and operations apps now deliver rich, interactive reports that seamlessly integrate into application workspaces. By using graphics and visuals supported by Power BI, workspaces provide a highly visual, yet interactive experiences for users.

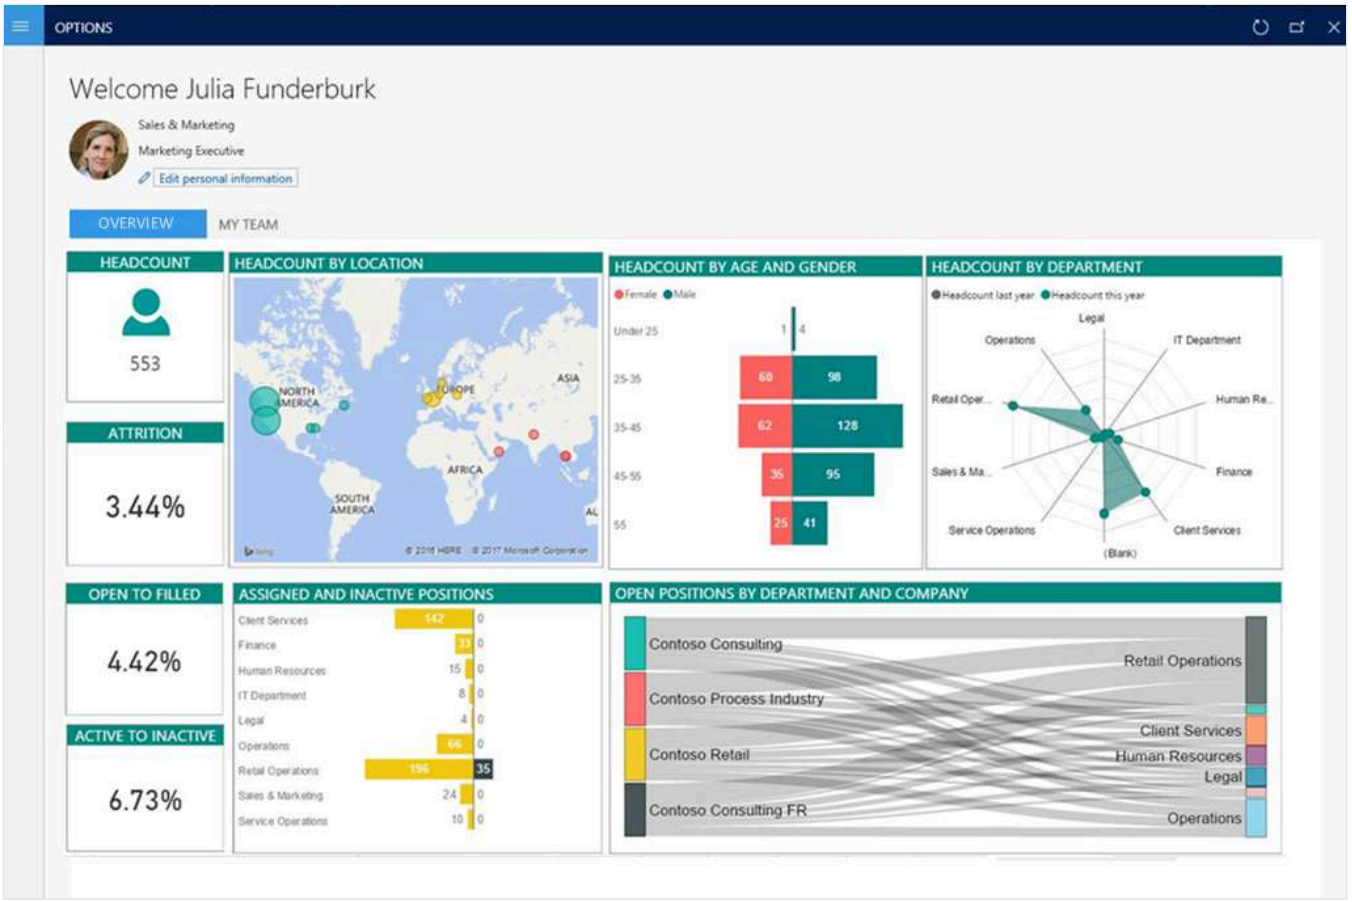
Overview

Workspaces in the application provide an overview of business processes or business units. With rich workspaces, users get a bird's-eye view of the state of business before diving into details and taking action. Workspaces contain visuals, count tiles, and KPIs as well as quick links to reports and pages. Within a workspace, all controls are tightly integrated to provide a highly productive and engaging work environment to the user. Power BI Embedded is a Microsoft Azure service that enables ISVs and app developers to surface Power BI data experiences within their applications. With Power BI Embedded, developers can deliver always-up-to-date views with Direct Query. To learn more about how the Power BI Embedded service integrates with the application, see Power BI Embedded integration.

Power BI in workspaces

The application now delivers interactive reports that seamlessly integrate into application workspaces. By using rich infographics and visuals supported by Power BI (including the large number of controls provided by third parties), workspaces provide a highly visual, yet interactive experience for users. Using infographics in the overview page, users get a quick glance of the state of the business. They can interact with data by simply clicking or touching visuals on the page. They can see the cause and effect, perform simple what-if operations without leaving the workspace. With interactive visuals, your users have fun exploring data and discovering hidden trends.

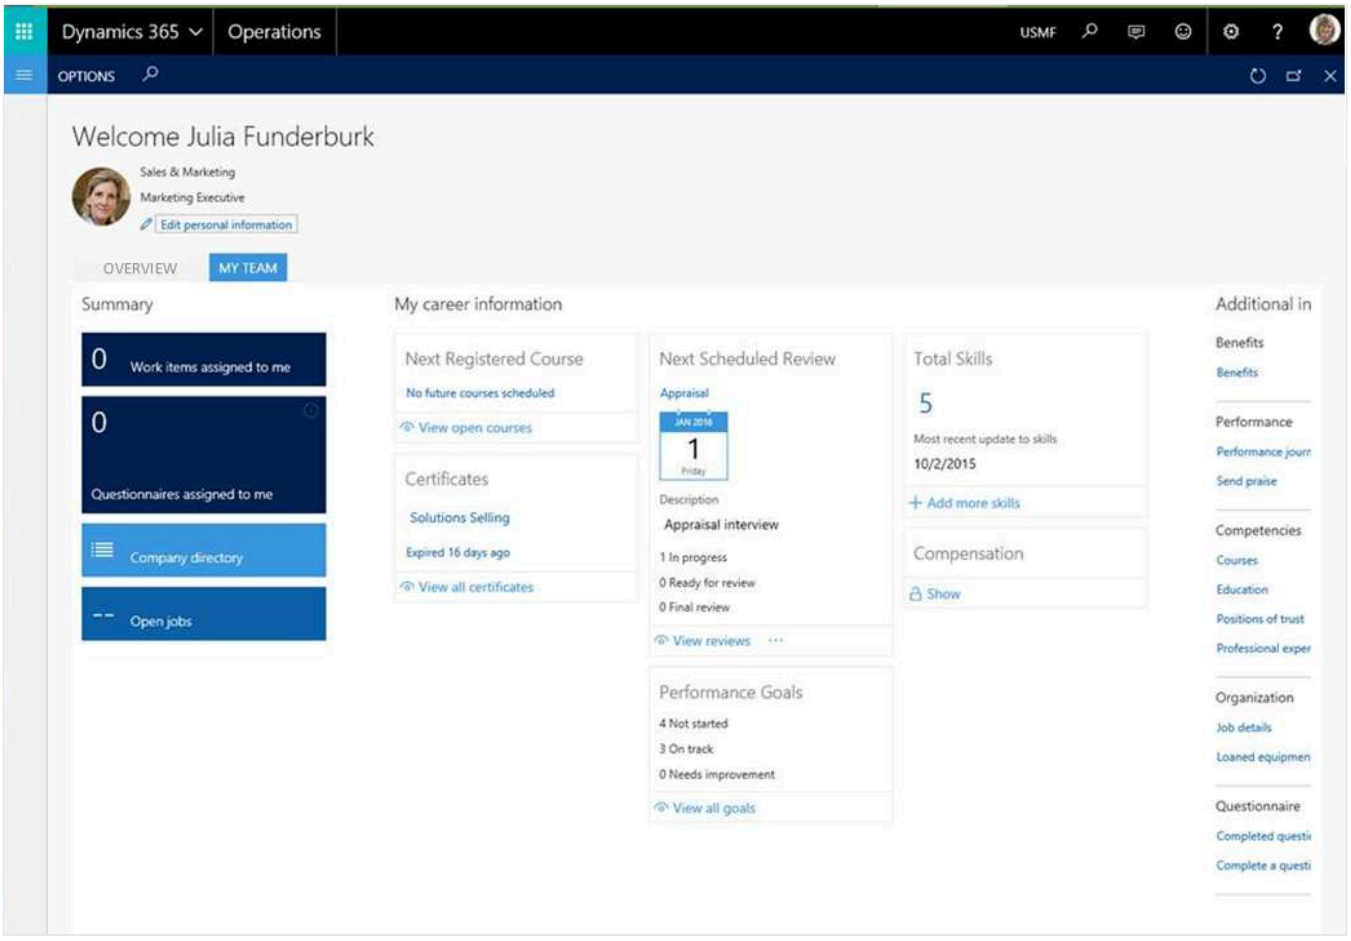
The following screenshot shows Power BI in a workspace.



Power BI vs operational workspaces

Power BI workspaces complement operational views with analytical insights based on near real-time information. The following section offers a visual comparison of a Power BI workspace and an operational workspace.

The following screenshot shows an operational workspace.



Edit embedded reports in analytical workspaces

https://learn-video.azurefd.net/vod/player?id=ea74f876-1a5f-49cc-b692-6a7bacf12ea3&locale=en-us&embedUrl=%2Fdynamics365%2Ffin-ops-core%2Fdev-itpro%2Fanalytics%2Fembed-power-bi-workspaces

The How to edit an embedded report in an analytical workspace video (shown preceding) is part of the Playlist available on YouTube.

What's next?

Going forward, new cloud deployments come bundled with the Power BI Embedded service. Other documentation describing the Developer ALM process is available to help partners and ISVs create new solutions that take advantage of the Power BI Embedded service integration options.

Power BI Embedded integration

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can embed Microsoft Power BI content that partners and independent software vendors (ISVs) develop directly into Microsoft Dynamics 365 Finance. This article describes some of the ways that you can use the Microsoft Power BI Embedded integration.

Overview

The integration of the application and Power BI enables data mash-up scenarios that require access to external data sources that Microsoft Power Query for Excel supports. Users can personalize workspaces by embedding tiles that PowerBI.com hosts. Users can also add direct links to reports that PowerBI.com hosts. In this way, users can access and interact with the reports without leaving the application. Partners and ISVs can embed Power BI content (PBIX files) directly into the application. PBIX files that are associated with a model file are automatically published in Power BI Embedded as part of the application deployment process. Additionally, you can add X++ extensions for embedded reporting scenarios that require the following functionality:

- Drill-down navigation into detailed pages in response to user interactions
- Report filters that are based on user and session context information, such as company or date range
- The ability to navigate directly to a specific tab on a Power BI report via menu items

For more information about customizations that use extensions, see Customize through extension and overlayering.

Advantages of Power BI Embedded

- **Deliver Power BI workspaces and reports in the application.** If you're a power user or a business analyst, you can tweak ready-made reports or create new reports by using Power BI tools. As a developer, you can use the reports that your users create to provide rich navigation experiences in the product through workspaces. If you're in the partner and

ISV community, you can build rich workspaces that include Power BI experiences, and then release those workspaces as part of your solution.

- **The Power BI Embedded service license is bundled with the application.** If you're an ISV or a systems integrator, you can package workspaces that are enabled for Power BI (and navigational experiences that those workspaces provide) as part of a Microsoft Dynamics Lifecycle Services (LCS) solution. Your customers get the same experience without needing a PowerBI.com subscription. The workspaces just work with finance and operations applications.
- **Enable drill-down into detailed pages from Power BI.** The visuals are the starting point for action. Your users can drill down to business processes and pages to act immediately on issues that they uncover. The visuals let users filter data and uncover trends. Action pages reflect just the set of data that requires attention.
- **Help secure access to Power BI reports by using menu items.** As a developer, you can use familiar programming concepts that are available in finance and operations apps, because we extended the same concepts to workspaces that are based on Power BI. You can create new workspaces or extend existing workspaces by adding an overview page that Power BI drives. Developers can associate menu items with Power BI reports and include them as links in workspaces. The role-based and task-based security in finance and operations apps can help secure these menu items.
- **Filter reports based on application context.** You can build navigation experiences by passing one or more filters to Power BI reports. For example, depending on a user's actions or context, you can filter the Power BI report to reflect data from one business unit or a specific product. The user doesn't have to filter the data. You can define drill-through links to finance and operations pages, so that users can go directly to the transactional details pages.

For more information about the Power BI Embedded service, see the Power BI FAQ.

Service availability

The Power BI Embedded service is automatically deployed and configured for all cloud-hosted, multibox deployments. Because the service relies on Microsoft Azure services, application analytical workspaces and reports are unavailable in one-box environments. The Power BI Embedded service is already available in most Azure datacenters. You can check the latest availability on the Azure status page.

Frequently asked questions

Can I customize the Power BI embedded reports?

Yes. To customize the Power BI embedded reports, install Power BI Desktop in a one-box environment, and follow the steps in Create analytical reports by using Power BI Desktop.

Do customers have to purchase a separate Power BI license to use the new embedded analytics?

No, customers don't have to purchase a separate Power BI license to use the new embedded analytics. However, a Power BI Pro license is required to connect to Entity Store from PowerBI.com by using DirectQuery.

Can I help secure data to only those companies that I have access to?

Yes, the single company view prevents users from accessing data from companies that they don't have access to. For more information about how to help secure custom solutions, see Help secure analytical workspaces and reports by using Power BI Embedded.

How is currency shown across multiple companies?

Currency is shown as a system currency. The system currency is defined on the **System parameters** page.

Can I drill from summary balances back into finance and operations?

Yes, you can drill into the details on a Power BI report. However, there's limited support for drill-down into finance and operations apps.

What languages are currently supported?

Currently, only English is supported. However, the Power BI team plans to add support for other languages.

Can I access analytical workspaces and reports in the on-premises version of finance and operations?

No, you can't currently access analytical workspaces and reports in Dynamics 365 Finance + Operations (on-premises). Systems of Intelligence functions rely on cloud-hosted solutions.

Customize embedded reports in analytical workspaces

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Analytical workspaces

Analytical workspaces come with the application suite. Through reporting, they give users insights into data based on standard business operations. The reports are generic reports that business professionals define. They include metrics that interest a wide range of users from any industry.

However, in some cases, the standard reports include data that isn't relevant to all customers. More often, customers want to access data points or calculations that the standard reports leave out.

Power users can use web-friendly design tools to customize the analytical reports embedded in the application. By using the free-form canvas designer, users who are familiar with the relevant business insights that are required can help make the organization successful.

> **Important**
>
> The service automatically deploys customizations that you make to the embedded analytical reports and makes them available to other users of the system.

Edit embedded reports in analytical workspaces

https://learn-video.azurefd.net/vod/player?id=ea74f876-1a5f-49cc-b692-6a7bacf12ea3&locale=en-us&embedUrl=%2Fdynamics365%2Ffin-ops-core%2Fdev-itpro%2Fanalytics%2Fcustomize-analytical-workspace

The How to edit an embedded report in an analytical workspace video (shown above) is included in the Playlist available on YouTube.

Important points about embedded analytical reports

Although the standard reports deliver insights that are tailored to a given business persona, customizations can often maximize the value of these standard reports.

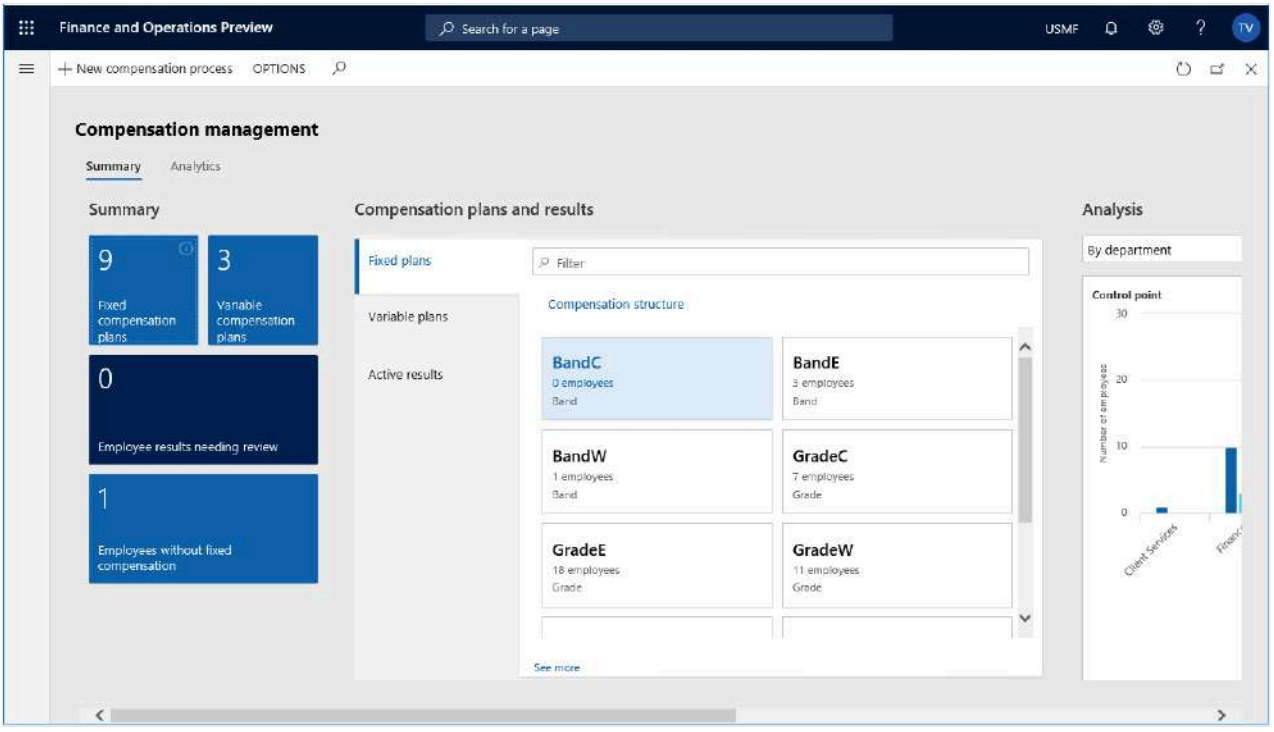
Here are some important points to note about this service capability:

- You can only customize the report design canvas. You can't change the definitions of report data sets.
- When you customize reports in the analytical workspace, the changes apply to all users in the environment.
- The service automatically preserves report customizations during product upgrades.
- The service doesn't support the export of customizations that you make to analytical workspaces.

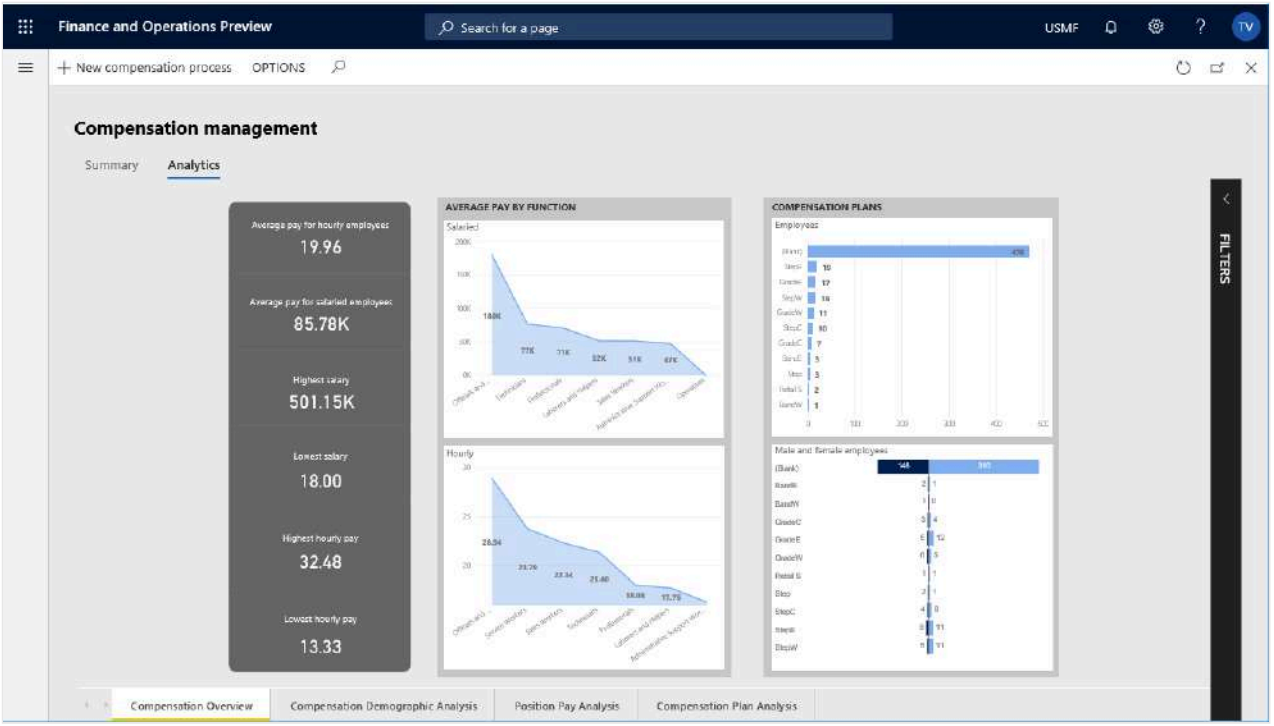
Customize an analytical workspace

To customize the embedded application solutions, assign the **System report editor** security role to a user. Users with this security role can use the buttons on the **Options** tab on the Action Pane of the application workspaces to make customizations. This example shows how to customize one of the standard analytical workspaces that are bundled with the application suite.

1. Sign in and open the application workspace that you want to customize. In this example, you replace the standard analytical report that's embedded in the **Compensation management** workspace.



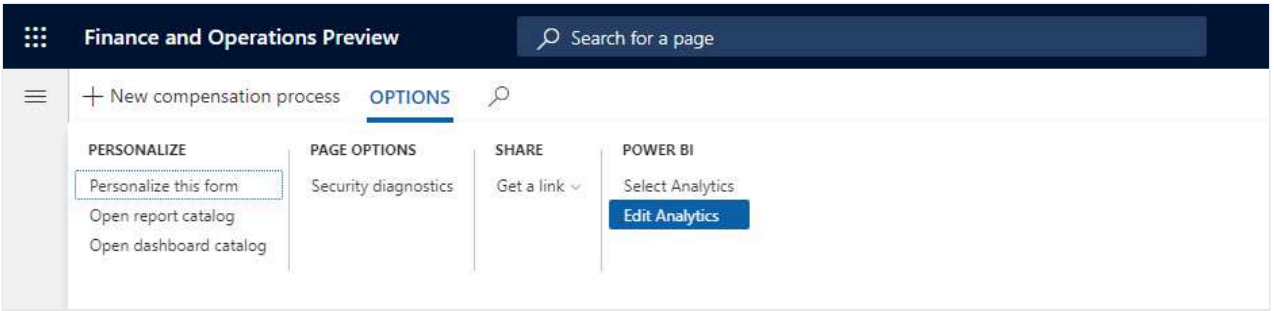
2. Select the **Analytics** tab to access the workspace's embedded analytical report.



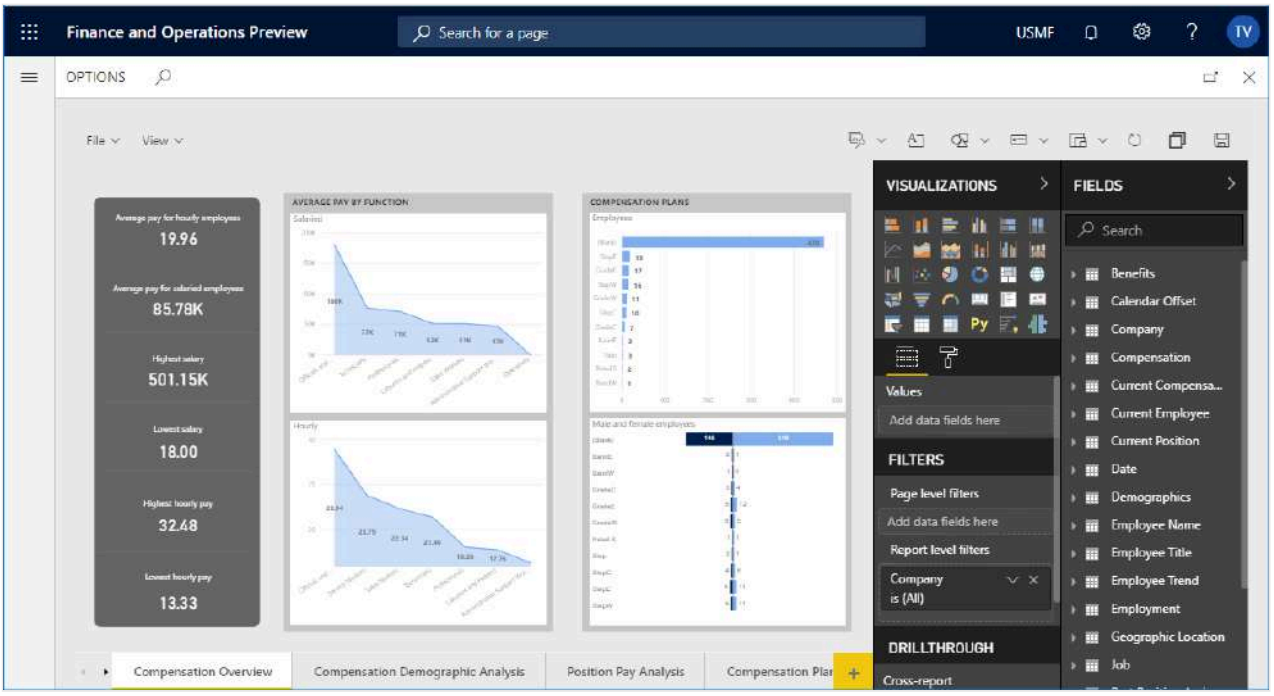
By default, you see the standard analytical workspace solution that's packaged with your application. The provisioning process automatically deploys and configures the reports in this solution for your environment.

> **Note**
>
> The analytical workspaces require a hosted Microsoft Power BI service that's available only for dedicated environments. For more information, see Accessing Analytical Workspaces and Reports on 1Box environment.

3. On the Action Pane, on the **Options** tab, in the **Power BI** group, select **Edit Analytics**.



The analytical workspace opens in edit mode, and you have direct access to the Power BI web designer tools.



4. Use the Power BI web designer tools to customize the report canvas. The intuitive web controls let you perform typical actions such as adding and removing visuals, changing visual types, and formatting the content. You can also inspect the source of the report visualizations to make sure that decisions are based on the most relevant data that's available in the system. For more information, see Add visualizations to a Power BI report.

5. After you complete your report customizations, select the **Save** button to promote the report edits. Customizations to the report are reflected immediately in the service. Therefore, users in your organization have access to the latest innovations.

> **Note**
>
> Customizations made in the web editor aren't saved back to the underlying PBIX report and aren't retrievable if the PBIX report is later customized on a development environment.

Restore the standard application solution

Follow these steps to restore the analytical workspaces that are bundled with the application solution.

1. In the analytical workspace, on the Action Pane, on the **Options** tab, in the **Power BI** group, select **Restore Analytics**.
2. To view the updates to the workspace, reload the page. Either move away from the workspace and then return, or refresh your browser.

3. In the **Compensation management** workspace, select the **Analytics** tab to access the original analytical workspace that was packaged with the application.

Troubleshooting

Follow these steps to address common issues encountered while attempting to use analytical workspaces.

Error message: *Please log into Power BI to access its resource*

The Power BI service requires explicit permission from the user to allow access to hosted content. Use the following steps to ensure the current user is able to connect to reports hosted on PowerBI.com from the application suite.

1. Open any application workspace containing a section titled **Link**. For example, "Bank management."
2. Select **Options**, and then select **Open report catalog** on the top left.
3. Follow the steps in the dialog box to **Authorize to Power BI** to access finance and operations apps for the current user.

Document Reporting Services

This article describes the integrated reporting solutions that are available. This solution simplifies service administration, increases developer productivity, and provides an enhanced report viewing experience for users.

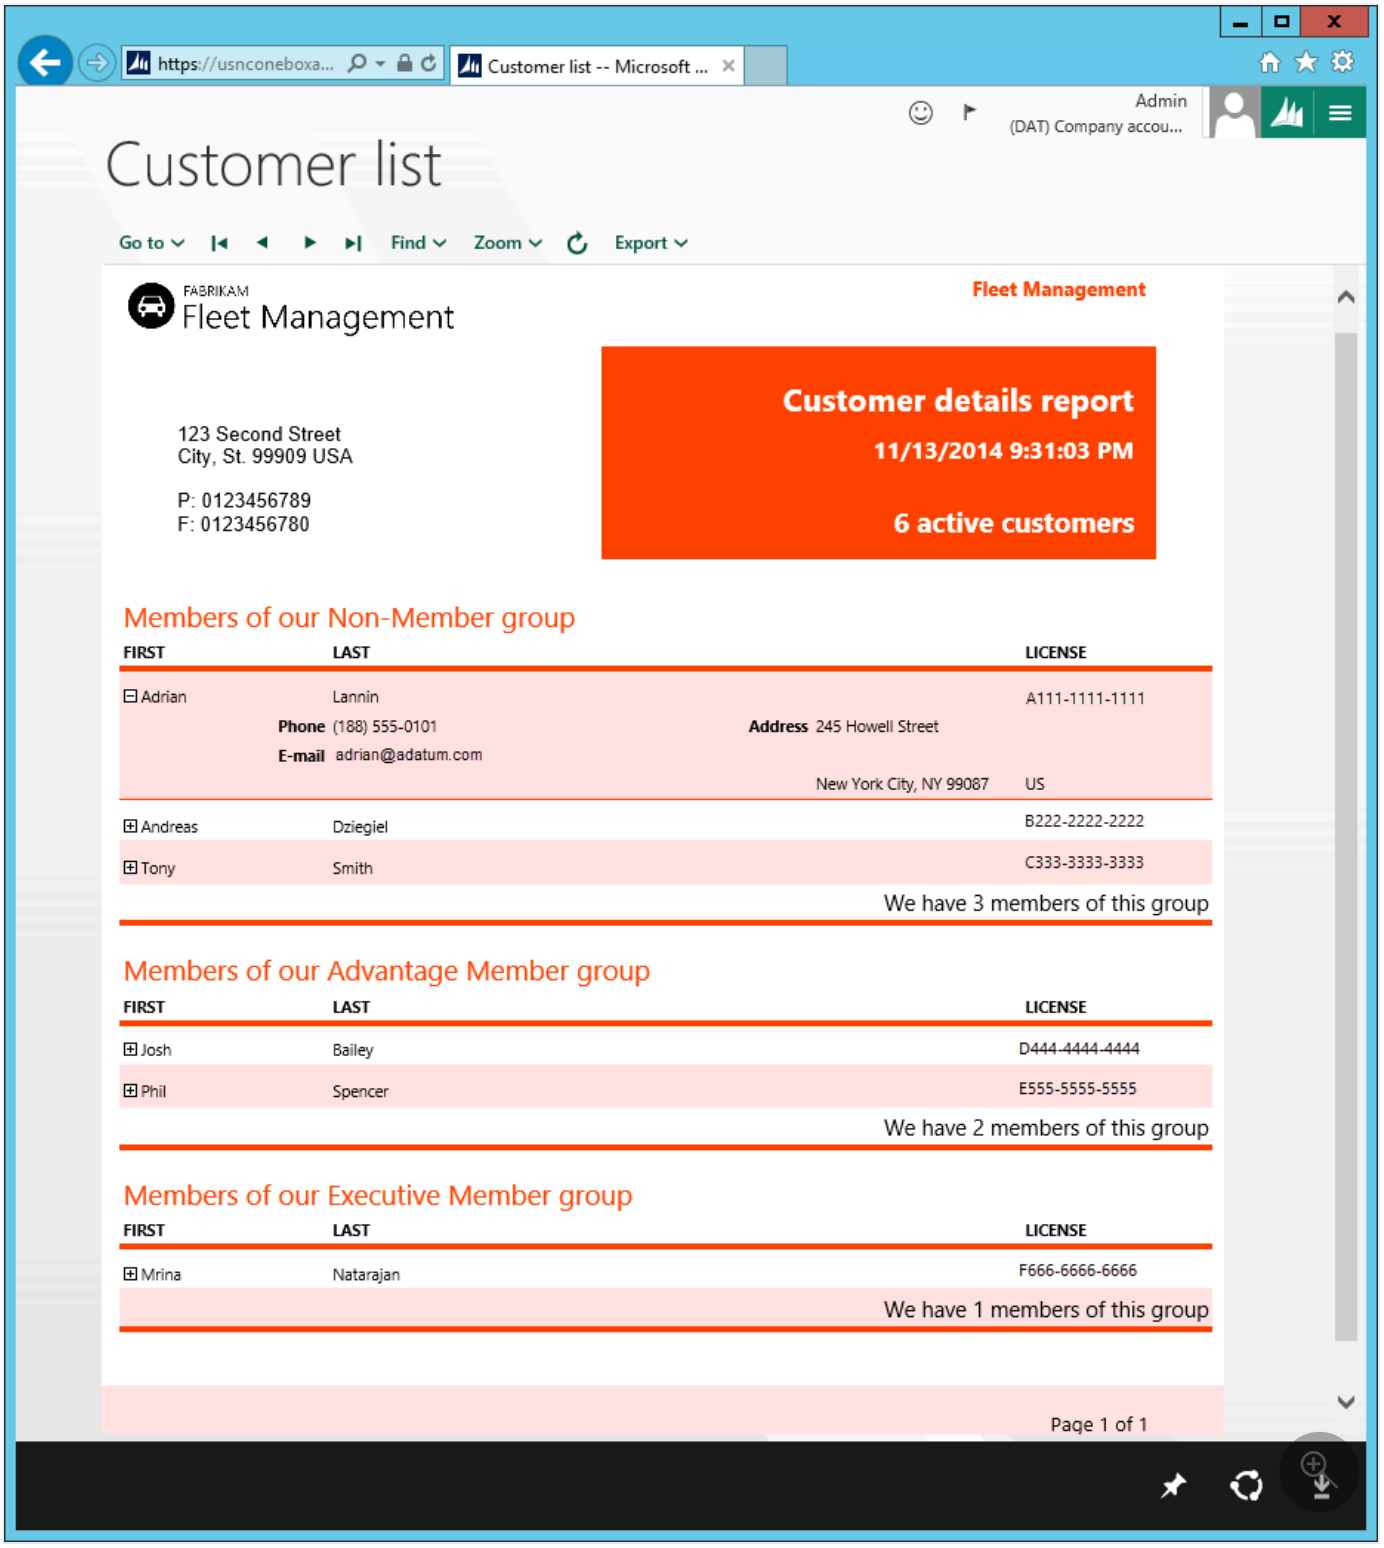
Document Reporting Services are based on Microsoft SQL Server Reporting Services (SSRS). In the current version of the application, these services are hosted in the Microsoft Azure Compute service. If you're developing in a one-box environment, the services also run locally in the Azure Compute Emulator.

Service deployment – Local vs. cloud

In a one-box environment, developers can create, modify, and preview reports, from end to end, by using Microsoft Visual Studio. You don't need a separate process to add reports to the application's metadata store. Changes to reports are packaged together with other solution updates and then deployed to the cloud after development is completed in the local environment.

Viewing reports

The enhanced report viewing experience that the solution provides for end users is the same as the report preview experience in Microsoft Visual Studio. You no longer use a separate design preview in Visual Studio. Instead, just press Ctrl+F5 to build and preview the report in a Microsoft Edge window. The report appears exactly as it would appear in the client. Even the user's parameter experience is the same. The following image shows an example of a report preview that is opened from Visual Studio.



Service administration prerequisites

The following table compares the service administration prerequisites for Microsoft Dynamics AX 2012 and the current version of the application.

Expand table

AX 2012	The current version of the application
A report development environment has the following prerequisites: • SSRS must be installed. • SSRS must be configured by using Reporting Services Configuration Manager. • SSRS extensions for the application must be installed.	Reporting services run in the Azure compute emulator, together with the application server. Therefore, there are no SSRS service administration prerequisites. After the reports are deployed to the local reporting services, you can access them from the client.

Developing application reports

Developing a report in the current version is easier than it is in AX 2012, because you can create and validate a reporting solution entirely in Visual Studio. The following table describes how the application simplifies the basic procedure for adding an automatic design report that's based on a query.

Expand table

AX 2012	The current version of the application
1. In the application, create a query in the Application Object Tree (AOT). 1. In Visual Studio, create a reporting project, and add the query to it. 1. Edit the report in the Visual Studio model editor. 1. Preview the report design in Visual Studio by using the model editor toolbar. 1. Use Visual Studio to add the report to the AOT. 1. Use the AOT in the client to create a menu item for the report, and add the menu item to a menu. 1. Use the AOT to deploy the report to the report server. 1. Verify the report in the client.	1. In Visual Studio, create a reporting project and the query. 1. Edit the report in Visual Studio. 1. In Visual Studio, add the report to a menu item, and set the menu item as a startup object. 1. Use the AOT to deploy the report to the report server. 1. Press Ctrl+F5 to verify the report in the application. **NOTE:** There's no longer a separate preview of the report design from the model editor. 1. When the whole solution is completed, deploy it to the cloud in one package.

>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Finance and operations apps include access to hundreds of standard, business-ready fonts for documents rendered by the cloud-hosted service.

This portfolio continues to grow as the service expands into new regions and industries. The service doesn't support installing custom fonts in customer environments.

The following list captures the portfolio of font families available for documents produced using SQL Server Reporting Services (SSRS) services in finance and operations apps.

Supported fonts for application version 8.3 with Platform update 32 or later

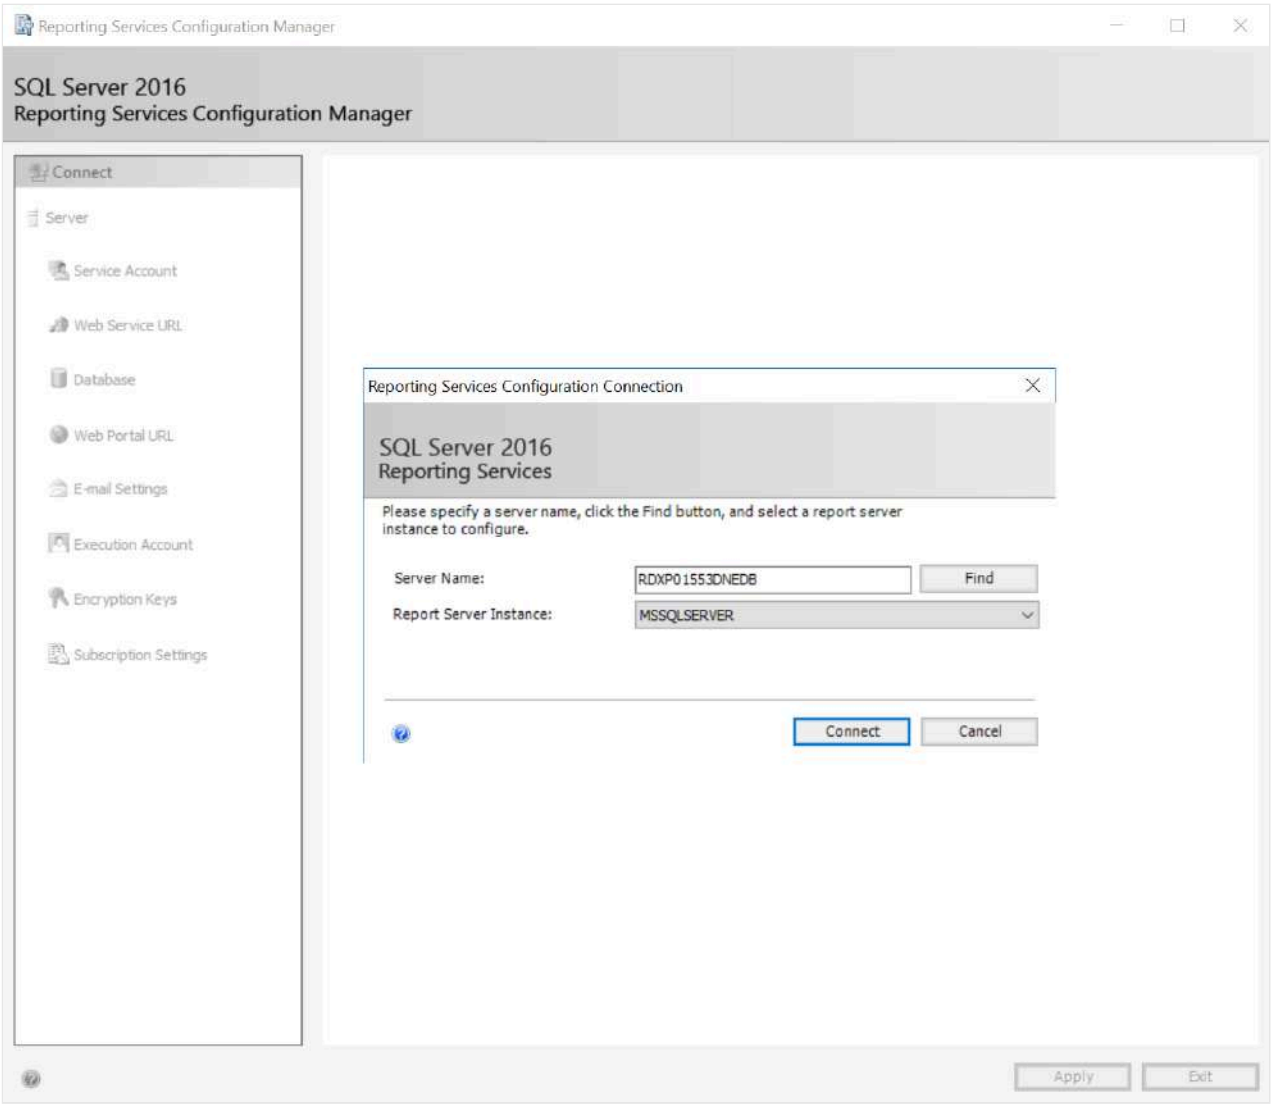
Configure SQL Server Reporting Services for on-premises deployments

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use the steps in this article to configure SQL Server Reporting Services (SSRS) for your Microsoft Dynamics 365 Finance + Operations (on-premises) deployment.

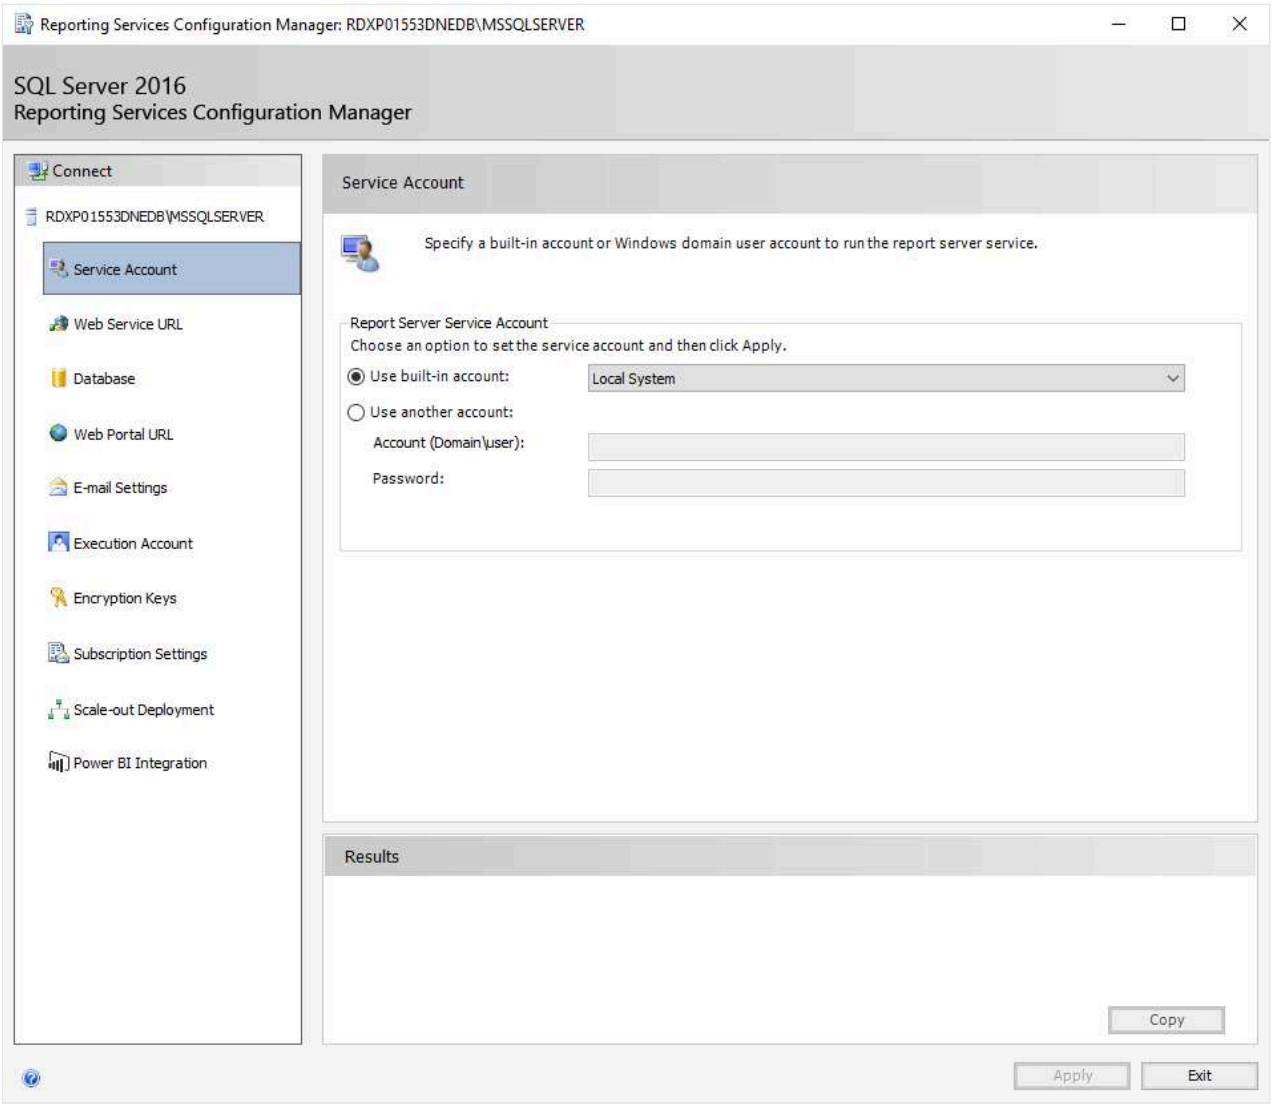
> **Important**
>
> Only follow this guide if you deployed your environment by using a base deployment older than Application version 10.0.17 (with Platform update 41).

1. Open the Reporting Services Configuration Manager application.
2. Leave the default **Server name**, which should be the name of the current machine, and the **Report Server Instance**, **MSSQLSERVER**.
3. Select **Connect**.

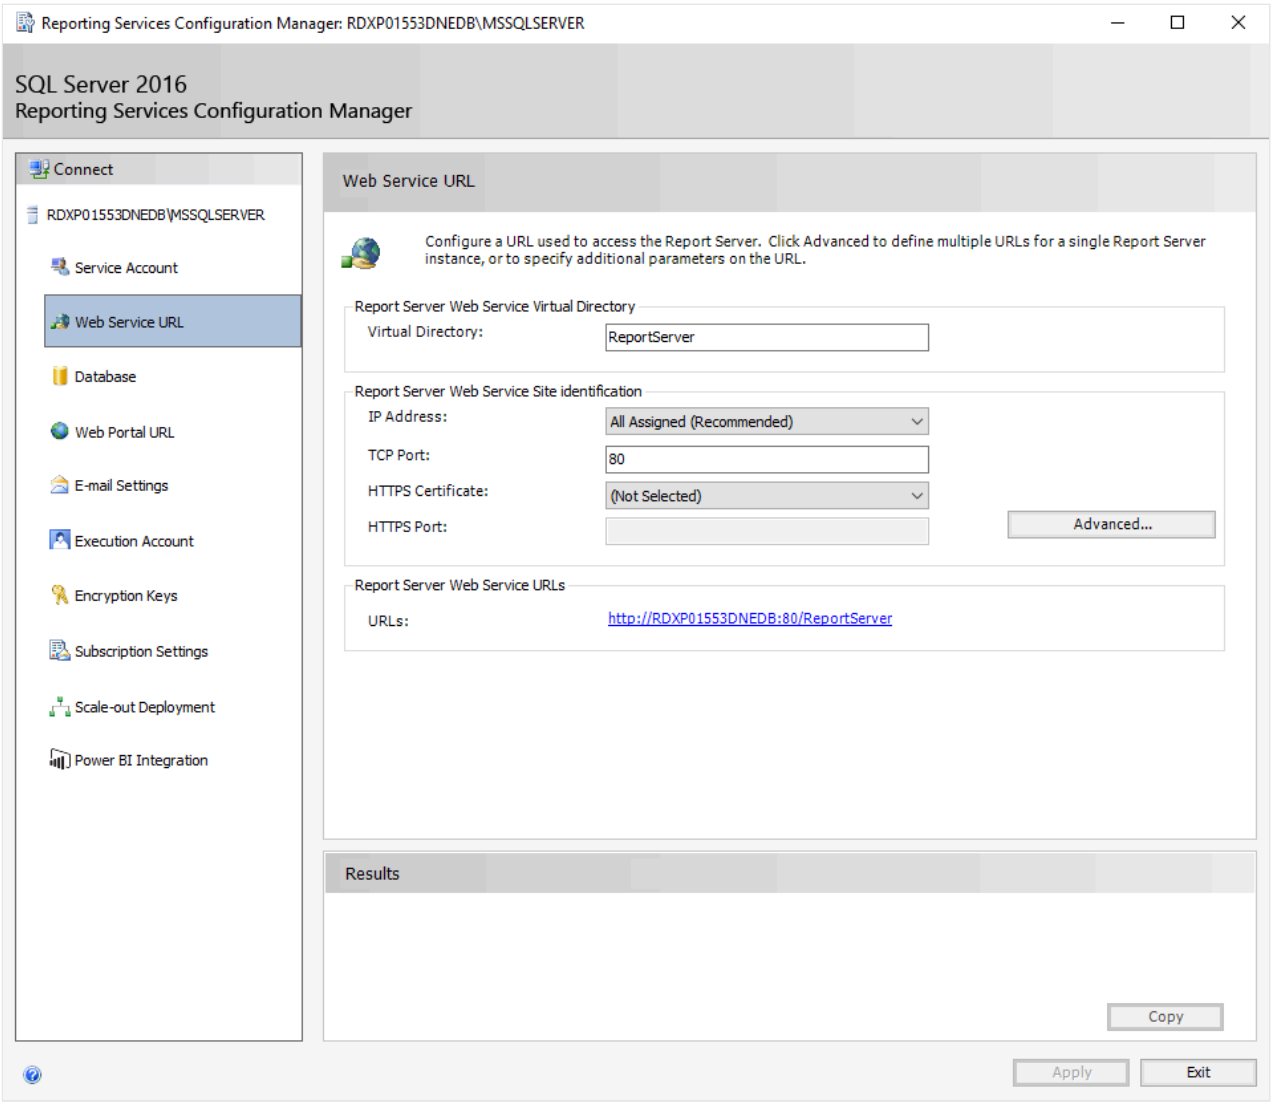


4. Select the **Service Account** tab and verify that the settings match the following graphic.

> ⓘ **Note**
>
> SQL Server Reporting Services 2019 no longer supports choosing the **Local System** account. Instead, use the **NETWORK SERVICE** account.

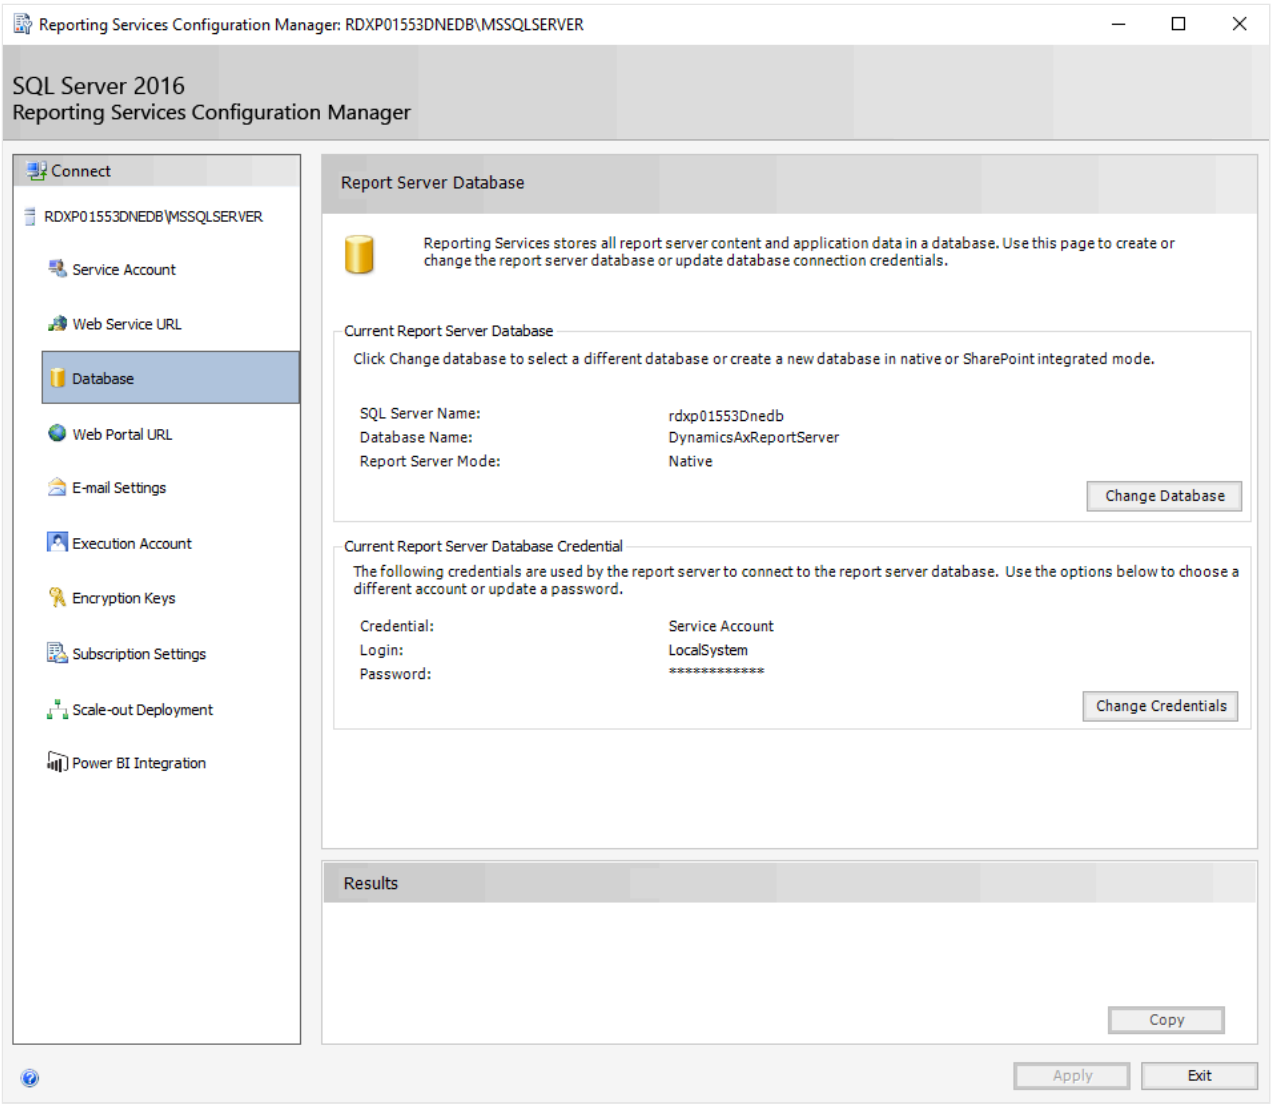


5. Select the **Web Service URL** tab and verify that the settings match the following graphic.



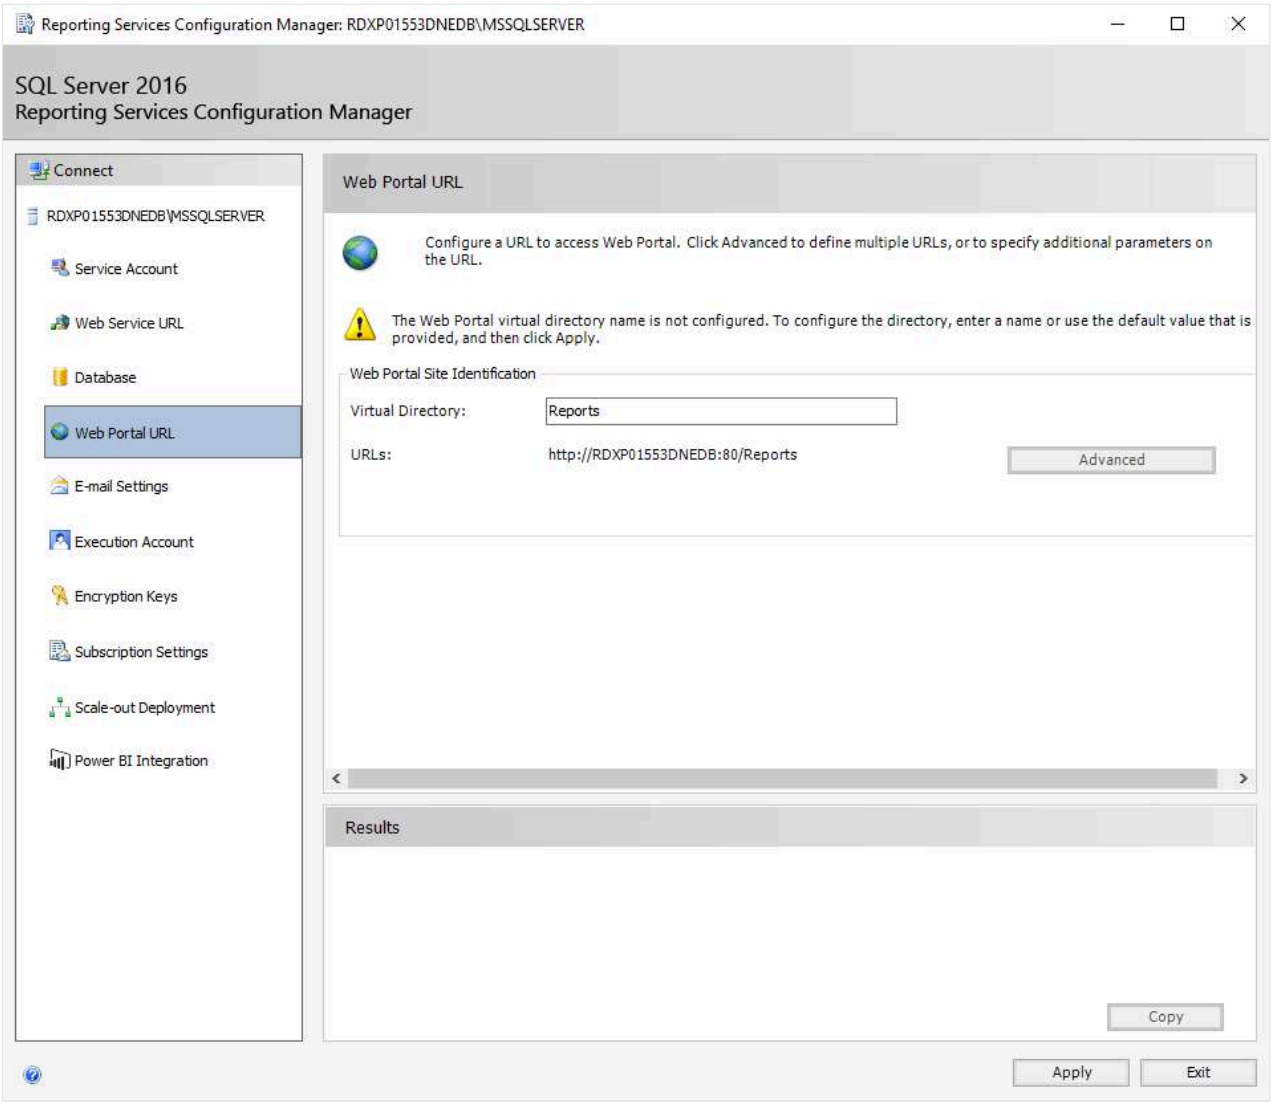
6. Select the **Database** tab and verify that the **Database Name** and **Credential settings** match the following graphic.

> **Note**
>
> You need to create a new database. To do this, select **Change Database**, and then verify that the new database name is: **DynamicsAxReportServer**.

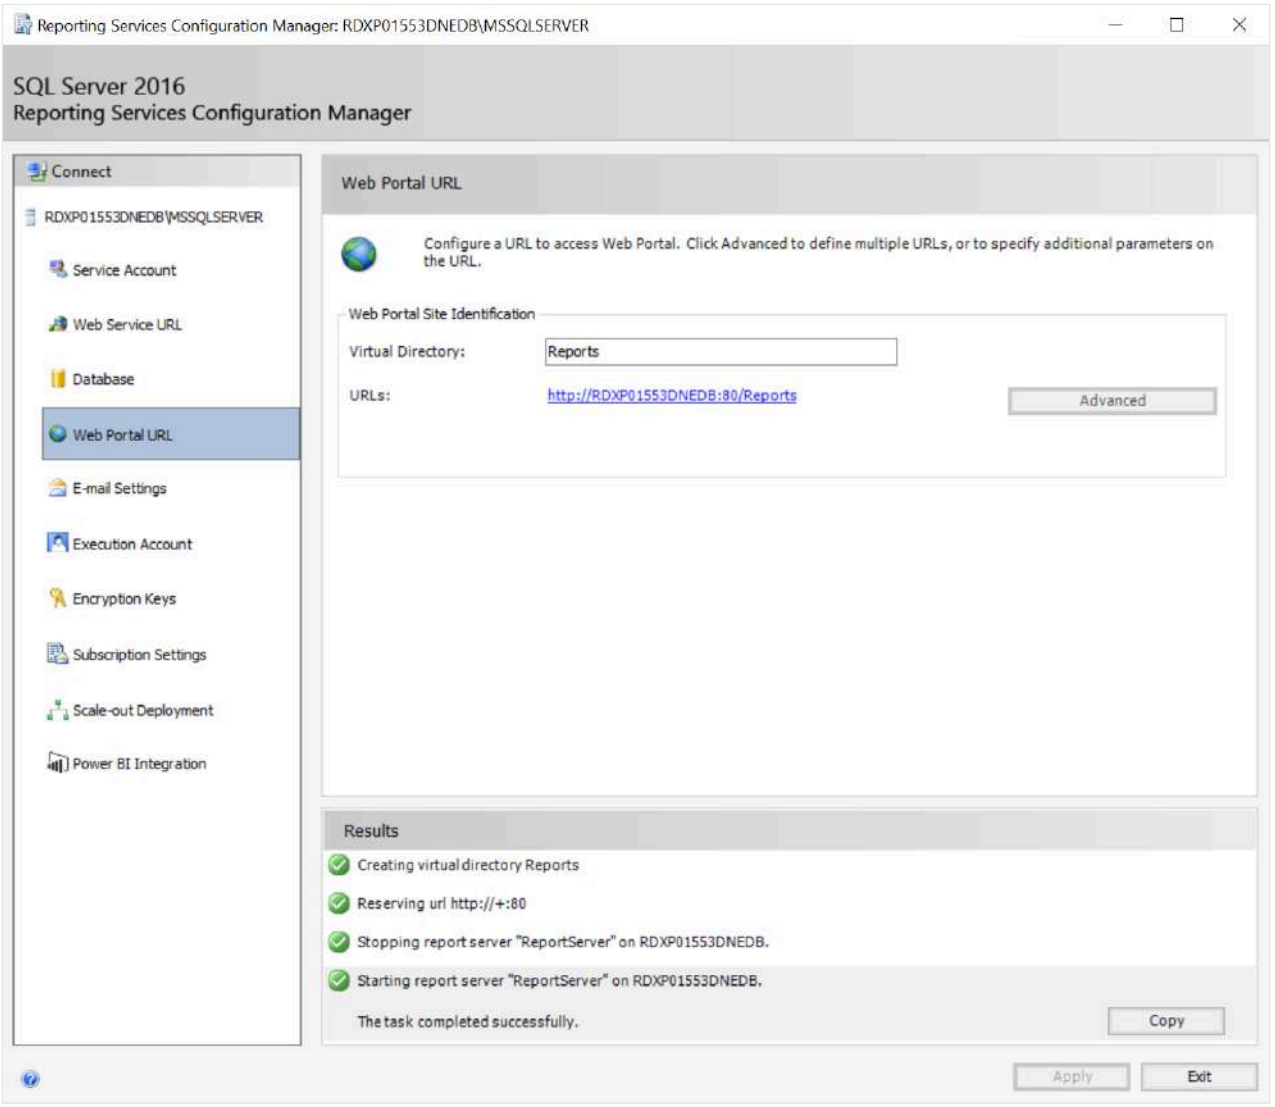


7. Select the **Web Portal URL** tab and verify that the settings match the following graphic.

> ⓘ **Note**
>
> You must select **Apply** to create and properly configure the portal.

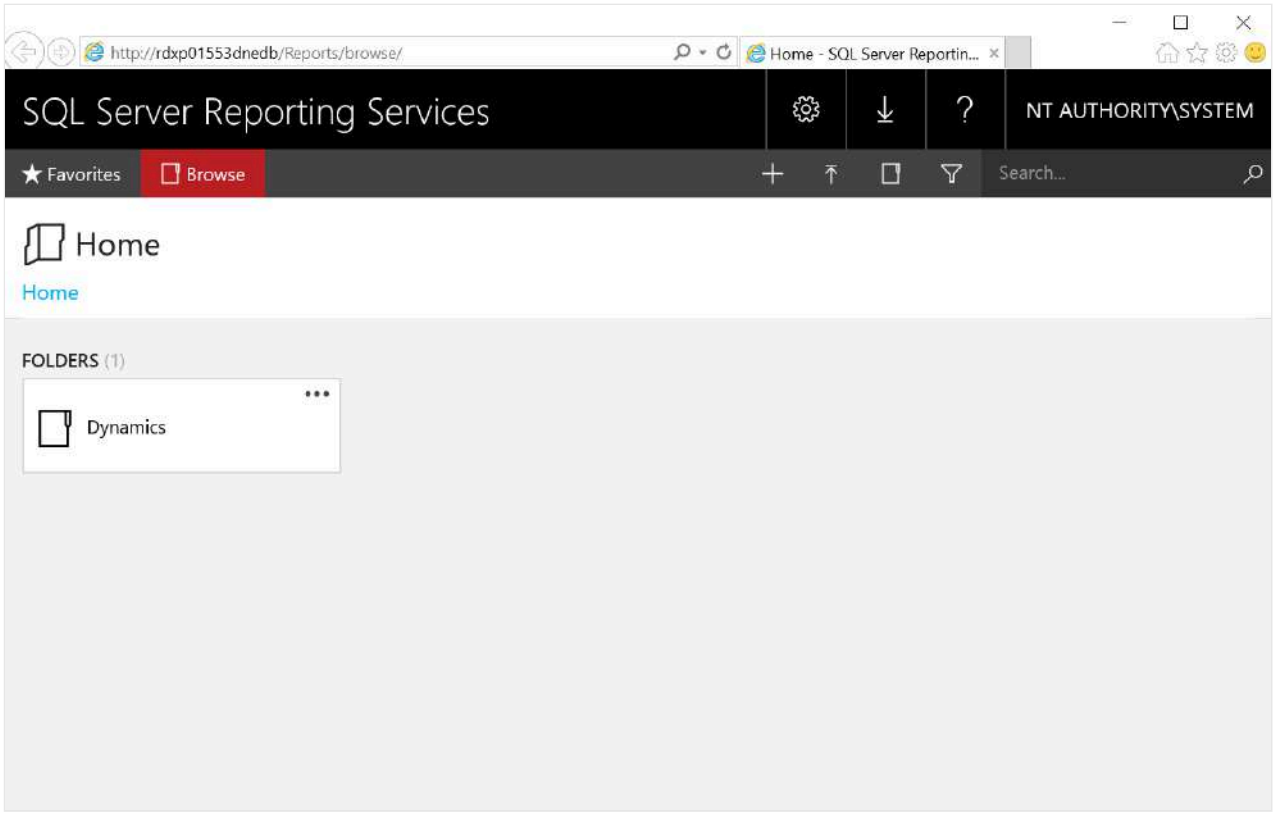


After the portal is configured, the **Web Portal** tab matches the following graphic.

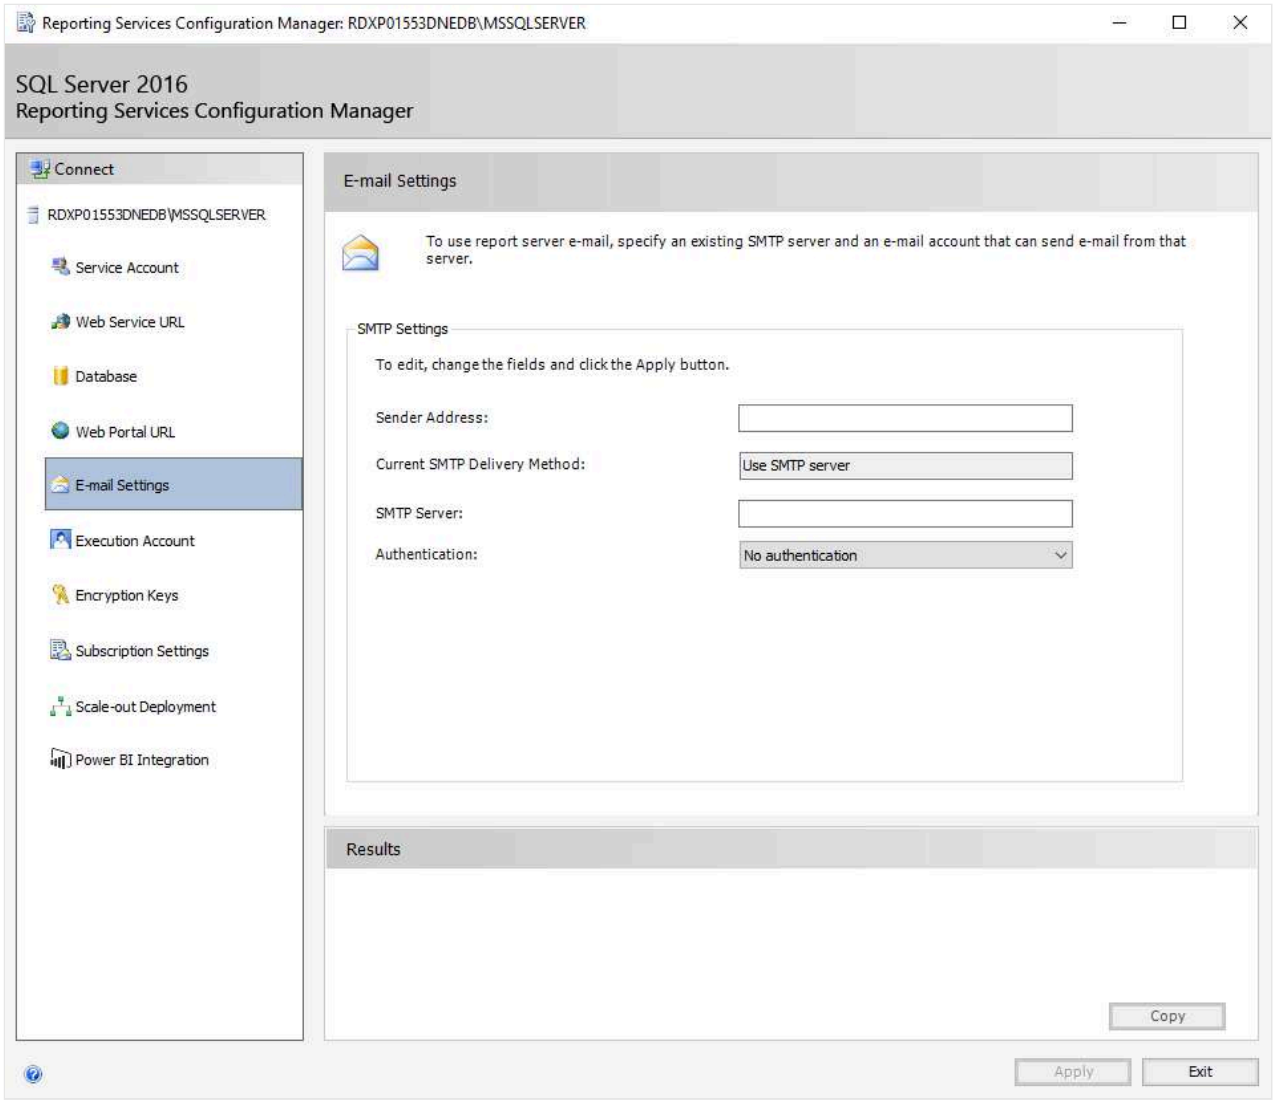


8. Select the reports URL to view the SQL Server Reporting Services web portal.

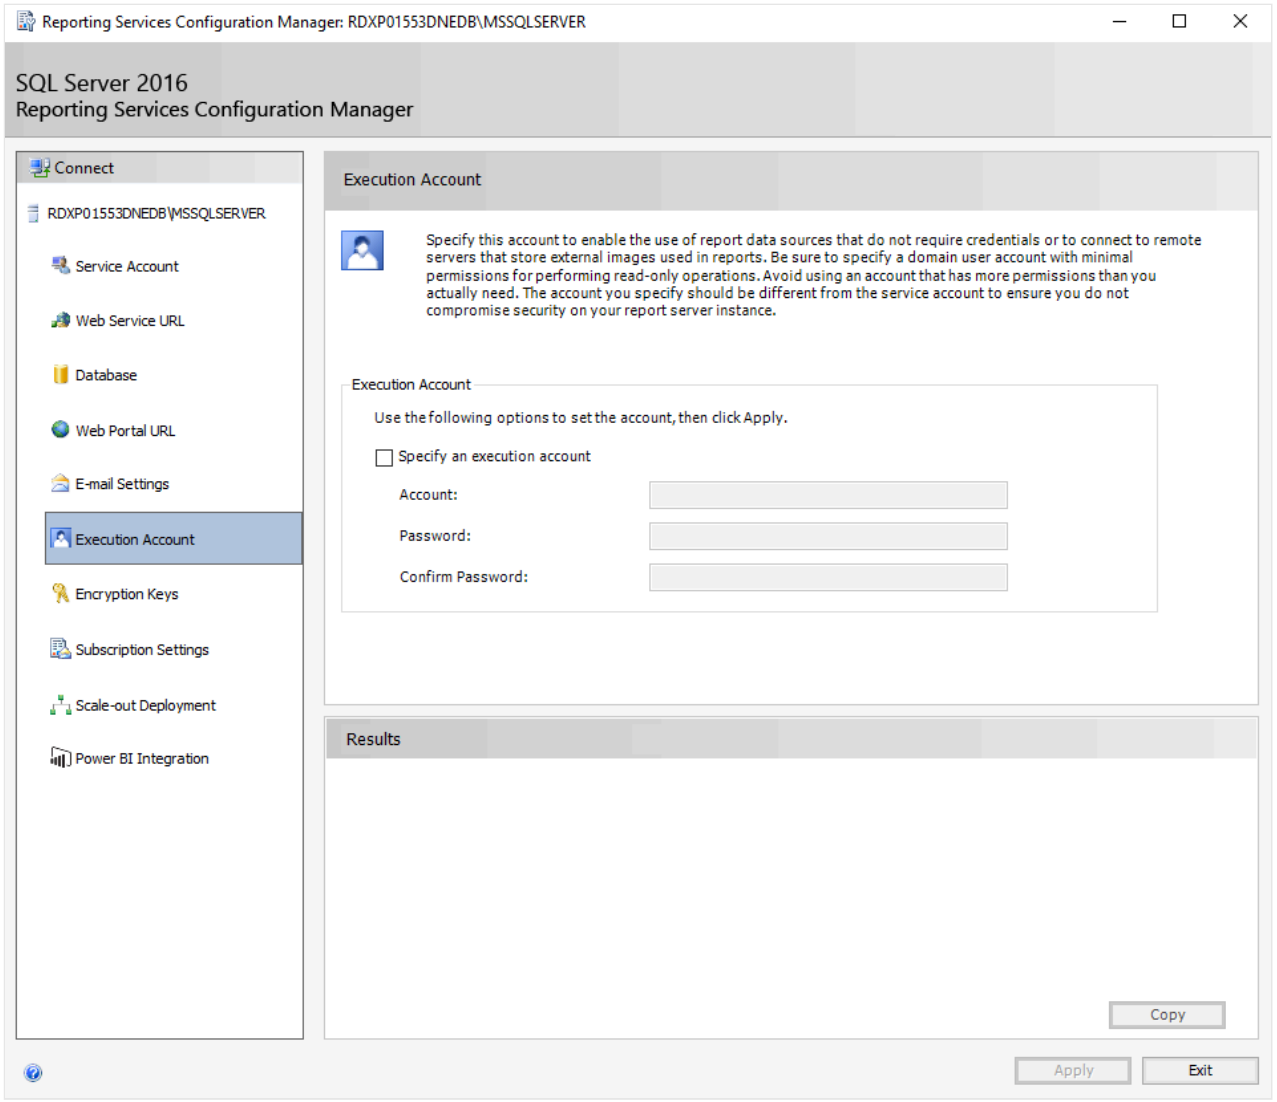
9. When you're in the portal, create a new folder named **Dynamics**.



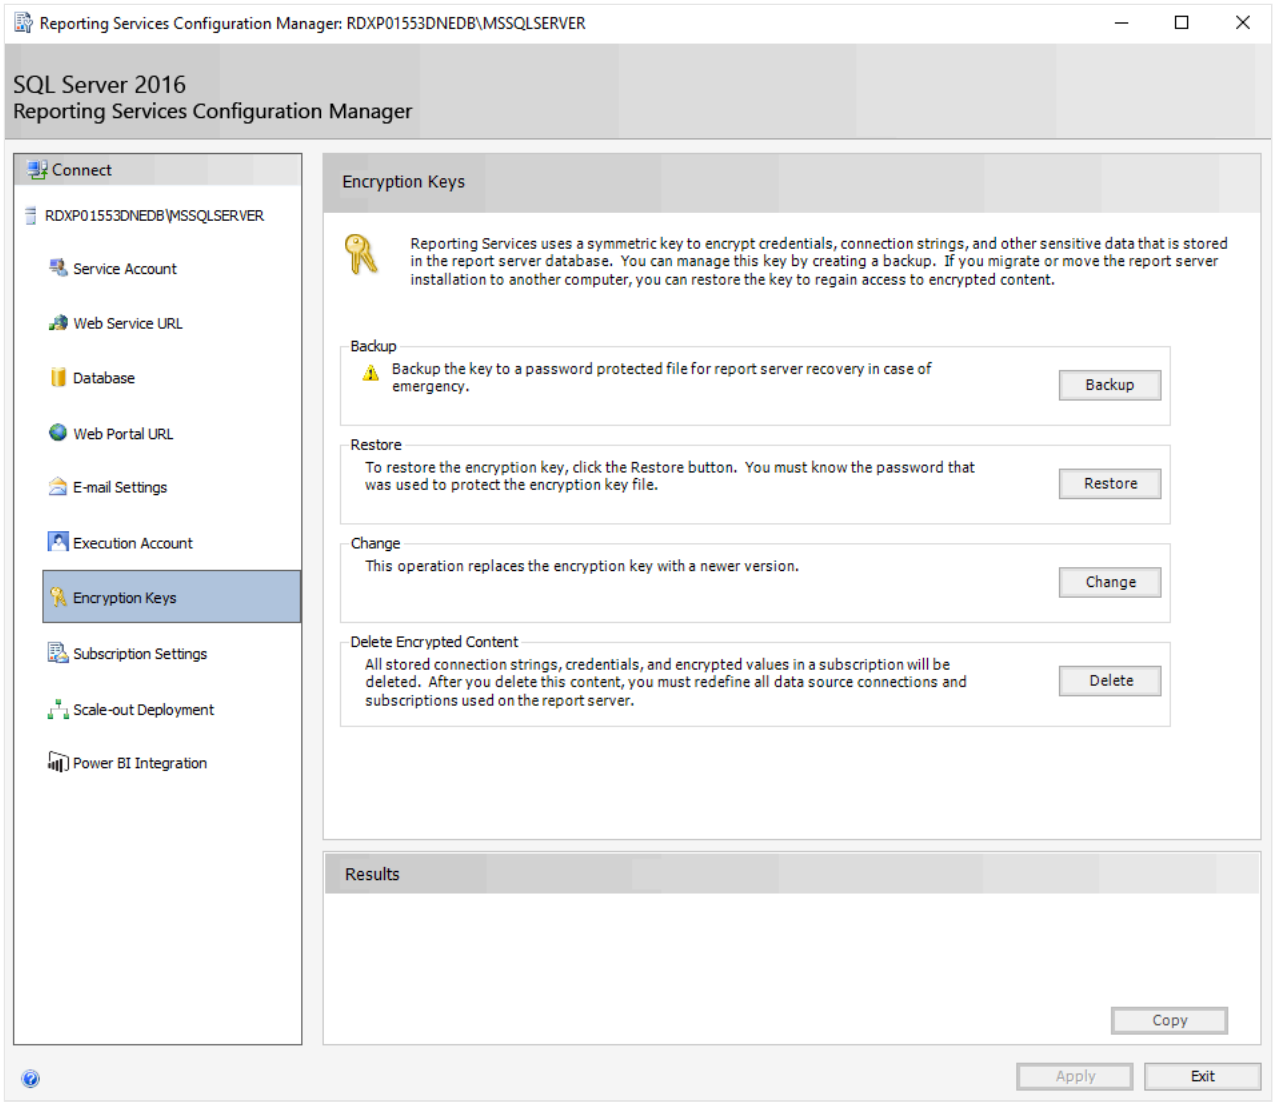
10. In the **Reporting Services Configuration Manager**, select the **E-mail Settings** tab and verify that the settings match the following graphic.



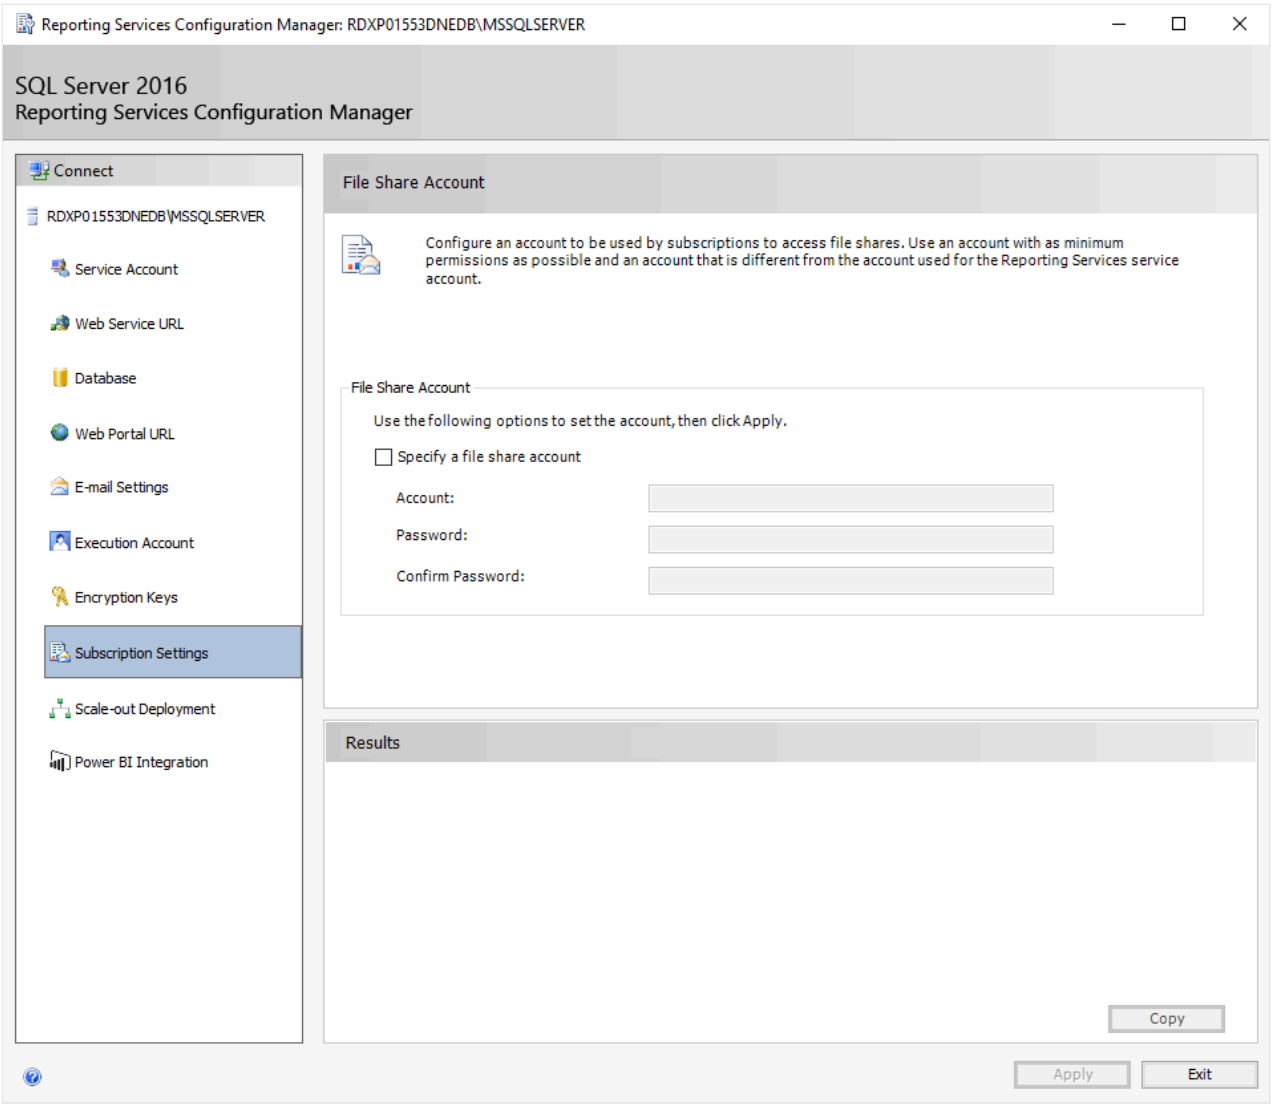
11. Select the **Execution Account** tab and verify that the settings match the following graphic.



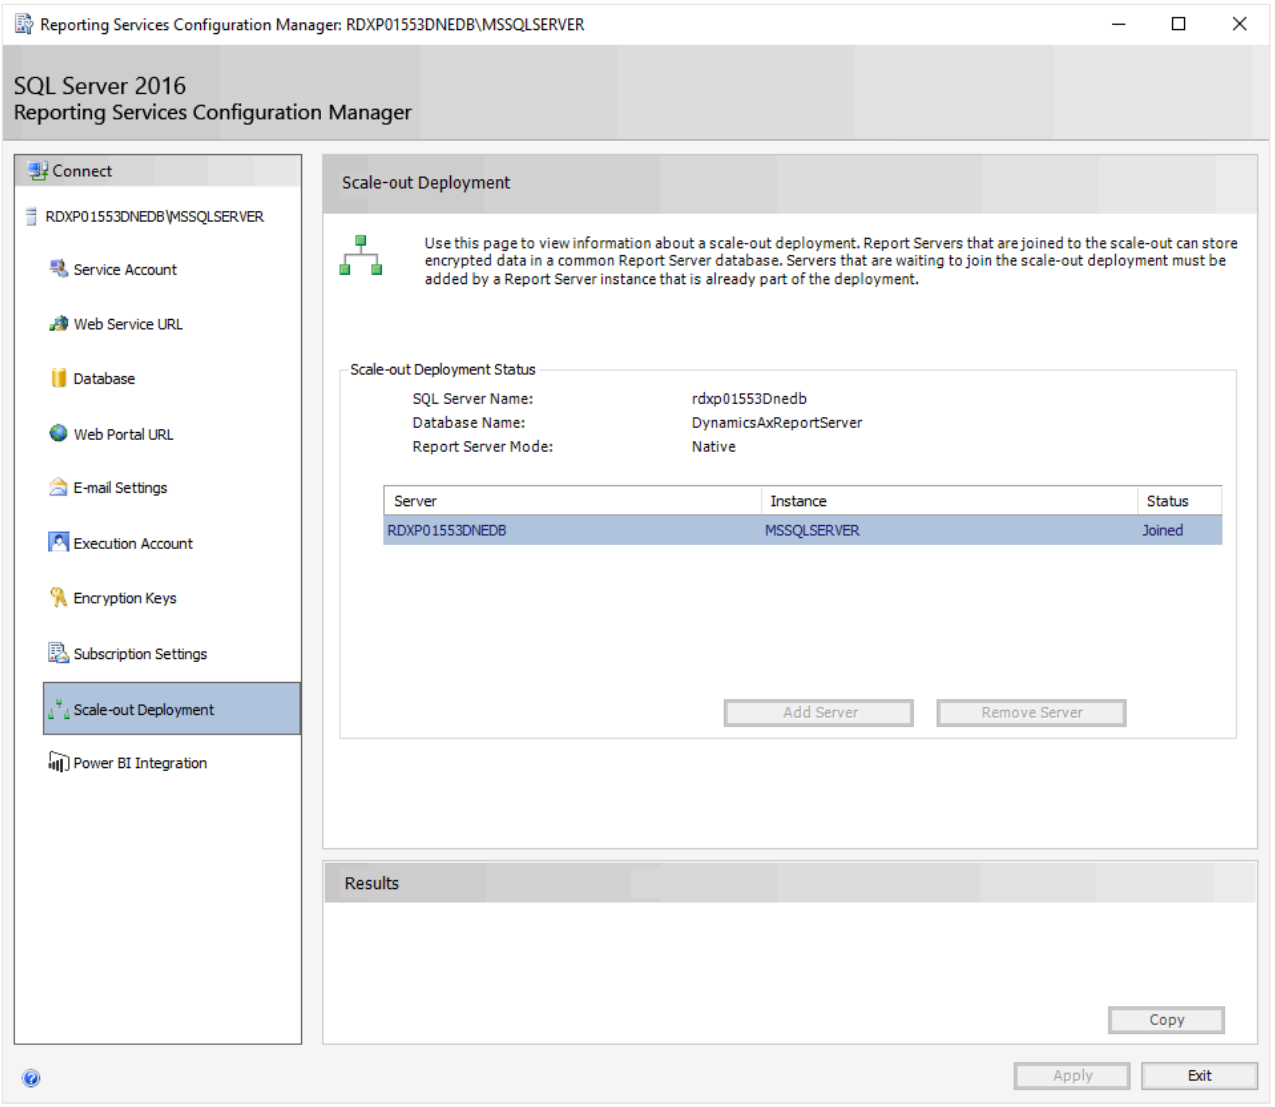
Don't change the default settings on the **Encryption Keys** tab.



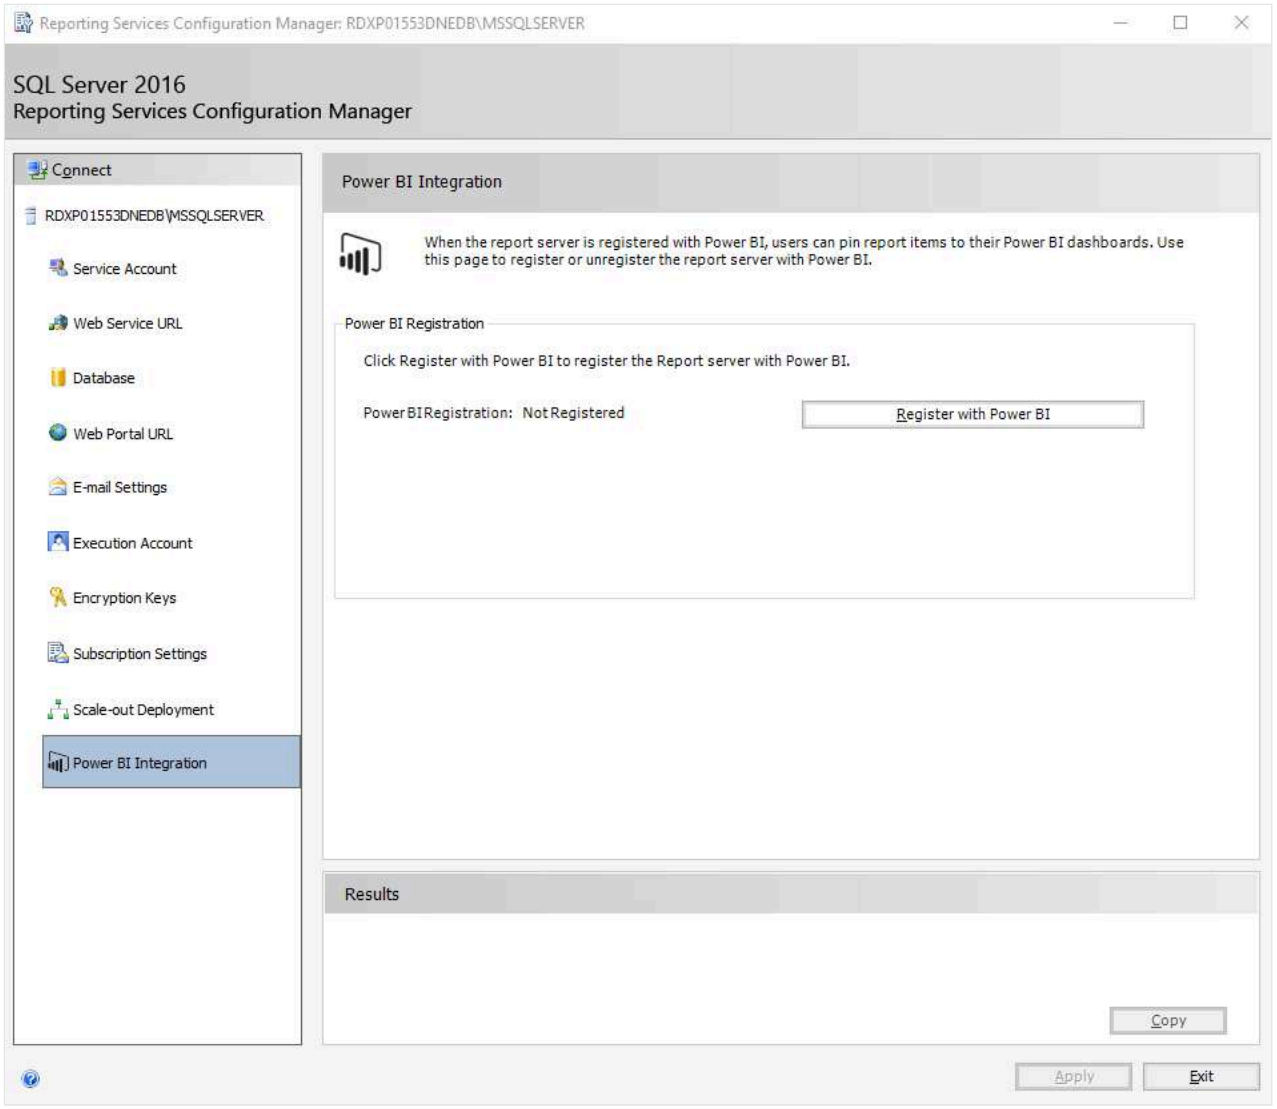
12. Select the **Subscription Settings** tab, and verify that the settings match the following graphic.



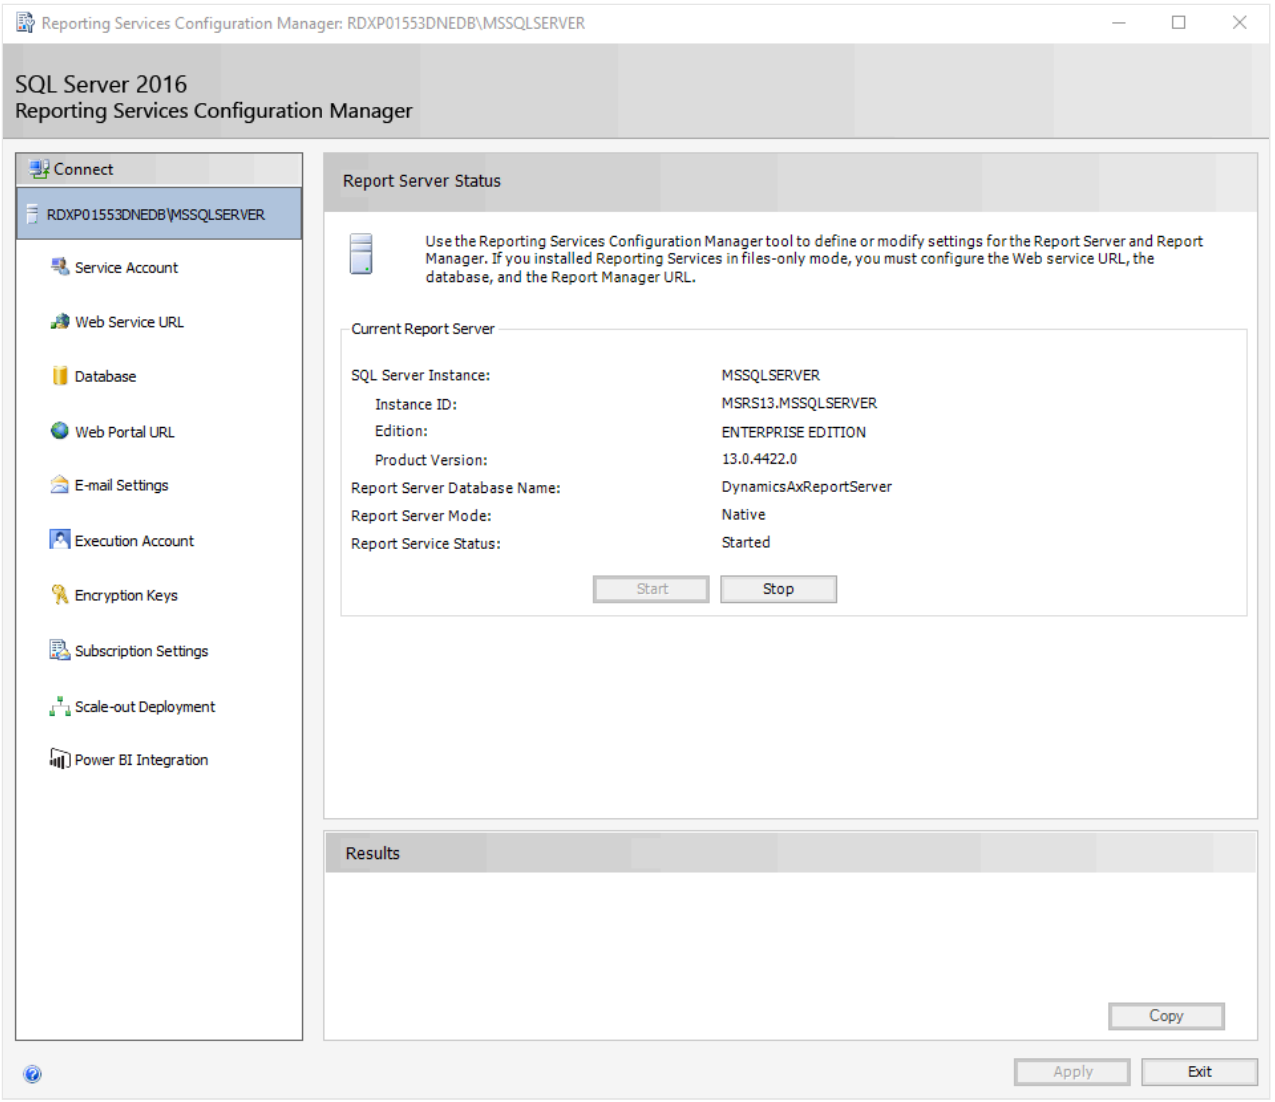
Don't change the default settings on the **Scale-out Deployment** tab.



Don't change the default settings on the **Power BI Integration** tab.



13. Select **Exit** to close the **Reporting Services Configuration Manager**.



14. For SQL Server 2019 only, you need to manually grant **NETWORK SERVICE** the permissions to read the private keys of these certificates:

    - DataEncryption
    - DataSigning
    - ReportingService

Reduce long-running transactions in TempDB preprocessing reports

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to reduce long-running transactions and tempDB transaction log pressure caused by preprocessing SSRS reports that use the TempDB pattern, by opting out of the reporting framework's transaction scope.

This article is for anyone who maintains custom SSRS reports and whose Report Data Provider (RDP) class extends `SrsReportDataProviderPreProcessTempDB`.

Applies to

Platform Update 55 and later. Every currently supported environment includes the fix.

Background

Reports that use the TempDB preprocessing pattern stage their results in temporary database tables during a preprocessing step. By default, the reporting framework wraps the entire preprocessing step in a single transaction scope and commits only after preprocessing finishes.

On cloud deployments backed by Azure SQL, the tempDB transaction log is a shared resource. While a long-lived transaction stays open, log space can't be released. For reports that process large data sets, this behavior can hold a transaction open for the full duration of preprocessing, delay log truncation, and in extreme cases, fill the tempDB log and impact other workloads on the same database.

What this capability changes

The framework exposes an opt-in switch (`parmSkipReportTransaction`) that lets a report data provider skip the framework's transaction scope. When a report opts in:

- The framework no longer opens transactions around your `processReport` method.
- Each statement you execute commits independently.
- Transaction log space is released as work progresses, instead of being held until the end of preprocessing.

This change isn't a runtime optimization for the report itself. The report does the same amount of work in roughly the same amount of time. What changes is the transaction boundary, which improves the health of the shared environment.

When to use it

For any report that extends `SrsReportDataProviderPreProcessTempDB` and processes meaningful data volumes, **opting in is the recommended default**. The legacy behavior (a framework-managed transaction wrapping the entire preprocessing step) exists for historical reasons, not because it's the better design. Holding a single transaction open during preprocessing increases tempDB log pressure and can contend with other operations running in your environment at the same time: batch jobs, other reports, and interactive users.

The only valid reason to keep the legacy behavior is when your preprocessing step has a genuine business requirement for atomic rollback of the entire step, and the work can't be restructured into explicit transaction boundaries. This situation is uncommon. "It's easier to leave it as-is" isn't a valid reason. The transaction management you take on is straightforward and is fully covered in the next section.

How to opt in

Override `parmSkipReportTransaction` in your report data provider so it returns `true`. The recommended pattern mirrors the platform team's reference implementation:

X++

```
public class MyLargeReportDP extends SrsReportDataProviderPreProcessTempDB
{
    public boolean parmSkipReportTransaction(boolean _skipReportTransaction =
skipReportTransaction)
    {
        skipReportTransaction = true;
        return skipReportTransaction;
    }
```

```
    public void processReport()
    {
        // Your preprocessing logic.
        // See "Manage your own transactions" below.
    }
}
```

The override is read at run time, so the change is scoped to the report data providers you explicitly opt in to. All other reports continue to behave as before.

Important: manage your own transactions

When you opt in, the framework removes **two** transactions that previously surrounded your `processReport` call:

Expand table

Transaction	What it covered	What replaces it when you opt in
Ambient transaction (`ttsbegin` / `ttscommit`)	Regular table operations in `processReport`	You wrap them yourself with `ttsbegin;` / `ttscommit;` where needed.
User connection transaction (`userConnection.ttsBegin()` / `ttsCommit()`)	Operations against tables attached to the report's user connection (the temp tables)	You wrap them yourself with `parmUserConnection().ttsBegin()` / `ttsCommit()`.

The most common mistake is updating or deleting a user-connection-bound record without an open transaction on that connection. You see the following error message:

> Cannot select a record for update when the transaction is not started on the user connection attached. You need to begin transaction on the user connection first.

A plain `ttsbegin;` doesn't resolve this issue. The data tables are on the user connection, not the ambient connection. Begin the transaction on the user connection explicitly:

X++

```
public void processReport()
{
    UserConnection userConnection = this.parmUserConnection();

    // Wrap operations that update or delete user-connection-bound records.
    userConnection.ttsBegin();
    // selectForUpdate / update() / delete() against temp tables
```

```
    userConnection.ttsCommit();

    // Wrap operations against regular (non-temp) tables if they need atomicity.
    ttsbegin;
    // updates against regular tables
    ttscommit;
}
```

Guidelines:

- Prefer set-based operations (`insert_recordset`, `update_recordset`, `delete_from`). They minimize the time any transaction stays open.
- Watch for silent row-by-row downgrades. A set-based statement that is internally downgraded to row-by-row execution (for example, because a data event handler is registered on the table) reintroduces the same long-running pattern you were trying to avoid. Where possible, restructure the code or remove the cause of the downgrade.
- Keep each explicit transaction as small as possible. Wrapping the whole `processReport` body defeats the purpose of opting in.

How to opt out

Opt-out is the default. To revert a report you previously opted in, change the override to return `false` or remove the override entirely, and redeploy.

Things to keep in mind

- **No automatic rollback.** A failure partway through preprocessing no longer rolls back the whole step. If a section needs all-or-nothing behavior, define an explicit transaction boundary around it (on the right connection).
- **Review customizations.** Code paths that update or delete records during preprocessing are the most common source of the user-connection error. Audit them before enabling the switch.
- **Validate report output.** Confirm the report produces the same output as before, particularly in failure and cancellation scenarios.

Recommended rollout

Roll out the change gradually so you can isolate and revert any individual report quickly.

1. **Development / test.** Opt in one report at a time. Exercise the update/delete paths and any failure paths. Confirm the report produces correct output.

2. **Sandbox (UAT) with production-like data.** Validate correctness at realistic scale and confirm that the long-running transaction is gone.
3. **Production.** Enable for a small set of high-impact reports first, then expand.

Common issues

Expand table

Symptom	Likely cause	Action
"Can't select a record for update when the transaction isn't started on the user connection attached."	An update or delete on a user-connection-bound table is no longer inside a transaction.	Wrap the affected statements in `parmUserConnection().ttsBegin()` / `ttsCommit()`. A plain `ttsbegin` doesn't resolve this issue.
Partial or inconsistent data after a failure	No explicit transaction boundary around logic that needs atomicity.	Add an explicit transaction block around the section that must be all-or-nothing, on the correct connection (ambient or user connection).
Report compiles but `parmSkipReportTransaction` is reported as unknown.	Environment is on a platform build older than PU55.	Update the environment to a current platform release.

Last updated on 06/25/2026

Document Reporting Service in Dynamics 365 applications

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Reporting scenarios in ERP

The Document Reporting Service bundled with finance and operations apps provides user tooling to facilitate two basic user functions, or generic scenarios, in enterprise resource planning (ERP): **document generation** and **business intelligence (BI) and analytics**. These generic scenarios represent the two most frequently used methods for accessing business data.

- **Document generation** – The production of structured documents, where the primary purposes are often printing and bulk email distribution.
- **BI and analytics** – Interactive visualizations that are based on aggregations and that contain embedded links to referenced data. Users rely on these visualizations to identify patterns and trends in large amounts of data.

Although the Document Reporting Service continues to be the ideal tool for bulk production of business documents, it lacks the extensibility options that power users require so that they can adapt analytical views and account for frequent changes in the business environment. At the same time, the Microsoft Power BI service is recognized as an industry leader in the delivery of powerful analytics for businesses of all sizes. Integration options for finance and operations apps and the Power BI service are available to accommodate seamless exploration of customer business data.

> **Note**
>
> When the platform updates for version 10.0.12 are released, the Dynamics 365 service discontinues support for the Report Viewer control that facilitates BI and analytics

interactions with paginated reports. Instead, reports that the Document Reporting service renders on the screen use the embedded PDF viewer. For more information about the embedded PDF viewer, see Preview PDF documents with an embedded viewer.

Comparison of report scenarios

In document generation scenarios, a simple business activity, either automated or manual, can trigger the production of between one and hundreds of documents. These documents often include graphics with commercial branding. You can distribute the documents to both internal and external recipients by using predefined delivery routing instructions.

The following table compares the fundamentals of the two reporting experiences.

Expand table

Item	Document generation	BI and analytics
Display format	PDF and Office documents	HTML
Data volume	One to hundreds of rows	Tens of thousands of rows or more
Interactive features	Printing, text search, and sharing	Drill-through, drill-down, and nested regions
Data source	Transactional database	Data warehouse
Report author	Developer	Power user
Layout	Structured, predefined layout	Adaptive, flexible layout
Recommended tooling	Document Reporting Service/configurable Office documents	Power BI.com/analytical workspaces

Enhancements in paginated reporting

Using PDFs to interact with documents that the Document Reporting Service renders and bundles with finance and operations apps provides several advantages:

- **Reports appear on the screen more quickly.** Users benefit from improved performance when reports appear on the screen. This performance improvement includes a reduction in the number of progress bars, so that reports are faster.
- **Service reliability is enhanced.** The latest Document Reporting Service architecture delivers the power of the cloud scale to customer environments. The service includes automatic

scaling to help maximize resource utilization.

- **Printed output has higher fidelity.** Documents appear in PDF formats to provide consistency with printer output.
- **Local devices can print documents.** You can maintain user identity when you send documents directly from your browser to a printer. You can use the built-in user options on the control toolbar to help secure print jobs when you print documents.

For more information about how to preview the embedded PDF viewer in environments, see Preview PDF documents with an embedded viewer.

Turn off BI and analytics in one-box environments

In the platform updates for version 10.0.11, developers can preview existing solutions by forcing the local Document Reporting Service to render RDL while the BI and analytics features are turned off. This viewing mode is referred to as **RDL sandboxing**. You can turn it on or off by using Windows PowerShell commands.

Follow these steps to turn on RDL sandboxing in your local one-box environment.

1. Sign in to your one-box environment that uses version 10.0.11 or later.
2. Open Windows PowerShell, and go to `C:\AOSService\PackagesLocalDirectory\Plugins\AxReportVmRoleStartupTask\`.
3. Run the **UpdateRDLSandboxRule.ps1** command. Here's a list of the parameters:
    - **ConfigPath** – If SQL Server Reporting Services (SSRS) isn't deployed in the default location, specify the configuration location.
    - **RemoveRules** – Set this parameter to remove the rules.
    - **ForceUpdate** – Set this parameter to force the rules to be re-created.
    - **LogDir** – Specify a location to write the log to. The default location is the location of the **UpdateRDLSandboxRule.ps1** command.

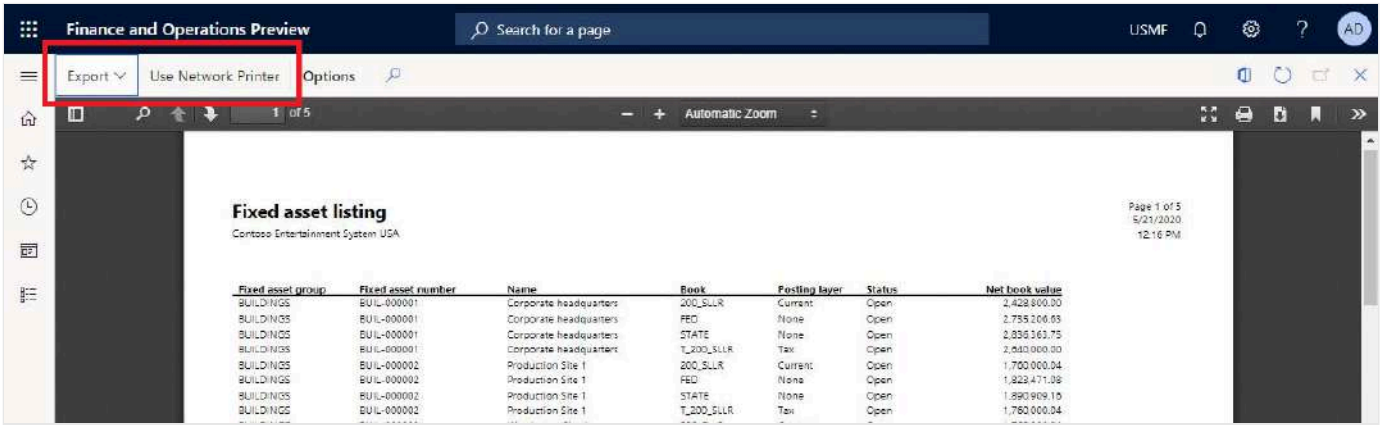
Document reporting preview options

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Finance and operations apps offer an expanded collection of options to use while previewing documents within the embedded PDF viewer. This article describes the **Export** and **Network Printer** options.

Overview

The efficient publication and distribution of documents is not only a key component to many operations, but it's also critical to daily business functions. Use documents to capture transaction details and represent agreements between two parties. Business documents come in many forms, from quotations to sales invoices used in the packing slip process, which ultimately produces receipts and customer statements. The document reporting preview options empower you to quickly take the appropriate action on documents.



File export

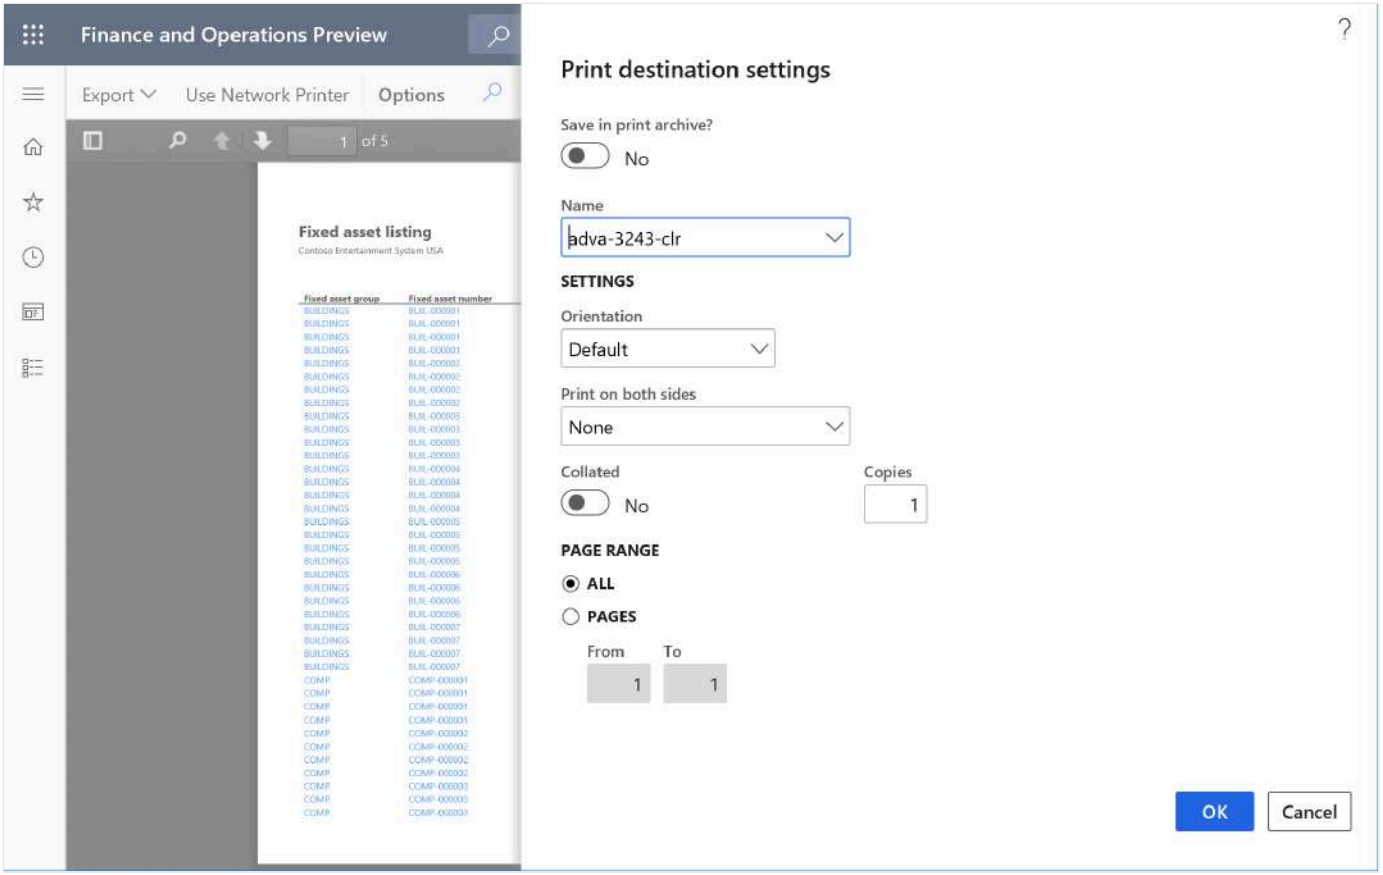
Additional user options replace functions previously supplied by the HTML-based **Report viewer** control. Use these toolbar options to export files to the various supported formats. This list includes Microsoft Word, Excel, HTML, CSV, and more. To ensure a consistent layout with the

printer output, the new modern experience displays documents by using the PDF pagination rules. For more information, see Pagination in reports.

Network printing

You can choose to print on locally connected devices by using the **Print** button or send documents directly to network printers by using the toolbar option. With the network print option, you can initiate print instructions to network connected printers while working remotely from nearly any internet connected device, including mobile phones.

Use the toolbar option to choose the network printer and establish print settings.



Access preview options

Use the Feature Management area to access the document preview options. The two additional features are:

- **Enable Export on Report PDF viewer**
- **Enable Network Printing on Report PDF viewer**

Select these features, then select **Enable now** to start using the new user options. For more information, see Feature management overview.

Last updated on 11/26/2025

Document printing overview

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

You can print documents by using either a local printer or a network-connected device. This article provides an overview of how documents are printed.

Printing overview

The application provides integrated services and client applications that make it easy to generate, store, and distribute documents that support business activity. You can print documents by using either a local printer or a network-connected device. In addition, you can export pages and reports directly from the client as PDF files or Microsoft Office documents. Finally, the distributed workload lets you print business documents directly from a mobile device by using network resources. Although printing requirements might vary, all industries typically must create hard copies of business documents by using the application. Printing documents on network devices from hosted applications presents a unique set of challenges. Here are some examples:

- Print drivers might not be available on the user's device.
- The user's device might not be connected to the corporate network.

By using a dedicated host and following a few easy steps, system administrators can configure deployments so that users can print directly from business applications on network devices.

Application printing scenarios

The following table describes the three primary printing scenarios.

Expand table

Scenario	Goal	Solution
1. Printing what you see	Print what is currently shown in the browser.	Generate a "print-friendly" version of the webpage for the browser.

Scenario	Goal	Solution
2. Interactive printing	Print a precision document on a locally connected device.	Export a PDF version of the report and download it to the browser.
3. Printing on a network device	Send a precision document to a domain printer device.	Send a precision document to a client application that runs on a server that is hosted in the customer's domain.

Because the solution varies depending on the scenario, applications provide built-in services and tooling to help users accomplish their goals:

- **Scenario 1** is supported by the browser's rendering of the HTML5 client.
- **Scenario 2** uses client applications and Microsoft 365 services.
- **Scenario 3** requires support from client applications and from services that are hosted in Microsoft Azure.

In addition to the platform that you deploy to the Azure subscription, finance and operations applications provide customers with an integrated, first-party Azure application that helps them more easily use domain-hosted devices to print documents.

> ⓘ **Note**
>
> When using the Document Routing Agent to print a report that includes barcodes on a network printer, some printouts might show plain text (for example, *LoadNumber*) instead of the barcodes. This issue can occur because the required font isn't available to Microsoft SQL Server Reporting Services (SSRS). To work around this issue, print the report to the screen and then print the preview document.

Service overview

While documents that the hosted applications produce wait to be printed on a network-connected device, the service stores them in Azure blob storage. The Install the Document Routing Agent to enable network printing uses Azure authentication to establish a secure channel to the Azure services.

Here's the execution sequence:

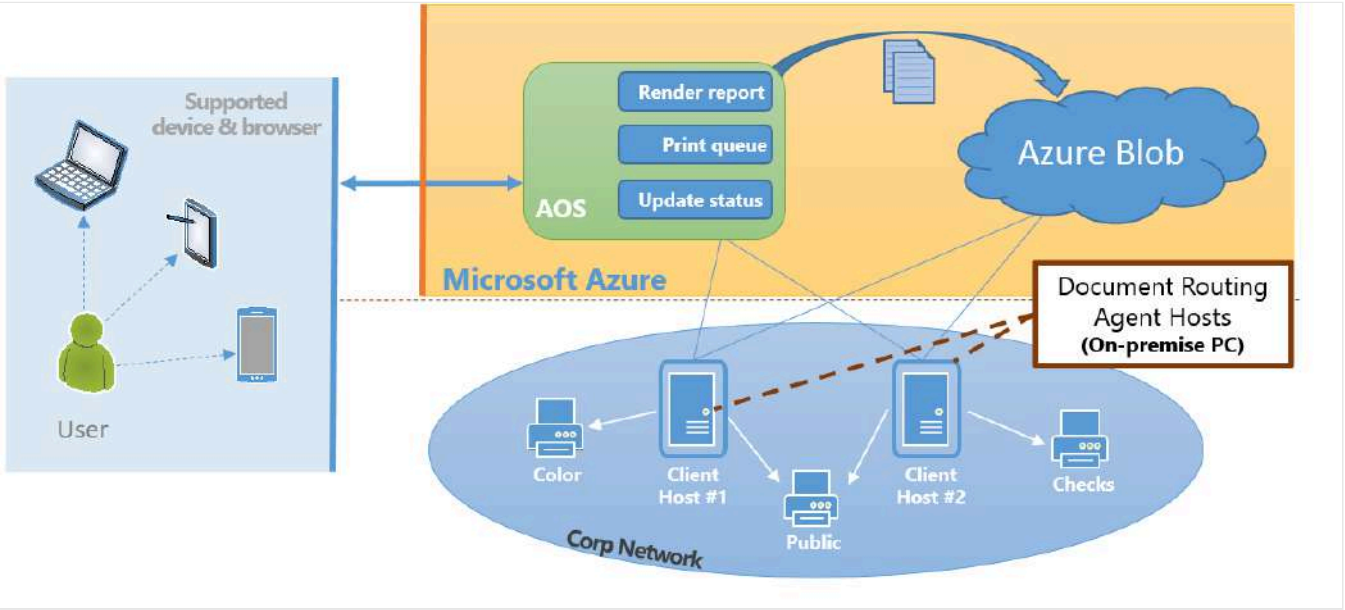
1. Microsoft SQL Server Reporting Services (SSRS) generates the report and stores it in Azure blob storage. The service stores the attached printer settings with the document.
2. The Document Routing Agent queries the Azure Service Bus queue for active jobs.

3. The Document Routing Agent downloads the document and spools it to the network printer.

This client-based solution lets customers manage the scale of their printing needs. Customers who have heavy-volume printing workloads can install many Document Routing Agents to increase the number of concurrent printing operations. Alternatively, some customers require very few installations of the Document Routing Agent to handle their anticipated printing needs.

Service components for network printing

The following diagram shows the basic components that help support network printing operations.



A single printer can be registered with multiple Document Routing Agents. To resolve the printer preferences, the hosted service uses the network path that uniquely identifies every network printer. As a result, even when multiple clients register a printer, it appears as a single selection in the list of printers available in applications.

Install the Document Routing Agent to enable network printing

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to install and configure the Document Routing Agent. The Document Routing Agent is a downloadable application that you can use to enable network printing scenarios. You can enable network printers for specific companies by using in-client administrative pages.

Preparing to install the Document Routing Agent

- Supported on Windows 8.1, Windows 10, Microsoft Windows Server 2012 R2, Microsoft Windows Server 2016, Microsoft Windows Server 2019, Microsoft Windows Server 2022, or Microsoft Windows Server 2025.
- Access to network printing resources requires Active Directory Domain Services (AD DS) authentication.
- When installing the Document Routing Agent, make sure you're signed in as the Admin user.
- The Microsoft Entra ID (Azure AD) account that you use to configure the Document Routing Agent must share the same domain as the Azure tenant.
- The Document Routing Agent requires .NET 4.7.2 or later and Adobe Acrobat Reader 32-bit or 64-bit on the client.
- Configure Adobe client print settings to prevent document scaling.
- The person installing the Document Routing Agent and configuring printers needs to have the "Document routing client" security role.

Network printers that are registered for applications can be used by all legal entities (also known as companies) that are defined in the environment. Network printer settings are company-specific. Therefore, administrators can restrict access, based on the user's active company. For

example, users in the active company might have access to all the network printers that are registered by the Document Routing Agent. However, users in another company don't have access to those printers until access is explicitly enabled for that company.

Key concepts

This article helps you with the following tasks:

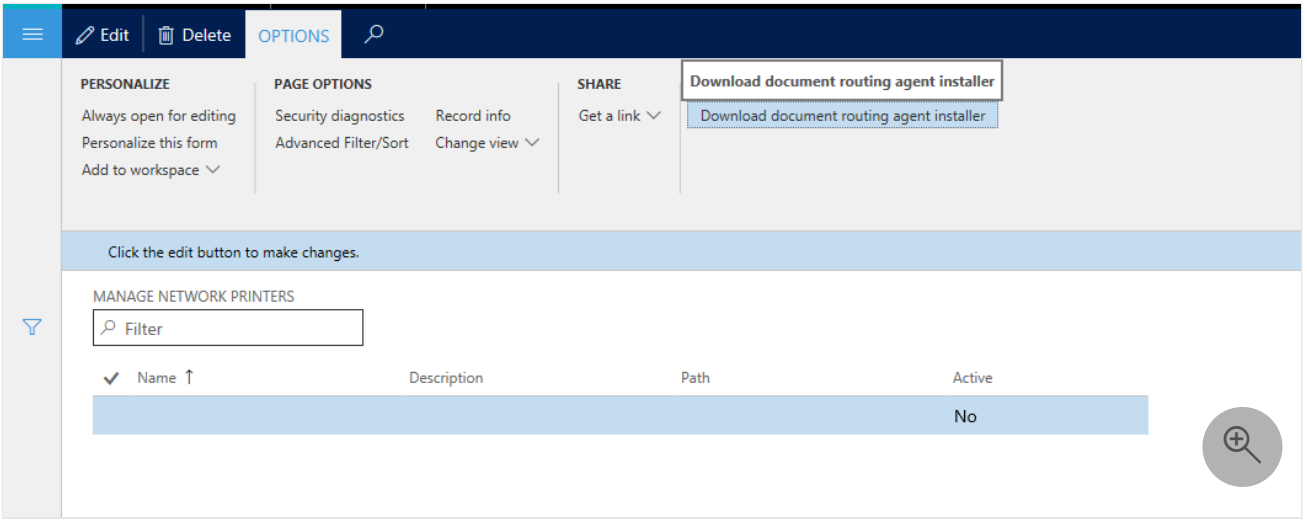
- Identify the key components that are involved in the support for network printing in applications.
- Learn about the function of the Document Routing Agent.
- Configure the Document Routing Agent to work against an existing application.
- Use administration pages to manage access to network printers.

Install the Document Routing Agent

Applications use the Document Routing Agent to manage the spooling of documents to network printer devices. You can get the client by using direct links that are embedded in the web application. Use the following procedure to download the application to your local computer. You can then access both local and network printers that are connected to your computer, from a single deployment. Ensure the user installing the agent has the **Document routing client** security role.

1. Open the **Manage network printers** page (**Organization administration** > **Setup** > **Network printers**).

2. On the **Options** tab, in the **Application** group, select **Download document routing agent installer**.



3. Run the downloaded file to begin the installation process.

4. Complete the setup process.

After you install the application, you can register local printers as network printers for the applications.

> ⓘ **Note**
>
> It's recommended to update the Document Routing Agent to the most current version whenever the application release on the environment has been updated, othgerwise you might experience issues such as:
>
> Observable performance degradation in applications, Document loss that is associated with orphaned print jobs, Inconsistent handling of printed documents that have custom margins
>
> For more information, see **Update the Document Routing Agent**.

If you don't update existing installations of the DRA the most current version, you might experience issues such as:

Observable performance degradation in applications Document loss that is associated with orphaned print jobs Inconsistent handling of printed documents that have custom margins

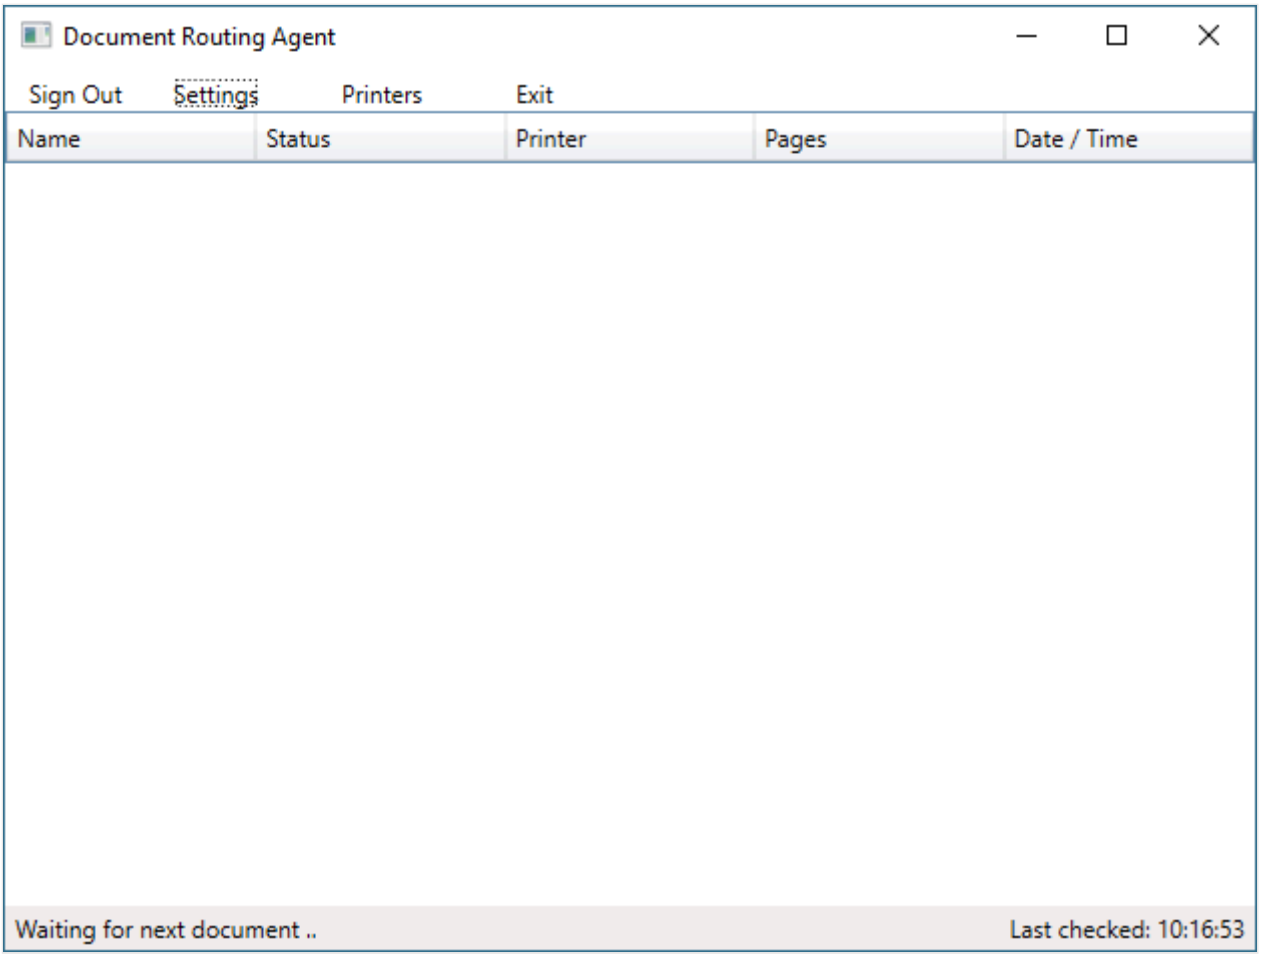
Configure the Document Routing Agent

Use the following procedure to configure the client application so that it can communicate with the Azure services that host the documents that are in-flight.

1. Close all browser instances that are running the application. This action resets the local Azure authentication tokens.

2. On your desktop, run the Document Routing Agent.

3. On the toolbar, select **Settings**.



4. Add the following settings:

    - **Application ID** – The ID that's unique to the application and should be entered automatically.
    - **finance and operations URL** – The base URL of the application.
    - **Azure AD tenant** – The domain name of the Azure AD.

5. Select **OK**.

6. Select **Sign In** to sign in to your account.

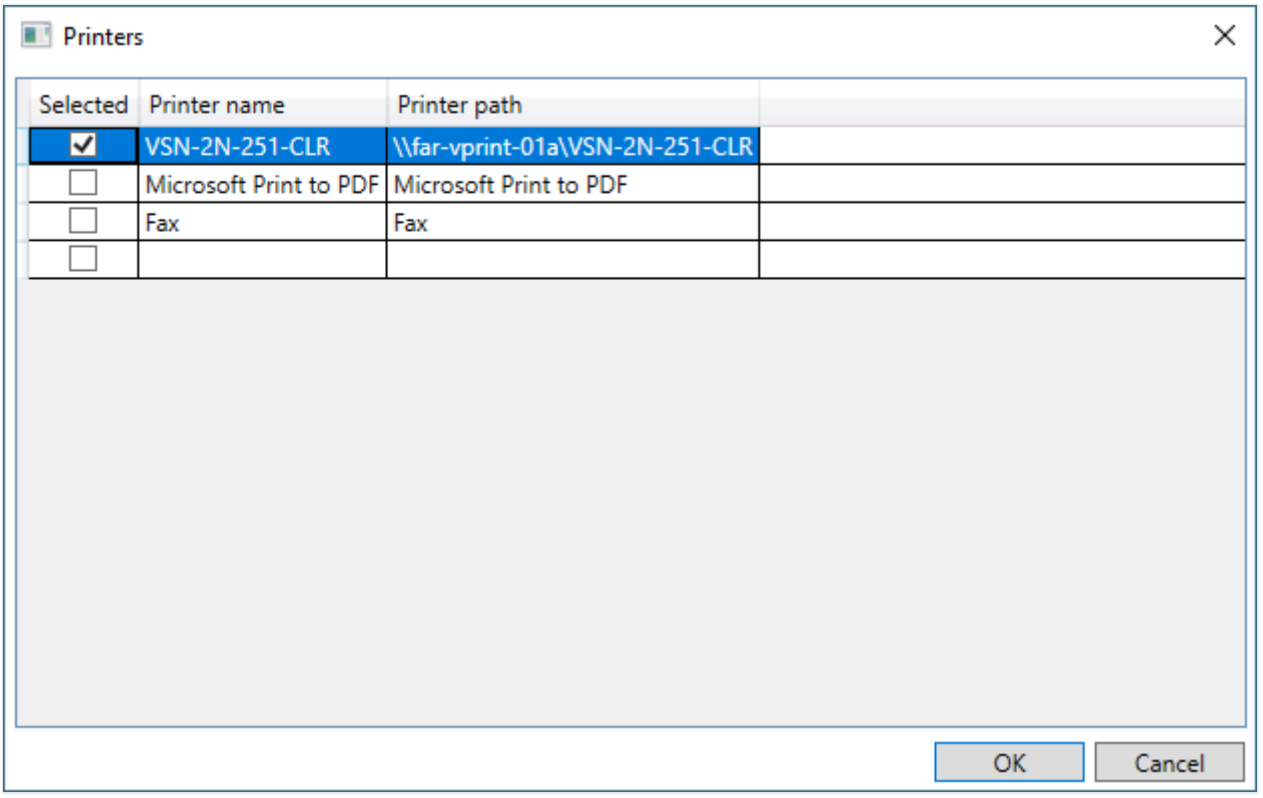
> ⓘ **Note**
>
> The account must share the same domain as the Azure AD that is associated with the application. The Document Routing Agent is now ready to process documents.

After you sign in, the **Printers** button becomes available on the toolbar.

Register network printers

Before you complete this procedure, make sure that you installed all the network printers on the local host computer. All the printer devices that you install are available for service registration. Be sure to select only the printers that you want to expose in the applications.

1. On the toolbar, select **Printers**.
2. Select the printers to make available in the applications.



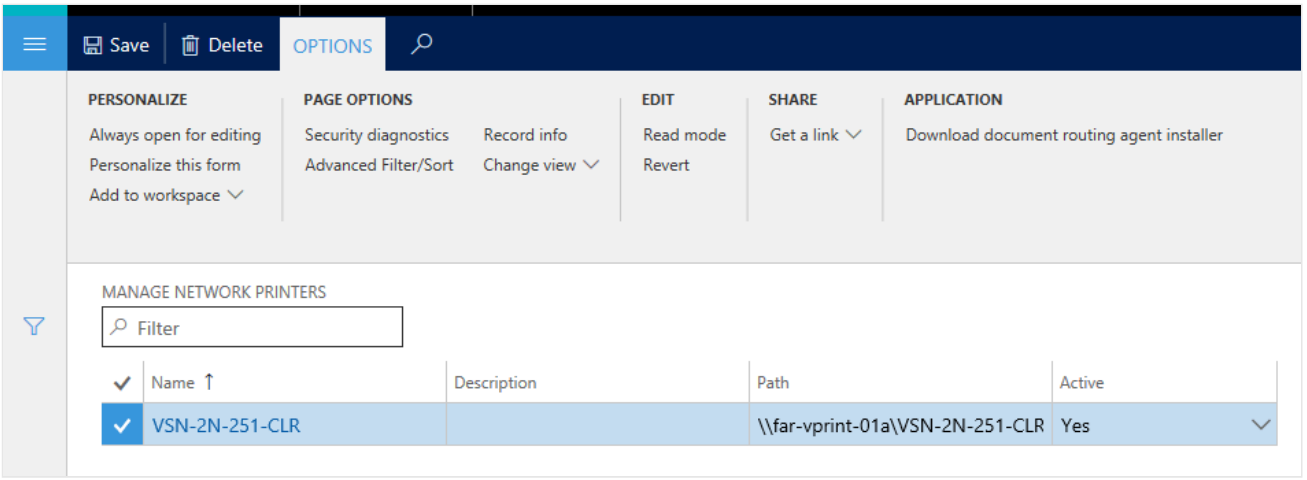
3. Specify a default name for the printer.
4. Select **OK**.

After you complete this procedure, the selected printer devices are registered in the application's network printer catalog. System administrators can now enable the printers for access from within the application.

Administer network printers

Use client pages to manage access to the network printers that one or more Document Routing Agents register. Network printers are uniquely identified by their path. Therefore, printers are listed one time, even if more than one Document Routing Agent registers them. Use the following procedure to activate the Application Object Server (AOS) network printers.

1. Open the **Manage network printers** page (**Organization administration** > **Setup** > **Network printers**).



2. Edit the existing entries that are mapped to each network printer. As part of your changes, edit the connection path.

3. To include a printer as an option in the **Print Destinations** field, set the **Active** field to **Yes**.

The network printers can now be used in the application.

> **Note**
>
> Ensure that your network printer destinations are kept up to date, and that document routing is properly configured with printers that are registered against Document Routing Agents. If you send documents to a printer that no longer exists, the print queue continues to grow and slow down queries that poll the print queue.

Adjust the document routing history cleanup batch job

A cleanup batch job for document routing history is enabled by default and runs daily. This batch job purges document routing history that's older than seven days. Use this history for troubleshooting or traceability if there are issues with printing. Depending on how you intend to access this historical data, you can reduce the retention period from the default value of seven days, which is considered an upper limit. Having fewer records in this table ensures that printing has optimal performance. You can configure this setting at `https://[host_adress]/?mi=DocumentRoutingHistoryCleanupConfig`. Set the value for **JobHistoryHours** (number of hours to retain history).

As part of the Document Routing Agent polling, a query runs against this table. This query should execute quickly, but if there are many records in this table, a large print job can be slow. Ensure that this batch job runs daily, and configure this setting to reduce how much print history you retain.

Excluding printers with stuck print jobs

The **Enable excluded printers** setting handles problematic printers and drivers. When you enable this setting, if a print job is sent to the printer spool and doesn't return with a **Pending** status, the Document Routing Agent adds the printer to an excluded list after the time specified in the **Abort a stuck print job at** field. (The default time is five minutes). The **Reset this printer every x minutes** field, which has a default value of 30 minutes, adds the printer back after the specified time and attempts sending print jobs.

The administrator can also see any excluded printers in the **Network printers** section in the **Spooler status** column. The administrator can reset any excluded printer by selecting the **Reset** icon in the **Reset** column. In addition, the administrator can send a test page to the printer by using the **Print test page** button.

Frequently asked questions

Does the Document Routing Agent need to be installed on each computer where a user connects by using a browser?

No. Individuals who access the provisioned environment can share client installations of the Document Routing Agent. We recommend that you install agents on one or more print servers or other domain-hosted clients that have access to network printers.

If the Document Routing Agent belongs on a network print server, why doesn't the client run as a service?

The Document Routing Agent now supports running in the background as a service. Ensure that you download the latest version of the client. For more information, see Run the Document Routing Agent as a Windows service.

Do I need to update credentials or refresh Microsoft Entra authentication tokens on a recurring basis?

Yes. The Microsoft Entra token must be refreshed every 90 days. If you don't refresh the token, the Document Routing Agent can't authenticate and retrieve printing instructions applications.

Is the Document Routing Agent supported on Microsoft Windows Server 2019?

Yes. Microsoft Windows Server 2019 supports the Document Routing Agent.

> ⓘ **Note**
>
> If you configure the server to prevent background service, the Document Routing Agent client can't run as a service. For more information, see **Run the Document Routing Agent as a Windows service**.

Will Microsoft add support for Microsoft Windows Server 2008 servers?

No, not at this time. The Document Routing Agent has several dependencies on Azure capabilities that are available only in Microsoft Windows Server 2012 R2 and Microsoft Windows Server 2016.

Does the user who installs the Document Routing Agent have to be part of a finance and operations apps security group?

Yes. To access the agent installation links, the user must be part of the **Document routing client** security role.

How many network printers can the Document Routing Agent support?

The number of supported network printers depends on the number of legal entities and the number of network printers deployed. If you have 50 printers and one legal entity, a single Document Routing Agent can handle the load (although you'd want more than one to ensure high availability). If you have a large number of printers and legal entities, you should do some performance testing to determine the number of Document Routing Agents that you need.

How many Document Routing Agents should be configured per printer?

You should configure multiple Document Routing Agents for your printers to ensure high availability. However, limit the number of agents per printer to no more than three agents. Each Document Routing Agent poll needs to query the queue to pick up documents sent to printers registered in that Document Routing Agent client. The more printers that are associated with a Document Routing Agent, the slower the query is. This issue is especially true when there are a

large number of pending jobs in the queue. It's better to have a smaller number of printers across two to three Document Routing Agents, than a large number of printers across three or more Document Routing Agents.

Last updated on 05/05/2026

Update the Document Routing Agent

The solution for managing the print job queue helps you scale Dynamics 365 finance and operations apps to meet high-volume printing needs. Although the public service endpoints that manage print jobs are backward-compatible, update **all** existing Document Routing Agent (DRA) clients.

If you don't update existing installations of the DRA to the most current version, you might encounter problems such as:

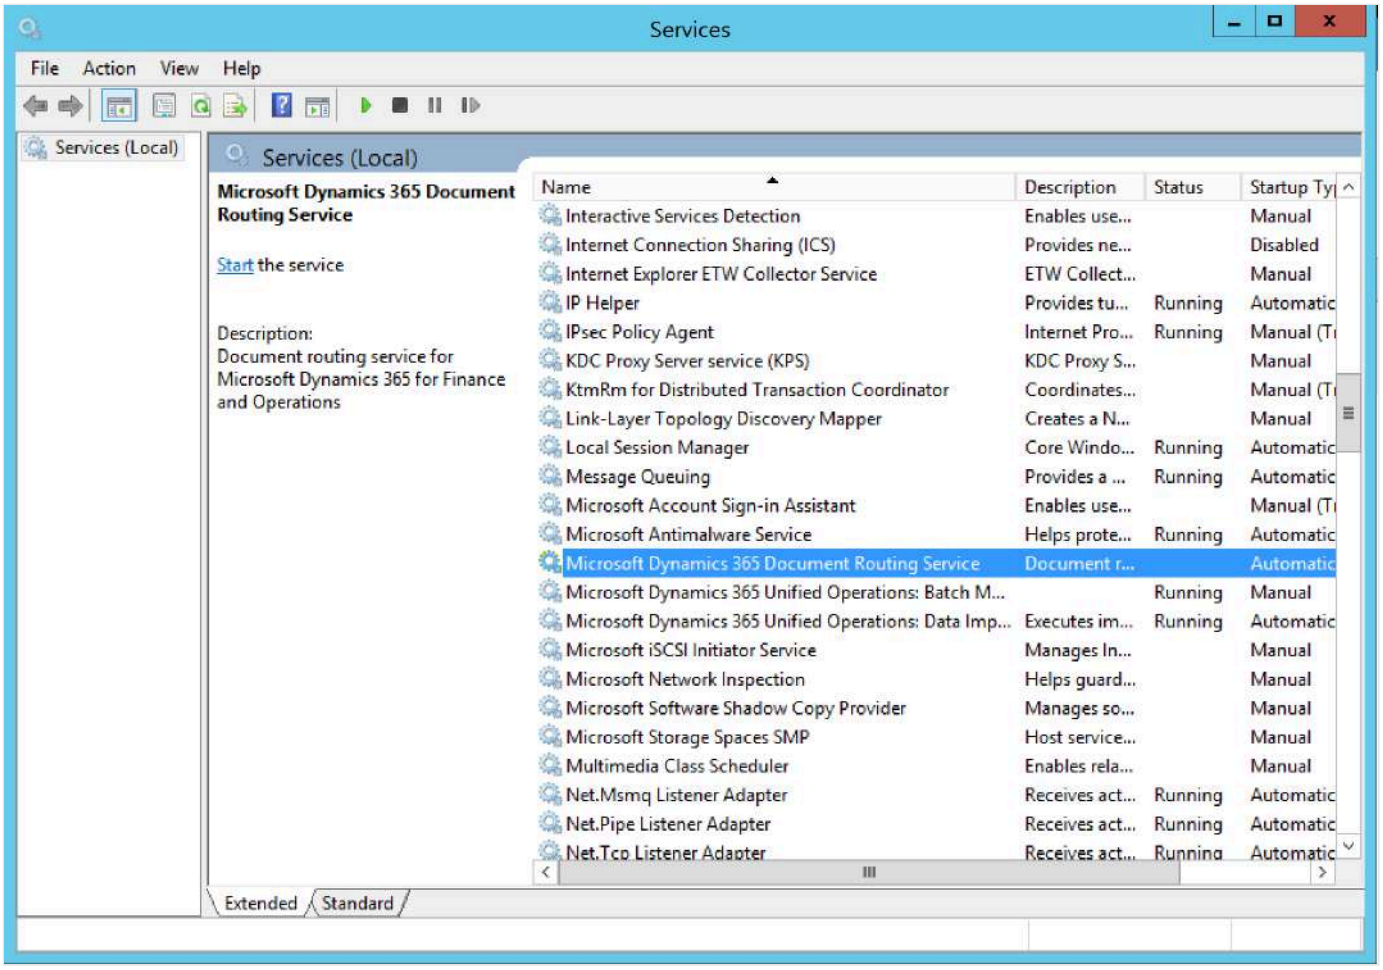
- Observable performance degradation in applications
- Document loss associated with orphaned print jobs
- Inconsistent handling of printed documents that have custom margins

IT administrators must perform the following procedures on each domain resource that hosts a DRA.

> ⓘ **Note**
>
> When you complete a DRA update, register any printers that connect through the host server. For network printers that are identified by their network paths, if the paths didn't change, updates aren't required.

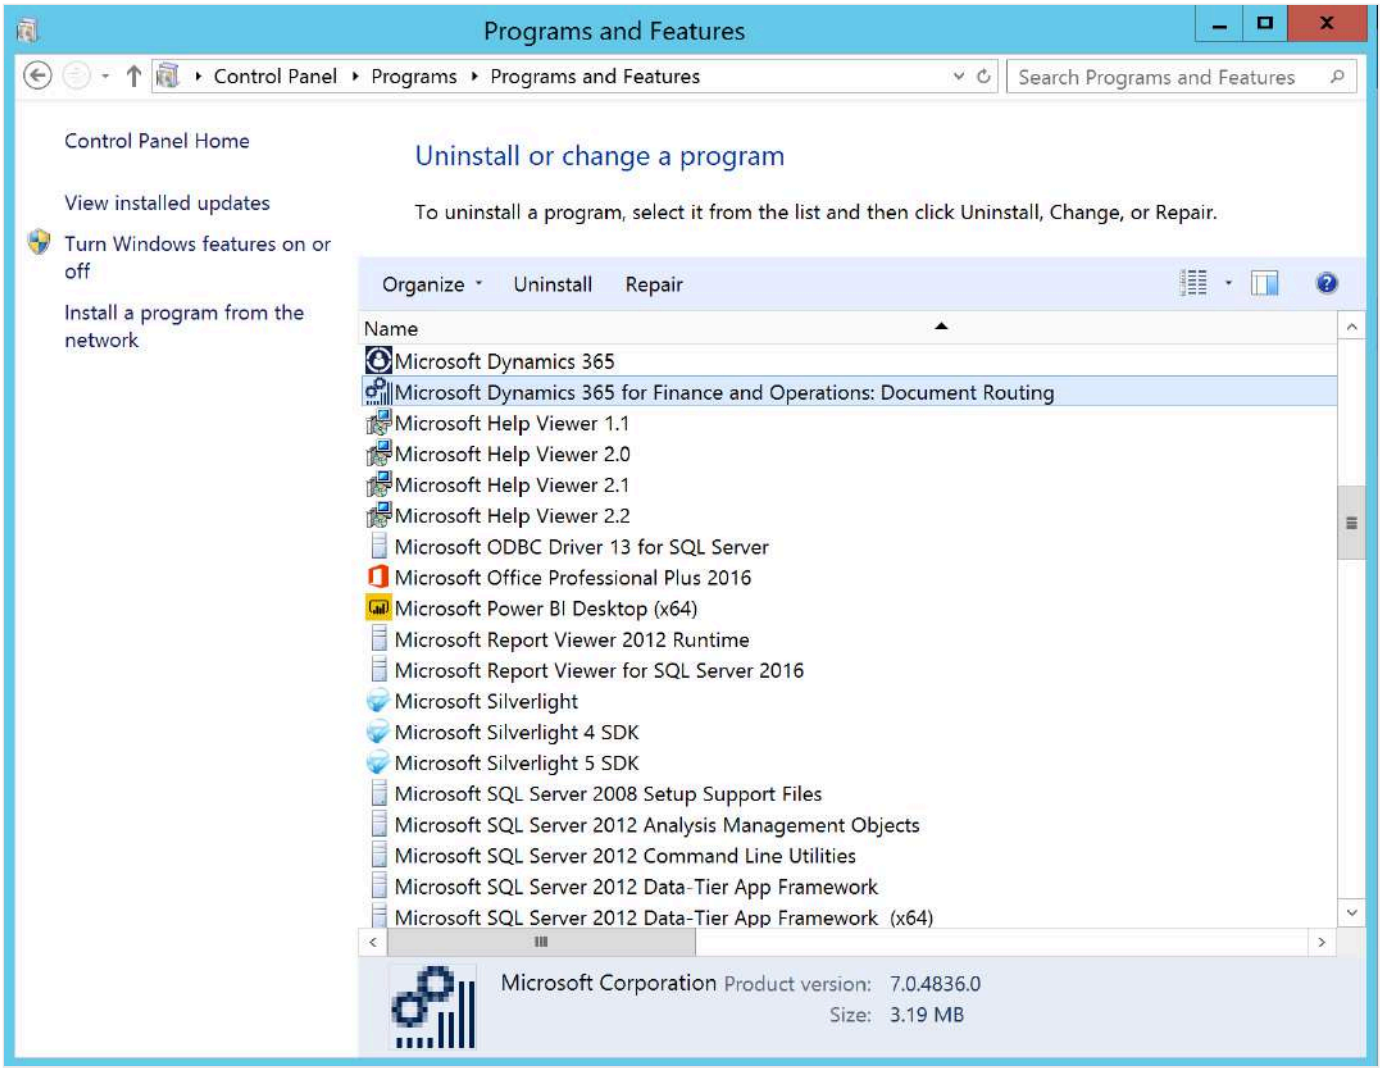
Get started

To keep running the DRA as a Microsoft Windows service, you need both the user name and password of the domain account that runs the service. You must have this information after the update finishes. To find the information for the active service account, start the Microsoft Management Console (MMC) Services snap-in and select **Microsoft Dynamics 365 Document Routing Service** in the list.

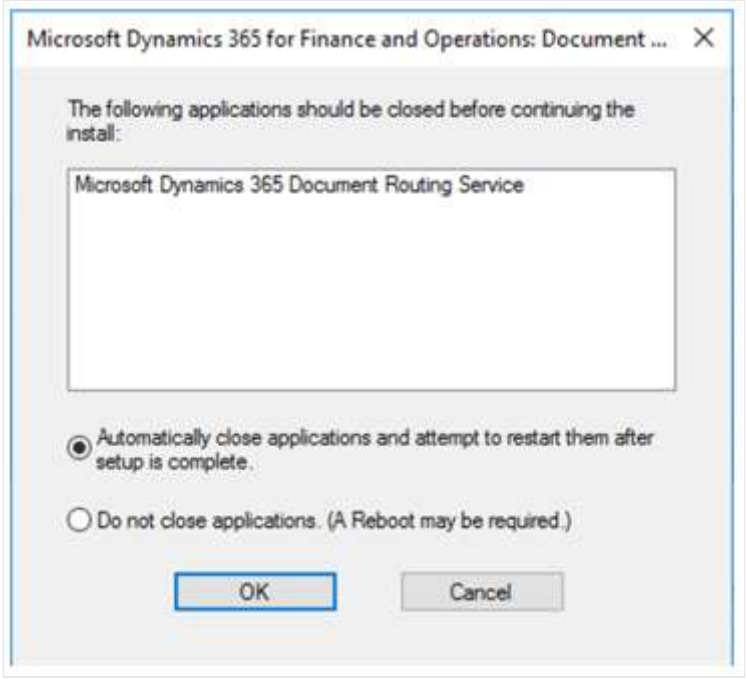


Uninstall an existing Document Routing Agent

Open **Programs and Features**, and then find and uninstall **Microsoft Dynamics 365 Finance: Document Routing**.



During the uninstallation process, if you're prompted to close the Microsoft Dynamics 365 Document Routing Service application, select **Automatically close applications and attempt to restart them after setup is complete**.



Install the latest Document Routing Agent

For information about how to install the latest DRA that's available with your subscription, see Install the Document Routing Agent to enable network printing.

> **Note**
>
> Open the DRA client after upgrading to refresh network user credentials.

Best practices

When you create a support ticket specific to the Document Routing Agent, consider exporting event logs that contain events at the time the issue occurred from the Document Routing Agent machine.

The default event log size is only 1 MB, so if the issue is intermittent, such as a performance issue, consider increasing the event log size. Then wait some time before you export the event logs.

- \Applications and Services Logs\Microsoft\Dynamics\Ax-DocumentRouting\Operational
- \Applications and Services Logs\Microsoft\Dynamics\Ax-DocumentRouting\Admin

Install network printer devices in on-premises environments

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to connect an on-premises deployment of Microsoft Dynamics 365 Finance + Operations (on-premises) to existing network printer devices. The Print and Document Services feature in Microsoft Windows Server 2016 supports network printing in the on-premises application. This feature centralizes tasks that are related to printer management. To install and configure Print and Document Services, you must have administrative access to the server that hosts the primary instance of Application Object Server (AOS).

Two roles are associated with the configuration of network printing services:

- **Service Administrator** – The person responsible for installing and configuring components of the platform infrastructure. Traditionally, this role is an Active Directory account that has elevated domain privileges. It has enough privileges to install components of Microsoft Windows Server.
- **Organization Administrator** – The person who manages application security privileges. This Active Directory account is assigned to the **System Administrator** role.

Before the organization administrator can add network printers, the service administrator must install and configure Print and Document Services on the server that hosts the primary AOS instance. The organization administrator can then use built-in tools to configure network printer devices.

Install and configure Print and Document Services

The environment administrator uses the information in this section to enable network printing services.

1. Install Print and Document Services by following the instructions in Install Print and Document Services.
2. Configure Print and Document Services by following the instructions in Configure Print and Document Services.
3. Follow these steps for each server that hosts the AXService application:
   a. On the local server, start the **Local Users and Groups** manager.
   b. Select the **Groups** node.
   c. Right-click **Print Operators**, and then select **Add to Group**.
   d. Add the network Active Directory account that runs the AXService application to the group.

> ⓘ **Note**
>
> Starting with version 2.9.0 of the infrastructure scripts, the accounts are automatically added to the appropriate group.

Install printers on nodes where AXService runs under a domain account

To install printers on nodes where AXService runs under a domain account, follow these steps:

1. Install network printers by using the AXService user account. This step ensures that the printer driver is available to the AXService user account.
2. Print a test page on the installed printers to make sure that all the connections are correctly configured.
3. Restart the AXService application to help ensure that the user's profile is correctly loaded so that it can locate the printer driver.

Install printers on nodes where AXService runs under a group Managed Service Account (gMSA)

To install printers on nodes where AXService runs under a gMSA, follow these steps:

> ⓘ **Important**
>
> This section requires at least version 2.9.0 of the infrastructure scripts. Additionally, you need to download the SysInternals Suite.

1. Update the `Printers.json` file by adding the network location of each printer that should be available to the AOS. Ensure that you remove the example entries.
2. Run the following command from the Infrastructure Scripts folder.

PowerShell

```
# Exports the script files to be executed on each VM into a directory VMs\<VMName>.
.\Export-Scripts.ps1 -ConfigurationFilePath .\ConfigTemplate.xml
```

1. Copy the contents of each `infrastructure\VMs\<VMName>` folder to the corresponding VM. If you use the remoting scripts, they automatically copy the contents to the target VMs. Then run the following command as an administrator.

> **Note**
>
> - The following procedure requires execution on multiple VMs. However, to simplify the process, you can use the remoting scripts that are provided. These scripts let you run the required scripts from a single machine, such as the same machine that you use to run the **.\Export-Scripts.ps1** command. When the remoting scripts are available, they are declared after a **# If Remoting** comment in the Windows PowerShell sections.
> - Remoting uses WinRM. In some cases, it requires that CredSSP be enabled. The remoting module enables and disables CredSSP on an execution-by-execution basis. Disable CredSSP when it isn't used. Otherwise, there's a risk of credential theft. When you complete the setup, run the following command.
>
> PowerShell
>
> ```
> .\Disable-CredSSP-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml.
> ```

PowerShell

```
# If Remoting, execute
# .\Install-PrintersOnGmsa-AllVMs.ps1 -ConfigurationFilePath .\ConfigTemplate.xml -
SysInternalsFolderLocation \\networkshare\SysInternalsSuite -ForcePushLBDScripts

.\Install-PrintersOnGmsa.ps1 -PrintersJsonFilePath .\Printers.json -
SysInternalsFolderLocation \\networkshare\SysInternalsSuite
```

Manage network printers

Use the information in this section to define network printers.

1. Go to **Organization administration** > **Setup** > **Network printers**.
2. On **Network printers**, add new printers. For each printer, specify a name, description, path, and status. Make sure that the printer path matches the network path of the installed printer.

When you mark a printer **Active**, application users can immediately use it to print document-style reports on network printer devices.

Last updated on 04/13/2026

Document generation, publishing, and printing in on-premises deployments

This article describes the capabilities for generating, publishing, and printing documents in on-premises deployments of Microsoft Dynamics 365 Finance + Operations (on-premises). The application provides a fully integrated experience for enterprise document generation that's powered by Microsoft SQL Server Reporting Services (SSRS). From any supported device, users can produce standard industry documents that are linked to business processes. These documents include sales invoices, checks, and packing slips. Built-in tools let administrators configure the service so that users can securely connect to network printers.

You can upgrade solutions that are built on the Microsoft Dynamics AX 2012 SQL Reporting Services framework, or you can take advantage of the modern solutions that are available in Microsoft Dynamics Lifecycle Services.

Document publishing services: secure, reliable, and convenient

Employees spend lots of time on the go. Therefore, businesses depend on their employees' ability to stay productive while they work remotely. However, even today, documents remain critical for business transactions and record keeping.

From their mobile devices, users can print documents on network printers. Users can also automate the creation of business documents and use built-in tools to configure instructions for routing documents to multiple recipients.

The following options are available for document publishing:

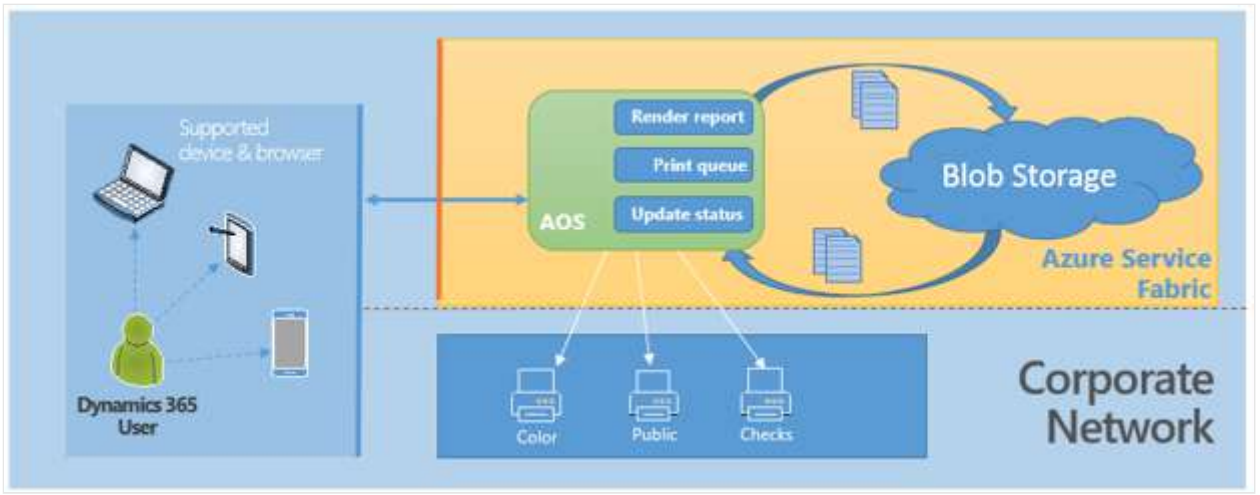
- **Email** – Distribute mail via a server, and link reports as attachments.
- **Archive** – Store reports for future reference and regulatory compliance.
- **File** – Produce a PDF file that is downloaded directly to the browser for local printing.
- **Print** – Send documents directly to network printers from all supported platforms. These platforms include mobile devices.

For a high-level summary of the options for information access that are available in the cloud-hosted solution, see Document printing overview.

Comparing the cloud-hosted and on-premises services

Unlike the cloud-hosted service, the on-premises publishing service produces documents as PDF files that the browser automatically downloads. Therefore, users can save documents or print hard copies by using locally connected devices. Administrators can manage access to network printers directly from the application by using built-in administrative pages. Users can interact with reports on demand, or they can schedule automatic jobs to securely generate and distribute documents on a recurring basis.

The following illustration shows the components that are involved in document printing.



For information about how to use extensions to manage availability of the embedded drill-through links in application reports, see the Appendix.

Managing access to network printers

Administrators can use built-in administrative pages to manage access to network printers. Network printers are secured per company and shared by users of the application. Documents are then printed by using a privileged domain account, based on settings that the user provides. In on-premises deployments, you don't have to install an adapter to connect to domain resources such as printers and fax machines.

The following illustration shows the page that is used to manage network printers.

Appendix

Turning on embedded links in business documents

Here's the code that you can use to make embedded drill-through links available in PDF documents.

```
X++
```

```
class Controller extends SrsReportRunController
{
    protected void preRunModifyContract()
    {
        this.parmReportContract().parmRdlContract().parmEnableFileDrillThrough(true);
        super();
    }
    static void main(Args _args)
    {
        ...
    }
}
```

Last updated on 06/26/2026

Run the Document Routing Agent as a Windows service

The Document Routing Agent includes an option that lets you select the mode of execution. The process can run as either a desktop application or a Microsoft Windows service. When the application runs as a Windows service, it can start automatically after a computer restart. You can also configure it to run under the security context of a specific user account. This enhancement lets you host the Document Routing Agent on secured domain resources such as network print servers.

This article provides important information that helps you select the correct execution mode.

Service applications

An application is a program that a user interacts with on the desktop. A service is a process that runs in the background and doesn't have an active window. The Document Routing Agent now supports both execution modes. It's important that you understand why you might select one mode instead of the other and the steps that are involved in running the process as a service. For more information about Windows services, see Introduction to Windows Service Applications. Here are some of the main benefits of running the Document Routing Agent as a background service:

- You can configure the service to start automatically after a computer restart. No user intervention is required.
- The service runs in the background. No active application runs in the notification area.
- The service routes documents without requiring that a user sign in by using cached credentials.

Although there are many benefits of running the Document Routing Agent as a Windows service, there are also limitations. The next section discusses an issue that affects the handling of document reports, such as checks, that require custom page margins.

Documents that require custom margins

When the Document Routing Agent runs as a Windows service, document reports, such as checks, that require custom margins can't be printed directly to network printers. Instead, the Document Routing Agent automatically routes those documents to a target folder. New

configuration properties in the application's **Settings** dialog box let you define the target location for document reports that require custom margins.

When the Document Routing Agent runs as a desktop application, it continues to take advantage of Adobe Reader to spool the document to the shared printer device that is selected in finance and operations. To handle scenarios where documents that have custom margins must be printed, install the Document Routing Agent in multiple locations. Then install the printers that handle those documents only on the Document Routing Agents that run in desktop application mode. Alternatively, use a post-execution process to pick up the files in the target directory and direct them in the appropriate manner.

Install the latest build

1. Save a copy of the current Document Routing Agent configuration file. This file is located at `C:\Users\<UserID>\AppData\Local\Microsoft\Microsoft Dynamics 365 Finance Document Routing\Microsoft.Dynamics.AX.Framework.DocumentRouting.config`. In this path, `<UserID>` is the Active Directory Domain Services (AD DS) user name that you used to install the Document Routing Agent.

2. Uninstall the current version of the Document Routing Agent.

3. Install the latest version of the Document Routing Agent by following the instructions in Install the Document Routing Agent to enable network printing.

   > **Note**
   >
   > Although you install the application at this point, don't run it yet.

4. Copy the configuration file from step 1, and paste it into the following directory: `C:\ProgramData\Microsoft\Microsoft Dynamics 365 Finance Document Routing`. This step helps guarantee that all your previous configuration settings are used for the new version of the Document Routing Agent application.

5. Run the Document Routing Agent.

6. Sign in by using your Microsoft Entra ID or your credentials for your finance and operations apps.

7. View and verify your settings and printers by clicking the appropriate menu items.

The next section provides detailed instructions for selecting the Windows service execution mode.

Change the default execution mode

By default, the Document Routing Agent runs as a desktop application. To run the process as a Windows service, make sure that you're familiar with the process for installing the Document Routing Agent to enable network printer devices. Then complete the following tasks.

Update the execution mode for the Document Routing Agent

1. Start the Document Routing Agent by using the desktop icon.
2. Select the **Sign In** option, and sign in by using your Microsoft Entra ID credentials.
3. On the ribbon, select **Settings**.
4. Enable the **Run as a Windows Service** option.
5. Provide a target folder for PDF files that are produced for documents that have custom margins.
6. Select **OK**, and close the Document Routing Agent window.

Configure and start the Windows service

1. In Windows, start Service Manager.
2. In the list, select **Microsoft Dynamics 365 Finance Document Routing Service**.
3. Right-click the name, then select **Properties**.
4. On the **Log On** tab, select the **This account** option, then supply the AD DS credentials that run the service.

   > ⓘ **Note**
   >
   > The selected account must have access to the shared network devices. The Windows domain account or local machine account that runs the Windows service must be the same as the account that starts the Document Routing Agent desktop app.

5. Select **OK**.
6. Start the service.

The Document Routing Agent now runs as a Windows service.

Troubleshooting tips

Verify the network printer connection

- Verify that the active account has enough access rights to the network printer.
- Verify that the user account can successfully print to the network device by using Notepad or another local application.

Verify security roles

- To access the application links that are used to install the Document Routing Agent, the user must be part of the **Document routing client** security role.

Review the service account's access rights

- Verify that the **DocumentRoutingService** service runs as a domain account that has access to the network devices.

Refresh the Azure service token

- Azure authentication tokens must be **refreshed every 90 days** while the Document Routing Agent runs as a Windows service. To refresh the service token, start the client, then sign out and sign back in by using the menu items.

Disable shared printers for remote access

- When you connect to the host machine by using Microsoft Remote Desktop, make sure that you clear the **Printers** option in the **Local devices and resources** section on the **Local Resources** tab.

Review the event logs

1. On the host machine, start Event Viewer.
2. Review the logs at **Application and Services Logs** > **Microsoft** > **Dynamics** > **AX-DocumentRouting**.

SQL Server Reporting Services (SSRS) reports that are available

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article points you to a report that lists the SQL Server Reporting Services (SSRS) reports available.

You can define reports as any visualization of a structured data set. This definition includes transactional data presented in a tabular layout and advanced graphical views of aggregate information. To account for this broad definition, the application offers several tools to produce reports that satisfy complex business requirements. One of these tools is SSRS. SSRS reports provide the following advantages:

- Back office document management capabilities, including email support, scheduled executions via batches, and print archive functionality.
- Parameterized views with drill-through navigation to application pages and other reports.
- Precision documents for compliance with local regulatory business practices.

For more information, see Create reporting solutions.

To view the report

The **SQL Server Reporting Services Reports report**, included with the Technical reference reports, lists each available SSRS report. The report indicates the data set used for each report, as well as the filters and fields available on each report.

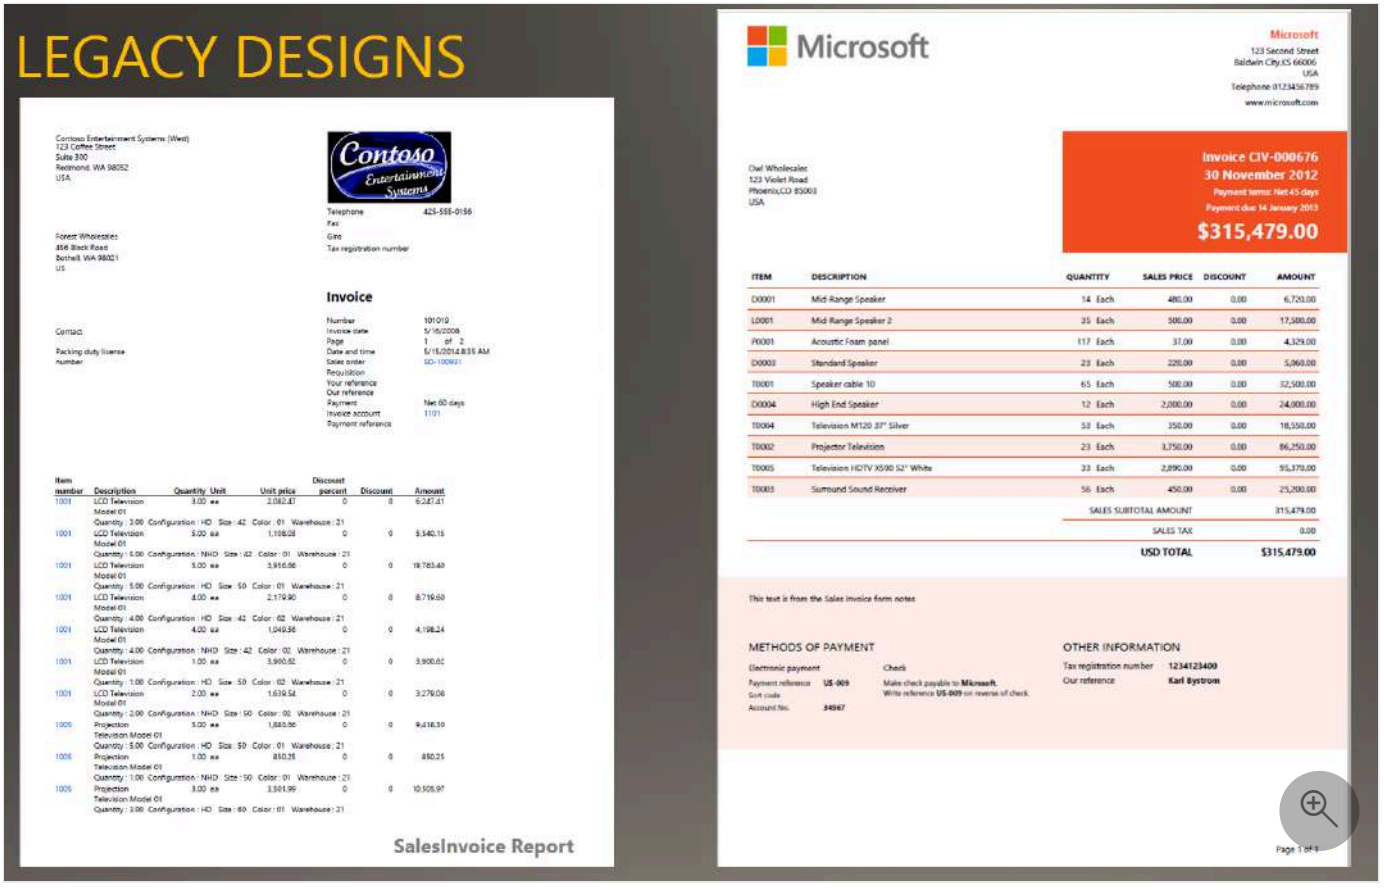
Last updated on 11/26/2025

Install modern report design templates

This article explains how to install the modern report design templates in the application suite. You can use these samples to create graphically rich business documents that have flexible branding in the header and footer.

Introduction

A new set of developer tools is available that takes the form of report designs for several core business documents in the application suite. These report designs have been reimagined so that flexible branding appears in the header and footer of public-facing documents when transactions are generated in the application. The following illustration shows how an earlier design for a sales invoice differs from a modern sales invoice design.



After you complete the installation, you can use the built-in brand management tools to define brand settings that should be applied to the modern designs for application business documents. The brand management tools are available at **Organization administration** > **Setup** > **Document branding** > **Branding details**.

Why aren't these designs the default designs for the application suite reports?

We're maintaining the legacy solutions for two primary reasons:

- **Modern designs don't include code.** Although the legacy solutions use embedded Microsoft Visual Basic (VB) code to recognize configuration keys and honor regulatory requirements that vary by region, the modern report designs offer much less flexibility. The benefit of a simple design that has minimal code behind it comes at the expense of reusability across regions.
- **Modern designs aren't available for all business documents.** There's a gap between the supported business documents and the availability of modern report designs. Although the legacy designs aren't as aesthetically pleasing, they provide a sense of consistency.

> **Important**
>
> The simple modern designs aren't recommended for all types of deployments. They're intended for cases where the customer doesn't require runtime control over the layout of the document through existing application configuration settings.

Apply the modern designs

The modern report designs are bundled into a model file and posted to Microsoft Dynamics Lifecycle Services. You can easily access them from your existing subscription. Use the following procedure to obtain the modern report design solutions and install them in your local development environment. You must then apply some customizations to incorporate the modern report designs into the appropriate scenarios.

Follow these steps to install the modern report designs for the application suite.

1. Sign in to Lifecycle Services to access the deployment dashboard. Then, on the **Shared asset library** page, select the **Model** asset type, and download the **ApplicationSuiteModernDesigns** model file. Save the model file to a location that's accessible from the development environment.

   > **Note**

Be sure to select the appropriate model file for the version of the application that you're using.

2. Import the model file into your local development environment. To install a model file in a development environment, use the ModelUtil.exe tool and the **-import** directive. Here's an example.

   Console

   ```
   ModelUtil.exe -import -metadatastorepath=[path of the metadata store] -file=[full path of the file to import]
   ```

3. Navigate to the **<AOSServiceDrive>:\AOSService\PackagesLocalDirectory\bin** folder.

4. Run the following command.

   Console

   ```
   ModelUtil.exe -import -metadatastorepath=J:\AOSService\PackagesLocalDirectory -file="E:\Test\AppSuiteModernDesigns.axmodel"
   ```

   For more information about how to import model files, see Export and import models. After you import the model file, start Microsoft Visual Studio. In Application Explorer, verify that the **Application Suite - Modern Designs** collection appears under the **AOT** node. For more information about how to use the Application Explorer, see Development tools tutorial.

Now that you successfully imported the Application Suite Modern Designs model, you must rebuild the application suite to update the metadata elements.

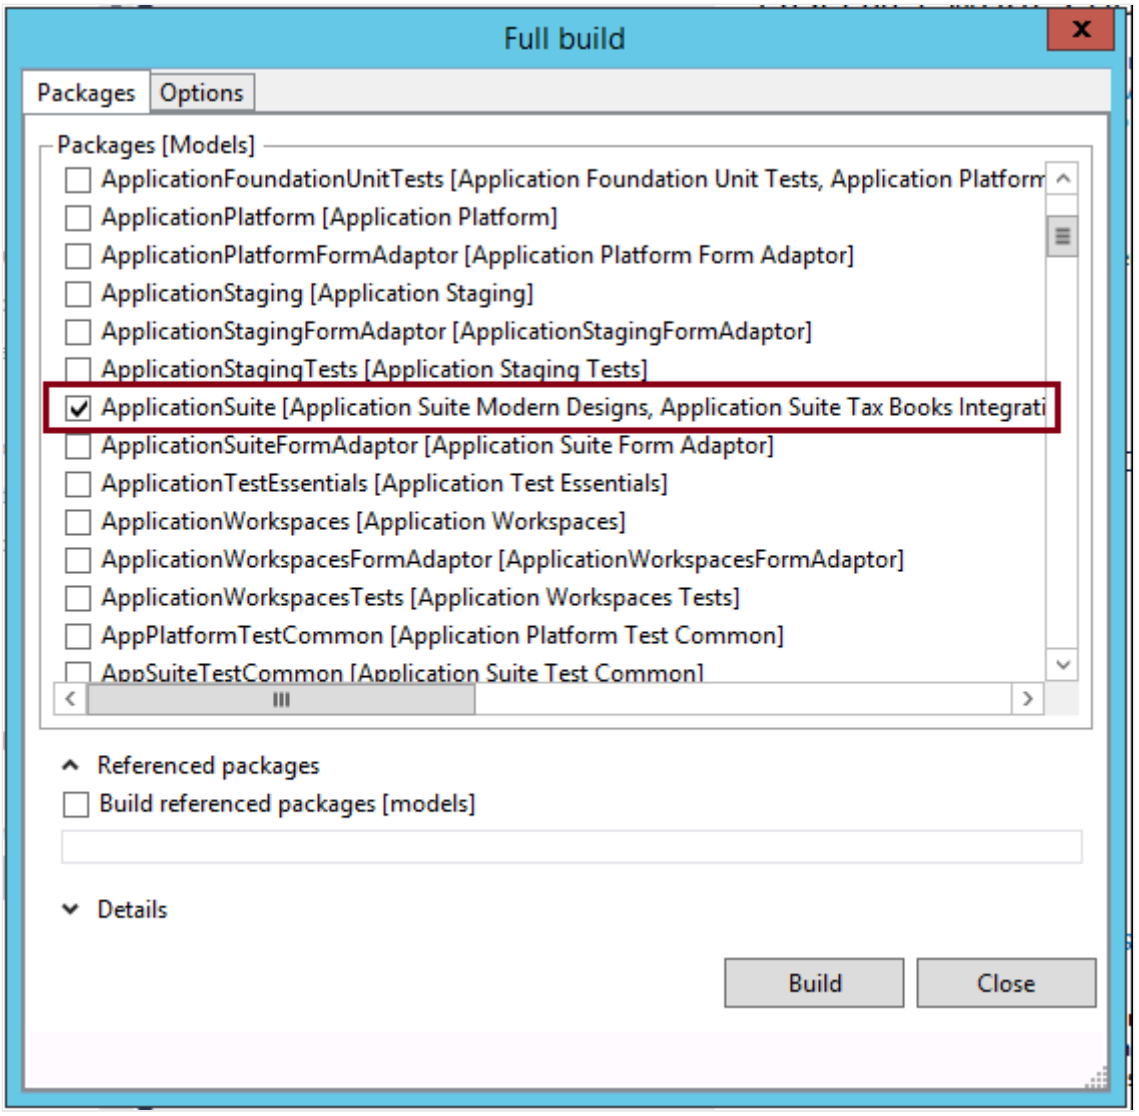
Build the application suite

The Application Suite Modern Designs model extends the Application Suite model. To update all application references so they target the model extensions, build the Application Suite model by using Microsoft Visual Studio.

1. Start Visual Studio, or use the existing instance.

2. On the **Dynamics 365** menu, select **Build models**.

3. In the list, select the check box for the **ApplicationSuite** package.



> ⓘ **Note**
>
> The Application Suite Modern Designs model is included in the package definition.

4. Select **Build** to do a full build of the application suite.

This process might take up to 20 minutes, depending on the size of your machine.

Deploy the modern designs (one-box environments)

After you compile the application suite that includes the modern report design templates, verify the changes locally. To verify the changes, deploy the new modern report design solutions to the instance of Microsoft SQL Server Reporting Services (SSRS) that's running locally.

Follow these steps to incorporate the modern report design into an existing application suite report.

1. Create a project that contains the application suite report. In Application Explorer, under the **Application Suite Modern Designs** model, expand the **Reports** node, and then expand the **Reports** subnode. Select all the items in the folder, right-click, and then select **Add to new project**.
2. Complete the **New Project** wizard. Accept all default values.
3. In Solution Explorer, select the project, right-click, and then select **Deploy reports** to deploy the build and deploy the reports locally.

When you add the modern report design to an existing report, you can reuse both the parameter handling and the data provider that the out-of-box solution uses.

Update Print management settings

At this point, you should be able to access the modern report designs from the application. Make sure that you thoroughly test the modern report design templates before you deploy them to production environments. To test the templates, you must activate the modern report designs for the application business process.

Follow these steps to update the Print management settings for customer sales orders by selecting the modern report design solution as the default report design.

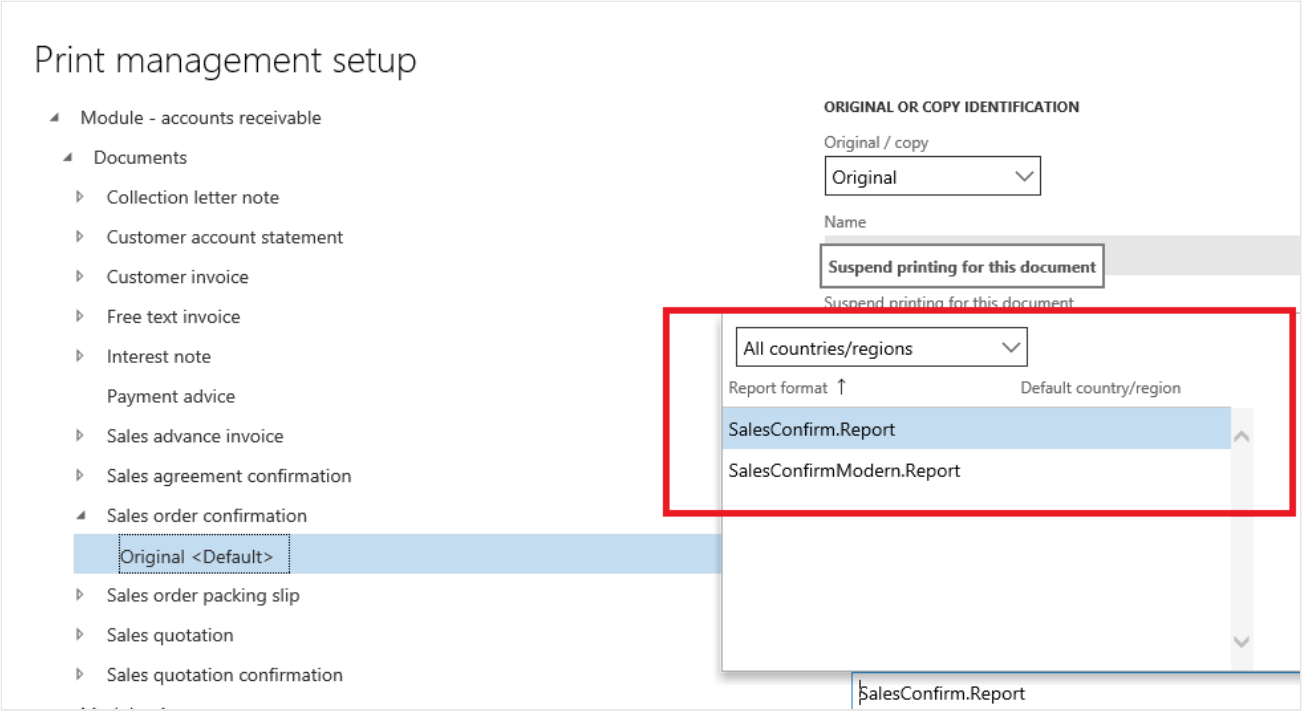
1. Open the **Form setup** page for the module. For example, for Accounts receivable, select **Accounts receivable** > **Setup** > **Forms** > **Form Setup**.

2. Select **Print management** to open the **Print management setup** page.

3. Expand the tree, and find the settings for the **Sales order confirmation** document.

4. Select **Original <Default>** to begin to modify the default document routing.

5. In the **Report format** list, select **SalesConfirmModern.Report** to enable the modern report design solution.



6. Open another page. This step forces a save operation to occur.

7. Post a sales order to view the modern design in the application.

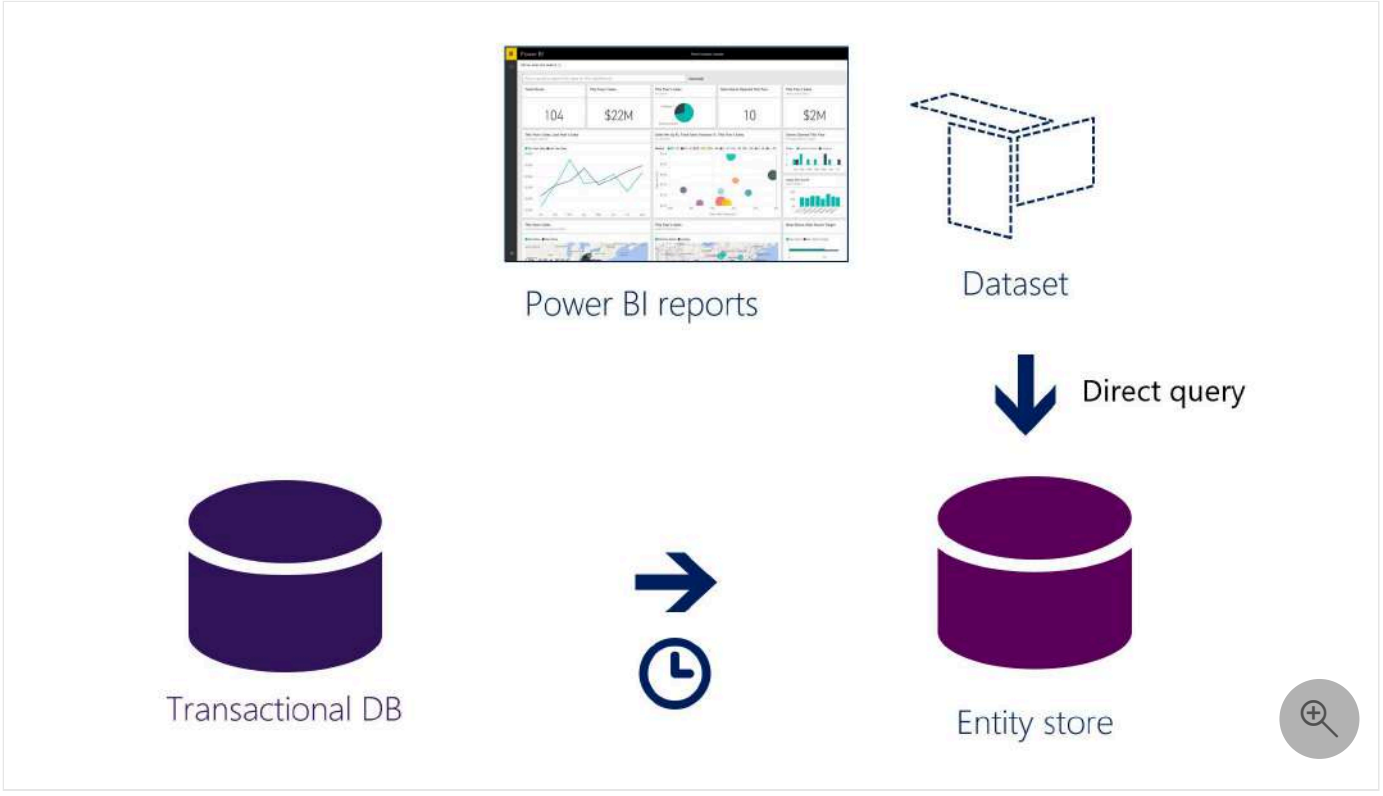
Power BI integration with Entity store

Entity store is an operational data store that's included with Microsoft Dynamics 365 Finance. This article describes how Entity store enables Power BI integration.

Entity store is an operational data store that's included with the application. The Microsoft Dynamics AX platform update 1 (May 2016) release introduced the Entity store feature. This feature lets an administrator or power user stage aggregate measurements in a dedicated data store for reporting and analytics. (Aggregate measurements are a star schema that is modeled by using entities.) This data store is called Entity store. It's a database that's optimized for reporting purposes. Entity store uses the in-memory, clustered columnstore index (CCI) functionality that is built into Microsoft SQL Server to optimize reporting and queries. Customers can use Microsoft Power BI DirectQuery models together with Entity store to enable high-volume, near-real-time analytical reporting over large volumes of data.

Power BI DirectQuery mode

In the February 2016 release of Microsoft Dynamics AX, you could create Power BI reports by using OData endpoints that data entities expose. Both aggregate data entities and detailed or regular data entities expose these OData endpoints. Although this approach is still supported, Entity store also lets power users create Power BI DirectQuery reports.



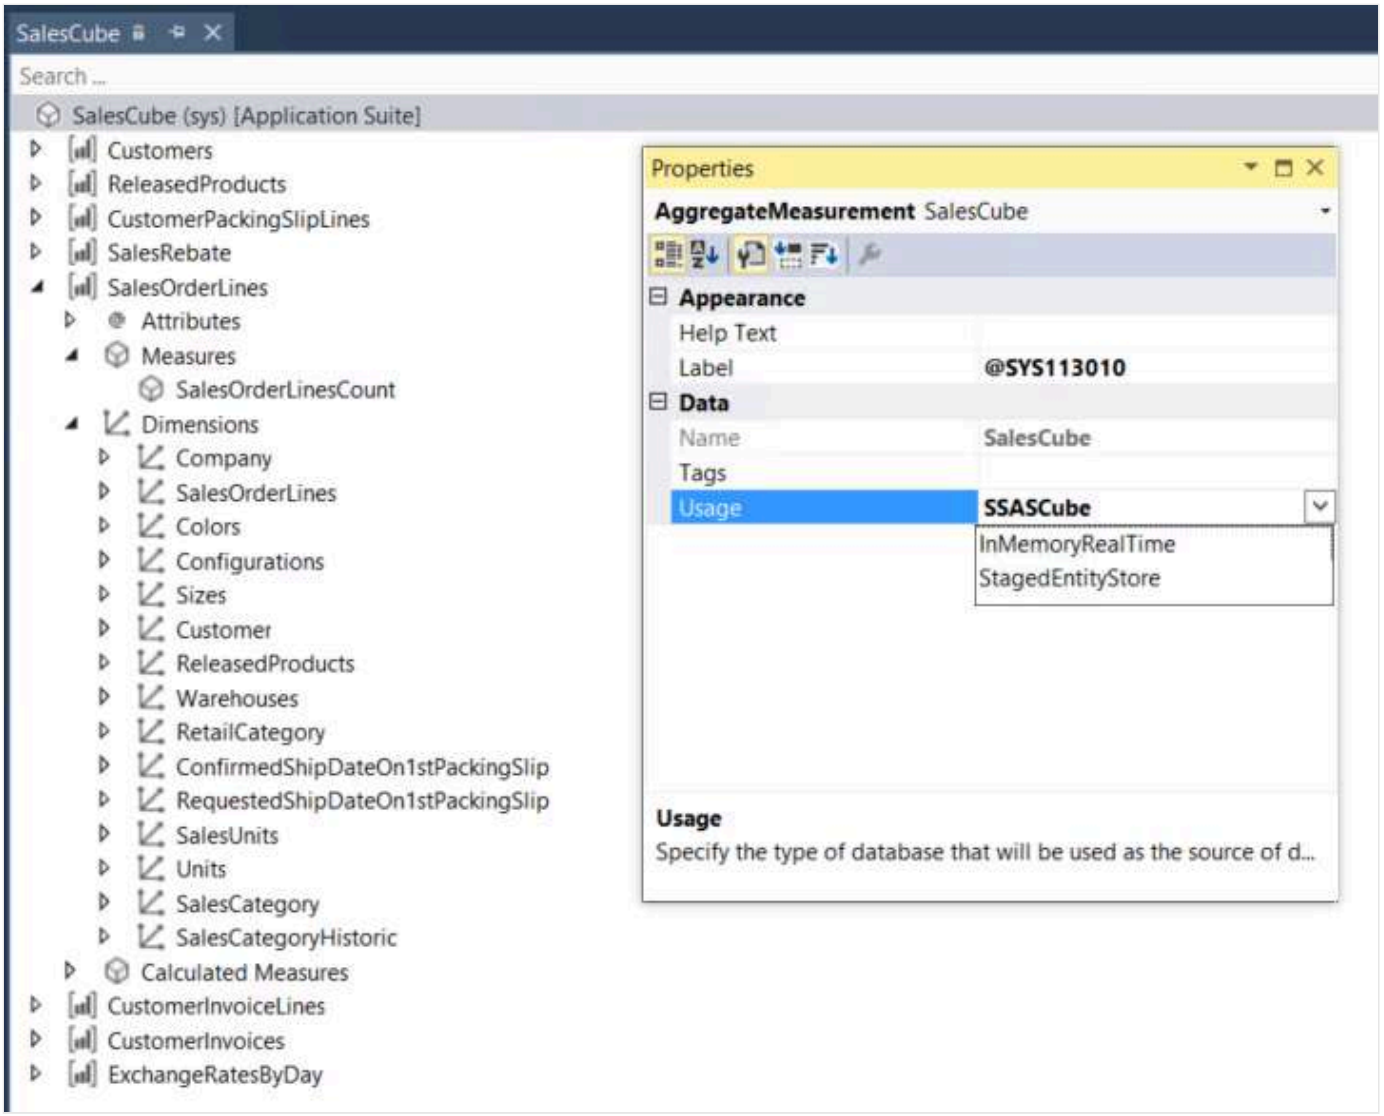
As the preceding illustration shows, DirectQuery is a reporting mode that runs reports directly on Entity store. In this reporting mode, data isn't staged in Power BI caches. This mode provides two immediate benefits:

- You can create Power BI reports over large data volumes.
- Reports don't have to be updated by using Power BI. When Entity store is updated, reports reflect the latest data.

Additionally, data doesn't leave your environment, because no data is cached in the Power BI service.

Stage aggregate measurements in Entity store

Aggregate measurements use a star schema that's designed for analytical scenarios. In the February 2016 release, Microsoft introduced real-time, in-memory aggregate measurements. By using real-time aggregate measurements, you can enable embedded charts and key performance indicators (KPIs) that react to real-time operations on data. For more information, see Transition from Analysis Services cubes to aggregate models. Real-time aggregate measurements take advantage of the in-memory, nonclustered columnstore index (NCCI) technology. Visuals and aggregate calculations that are built over real-time aggregate measurements reflect transactions within seconds. In the platform update 1 (May 2016) release, Microsoft introduced aggregate measurements that you can stage in Entity store. You can use aggregate measurements that are staged in Entity store for near-real-time analytical scenarios where you need to explore large volumes of data by using Power BI. As a developer, you learned how to model an aggregate measurement for real-time analytics in Model aggregate data. In the platform update 1 (May 2016) release, Microsoft added the capability to model aggregate measurements that you can stage in Entity store. In Microsoft Visual Studio, you can specify **StagedEntityStore** as the usage property of an aggregate measurement. This new property was added in May 2016. Previously, **InMemoryRealTime** was available as the usage property.



However, you might wonder why you would model an aggregate measurement for staging. Why wouldn't you use in-memory real-time aggregate measurements all the time? Several reasons exist for using the **StagedEntityStore** pattern:

- You need to explore and analyze large amounts of data.
- You migrated Analysis projects (that is, cubes) from Microsoft Dynamics AX 2012 R3 as part of the code upgrade process. Because of the complex views and joins that are present in the schema, query response times might not be acceptable for embedded visuals. However, you might not want to refactor the visuals to take advantage of NCCI technology immediately.
- Unlike the operational database schema, the schema in Entity store is modeled specifically for reporting. Therefore, it's easier to build new reports from the schema in Entity store.
- Your scenario doesn't require that analytical data be updated within seconds of an operation. Most Power BI reports that are built to enable data exploration fall into this category. If data freshness of approximately 10 minutes is acceptable for your scenario, you might want to use the staged pattern.

If one of the preceding reasons covers your situation, stage your aggregate measurement in Entity store and use it for Power BI integration.

Update Entity store

The system automates and manages Entity store refresh. In the client, you can find the **Entity Store** page at **Systems administration** > **Setup** > **Entity Store**. For more information, see Automated Entity store refresh.

Connecting to the Entity store database

For troubleshooting and diagnostics, you can connect to the Entity store database directly from a related sandbox environment. To connect:

1. Use Remote Desktop to access the sandbox. You can download the RDP file from the **Environment Details** page after you include your IP address in a safe list.
2. Open SQL Server Management Studio, and connect to the server specified on the **Environment Details** page.
    - Find the section titled **Database Accounts** Locate the entry for the user with the name **axdwadmin**.
    - The server name is the first portion of the **SQL Server\Database Name** field. Use the format **SQLServerName.database.windows.net**, where SQLServerName is the value from LCS.
    - Change the authentication type from Windows Authentication to SQL Server Authentication.
    - Use **axdwadmin** as the sign-in name and use the password from LCS.
3. Use the **Options** button or browse to the **Connection Properties** tab. Change the **Connect to database** property from the default value to your **Database Name** value from LCS.
4. Select **Connect** to access the database.

Last updated on 06/26/2026

Resolve problems after entity store maintenance

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you perform maintenance on the entity store, it affects the following components:

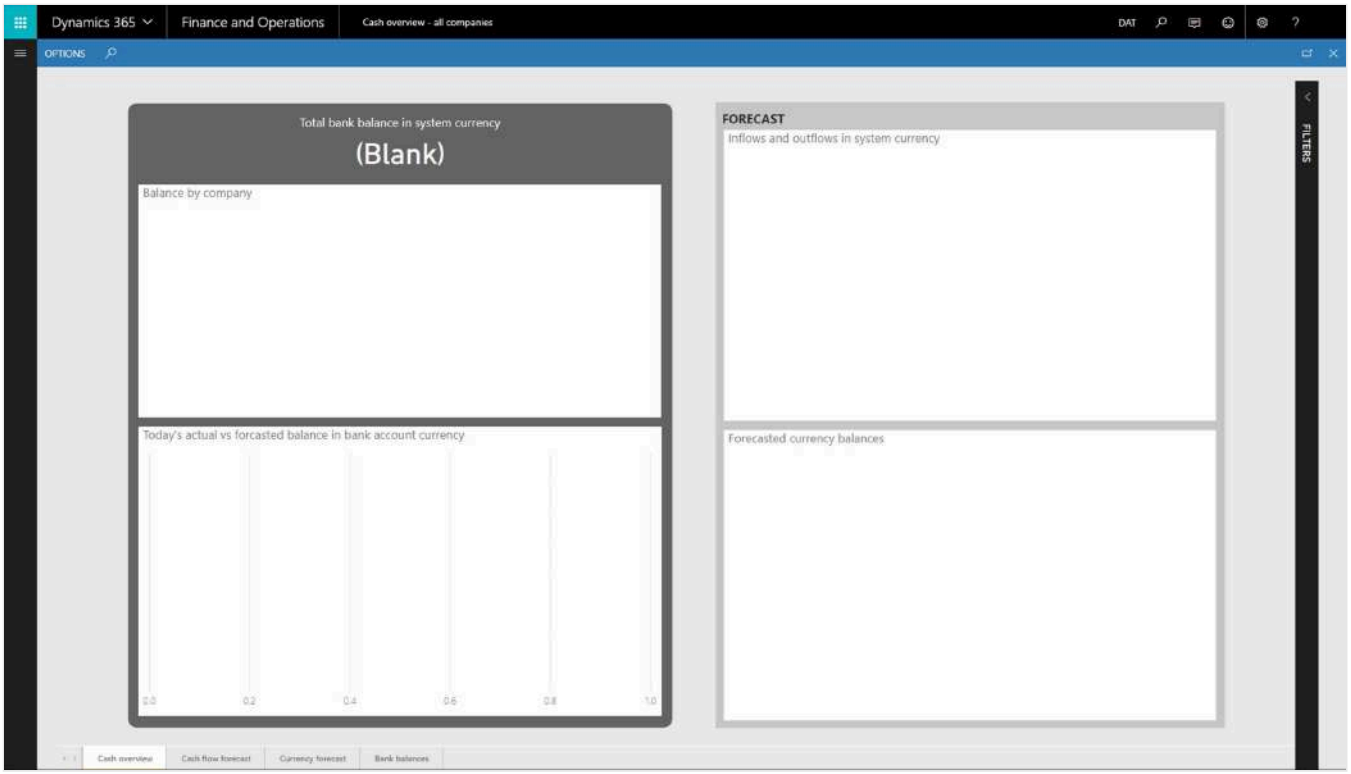
- Application analytical workspaces.
- Entity store-based reports deployed to PowerBI.com.

To resolve problems with these components, follow the procedures in this article.

> **Note**
>
> There's no impact to the normal operation of your application.

If you're using application analytical workspaces

Application analytical workspaces and reports might not show data after certain maintenance operations. The following screenshot shows an example of this problem.



To fix this problem:

1. Sign in to the application.
2. Go to **System administration** > **Inquiries** > **Batch jobs**.
3. On the **Batch jobs** page, delete all pending batch jobs that are associated with the entity store. These batch jobs:
   - Have a status of **Waiting**.
   - Typically have a description of **Deploy measurement**, **Full reset**, or **Incremental update**.

   > ⓘ **Note**
   >
   > The default description is **Deploy measurement** in older versions and **Full reset** in newer versions. If you enable Data Lake integration by using the **Trickle update Data Lake** option, an **Incremental update** batch job is created. You can verify whether a batch job is associated with the entity store by looking at the class name if the description is customized. Batch jobs associated with the entity store have a class name of **BIMeasurementDeployManagementEntityBatchJob**, **BIMeasurementProcessorFull**, or **BIMeasurementProcessorIncremental**.
4. Go to the **Entity store** page (**System Administration** > **Setup** > **Entity Store**).
5. Select all measurements that need to be refreshed.

6. Select **Refresh**, and then select **OK**.

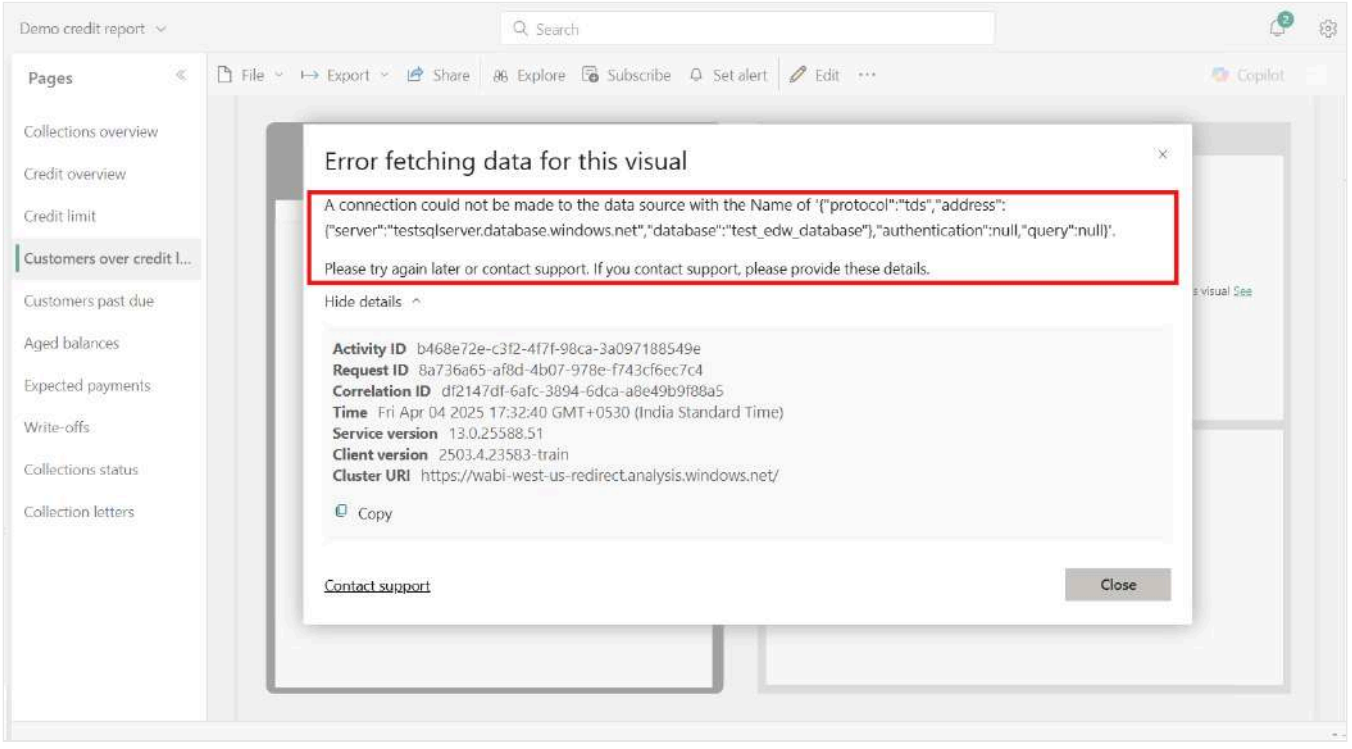
After the refresh finishes, the application analytical workspaces and reports show data.

Deployed entity store-based reports to PowerBI.com and using the PowerBI.com reports

Refresh the Entity store measurements as described above.

The reports deployed to PowerBI.com may receive the following errors:

- The credentials provided for the SQL source are invalid.
- Login failed for user <user_name>.
- A connection couldn't be made to the data source with the Name of '{"protocol":"tds","address":{"server":"testsqlserver.database.windows.net","database":"test_edw_database"},"authentication":null,"query":null}'. Try again later or contact support. When you contact support, provide these details:



These errors can occur if the credentials of Entity store database are rotated and PowerBI.com reports are configured with old credentials.

To resolve this issue, follow one of the following solutions:

1. Redeploy the reports where the error occurred. Go to **System Administration** > **Setup** > **Deploy Power BI files**.

- This action overwrites the current report and any customizations not in Microsoft Dynamics Lifecycle Services as PBIX are lost. If there are customizations in PowerBI.com, export the report as a PBIX file and upload it to Microsoft Dynamics Lifecycle Services for redeployment.

2. Deploy a sample report Go to **System Administration** > **Setup** > **Deploy Power BI files**. This fixes the above errors for any Entity store based reports in PowerBI.com

    - Users encountering this issue need to perform this action individually.

> **Note**
>
> For errors with the PowerBI.com reports after maintenance activity or if the above solution didn't resolve the issue, you may need to delete the report and the related dataset, and redeploy the report. To redeploy the report, go to **System Administration** > **Setup** > **Deploy Power BI files**. Any customizations not in Microsoft Dynamics Lifecycle Services as PBIX are lost.

Last updated on 01/22/2026

Configure PowerBI.com integration

Overview

Users can pin tiles, dashboards, and reports from their own PowerBI.com account to application workspace.

This functionality requires a one-time configuration of your environment. An administrator must complete this step to enable Microsoft Power BI to communicate and authenticate correctly.

For a workspace to show a Power BI tile, the server must contact the Power BI service on behalf of a user and access the visualization. It must then redraw the visualization in the application workspace. The fact that the server contacts the Power BI service "on behalf of a user" is important. When a user, such as `D365User@contoso.com`, contacts the PowerBI.com service, Power BI shows only tiles and reports from the user's PowerBI.com subscription.

By completing this configuration step, you enable them to contact the PowerBI.com service.

Things you must know before you start

- You must be a system administrator in the application. This option is available on the **System administration** menu.
- You must have a PowerBI.com account. You can create a trial account if you don't have an account. (A Pro license isn't required for this configuration step.)
- You must have at least one dashboard and one report in your Power BI account. Although the dashboard and report aren't required for this configuration step, you might not be able to validate the configuration if you don't have any content in your PowerBI.com account.
- You must be an administrator for your Microsoft Entra account. If you aren't the administrator, an administrative user must perform this configuration step for you.
- The Microsoft Entra domain that is configured must be the same domain that you used for your PowerBI.com account. For example, if you provisioned the application in the Contoso.com domain, you must have Power BI accounts in that domain, such as `Tim@ContosoAX7.onmicrosoft.com`.
- Users navigating to these pinned tiles must have a valid Power BI.com license.

Registration process

1. Sign in to https://portal.azure.com/ with an Azure tenant admin account.

   > **Note**
   >
   > The user who completes this procedure must have admin rights for the tenant to register applications.

2. Go to **Microsoft Entra** > **App registrations** > **New application registration**.

3. Enter the following values:

   - **Name** – Enter the name of your app.
   - **Supported account types** – Enter only accounts that are directly in this organization (single tenant).
   - **Application type** – Enter **Web**.
   - **Redirect URI** – Enter the base URL of your client with **oauth** appended to the end, such as `https://contosoax7.cloud.dynamics.com/oauth`.

4. Select **Register**.

5. Copy the **Application (client) ID** value. You use this value to connect to the PowerBI.com service.

   > **Important**
   >
   > Be sure to capture the **Application (client) ID** value.

6. Select **Manage** > **API permissions** > **Add a permission** > **Microsoft APIs** > **Power BI Service**.

   > **Note**
   >
   > For Government Community Cloud, instead of selecting **Power BI Service**, search for and select **Microsoft Power BI Government Community Cloud** in the **APIs my organization uses** tab.

7. Select **Select Delegated permissions**.

8. Enable the following permissions:

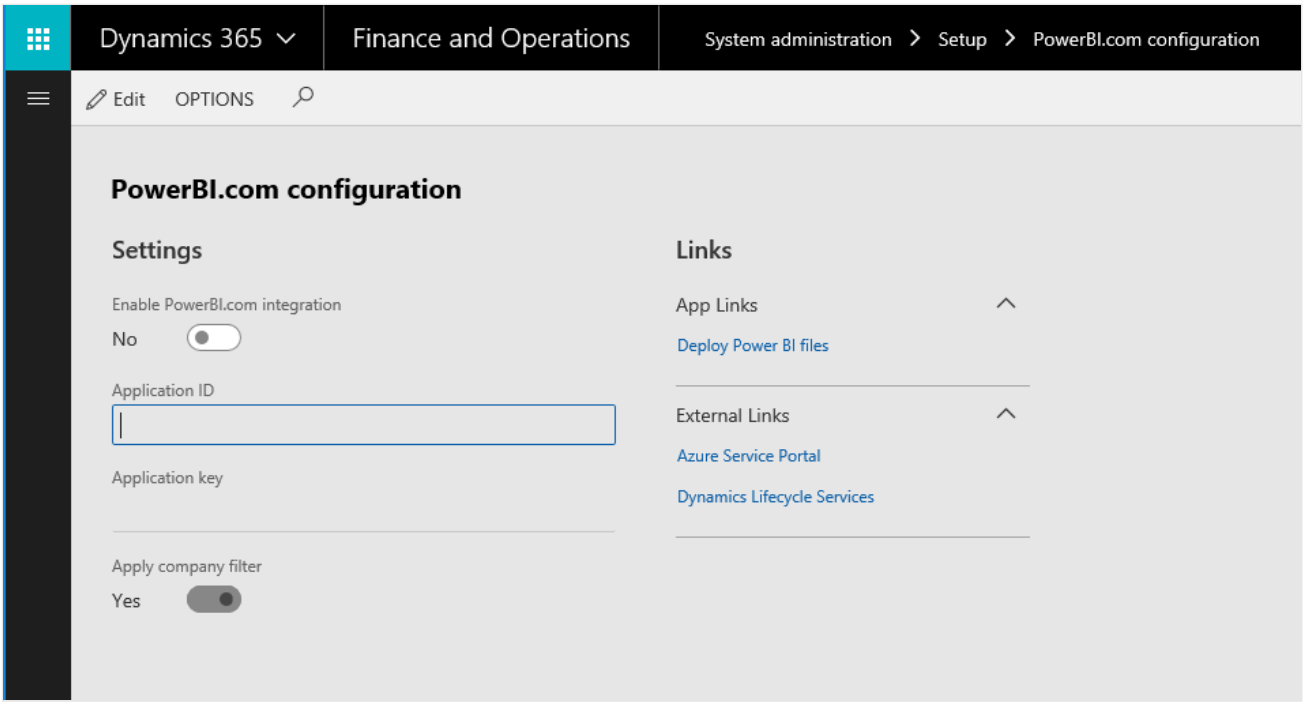
- **Content**
  - Content.Create
- **Dashboard**
  - Dashboard.Read.All
- **Dataset**
  - Dataset.Read.All
  - Dataset.ReadWrite.All
- **Report**
  - Report.Read.All
- **Workspace**
  - Workspace.Read.All

9. Select **Add permissions**. You must grant admin consent for the permissions to allow reports to be published to Power BI.
10. Select **Manage** > **Certificates & secrets**.
11. In the **Client secrets** field, select **New client secret**.
12. Enter a value in the **Description** and **Expires** fields, and then select **Add**.
13. Make a note of the **Application ID** and **Secret Value** values. You use these values in the next procedure.

    > ⓘ **Important**
    >
    > Be sure to capture the **Application (client) ID** and **Secret Value** values before you continue.

Specify Power BI settings in finance and operations

1. In the finance and operations client, open the **PowerBI.com configuration** page.



2. Select **Edit**.
3. Set the **Enabled** option to **Yes**.
4. In the **Application ID** field, enter the **Application ID** value that you got from Power BI in the previous procedure.
5. In the **Application key** field, enter the **Secret Value** value that you captured in Microsoft Entra ID in the previous procedure.

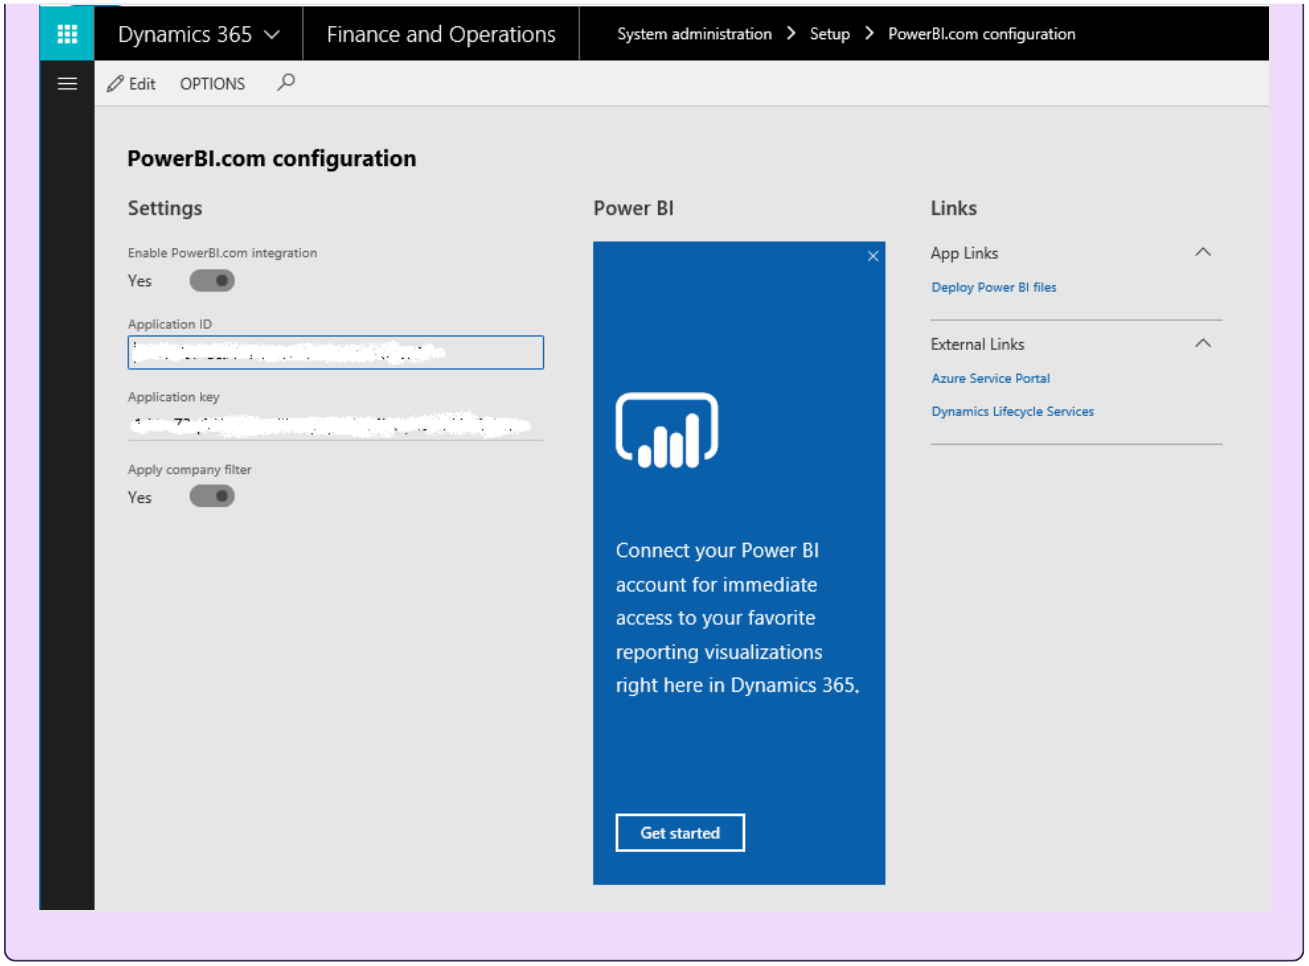
   You can apply the company filter only if your Power BI content has a table named **Company** and a column named **ID**. Ready-made Power BI content that is released uses this convention.
6. Select **Save**.

To verify the changes and enable PowerBI.com integrations, complete the steps in the next section.

Pin tiles to a workspace

1. To validate the PowerBI.com configuration, select **Get started**.

> **Note**
>
> You might need to refresh the browser to apply the changes.



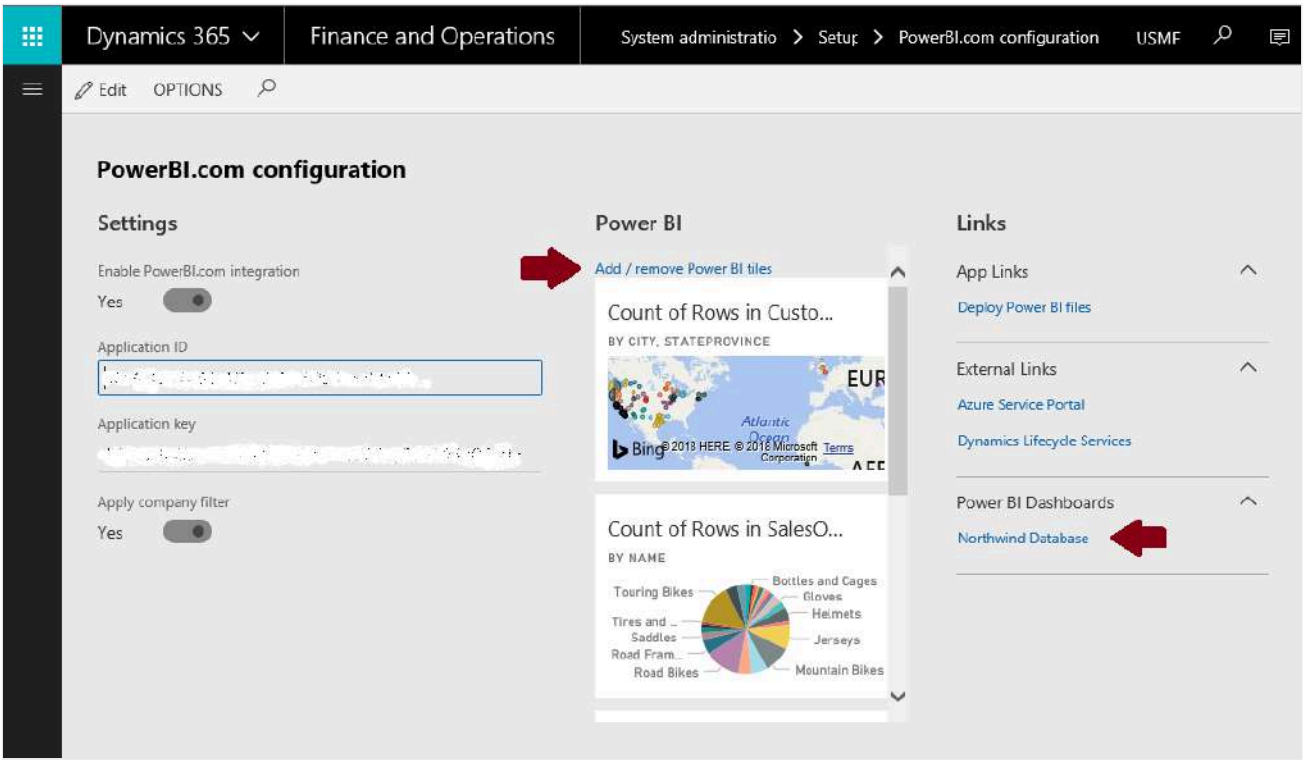
If you start Power BI from the application for the first time, you're prompted to authorize sign-in to Power BI from the client. Select **Click here to provide authorization to Power BI**.

Users must complete this step the first time they pin Power BI content.

2. The Microsoft Entra consent page asks for your consent. User consent is required for the application to access PowerBI.com on behalf of the user. Select **Accept**.

3. Because you're already signed in to Microsoft Entra ID, you don't have to enter your credentials again. A new tab appears, where you're prompted to authorize the connection between the application and Power BI. Authorize the connection, then return to the original tab.

4. A list of tiles from your PowerBI.com account appears. Select one or more tiles to pin to the selected workspace.



Troubleshooting common errors

In the previous procedure, after you select **Accept**, you might receive the following error message if the process isn't successful. The details of the error appear at the bottom of the message. More technical information provides clues that can help you determine what went wrong.

Common issues and resolution steps

Expand table

Error	Resolution
The Power BI service is unavailable.	This issue doesn't occur often, but the Power BI service might sometimes be unreachable. You don't need to re-register. Try to pin a tile to a workspace later.
You can't access the application.	You probably didn't select all the check boxes under **Step 8 in the Registration process** during the registration process. Start Power BI, and rerun the registration process.
The Power BI tiles page is empty (no content is shown).	Your PowerBI.com account might not have a dashboard or any tiles. Add a dashboard, such as a sample dashboard, and try to pin a tile again.
Error when authorizing Power BI	On the Azure Admin dashboard, under **Users and Groups** > **User settings**, make sure that the **Users can consent to apps accessing company data on their behalf** option is set to **Yes**.

Error	Resolution
Sorry, something went wrong. The authentication process wasn't successful. Contact your system administrator.	This error might occur when service keys are expired. Perform the registration process previously described, starting with step 3. When complete, be sure to update the PowerBI.com settings at **AX client** > **System administration** > **Set up** > **PowerBI.com integration**.

Last updated on 11/26/2025

Bring your own database (BYOD)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how administrators can export data entities from the application into their own Microsoft Azure SQL database. This feature is also known as *bring your own database* (BYOD).

The BYOD feature lets administrators configure their own database, and then export one or more data entities that are available in the application into the database. (Currently, more than 1,700 data entities are available.) Specifically, this feature lets you complete these tasks:

- Define one or more SQL databases that you can export entity data into.
- Export either all the records (*full push*) or only the records that changed or deleted (*incremental push*).
- Use the rich scheduling capabilities of the batch framework to enable periodic exports.
- Access the entity database by using Transact-SQL (T-SQL), and even extend the database by adding more tables.

Entity store or BYOD?

If you followed the series of blog posts about Microsoft Power BI integration, you're familiar with Entity store. Entity store is the operational data warehouse. Entity store provides built-in integration of operational reports with Power BI. Ready-made reports and analytical workspaces use Entity store. If you write Power BI reports by using data in your application environment, you should use Entity store.

However, the BYOD feature is recommended for the following scenarios:

- You must export data into your own data warehouse.
- You use analytical tools other than Power BI, and those tools require T-SQL access to data.
- You must perform batch integration with other systems.

> **Note**

The application doesn't allow T-SQL connections to the production database. If you're upgrading from a previous version of finance and operations, and you have integration solutions that require direct T-SQL access to the database, BYOD is the recommended upgrade path.

You can use either Entity store or BYOD. The default operational reports take advantage of embedded Power BI and Entity store. Use the default operational reports as your first choice. You can also extend the ready-made operational reports to meet your requirements. Consider BYOD a complementary option that you use as you require.

Creating a SQL database

Before you can configure the entity export option and use the BYOD feature, you must create a SQL database by using Azure portal.

For one-box development environments, you can create a database in the local Microsoft SQL Server database. However, use this database only for development and testing purposes. For production environments, you must create an Azure SQL database.

You should also create a SQL user account for sign-in to the database. Write down the server name, database name, and the SQL user ID and password. You use this information when you configure the entity export option in the next section.

If you're using the BYOD feature for integration for analytical purposes, consider using clustered columnstore indexes as described in Columnstore indexes: Overview.

Note

Finance and operations apps must access your BYOD database. If you encounter problems where you can't access BYOD, make sure firewall rules in your BYOD are configured appropriately. For more information, see Self-service deployment FAQ.

Selecting the correct service tier and compute size is critical to secure expected performance. While doing this, consider the total, targeted workload, and not just the load based on the finance and operations export. For production environments, use at least the minimum tier specified in the following table:

Expand table

Edition	Minimum Tier
Premium	P4 or higher
Standard	S6 or higher
Business Critical	BC_Gen5_8 or higher
Hyperscale	HS_Gen5_24 or higher
General Purpose	GP_Gen5_8 or higher

Your specific BYOD usage might require a service tier greater than the minimum. For more information about tiers and compute sizes, see SQL Azure service tiers and Detailed resource limits. To determine DTU needs or utilization, see Determine number of DTUs needed by a workload.

Configuring the entity export option

1. Start the client, and then, in the **Data management** workspace, select the **Configure Entity export to database** tile.

2. If you configured any databases, you see a list. Otherwise, you must configure a new database. In this case, select **New**, and then enter a unique name and a description for the new database. You can export entities into multiple databases.

3. Enter the connection string in the following format:

   Data Source=<logical server name>,1433; Initial Catalog=<your DB name>; Integrated Security=False; User ID=<SQL user ID>; Password=<password>

   In this connection string, the logical server name should resemble **nnnn.database.windows.net**. You find the logical server name in Azure portal. The following illustration shows an example of a connection string.

> ⓘ **Note**
>
> The default extension field shown in the previous image doesn't apply to BYOD.

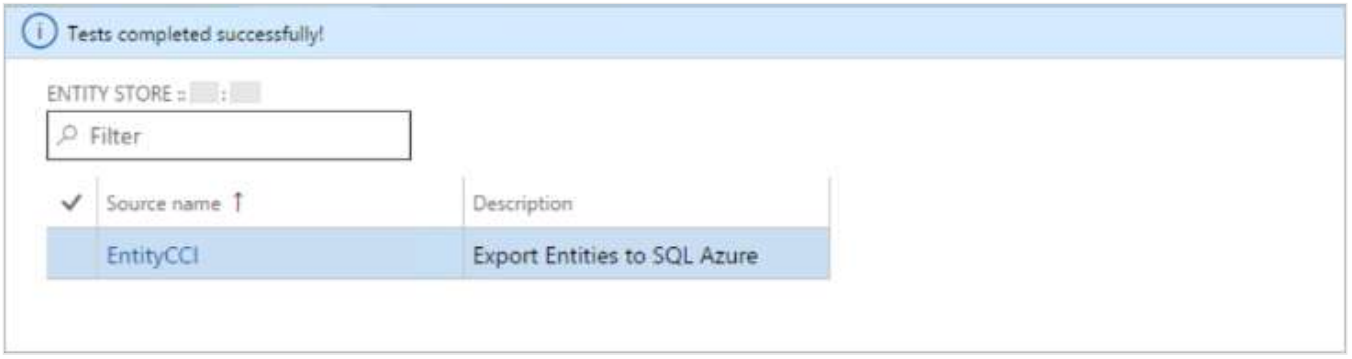
1. Select **Validate**, and make sure that the connection is successful.

   - The **Create clustered column store indexes** option optimizes the destination database for selected queries by defining columnstore indexes for entities that you copy.

- The **Enable triggers in target database** option sets jobs to enable SQL triggers in the target database. This option lets you hook downstream processes into the trigger to orchestrate actions that must be started after records are inserted. One trigger is supported per bulk insert operation. The size of the bulk insert is determined by the **Maximum insert commit size** parameter in the Data management framework.

For scenarios in which analytical applications read data from BYOD, there's always the challenge of ensuring that the reporting systems get consistent data from BYOD while the sync is in progress. You can achieve this result by not reading the analytical data apps directly from the staging tables that the BYOD process creates. The staging tables hold the data while data is being synced from the instance and hence constantly changes. Use the SQL trigger feature to determine when the data sync is completed, and then transform and fill data to the downstream analytical data scenarios.

When the validation passes, the database that you configured for entity appears in lists of databases, as shown in the following illustration.



You can now publish one or more entities to the new database by selecting the **Publish** option on the menu.

Publishing the entity schema to the database

The **Publish** page enables several scenarios:

- Publish new entities to the database.
- Delete previously published entities from the database. For example, you might want to re-create the schema.
- Compare published entities with the entity schema. For example, if you add new fields later, you can compare the fields with your database schema.
- Configure change tracking functionality that enables incremental updates of your data.

The following sections discuss each option.

Publish

The **Publish** option defines the entity database schema on the destination database. When you select one or more entities, and then select the **Publish** option, a batch job starts. This job creates the entities in the destination database. When the database definition job finishes, you receive a message, which you can access by using the bell symbol in the upper right.

The actual data update occurs when you export data. At this point, you're just creating the schema.

Drop entity

The **Drop entity** option deletes the data and the entity definition from the destination database.

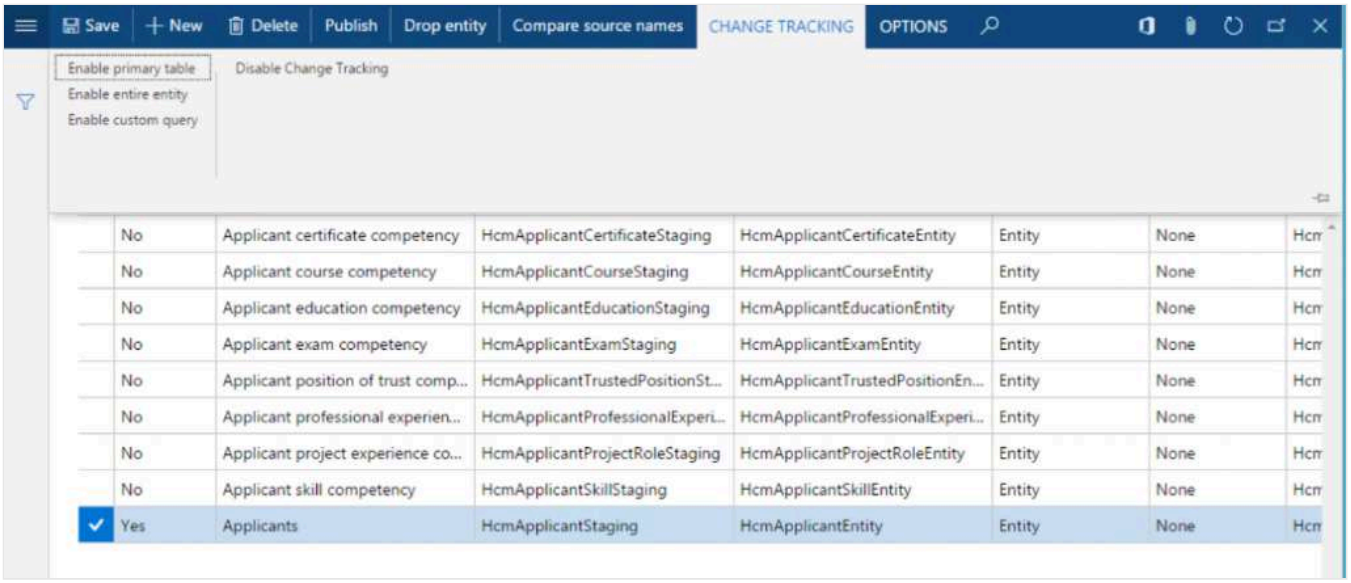
Compare source names

The **Compare source names** option lets you compare the entity schema in the destination with the entity schema in the application. Use this option for version management. You can also use this option to remove any unwanted columns from the destination table.

Configure change tracking

Change tracking is a feature that's provided in SQL Server and SQL Database. Change tracking enables the database to track changes, including deletes, that are made on tables. The system uses change tracking to identify changes that are made to tables as transactions. However, because the application must track changes at the data entity level, there's more logic on top of SQL change tracking to make this functionality work. The steps to enable change tracking are explained later in this section.

The **Change tracking** option on the **Publish** page lets you configure how changes are tracked on the underlying entity.



The following table describes the change tracking options that are available.

Expand table

Option	Description
Enable primary table	An entity consists of several tables. Select this option to track all changes that are made to the primary table of the entity. When you change the primary table, the system inserts or updates the corresponding record in the destination database. Although data from the whole entity is written to the destination table, the system triggers the insert or update option only when the primary table is modified.
Enable entire entity	Select this option to track all changes to the entity. These changes include changes to all the tables that make up the entity. When you change the entity, you make corresponding updates to the destination.
Enable custom query	This option lets a developer provide a custom query that the system runs to evaluate changes. This option is useful when you have a complex requirement to track changes from only a selected set of fields. You can also select this option when the exported entities were built by using a hierarchy of nested views. For more information, see Enable change tracking for entities.

To use change tracking, you must enable the **Change tracking** option as shown earlier in data management. This action is available on the **Data entities** list page, by going to **Data management** > **Data entities**. You need to select an entity and select from one of the options listed earlier to enable change tracking on the data entity.

If you republish an entity that exists in the destination database, the system warns you that existing data is deleted because of the new operation.

When you confirm the publish operation, the system publishes the schema to the database, and you're notified when the operation is completed.

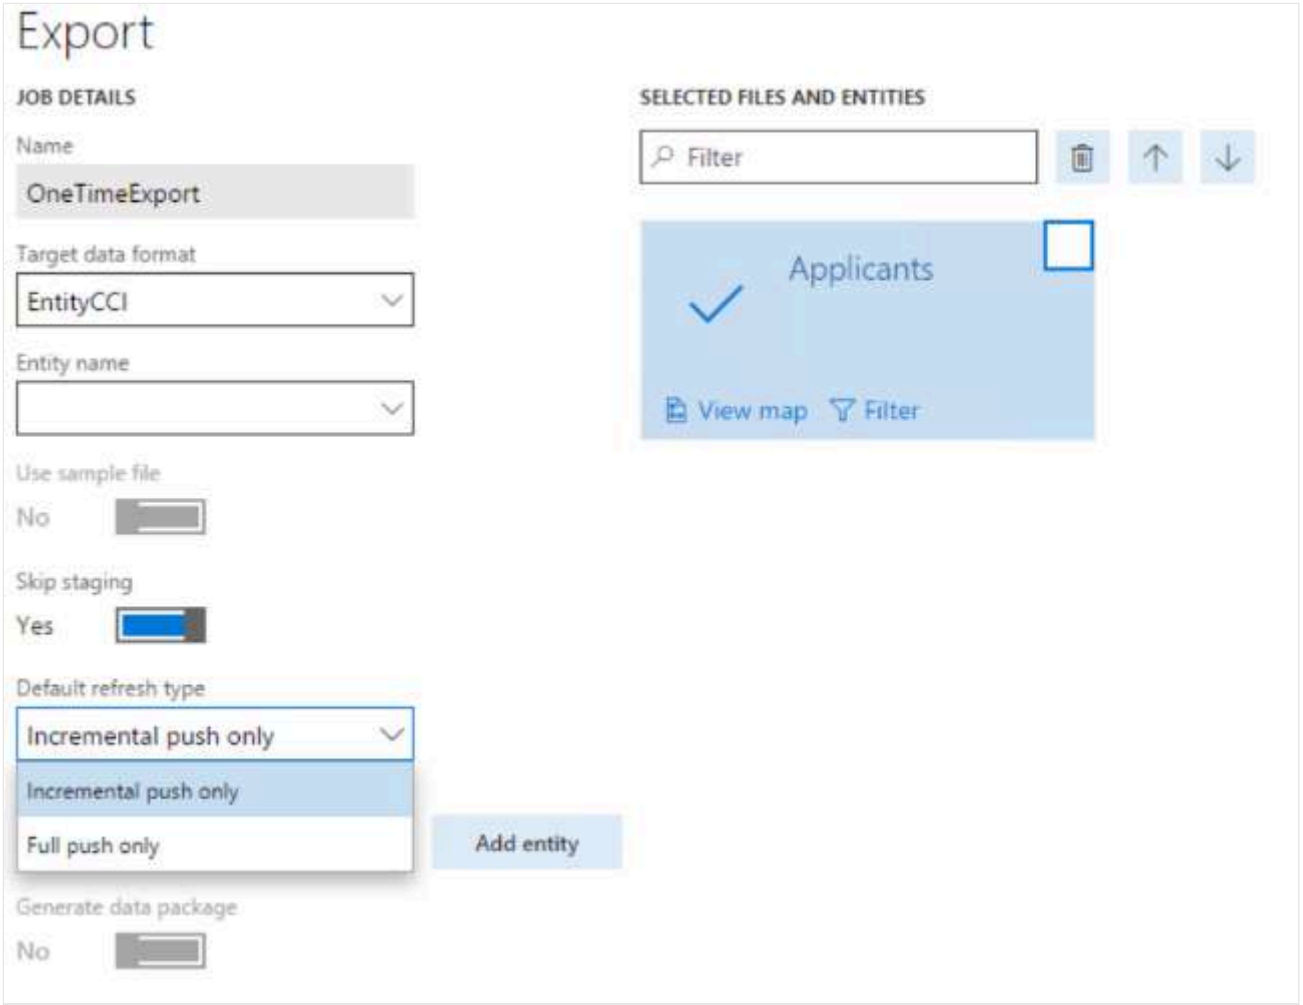
By selecting the **Show published only** option on the **Publish** page, you can show only the entities that you published to a given destination database. The Publish function creates the entity schema in the database. You can go to the database and see the table schemas that were created, together with corresponding indexes.

> **Note**
>
> Currently, you can't use BYOD to export composite entities into a database. You must export each entity in the composite entity.

Export data into your database

After you publish entities to the destination database, use the Export function in the **Data management** workspace to move data. The Export function lets you define a Data movement job that contains one or more entities.

Use the **Export** page to export data into many target data formats, such as a comma-separated values (CSV) file. This page also supports SQL databases as another destination.



You can create a data project that has multiple entities. Schedule this data project to run by using the batch framework. You can also schedule the data export job to run on a periodic basis by selecting the **Export in batch** option.

Export data across companies

Use jobs that run in batch to export data across companies. This batch export requires that the **Enable all company export** option is enabled under **Data import/export framework parameters** > **Bring your own database**. Concurrent exports for the same entity to the BYOD database might cause high DTU usage and can result in data loss for incremental exports. To avoid this risk, starting in version 10.0.16, all execution across companies is sequential per company. This execution means that jobs with a high number of entities and companies take longer to run.

To reduce the overall export times, consider the following practices:

- Make sure that the same data entity isn't in multiple projects so that the projects can run without conflicting with each other.
- Put entities that take a long time to run in separate projects. This separation allows the other projects to run faster.
- Use **Full push only** exports instead of **Incremental only** exports for smaller data sizes. For example, you might want to use this approach if some of the entities have record counts of around 1,000 or less.
- Create cross-company entities if you don't need to export data per company, individually.

To create a cross-company entity:

1. Copy the current per company entity.
2. Change the name of **PublicCollectionName** and **PubliceEntityName** of the copied entity.
3. Add a column for **DataAreaId**, if needed.
4. Remove the value for the **PrimaryCompanyContext** property in order to not filter by the primary company during export.
5. Generate the staging table, and then build and deploy the new entity.
6. Test the new entity to make sure that it works properly and performs adequately at required scale.
7. Schedule an export job in batch for the new entity, without selecting the **Export across all companies** option.

> **Note**
>
> Add multiple entities to an export project for BYOD carefully to ensure that the overall reliability of the BYOD export isn't compromised. Consider different parameters when

deciding the number of entities to add to the same project. Consider the degree of complexity of the entities, data volume per entity that you expect, and the overall time for export to complete at the job level. Avoid adding hundreds of entities. Create multiple jobs with a smaller number of entities.

Use of recurring exports in **Manage** > **Manage recurring data jobs** for BYOD isn't supported. You must use the **Export in batch** option.

Incremental export

When you add an entity for data export, you can select an incremental export (also known as incremental push) or a full push. For incremental push to work, you must enable the **Change tracking** option in the database and specify an appropriate change tracking option, as described earlier in this article.

> ⓘ **Note**
>
> A full push deletes all existing records from an entity and then inserts the current set of records from the selected entity.

If you select an incremental push, the first push always uses a full push. This push uses a full push because SQL needs to know which records are tracked in order to track subsequent changes. Whenever you insert a new record or add or delete a record, the corresponding changes are reflected in the destination entity.

Because the first push always uses a full push, don't perform an explicit full push before you enable change tracking.

Enable change tracking and schedule an export job with incremental push. This change takes care of the first full push and the subsequent incremental exports.

> ⓘ **Note**
>
> If you notice that the incremental push setting acts like a full push in certain scenarios, two possible reasons exist:
>
> 1. The entity is being exported for the first time by using incremental push, so it behaves as a full push.
> 2. The incremental push export doesn't run within the retention period. To prevent data loss, the export automatically falls back to the full push setting.

Timeouts

The default timeouts for BYOD exports are set to 10 minutes for truncation operations and one hour for actual bulk insert operations. When volumes are high, these timeout settings might not be sufficient and you must update them. You can update the timeout settings by going to **Data management** > **Framework parameters** > **Bring your own database**. These timeouts are company specific and you must set them separately for each company.

Known limitations

The BYOD feature has the following limitations.

Don't have active locks on your database during synchronization

Because BYOD is your own database, you must ensure that there are no active locks on your Azure SQL database when data is syncing. Active locks on your database during synchronization can result in slow writes or even failure to export to your Azure SQL database.

You can't export composite entities into your own database

Currently, composite entities aren't supported. You must export individual entities that make up the composite entity. You can do this export in the same data project.

You can't export entities that don't have unique keys by using incremental push

You might face this limitation especially when you try to incrementally export records from a few ready-made entities. Because these entities were designed to enable the import of data, they don't have a unique key. However, you can enable change tracking only for entities that have a unique key. Therefore, there's a limitation on incremental push. One workaround is to extend the required entity and define a unique key.

Troubleshooting

Incremental push isn't working correctly

Problem - When a full push occurs for some entity, you can see a large set of records in BYOD by using a select statement. However, an incremental push results in only a few records in BYOD. It seems as if the incremental push deleted all the records and added only the changed records in BYOD.

Solution - In cases like this, disable and re-enable change tracking for the entity in question. The state of the SQL change tracking tables might not be in the expected state. Also verify that there are no other incremental exports that cover the same tables (DMF, MR, Retail).

SSIS error code DTS_E_OLEDBERROR. An OLE DB error occurred. Error code: 0x80004005

Problem - Export to BYOD fails with an SSIS exception.

Console

```
An OLE DB error has occurred. Error code: 0x80004005.

An OLE DB record is available. Source: "Microsoft SQL Server Native Client 11.0"
Hresult: 0x80004005  Description: "Communication link failure".

An OLE DB record is available. Source: "Microsoft SQL Server Native Client 11.0"
Hresult: 0x80004005  Description: "TCP Provider: An existing connection was forcibly
closed by the remote host.

Failed to open a fastload rowset for <entityStaging>. Check that the object exists
in the database.

OLE DB Destination failed the pre-execute phase and returned error code 0xC0202040.
```

Solution - This problem occurs if the connection policy on the Azure SQL BYOD server is set to Proxy. Change this policy to **Redirect**. For more information, see SQL DB Connectivity Architecture.

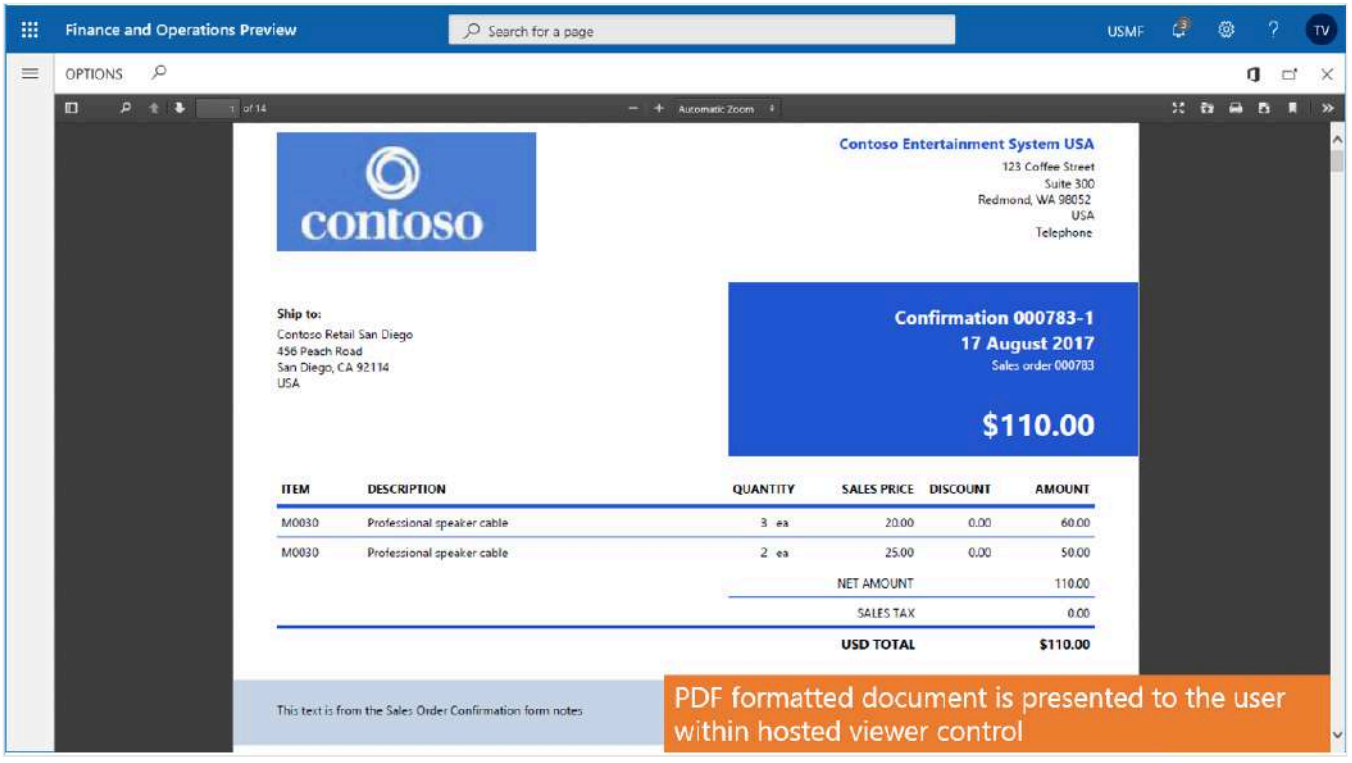
Preview PDF documents by using a PDF viewer

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Streamline application experiences that result in the production of business documents by taking advantage of the embedded PDF Preview option. Finance and operations applications deliver a modern experience to preview business documents that the service produces. You can use the built-in toolbar to navigate and download the document or to print to locally connected devices.

The embedded viewer offers consistency between the screen presentation and the printed output. In addition, report viewing times are drastically reduced when compared to the legacy experience. The Preview option is available on all supported devices and doesn't require any additional third-party software. You can easily download and navigate documents by using the built-in viewer toolbar options.

The following illustration shows a preview of the experience with a modern business document.



The legacy HTML-based preview experience is being replaced by a true document preview experience. The modern PDF preview experience offers several key advantages. These advantages include:

- Fidelity between the screen presentation and the printed output.
- A consistent document report preview experience across devices and platforms, including on-premises deployments.
- Server-side rendering that improves the performance when producing the document.
- Built-in tooling that allows users to quickly navigate the contents of the business document.

Accessing the PDF preview experience (Platform update 36 or later)

The PDF preview experience is enabled by default in Self-Service deployments and in environments hosted on Platform update 39 or later. To use the PDF preview experience in cloud-hosted and Microsoft-managed environments running Platform updates 36 through 38, use Feature Management to enable the **Report PDF viewer** feature.

Additional feature information

- Expandable and collapsible sections are available by default. These interactive operations don't function after the PDF document is created.
- The printer drop-down menu allows users to choose from locally connected devices. This list doesn't include network printers connected through the service.
- The built-in toolbar actions download documents to the local device.
- Use the **Print destination** options to produce documents in formats other than PDF.
- Use the **Enable accessibility feature on report PDF Files** feature flag to render PDF files as an accessible and tagged PDF, which is larger in size but easier for screen readers and other assistive technologies to read and navigate. The default is off.

Feature limitations

The Embedded PDF viewer experience delivers a closed document that exactly matches the printed output of the document. Recipients can't modify these documents, making the format ideal for business operations. However, as a closed format, the documents are far less interactive on the screen when compared to HTML presentations. The following end-user capabilities aren't supported when previewing documents by using the embedded PDF viewer.

- By default, embedded drill-thru navigation links are only available while previewing PDF documents.
- PDF documents don't support expandable and collapsible sections.

Analytics, aggregate measurements, and KPI modeling

This article discusses the embedded business intelligence (BI), aggregate measurements, dimensions, data entities, and aggregate programming model.

Embedded business intelligence

The term embedded business intelligence (BI) refers to experiences that use highly intuitive and fluid visualizations to provide insights that are relevant to a task, so that the user is more informed and can make better choices. For example, a rental clerk in a car rental organization views the previous rental preferences of a customer when the customer makes a reservation. In this case, the clerk can see the vehicles and colors that the customer selected in the past, and therefore can offer options that are likely to please the customer. Use embedded BI throughout the user interface. At a technical level, building rich visualizations requires a powerful charting framework, and also an efficient way to access aggregated data that enables the display of fluid visualizations. Microsoft Dynamics 365 finance and operations meets both of these requirements, so that application developers can build rich and deep embedded BI–enabled scenarios.

Where are the perspectives?

Perspectives were designed to present data from a reporting point of view. Perspectives have evolved over the past three releases for analytical scenarios.

Expand table

Version	Description
Microsoft Dynamics AX 4.0	Perspectives provided the ability to model ad-hoc reporting models.
Microsoft Dynamics AX 2009	Perspectives added support for modeling analysis cubes.
Microsoft Dynamics AX 2012	Perspective modeling capabilities were improved through richer modeling support and deeper integration with the Application Object Tree (AOT).
Finance and operations apps	Perspectives are a first-class citizen in the data access framework. You can consume them via X++ or C# code, and also in a model-driven way.

Perspectives reside within the analytics collection in the Application Explorer. Perspectives underwent a major upgrade and now incorporate the following improvements:

- You can model new aggregate models and customize existing aggregate models as a star schema within Application Explorer.
- Modeling for key performance indicators (KPIs) in Application Explorer is supported.
- You can model data entities by referencing aggregate models. You can expose data entities to external reporting tools, such as PowerBI, as OData endpoints. You can also consume data entities.
- You can consume aggregate models directly in the programming model by using X++ or C# code. You no longer have to write MDX code to consume aggregate data.
- Aggregate data is a first-class citizen within application data access. Its behavior is similar to the behavior of detailed data. For example, you can enrich aggregate data with extended data types (EDTs) and enumerations, and you can help secure them by using application security concepts.
- The aggregate data infrastructure is maintained completely within the environment. By default, aggregate measurements are real-time. As a system administrator, you can manage the latency of aggregate data and controls based on available resources and business needs, without having to deal with the complexity of scheduling and external tools.
- Developers can reuse existing business models, making the modeling process quicker and easier.

You can upgrade projects that were generated by using perspectives from Dynamics AX 2012 and later to finance and operations metadata equivalents.

Aggregate measurements and aggregate dimensions

An aggregate measurement is a model that contains a collection of measures together with their corresponding dimensions. Measures are aggregate numbers, such as Total Sales or Number of Orders. Dimensions are slicers, such as Product, Vendor, or Customer, that help you analyze the measure. For example, the measure of Total Sales isn't useful unless it can be sliced by Product, Region, and Customer. Aggregate measurements are the evolution of AX 2012 analysis cubes. Whereas a cube was based on a multidimensional online analytical processing (OLAP) technology, an aggregate measurement abstracts the underlying technology. Therefore, you no longer have to know a lot about the underlying implementation technology. Additionally, the underlying technology infrastructure can take advantage of improvements in in-memory real-time technology without requiring the developer to rewrite the program. Aggregate dimensions are shared across an implementation. Aggregate measurements associate themselves with

relevant aggregate dimensions. For example, Total Sales can be associated with Customer, Product, and Sales Region dimensions. However, Total Sales can't be associated with Vendor and Warehouse dimensions. You model aggregate dimensions and aggregate measurements by using Visual Studio tools. The Upgrade tool lets customers and partners migrate existing Dynamics AX 2012 cubes to newer versions of the product.

Aggregate data entities

By using the model-driven approach, you can create data entities by directly referencing aggregate measurements and aggregate dimensions. These data entities are known as aggregate data entities. Aggregate data entities are read-only data entities that you use for reporting purposes. To consume aggregate data when you build charts and other client controls, add the aggregate data to a form as a data source. You can also consume aggregate data entities programmatically in C# or X++ code.

Aggregate programming model

The Aggregate programming model lets a developer consume aggregate data programmatically by using either X++ or C# code. Data that you retrieve by using the Aggregate programming model can be used as a data source in forms and reports. A developer can add aggregate data that is modeled in perspectives to an **AXQuery** object. The developer can also use an existing aggregate data entity to create a query that can be extended by adding filters and additional columns that aren't present in the aggregate data entity. Bulk Move is a capability that is associated with the Aggregate programming model. When a query is run by the kernel, the developer can move all the records to a temporary or regular table without iterating row by row. Bulk Move provides a very efficient way to move data from aggregate models to temporary tables.

Method expressions

Method expressions are a programming model for constructing rich calculations that are used to define fields in a data entity. Method expressions enhance the computed column capability that was introduced in AX 2012 views. Method expressions let you build expressions by using the C# or X++ programming language. You can also create calculations on aggregate data that was previously coded by using MDX. Method expressions can be shared across the program.

In-memory, near-real-time aggregate measurements

You deploy aggregate measurements to Microsoft SQL Server nonclustered columnstore indexes (NCCI). Therefore, they take advantage of the in-memory computing (IMC) engine that is built into Microsoft SQL Server 2016 as Azure DB. Aggregate measurements that have the IMC engine as their destination are referred to as in-memory, near-real-time (IM-NRT) aggregate measurements. These aggregate measurements don't require that a Microsoft SQL Server Analysis Services (SSAS) server be used. Because these models don't involve data updates, the queries that are sent to them reflect the latest state of data in the operational database. That is why it's referred to as near-real-time.

KPI modeling and customization

In AX 2012 and earlier versions, you had to model KPIs and business indicators by using native SQL Server development tools. Although users could pin a KPI or business indicator to a Role Center by using the **Business Overview** Web Part, they couldn't modify a KPI definition, such as the goal. Users can use a rich client form to modify a KPI definition that a developer built and shipped. Users can also define new KPIs by using the aggregate data that is contained in aggregate measurements. A developer can model a KPI definition in Microsoft Visual Studio and ship it to a customer, either as a project or together with an independent software vendor (ISV) solution. After a KPI is defined, users can customize it at run time.

Model aggregate data

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This tutorial shows you how to model aggregate data.

Prerequisites

This tutorial requires you to access the environment by using Remote Desktop and be provisioned as an administrator. For more information, see Deploy and access development environments.

Key concepts

- **Aggregate measurements**, similar to **perspectives** and **Cubes** from earlier versions, enable you to model and consume aggregate data.
- **Key Performance Indicators (KPIs)** are a form of analytic controls that track organizational performance against the current status. KPIs are represented as tiles in a **workspace** or the **dashboard**. In this tutorial, you model a KPI in Visual Studio.
- You can modify KPIs that you model in Visual Studio in the client. A user can also model new KPIs by using the client.
- A **workspace** is an overview page that's specific to a particular subject area. All users share workspaces.
- The **dashboard** is the default home page for each user.
- **Tiles** are securable objects that you can pin to a workspace or the dashboard. You can secure KPIs and aggregate data that show on the dashboard or a workspace by using menu items.
- You can consume aggregate data in building charts and other controls. By using the model driven approach, you can create data entities by directly referencing aggregate measurements and aggregate dimensions. These entities are referred to as **Aggregate data entities**. Aggregate data entities are read-only data entities used for reporting purposes.
- **The aggregate programming model** enables a developer to consume aggregate data programmatically by using either X++ or C# code. You can use data retrieved by using

the aggregate programming model as a data source in forms.

- **Method expressions** enable a developer to build rich expressions by using aggregate data. Method expressions are an X++ class. By using method expressions, you can model KPIs, thereby eliminating the need to build MDX expressions.
- **Contextual BI** refers to providing required insights as part of the user experience such that the user has relevant insights to not only achieve the task at hand, but be highly-productive during the day.
- **Embedded BI** refers to analytic content being embedded within the user experience. Contextual BI and embedded BI teams are closely related. Contextual BI implies the added notion that the context of analytic context revolves around the data or the task.
- **Self-service BI** refers to enabling a user to tweak existing and/or create new analytic content such as reports, KPIs, and dashboards.

Set up

If this tutorial is the first tutorial you're working on, make sure you configure the administrator user if you're running on a local VM.

Import the tutorial project

If you already imported the Fleet management tutorial project, go to the next section. In Visual Studio, on the **Dynamics 365** menu, select **Import Project**.

1. Download the Fleet Management sample from https://github.com/Microsoft/FMLab, save it to **c:**, and unzip it.
2. In the **Import Project** window, next to the **Filename** text box, select the ellipsis button.
3. In the **Select the file to import** window, browse to the location of the **FMLab** folder, select **FMTutorialDataModel.axpp**, and then select **Open**.
4. In the **Project file location** text box, enter **C:\FMLab**.
5. Select the **Overwrite Elements** check box, and then select **OK**.

Open the tutorial project

1. In Visual Studio, open the **FMTutorial** project. On the **File** menu, point to **Open**, and then select **Project/Solution**.
2. In the **Open Project** dialog box, browse to C:\FMLab\FMTutorial, and then select FMTutorial. Select **Open**. The **FMTutorial** project appears in **Solution Explorer**.
3. Use the FMTDataHelper class to load data for the Fleet Management tutorial. In **Solution Explorer**, in the FMTutorial project, expand **Classes**. Right-click **FMTDataHelper**, and then select **Set as Startup Object**.

4. On the **Build** menu, select **Rebuild Solution**. Use the rebuild to update the timestamps of the imported artifacts. You can view the build progress in the **Output** window.
5. Press Ctrl+F5 to run the project and load the data.

Model an aggregate measurement for rental charges

Often, when a user asks for additional information, you get a request for one or more new reports. Imagine that the manager of a rental car company calls and asks for a report. The manager is interested in finding out how the rental business is performing. The manager wants a report that shows rental revenue by month. You soon find out that the manager is interested in a breakdown of rental revenues. The manager wants to know whether the rental revenue is high in cases where they sold additional services, such as car seats, GPS, refueling, as opposed to the base rental charge. As it turns out, the manager suspects that specific customer groups are driving up revenue, and this is why the manager wanted the report in the first place. The manager insists on adding Customer group to the report. Because the revenue must be considered in relation to the number of rentals, the manager doesn't want a few large corporate rentals to skew the analysis. You both agree that the number of rentals needs to be shown along with revenue. You could represent this requirement as a set of business questions using a matrix. Rows indicate the **measures** (or numbers) and the columns indicate the **dimensions** (or slicers). An "X" in the intersection between a measure and a dimension indicates that the measure needs to be "grouped by" the dimension.

Expand table

Item	Rental date	Customer group	Rental charge type
Revenue	X	X	X
Number of rentals	X	X	X

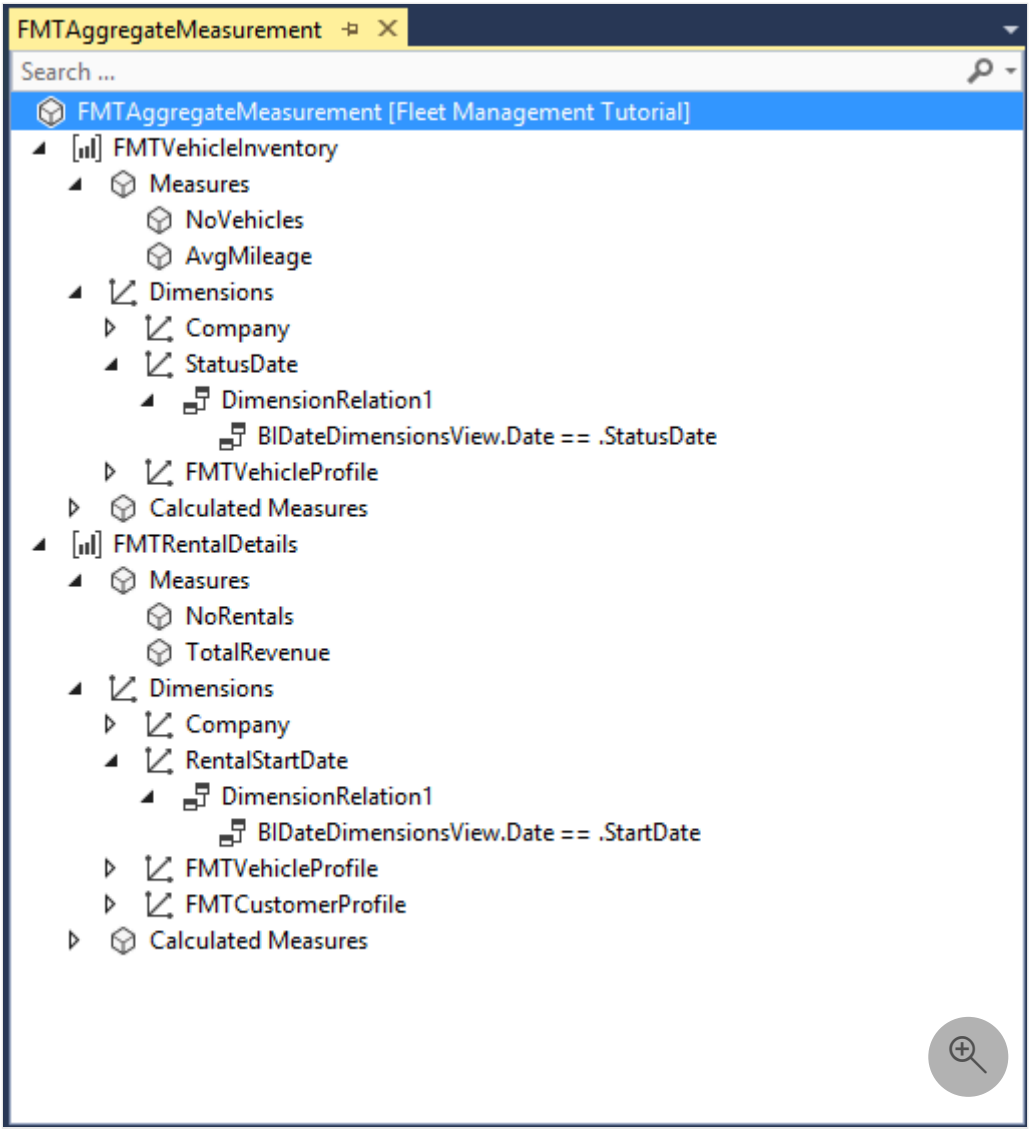
Next, model an aggregate measurement to answer this business question.

Add a measure group for rental charges by using an existing view

In this section, you add a new measure group to an existing aggregate measurement.

1. In **Solution Explorer**, expand the **Analytics** folder of the project, and then double-click the aggregate measurement, **FMTAggregateMeasurement**. The aggregate measurement opens in the designer. Notice that the existing aggregate measurement contains two

measure groups related to vehicle inventory and rental details. You create a new measure group related to rental charges.



2. In **Solution Explorer**, expand the **Views** folder of the project, and then select the **FMTRentalChargeExtendedView** view.

3. Drag and drop the **FMTRentalChargeExtendedView** into the root node of the **FMTAggregateMeasurement** aggregate measurement in the designer. A new measure group is created and the values of properties are applied as follows.

Expand table

Property	Value
Name	FMRentalChargeExtendedView
Table	FMRentalChargeExtendedView

4. In **Solution Explorer**, double-click the **FMRentalChargeExtendedView** view. When the designer form opens, expand the **Fields** node.

5. Select the **ExtendedAmount** and **RentalID** fields, and then drag and drop the two fields onto the **Measures** node of the newly created **FMAggregateMeasurement** measure group called **FMRentalChargeExtendedView**. As you drag the fields, hover your cursor over the **FMAggregateMeasurement** tab to access the **Measures** node. By default, when you drag and drop the fields, the system assumes that you want counts of the measures. In this case, you need to modify default properties for the **ExtendedAmount** and **RentalId** measures as follows:

Expand table

Property (ExtendedAmount)	Value
Default Aggregate	**Sum**
Field	ExtendedAmount (no change required)
Name	Revenue

Expand table

Property (RentalId)	Value
Default Aggregate	**DistinctCount**
Field	RentalId (no change required)
Name	NumRentals

6. Next, create another measure that calculates **Revenue per Rental** by copying an existing measure. Select the **TotalRevenue** measure. Right-click and select **Copy** from the **Context** menu.

7. Select the **FMRentalDetails** measure group. Right-click and select paste. Rename the newly created measure to **RevenuePerRental**. Modify the aggregation function to **Average**.

Model an aggregate dimension charge type

To analyze rental revenue by the different charge types, you need to be able to slice revenue by the charge type. For this purpose, model a charge type dimension.

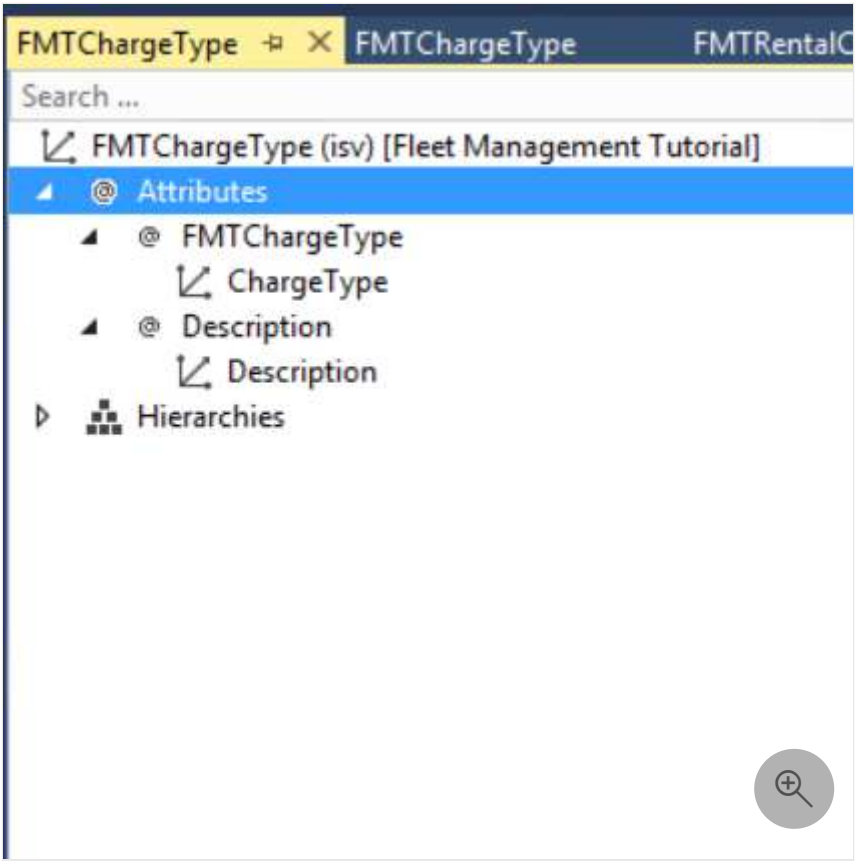
1. In **Solution Explorer**, under **FMTutorial**, right-click **Analytics**, point to **Add**, and then select **New Item**.

2. Select **Dynamics 365 Artifacts** > **Analytics** > **Aggregate Dimension** from the list of items.

3. In the **Name** property, enter **FMTChargeType**. This name is the aggregate dimension that you create. It must be unique. Select **Add**. The new dimension appears in Visual Studio.

4. In **Application Explorer**, expand the **AOT** and select **Data Model** > **Tables**. Drag and drop the **FMTChargeType** table from **Application Explorer** onto the root node of the newly created **FMTChargeType** dimension in the designer. The **AutoReport** field group of the table adds dimension attributes and corresponding keys.

5. Expand the **Attributes** node of the new dimension. Several attributes are created by default. The system also creates a dimension key based on unique indexes of the table. You can add extra fields by dragging and dropping them into the **Fields** node.



6. Save the new dimension.

7. You might get a warning that asks you to rename the field name **Description** to avoid the MDX reserved word. Even though you might not deploy the aggregate dimension to SSAS in this aggregate measurement, it's possible that this dimension might be used by an aggregate measurement deployed to SSAS in the future. To avoid potential problems, rename the field name **Description** to **ChargeDescription**.

Model dimension references for customer profile and charge type dimensions

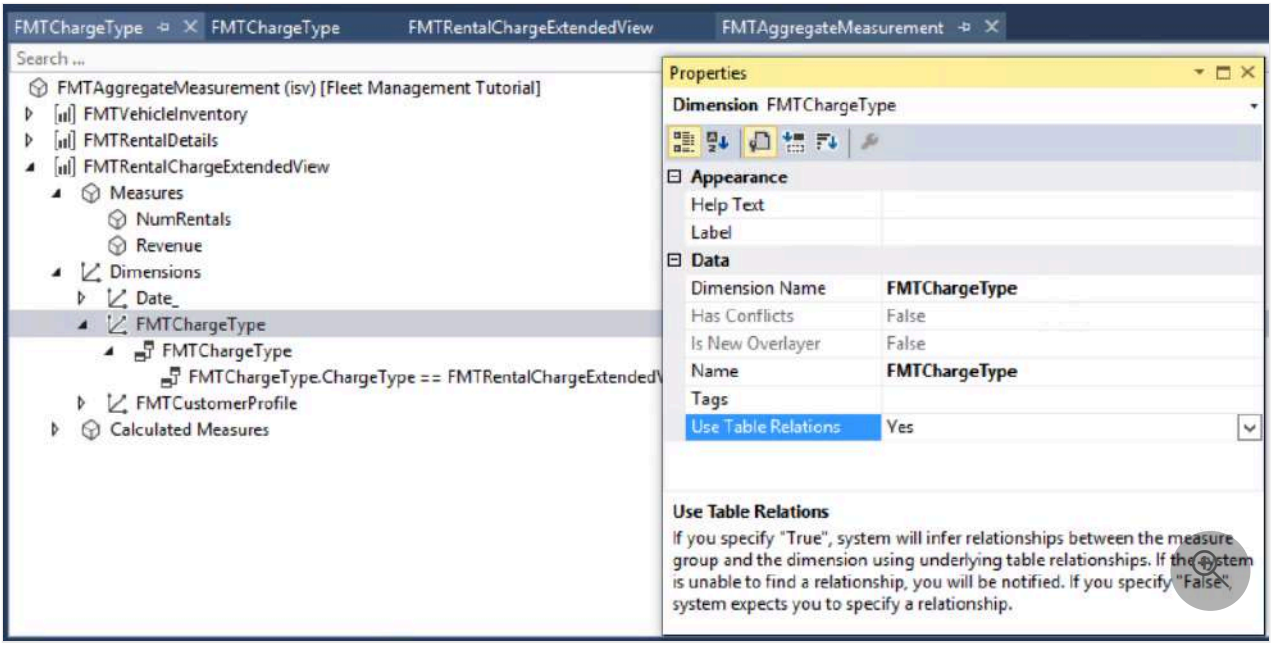
Next, create dimension references to new and existing dimensions so that you can slice revenue by customer and charge type.

1. In **Solution Explorer**, double-click **FMTAggregateMeasurement** or, if you have it open, navigate to it in the designer.

2. In **Solution Explorer**, select the dimensions **FMTChargeType** and **FMTCustomerProfile**.

3. Drag and drop these dimensions into the **Dimensions** node of the **FMTRentalChargeExtendedView** measure group. Notice that you create dimension references along with relations.

4. Save changes to **FMTAggregateMeasurement**. Review the property sheet for the dimension relation and notice that the **Use Table relations** property is set to **Yes**. Notice that the drag-and-drop operation created relationships between the measure group dimensions **FMTRentalChargeExtendedView** and **FMTChargeType**, **FMTCustomerProfile**. Review the property sheet for the dimension relation and notice that the **Use Table relations** property is set to **Yes**.



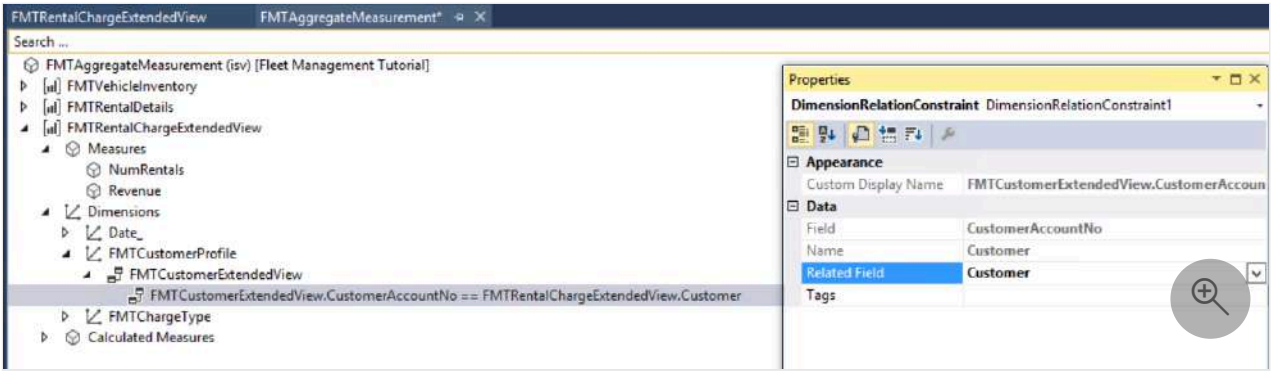
> **Note**
>
> In platform update 1611 and later, the **UseTableRelations** property is removed. When you create a new dimension reference, the system defaults existing relationships. You can continue to provide an explicit relationship by changing the relationship field that was defaulted. Providing an explicit relationship is equal to setting **UseTableRelationship** to **No**.

5. Expand the Dimension relations node for the **FMTCustomerProfile** dimension. Notice that the **UseTableRelations** property is set to **No**. In this case, the system can't find a suitable relationship between the measure group and dimension. You need to specify one manually.

6. Expand the **FMTCustomerProfile** dimension reference if you didn't already. Select the node **FMTCustomerExtendedView**. Right-click and see the property sheet.

7. Select **CustomerID** as the value for property **DimensionAttribute**. Select the relationship shown in the following image. Select **Customer** for the property value **RelatedField**.

8. Save changes to **FMTAggregateMeasurement**.



9. In this scenario, you specify a relationship because the system was unable to find one. You can also specify a different relationship if you want to override the system choice by setting **Use Table Relations property** to **No**.

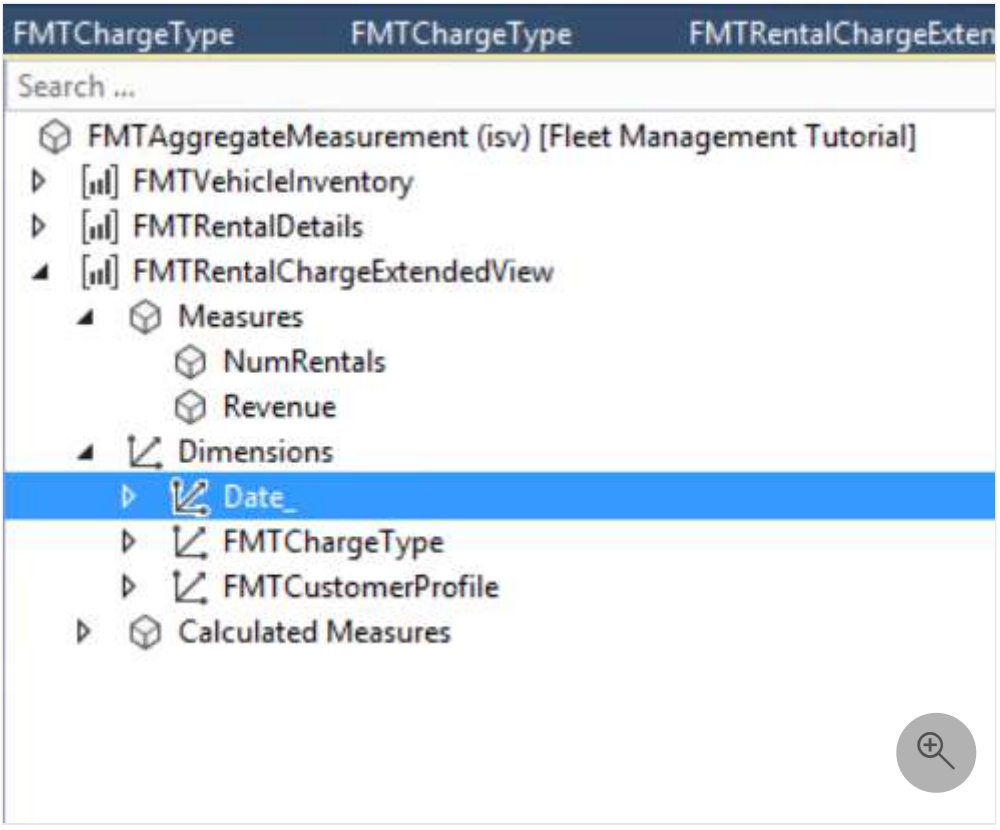
Model dimension references for the date dimension's rental start date and transaction date

Assume that for analysis purposes, you want to enable slicing by the start date of the rental. But for accounting purposes, you want to enable slicing by the transaction date for each of the charges. To do this, you need to associate the rental charges measure group with two date dimensions. In the BI world, this pattern is known as **Role Playing dimensions**. By default, a date dimension is added to the measure group. You can rename the default name appropriately and add new date dimensions as required.

1. Expand the **Dimensions** node of the **FMTRentalChargeExtendedView** measure group. Notice that the **Date_** dimension is already included as dimension slicers.

> ⓘ **Note**
>
> If the table or the view used to model the measure group is a Company-specific table, for example it contains DATAAREAID as part of the key, a **Company** dimension

relation is created by default. In this case, the view you used isn't a company specific one.



2. Select the **Date** dimension and specify the following properties.

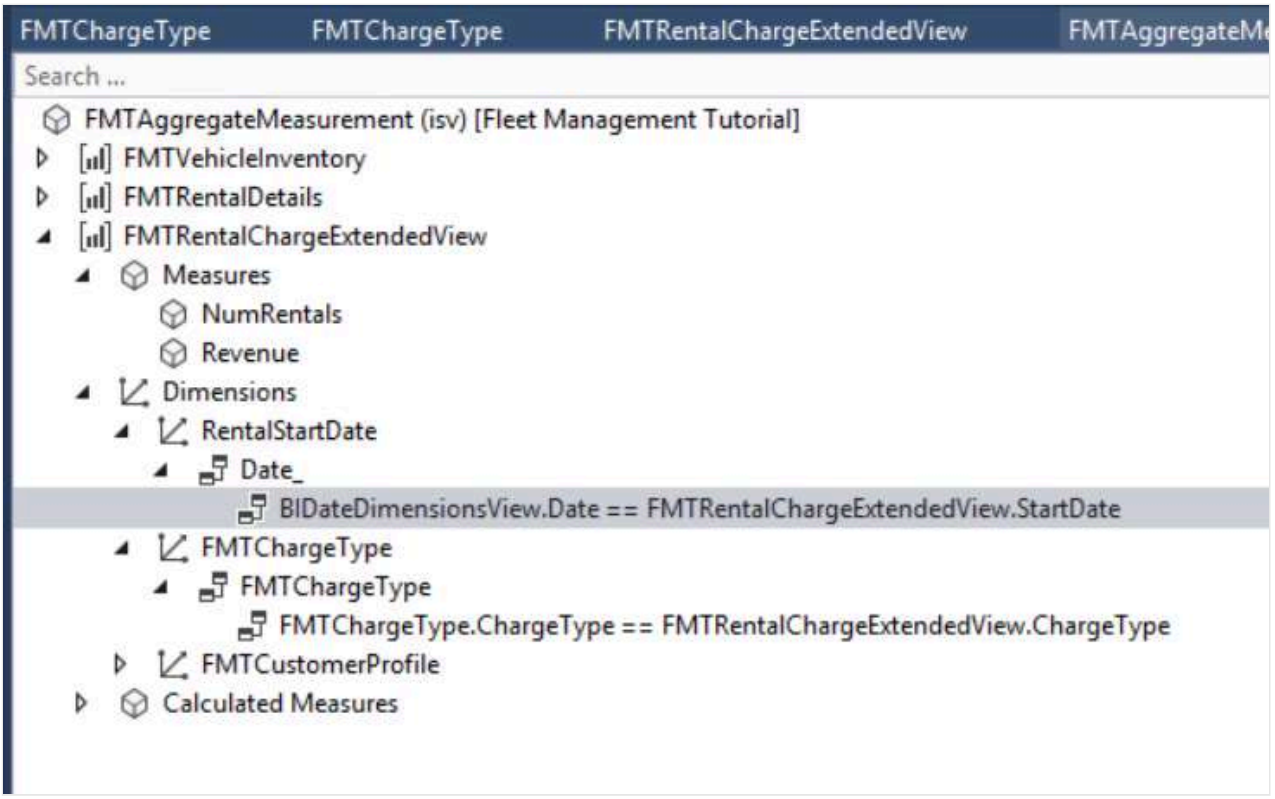
Expand table

Property	Value
Name	RentalStartDate
Use Table Relations	No (This is the default – no need to change)

3. Define the table relationship. Expand **RentalStartDate**, and then expand the **Date** node.

4. Select the Relationship shown. Right-click and select the property sheet. Select **StartDate** for the value of **Related field** property.

5. The relationship you defined should look like the following screenshot.



6. Next, enable slicing of measures by the TransactionDate dimension. TransactionDate is also a date dimension, so add another reference to the date dimension and associate that reference with the corresponding field that contains the transaction date. When you use more than one date dimension as a slicer, each date dimension is known as a **Role playing date dimension**.

7. Under the **FMTRentalChargeExtendedView** measure group, right-click the **Dimensions** node, and then select **New Dimension**. A new dimension is added to the list of dimension references.

8. Specify the following properties for the new dimension reference.

Expand table

Property	Value
Dimension Name	Date_ **NOTE:** If you select the Dimension Name in the wrong order, it resets the other values you already set.
Name	TransactionDate
Use table relations	No
Tags	RolePlayingDate; Fleet

Notice the new property called **Tags**. This property enables the discovery of patterns within code and metadata from within the Visual Studio environment. You can enter any

number of tags and they can be searched by using the hot keys or the **Dynamics 365** menu in Visual Studio.

9. Define the table relationship. Right-click **TransactionDate**, and then select **New Relation**. You don't need to specify any properties in the DimensionsRelation at this point.

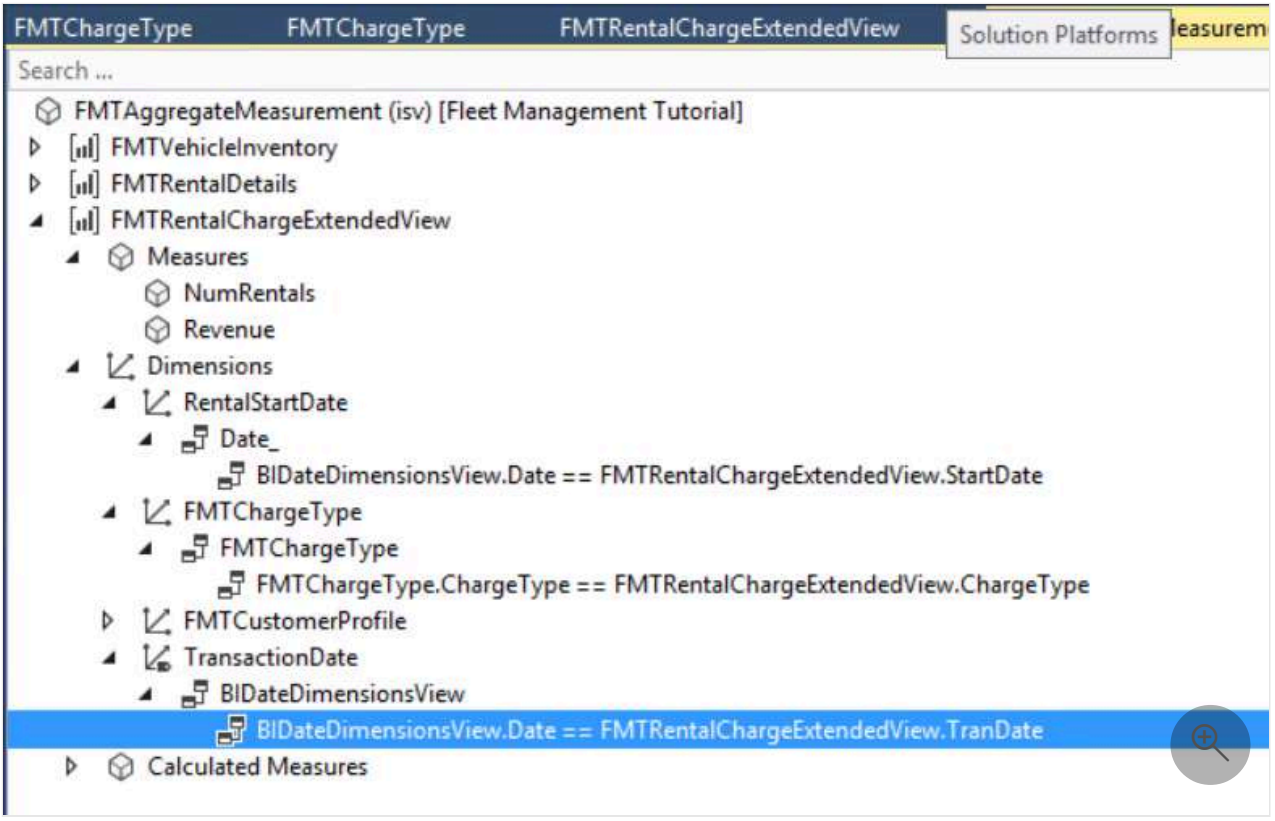
10. Expand **BIDateDimensionValue**, and then select the **Relationship Constraint**. Right-click and select the property sheet.

11. Specify the following properties for the BIDateDimensionsView relation constraint.

Expand table

Property	Value
Field	Date
Related Field	TranDate

The relationship you defined should look like the following screenshot.



12. Save the aggregate measurement.

Deploy the newly generated aggregate measurement

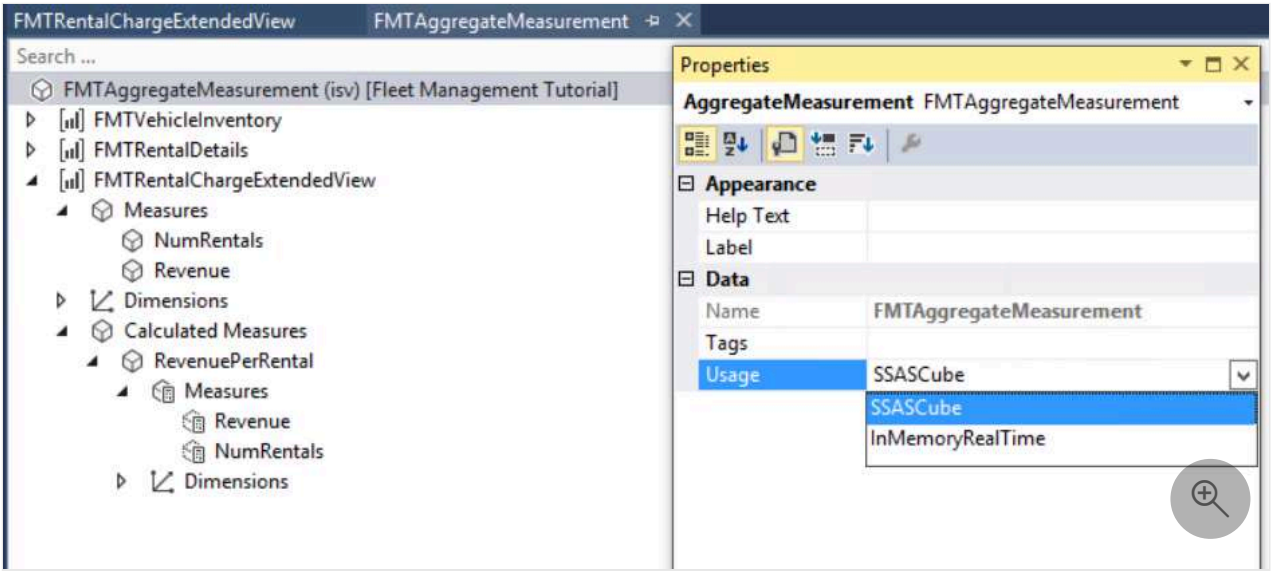
After modeling the aggregate measurement, deploy it so you can continue building KPIs and visualizations. You have two deployment choices:

Expand table

Option	Considerations
In-memory real-time	Use this option to apply the in-memory column store indexes of the SQL Server database for deploying aggregate measurements. Use this option when the aggregate measurement supports embedded analytics within the client and you need **real-time analytics**. For an overview of concepts on real-time analytics, see Analytics, aggregate measurements, and KPI modeling.
Stage in Entity Store	Use this option to apply the entity store, the operational data store that enables **near real-time PowerBI reporting**. If you choose this option, you can deploy the aggregate measurement to the entity store and schedule the data to be refreshed periodically. For an overview of this approach, see Power BI integration with Entity Store in Dynamics AX 7 May Update.

> **Note**
>
> The **SSAS Cube** option is no longer supported when modeling aggregate measurements.

1. Select the **FMTAggregateMeasurement** node. Right-click and select **Properties**. Select **InMemoryRealTime** as the value for the property **Usage**.



2. Deploy InMemoryRealTime aggregate models to SQL Server by using Non-Clustered Column Store Index (NCCI) technology. NCCIs is an in-memory technology that enables analytical and operational workloads to be served from SQL server database. Define NCCI indexes on tables similar to any other index. While you can define NCCI indexes manually, the framework can analyze index requirements and add them to underlying tables where necessary.

3. Right-click **FMAggregateMeasurement** in Solution Explorer, and then select **Add Column store indices option**. You add several new indexes.

4. Save and build the project.

5. InMemoryRealTime aggregate models don't require data processing because the models are queried real-time. If you didn't enable database synchronization along with the build, manually synchronize the database.

Model a KPI to show revenue per rental

Model a KPI in Visual Studio

Model a KPI definition in Visual Studio by using the aggregate measurement you defined earlier.

1. In **Solution Explorer**, right-click **FMTutorial**, point to **Add**, and then select **New Item**.

2. Select **Dynamics 365 Artifacts** > **Analytics** > **Key Performance Indicator**. Enter `FMTRevenuePerRental` as the name of the KPI, and then select **Add**. The name must be unique across KPIs. The KPI is created.

3. Select **FMTRevenuePerRental**, and specify the **Measurement**. Leave the default values for the other properties.

Expand table

Property	Value
Measurement	FMTAggregateMeasurement
Bad Threshold	0
Good Threshold	0
Scoring Pattern	MoreIsBetter
Show Goal	Yes
Show Status and Trend	Yes
Threshold Type	Value

4. Define the expression for the KPI value. Under **FMTRevenuePerRental**, select **Value**, and specify the following properties.

> **Note**
>
> Enter the values in the order they appear in the table:

Expand table

Property	Value
Value Type	BasedOnMeasure
Measure Group	FMTRentalChargeExtendedView
Measure	RevenuePerRental

5. Define the expression for the KPI Goal. Select **Goal**, and specify the following properties.

Expand table

Property	Value
Goal Type	BasedOnValue
Value	250

> **Note**
>
> You can define a goal based on an aggregate measure as well. In this case, define a number as the goal.

6. Save the KPI definition.

Preview KPI in client

Next, preview the KPI definition in the client.

1. Right-click **FMTutorial**, and then select **Re-Build**. When the build finishes, select the **Synchronize ... database** option.
2. Open Microsoft Edge, and go to your Rainier instance base URL.
3. Go to the **Reservation Management workspace** under **App links** > **Fleet Management** > **Workspaces** > **Reservation Management**.
4. Select the KPI tile **Total Revenue**. The KPI details page for the **Total Revenue** KPI appears.

5. To go to the newly defined KPI, select the **Show list** icon on the top left. From the list of KPIs, select **FMTRevenuePerRental**.

   The KPI details page for the new KPI, **FMTRevenuePerRental** appears. Even though you didn't define trend charts, the system created a set of charts based on the limited metadata you defined. Users can modify KPI definitions and create new ones in the client. Next, modify the newly defined KPI.

6. To demonstrate this capability, change the KPI goal. Select the **Edit** button on the top left, and enter 900 as the goal value.

7. Modify the threshold properties as follows:

Expand table

Property	Value
Threshold Type	Percentage
Red if less than	90
Green if more than	110

8. Select **Save** on the bottom left to save changes. The KPI status color changes in the KPI tile.

Last updated on 01/22/2026

Add financial dimensions to aggregate measurements

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This feature lets power users include financial dimensions in ready-made Microsoft Power BI reports. Power users can also create new Power BI reports that use financial dimensions.

Financial dimensions are user-defined configuration data that enables the ledger chart of accounts to retain extra information. By adding financial dimensions, you can configure extra data fields that appear with the chart of accounts and financial reports. You can slice and dice the ledger chart of accounts based on those fields. This feature provides powerful financial reporting. For example, you can explore ledger data by using the new financial dimensions that you add. Because the ready-made Power BI reports don't include financial dimensions when they're released, you must add these extra fields to the ready-made reports.

After you add financial dimension fields to the report, you can share the report with other users. Those other users can modify existing visuals, such as charts, by including all or some of the financial dimension fields.

> **Note**
>
> This feature is available in Microsoft Dynamics 365 Finance, Enterprise edition (July 2017). Platform update 8 or later is also required.

How does this feature work?

The Entity store is an operational data warehouse that power users can use to create reports. Whenever the Entity store updates, it includes all available financial dimensions. Here's an example from the **Ledger Activity** aggregate measurement that contains General ledger journal-level details.

The following list shows some of the tables that the Entity store fills when it updates. Tables that changed are bold.

- LedgerActivityMeasure_LedgerActivityMeasureGroup
- LedgerActivityMeasure_TransactionDate
- LedgerActivityMeasure_Currency
- LedgerActivityMeasure_FiscalPeriodDateAggregtateDimension
- LedgerActivityMeasure_LedgerFactDimension
- LedgerActivityMeasure_FiscalYearOffsetDimension
- LedgerActivityMeasure_MainAccount
- **LedgerActivityMeasure_DimensionCombination**
- LedgerActivityMeasure_Ledger
- LedgerActivityMeasure_MainAccountCategory
- LedgerActivityMeasure_Company
- LedgerActivityMeasure_MainAccountLegalEntity
- **LedgerActivityMeasure_Agreement**
- **LedgerActivityMeasure_BankAccount**
- **LedgerActivityMeasure_BusinessUnit**
- **LedgerActivityMeasure_Campaign**
- **LedgerActivityMeasure_Cargo**
- **LedgerActivityMeasure_Cargo_CN**

For each financial dimension that you define in your system, you might see a corresponding table in the Entity store.

If you examine the LedgerActivityMeasure_DimensionCombination table, you see that the list of fields has been expanded and now includes additional fields. Each new field corresponds to a financial dimension. For example, here are some of the additional fields:

- Agreement_FK
- Agreement_Description
- Agreement_Value
- BankAccount_FK
- BankAccount_Description
- BankAccount_Value
- BusinessUnit_FK
- BusinessUnit_Description
- BusinessUnit_Value

If a user defines a new financial dimension named **vendor**, the Entity store adds a new table named LedgerActivityMeasure_Vendor when it updates.

The LedgerActivityMeasure_DimensionCombination table also contains the following new set of fields:

- Vendor_FK

- Vendor_Description
- Vendor_Value

How a Power BI report author can create reports that use financial dimensions

A business user can create a new report that uses financial dimensions by using Power BI desktop. Existing reports that use financial dimensions can be updated so that they include extra fields.

In this example, use Power BI desktop to create a report that uses the Ledger Activity measure group.

1. In a development environment, connect to the Entity store database by using Power BI desktop.

2. Select the following tables:

    - LedgerActivityMeasure_LedgerActivityMeasureGroup
    - LedgerActivityMeasure_FiscalPeriodDateAggregtateDimension
    - LedgerActivityMeasure_DimensionCombination

3. Use the **Manage relationships** option in Power BI desktop to define the following relationships between table fields:

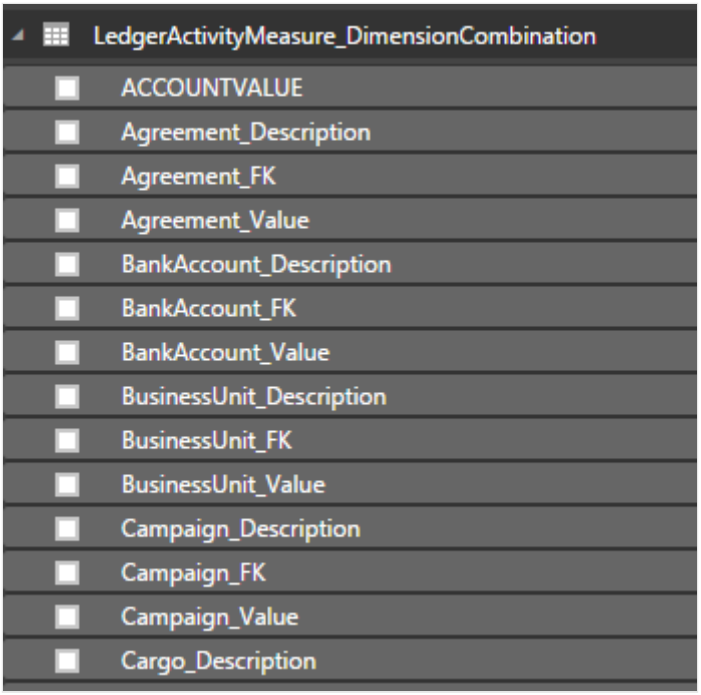
    - Define a join between **LedgerActivityMeasure_LedgerActivityMeasureGroup.LEDGERDIMENSION** and **LedgerActivityMeasure_DimensionCombination.DIMENTIONCOMBINATIONRECID**.
    - Define a join between **LedgerActivityMeasure_LedgerActivityMeasureGroup.LEDGERGREGORIANDATEID** and **LedgerActivityMeasure_FiscalPeriodDateAggregateDimension.LEDGERPERIODGREGORIANDATEID**.

4. Create a matrix report that uses the **Sales** and **YearName** fields. The report should resemble the following example.

YEARNAME	SALES
2015	355,958,240.86
2016	478,064,122.48
2017	10,712,838.30
Total	**844,735,201.64**

Next, add financial dimension values.

5. In the list of fields in Power BI desktop, expand the **LedgerActivityMeasure_DimensionCombination** table. You see that the list of dimension fields is expanded into table fields, as shown here.



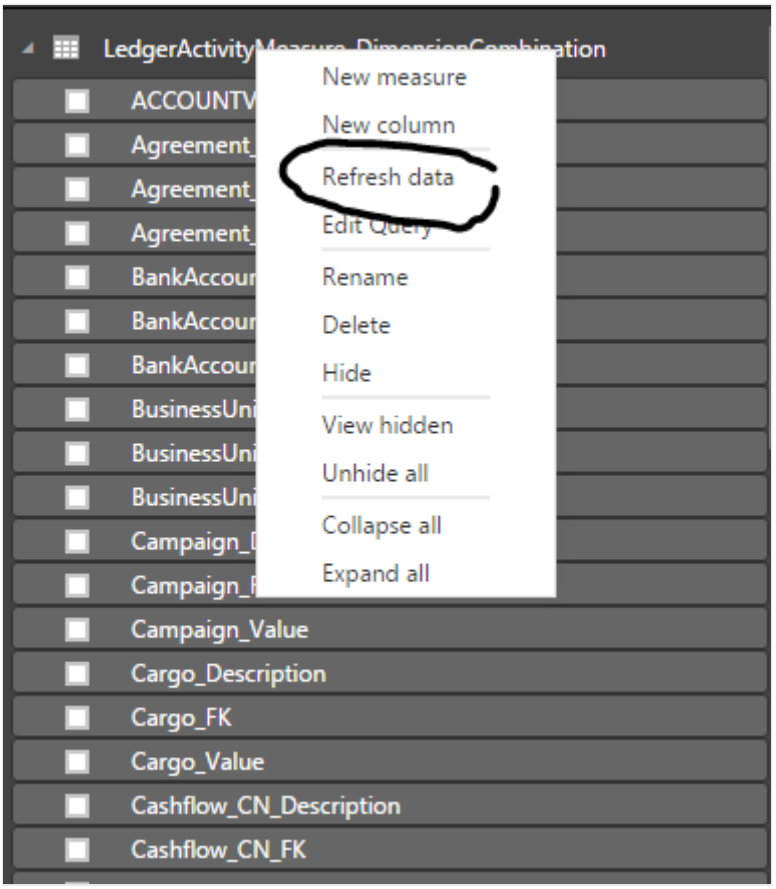
6. Include the **BusinessUnit_Description** field in the report. Your report now shows sales by business unit, as shown in the following example.

YEARNAME	Electronics	Home	IT Consulting Practice	Management Consulting Practice	Sporting	**Total**
2015	7,362,985.20	152,524,507.23	100,045,909.46	699,928.66	7,937,635.30	**355,958,240.86**
2016	6,374,315.40	167,483,885.95	115,009,475.39	769,787.36	7,622,420.20	**478,064,122.48**
2017	100,000.00	10,390,021.77	0.00	26,571.26		**10,712,838.30**
Total	**13,837,300.60**	**330,398,414.95**	**215,055,384.85**	**1,496,287.28**	**15,560,055.50**	**844,735,201.64**

Notice that you have the **BusinessUnit_description** field and the **BusinessUnit_Value** field. The value field lets you get a numerical value that you can use to sort columns.

7. Define a new financial dimension, and update the Entity store.

8. When the update finishes, right-click the **LedgerActivityMeasure_DimensionCombination** table, and then select **Refresh data**. Notice that the new financial dimension that you defined is reflected in the list of fields that are available for reporting.



9. You can include the new financial dimension fields in the report.

Creating reports that use expanded financial dimension tables

As discussed earlier, new tables are created in the Entity store. Each financial dimension field is added to a new table. The new tables contain individual fields for the name, value, and description.

The new tables contain a key that you can use to join them with the **LedgerActivityMeasure_DimensionCombination** table that you use to create the report. If you want to use fields from these additional tables, include them in the report and relate them by using the keys.

1. Open the report that you created earlier.

   Now, add a financial dimension table to the report.

2. In Power BI Desktop, select **Recent Sources** on the menu, and then select the **AXDW** data connection. The table navigator is shown.

3. Select the **LedgerActivityMeasure_LegalEntity** table for the report.

   > **Note**
   >
   > If you're using a development or demo environment, you see this table because **LegalEntity** is a financial dimension that's defined in demo data. If you're working with your own data, the tables that you see correspond to financial dimensions that you define.

   Now, relate the selected table to existing tables in the report.

4. In the report, open the **Manage relationships** dialog box.

5. Join **LedgerActivityMeasure_DimensionCombination.LegalEntity_FK** to **LedgerActivityMeasure_LegalEntity.KEY_**.

If you select a different dimension table in step 3, you must relate the corresponding **FieldName_FK** field from the combination table to the **KEY_** field in the dimension table.

How a developer can enable financial dimensions

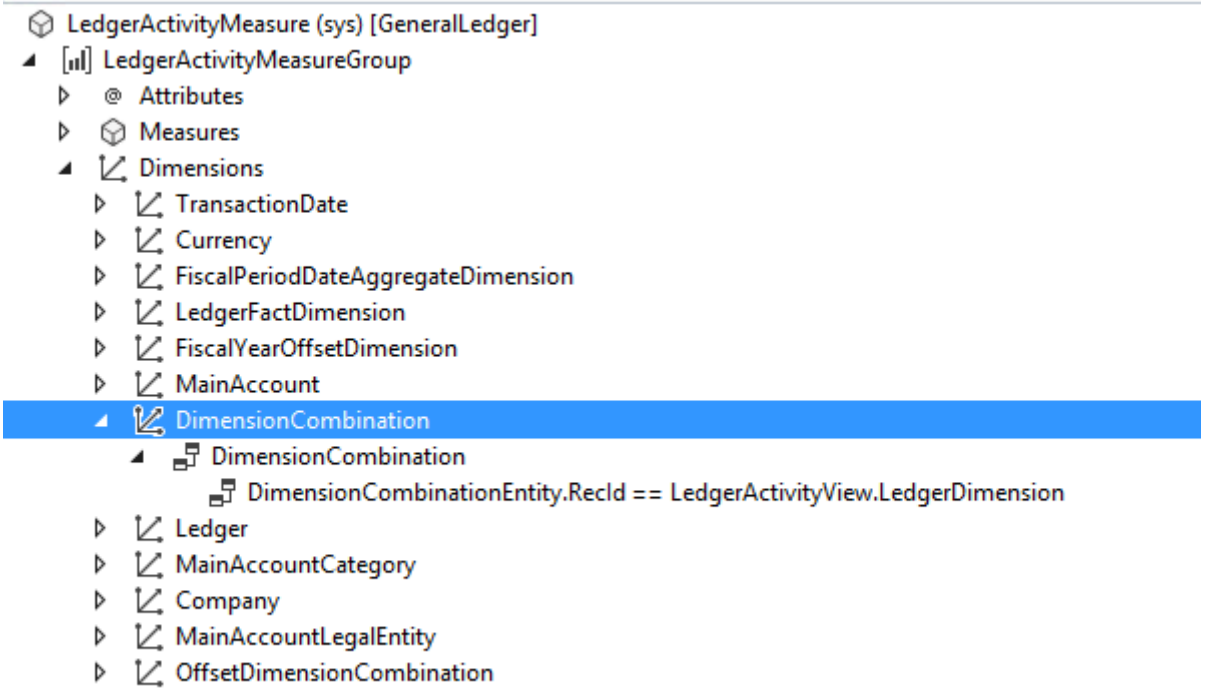
Before users can see expanded financial dimensions in the Entity store, a developer must enable the use of financial dimensions in aggregate measurements. As a best practice, include financial dimensions when you model any aggregate measurement that involves financial data. To include financial dimensions, create an aggregate dimension that is based on "financial dimension tables." As shown earlier, an aggregate dimension that you create by using financial dimension tables expands at runtime.

What are financial dimension tables?

Financial dimension tables are base tables that contain financial dimension data. Examples include **DimensionAttributeValueCombination** and **DimensionAttributeValueSet**.

If you use a table, a view, or an entity that's based on those two tables, you see the fields of the aggregate dimension expanded at runtime.

Consider the following example from the LedgerActivityMeasure aggregate measurement.



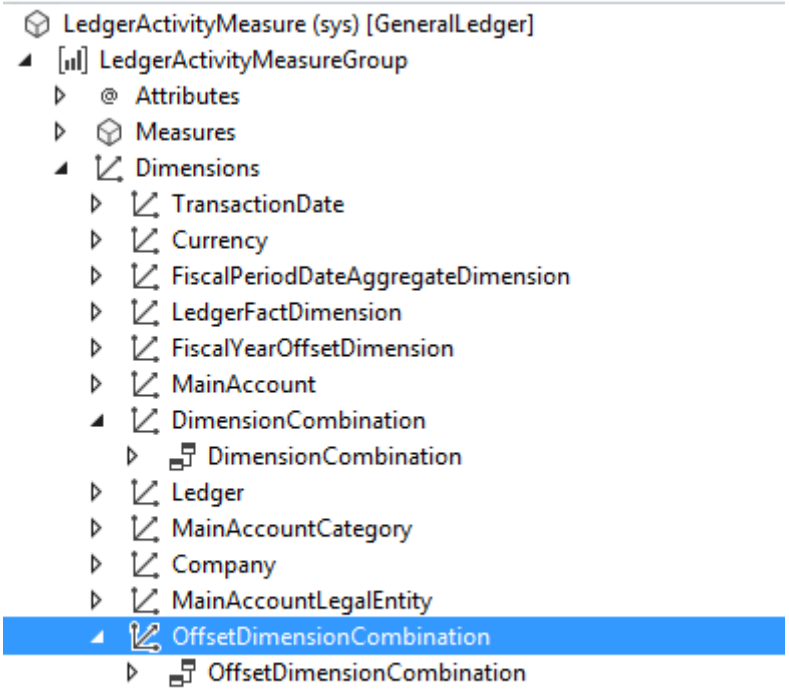
DimensionCombination is an aggregate dimension that the DimensionAttributeValueCombination base table models. In this case, the developer references the aggregate dimension by using the LedgerActivityMeasureGroup measure group.

At runtime, new dimension fields are added (that is, the DimensionCombination table is expanded) as you define new financial dimensions in the system.

Creating role-playing financial dimensions

When you report by using ledger data, you might need to report on primary accounts and offset accounts. For example, if a ledger transaction involves the transfer of an amount from one account to another account, the primary account is the "from" account, whereas the offset account is the "to" account. This pattern is known as the *role-playing dimensions* pattern.

You must associate both primary accounts and offset accounts with transaction data. Therefore, you must expand financial dimension fields of both primary accounts and offset accounts. The following example shows how you can meet this requirement.



You model two dimension references for `LedgerActivityMeaureGroup`. The first reference, `DimensionCombination`, is joined by using the **LedgerDimension** field. You saw this pattern earlier in this article.

The second reference, `OffsetDimensionCombination`, is another reference to the same dimension. You reuse the `DimensionCombination` aggregate dimension and give it a new name. In the second case, you can join by using the **OffsetLedgerDimension** field.

At runtime, the system expands both these dimensions with extra fields. Therefore, you can report on primary and offset dimension fields.

Last updated on 01/22/2026

Create analytical reports by using Power BI Desktop

If you're a power user or a business analyst, you probably create many reports for your organization. You might create these reports in Microsoft Excel by formatting and relating data before you share it with other people. People in your organization might even come to you when they require modifications to the report. This solution offers an easy way to create rich, interactive reports. As a report writer, you can use Microsoft Power BI Desktop as the reporting tool. The reports that you create can then be published to PowerBI.com. For more information about Power BI Desktop, see Create stunning reports and visualizations with Power BI Desktop.

Accessing the local Entity Store by using DirectQuery

You can create Microsoft Power BI reports by using Open Data Protocol (OData) endpoints that are exposed via data entities. Despite the limitations of this approach, the Entity Store still supports it for legacy solutions. However, DirectQuery is now the preferred method for sourcing data for analytical solutions. For more information about the benefits and limitations of DirectQuery, see Use DirectQuery in Power BI Desktop.

When you use Power BI Desktop, you can create a report in your development or test environment by connecting directly to the local Entity Store database. When you're satisfied with the report, your administrator can help you migrate it to your production environment. The rest of this section walks you through this process.

> **Note**
>
> To develop or extend analytical workspaces and reports in the application suite, customers must use a development environment running in their own subscription or on local machines. You won't be able to develop or extend embedded analytical reports in Microsoft-provided Tier-1 environments. You need administrator rights to install Power BI Desktop.

> Power BI embedded integration has upgraded the infrastructure as part of the 10.0.22 release. This was an infrastructure change and will happen automatically when an environment is upgraded to release 10.0.22. With this change, users are now able to use the *latest version* of Power BI desktop when editing workspace reports.

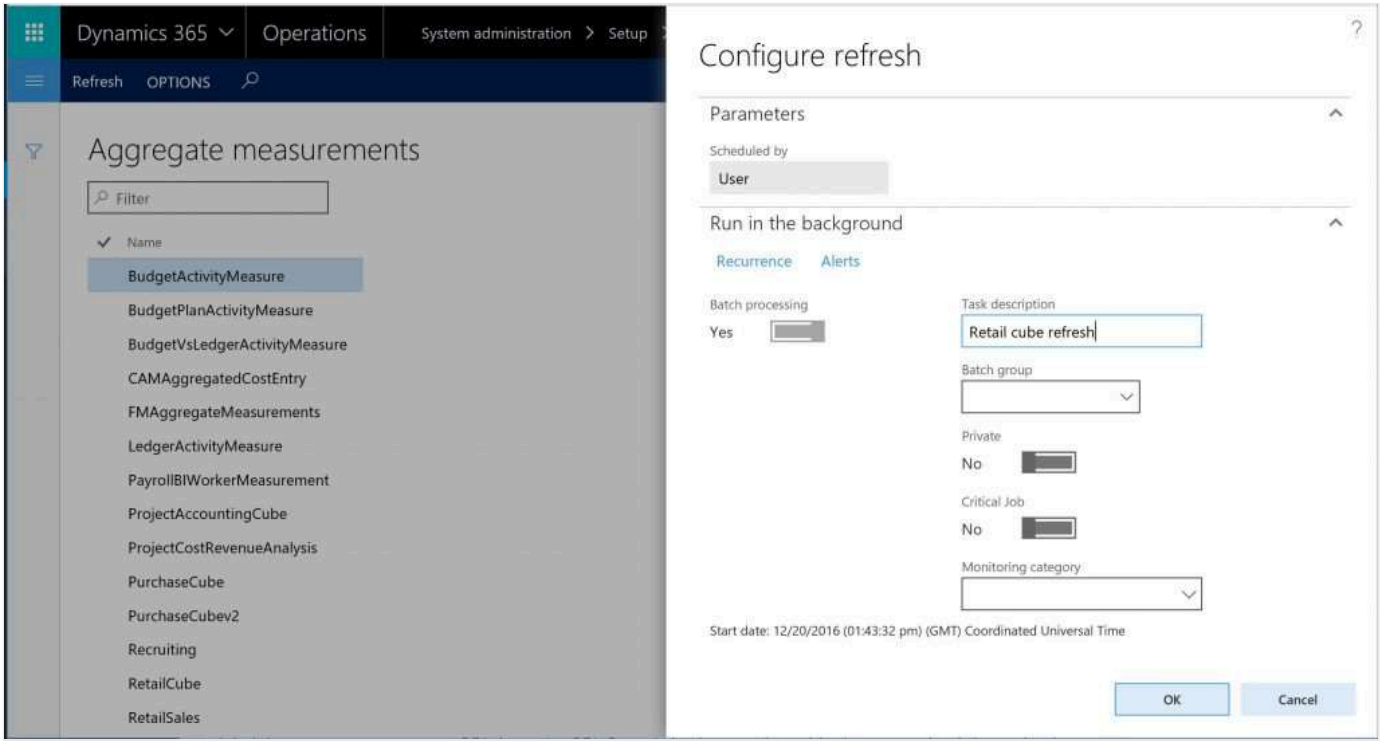
> For environments running version 10.0.21 or earlier, you must still use the previous build of Power BI Desktop pre-installed on the development environment. Alternatively, you can use the *compatible* Power BI Desktop August 2020 release of Power BI Desktop with preview features turned off to author analytical reports for finance and operations apps. You can download the Power BI Desktop August 2020 release from the LCS Shared asset library.

Step 1: Populate the local Entity Store database

For this example, we'll stage the aggregate models that the Commerce analytical solution consumes in the local Entity Store. The models that the application uses are defined in the RetailCube aggregate measurement.

1. In the client, open the **Entity Store** page. (Select **System administration** > **Setup** > **Entity Store**.)
2. Select the **RetailCube** aggregate measurement, and then select **Refresh**.
3. Enter a name for the job that will be run in the background, and then select **OK**.

The following illustration shows the administrator dialog box that is used to configure the frequency of updates for the aggregate model.



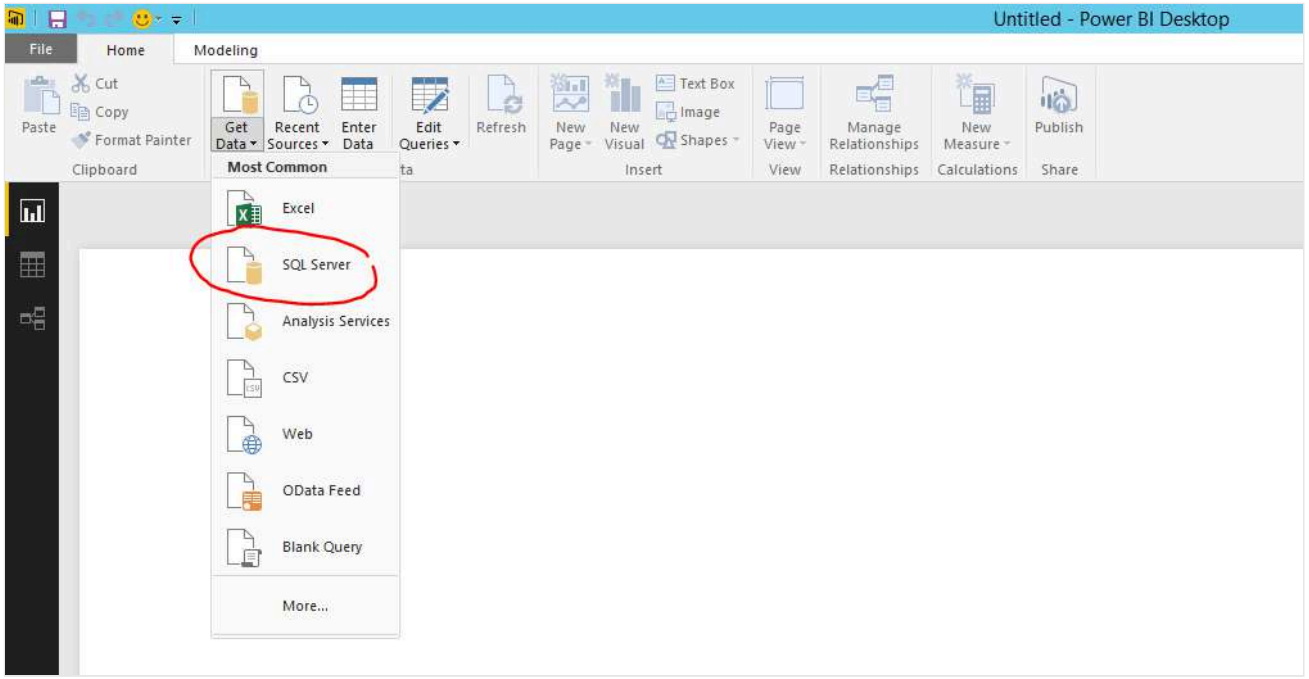
To monitor the progress of the job that stages the data, you can use the batch job monitoring page. (Select **System administration** > **Database** > **Batch jobs**.) If you're using demo data, the job should take about a minute. After the data is in the Entity Store, you can write reports.

Step 2: Connect to the local Entity Store database

1. Start Power BI Desktop. If any updates are available for Power BI Desktop, you might have to download and apply them.

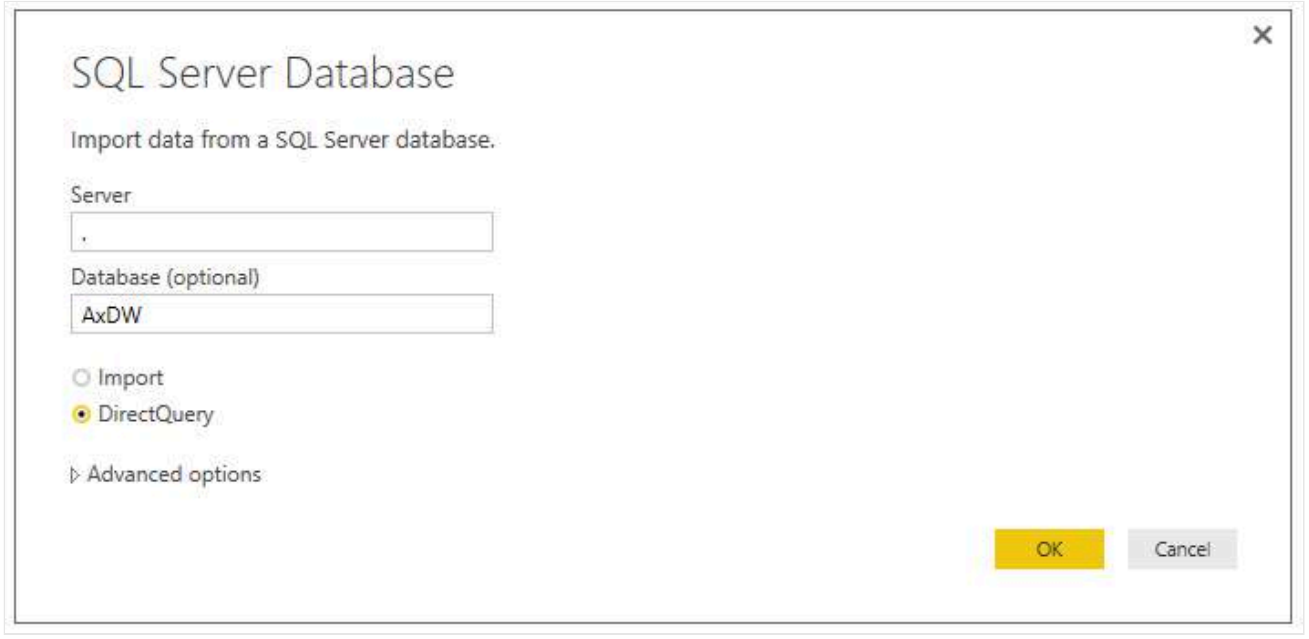
2. On the Power BI **Welcome** page, select **Get data**.

   Alternatively, when Power BI Desktop starts, you can select **Get Data** > **SQL Server**.



3. In the **SQL Server Database** dialog box, enter.** as the server name and **AxDW** as the database name. Then select the **DirectQuery** option.

   The following illustration shows the settings that enable Power BI Desktop to access the local Entity Store database.



> **Note**
>
> The **Import** option isn't currently supported.

4. Select **OK**.

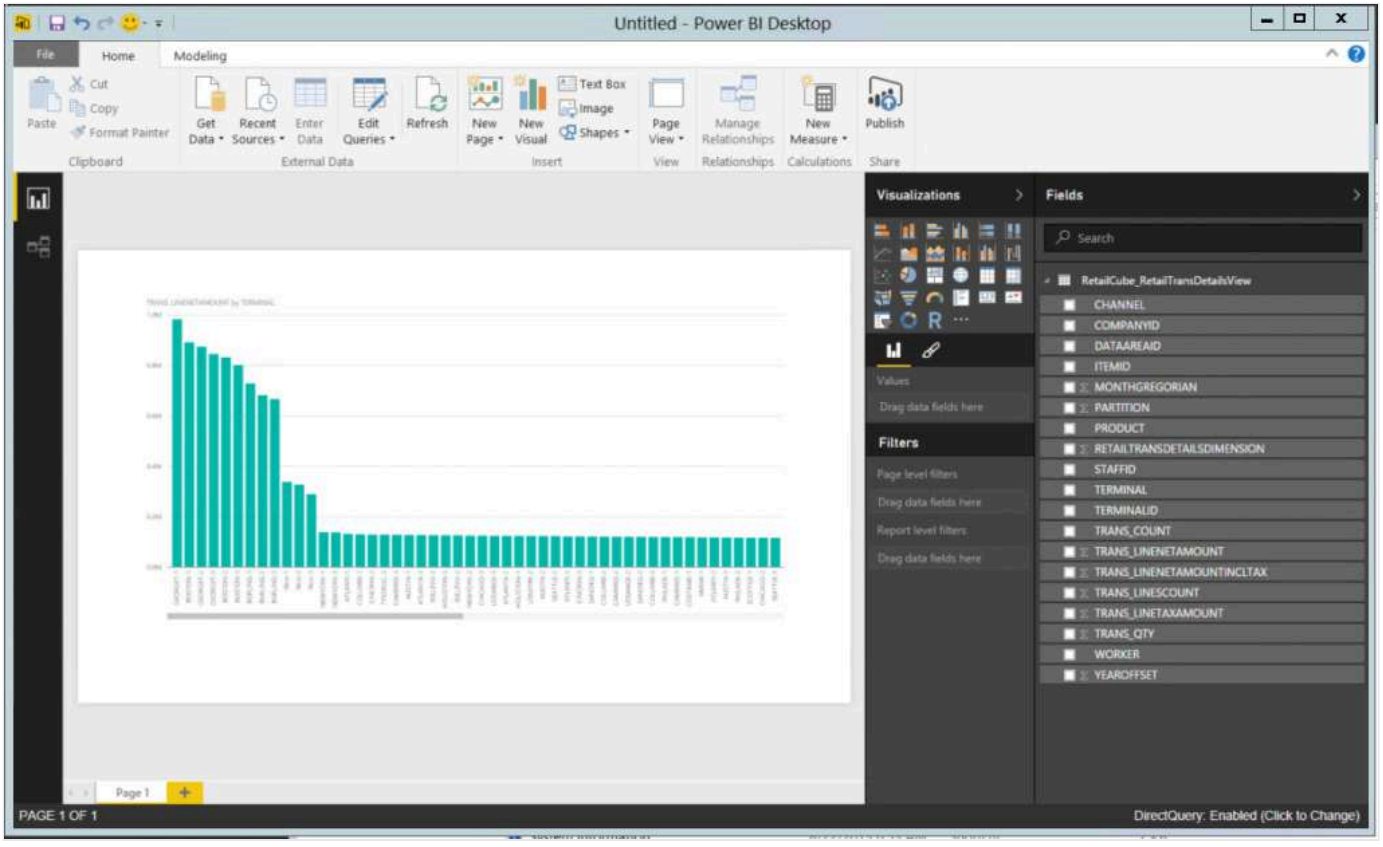
   The **Navigator** dialog box appears. You use this dialog box to select which tables and views from the Entity Store you want to report on.

5. In the search box, enter **Retail** to filter for entities that are related to the RetailCube aggregate measurement.

6. Select the **RetailCube_RetailTransDetailsView** table that is shown in the navigator, and then select **Load**.

You can now create a report. You can drag measures and fields to the canvas, and can explore data and trends interactively.

The following illustration shows a basic report that uses the local Entity Store database as its source.



Power BI Desktop also supports the creation of calculations and lets you combine data from multiple aggregate measurements. Within minutes, you can create analytical reports by using

data in the local development environment. When you're satisfied with the report, you can migrate it to the production environment, so that users can use the report to interact with production data.

Validating reports in a demo environment

The report shows the demo or test data in your developer environment. If you want to integrate the report into a demo environment, you can continue to publish this report to your PowerBI.com account and pin it to the client.

Add analytics to workspaces by using Microsoft Power BI Embedded

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Note**
>
> This feature is supported in finance and operations (version 7.2 and later).

Introduction

This article shows how to embed a Microsoft Power BI (PBI) report on the **Analytics** tab of a workspace. In this example, you extend the **Reservation management** workspace in the Fleet Management application to embed an analytical workspace on an **Analytics** tab.

Prerequisites

- Access to a developer environment that runs Platform update 8 or later.
- An analytical report (.pbix file) that you created by using Microsoft Power BI Desktop, with a data model sourced from the Entity store database.

Overview

Whether you extend an existing application workspace or introduce a new workspace, you can use embedded analytical views to deliver insightful and interactive views of your business data. The process for adding an analytical workspace tab has four steps.

1. Add a .pbix file as a Microsoft Dynamics 365 resource.
2. Define an analytical workspace tab.
3. Embed the .pbix resource on the workspace tab.
4. Optional: Add extensions to customize the view.

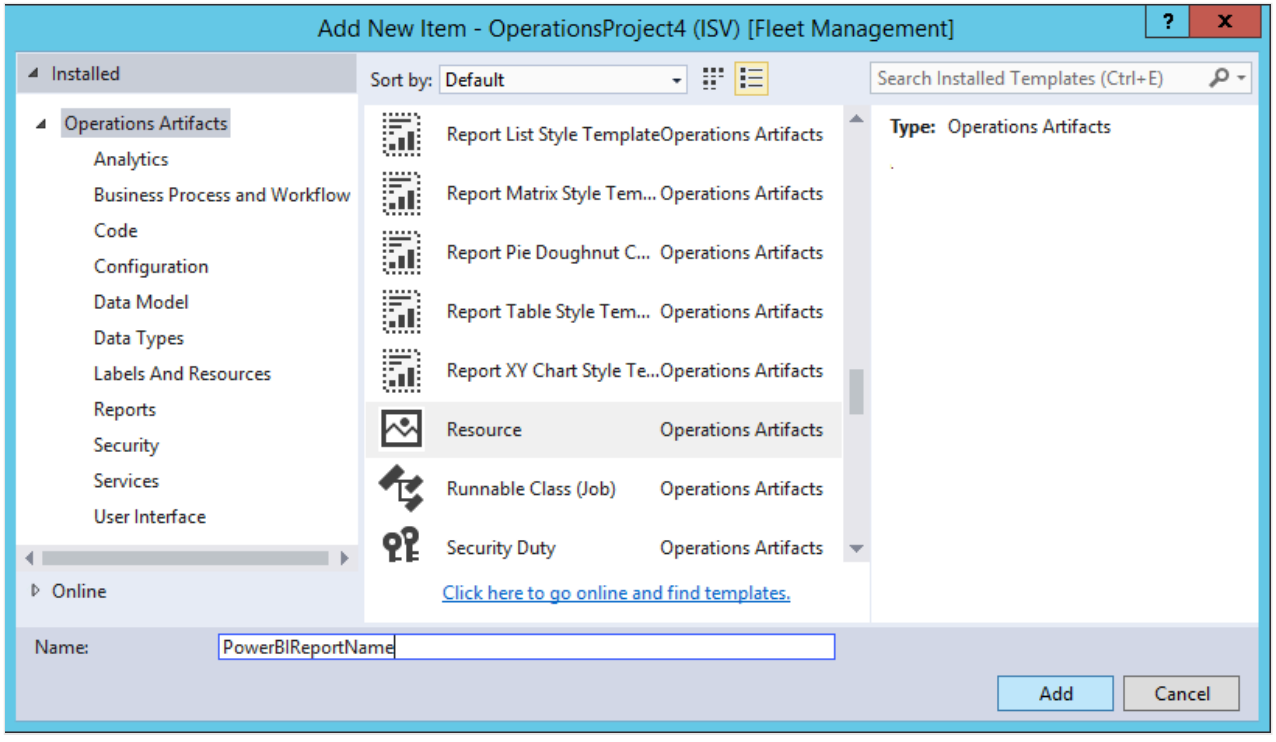
> **Note**
>
> For more information about how to create analytical reports, see Getting started with Power BI Desktop. This page is a great source for insights that can help you create compelling analytical reporting solutions.

Add a .pbix file as a resource

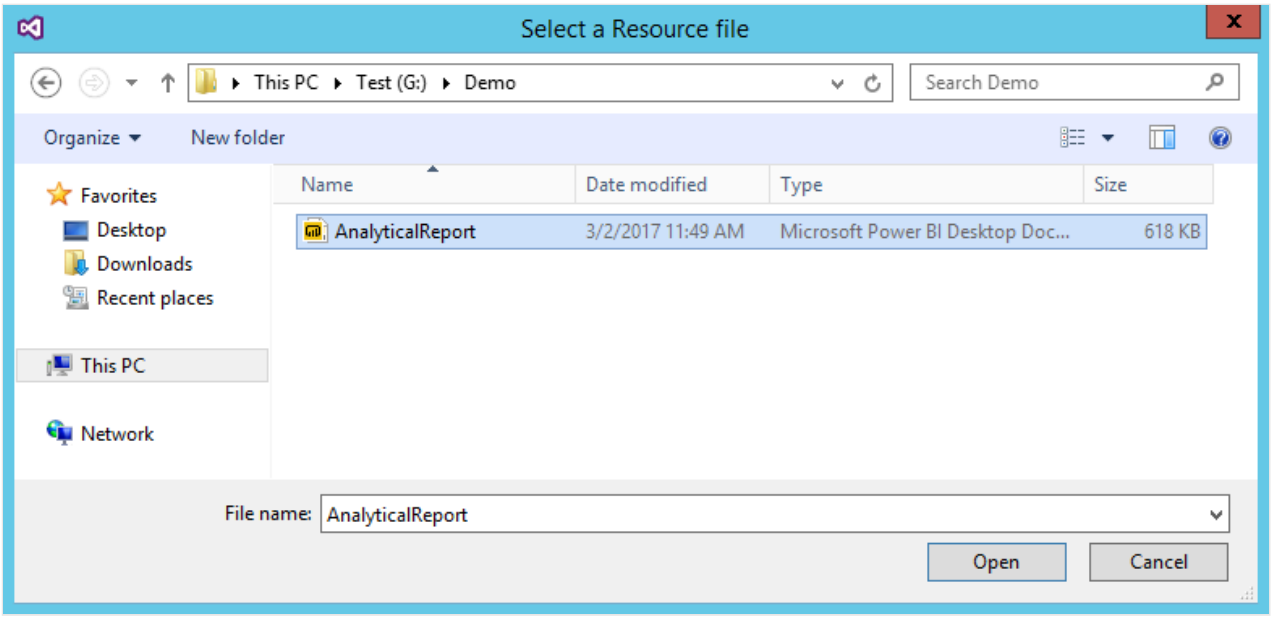
Before you begin, you must create or obtain the PBI report that you want to embed in the workspace. For more information about how to create analytical reports, see Getting started with Power BI Desktop.

Follow these steps to add a .pbix file as a Microsoft Visual Studio (VS) project artifact.

1. Create a new project in the appropriate model.
2. In Solution Explorer, select the project, right-click, and then select **Add** > **New Item**.
3. In the **Add New Item** dialog box, under **Operations Artifacts**, select the **Resource** template.
4. Enter a name that you use to reference the report in X++ metadata, then select **Add**.



5. Find the .pbix file that contains the definition of the analytical report, then select **Open**.

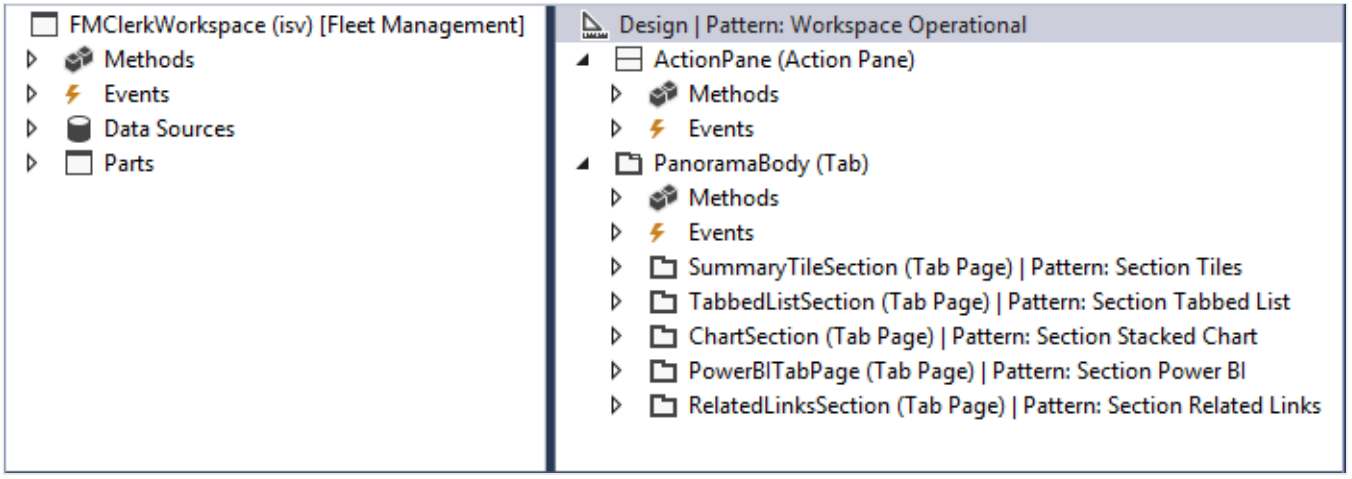


After you add the .pbix file as a Microsoft Dynamics 365 resource, you can embed the reports in workspaces and add direct links by using menu items.

Add a tab control to an application workspace

In this example, you extend the **Reservation management** workspace in the Fleet Management model by adding the **Analytics** tab to the definition of the **FMClerkWorkspace** form.

The following illustration shows what the **FMClerkWorkspace** form looks like in the designer in Microsoft Visual Studio.

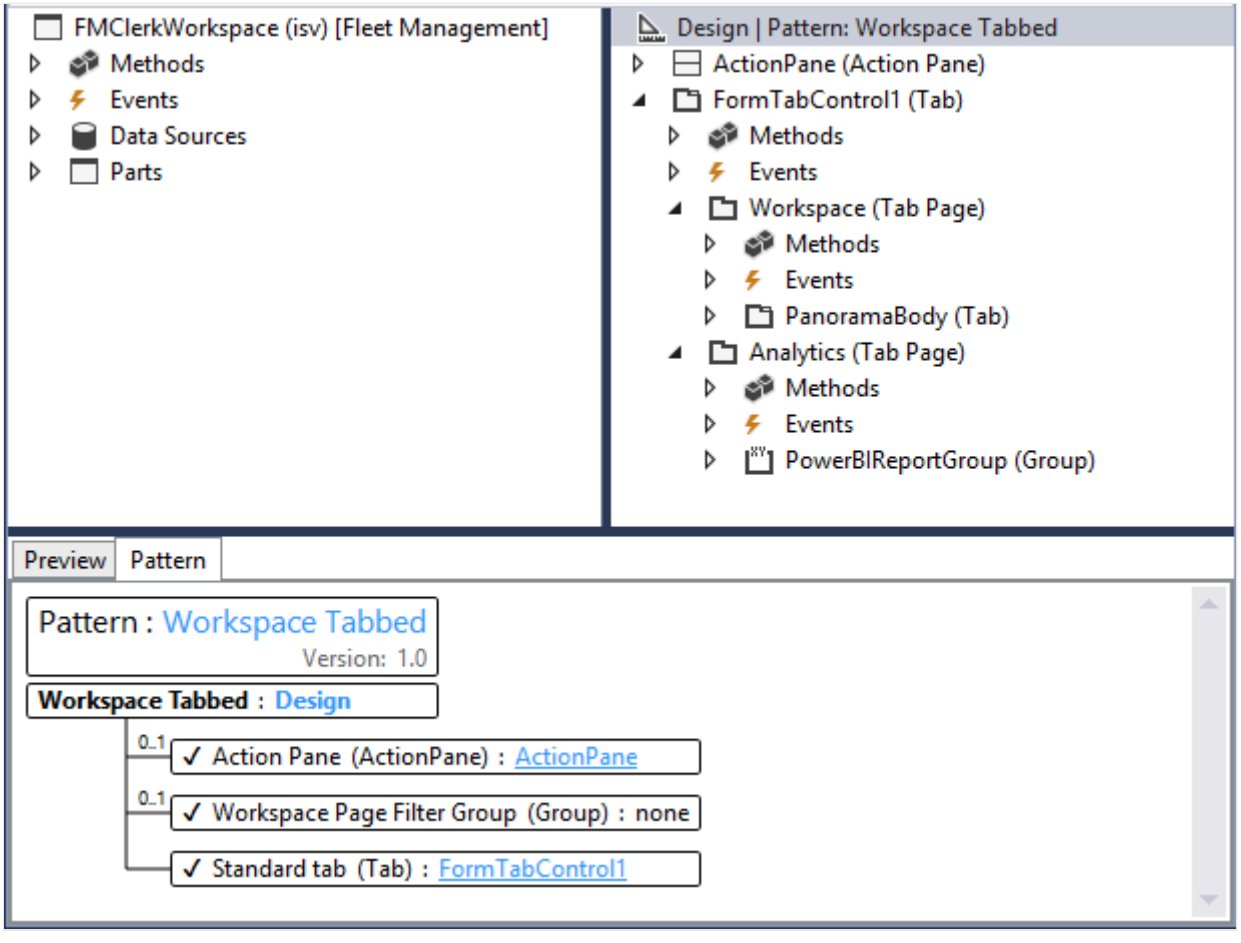


Follow these steps to extend the form definition for the **Reservation management** workspace.

1. Open the form designer to extend the design definition.
2. In the design definition, select the top element that is labeled **Design | Pattern: Workspace Operational**.
3. Right-click, and then select **New** > **Tab** to add a new control that is named **FormTabControl1**.

4. In the form designer, select **FormTabControl1**.
5. Right-click, and then select **New Tab Page** to add a new tab page.
6. Rename the tab page to something meaningful, such as **Workspace**.
7. In the form designer, select **FormTabControl1**.
8. Right-click, and then select **New Tab Page**.
9. Rename the tab page to something meaningful, such as **Analytics**.
10. In the form designer, select **Analytics (Tab Page)**.
11. Set the **Caption** property to **Analytics**, and set the **Auto Declaration** property to **Yes**.
12. Right-click the control, and then select **New** > **Group** to add a new form group control.
13. Rename the form group to something meaningful, such as **powerBIReportGroup**.
14. In the form designer, select **PanoramaBody (Tab)**, and then drag the control onto the **Workspace** tab.
15. In the design definition, select the top element that is labeled **Design | Pattern: Workspace Operational**.
16. Right-click, and then select **Remove pattern**.
17. Right-click again, and then select **Add pattern** > **Workspace Tabbed**.
18. Build the project to verify your changes.

The following illustration shows what the design looks like after these changes are applied.



Now that you've added the form controls that are used to embed the workspace report, you must define the size of the parent control so that it accommodates the layout. By default, both

the **Filters Pane** page and the **Tab** page are visible on the report. However, you can change the visibility of these controls as appropriate for the target consumer of the report.

> ⓘ Note
>
> For embedded workspaces, use extensions to hide both the **Filters Pane** and **Tab** pages, for consistency.

You've now completed the task of extending the application form definition. For more information about how to use extensions to do customizations, see Customize through extension and overlayering.

Add X++ business logic to embed a viewer control

Follow these steps to add business logic that initializes the Microsoft Report Viewer control embedded in the **Reservation management** workspace.

1. Open the **FMClerkWorkspace** form designer to extend the design definition.
2. Press F7 to access the code behind the code definition.
3. Add the following X++ code.

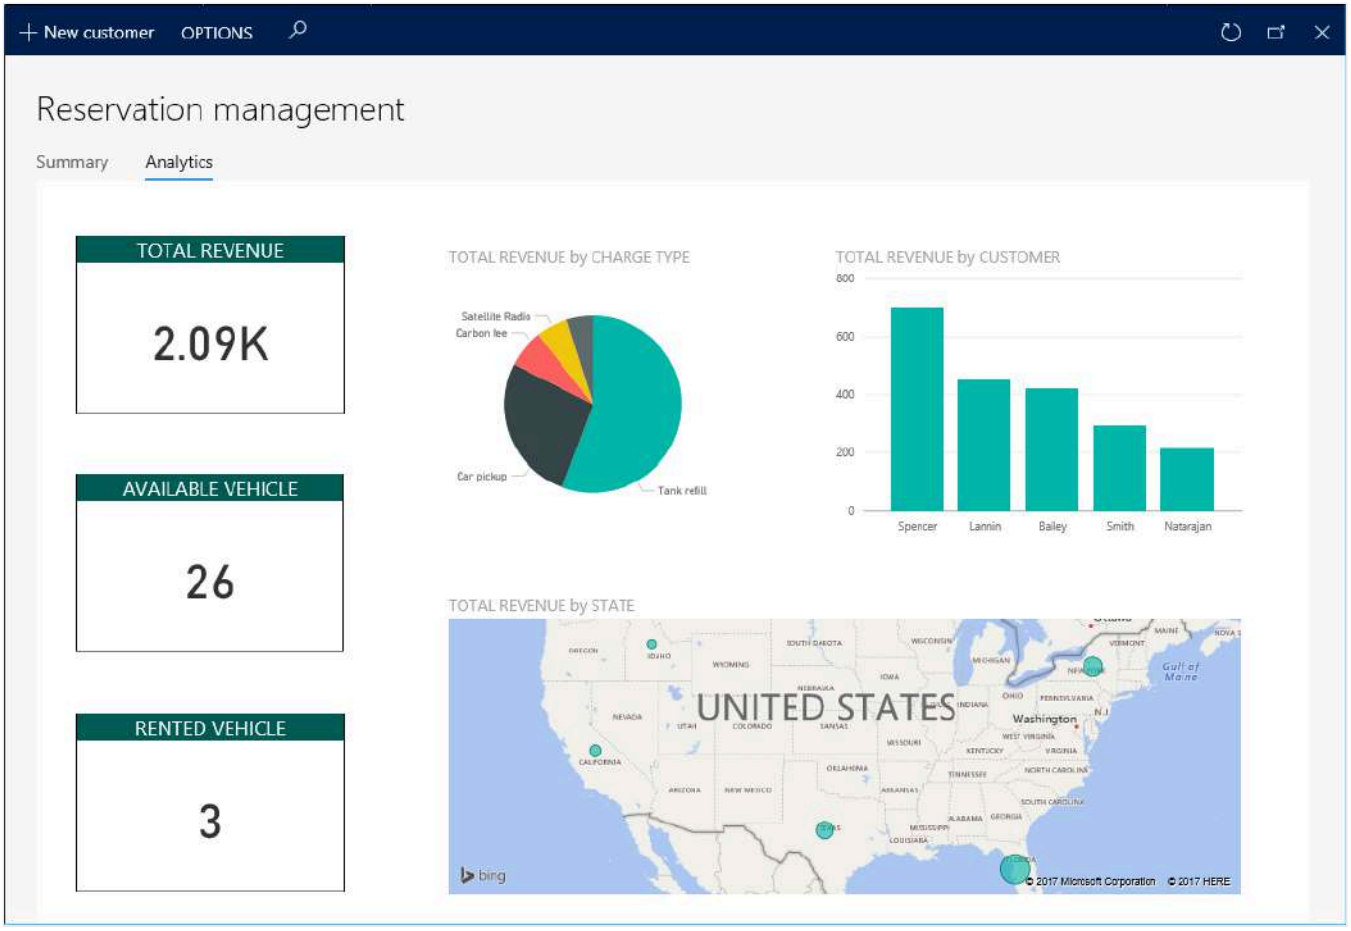
X++

```
[Form]
public class FMClerkWorkspace extends FormRun
{
    private boolean initReportControl = true;
    protected void initAnalyticalReport()
    {
        if (!initReportControl)
        {
            return;
        }
        // Note: secure entry point into the Workspace's Analytics report
        if (Global::hasMenuItemAccess(menuItemDisplayStr(FMClerkWorkspace),
MenuItemType::Display))
        {
            // initialize the PBI report control using shared helper
            PBIReportHelper::initializeReportControl('FMPBIWorkspaces',
powerBIReportGroup);
        }
        initReportControl = false;
    }
    /// <summary>
    /// Initializes the form.
```

```
    /// </summary>
    public void init()
    {
        super();
        this.initAnalyticalReport();
    }
}
```

4. Build the project to verify your changes.

You've now completed the task of adding business logic to initialize the embedded Microsoft Report Viewer control. The following illustration shows what the workspace looks like after these changes are applied.



> **Note**
>
> You can access the existing operational view by using the workspace tabs that appear below the page title.

Reference

PBIReportHelper.initializeReportControl method

This section provides information about the helper class that is used to embed a Power BI report (.pbix resource) in a form group control.

Syntax

X++

```
public static void initializeReportControl(
    str                 _resourceName,
    FormGroupControl    _formGroupControl,
    str                 _defaultPageName = '',
    boolean             _showFilterPane = false,
    boolean             _showNavPane = false,
    List                _defaultFilters = new List(Types::Class))
```

Parameters

Expand table

Name	Description
resourceName	The name of the .pbix resource.
formGroupControl	The form group control to apply the Power BI report control to.
defaultPageName	The default page name.
showFilterPane	A Boolean value that indicates whether the filter pane should be shown (**true**) or hidden (**false**).
showNavPane	A Boolean value that indicates whether the navigation pane should be shown (**true**) or hidden (**false**).
defaultFilters	The default filters for the Power BI report.

Secure analytical workspaces and reports by using Power BI Embedded

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Note**
>
> This feature is supported in Microsoft Dynamics 365 Finance, Enterprise edition (July 2017) (version 7.2), and later releases.

Introduction

This article provides a walkthrough for application developers who want to help secure analytical workspaces and reports that are delivered by using Microsoft Power BI Embedded. It describes the recommended strategies for securing access to both the reports and the dataset, based on viewer access rights. By using the techniques described in this article, you can hide reports from users and filter reports to show the dataset that's appropriate for a specific user, based on the active company context.

Prerequisites

- Access to a developer environment that runs Platform update 8 or later
- An analytical report (.pbix file) that was created by using Microsoft Power BI Desktop, and that has a data model that's sourced from the Entity store database

Overview

Whether you're extending an existing application workspace or adding your own workspace, you can use embedded analytical views to deliver insightful and interactive views of your business data. Before you add new analytical workspaces and reports, it's important that you establish a strategy to secure the content.

Consider several factors when you develop analytical solutions by using Power BI Embedded. Analytical reports are secured by using menu items. After they have access to a report, all viewers can access the underlying data model that is defined in the report. Although service options are available that automatically hide the fields that back a report data set, all viewers of the report have effective access to the fields in the data model. Additionally, X++ extensions are available that influence how the report is presented in the client. Both the **Filter** pane and the **Report** tabs can be hidden. However, Microsoft Power BI filters can be modified by client-side script injections.

Recommendation

To deliver analytical views, create scenario-specific .pbix files:

- Area overviews that are delivered by workspaces
- Subject matter–specific analytical reports

> **Note**
>
> These analytical reports are often used to deliver reports that contain medium-business-impact and high-business-impact data.

For more information about how to create analytical reports, see Getting started with Power BI Desktop. This page is a great source for insights that can help you create compelling analytical reporting solutions.

Help secure analytical views that are provided through embedded Power BI reports

Power BI report filters and the **Filter** pane serve as a mechanism for passing session context into the report embedded on the **Analytics** tab. The capability to turn the visibility of the **Filter** pane on and off isn't a security feature. Power BI report filters and the capability to hide and show the **Filter** pane are user experience (UX) decisions that the application designer makes.

Row-level security defined isn't inherited by Power BI reports. Instead, application developers can help secure the workspace or the report.

Help secure analytical workspaces on the Analytics tab

Analytical workspaces are embedded Power BI reports that are shown in a form control. Unless you complete the following procedure, anyone who has access to the workspace can see the **Analytics** tab and access the Power BI reports.

1. Add a menu item for the analytical workspace.
2. Verify that the form initialization uses the **hasMenuItemAccess** application programming interface (API) to verify that the user has access to the menu item.

```
X++
```

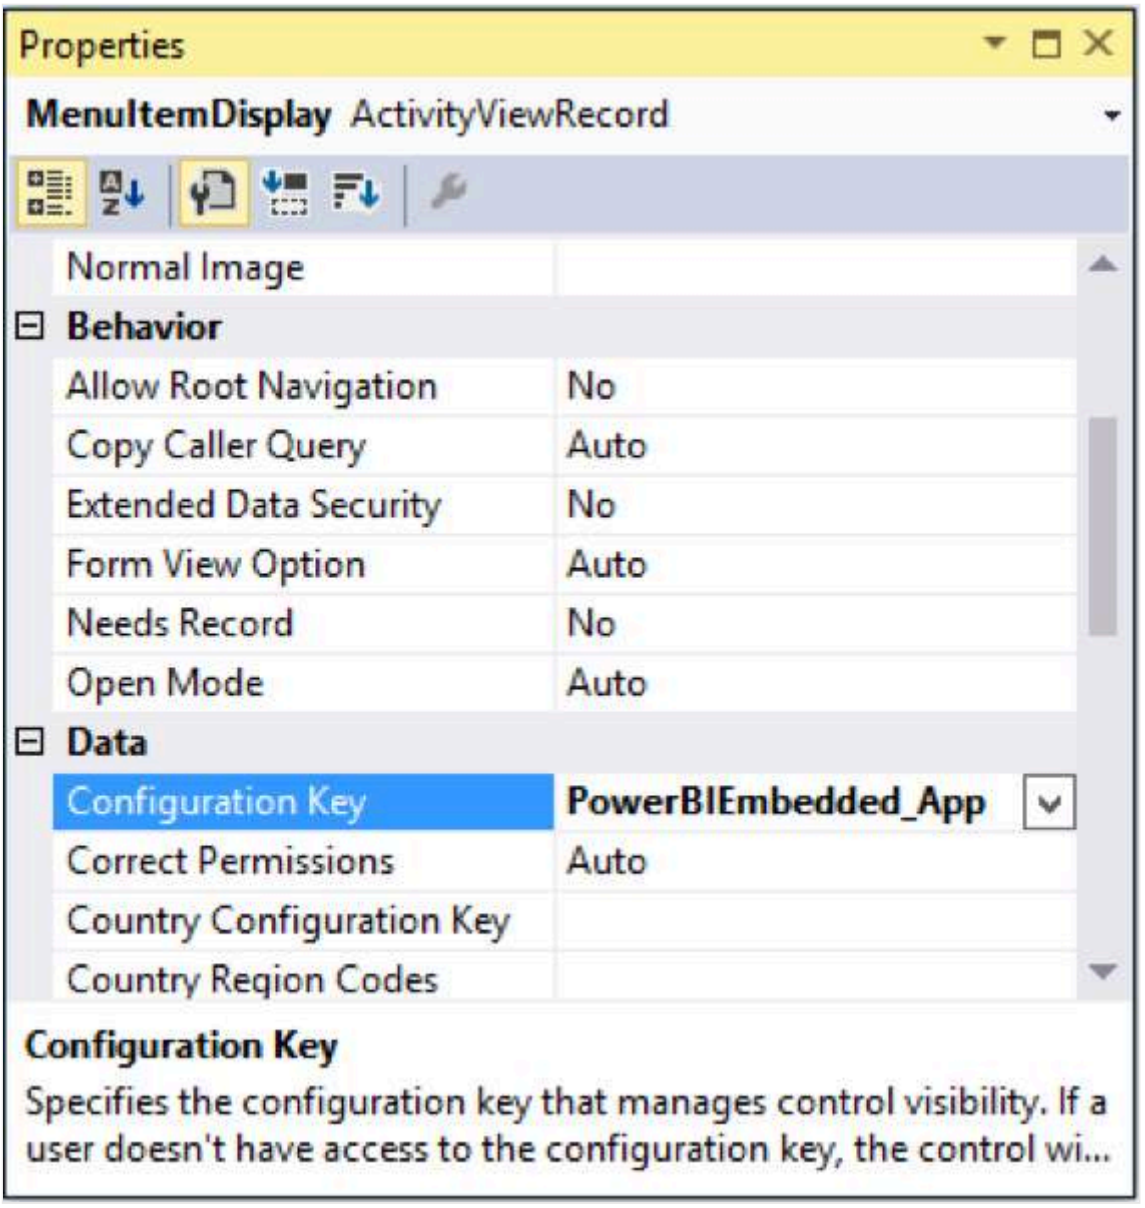
```
// Note: secure entry point into the Workspace's Analytics report
if (Global::hasMenuItemAccess(menuItemDisplayStr(FMClerkWorkspace),
MenuItemType::Display))
{
    FMPBIWorkspaceController controller = new FMPBIWorkspaceController();
    PBIReportHelper::initializeReportControl('FMPBIWorkspaces',
powerBIReportGroup);
}
```

The preceding logic prevents the Power BI Viewer control from being initialized. Therefore, an empty tab appears on the page. By default, the framework automatically hides empty tabs. Therefore, the **Analytics** tab is hidden and can't be access if the user doesn't have access to the menu item that is associated with the analytical workspace.

Help secure analytical reports

Embedded Power BI reports in the application are secured by using menu items. Users who try to access a Power BI report directly, by using a menu item in application, will receive an error. Follow these steps to help secure the analytical reports.

1. Add a menu item for the report or the appropriate tab. By default, the first tab of the report is shown if no other tab is selected.
2. Link the menu item to the **PowerBIEmbedded_App** configuration key.



The menu item is now associated with the availability of the Power BI Embedded service. If the service is unavailable, the links for the menu items are removed from the application.

Help secure analytical workspaces and reports by company

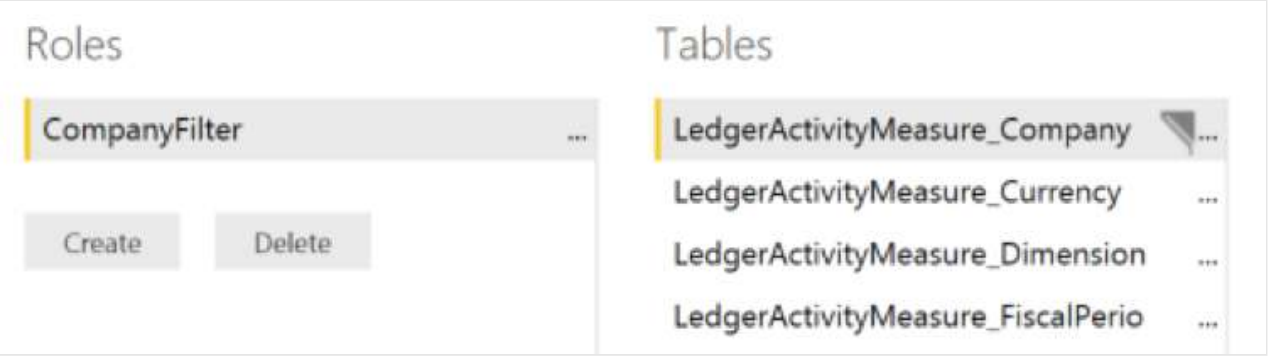
You can secure Power BI workspaces and reports by company (for example, **DataAreaID** value). Application solutions apply the following steps for company-level security in analytical workspaces and reports.

In this scenario, the workspaces and reports that the sales manager from Contoso USA sees are limited to data that is related to Contoso USA. The report viewer doesn't have access to data associated with any other company, unless the company context is changed.

1. Open the analytical report in Power BI Desktop by double-clicking the resource in a Microsoft Visual Studio project.

2. On the **Modeling** tab, select **Manage Roles**.

3. Create a new role against a column in the data model that contains the **Company** field. Name the new role **CompanyFilter**. A **COMPANY** field is present in the data model to restrict access by company.



4. In the **Table filter DAX expression** field, enter **[COMPANY]=username()**.

5. To make sure that the rules work, on the **Modeling** tab, select **View as Roles**. In the dialog box, set the following fields:
   a. Clear the **None** check box.
   b. Select the **Other user** check box, and then enter **USMF** in the text box.
   c. Select the **CompanyFilter** check box.

The reports show data as if you're running the USMF company.

This tutorial shows how to export data and create a report, expand predefined views and add navigation to charts, use the free-form report designer, and customize the parameter experience.

Prerequisites

For this tutorial, you must access the application environment, and you must be provisioned as an administrator on the instance.

Key concepts

- Describe the various ways reports can be created and consumed
- Add interactivity to embedded aggregate reports in forms and workspaces
- Use framework extensions to customize the parameter experience for SSRS based business documents
- Export List Page data to create reports with external tools including Microsoft Excel
- Author modern report designs using enhanced developer tooling in Visual Studio

What's new in Reporting?

- Embedded report drill-through navigation to AX forms and reports
- Navigate between reports using embedded report drill-through links
- Several Document Routing Service enhancements including support for custom print settings
- Introduced Document Brand Management administrative tools
- More visualizations available through the Embedded Charting Control
- Dates and Amounts in the report body are formatted based on the "Date, time, and number format" user setting
- Network Print monitoring form
- Table extensions need to be supported through the VS Query picker

What is a report in Dynamics 365 finance and operations apps?

Reports are any visualization of a structured data set. This definition includes transactional data presented in a tabular layout and advanced graphical views of aggregate information. To account for this broad definition, the application offers several tools to produce reports that satisfy complex business requirements. Some common applications of reports in an ERP include:

- Creating and archiving transactional documents as part of a posting process
- Producing packing slips for tracking orders from Manufacturing to Warehousing to Sales
- Monitoring key performance metrics and surfacing trends in data
- Navigating the client through filtered searches
- Distributing heavily branded documents to customers and employees
- Extracting data in such a way that it articulates the health of a business

The most difficult task for developers is selecting the *right* Business Intelligence visualization tool for the job, given a customer's requirements. To accomplish this task, it's important to understand the capabilities offered through the tools that are available for creating reports. We offer tooling to support the following basic reporting requirements:

- **Excel Integration** – Allows data management and analysis using Microsoft Excel
- **Embedded Analytics** – Add aggregate data to Workspaces by using native controls like charts and grids
- **Reporting Services** – Create business documents that require precision by using SSRS-based solutions
- **Power BI Integration** – Author and share reports that can be accessed anywhere
- **Management Reporter** – Designed to help users create financial reports

The following table can be used to compare the basic characteristics of these reporting tools:

Expand table

Tool	Author	Target	Data	Consumption	Designer
Excel	Power User	Power User	Transactional	External	Free form
Embedded BI	Developer	All users	Aggregates	Internal	Modeled
SSRS Report	Developer	All users	Transactional and Aggregates	Internal/External	Free form

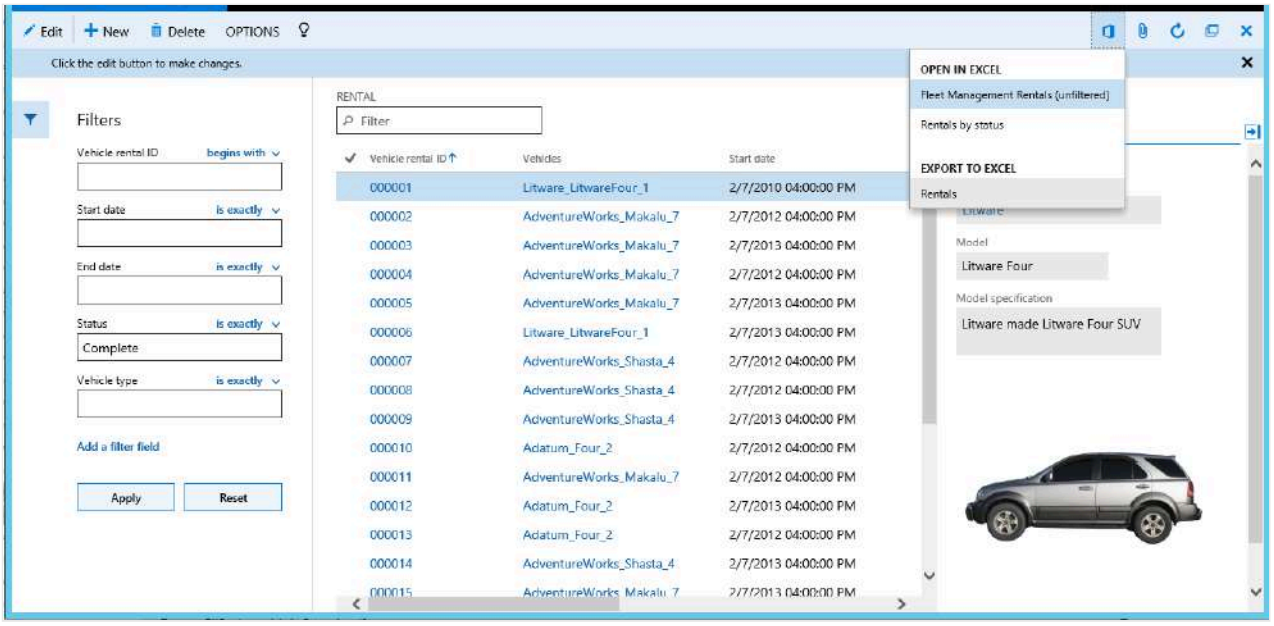
Tool	Author	Target	Data	Consumption	Designer
Power BI	Power User	All users	Aggregates	Internal/External	Free form
Management Reporter	Power User	Power User	Transactional	External	Modeled

Create a report using List Pages

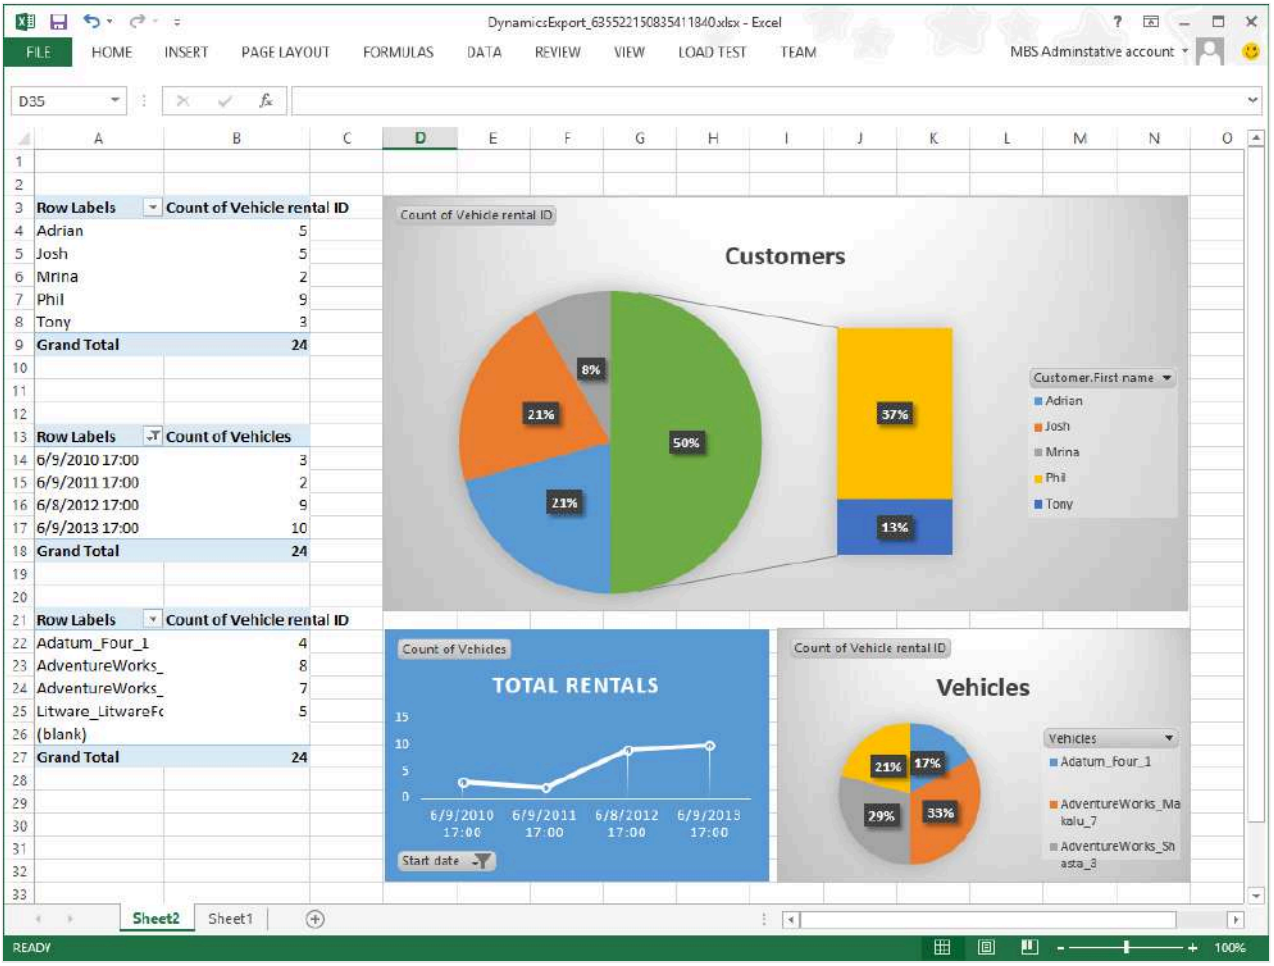
This section walks you through the process of exporting data displayed in an entity details form. It demonstrates how every form can be viewed as a source of data for management and analysis by using the power of Excel.

Create an analysis report based on all rentals in Fleet Management that are marked as complete

1. Open Microsoft Edge, go to your instance base URL, and sign in.
   a. On the cloud environment, you get the base URL from LCS.
   b. On a local VM, the base URL is `https://usnconeboxax1aos.cloud.onebox.dynamics.com`.
2. On the Dashboard, scroll to the far right, and select the **Reservation management** tile.
3. Under the **Summary** section, select on the **All rentals** tile.
4. Expand the **Filters** pane by selecting on the Filters icon next to the main grid.
5. Select **Add a filter field**, then select **Status** in the drop-down list.
6. Enter **Complete** in the Status filter field, then select **Apply**.
7. Expand the page action bar, select **Open in Office**, then select **Rentals**.



After the data is exported, you can use the power and flexibility of the Excel tools to create reports for presentation or other analysis. The following image is an example of a self-service report authored with Excel.



8. Close the browser session and the exported Excel file.

Advantages of list pages

- Flexible source for accessing transactional business data by using external reporting and analytical tools like Excel
- Allows end users to model the data sets they need without requiring a developer
- Direct access to real-time business information

Expand predefined views and add navigation to charts

Business Intelligence can be useful at every level of an organization. Use embedded controls to elevate the most relevant information based on the target persona. Native controls offer users an intuitive and convenient way of interacting with aggregate data, allowing for informed decision making.

Create development project

1. On the desktop, right-click the **Visual Studio** shortcut, and select **Run as administrator** to open the development environment.

2. On the toolbar, select **View**, then select **Application Explorer**.

3. Use the **Application Explorer** to search for the **FMReservationsReport** form in the **Fleet Management** module.

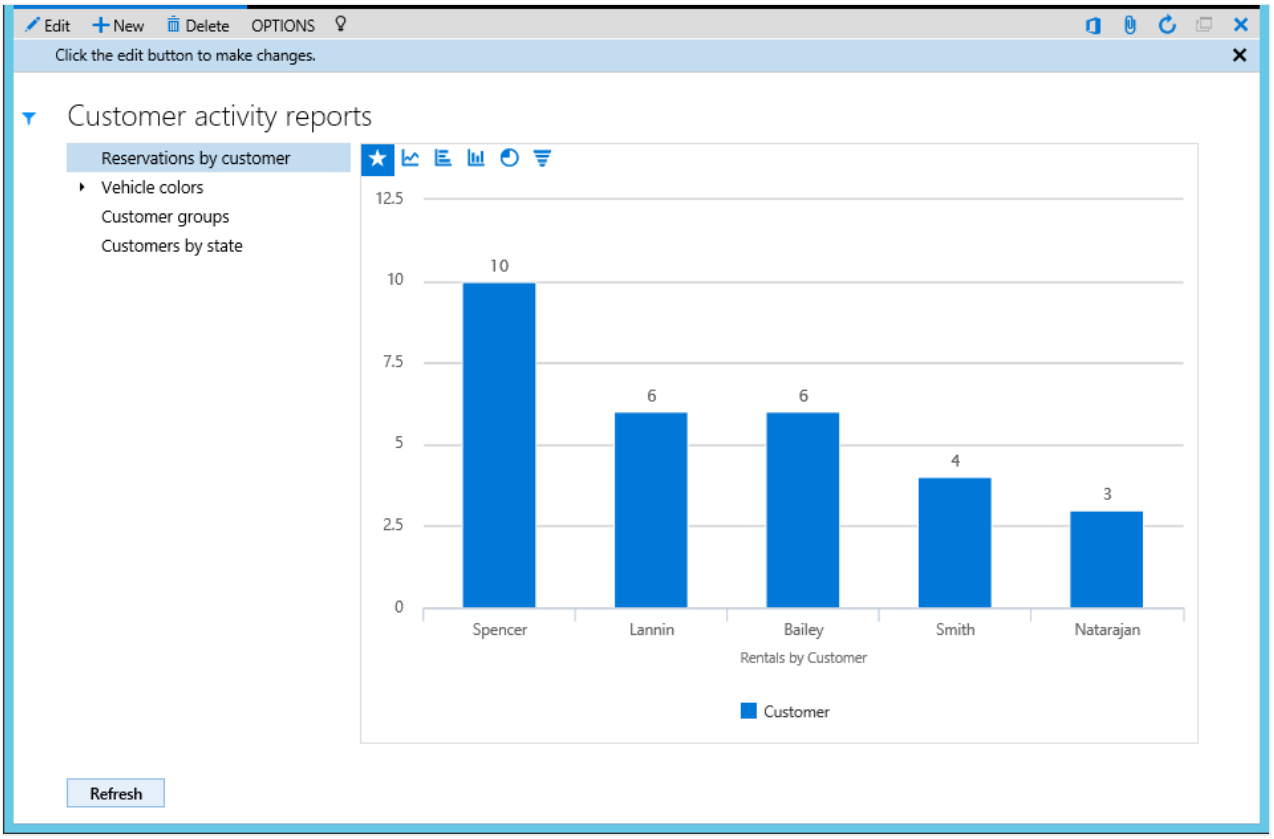
4. In the **Application Explorer's** search results, right-click **FMReservationsReport** form, then select **Add to new project**.

5. Select the **finance and operations Project** template, then select **OK** to create the project.

6. In **Solution Explorer**, right-click **FMReservationsReport** menu item, then select **Set as startup object.**

7. Press Ctrl+Shift+B to save and build the project.

8. Press Ctrl+F5 to load the form containing the report.

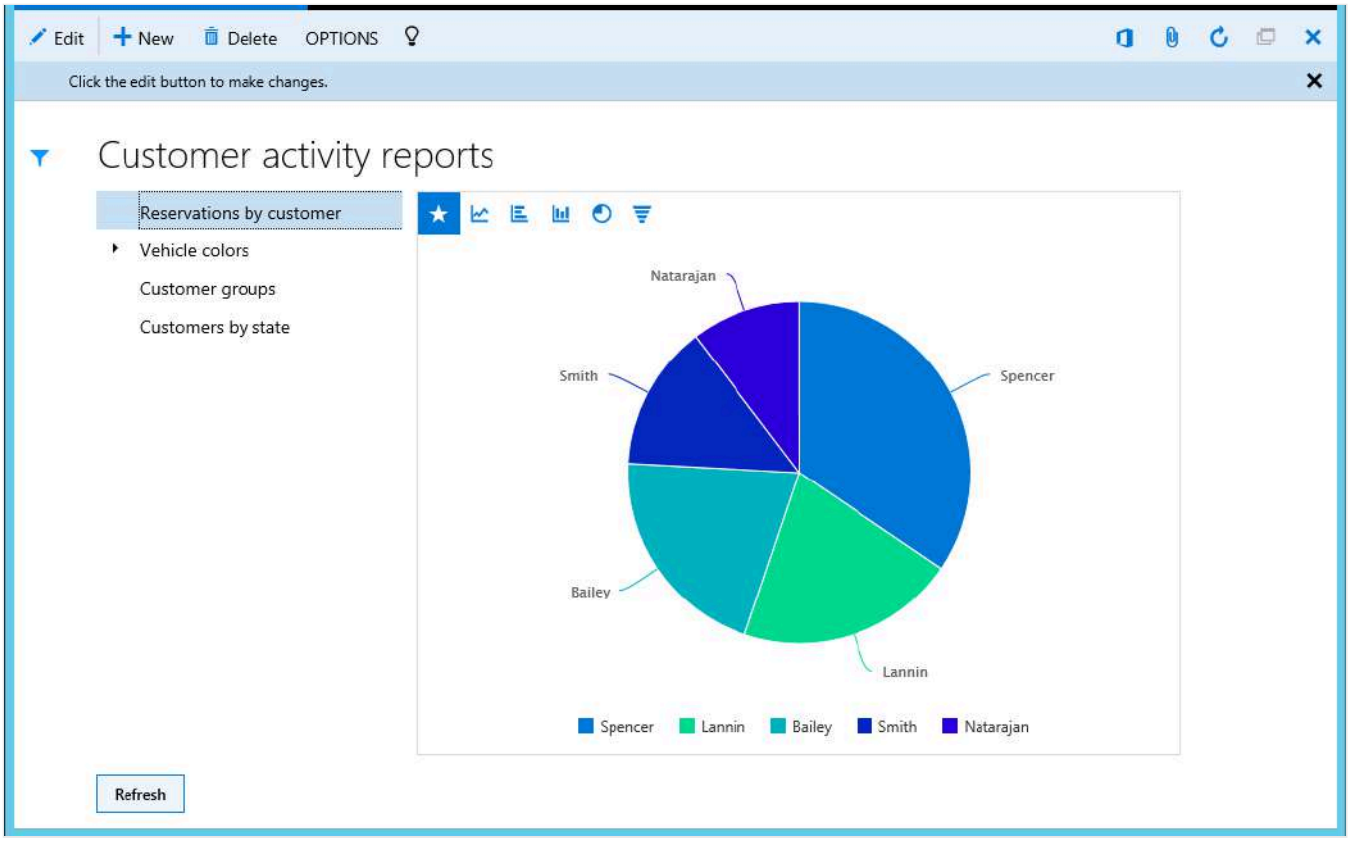


At this point, you have a collection of predefined chart visualizations of aggregate data. The controls offer basic interactive features like hover text, series filtering, and touch expansion. However, it's often appropriate that a greater degree of user interactivity is required.

Change the default chart type for the visualization

1. Close the browser session and return to the Visual Studio project.
2. Open the **Application Explorer**, locate the **FMReservationsByCustPart** form, right-click, and then select **Add to project**.
3. Open the **FMReservationsByCustPart** form designer.
4. Access the **Series** collection in the **ReservationsByCust** chart definition.
5. Select the **SysBuildChatMeasure1** series definition.
6. Locate the **Appearance** section in the **Properties** window.
7. Update the **Chart type** value and select **Pie**.
8. Press Ctrl+Shift+B to save and rebuild the project.
9. To run the report, press Ctrl+F5.

The **Reservations by customer** view now visualizes the aggregate data set by using a Pie chart. This chart type simplifies the task of comparing rental activity across customers.



Other functions include:

- Define contextual drill-through navigation by using modeled properties
- Manage drill-through links by using X++ form logic

Advantages of embedded aggregate visualizations

- Designed to be simple and intuitive to promote informed decisions at every level of the organization
- Predefined views tailored to meet the needs of the consumer
- Augments the user's ability to recognize key performance trends in the data

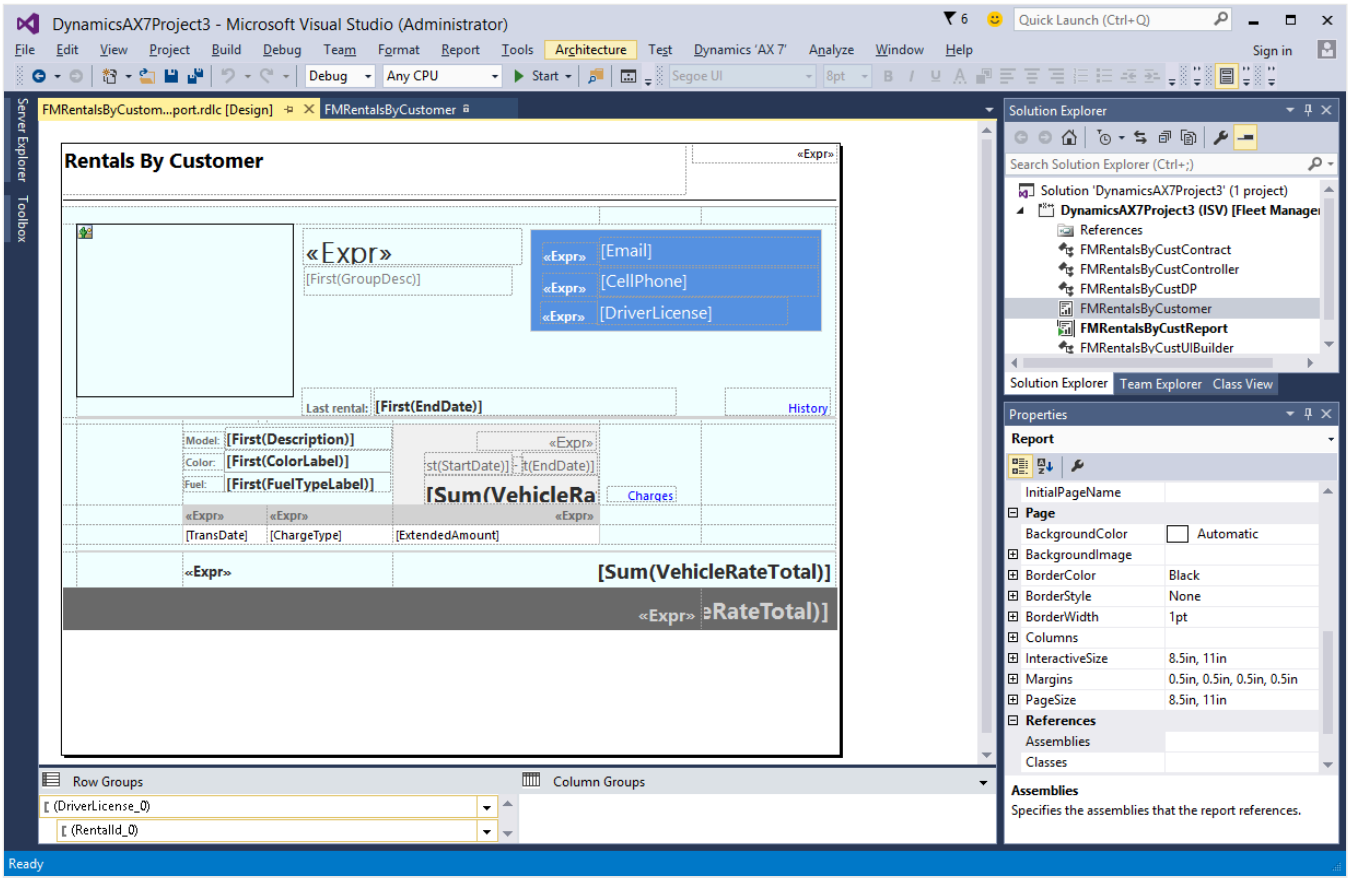
Using the freeform report designer

SSRS continues to be the platform for producing advanced Business Document solutions for your ERP application. The hosted service is designed for high volume and heavily transactional reports with an integrated parameter experience. Backed by the Document Printing & Distribution Services, these solutions are ideal for producing precision documents that are intended for email, printing, archive, and bulk distribution.

Open the Precision Designer

1. Close the browser session and return to the Visual Studio project.

2. Select **File** > **Close Solution** to close the active project.
3. Use the **Application Explorer** to search for objects with **FMRentalsByCust** in the name.
4. In the **Application Explorer's** search results, select all **Classes**, the **Output Menu Item**, and the **FMRentalsByCustomer** report.
5. Right-click and then select **Add to new project**.
6. Select the **Dynamics 365** template, then select **OK** to create the project.
7. In **Solution Explorer**, double-click on the **FMRentalsByCustomer** report to open the designer.
8. Expand the **Designs** collection in the designer to view the list of design definitions.
9. Double-click on the **Report** design to view the report definition using the Precision Designer.



The preceding screenshot shows the FMRentalsByCustomer report design definition as viewed by using the Visual Studio Precision Designer. The Precision Designer offers a free-form design surface with built-in tools that you can use to customize the content and layout of the report. You can also take advantage of embedded VB code to create run-time design manipulations and support user interactions. As an integrated tool, developers can reference AX labels and public APIs to format data in the report body based on AX EDTs. MSDN offers a rich collection of developer documentation related to SSRS formatting capabilities. For a good primer on designing effective SSRS reports, see the article Reporting Services Reports (SSRS).

Customizing the parameter experience

The Reporting Framework offers flexibility through service extensions to facilitate advanced solutions with requirements that can't be addressed by using a modeled solution. Use the VS designer to add basic parameter formatting, grouping, and input validation. X++ based data contract validation is available for more advanced scenarios. Consider adding User Interface (UI) Builder Classes to customize the parameter pane used to prompt for session inputs before running a report. These custom extensions are effective for addressing the following functions:

- Overriding dialog field events
- Validating report parameters inline
- Adding customized lookups to dialog fields
- Changing the layout of the dialog controls
- Adding custom controls including images

Defining parameters defaulting using code

1. In **Solution Explorer**, double-click on the **FMRentalsByCustUIBuilder** class to open the designer.

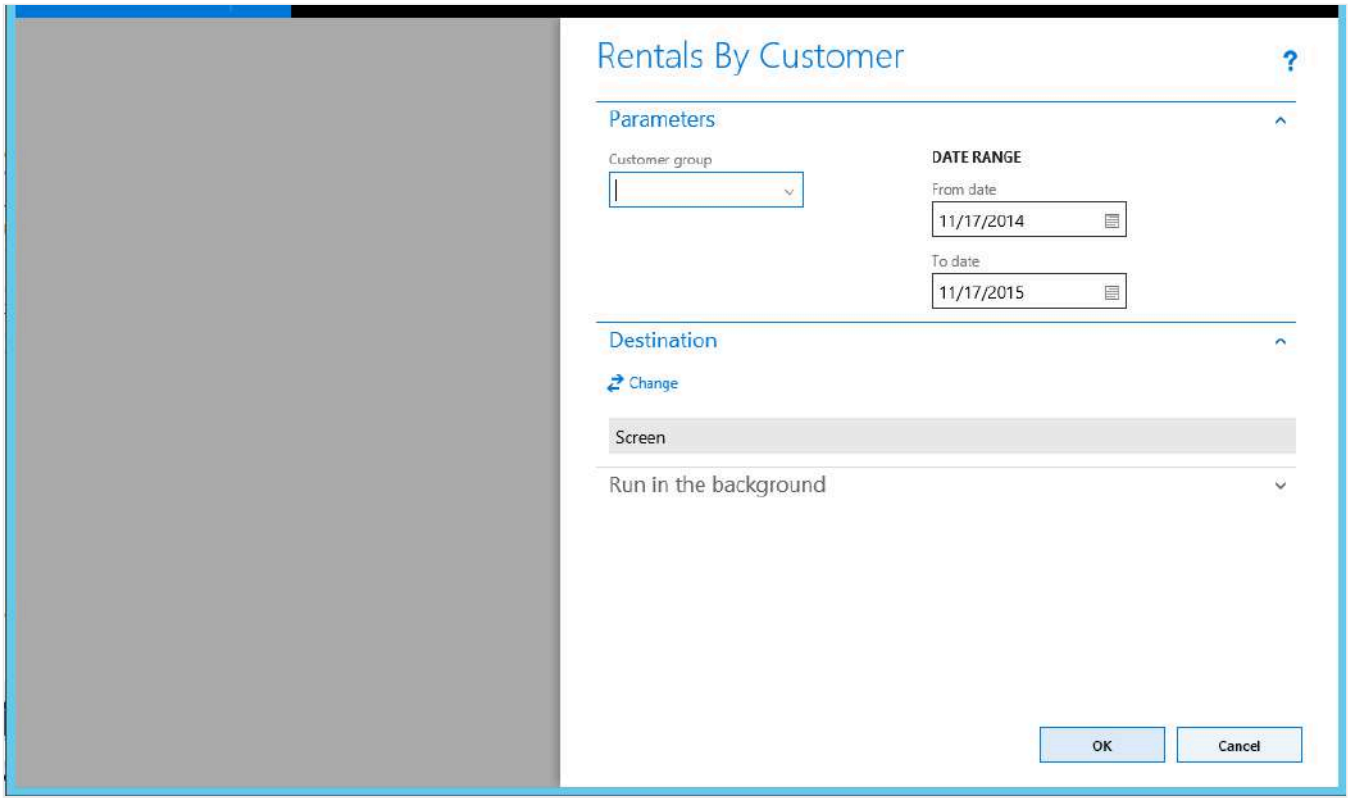
2. Locate the class **build** method and update the initialization code as follows

   X++

   ```
   public void build()
   {
       Dialog dialogLocal = this.dialog();
       contract = this.dataContractObject() as FMRentalsByCustContract;//
   associate dialog field with data contract method
       this.addDialogField(methodStr(FMRentalsByCustContract, parmCustGroupId),
   contract);dialogLocal.addGroup("@SYS41297");
       fromDateField = this.addDialogField(methodStr(FMRentalsByCustContract,
   parmFromDate), contract);
       toDateField = this.addDialogField(methodStr(FMRentalsByCustContract,
   parmToDate), contract);// set the default date range values
       fromDateField.value(today() - 365);
       toDateField.value(today());
   }
   ```

3. Press Ctrl+Shift+B to save and rebuild the project.

4. Press Ctrl+F5 to run the report.



The parameter initialization code sets the default values of the report execution relative to today's date. Use the classes UIBuilder to override the framework's default handling of report parameters. Other extension scenarios supported:

- Automatically set query ranges based on session context using Controller classes
- Select report designs at runtime using a shared menu item
- Modify report data contract values using business logic

> **Note**
>
> This example demonstrates a UIBuilder extension with an RDP-based report. For a Query based example that includes a UIBuilder extension, see the **FMCustomerList** report.

Using VB code to manage running balances

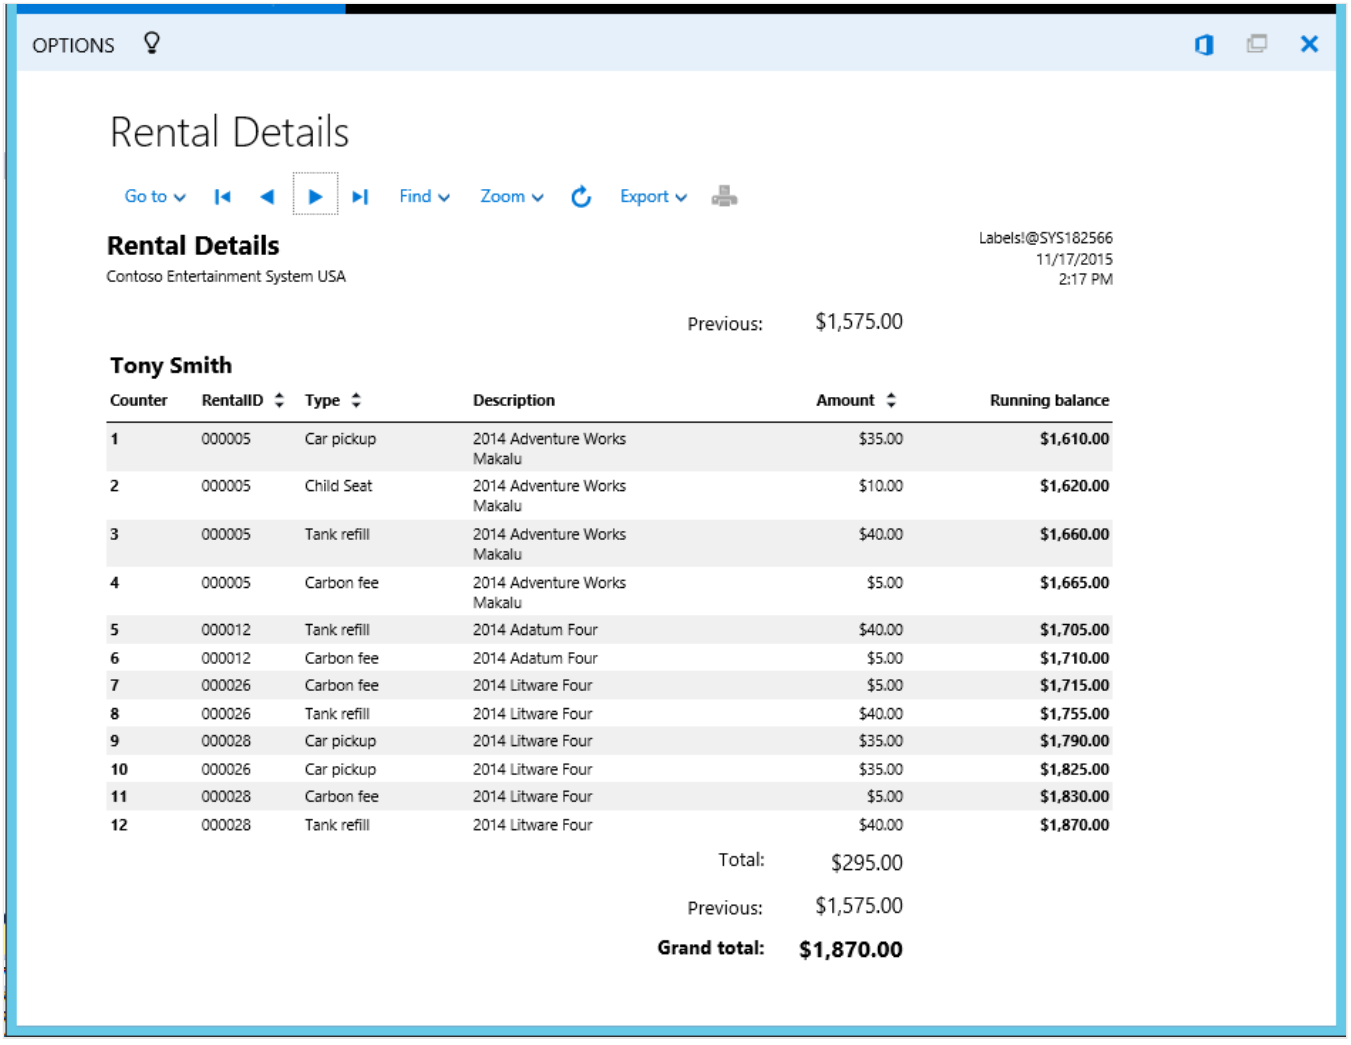
The Reporting Framework offers flexibility through service extensions to facilitate advanced solutions with requirements that can't be addressed by using a modeled solution. Use the VS designer to add basic parameter formatting, grouping, and input validation. X++ based data contract validation is available for more advanced scenarios. Consider adding User Interface (UI) Builder Classes to customize the parameter pane used to prompt for session inputs before running a report. These custom extensions are effective for addressing the following functions:

- Overriding dialog field events
- Validating report parameters inline

- Adding customized lookups to dialog fields
- Changing the layout of the dialog controls
- Adding custom controls including images

Import the section resources

1. Close the browser session and return to the Visual Studio project.
2. On the toolbar, select **DYNAMICS AX**, then select **Import Project...**
3. In the File name window, browse to `C:\FmLab\Lab10-3`, select **FMRentalDetailsReport.axpp**, then select **Open**.
4. In the Project file location text box, enter `C:\FmLab\Lab10-3`.
5. Select the **Current solution** radio button.
6. Select **OK** to close. Wait for the project to be imported and opened.
7. In the **Solution Explorer**, select the new project, right-click, then select **Set as startup project.**
8. In the **Solution Explorer**, right-click **FMRentalDetails** menu item, then select **Set as startup object.**
9. Select the project in Solution Explorer, right-click, then select **Deploy Reports**
10. Press Ctrl+F5 to view the report.



This report uses embedded VB script to keep track of running totals so that the balances from the previous page can be referenced on the active page. To inspect the report's VB code, load the report design in the Precision Designer, access the **Report Properties**, then select the **Code** section. Here you see several functions referenced by the report designs to surface running balances within the report headers and footers.

Advantages of SSRS reports

- Built-in back office document management capabilities including email support, scheduled executions via Batch, and Print Archive
- Parameterized views with drill-through navigation to forms and other reports
- Used to produce precision documents for compliance with local regulatory business practices

Customize App Suite reports by using extensions

This article discusses a series of scenarios for customizing App Suite reports.

Finance and operations offer an expanded set of tools to support custom solutions. Customizations to reporting solutions in the standard application are fully supported using a pure extension model. This article contains guidance about how to add the most common customizations to standard application reports without overlayering Application Suite artifacts. Here are some of the key benefits of using an extension-based approach when customizing the application:

- It reduces the footprint of your application solutions by minimizing code duplication.
- Custom reports benefit from enhancements made to standard solutions including updates to business logic in Report Data Provider (RDP), data contracts, and UI Builder classes.
- Standard application solutions are unaffected and continue to be available in concert with custom reports.

Report extensions don't break or prevent access to standard application reports. Instead, the platform supports run-time selection of the target report allowing you to choose the appropriate report design based on the context of the user session. For more information about customizations using extensions, see Customize through extension and overlayering

Scenarios

There are four key scenarios that demonstrate the flexibility available. The first two scenarios involve extending existing RDP classes for custom reporting solutions.

- Expand Application Suite report data sets – Use table extensions and integrate custom business logic to add custom columns to an existing dataset.
- Composing custom datasets – Add more data to application reports by extending an existing RDP class to return a custom dataset.

The other two scenarios offer insights on how to use extensions to redirect application navigation to your custom solutions.

- Extend report menu items to redirect user navigation – Customize application menu items to redirect references to a custom report design.

- Create custom designs for business documents – Delegate handlers allow you to add custom report designs to an existing Print Management document instance.

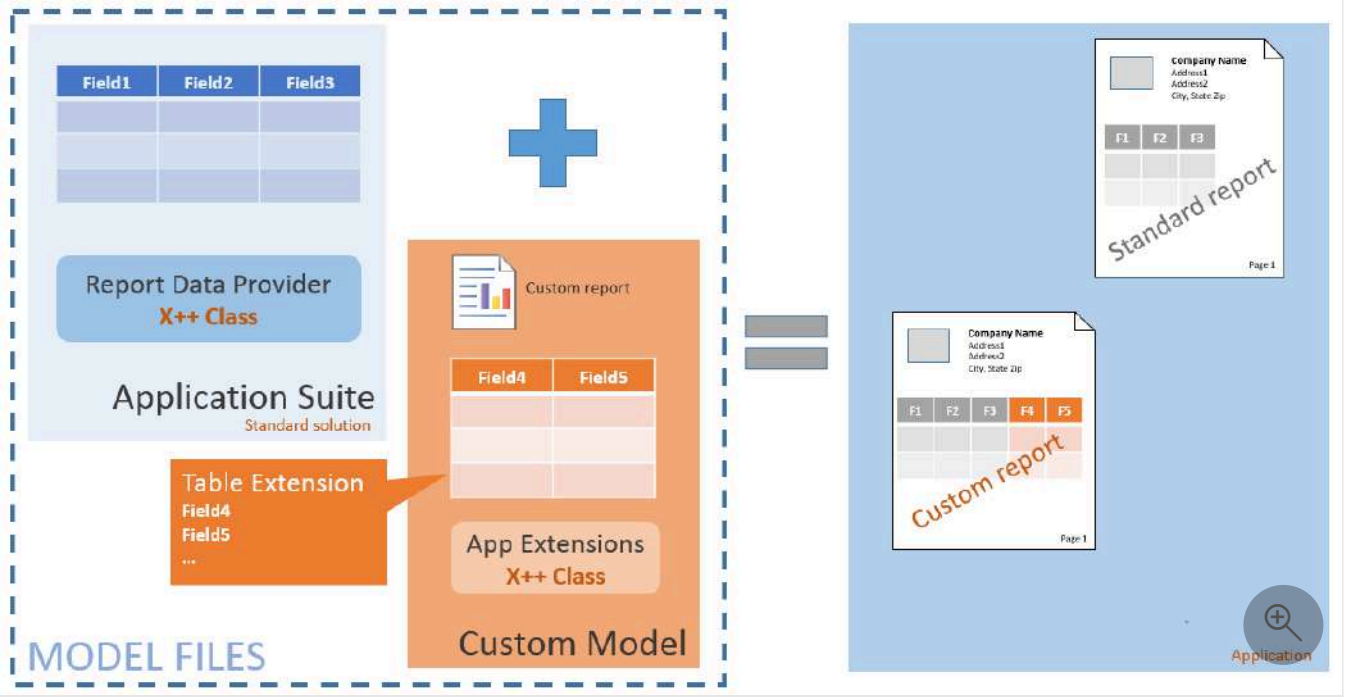
Last updated on 06/26/2026

Expand Application Suite report data sets

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article shows how to expand an existing report data set that uses X++ business logic in a report data provider (RDP) class.

This article focuses on expanding an existing report data set that uses X++ business logic in a report data provider (RDP) class. You use custom delegate handlers and table extensions to include more field data and calculations. You don't have to over-layer the Application Suite. You then create custom designs that replace the standard application solutions and present the data to users. The following illustration shows a typical application customization, as described in this article.



Important considerations

Before you apply this solution, be aware of the following considerations.

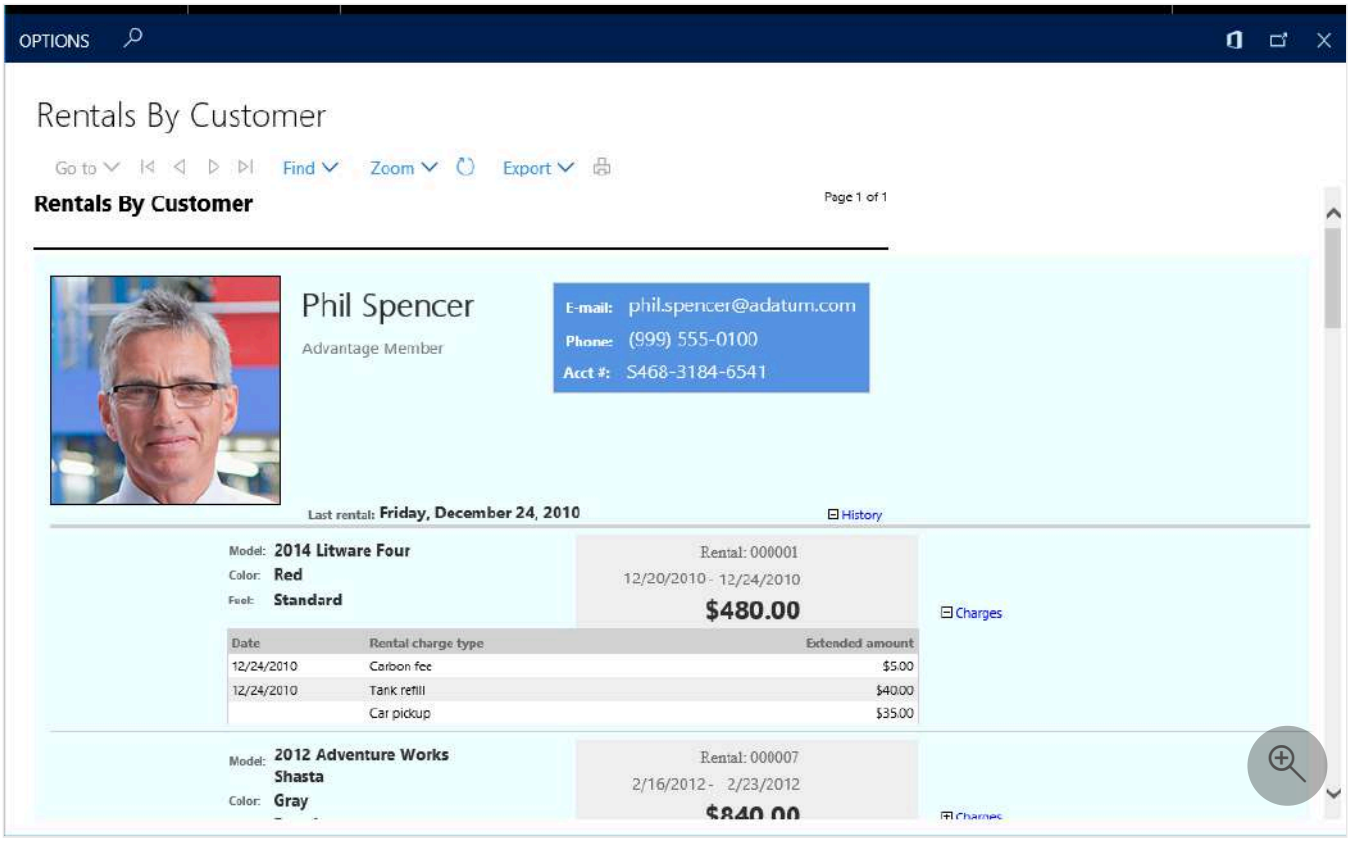
- **You can't directly extend RDP classes.** However, the platform provides extension points that enable data set expansion without duplicating business logic in the standard application.

- **Two methods are available to expand report data sets.** Use the strategy that's appropriate for your solution:
  - **Data processing post-handler** – This method is called only one time, after the **ProcessReport** method completes and before the data set is returned to the report server. Register for this post-handler to perform bulk updates on the temporary data set that the standard application solution produces.
  - **Temp table inserting event** – This method is called for each row that is added to the temporary table. It's more suitable for calculations and inline evaluations. Avoid expensive queries that have many joins and look-up operations.
- **Use event handlers to redirect menu items to your new report design.** You can customize all aspects of an application reporting solution by using event handlers. Add a **PostHandler** event for the controller class to reroute user navigation to a custom report design.

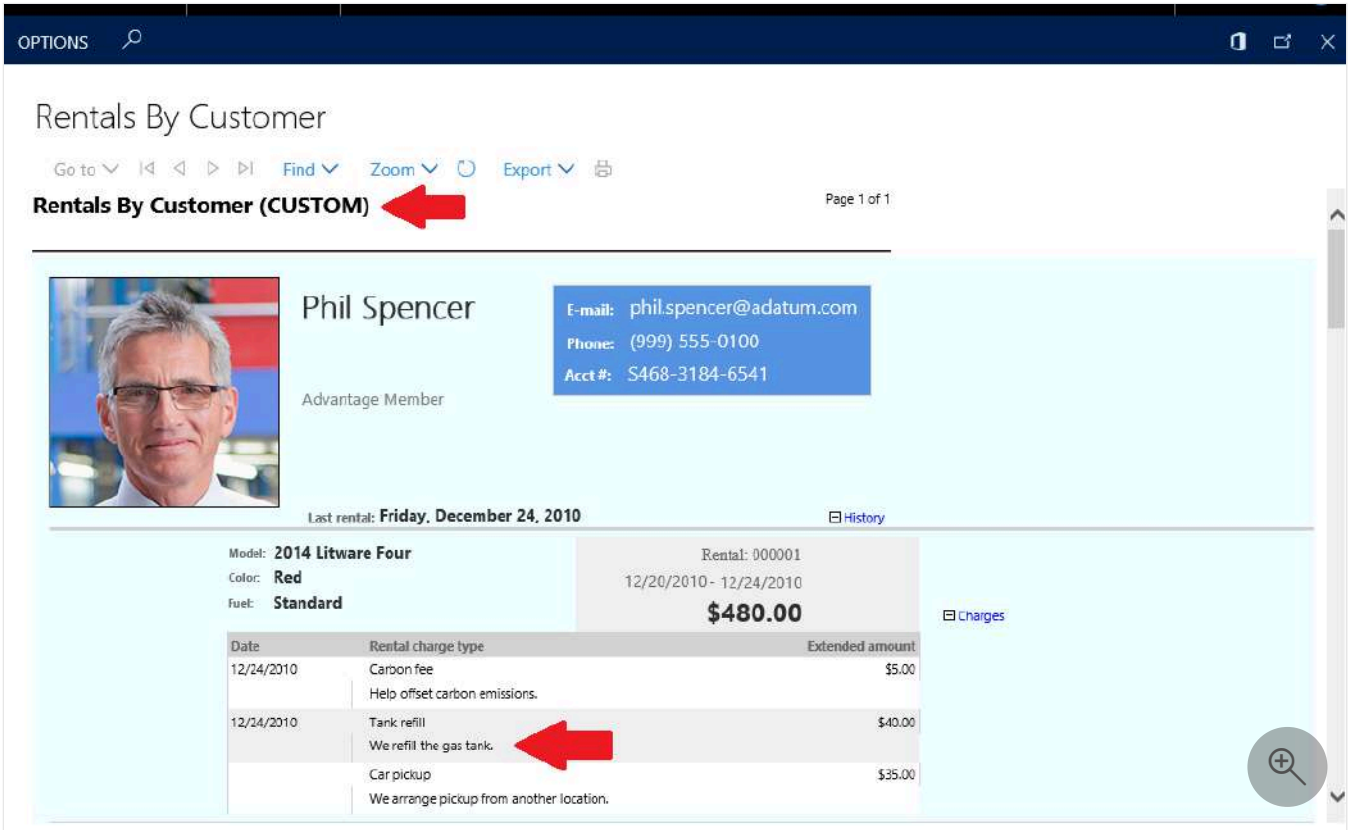
Expand a report data set

The following walkthrough shows the process of expanding an existing application data set by using a "pure" extension-based solution. The solution includes a custom **Rentals list** report for the Fleet Management application. The new report includes more rental charge data in the rental details. The application customizations are defined in an extension model. The following illustrations show the standard design and the custom solution.

Before (standard design)

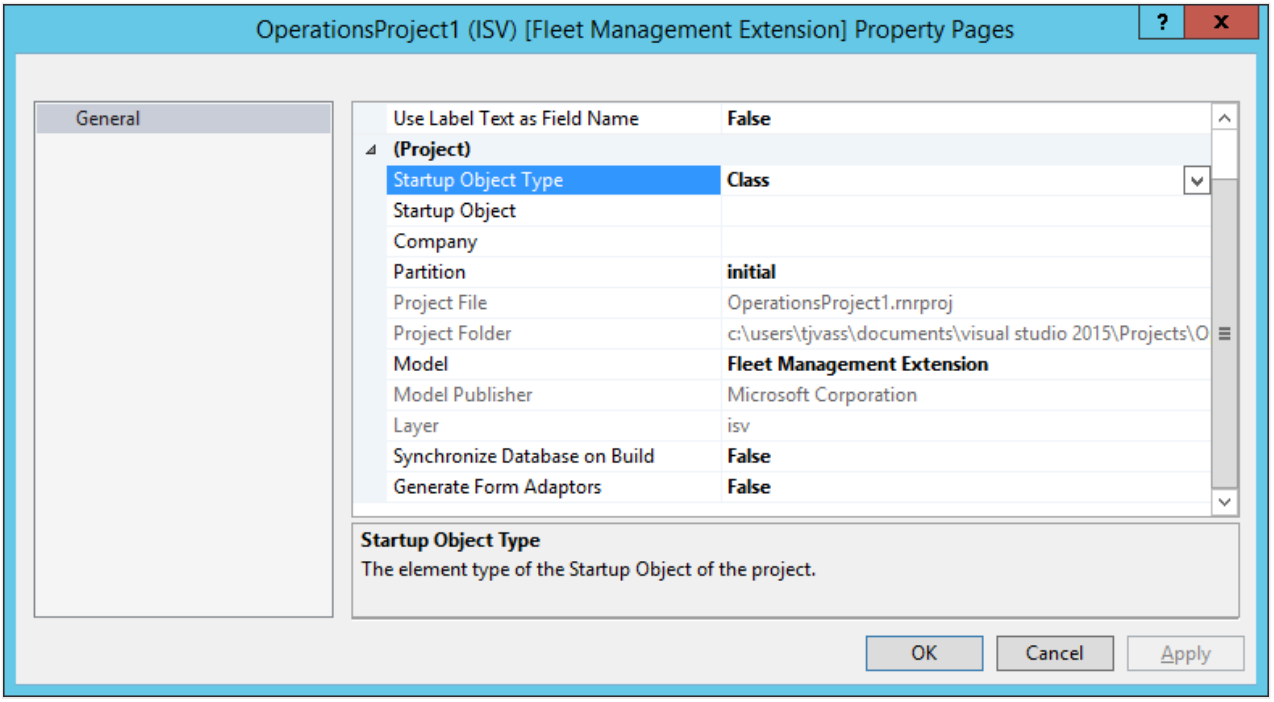


After (custom solution)

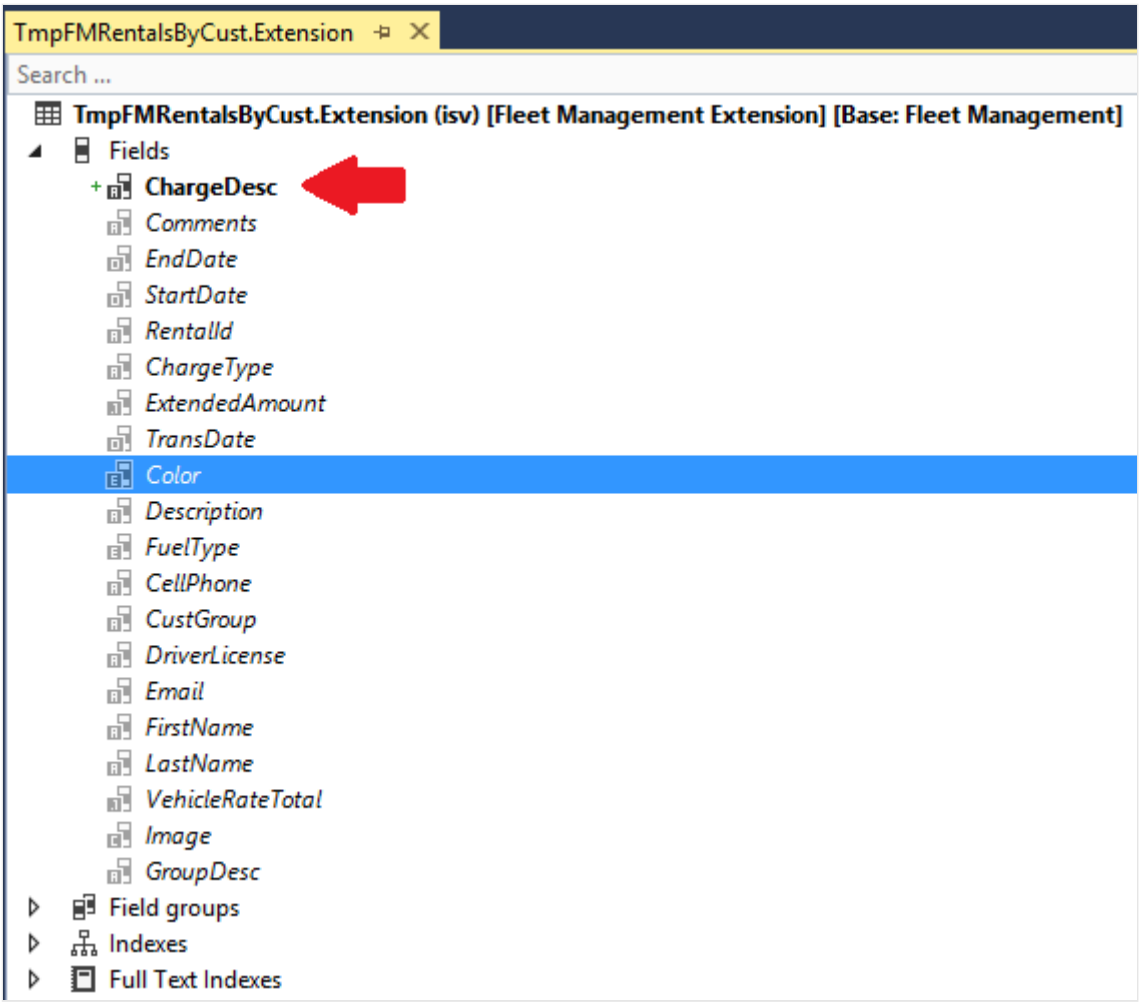


1. **Create a new model for your application customizations.** For more information about extension models, see Customize through extension and overlayering. For this example, add a custom report to the **Fleet Management Extensions** model.

2. **Create a new project in Microsoft Visual Studio.** Make sure that the project is associated with your extension model. The following illustration shows the project settings.



3. **Add a table extension to store the custom report data.** Find the temporary cache for the **TmpFMRentalsByCust** data set that the RDP class populates, and create an extension in your model. Define the fields that store the data for the report server, and then select **Save** to save your changes. The following illustration shows the table extension that is required for this example.

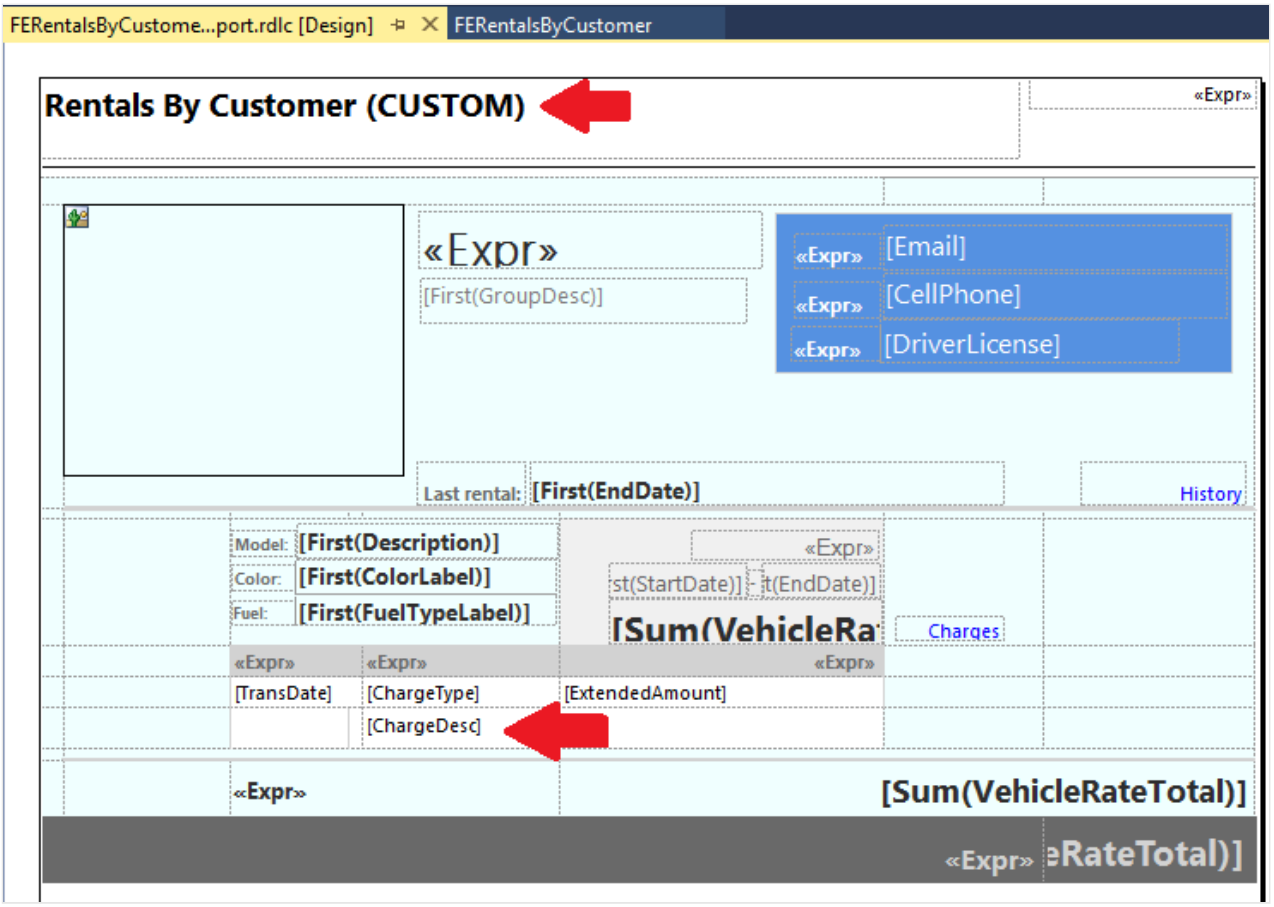


4. **Add your custom report to the project.** The custom design closely resembles the standard solution. Therefore, you can just duplicate the existing application report in the **Fleet Management Extension** model, and then update the report design so that it includes the custom title and another text box in the Rental Charges container.

5. **Rename the report so that it has a meaningful name.** For this example, rename the custom report **FERentalsByCustomer** to distinguish it from the standard solution.

6. **Restore the report data set references.** Open the report designer, expand the **Datasets** collection, right-click the data set named **FMRentalsByCustDS**, and then select **Restore**. The data set expands so that it includes the newly introduced columns. Therefore, these columns are now available in the report designer.

7. **Customize the report design.** The designer offers a free-form design surface that you can use to create the custom solution. The following illustration shows the custom design that is used for this example.



8. **Add a new report handler (X++) class to the project.** Give the class a name that appropriately describes that it's a handler for an existing application report. For this example, rename the class **FERentalsByCustomerHandler** to distinguish it from other report handlers.

9. **Add a PostHandler method to begin to use your custom report.** In this example, extend the controller class in the standard solution, **FMRentalsByCustController**, by using the following code.

X++

```
class FERentalsByCustomerHandler
{
    [PostHandlerFor(classStr(FMRentalsByCustController),
staticMethodStr(FMRentalsByCustController, construct))]
    public static void ReportNamePostHandler(XppPrePostArgs arguments)
    {
        FMRentalsByCustController controller = arguments.getReturnValue();
        controller.parmReportName(ssrsreportstr(FERentalsByCustomer, Report));
    }
}
```

User navigation in the application now reroutes to the custom reporting solution. Take some time to deploy the custom report to the report server and verify that the application is using it. At this point, you just need to add the business logic that

populates the custom fields that you introduced in step 3. In the next step, you must select the method of data set expansion that's appropriate for your solution.

10. **Add X++ business logic to populate the custom field data.** Select the data processing technique that makes sense for the type of transformation that you require for the solution.

    - **Option 1: Add a data processing post-handler.** Apply this technique for bulk insert operations that use a single pass over the result set of the standard solution. Here's the code that expands the data set by using a table lookup.

      X++

      ```
      class FERentalsByCustomerHandler
      {
          [PostHandlerFor(classStr(FMRentalsByCustDP),
      methodstr(FMRentalsByCustDP, processReport))]
          public static void TmpTablePostHandler(XppPrePostArgs arguments)
          {
              FMRentalsByCustDP dpInstance = arguments.getThis() as
      FMRentalsByCustDP;
              TmpFMRentalsByCust tmpTable = dpInstance.getTmpFMRentalsByCust();
              FMRentalCharge chargeTable;
              ttsbegin;
              while select forUpdate tmpTable
              {
                  select * from chargeTable where chargeTable.RentalId ==
      tmpTable.RentalId;
                  tmpTable.ChargeDesc = chargeTable.Description;
                  tmpTable.update();
              }
              ttscommit;
          }
      }
      ```

    - **Option 2: Add a temp table Inserting event.** Apply this technique for row-by-row calculations. Here's the code that expands the data set by using a table lookup.

      X++

      ```
      class FERentalsByCustomerHandler
      {
          [DataEventHandlerAttribute(tableStr(TmpFMRentalsByCust),
      DataEventType::Inserting)]
          public static void TmpFMRentalsByCustInsertEvent(Common c,
      DataEventArgs e)
          {
              TmpFMRentalsByCust tempTable = c;
              FMRentalCharge chargeTable;
              // update the value of the 'ChargeDesc' column during 'insert'
      ```

```
operation
        select * from chargeTable where chargeTable.RentalId ==
tempTable.RentalId
        && chargeTable.ChargeType == tempTable.ChargeType;
        tempTable.ChargeDesc = chargeTable.Description;
    }
}
```

You finished expanding the report data set. After you compile the application, it reroutes user navigation to the new report design by using the custom X++ business logic that you defined in the report class handler that is defined in the extension model.

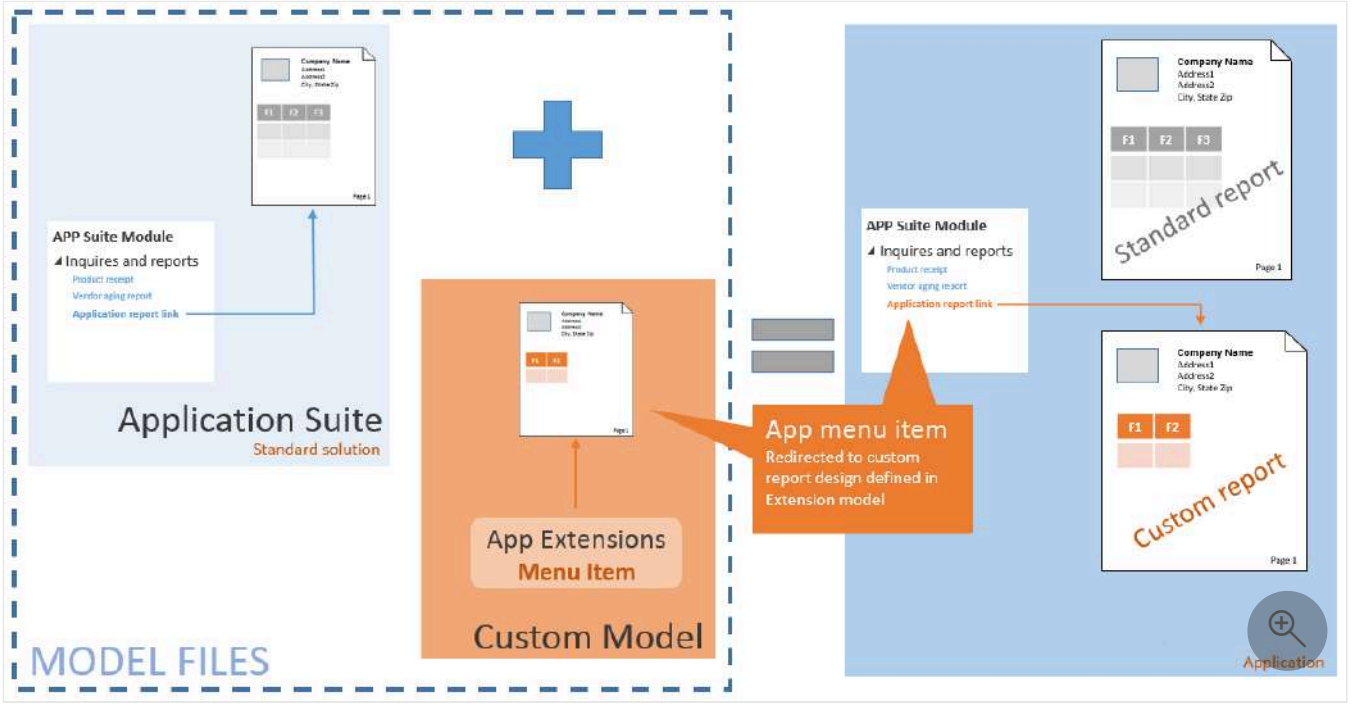
Last updated on 11/26/2025

Extend report menu items to redirect user navigation

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article shows how to extend existing application menu items so that, with only minimal code changes, you can redirect navigation to a custom reporting solution.

This article focuses on the process of extending existing application menu items so that, with only minimal code changes, you can redirect navigation to a custom reporting solution. By using this technique, you avoid the inconvenience of tracking down and replacing all references to an existing application report. Just extend an existing application menu item to redirect application navigations to reports that you define in an extension model. The following illustration shows a typical application customization.



What's important to know?

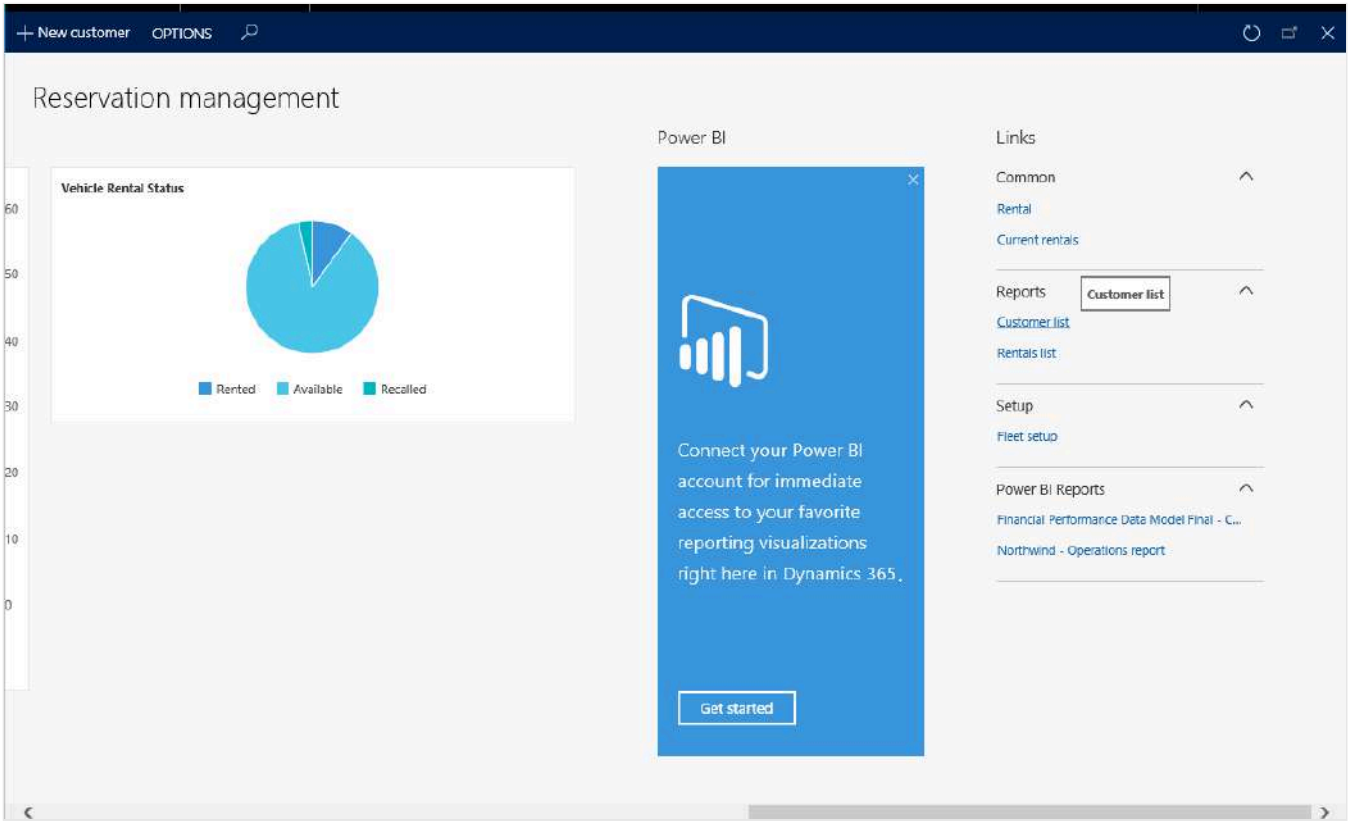
Before you apply this solution, be aware of the following basic assumptions.

- Extended menu items let you override both the display string and the target.

- You can use this technique for all types of reports, from simple query-based reports to complex report data provider (RDP)–based reports.
- Extended menu items are available for direct references to reports and solutions that orchestrate the reporting session by using a controller class.

Extend report menu items

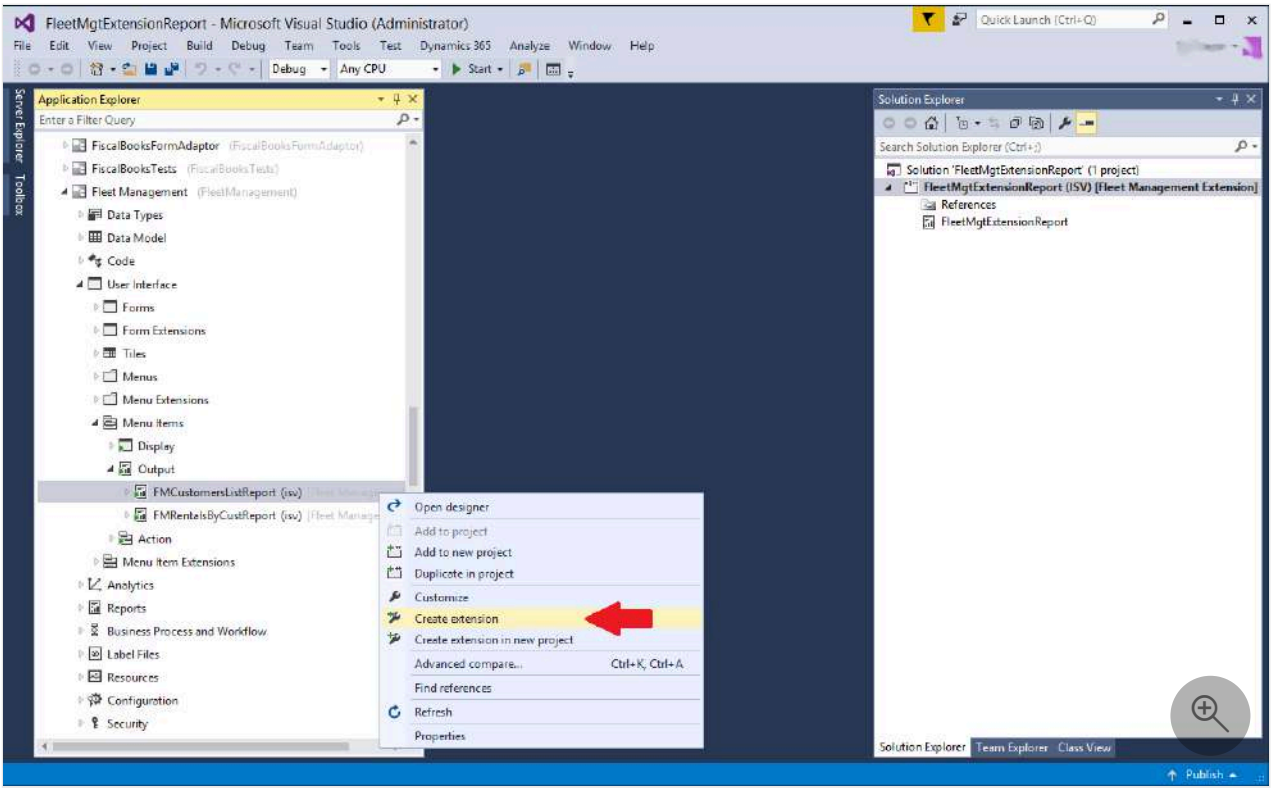
The following walkthrough shows how to use menu item extensions to redirect user navigations in the application to a custom solution. The solution includes a custom **Customer list** report for the Fleet Management application and defines all the application customizations in a pure extension model. The following illustration shows the menu item that you use to access the custom **Customer list** report.



1. **Create a new model for your application customizations.** For more information about extension models, see Customize through extension and overlayering.

2. **Create a new project in Microsoft Visual Studio, and add your custom report.** Additionally, add all the solution artifacts. These artifacts include the RDP class or source query, the controller class, and UI builders, if they're present.

3. **Create an extension of the menu item that is used to access the report.** In this example, the output menu item is named **FMCustomerListReport**. Use the menu item structure to find the menu item name that the application exposes. The following illustration shows the action in Application Explorer.



4. **Modify the properties of the menu item extension.** Update the report design or controller reference in the menu item to direct navigations to your custom solution.

> ⓘ **Note**
>
> The property changes that you can make on the object depend on the original application solution. If the application report manages the solution by using a controller, a controller class is required for the report.

5. **Rebuild the solution, and deploy the custom report.**

You finished extending the report menu item. Navigations to the standard menu item now redirect to your custom reporting solution.

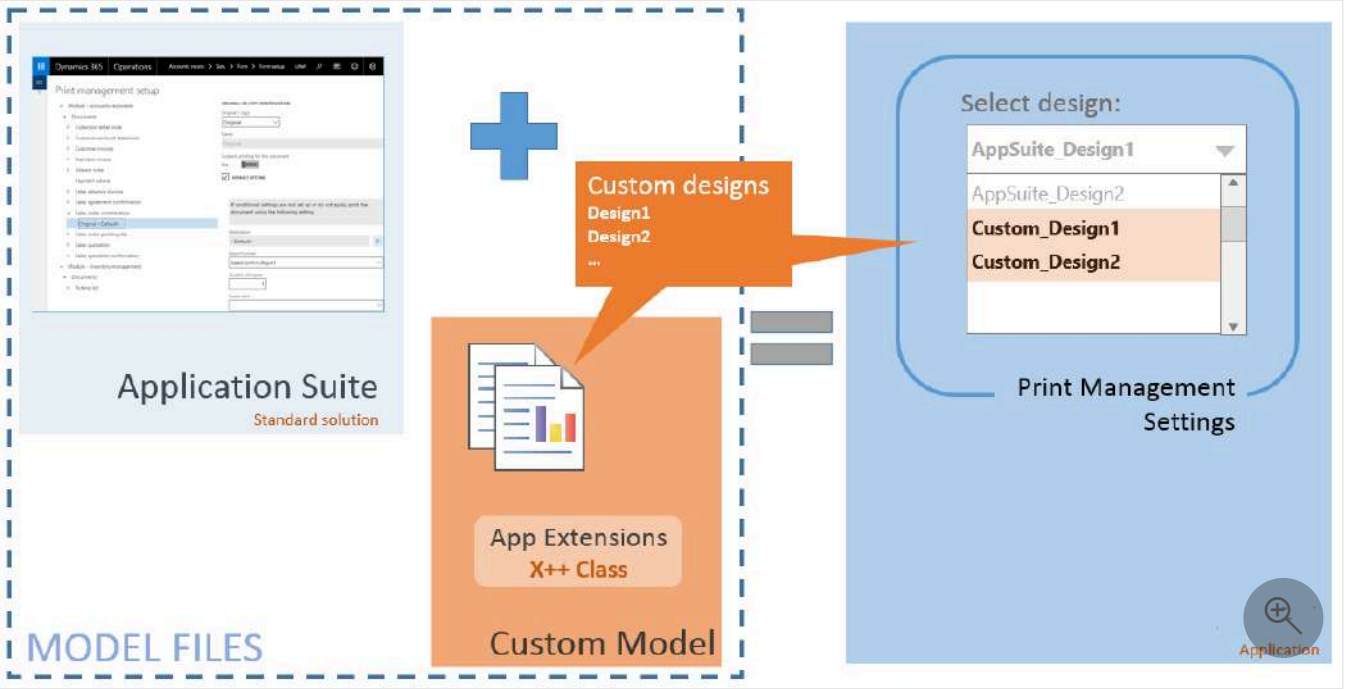
Create custom designs for business documents

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article shows how to create a custom report design for an existing application business document by using a pure extension model.

Microsoft Dynamics 365 Finance includes an expanded set of tools to support custom solutions. This article focuses on the steps for creating a custom report design for an existing application business document by using a pure extension model. Follow the steps later in this article to associate a custom report design with an instance of an application document. When you finish, users can configure Print management settings to select the custom design whenever it's appropriate, based on transaction details. The following illustration shows a typical application customization.



What's important to know?

Before you apply this solution, be aware of the following points:

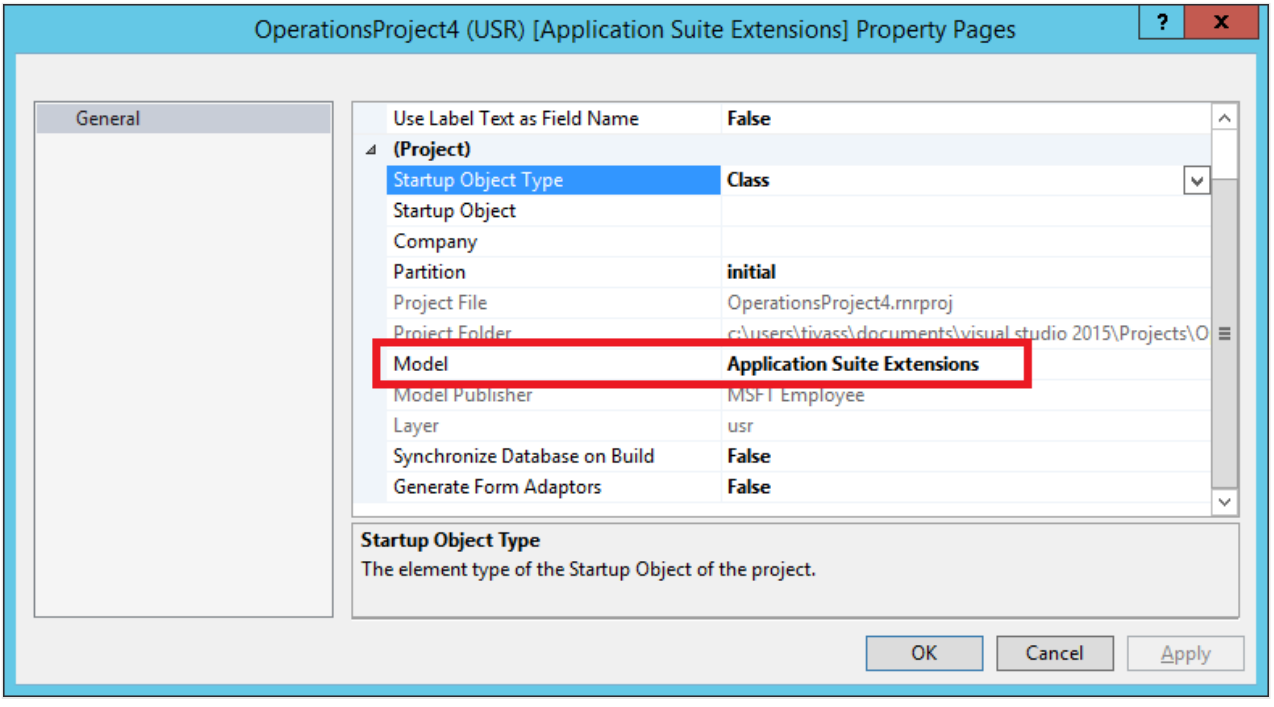
- Print management settings are scoped to the active legal entity. You can associate custom designs with one or more Print management settings.
- Standard report designs continue to be available alongside custom solutions. Use Print management settings to select the appropriate design, based on transaction details.
- If you introduce a business document for a custom business process, you need to do more work. For more information about how to create a custom business document solution, see the Print Management Integration Guide.

Customize a business document

The following walkthrough shows the process of introducing a custom report design for an existing application business document and then using Print management to select the new design. The solution includes a custom design definition for the **Sales confirmation** report that is provided in the standard application as part of the Application Suite model. You define the application customizations in an extension model.

1. **Create a new model for your application customizations.** For more information about extension models, see Customize through extension and overlayering. For this example, add a model named **Application Suite Extensions** that references the Application Suite, Application Platform, and Application Foundation packages.

2. **Create a new project in Microsoft Visual Studio.** Make sure that the project is associated with your extension model. The following illustration shows the project settings.

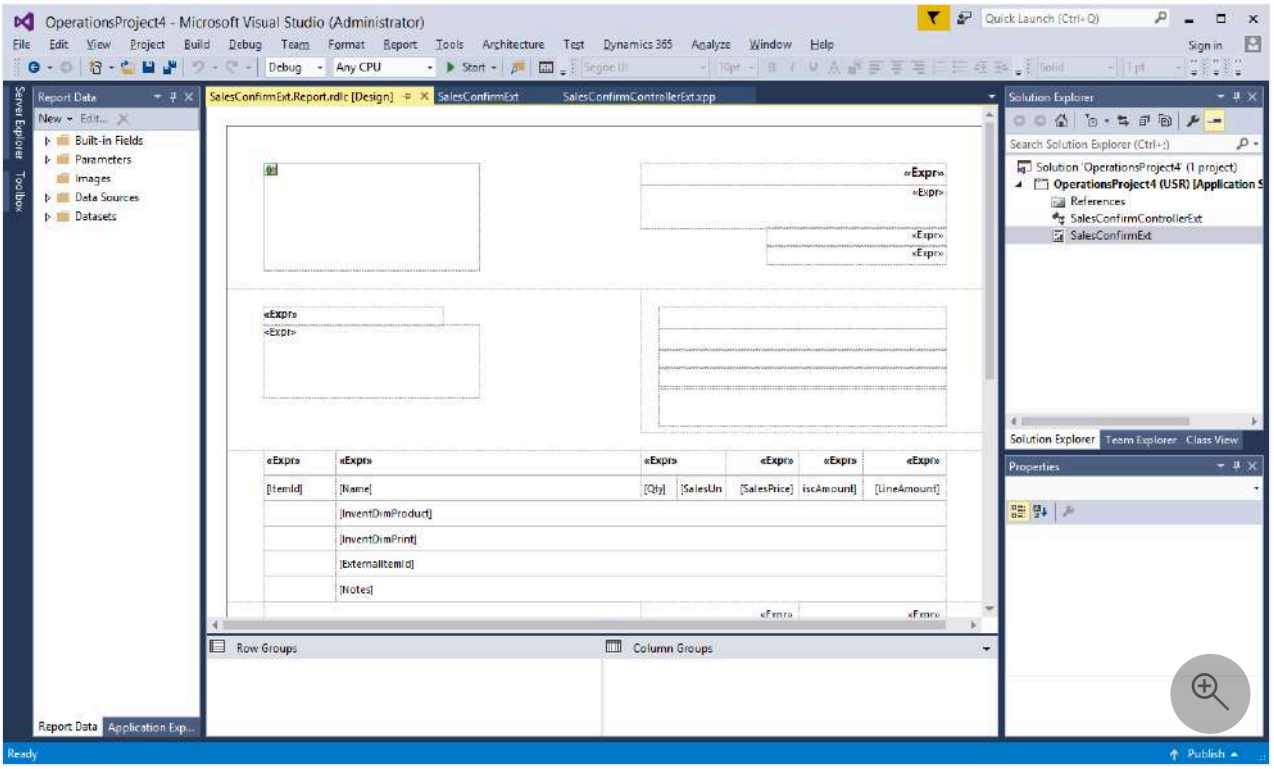


3. **Create a custom report design for the business document.** Make sure that your custom solution consumes the correct report data contract. Find the existing Application Suite

report in Application Explorer. This report is named **SalesConfirm**. Right-click it, then select **Duplicate in project** to create the custom solution.

4. **Rename the report so that it has a meaningful name.** For this example, name the custom report **SalesConfirmExt** to distinguish it from the standard solution. Compile the project, and deploy the report to verify that the changes have no errors.

5. **Use the free-form designer to customize the report design.** Select the report design named **Report**, right-click it, and open the precision designer. Customize the design to satisfy the organization's business requirements. The following illustration shows a custom design definition for the **Sales confirmation** report.



6. **Add a new X++ class that extends the standard report controller.** Give the class a name that appropriately describes that it's a handler for an existing application report. For this example, rename the class **SalesConfirmControllerExt** to distinguish it from other report controllers.

7. **Use the extended class to load the custom design.** Add a **main** method that refers to the custom report design. (You can just copy the **main** method from the standard solution and add references to the new **Controller** class.) Here's the code that extends the standard solution.

X++

```
class SalesConfirmControllerExt extends SalesConfirmController
{
    public static SalesConfirmControllerExt construct()
    {
```

```
        return new SalesConfirmControllerExt();
    }
    public static void main(Args _args)
    {
        SrsReportRunController formLetterController =
SalesConfirmControllerExt::construct();
        SalesConfirmControllerExt controller =
formLetterController;controller.initArgs(_args, ssrsReportStr(SalesConfirmExt,
Report));
        if (classIdGet(_args.caller()) == classNum(SalesConfirmJournalPrint))
        {
            formLetterController.renderingCompleted +=
eventhandler(SalesConfirmJournalPrint::renderingCompleted);
        }
        formLetterController.startOperation();
    }
}
```

8. **Add a new report handler (X++) class to the project.** Give the class a name that appropriately describes that it's a handler for Print management–based documents. For this example, rename the class **PrintMgtDocTypeHandlerExt** to distinguish it from other object handlers.

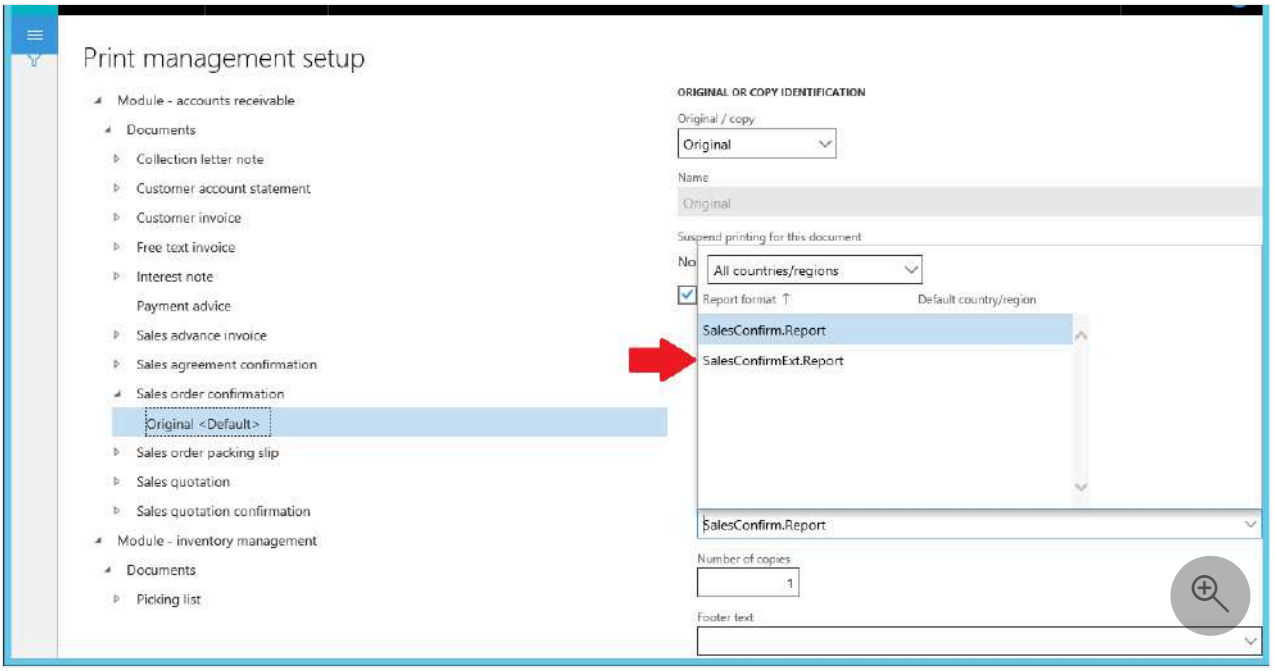
9. **Add a delegate handler method to start to use your custom report.** In this example, extend the **getDefaultReportFormatDelegate** method in the **PrintMgtDocTypeHandlerExt** class by using the following code.

X++

```
class PrintMgtDocTypeHandlersExt
{
    [SubscribesTo(classstr(PrintMgmtDocType), delegatestr(PrintMgmtDocType,
getDefaultReportFormatDelegate))]
    public static void getDefaultReportFormatDelegate(PrintMgmtDocumentType
_docType, EventHandlerResult _result)
    {
        switch (_docType)
        {
            case PrintMgmtDocumentType::SalesOrderConfirmation:
                _result.result(ssrsReportStr(SalesConfirmExt, Report));
                break;
        }
    }
}
```

10. **Extend the menu item for the application report.** Find the existing Application Suite menu item in Application Explorer. This menu item is named **SalesConfirmation**. Right-click it, then select **Create extension**. Open the new extension object in the designer, and set the value of the **Object** property to **SalesConfirmControllerExt** to redirect user navigation to the extended solution.

11. **Update the Print management settings to use the custom business document.** For this example, go to **Accounts receivable** > **Setup** > **Forms** > **Form setup**. Select **Print Management**, find the document configuration settings, then select the custom design. The following illustration shows the Print management settings after the changes have been compiled.



You've now finished customizing the business document. Users will now be presented with the custom report design for the business document when they process transactions in the application.

Help prevent long-running reports from timing out

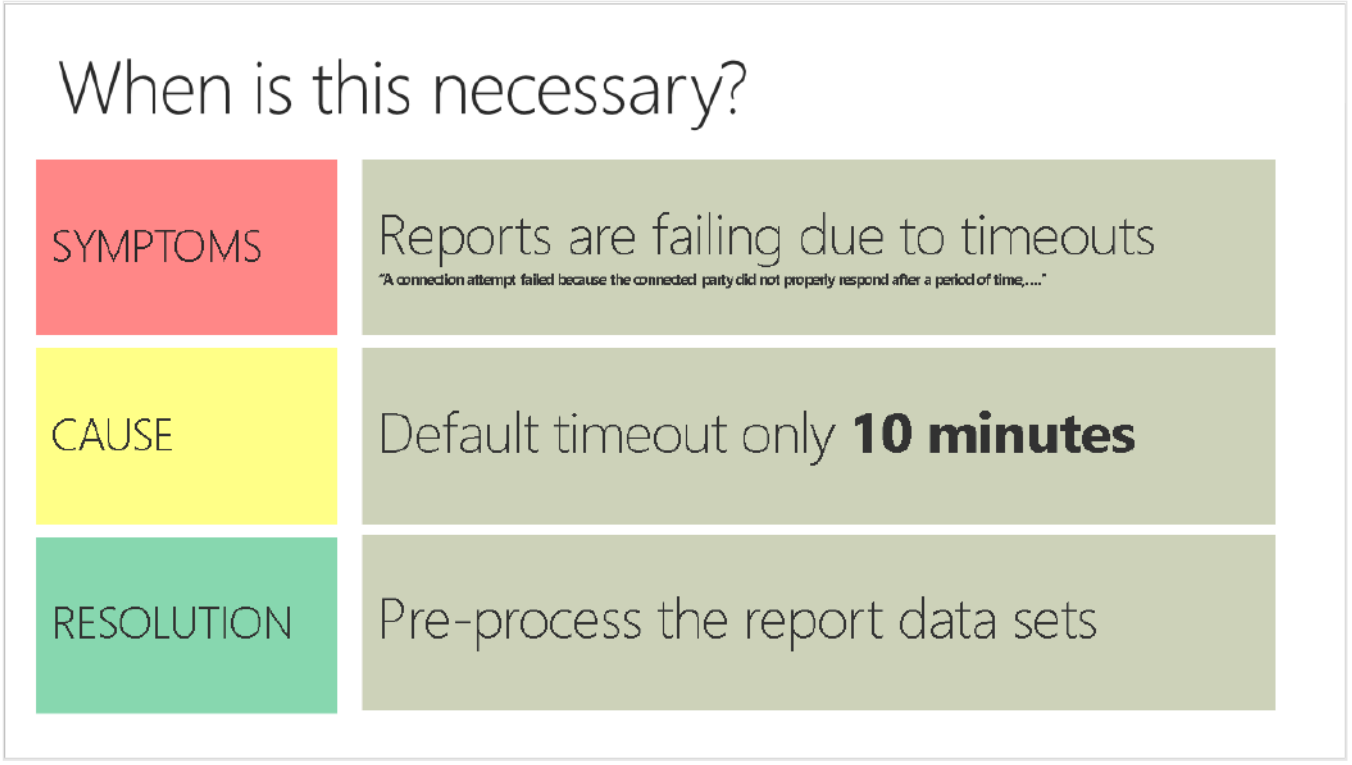
> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides tips that can help you prevent reports that run for a long time from timing out.

Paginated reports and documents are generated by using Microsoft SQL Server Reporting Services. Reporting Services retrieves report data from Application Object Server (AOS) by using a custom extension that uses Windows Communication Foundation (WCF) to communicate with AOS. The size of the data set and the complexity of the report that is generated can affect the time that is required to display the report. Additionally, if various time-outs and other thresholds are reached, report generation might fail. Service time-outs in deployments are fixed and limit interactive connections to 10 minutes. Any data set generation process that exceeds this service time-out limit isn't completed. This article describes the extensions that support long-running reports. These extensions help guarantee that long-running reports can be generated even if the process exceeds the 10-minute service time-out limit.

Preprocess the data source

If the report uses the Report Data Provider (RDP) to retrieve data, modify the report to use a pre-processed RDP class as the data source. In this way, processing logic is invoked before a call is made to Reporting Services. For more information about RDP classes, see Using Report Data Provider Classes to Access Report Data and Report Programming Guide.



How do I migrate a regular RDP to a pre-process data access solution by using TempDB?

1. Change the RDP base class from **SRSReportDataProviderBase** to **SRSReportDataProviderPreProcessTempDB**.
2. Update the table type from **InMemory** to **TempDB**.
3. Rebuild the report's RDP class.
4. Restore the data source that is linked to the RDP class in the report designer.
5. Redeploy the report.
6. Introduce a **Controller** class to run the report.
7. Update the Output Menu Item so that it points to the **Controller** class instead of the report.

Use batch processing

To improve performance when you print statements or reports that include large amounts of data, use batch processing. When you use batch processing, you can run specific tasks as batch jobs and then schedule those batch jobs to run on a different computer (a batch server). By moving the processing of these tasks to a batch server, you can improve the report performance on the client computer. You can also apply range restrictions to limit the size of each batch.

To further improve performance, don't submit one large batch. Instead, submit multiple smaller batches for processing at the same time on different servers. You can run many tasks as part of

batch jobs. For more information, see Batch processing overview.

Electronic reporting (ER) overview

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides an overview of the Electronic reporting (ER) tool. It includes information about key concepts, the scenarios that ER supports, and a list of formats that are designed and released as part of the solution.

ER is a configurable tool that helps you create and maintain regulatory electronic reporting and payments. It's based on the following three concepts:

- Configuration instead of coding:
  - A business user can configure the solution without needing a developer.
  - The data model is defined in business terms.
  - You use visual editors to create all components of the ER configuration.
  - The language used for data transformation resembles the language used in Microsoft Excel.

- One configuration for multiple Dynamics 365 Finance releases:
  - You manage one domain-specific data model that's defined in business terms.
  - You isolate application release details in release-dependent data model mappings.
  - You maintain one format configuration for multiple releases of the current version, based on the data model.

- Easy or automatic upgrade:
  - The solution supports versioning of ER configurations.
  - You can use the Dataverse as a repository for ER configurations, for version exchange.
  - You can introduce localizations that are based on original ER configurations as child versions.
  - An ER configuration tree is provided as a tool that helps control dependencies for versions.

    - The solution records differences in localization, or the delta configuration, to enable automatic upgrade to a new version of the original ER configuration.
    - You can easily manually resolve conflicts that are discovered during automatic upgrade of localization versions.

ER lets you define electronic format structures and then describe how the structures should be filled by using data and algorithms. You can use a formula language that resembles the Excel language for data transformation. To make the database-to-format mapping more manageable, reusable, and independent of format changes, the solution introduces an intermediate data model concept. This concept enables implementation details to be hidden from the format mapping and enables a single data model to be reused for multiple format mappings.

You can use ER to configure formats for both incoming and outgoing electronic documents in accordance with the legal requirements of various countries and regions. ER lets you manage these formats during their lifecycle. For example, you can adopt new regulatory requirements and generate business documents in the required format to electronically exchange information with government bodies, banks, and other parties.

The ER engine is targeted at business users instead of developers. Because you configure formats instead of code, the processes for creating and adjusting formats for electronic documents are faster and easier.

ER currently supports the TEXT, XML, JSON, PDF, Microsoft Word, Microsoft Excel, and OPENXML worksheet formats.

Capabilities

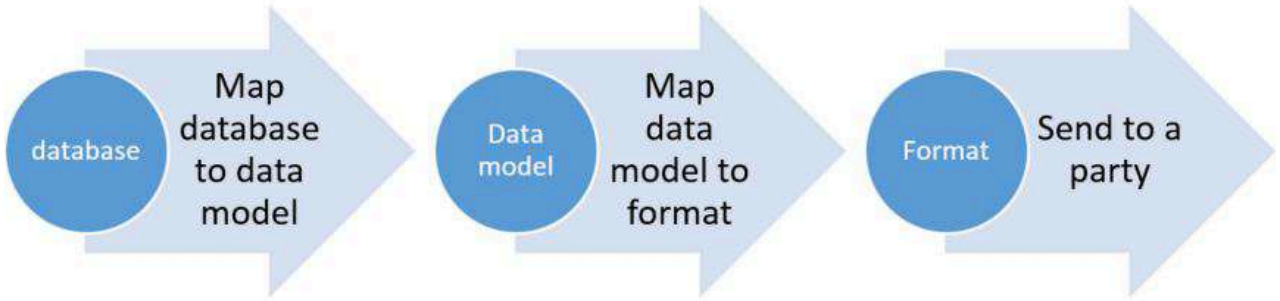
The ER engine has the following capabilities:

- It serves as a single shared tool for electronic reporting in different domains. It replaces more than 20 different engines that handle some type of electronic reporting for finance and operations.
- It insulates a report's format from the current implementation. In other words, the format works for different versions.
- It supports the creation of a custom format that's based on an original format. It also includes capabilities for automatically upgrading the customized format when the original format changes due to localization or customization requirements.

- It becomes the primary standard tool to support localization requirements in electronic reporting, both for Microsoft and for Microsoft partners.
- It supports the ability to distribute formats to partners and customers through Dataverse.

Key concepts

Main data flow



Component

ER supports the following types of components:

- Data model
- Model mapping
- Format
- Metadata

For more information, see Electronic reporting components.

Configuration

An ER configuration is the wrapper for a particular ER component. That component can be either a data model component or a format component. A configuration can include different versions of an ER component. A specific configuration provider owns each configuration. You can edit the **Draft** version of a component of a configuration when you select the owner of the configuration as an active provider in the ER settings in the application.

Each model configuration contains a data model component. You can derive a new format configuration from a specific data model configuration. In the configuration tree, the format configuration that you create appears as a child of the original data model configuration.

The format configuration that you create contains a format component. The data model component of the original model configuration is automatically inserted into the format component of the child format configuration as a default data source.

You share an ER configuration for application companies.

Provider

The ER provider is the party identifier that indicates the author (owner) of each ER configuration. ER lets you manage the list of configuration providers. Format configurations that are released for electronic documents as part of the finance and operations solution are marked as owned by the **Microsoft** configuration provider.

To learn how to register a new ER provider, see the task guide **ER Create a configuration provider and mark it as active** (part of the **7.5.4.3 Acquire/Develop IT service/solution components (10677)** business process).

Repository

An ER repository stores ER configurations. The following types of ER repositories are currently supported:

- File system
- Operations resources
- Dataverse

A **File system** repository provides access to the list of configurations that are located as XML files in the specific folder of the local file system of the machine where the AOS service is hosted. You select the required folder at the repository registration stage. You can import configurations from a **File system** repository into the current instance.

You can access this repository type in the following environments:

- Cloud-hosted environments deployed for development purposes (containing test models of enclosed suites)
- Locally deployed environments (on-premises)

For more information, see Import Electronic reporting (ER) configurations.

An **Operations resources** repository provides access to the list of configurations that Microsoft, as an ER configuration provider, initially releases as part of the application solution. You can import these configurations into the current instance and use them for electronic reporting or playing sample task guides. You can also use them for additional localizations and customizations. You must import the latest versions provided by Microsoft ER configurations from the Dataverse by using the corresponding ER repository.

A **Dataverse** repository provides access to the list of configurations that Microsoft, as an ER configuration provider. You can import these configurations into the current instance and use them for electronic reporting. Dataverse serves as the central source for configurations. You can import configurations from Dataverse into your Finance, and likewise, export configurations into Dataverse. For details, see Import Electronic reporting (ER) configurations from Dataverse.

Register required repositories individually for each configuration provider of the current instance. Each repository can be dedicated to a specific configuration provider.

Supported scenarios

Building a data model

ER provides a model designer that you can use to build a data model for a particular business domain. You can present all domain-specific business entities and the relations between them in a data model as a hierarchical structure.

To become familiar with the details of this scenario, review the article, Design domain specific data model.

Translating data model content

You can translate data model content (labels and descriptions) into other languages that the applications support. Translate data model content for the following reasons:

- At design time, to make the content more intelligible for format designers who speak other languages and who use the data model for data mapping of format components.
- At run time, to make the content more user-friendly by presenting prompts and help for run-time parameters, and configured validation messages (errors and warnings), in the language that the currently signed-in user prefers.

Configuring data model mappings for outgoing documents

ER provides a model mapping designer that users can use to map data models they design to specific application data sources. Based on the mapping, the data imports at run time from selected data sources into the data model. The data model is then used as an abstract data source of ER formats that generate outgoing electronic documents.

To become familiar with the details of this scenario, review the articles, Define ER model mappings and select data sources for them and Map data model to selected data sources.

Configuring data model mappings for incoming documents

ER provides a model mapping designer that users can use to map data models they design to specific destinations. For example, you can map data models to the updatable data components (tables, data entities, and views). Based on the mapping, the data updates at run time by using the data from the data model. As abstract storage of the ER format, the data model fills with data that imports from an incoming electronic document.

Storing a designed model component as a model configuration

ER can store a designed data model, together with associated data mappings, as a model configuration of the current instance.

To become familiar with the details of this scenario, review the article Map data model to selected data sources.

Building a format that uses a data model as a base

ER supports a format designer that you can use to build the format of an electronic document for a selected business domain by selecting the model component as a base. The same ER format designer lets you map a format that you create to a selected domain's data model mapping as a data source.

Building a configuration to generate electronic documents in OPENXML worksheet format

Use the ER format designer to build an electronic document in OPENXML worksheet format.

To become familiar with the details of this scenario, review the Design a configuration for generating reports in OPENXML format. As part of importing a template, use the Template of Payment Report (SampleVendPaymWsReport.xlsx) Excel file as a template.

Building a configuration to generate electronic documents in a Word document format

Use the ER format designer to build an electronic document in a Word document format. This format reuses the existing ER configuration that was originally designed to generate the report output in OPENXML format.

To become familiar with the details of this scenario, review the article, Design a new ER configuration to generate reports in Microsoft WORD format. As part of the task guide step for importing a template, use the following Word files as templates for the ER format:

- Template of Payment Report (SampleVendPaymDocReport.docx)
- Bounded template of Payment Report (SampleVendPaymDocReportBounded.docx)

Building a configuration to import data from incoming electronic documents

Use the ER format designer to describe an electronic document that you plan to import data from in either XML or text format. The designed format is used to parse an incoming document. Use the ER format mapping designer to define the binding of the elements of the designed format to the data model.

To become familiar with the details of this scenario, see [Create required configurations to import data from an external file](Create required configurations to import data from an external file.md). Use the following files to complete the steps in this article:

- ER data model configuration (1099model.xml)
- ER format configuration (1099format.xml)
- Sample of the incoming document in XML format (1099entries.xml)
- Sample of the workbook to manage data of incoming document (1099entries.xlsx)

Storing a designed format component in a format configuration

Electronic Reporting (ER) can store a designed format together with the configured data mappings as a format configuration of the current instance. The preceding illustration shows

an example of this type of format configuration (**BACS (UK)**, which is a child of the **Payment model** configuration).

Configuring Finance to start using a created format internally

You can configure the application to start using a created format to generate electronic reports. Define the reference to the created format configuration in the settings of a specific domain. For example, to start using an ER format configuration for electronic vendor payments in BACS format, reference the format configuration in specific methods of payment.

For more information, see Generate electronic documents for payments using a format configuration.

Handling ER components

Building a format by selecting another format as a base (customization)

ER lets you create (derive) a new component from the current version of a component (base) that you imported from a repository. For example, you might want to derive a new format to implement some special requirements for an electronic document, such as an additional field or an extensive description, to support a customization scenario. For more information, see ER Upgrade your format by adopting a new, base version of that format.

Upgrading a format by selecting a new version of base format (rebase)

ER automatically adopts changes from the latest version of the base component in the current draft version of the derived component. This process is known as *rebasing*. For example, a new regulatory change that is introduced in the latest version of the format that you imported from Dataverse can be automatically merged into the customized version of this format of the electronic document. Any changes that can't be merged automatically are considered conflicts. The designer tool presents these conflicts for manual resolution. For more information, see ER Upgrade your format by adopting a new, base version of that format.

List of ER configurations that are released in Finance

The list of ER configurations for Finance is constantly updated. Open the **Global repository** to review the list of ER configurations that are currently supported. On the **Discontinuation**

details FastTab, you can review the information about configurations that are discontinued or that are no longer maintained.

Electronic reporting components

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) supports the following types of components:

- Data model
- Model mapping
- Format
- Metadata

Data model component

A data model component is an abstract representation of a data structure. It describes a specific business domain area in enough detail to satisfy the reporting requirements for that domain. A data model component consists of the following parts:

- **Data model** – A set of domain-specific business entities and a hierarchically structured definition of relations between those entities.
- **Model mapping** – Selected application data sources are linked to individual elements of a data model that specifies, at runtime, the data flow and rules for entering business data in a data model component.

The business entity of a data model is represented as a container, or record. Business entity properties are represented as data items, or fields. Each data item has a unique name, label, description, and value. The value of each data item can be designed so that it's recognized as a string, integer, real, date, enumeration (enum), or Boolean value. Additionally, the data item can be another record or record list.

A single data model component can contain several hierarchies of domain-specific business entities. It can also contain model mappings that support a report-specific data flow at runtime. The hierarchies are differentiated by a single record that is selected as a root for model

mapping. For example, the data model of the payment domain area might support the following mappings:

- Company > Vendor > Payment transactions of the AP domain
- Customer > Company > Payment transactions of the AR domain

Business entities, such as company and payment transactions, are designed only one time. Different mappings can reuse them as required.

Model mapping component

Model mapping links application data sources to individual elements of a data model. It specifies the data flow and rules for entering business data in a data model component at runtime.

A model mapping that supports outgoing electronic documents has the following capabilities:

- It uses different data types as data sources for a data model. These data types include tables, data entities, methods, and enums.
- It supports user input parameters that you can define as data sources for a data model when some data must be specified at runtime.
- It supports data transformation into required groups. You can also filter, sort, and sum data, and append logical calculated fields that are designed through formulas that resemble Microsoft Excel formulas. For more information, see Formula designer in Electronic reporting (ER).

A model mapping that supports incoming electronic documents has the following capabilities:

- It uses different updatable data elements as targets. These data elements include tables, data entities, and views. The data can be updated by incoming data from electronic documents. You can use multiple targets in a single model mapping.
- It supports user input parameters that you can define as data sources for a data model when some data must be specified at runtime.

You design a data model component for each business domain. Use it as a unified data source for reporting. The unified data source isolates reporting from the physical implementation of data sources. The component represents domain-specific business concepts and functionalities in a form that makes a reporting format's initial design and further maintenance more efficient.

Format component

Format components for outgoing electronic documents

A format component is the scheme of the reporting output that the system generates at runtime. A scheme consists of the following elements:

- A format that defines the structure and content of the outgoing electronic document.
- Data sources, as a set of user input parameters and a domain-specific data model that uses a selected model mapping.
- A format mapping, as a set of bindings of format data sources that have individual elements of a format that specify, at runtime, the data flow and rules for generating format output.
- A format validation, as a set of configurable rules that control report generation at runtime, depending on the running context. For example, there might be a rule that stops output generation of a vendor's payments and throws an exception when specific attributes of the selected vendor are missing, such as the bank account number.

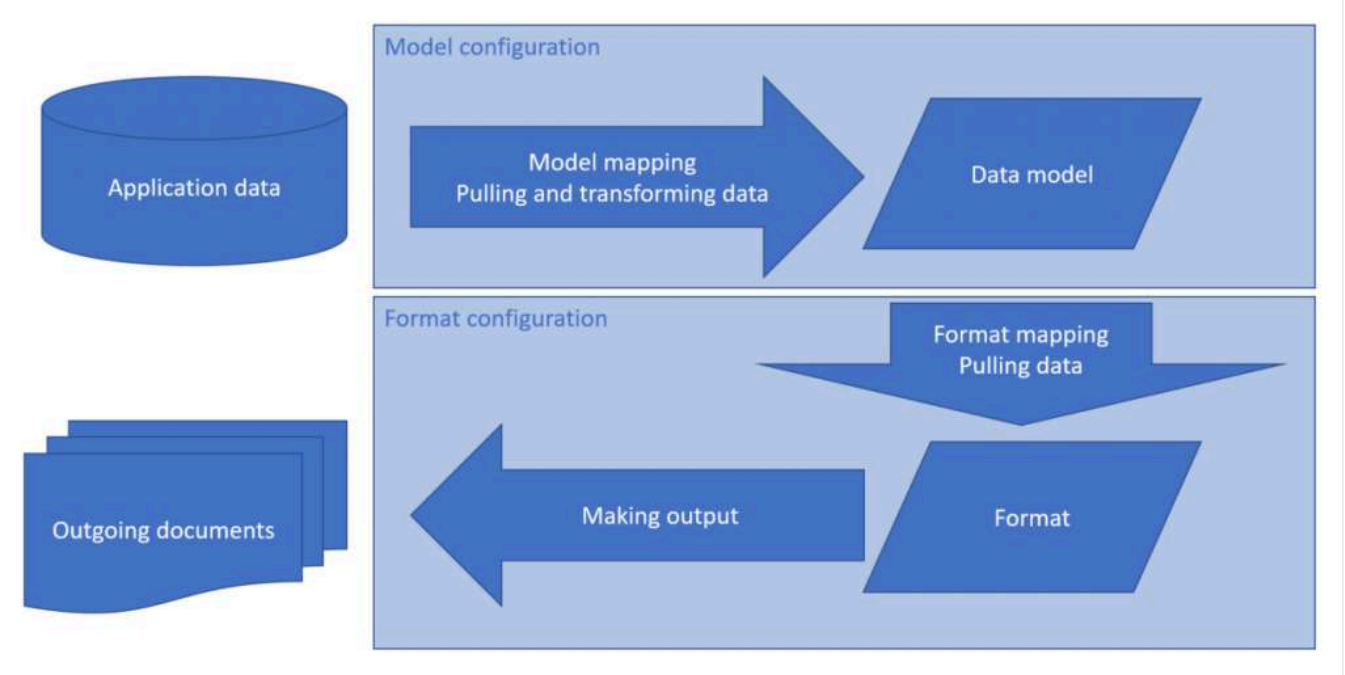
A format component supports the following functions:

- Creating a reporting output as individual files in various formats, such as text, XML, Microsoft Word document, or worksheet.
- Creating multiple files separately and encapsulating them into zip files.

A format component lets you attach specific files that you can use in the reporting output:

- Excel workbooks that contain a worksheet that you can use as a template for output in the OPENXML worksheet format.
- Word files that contain a document that you can use as a template for output in the Microsoft Word document format.
- Other files that you can incorporate into the format's output as predefined files.

The following illustration shows how the data flows for these formats.



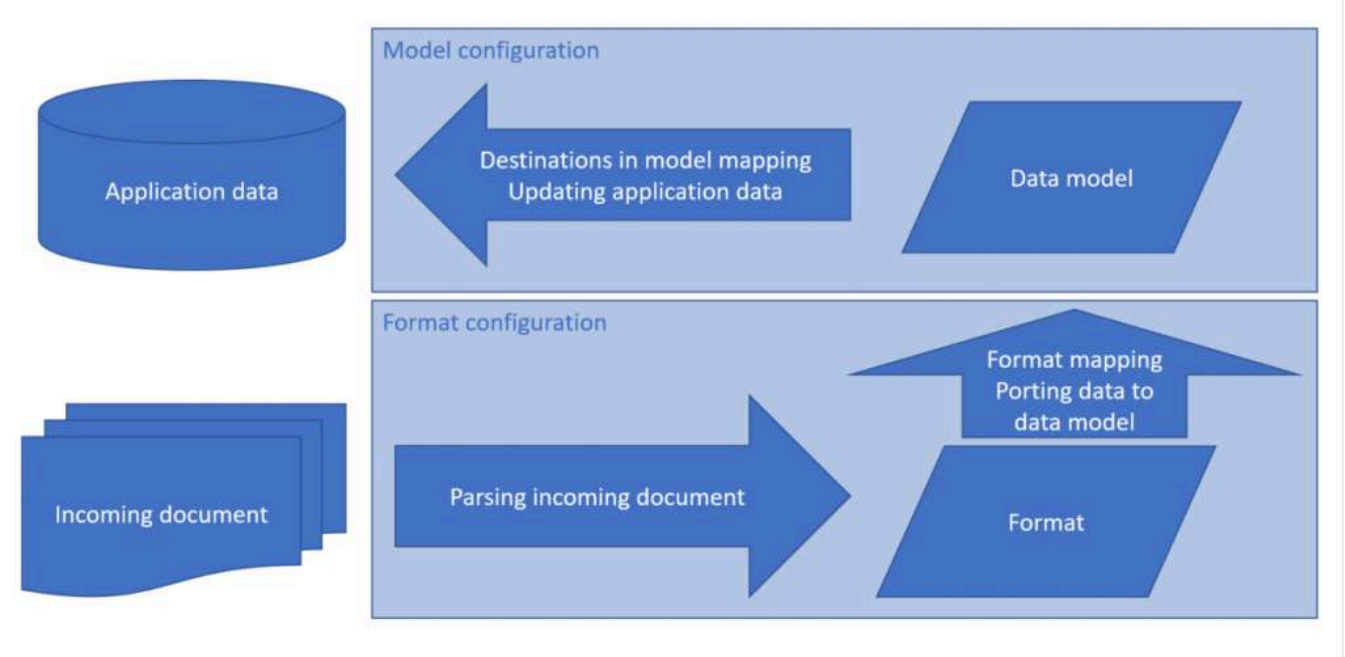
To run a single ER format configuration and generate an outgoing electronic document, you must identify the mapping of the format configuration.

Format components for incoming electronic documents

A format component is the scheme of the incoming document that the system imports at run time. A scheme consists of the following elements:

- A format that defines the structure and content of the incoming electronic document. The document contains data that the system imports at run time. Use a format component to parse an incoming document in various formats, such as text and XML.
- A format mapping that binds individual format elements to elements of a domain-specific data model. At run time, the elements in the data model specify the data flow and the rules for importing data from an incoming document, and then store the data in a data model.
- A format validation, as a set of configurable rules that control data import at run time, depending on the running context. For example, there might be a rule that stops data import of a bank statement that has a vendor's payments and throws an exception when a specific vendor's attributes are missing, such as the vendor identification code.

The following illustration shows how the data flows for these formats.



To run a single ER format configuration to import data from an incoming electronic document, you must identify the desired mapping of a format configuration, and also the integration point of a model mapping. You can use the same model mapping and destinations together with different formats for different types of incoming documents.

Component versioning

ER components support versioning. Use the following workflow to manage changes in ER components:

1. Mark the originally created version as a **Draft** version. You can edit this version, and it's available for test runs.
2. Convert the **Draft** version to a **Completed** version. Use this version in local reporting processes.
3. Convert the **Completed** version to a **Shared** version. Publish this version in Microsoft Dynamics Lifecycle Services and use it in global reporting processes.
4. Convert the **Shared** version to a **Discontinued** version. You can delete this version.

Other data interchange can access versions with **Completed** or **Shared** status. You can perform the following actions on a component with these statuses:

- Serialize the component in XML format and export it as an XML file.
- Reserialize the component from an XML file and import it into the application as a new version of an ER component.

For more information, see Import a new data model configuration and Export completed version of a derived format.

Draft versions at runtime

In your personal user parameters for the ER framework, you can enable the option that lets you specify whether the runtime should use the draft version of an ER configuration. For information about how to make the **Run Draft** option available for your ER configurations, see Mark a custom format as runnable.

> ⓘ **Note**
>
> The ER user parameters are company-specific and user-specific.

Draft format versions at runtime

By default, when you run an ER solution, the runtime ignores the draft versions of its format components. Instead, it uses only the relevant version that has a status other than **Draft**. Sometimes, you might want to force ER to use the draft version of your ER format configuration at runtime. For example, after you introduce necessary changes in your draft version, you can use that draft version to do the test run. In this way, you can validate the correctness of your changes. To start using the draft format version, set the **Run Draft** option of the relevant ER configuration to **Yes**.

Draft model mapping versions at runtime

By default, when you run an ER solution, it uses the draft versions of its model mapping components. Sometimes, you might want to force ER to ignore the draft version of your ER model mapping configuration at runtime. In **version 10.0.29 and later**, you can enable the **Always take into consideration the "Run draft" option for ER model mappings** feature to control the model mapping version that is used at runtime. When you enable this feature, the following behavior occurs:

- When you set the **Run Draft** option to **No** for a model mapping configuration, the highest non-draft version of that configuration is used at runtime. An exception is thrown if the configuration isn't available in the current Finance instance.
- When you set the **Run Draft** option to **Yes** for a model mapping configuration, the draft version of that configuration is used at runtime.

Component date effectivity

ER format component versions are date-effective. You can set the "effective from" date for an ER format component to specify the date when the component becomes effective for reporting processes. The application session date is used to define whether a component is valid for execution. If more than one version is valid for a specific date, the latest version is used for reporting processes.

Component access

Access to ER format and model mapping components at runtime depends on the setting for the International Organization for Standardization (ISO) country/region code. If this setting is blank for a selected version of a format or model mapping configuration, you can access a format or model mapping component from any company at runtime. If the setting contains ISO country/region codes, a format or model mapping component is available only from companies that have a primary address defined for one of a format component's ISO country/region codes.

Different versions of a format or a model mapping component can have different settings for ISO country/region codes.

For more information, see Configure country/region context dependent ER model mappings.

Create Electronic reporting (ER) configurations

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

As part of the requirements for Microsoft Dynamics Lifecycle Services solutions for localization and translation, localization ISV solution providers must implement features specific to a country/region or solutions by using the Electronic reporting tool. This article provides background information that helps you start using Electronic reporting for creating configurations. This article isn't meant to replace any available and upcoming Electronic reporting documentation, but is intended as a supplemental view from the perspective of localization requirements.

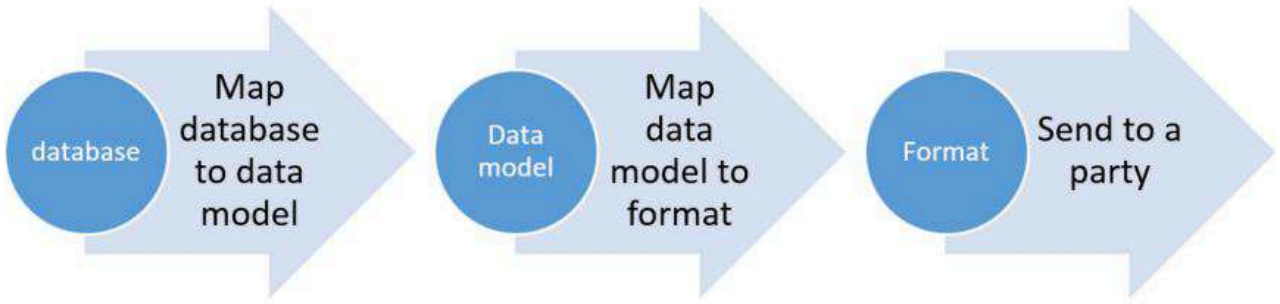
Electronic reporting (ER) is a configurable tool that helps you create and maintain regulatory electronic reporting and payments, based on the following three concepts:

- Configuration instead of coding
- One configuration for multiple Dynamics 365 Finance releases
- Easy or automatic upgrade

By using Lifecycle Services, ER provides one common way for Microsoft and partners to distribute electronic document configurations to other partners and customers. ER also makes it easier for partners and customers to customize, upgrade, and distribute electronic document formats for their specific business requirements.

You can use ER to set up data models that are domain-specific and independent of the database as data sources for document formats. You can configure formats based on these domain-specific data models by using simple visual tools that are similar to Excel. Data models and formats support versioning, and formats can be date-effective.

Main data flow



Data model configuration creation

Reuse and customize data models that Microsoft releases whenever you can. Or, create a business domain area–specific data model that introduces the abstract model of required entities and their relations. By using this approach, you stay aligned with future updates that Microsoft releases. You can also reuse your model for the design and maintenance of multiple domain–specific electronic documents that have different formats that are required in different scenarios or countries/regions.

Design the data model of the created model configuration

Design a data model to recognize and describe the required business entities and the relations between them in the selected domain. A data model consists of descriptors that express entities by using data containers (records). Use data items to express properties of entities. A record definition is an entity that contains fields (the data items). Each data item has a unique name, label, description, and value. You can desigh the value of each data item so that it's recognized as string, integer, real, date, enumerate type, and so on. Additionally, the value can be another record or record list. You can select a single record definition as a root of the data model. A root is the starting point of the entire model for data source mapping. In this case, the model is used as a data source that delivers data according to the single predefined data flow. If no record definition is selected as a root of the data model, the data model contains record definitions that can be assigned as a root at the format mapping stage. You can define the data flow of such a model as a data source in multiple ways, depending on the nature of the format. For example, you can design a single data model for the payments domain area. This data model can include data record definitions for the company as a legal entity, for vendors and customers, and also for payments. However, according to the nature of the

format, the data must be presented in the following way: payer > payee > payments. Therefore, a single data model can offer data according to the following alternative paths:

- Company > vendor > payment for the Accounts payable domain when you select the company record definition as a root.
- Customer > company > payment for the Accounts receivable domain when you select the customer record definition as a root.

Format configuration creation

Use the data model configuration created to hold abstract data for a new electronic format that you want to design. If you intend to consume a data model prepared earlier when you create a new format, make sure that you select the **Format based on data model** option for **Create configuration**. After you have a format configuration, you must define a format structure. You can create the structure manually or automatically by importing an example of an XML file or an Excel template. The data model of the parent configuration is automatically offered for format mapping, together with a proper root container. Nevertheless, a format might require that data be represented in a specific way. Therefore, you can use formula designer to define expressions as virtual data items (calculated fields) for your data containers.

> **Note**
>
> Although you can map format components directly to database and application artifacts, such as tables or data entities, enumerations, or classes and objects in ER, don't use this approach. It's likely that multiple formats are maintained in some business domain areas that use the same data sources. Whenever the structure of the database artifacts changes, you must also change the format mapping to those database artifacts. The cost of these changes multiplies by the number of maintained formats. Therefore, work through the data model as the abstract description of the domain-specific data structure. Use the direct binding of format elements to database components only for simplification and for coverage for specific customizations. For example, use direct binding to refer to custom tables when those references are required in a limited number of maintained formats.

> **Tip**

If you still have to add ER data sources to configure a format component to access database and application artifacts at runtime, select **Show details** on the Action pane of the **Format designer** page.

Version control

One of the principles behind the design of Electronic reporting is that you can easily distribute a data model and formats together with an enhanced maintenance model for their customizations. All the configurations are versioned, and you can "clone" an existing customization to derive a new configuration for localization or customization implementation. For example, you represent a company named Proseware, Inc. You subscribe to the service of a company named Litware Inc., which provides you with the Intrastat returns configuration and supports all legal requirements in it. You receive specific configurations from Litware Inc., together with data model and formats, and deploy them. Your company works in a district where, in addition to the federal requirements, you must support the following regional requirements:

- As part of Intrastat transactions details, your XML file must show the statistical procedure code that isn't required anywhere else.
- You must limit the length of the company name that is presented in the Intrastat returns header block to 200 characters.

To support these requirements and comply with local district authorities, you must implement this localization as a localized configuration. However, you must keep the link with the origin configuration, so that you can adopt any future changes that are introduced at the federal level as new versions of the origin configuration. Therefore, you import the Litware Inc. origin configuration from Lifecycle Services, derive it as a new localized configuration, introduce the required changes, complete this work by introducing a first version of the localized format, and start to use it internally. Whenever Litware Inc. offers you a new version of the origin configuration, you import it from Lifecycle Services, rebase your localized configuration to this version, adopt changes to support new federal requirements, complete this work by introducing a next version of the localized format, and continue to use it internally.

Note

The draft version of any configuration must be "completed" before it can become available locally for further action, such as the following:

- Make it available so that it can be referenced as a data source from a new format.
- Enable configuration exchange between companies or instances via configuration import/export, and so on.

Electronic reporting domain coverage

You can use several out-of-the-box configurations to meet electronic reporting requirements for specific countries/regions. The following list shows some examples of format configurations that are grouped into business domains. To get a complete, up-to-date list of available and supported configurations, open a configuration repository setup to show the configurations that are available for import from either resources or an Lifecycle Services Assets library.

- Audit file
  - FEC
  - GDPdU...
- Payments (ISO20022)
  - SEPA CT
  - SEPA DD
  - JBA
  - BACS...
- Statistical reports
  - EU Intrastat...
- Tax reports
  - CIS
  - BAS
  - ELSTER
  - EU Sales list...
- Customer e-Invoice
  - OIOUBL...

Your solution uptake

You can choose how to move your electronic reporting functionality into ER. However, consider the following high-level steps when you plan that move.

1. Review the electronic reporting functionality that your solution currently provides.

2. Identify domain areas that your solution covers, such as Payments and E-Invoices.
3. Review the configurations that Microsoft provides. It's likely that you find a configuration that you can use as a base. For example, if your solution customizes the SEPA CT payment format, extend the SEPA CT configuration.
4. Create new configurations that are based on either an existing model or format, or a new model or format.
5. Define input parameters that users must select when they run the report, and validations for the content of the report.
6. Define mappings with the model by using arithmetic, string, date, or other available Excel-like functions.
7. Define labels and translation to different languages, where applicable.
8. Define templates that include named ranges, and set links from the configuration for the Excel report, if applicable.

Terminology

Expand table

Term	Definition
ER	Electronic reporting is an engine that simplifies the creation of electronic reports for information interchange with governments, banks, and other parties. Currently, Electronic reporting supports text, XML, and OpenXML spreadsheet formats, and provides an extension interface to support more formats.
Transformation	If you have a typical action that must be done on the source of data before it's sent as output to a format, you can introduce a transformation and attach it to format components. A transformation is an ER formula that takes one value as a parameter and returns another value. For example, you have many format fields that contain spaces, and the spaces should be replaced by spaces when the fields are exported. In this case, you can create a transformation that takes a string argument and uses the REPLACE function to do the job. You can then create string components and associate them with that transformation.
Data model	A data model provides a structure for data. This structure is used to abstractly describe certain business domain areas at sufficient detail to satisfy the reporting requirements in this domain.
Configuration	A container for either a data model or a format, together with its mappings to data sources, that can be maintained and executed, and that supports versioning. The configuration is the entity that's imported or exported to organize electronic document format exchange between finance and operations instances.
Derive action	An operation that uses an existing configuration as a basis to create a new configuration.

Term	Definition
Rebase action	An operation that updates a derived configuration with changes that were introduced in a new version of the base configuration. The version number is selected at the rebase initialization stage.
Update conflict	A conflict discovered during the rebase action, where the new base version contains adjustments of a format/mapping element (name, property, and so on) that's also adjusted in the derived version.
Relocation conflict	A conflict discovered during the rebase action, where the new base version contains a new position (parent element) of a format element (name, property, and so on) that's also relocated to a different position in the derived version.
Duplication conflict	A conflict discovered during the rebase action, where the new base version introduced a new format element that is the same as an element (it has the same name and child components) that's also entered in the derived version.

Electronic reporting (ER) overview

Manage the Electronic reporting (ER) configuration lifecycle

Last updated on 04/13/2026

Define the dependency of ER configurations on other components

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To complete these steps, you must first complete the steps in the task guide, **ER Manage model mapping configurations**, and you must have access to Microsoft Dynamics Lifecycle Services.

This procedure shows how to design an Electronic reporting (ER) configuration and specify its dependency on other software components. By specifying these dependencies, you help guarantee that the configuration is correctly downloaded to a specific version of finance and operations. In this example, you create required ER configurations for the sample company Litware, Inc.

This procedure is intended for users who have the **System administrator** or **Electronic reporting developer** role assigned to them. You can perform the steps in any company, because ER configurations are shared among companies.

1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
    - Make sure that the configurations tree contains the **Sample data model** configuration and subordinate items. Otherwise, complete the steps in the task guide, **ER Manage model mapping configurations**, and then start this guide again.

Define the dependency of ER configurations on other components

1. In the tree, expand **Sample data model**.
2. In the tree, select **Sample data model\Sample mapping**.

- You selected the draft version of the **Sample mapping** model mapping configuration. You can now define its dependency on other software components. This step is a prerequisite for controlling the download of this configuration version from an ER repository and any further use of this version.

3. Expand the Prerequisites section.

   - The **Implementations** prerequisites group is added automatically at this stage. This group contains the prerequisite component that refers to the data model configuration and has the Implementation flag turned on. This flag indicates that the **Sample mapping** mapping configuration is considered the implementation of the **Sample data model** data model. This component forces ER to download the **Sample mapping** mapping configuration from an ER repository whenever the **Sample data model** model configuration is downloaded.

4. Select **Edit**.

   - You can specify a single dependency of the current version of a configuration on a software component by using the definition of the component's type, and either the component version or a range of component versions.
   - You can group desired dependencies together. When you select the **All of** grouping type, the dependency condition of this group is considered satisfied when each dependency condition from this group and subordinate group is satisfied. When you select the **One of** grouping type, the dependency condition of this group is considered satisfied when at least one dependency condition from this group is satisfied.

5. Select **New**.
6. Select **Product prerequisite component**.
7. Select **Microsoft Dynamics 365 for Operations (1611)**.
8. In the **Version** field, type `[7.1.1541.3036,8)`.

   - [7.1.1541.3036,8)
   - Dependencies that you enter are evaluated when this configuration is downloaded from any ER repository. This configuration version is downloaded from the ER repository when version 1 of the **Sample data model** configuration is either already in place or downloaded in advance. If it's downloaded in advance, it must be completed in finance and operations version 7.1.1541.3036 or later, but must not exceed major version 8.

9. Select **Save**.

10. Close the page.
11. Select **Change status**.
12. Select **Complete**.
13. Select **OK**.
14. In the tree, select **Sample data model\Sample mapping (alternative)**.
15. Select **Edit**.
16. Select **New**.
17. Select **Product prerequisite component**.
18. Select **Microsoft Dynamics AX 7.0 RTW**.
19. In the **Version** field, type `[7.0.1265.3015,7.1)`.

    - [7.0.1265.3015,7.1)
    - Dependencies are evaluated when the configuration is downloaded from any ER repository. This configuration version is downloaded from the ER repository when version 1 of the **Sample data model** configuration is either already in place or downloaded in advance. If it's downloaded in advance, it must be completed in Microsoft Dynamics 365 Finance, Enterprise edition, the version of which must be 7.0.1265.3015 or later, but must not exceed minor version 1.

20. Select **Save**.
21. Close the page.
22. Select **Change status**.
23. Select **Complete**.
24. Select **OK**.

Configure the ER repository

1. Close the page.
2. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

    - Open the list of ER repositories for the current ER provider, Litware, Inc.

3. In the list, select the row.
4. Select **Repositories**.
5. Select **Show filters**.
6. Enter a filter value of **LCS** in the **Type name** field by using the **contains** filter operator.

    - If the Lifecycle Services repository is already registered for the current ER provider, you can skip the remaining steps in this sub-task. If the Lifecycle Services repository

isn't already registered, complete the remaining steps.

7. Select **Add** to open the drop dialog.
8. In the **Configuration repository type** field, enter **LCS**.
9. Select **Create repository**.
10. In the **Project** field, enter or select a value.

    - Select the desired Lifecycle Services project from the lookup of the **Project** field.

11. Select **OK**.
12. Close the page.

Upload configurations to Lifecycle Services

1. Select **Reporting configurations**.
2. In the tree, select **Sample data model**.
3. Select the completed version of this configuration.
4. Select **Change status**.
5. Select **Share**.
6. Select **OK**.

    - Version 1 of this model configuration is uploaded to Lifecycle Services by using the Lifecycle Services project for the ER repository that you previously configured.

7. In the tree, expand **Sample data model**.
8. In the tree, select **Sample data model\Sample mapping**.
9. Select the completed version of this configuration.
10. Select **Change status**.
11. Select **Share**.
12. Select **OK**.

    - Version 1.1 of this model mapping configuration is uploaded to Lifecycle Services by using the Lifecycle Services project for the ER repository that you previously configured.

13. In the tree, select **Sample data model\Sample mapping (alternative)**.
14. Select the completed version of this configuration.
15. Select **Change status**.
16. Select **Share**.
17. Select **OK**.

- Version 1.1 of this model mapping configuration is uploaded to Lifecycle Services by using the Lifecycle Services project for the ER repository that you previously configured.

Evaluate ER configuration dependencies

You delete created configurations from the system and download them back from the Lifecycle Services repository.

1. In the tree, select **Sample data model\Sample mapping**.
2. Select **Delete**.
3. Select **Yes**.
4. In the tree, select **Sample data model\Sample mapping (alternative)**.
5. Select **Delete**.
6. Select **Yes**.
7. In the tree, select **Sample data model\Sample format**.
8. Select **Delete**.
9. Select **Yes**.
10. In the tree, select **Sample data model**.
11. Select **Delete**.
12. Select **Yes**.
13. Close the page.

    - Open the list of ER repositories for the current ER provider, Litware, Inc.

14. Select **Repositories**.
15. Select **Show filters**.
16. Enter a filter value of **LCS** in the **Type name** field by using the **contains** filter operator.
17. Select **Open**.
18. In the tree, select **Sample data model**.

    - You can view an evaluation of whether prerequisite conditions are satisfied for each version of the ER configurations for the current repository. To view this evaluation, select **Check prerequisites**.

19. Select **Check prerequisites**.
20. Select **Import**.
21. Select **Yes**.
22. Close the page.

23. Close the page.
24. Close the page.
25. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
26. In the tree, expand **Sample data model**.

    - The model **Sample mapping** mapping configuration is downloaded together with the selected data model configuration. You download the two files together because **Sample mapping** is defined as implementing the selected data model, and because it's applicable for the application. The **Sample mapping (alternative)** configuration isn't downloaded because the condition for the required application version isn't satisfied.
    - If you sign in to finance and operations, register the same provider, access the same Lifecycle Services project, and download the same data model configuration, the **Sample mapping (alternative)** configuration downloads, whereas the **Sample mapping** configuration is skipped.

Manage the Electronic reporting (ER) configuration lifecycle

Last updated on 04/13/2026

ER design domain specific data model

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can create a new Electronic reporting (ER) configuration that contains a data model for electronic payment documents. You use this data model as a data source when you create the format of the payment documents.

In this example, you create a configuration for sample company, Litware, Inc. You can perform these steps in any company because ER configurations are shared among companies. To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

   Select the configuration provider for sample company, Litware, Inc. If you don't see this configuration provider, you must first complete the steps in the "Create a configuration provider and mark it as active" procedure.

2. Select **Reporting configurations**.

   You create a configuration that contains a data model for electronic payment documents. You use this data model as a data source when you create the format for the payment documents.

Create a new data model configuration

1. Select **Create configuration** to open the dialog.

2. In the **Name** field, type *Payments (simplified model)*.

3. In the **Description** field, type *Payment model configuration*.

The active configuration provider is automatically entered here. This provider can maintain this configuration. Other providers can use this configuration, but can't maintain it.

4. Select **Create configuration** to complete the configuration creation task.

Create a data model

Create a new data model for the selected configuration. This configuration version has a status of Draft.

1. Select **Designer**.

Define the structure of a party participating in a payment process

1. Select **New** to open the drop dialog.
2. In the **Name** field, type `Party`.
3. Select **Add**.
4. Select **New** to open the drop dialog.
5. In the **Name** field, type `Name`.
6. In the **Item type** field, select `String`.
7. Select **Add**.
8. In the **Find** field, type `Party`.
9. Select **Find previous**.

Define the bank structure for this model

1. Select **New** to open the drop dialog.
2. In the **Name** field, type `Agent`.
3. In the **Item type** field, select `Record`.
4. Select **Add**.
5. In the **Description** field, enter `Financial institution (for instance, a bank) servicing an account for the party (debtor/creditor).`.

   Financial institution (for instance, a bank) servicing an account for the party (debtor/creditor).

6. Select **New** to open the drop dialog.
7. In the **Name** field, type `Name`.
8. In the **Item type** field, select `String`.
9. Select **Add**.
10. Select **New** to open the drop dialog.
11. In the **Name** field, type `SWIFT`.
12. Select **Add**.
13. In the **Description** field, enter `Bank identification code`.
14. Select **New** to open the drop dialog.
15. In the **Name** field, type `RoutingNumber`.
16. Select **Add**.
17. In the **Description** field, enter `Routing number`.
18. Select **Find previous**.

Define the bank account structure for this model

1. Select **New** to open the drop dialog.
2. In the **Name** field, type `Account`.
3. In the **Item type** field, select `Record`.
4. Select **Add**.
5. In the **Description** field, enter `Identification of an account of a party in a financial institution (for instance, a bank).`.

   Identification of an account of a party in a financial institution (for instance, a bank).
6. Select **New** to open the drop dialog.
7. In the **Name** field, type `Currency`.
8. In the **Item type** field, select `String`.

9. Select **Add**.
10. In the **Description** field, enter `Currency code`.
11. Select **New** to open the drop dialog.
12. In the **Name** field, type `Number`.
13. Select **Add**.
14. Select **New** to open the drop dialog.
15. In the **Name** field, type `IBAN`.
16. Select **Add**.
17. In the **Description** field, enter `International bank account number`.

Define the payment message structure for credit transfer payment type

1. Select **New** to open the drop dialog.
2. In **New node as a field**, enter *Model root*.
3. In **Name**, type *CustomerCreditTransferInitiation*.
4. Select **Add**.
5. In **Find**, type *CustomerCreditTransferInitiation*.
6. Select **Find previous**.
7. Select **New** to open the drop dialog.
8. In **Name**, type *MessageIdentification*.
9. Select **Add**.
10. In **Description**, enter *The point-to-point reference assigned by the instructing party (and sent to the next party) to identify a message.*.

    The point-to-point reference assigned by the instructing party (and sent to the next party) to identify a message.

11. Select **New** to open the drop dialog.
12. In **Name**, type *ProcessingDateTime*.
13. In **Item type**, select *DateTime*.
14. Select **Add**.
15. In **Description**, enter *Date and time at which the payment message was created.*.
16. Select **New** to open the drop dialog.

    Define the payment transaction structure for this model.

17. In **Name**, type *Payments*.
18. In **Item type**, select *Record list*.
19. Select **Add**.
20. In **Description**, enter *Payment lines of the current message*.
21. Select **New** to open the drop dialog.
22. In **Name**, type *Creditor*.
23. In the **Item type** field, select `Record`.
24. Select **Add**.
25. In **Description**, enter *Party to which an amount of money is due.*.
26. Select **Switch item reference**.
27. In the **Find** field, type `Party`.
28. Select **Find next**.
29. Select **OK**.
30. In **Find**, type *Payments*.
31. Select **Find next**.
32. Select **New** to open the drop dialog.
33. In **Name**, type *Debtor*.

34. Select **Add**.

35. In **Description**, enter *Party that owes an amount of money to the (ultimate) creditor.*.

36. Select **Switch item reference**.

37. In the **Find** field, type `Party`.

38. Select **Find next**.

39. Select **OK**.

40. Select **Find next**.

41. Select **New** to open the drop dialog.

42. In **Name**, type *Description*.

43. In the **Item type** field, select `String`.

44. Select **Add**.

45. Select **New** to open the drop dialog.

46. In the **Name** field, type `Currency`.

47. Select **Add**.

48. In the **Description** field, enter `Currency code`.

49. Select **New** to open the drop dialog.

50. In **Name**, type *TransactionDate*.

51. In **Item type**, select *Date*.

52. Select **Add**.

53. In the **Description** field, enter *Transaction date*.

54. Select **New** to open the drop dialog.

55. In the **Name** field, type *InstructedAmount*.

56. In the **Item type** field, select *Real*.

57. Select **Add**.

58. In the **Description** field, enter *The amount of money to be moved between the debtor and creditor, before deduction of charges. The amount should be expressed in the currency as ordered by the initiating party.*

    The amount of money to be moved between the debtor and creditor, before deduction of charges. The amount should be expressed in the currency as ordered by the initiating party.

59. Select **New** to open the drop dialog.

60. In the **Name** field, type *End2EndID*.

61. In the **Item type** field, select `String`.

62. Select **Add**.

63. In the **Description** field, enter *The unique identification assigned by the initiating party. This identification is passed on, unchanged, throughout the entire end-to-end chain.*

64. In the **Name** field, type *PaymentModel*.

    The **PaymentModel** name aligns with predefined interfaces of payment forms.

65. Select **Save**.

66. Close the page.

Last updated on 04/13/2026

Prepare application metadata to use in RCS

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can create a new Electronic reporting (ER) configuration that contains application metadata for designing ER model mapping configurations in Regulatory configuration service (RCS). Use this configuration to design a sample ER model mapping configuration to access foreign trade transactions. In this example, you create a configuration for sample company, Litware, Inc. You can perform these steps in any company. To complete these steps, you must first complete the steps in the article, Create configuration providers and mark them as active.

Prerequisites

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure Create configuration providers and mark them as active.
3. Select **Metadata configurations**.
4. Assume that RCS is used to design an ER solution for a Finance and Operation application that generates electronic documents that contain information from the foreign trade business domain. To specify the mapping between the ER data model and sources of required data, RCS needs access to metadata of the Finance and Operation application. Therefore, as part of designing the ER solution, you configure a new ER metadata configuration containing all metadata that is currently required for generating ER reports for the selected business domain.

Add metadata configuration

1. Select **Create configuration** to open the form.

2. In the **Name** field, enter *Foreign trade metadata*.
3. Select **Create configuration**.
4. Select **Designer**.
5. Select **Add**.

> **Note**
>
> You can select all metadata for the entire application or selected models or selected modules. When you choose this option, the following metadata is automatically added: tables of records, enumerations, and extended data types. If you need other types of metadata, add them manually.

You can add foreign trade transaction-related metadata by selecting metadata items manually.

1. Select **Add data source**.
2. Select **Table records**.
3. Use the Quick Filter to filter on the **Name** field with a value of *Intrastat*.
4. Select the **Intrastat** table record.
5. Select **OK**.

You added metadata information about the Intrastat table of records.

1. In the tree, expand **Table records Intrastat** > **Relations**.
2. In the tree, select **Table records Intrastat** > **Relations** > **IntrastatCommodity (Table records EcoResCategory)**.
3. Select **Add metadata**.

> **Note**
>
> You must add metadata about required relations for selected table of records manually.

1. Select **Add data source**.
2. Select **Enumeration**.
3. Use the Quick Filter to filter on the **Name** field with a value of *IntrastatDirection*.
4. Select the **IntrastatDirection enumeration** record.
5. Select **OK**.
6. Select **Save**.
7. Close the page.

Complete the draft version of metadata configuration

1. Select **Change status**.
2. Select **Complete**.
3. Select **OK**.
4. Select version **1**.

Export the completed version of metadata configuration from application as XML file

1. Select **Exchange**.
2. Select **Export as XML file**.
3. Select **OK**.

The created ER metadata configuration is saved as an XML file. You can import this file to RCS and use it as the source of information about metadata for the foreign trade business domain. Based on this information, you can specify the mapping between application metadata and ER data model.

Access application metadata by using ER configuration

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a Regulatory configuration service (RCS) user in the System Administrator or Electronic Reporting Developer role can design a new Electronic reporting (ER) model mapping by using the application metadata. You access application metadata by using an ER metadata configuration that contains a sample set of metadata to access foreign trade transactions. To complete these steps, in RCS you must first complete the steps in the article, Create configuration providers and mark them as active procedure. Then complete the steps in the article, Prepare application metadata to be used in RCS.

Prerequisites

1. Go to **All workspaces** > **Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure Create configuration providers and mark them as active.

Import metadata configuration

1. Select **Metadata configurations**.
2. Import the ER metadata configuration that contains metadata that is configured to generate electronic documents for foreign trade business. This ER metadata configuration is exported as XML file while the steps in the Prepare application metadata to be used in RCS procedure are completed.
3. Select **Exchange**.
4. Select **Load from XML file**.
5. Select **Browse** and select the **Foreign trade metadata.xml** file.

6. Select **OK**.
7. Close the page.

Create data model configuration

1. Select **Reporting configurations**.
2. Select **Create configuration** to open the form.
3. In the **Name** field, enter *Foreign trade model*.
4. Select **Create configuration**.
5. Select **Designer**.
6. Select **New** to open the form.
7. In the **Name** field, enter *Root*.
8. Select **Add**.
9. Select **New** to open the form.
10. In the **Name** field, enter *Transaction*.
11. In the **Item type** field, select **Record list**.
12. Select **Add**.
13. Select **New** to open the form.
14. In the **Name** field, enter *Commodity code*.
15. In the **Item type** field, select **String**.
16. Select **Add**.
17. Select **New** to open the form.
18. In the **Name** field, enter *Invoiced amount*.
19. In the **Item type** field, select **Real**.
20. Select **Add**.
21. Select **New** to open the form.
22. In the **Name** field, enter *Date*.
23. In the **Item type** field, select **Date**.
24. Select **Add**.
25. Select **Root reference**.
26. Select **OK**.
27. Select **Save**.
28. Close the page.
29. Select **Change status**.
30. Select **Complete**.
31. Select **OK**.

Create model mapping configuration

1. Select **Create configuration** to open the form.
2. In **New**, enter *Model Mapping based on data model Foreign trade model*.
3. In **Name**, type *Foreign trade mapping*.
4. Select **Create configuration**.
5. Expand the **Prerequisites** section.
6. Select **Edit**.
7. Select **New**.
8. In the list, select the row.
9. In **Prerequisite component type**, select **Configuration**.
10. Select **Foreign trade metadata** configuration.
11. Select **Save**.
12. You add the reference to version 1 of the **Foreign trade metadata** configuration. Application metadata from this configuration is offered while you design this model mapping.
13. Close the page.
14. Select **Designer**.
15. Select **Designer**.
16. In the tree, select **Dynamics 365 for Operations\Table records**.
17. Select **Add root**.
18. In **Name**, type *Intrastat*.
19. Select **Intrastat** table records.
20. Select **OK**.

> ⓘ **Note**
>
> You see only two tables because you added only two tables into the set of metadata that you're currently using.

1. Select **Bind**.
2. In the tree, expand **Intrastat**.
3. In the tree, select **Intrastat\AmountMST**.
4. In the tree, expand **Transaction = Intrastat**.
5. In the tree, select **Transaction = Intrastat\Invoiced amount**.
6. Select **Bind**.
7. In the tree, select **Intrastat\TransDate**.

8. In the tree, select **Transaction = Intrastat\Date**.
9. Select **Bind**.
10. In the tree, expand **Intrastat>Relations**.
11. In the tree, expand **Intrastat>Relations\IntrastatCommodity**.
12. In the tree, select **Intrastat>Relations\IntrastatCommodity\Code**.
13. In the tree, select **Transaction = Intrastat\Commodity code**.
14. Select **Bind**.
15. Select **Validate**.

> ⓘ **Note**
>
> You successfully bind elements of data model with items of data sources that are described by using details of application metadata from the referred ER metadata configuration.

1. Select **Save**.
2. Close the page.
3. Close the page.
4. When needed, you can extend the existing set of metadata and then export the new completed version of ER metadata configuration. You can then import it to RCS, and update the prerequisites of the configured model mapping configuration referring to a new version of imported metadata configuration.

> ⓘ **Note**
>
> This way of getting information about application metadata is the only one available for locally deployed applications (when local business data (LBD), or on-premises, deployment model is used).

Access application metadata by using connected applications

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a Regulatory configuration service (RCS) user in the System Administrator or Electronic Reporting Developer role can design a new Electronic reporting (ER) model mapping by using metadata in finance and operations. The RCS connected application accesses application metadata online. You configure a sample ER model mapping to access foreign trade transactions. To complete these steps, in RCS you must first complete the steps in the article, Create configuration providers and mark them as active. If you didn't complete the steps in the article, Access application metadata by using ER configuration, download the Electronic reporting examples and save the following ER configurations: Foreign trade metadata.xml, Foreign trade model.xml, and Foreign trade mapping.xml, and then complete the steps in the procedure.

Prerequisites

1. Go to **All workspaces** > **Electronic reporting**.
2. Make sure that the configuration provider for the sample company, Litware, Inc., is available and marked as **Active**. If you don't see this configuration provider, complete the steps in the procedure Create configuration providers and mark them as active.

Get required ER configurations

1. Select **Reporting configurations**.
2. If you already completed the steps in the Access application metadata by using ER configuration procedure, you already have all necessary ER configurations (foreign trade metadata, model, and mapping configurations) in the current RCS instance. You can skip all the remaining steps of this sub-task.

3. Select **Exchange**.
4. Select **Load from XML file**.
5. Select **Browse** and select the **Foreign trade metadata.xml** file.
6. Select **OK**.
7. Select **Exchange**.
8. Select **Load from XML file**.
9. Select **Browse** and select the **Foreign trade model.xml** file.
10. Select **OK**.
11. Select **Exchange**.
12. Select **Load from XML file**.
13. Select **Browse** and select the **Foreign trade mapping.xml** file.
14. Select **OK**.

Register a connected application

1. Close the page.
2. Close the page.
3. Go to **All workspaces** > **Electronic reporting**.
4. Select **Connected applications**.
5. Make sure that the configured application is Azure based and accessible for the current RCS user. The current RCS user must also have access to the selected application and be registered as a user of this application with a role that gives them privileges to access the application's metadata.
6. Select **New**.
7. In the **Name** field, type `MyConnectedApp`.
8. In the **Application** field, type `https:// mycompany.operations.dynamics.com`.
9. In the **Tenant** field, type `mycompany.onmicrosoft.com`.
10. Select **Save**.
11. When you check connection to configured application, on the **Connect to remote application** page select **Click here to connect to selected remote application** link.
12. Select **Check connection**.
13. Select **Close**.
14. When the connection validation succeeds, version and tenant details are updated for the configured application in the current grid.

Review existing model mapping configuration

1. Close the page.

2. Select **Reporting configurations**.
3. In the tree, expand **Foreign trade model**.
4. In the tree, select **Foreign trade model\Foreign trade mapping**.
5. Expand the **Prerequisites** section.

> ⓘ **Note**
>
> Currently, this mapping refers to the metadata configuration. Application metadata from this configuration is offered while you design this model mapping.

6. Select **Designer**.
7. Select **Designer**.
8. In the tree, select **Dynamics 365 for Operations\Table records**.
9. Select **Add root**.
10. In the **Table** field, enter or select a value.

> ⓘ **Note**
>
> Currently, this mapping refers to the metadata configuration. Application metadata from this configuration is offered while you design this model mapping.

11. Select **Cancel**.
12. Close the page.
13. Close the page.

Assign connected application to model mapping

1. Select **Edit**.
2. Select **MyConnectedApp** application.

> ⓘ **Note**

Currently, this mapping refers to the metadata of the selected connected application. When the same mapping refers to metadata configuration and connected application at the same time, the metadata of the connected application is used.

3. Select **Designer**.
4. Select **Designer**.
5. In the tree, select **Dynamics 365 for Operations\Table records**.
6. Select **Add root**.
7. In the **Table** field, enter or select a value.

   > ⓘ **Note**
   >
   > You see more than two application tables because this mapping uses all the metadata of the connected application that you assigned to it.

8. Select **Cancel**.
9. Select **Validate**.

   > ⓘ **Note**
   >
   > You successfully bound elements of data model with items of data sources that are described by using details of metadata of the connected application that you assigned to this mapping.

10. Close the page.
11. Close the page.

To evaluate this model mapping by using metadata of a different version application, register another connected application, assign it to this model mapping, and validate it against new metadata.

Define ER model mappings and select data sources for them

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can select data sources for an Electronic reporting (ER) data model. Bind the data sources to individual components of the selected data model at design time. The data sources populate business data to that data model at runtime. In this example, you select data sources for an existing data model created for the sample company Litware, Inc.

Open the Electronic Reporting configurations tree

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.

Insert a new model mapping

1. In the tree, select **Payments (simplified model)**.
2. Select **Designer**.
3. Select **Map model to datasource**.
4. Select **New**.

    - This action creates a new record that maps the data model to data sources. In this example, you map the data model to data sources for the desired payment type: credit transfer. You can design more than one mapping for a particular data model. For example, you could create a mapping for different types of payments, such as for direct debit or for credit transfers. In this example, you create a mapping for credit transfers.

5. In the **Name** field, type **CT mapping**.

6. In the **Description** field, type **Payment model mapping CT**.
7. In the **Definition** field, type **CustomerCreditTransferInitiation**.
8. Resolve changes the Definition.
9. Select **Save**.

Define required data sources for the current model mapping

1. Select **Designer**.
2. In the tree view, select **Dynamics 365 for Operations\Table records**.
3. Select **Add root**.

    - Enter this data source to access payment transactions.

4. In the **Name** field, type **Transactions**.
5. In the **Label** field, enter **Transactions**.
6. In the **Help** field, enter **Ledger journal lines**.
7. In the **Ask for query** field, select **Yes**.
8. In the **Table** field, type **LedgerJournalTrans**.
9. Select **OK**.

    - Select the LedgerJournalTrans table as a data source for the current data model.

10. In the tree view, select **Functions\Calculated field**.
11. Select **Add** to add a new calculated field.
12. In the **Name** field, type **$EndToEndID**.
13. Select **Edit formula**.
14. In the tree view, select **String\CONCATENATE**.
15. Select **Add function**.
16. In the tree view, expand **Transactions**.
17. In the tree view, select **Transactions\Voucher**.
18. Select **Add data source**.
19. In the **Formula** field, enter **CONCATENATE(Transactions.Voucher, "-",**.

    - Type `, "-",` at the end of the formula.

20. In the tree view, select **String\TEXT**.
21. Select **Add function**.
22. In the tree view, select **Transactions\Record-ID(RecId)**.
23. Select **Add data source**.

24. In the **Formula** field, enter **CONCATENATE(Transactions.Voucher, "-", TEXT(Transactions.RecId))**.
    - Type `))` at the end of the formula.
25. Select **Save**.
    - Make sure that no errors exist for the created formula. See the **ERRORS** tab below the formula editor control.
26. Close the page.
27. Select **OK**.
    - Add the calculated field to this data source.
28. Select **Add** to add a new calculated field.
29. In the **Name** field, type **$Amount**.
30. Select **Edit formula**.
31. In the tree view, expand **Transactions**.
32. In the tree view, select **Transactions\Debit(AmountCurDebit)**.
33. Select **Add data source**.
34. In the **Formula field**, enter **Transactions.AmountCurDebit -**.
    - Type `-` at the end of the formula.
35. In the tree view, select **Transactions\Credit(AmountCurCredit)**.
36. Select **Add data source**.
37. Select **Save**.
38. Close the page.
39. Select **OK**.
    - This step adds the **$Amount** calculated field to the selected data source for the current data model.
40. In the tree view, select **Transactions$Amount**.
41. In the tree view, expand **Transactions**.
42. In the tree view, expand or collapse **Transactions$Amount**.
43. In the tree view, expand or collapse **Transactions**.
44. In the tree view, select **Dynamics 365 for Operations\Table records**.
45. Select **Add root**.
    - Enter this data source to access the company's bank account details.

46. In the **Name** field, type **BankAccount**.
47. In the **Label** field, enter **Bank Account**.
48. In the **Help** field, enter **Bank Account**.
49. Select **Yes** in the **Ask for query** field.
50. In the **Table** field, type **BankAccountTable**.
51. Select **OK**.

    - Select the **BankAccountTable** table as a data source for the current data model.

52. Select **Add root**.

    - Enter this data source to access the company's requisites.

53. In the **Name** field, type **Company**.
54. In the **Label** field, type a value.
55. In the **Help** field, enter **Company information**.
56. Select **Yes** in the **Ask for query** field.
57. In the **Table** field, type **CompanyInfo**.
58. Select **OK**.

    - Select the **CompanyInfo** table as a data source for the current data model.

59. In the tree view, select **Functions\Calculated field**.
60. Select **Add root**.

    - Insert a calculated field as a new data source.

61. In the **Name** field, type **ProcessingDateTime**.
62. In the **Label** field, enter **Processing date & time**.
63. Select **Edit formula**.
64. In the tree, select `Date/time\SESSIONNOW`.
65. Select **Add function**.
66. Select **Save**.
67. Close the page.
68. Select **OK**.

    - Add the **ProcessingDateTime** calculated field as a data source for the current data model.

69. Select **Save**.
70. Close the page.

Last updated on 04/13/2026

ER Map data model to selected data sources

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can map an Electronic reporting (ER) data model to selected data sources. You use this model mapping as a data source in a format configuration that manages electronic payment documents. In this example, you map a data model for sample company, Litware, Inc. to data sources. To complete these steps, you must first complete the steps in the "Select data sources for model mapping" procedure.

Open ER configurations tree

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Configurations**.

Select created model mapping

1. In the tree, select **Payments (simplified model)**.

    - Make sure that you created the model configuration **Payments (simplified model)**. Otherwise, stop now and return after completion of the task guide **Create a new configuration with data model of the selected domain**.

2. Select **Model designer**.
3. Select **Map model to datasource**.
4. Select the **CT mapping** record.

    - CT mapping

Bind created data sources to data model elements

1. Click Designer.
2. In the tree, select 'Processing date & time(ProcessingDateTime)'.
3. In the tree, select 'Processing date(ProcessingDateTime)'.
4. Click Bind.
5. In the tree, select 'Payment message identification(MessageIdentification)'.
6. In the tree, expand 'Transactions'.
7. In the tree, select 'Transactions\Journal batch number(JournalNum)'.
8. Click Bind.
9. In the tree, select 'Payments'.
10. In the tree, select 'Transactions'.
11. Click Bind.
12. In the tree, expand 'Payments= Transactions'.
13. In the tree, expand 'Payments= Transactions\Creditor'.
14. In the tree, expand 'Payments= Transactions\Creditor\Account'.
15. In the tree, select 'Payments= Transactions\Creditor\Account\Currency code(Currency)'.
16. In the tree, expand 'Transactions\vendBankAccountInTransactionCompany()'.
17. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\Currency(CurrencyCode)'.
18. Click Bind.
19. In the tree, select 'Payments= Transactions\Creditor\Account\IBAN code(IBAN)'.
20. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\IBAN(BankIBAN)'.
21. Click Bind.
22. In the tree, select 'Payments= Transactions\Creditor\Account\Number'.
23. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\Bank account number(AccountNum)'.
24. Click Bind.
25. In the tree, expand 'Payments= Transactions\Creditor\Agent'.
26. In the tree, select 'Payments= Transactions\Creditor\Agent\Name'.
27. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\Name'.
28. Click Bind.
29. In the tree, select 'Payments= Transactions\Creditor\Agent\Routing number(RoutingNumber)'.
30. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\Routing number(RegistrationNum)'.

31. Click Bind.
32. In the tree, select 'Payments= Transactions\Creditor\Agent\SWIFT code(SWIFT)'.
33. In the tree, select 'Transactions\vendBankAccountInTransactionCompany()\SWIFT code(SWIFTNo)'.
34. Click Bind.
35. In the tree, select 'Payments= Transactions\Creditor\Name'.
36. In the tree, expand 'Transactions\findVendTable()'.
37. In the tree, select 'Transactions\findVendTable()\name()'.
38. Click Bind.
39. In the tree, select 'Payments= Transactions\Currency code(Currency)'.
40. In the tree, expand 'Transactions>Relations'.
41. In the tree, expand 'Transactions>Relations\Currency table(Currency)'.
42. In the tree, select 'Transactions>Relations\Currency table(Currency)\Currency code(CurrencyCodeISO)'.
43. Click Bind.
44. In the tree, expand 'Payments= Transactions\Debtor'.
45. In the tree, expand 'Payments= Transactions\Debtor\Account'.
46. In the tree, select 'Payments= Transactions\Debtor\Account\Currency code(Currency)'.
47. In the tree, select 'Bank Account(BankAccount)'.
48. In the tree, expand 'Bank Account(BankAccount)'.
49. In the tree, select 'Bank Account(BankAccount)\Currency(CurrencyCode)'.
50. Click Bind.
51. In the tree, select 'Bank Account(BankAccount)\IBAN'.
52. In the tree, select 'Payments= Transactions\Debtor\Account\IBAN code(IBAN)'.
53. Click Bind.
54. In the tree, select 'Payments= Transactions\Debtor\Account\Number'.
55. In the tree, select 'Bank Account(BankAccount)\Bank account number(AccountNum)'.
56. Click Bind.
57. In the tree, expand 'Payments= Transactions\Debtor\Agent'.
58. In the tree, select 'Payments= Transactions\Debtor\Agent\Name'.
59. In the tree, select 'Bank Account(BankAccount)\Name'.
60. Click Bind.
61. In the tree, select 'Payments= Transactions\Debtor\Agent\Routing number(RoutingNumber)'.
62. In the tree, select 'Bank Account(BankAccount)\Routing number(RegistrationNum)'.
63. Click Bind.
64. In the tree, select 'Payments= Transactions\Debtor\Agent\SWIFT code(SWIFT)'.

65. In the tree, select 'Bank Account(BankAccount)\SWIFT code(SWIFTNo)'.
66. Click Bind.
67. In the tree, select 'Payments= Transactions\Debtor\Name'.
68. In the tree, select 'Company information(Company)'.
69. In the tree, expand 'Company information(Company)'.
70. In the tree, select 'Company information(Company)\Name'.
71. Click Bind.
72. In the tree, select 'Payments= Transactions\Description'.
73. In the tree, select 'Transactions\Description(Txt)'.
74. Click Bind.
75. In the tree, select 'Payments= Transactions\End to end identification code(End2EndID)'.
76. In the tree, select 'Transactions$EndToEndID'.
77. Click Bind.
78. In the tree, select 'Payments= Transactions\Instructed amount(InstructedAmount)'.
79. In the tree, select 'Transactions$Amount'.
80. Click Bind.
81. In the tree, select 'Payments= Transactions\Transaction date(TransactionDate)'.
82. In the tree, select 'Transactions\Date(TransDate)'.
83. Click Bind.

Validate created mapping

1. Click Validate.

    - Validate the new mapping to ensure that all bindings are okay.

2. Click the arrow to expand or collapse the Error List section.
3. Click Save.
4. Close the page.
5. Close the page.
6. Close the page.

Change the status of the current version of model configuration

1. Click Change status.

    - Change the status of designed model configuration – from Draft to Completed to make it available for payment format design.

2. Click Complete.
    - Select Complete.
3. In the Description field, type a value.
    - For example, 'version 1'.
4. Click OK.
5. Select the completed version of the current configuration.
    - Note that the created configuration is saved as completed version 1.

ER Create a format configuration (November 2016)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how a user in the System Administrator or Electronic Reporting Developer role can create a format configuration for Electronic reporting (ER). This format configuration defines the format of electronic documents that are used for processing payments. In this example, you create a format configuration for sample company, Litware, Inc. To complete these steps, you must first complete the steps in the "Map model to selected datasources" procedure.

Create a new format configuration

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. In the tree, select **Payments (simplified model)**.
4. Select **Create configuration** to open the dialog.

> **Note**
>
> If you don't see **Create configuration**, you must enable design mode on the **Electronic reporting parameters** page.

1. In **New**, enter **Format based on data model PaymentModel**.
2. In **Name**, type **BACS (UK fictitious)**.
3. In **Description**, type **BACS vendor payment format (UK fictitious)**.

    - The active configuration provider is automatically entered here. This provider can maintain this configuration. Other providers can use this configuration, but can't

maintain it.
    - You can define a particular format of electronic document. Leave this field blank if you want to select a format at run-time.
4. In **Data model definition**, enter or select a value.
5. Select **Create configuration**. You created a new configuration. Use the draft version to store the design format for managing electronic documents.

Design the format of an electronic document

1. Select **Designer**.
2. Select **Add root** to open the drop dialog.
3. In the tree, select **Common\File**.
4. In the **Name** field, type **Xml**.
5. In the **Encoding** field, type **UTF-8**.
6. Select **OK**.
7. Select **Add**.
8. In the tree, select **XML\Element**.
9. In the **Name** field, type **Message**.
10. Select **OK**.
11. In the tree, select **Xml\Message**.
12. Select **Add Element**.
13. In the **Name** field, type **ProcessingDate**.
14. Select **OK**.
15. Select **Add Element**.
16. In the **Name** field, type **MessageId**.
17. Select **OK**.
18. Select **Add Element**.
19. In the **Name** field, type **Payments**.
20. Select **OK**.
21. In the tree, select **Xml\Message\Payments**.
22. Select **Add Element**.
23. In the **Name** field, type **Item**.
24. Select **OK**.
25. In the tree, select **Xml\Message\Payments\Item**.
26. Select **Add**.
27. In the tree, select **XML\Attribute**.
28. In the **Name** field, type **Id**.

29. Select **OK**.
30. Select **Add**.
31. In the tree, select **XML\Element**.
32. In the **Name** field, type **Vendor**.
33. Select **OK**.
34. In the tree, select **Xml\Message\Payments\Item\Vendor**.
35. Select **Add Element**.
36. In the **Name** field, type **Name**.
37. Select **OK**.
38. Select **Add Element**.
39. In the **Name** field, type **Bank**.
40. Select **OK**.
41. In the tree, select **Xml\Message\Payments\Item\Vendor\Bank**.
42. Select **Add Element**.
43. In the **Name** field, type **RoutingNumber**.
44. Select **OK**.
45. Select **Add Element**.
46. In the **Name** field, type **AccountNumber**.
47. Select **OK**.
48. In the tree, select **Xml\Message\Payments\Item\Vendor**.
49. Select **Copy**.
50. In the tree, select **Xml\Message\Payments\Item**.
51. Select **Paste**.
52. In the **Name** field, type **Payer**.
53. In the tree, select **Xml\Message\Payments\Item**.
54. Select **Add Element**.
55. In the **Name** field, type **Currency**.
56. Select **OK**.
57. Select **Add Element**.
58. In the **Name** field, type **Description**.
59. Select **OK**.
60. Select **Add Element**.
61. Enter **TransDate** in the Name field.
62. Select **OK**.
63. Select **Add Element**.
64. Enter **Amount** in the Name field.
65. Select **OK**.

Prepare format components for mapping to data model elements

1. In the tree, select **Xml\Message\ProcessingDate**.
2. Click **Add** to open the drop dialog.
3. In the tree, select **Text\DateTime**.
4. In the **Format** field, type **yyyy-MM-dd**.
5. Select **OK**.
6. In the tree, select **Xml\Message\Payments\Item\TransDate**.
7. Click **Add DateTime**.
8. In the **Format** field, type **yyyy-MM-dd**.
9. In the **DateTime** type field, select **Date**.
10. Select **OK**.
11. In the tree, select **Xml\Message\MessageId**.
12. Click **Add** to open the drop dialog.
13. In the tree, select **Text\String**.
14. Select **OK**.
15. In the tree, select **Xml\Message\Payments\Item\Vendor\Name**.
16. Click **Add String**.
17. Select **OK**.
18. In the tree, select **Xml\Message\Payments\Item\Vendor\Bank\RoutingNumber**.
19. Click **Add String**.
20. Select **OK**.
21. In the tree, select **Xml\Message\Payments\Item\Vendor\Bank\AccountNumber**.
22. Click **Add String**.
23. Select **OK**.
24. In the tree, select **Xml\Message\Payments\Item\Payer\Name**.
25. Click **Add String**.
26. Select **OK**.
27. In the tree, select **Xml\Message\Payments\Item\Payer\Bank\RoutingNumber**.
28. Click **Add String**.
29. Select **OK**.
30. In the tree, select **Xml\Message\Payments\Item\Payer\Bank\AccountNumber**.
31. Click **Add String**.
32. Select **OK**.
33. In the tree, select **Xml\Message\Payments\Item\Currency**.
34. Click **Add String**.

35. Select **OK**.
36. In the tree, select **Xml\Message\Payments\Item\Description**.
37. Click **Add String**.
38. Select **OK**.
39. In the tree, select **Xml\Message\Payments\Item\Amount**.
40. Click **Add String**.
41. Select **OK**.
42. Click **Save**.
43. Close the page.

ER map components of the created format to data model elements (November 2016)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following procedure shows how a user in either the System administrator or Electronic reporting developer role can map data model elements to components of the created Electronic reporting (ER) configuration. This configuration defines an electronic document format for the payments business domain. You use this format later to generate electronic documents for processing payments. In this example, you create a format configuration for the sample company, Litware, Inc. You can perform these steps in any company because all companies share ER configurations. To complete these steps, you must first complete the steps in the "Create a format configuration" task guide.

Select a format configuration

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.
2. Select **Reporting configurations**.
3. In the tree, expand **Payments (simplified model)**.
4. In the tree, select **Payments (simplified model)\BACS (UK fictitious)**.
5. Select **Designer**.

Map format components to data model elements

1. Select **Expand/collapse**.
2. Select the **Mapping** tab.
3. In the tree, expand `model`.
4. In the tree, select `Xml\Message\ProcessingDate\DateTime`.
5. In the tree, select `model\ProcessingDateTime`.
6. Select **Bind**.

7. In the tree, select `Xml\Message\MessageId\String`.
8. In the tree, select `model\MessageIdentification`.
9. Select **Bind**.
10. In the tree, expand `model\Payments`.
11. In the tree, select `Xml\Message\Payments\Item\Amount\String`.
12. In the tree, select `model\Payments\InstructedAmount`.
13. Select **Bind**.
14. In the tree, select `Xml\Message\Payments\Item\TransDate\DateTime`.
15. In the tree, select `model\Payments\TransactionDate`.
16. Select **Bind**.
17. In the tree, select `Xml\Message\Payments\Item\Description\String`.
18. In the tree, select `model\Payments\Description`.
19. Select **Bind**.
20. In the tree, select `Xml\Message\Payments\Item\Currency\String`.
21. In the tree, select `model\Payments\Currency`.
22. Select **Bind**.
23. In the tree, select `Xml\Message\Payments\Item\Id`.
24. In the tree, select `model\Payments\End2EndID`.
25. Select **Bind**.
26. In the tree, expand `model\Payments\Creditor`.
27. In the tree, expand `model\Payments\Creditor\Account`.
28. In the tree, expand `model\Payments\Creditor\Agent`.
29. In the tree, select `Xml\Message\Payments\Item\Vendor\Name\String`.
30. In the tree, select `model\Payments\Creditor\Name`.
31. Select **Bind**.
32. In the tree, select `Xml\Message\Payments\Item\Vendor\Bank\RoutingNumber\String`.
33. In the tree, select `model\Payments\Creditor\Agent\RoutingNumber`.
34. Select **Bind**.
35. In the tree, select `Xml\Message\Payments\Item\Vendor\Bank\AccountNumber\String`.
36. In the tree, select `model\Payments\Creditor\Account\Number`.
37. Select **Bind**.
38. In the tree, select `Xml\Message\Payments\Item\Payer\Name\String`.
39. In the tree, expand `model\Payments\Debtor`.
40. In the tree, expand `model\Payments\Debtor\Account`.
41. In the tree, expand `model\Payments\Debtor\Agent`.
42. In the tree, select `model\Payments\Debtor\Name`.
43. Select **Bind**.

44. In the tree, select `Xml\Message\Payments\Item\Payer\Bank\RoutingNumber\String`.
45. In the tree, select `model\Payments\Debtor\Agent\RoutingNumber`.
46. Select **Bind**.
47. In the tree, select `Xml\Message\Payments\Item\Payer\Bank\AccountNumber\String`.
48. In the tree, select `model\Payments\Debtor\Account\Number`.
49. Select **Bind**.
50. In the tree, select `Xml\Message\Payments\Item`.
51. In the tree, select `model\Payments`.
52. Select **Bind**.
53. Select **Save**.

Validate format mapping

1. Select **Validate**.

    - Validate the new mapping to ensure that all bindings are correct.

2. Close the page.

Change status of the current version of format configuration

In the next steps, change the status of the format configuration from **Draft** to **Completed** to make it available for payment document generation.

1. Select **Change status**.
2. Select **Complete**.
3. In the **Description** field, enter a value.

    - For example, 'version 1'.

4. Select **OK**.
5. Select the completed version of the current configuration.

    - The configuration is saved as completed version 1.1: version 1 of the format based on version 1 of the data model.

Define effective date for completed version of format

You can configure each format version as available for usage starting from a certain date. When more than one format version is active on a certain date, the latest format (based on version number) is selected for usage. The session date value is used for proper version selection.

Restrict access to created format from companies

1. Expand the **ISO Country/region codes** section.

    - You can restrict each format access by identifying particular countries or regions in which a format is applicable. When the list of countries or regions for a particular format is empty, any company can use this format. When you add some ISO country or region codes to the list, companies can only use the format if the primary address is in the country or region.

Globalization Studio workspace features

> **Important**
>
> Regulatory Configuration Service (RCS) will be deprecated. All new RCS provisioning is stopped as of 10.0.39 GA. If provisioning is required, please register a support ticket. We will be providing tools and required support for migration from RCS to the **Globalization Studio** workspace. We plan to fully shut down RCS by August 1, 2024. For more information about migration to **Globalization Studio** workspace, see Regulatory Configuration Service merge to the Globalization Studio workspace

By using Globalization Studio, you can create Globalization features for use in the following Globalization services: Electronic Invoicing and Tax Calculation. You can:

- Define related components of a feature.
- Manage the feature lifecycle through a feature's status.

To use a Globalization feature, you must first import it from a Dataverse repository and create your own version of it. You can add Globalization features by:

- Adding a derived feature based on an existing feature that's published or shared.
- Adding a new feature that you created from scratch.

Feature component overview

Globalization features include several components:

- **Version** – This component supports feature lifecycle management. It lets you manage the status of different versions of the feature.
- **Configurations** – This component lets you manage, view, and edit related Electronic reporting (ER) formats and format mappings.
- **Setups** – This component lets users of Globalization services, such as an e-invoicing service, manage the setup of the related feature version. Therefore, it supports the flexible construction of communication and responses rules.

ER Generate electronic documents for payments using a format configuration

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can use a new Electronic reporting (ER) format configuration to generate electronic documents for processing payments. You can perform these steps in the GBSI sample company.

To complete these steps, you must first complete the steps in the "Create a configuration with format of payment document" procedure.

Change the configuration of the electronic payment method

1. Go to **Accounts payable** > **Payment setup** > **Methods of payment**.
2. Toggle the **File format** section to expand it, if needed.
3. Use the Quick Filter to find records. For example, filter on the **Method of payment** field with a value of **Electronic**.
4. Select **Edit**.
5. Set the **General electronic reporting** field to **Yes**.

    - Select **Yes** to use the General electronic reporting pattern for payment files generation.

6. In the **Name** field, select the drop-down button to open the lookup.
7. Select **BACS (UK fictitious)** format configuration.
8. Select **Save**.
9. Close the page.

Test the format of generated payment files

1. Go to **Accounts payable** > **Payments** > **Payment journal**.
2. Select **New**.
3. In the list, select the row.
4. In the **Name** field, select the drop-down button to open the lookup.
5. In the list, select the link in the selected row.

    - Select **VendPay**.

6. Select **Save**.
7. Select **Lines**.
8. In the **Company** field, enter `DEMF`.

    - Enter **DEMF**

9. In the **Account** field, enter `DE-01001`.

    - Enter **DE-01001**

10. In the **Description** field, enter `Payment`.

    - Enter **Payment**

11. In the **Debit** field, enter a number.

    - 1000

12. Select the **Payment** tab.
13. In the **Method of payment** field, select the dropdown button to open the lookup.
14. In the list, find and select the desired record.

    - Select the **Electronic** value.

15. In the list, select the link in the selected row.
16. Select **Save**.
17. Select **Generate payments**.
18. In the **Method of payment** field, select the dropdown button to open the lookup.
19. In the list, find and select the desired record.

    - Select the **Electronic** value.

20. In the list, select the link in the selected row.

- Select the **Electronic** value.

21. In the **File name** field, enter a value.
    - For example, enter `payments`.
22. In the **Bank account** field, select the dropdown button to open the lookup.
23. In the list, select the link in the selected row.
    - Select the value **GBSI OPER**.
24. Select **OK**.
25. Select **OK**.
    - Analyze the created payment file in XML format. Compare it with the designed document layout and defined payment transaction attributes.

Last updated on 04/13/2026

ER Upgrade your format by adopting a new, base version of that format

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following steps explain how a user in the System Administrator or Electronic Reporting Developer role can maintain an Electronic reporting (ER) format configuration. This procedure explains how to create a custom version of a format based on the format received from a configuration provider (CP). It also explains how to adopt a new, base version of that format.

To complete these steps, you must first complete the steps in the "Create a configuration provider and mark it as active" and "Use created format to generate electronic documents for payments" procedures. You can perform these steps in the GBSI company.

Select format configuration for customization

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

   In this example, sample company Litware, Inc. (https://www.litware.com) acts as a configuration provider that supports format configurations for electronic payments for a particular country/region. Sample company Proseware, Inc. (https://www.proseware.com) acts as a consumer of the format configuration that Litware, Inc. provided. Proseware, Inc. uses formats in certain regions of that country/region.

2. Select **Reporting configurations**.

3. Select **Show filters**.

4. Apply the following filters: Enter a filter value of **BACS (UK fictitious)** on the **Name** field by using the **begins with** filter operator.

The selected format configuration **BACS (UK fictitious)** is owned by provider Litware, Inc.

5. Select **Show filters**.
6. In the list, find and select the desired record.

   Proseware, Inc. uses the version of the format with the status of **Completed** for customization.

Create a new configuration for your custom format of electronic document

Proseware, Inc. receives version 1.1 of BACS (UK fictitious) configuration that contains the initial format to generate electronic payment documents from Litware, Inc. in accordance with their service subscription. Proseware, Inc. wants to start using this format as a standard for their country/region but some customization is required to support specific regional requirements. Proseware, Inc. also wants to keep the ability to upgrade a custom format as soon as a new version of it (with changes to support new country/region-specific requirements) comes from Litware, Inc. They want to perform this upgrade with the lowest cost.

To do this upgrade, Proseware, Inc. needs to create a configuration by using the Litware, Inc. configuration BACS (UK fictitious) as a base.

1. Close the page.
2. Select Proseware, Inc. to make it an active provider.
3. Select **Set active**.
4. Select **Reporting configurations**.
5. In the tree, expand **Payments (simplified model)**.
6. In the tree, select **Payments (simplified model)\BACS (UK fictitious)**.

   Select the BACS (UK fictitious) configuration from Litware, Inc. Proseware, Inc. uses version 1.1 as a base for the custom version.

7. Select **Create configuration** to open the drop dialog.

   This step lets you create a new configuration for a custom payment format.

8. In the **New** field, enter `Derive from Name: BACS (UK fictitious), Litware, Inc.`.

Select the **Derive** option to confirm the usage of BACS (UK fictitious) as the base for creating the custom version.

9. In the **Name** field, type `BACS (UK fictious custom)`.
10. In the **Description** field, type `BACS vendor payment (UK fictitious custom)`.

    The active configuration provider (Proseware, Inc.) is automatically entered here. This provider can maintain this configuration. Other providers can use this configuration, but can't maintain it.

11. Select **Create configuration**.

Customize your format for the electronic document

1. Select **Designer**.
2. Select **Expand/collapse**.
3. Select **Expand/collapse**.
4. In the tree, select `Xml\Message\Payments\Item\Vendor\Bank`.
5. Select **Add** to open the drop dialog.
6. In the tree, select `XML\Element`.
7. In the **Name** field, type `IBAN`.
8. Select **OK**.
9. In the tree, select `Xml\Message\Payments\Item\Vendor\Bank\IBAN`.
10. Select **Add** to open the drop dialog.
11. In the tree, select `Text\String`.
12. Select **OK**.
13. In the tree, select `Xml\Message\Payments\Item\Vendor\Name\String`.
14. In the **Maximum length** field, enter `60`.
15. Select the **Mapping** tab.
16. In the tree, expand `model`.
17. In the tree, expand `model\Payments`.
18. In the tree, expand `model\Payments\Creditor`.
19. In the tree, expand `model\Payments\Creditor\Account`.
20. In the tree, select `model\Payments\Creditor\Account\IBAN`.
21. In the tree, select `Xml\Message\Payments\Item = model.Payments\Vendor\Bank\IBAN\String`.
22. Select **Bind**.
23. Select **Save**.

Validate the customized format

1. Select **Validate**.

   Validate the customized format layout and data mapping changes to make sure that all bindings are correct.

2. Close the page.

Change the status of the current version of the custom format configuration

Change the status of the designed format configuration from **Draft** to **Completed** to make it available for payment document generation.

1. Select **Change status**.

   The current version of the selected configuration is in **Draft** status.

2. Select **Complete**.

3. In the **Description** field, enter a value.

4. Select **OK**.

5. In the list, find and select the desired record.

   The created configuration is saved as **completed version 1.1.1**. This version means it's version 1 of the custom BACS (UK fictitious custom) format, which is based on version 1 of the BACS (UK fictitious) format, which is based on version 1 of the Payments (simplified model) data model.

Test the customized format to generate payment files

Complete the steps in the "Use created format to generate electronic documents for payments" procedure in a parallel finance and operations session. Select the BACS (UK fictitious custom) format in electronic payment method parameters. Make sure that the created payment file contains the recently introduced XML node presenting IBAN code in accordance to regional requirements.

Update the existing country/region-specific configuration

Litware, Inc. needs to update the BACS (UK fictitious) configuration and adopt new country/region requirements for managing the format of the electronic document. Later, Litware, Inc. encloses this configuration in a new version that it offers to service subscribers, including Proseware, Inc.

In real service provision related processes, Proseware, Inc. can import each new version of BACS (UK fictitious) from Litware, Inc. configurations' LCS repository. In this procedure, you simulate this process by updating BACS (UK fictitious) on behalf of a service provider.

1. Close the page.
2. Select Litware, inc. provider.
3. Select **Set active**.
4. Select **Reporting configurations**.
5. In the tree, expand **Payments (simplified model)**.
6. In the tree, select **Payments (simplified model)\BACS (UK fictitious)**.

   The draft version owned by Litware, Inc. provider BACS (UK fictitious) is selected to bring in changes to support new country/region-specific requirements.

Localize the base format of the electronic document

Assume that Litware, Inc. needs to support new country or region-specific requirements:

- A value for the creditor's bank SWIFT code in each payment transaction.
- A limit of 100 characters for the length of text for the vendor's name in a generating file.
- New country or region-specific requirements.
- Select the draft version of the desired configuration to introduce required changes.

1. Select **Designer**.
2. Select **Expand/collapse**.
3. Select **Expand/collapse**.
4. In the tree, select `Xml\Message\Payments\Item\Vendor\Bank`.
5. Select **Add** to open the drop dialog.

6. In the tree, select `XML\Element`.
7. In the **Name** field, type `SWIFT`.
8. Select **OK**.
9. In the tree, select `Xml\Message\Payments\Item\Vendor\Bank\SWIFT`.
10. Select **Add** to open the drop dialog.
11. In the tree, select `Text\String`.
12. Select **OK**.
13. In the tree, select `Xml\Message\Payments\Item\Vendor\Name\String`.
14. In the **Maximum length** field, enter `100`.
15. Select the **Mapping** tab.
16. In the tree, expand `model`.
17. In the tree, expand `model\Payments`.
18. In the tree, expand `model\Payments\Creditor`.
19. In the tree, expand `model\Payments\Creditor\Agent`.
20. In the tree, select `model\Payments\Creditor\Agent\SWIFT`.
21. In the tree, select `Xml\Message\Payments\Item = model.Payments\Vendor\Bank\SWIFT\String`.
22. Select **Bind**.
23. Select **Save**.

Validate the localized format

1. Select **Validate**.
2. Close the page.

Change the status of the current version of the base format configuration

Change the status of the updated base format configuration from **Draft** to **Completed** to make it available for generating payment documents and updating format configurations derived from it.

1. Select **Change status**.

   The current version of the selected configuration is in **Draft** status.

2. Select **Complete**.

3. In the **Description** field, enter a value.

4. Select **OK**.

5. In the list, find and select the desired record.

Change the base version for the custom format configuration

Proseware, Inc. is informed that a new version 1.2 of BACS (UK fictitious) configuration is available to generate electronic payment documents in accordance with recently announced country/region-specific requirements. Proseware, Inc. wants to start using it as a standard for the country/region.

To do this, Proseware, Inc. needs to change the base configuration version for the custom configuration BACS (UK fictitious custom). Instead of version 1.1 of BACS (UK fictitious), use new version 1.2.

1. Go to **Organization administration** > **Workspaces** > **Electronic reporting**.

2. Select the Proseware, Inc. provider to mark it as active.

3. Select **Set active**.

4. Select **Reporting configurations**.

5. In the tree, expand **Payments (simplified model)**.

6. In the tree, expand **Payments (simplified model)\BACS (UK fictitious)**.

7. In the tree, select **Payments (simplified model)\BACS (UK fictitious)\BACS (UK fictitious custom)**.

   Select the BACS (UK fictitious custom) configuration, which Proseware, Inc. owns.

   Use the draft version of the selected configuration to introduce required changes.

8. Select **Rebase**.

   Select the new version 1.2 of the base configuration to apply as a new base for updating the configuration.

9. Select **OK**.

The system discovers some conflicts between merging the custom version and a new base version. These conflicts represent some format changes that can't be merged automatically.

Resolve rebase conflicts

1. Select **Designer**.

   The system can't automatically resolve changes to the vendor's name text length limit. Therefore, the system presents this change in a conflicts list. For each conflict of type **Update**, you see the following options:

   - **Apply a prior base value** (button on top of the grid): Bring in the previous base version value (0 in this case).

- **Apply a base value** (button on top of the grid): Bring in the new base version value (100 in this case).
  - **Keep your own (custom) value** (60 in this case).

1. Select **Save**.

   Saving the format will remove resolved conflicts from the conflicts list.

2. Close the page.

Change the status of the new version of the custom format configuration

1. Select **Change status**.

   Change the status of the updated custom format configuration from **Draft** to **Completed**. This change makes the format configuration available for generating payment documents. The current version of the selected configuration is in **Draft** status.

2. Select **Complete**.

3. In the **Description** field, enter a value.

4. Select **OK**.

   The created configuration is saved as completed version 1.2.2: version 2 of base BACS (UK fictitious custom) format, which is based on version 2 of base BACS (UK fictitious) format,

which is based on version 1 of Payments (simplified model) data model.

Test the customized format for payment files generation

Complete the steps in the "Use created format to generate electronic documents for payments" procedure in parallel finance and operations session. Select the created **BACS (UK fictitious custom)** format in electronic payment method parameters. Make sure that the created payment file contains recently introduced by Proseware, Inc. XML node presenting IBAN account code in accordance to regional requirements. The file also should contain the recently introduced by Litware, Inc. XML node presenting SWIFT bank code in accordance to country/region requirements.

Supported data source types for ER components

You can use the Electronic reporting (ER) framework to design an ER solution that you can run in the Microsoft Dynamics 365 Finance application to generate an outbound business document or parse an inbound business document. To fill in a generated document with application data or update the application database by using data from an inbound business document, configure your ER solution to specify how the data should be fetched from the appropriate data storage, transformed in accordance with the layout of the processed document, and formatted based on specific requirements. To specify data fetching, transformation, and formatting, use different types of ER data sources. The following ER data source types are currently supported for Finance:

- Data model
  - Data model
  - Enumeration
  - Enumeration user input parameter
  - Lookup
- Dynamics 365 application (Finance)
  - Class
  - Enumeration
  - Lookup
  - Number sequence
  - Object
  - Table
  - Table records
- Format
  - Export format
  - Import format
- Format enumeration
  - Enumeration
  - Enumeration user input parameter
  - Lookup
- Functions

    - Barcode
    - Calculated field
    - Data collection
    - Financial dimensions details
    - Group by
    - Inventory dimensions details
    - Join
    - Table metadata

- General
    - Empty container
    - Endless list
    - User input parameter

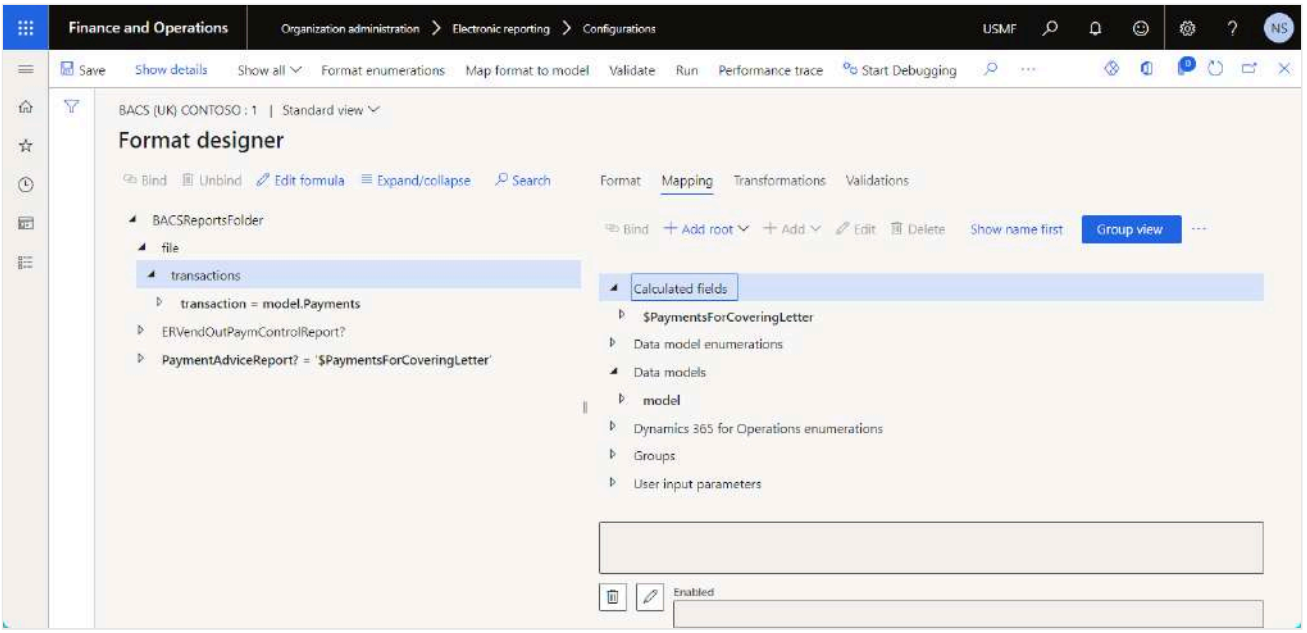
This article provides a summary of the ER data source types.

Add a new data source

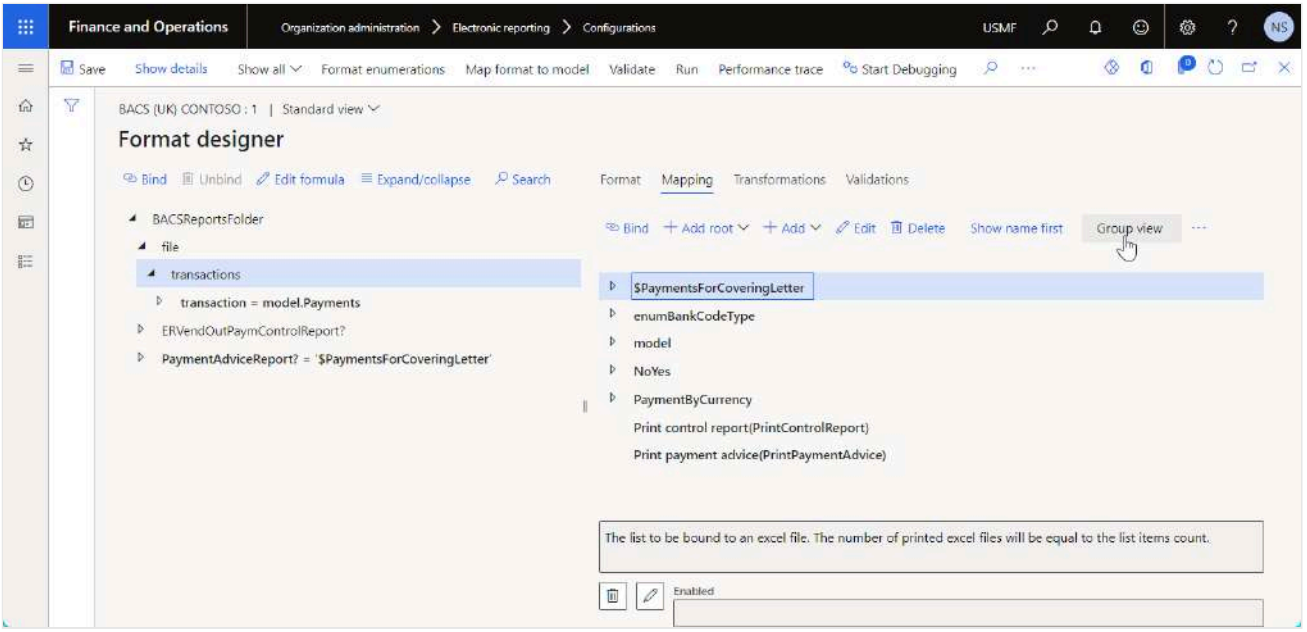
You can configure ER data sources in the ER model mapping and ER format components of your ER solution for data fetching, transformation, and formatting. You can then bind configured data sources with data consumers. Data consumers include a data model of the designed ER model mapping or format elements of the designed ER format.

Select a more convenient grouping mode to quickly discover a data source that you want to review or modify.

- When you turn on the **Group view** toggle button on the **Model mapping designer** or **Format designer** page, the configured data sources are grouped by the data source type.

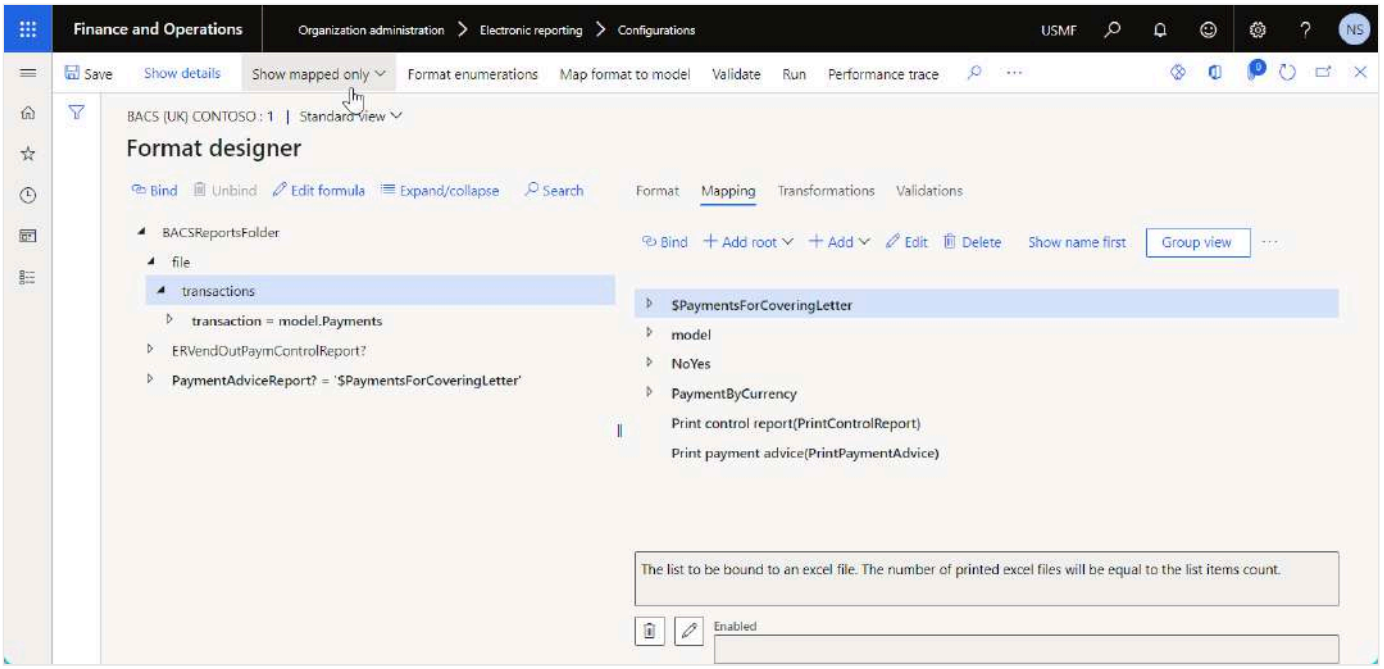


- When you turn off the **Group view** toggle button, the data sources are sorted in alphabetical order.



You can filter the list of configured data sources by selecting the more appropriate view mode on the **Model mapping designer** or **Format designer** page:

- Select **Show all** to list all configured data sources.
- Select **Show mapped only** to list only the data sources that you explicitly use in configured bindings.
- Select **Show not-mapped only** to list only the data sources that you don't use in configured bindings.



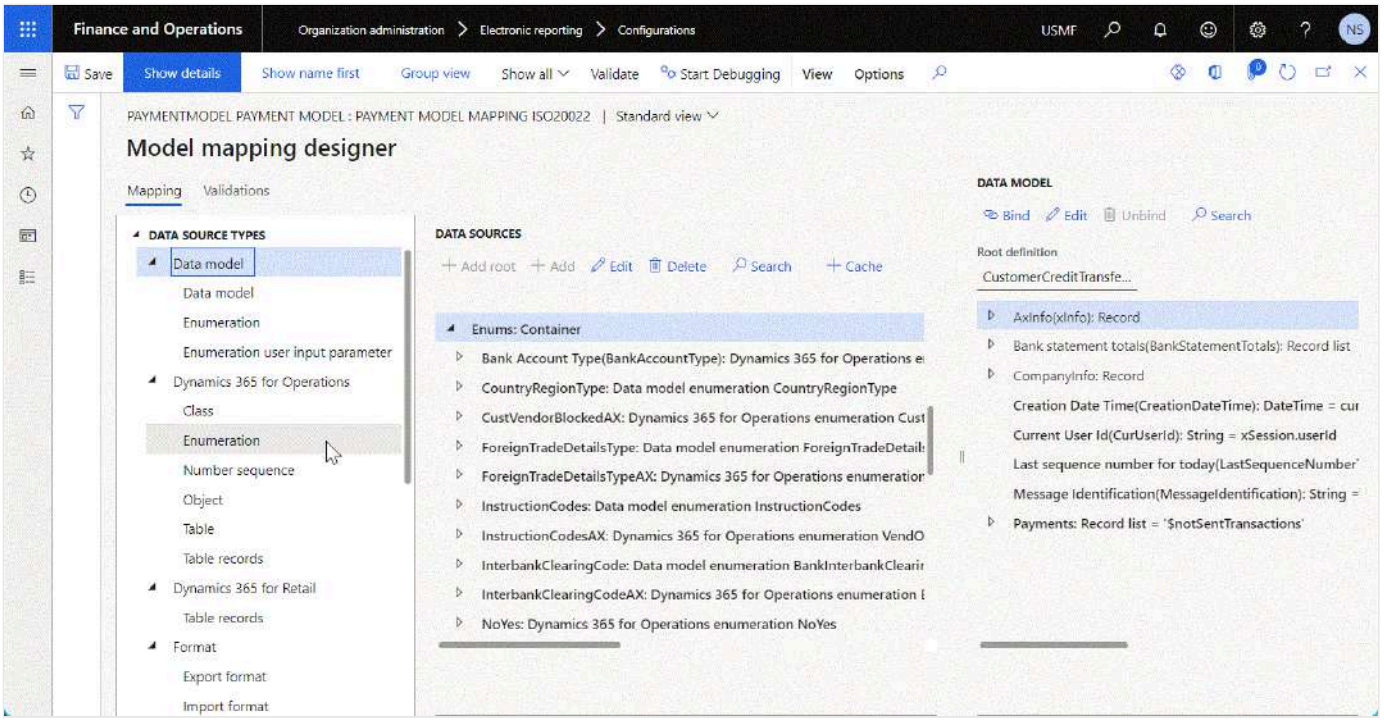
Model mapping designer

To add a new data source, select the data source type in the **Data source types** pane on the left side of the **Model mapping designer** page. This pane shows the tree of supported ER data sources.

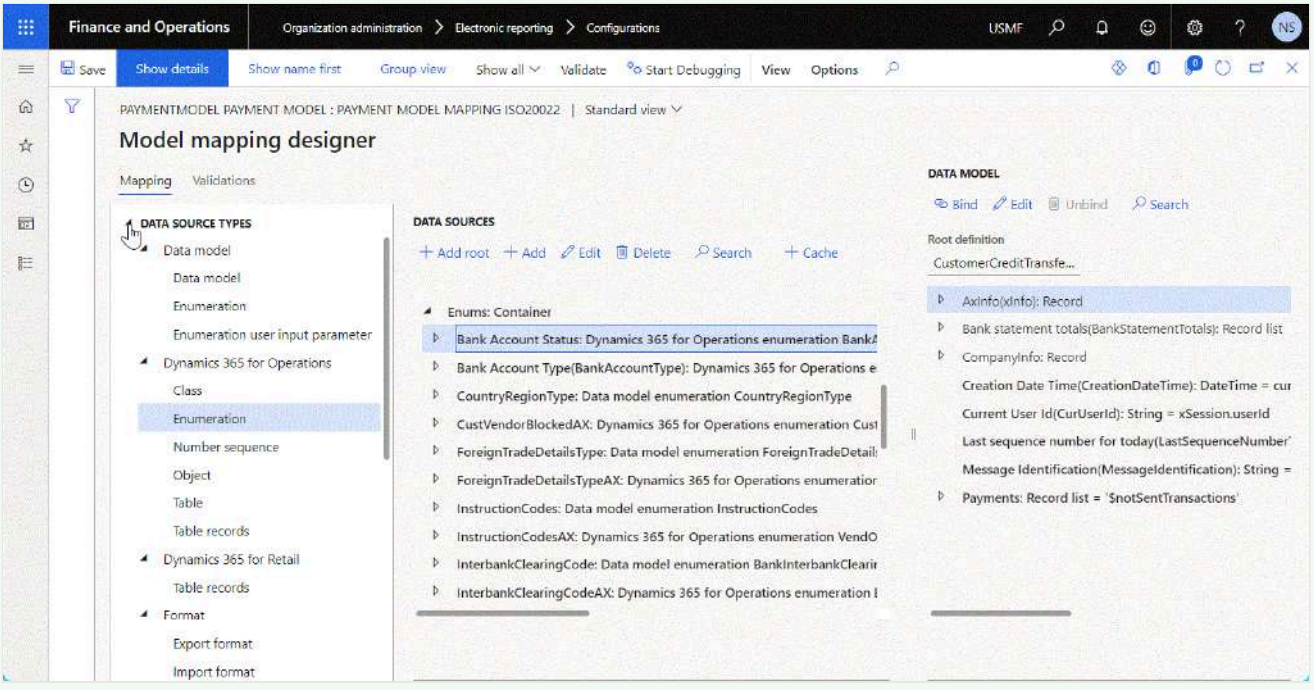
The **Data sources** pane in the middle of the page shows the data sources that you already added to the current model mapping. Use the **Add root** and **Add** buttons to add a new data source entry.

- To add a new top-level data source, select **Add root**.
- To add a new child data source, in the **Data sources** pane, select an existing data source as the parent node to add the new data source to. Then select **Add**.

The following illustration shows the addition of a new child data source of the *Enumeration* type.



> **Tip**
>
> To free up space so that you can enlarge the **Data sources** and **Data model** panes, select the arrow next to the **Data source types** heading in the left pane to collapse the tree. The whole pane is then collapsed.

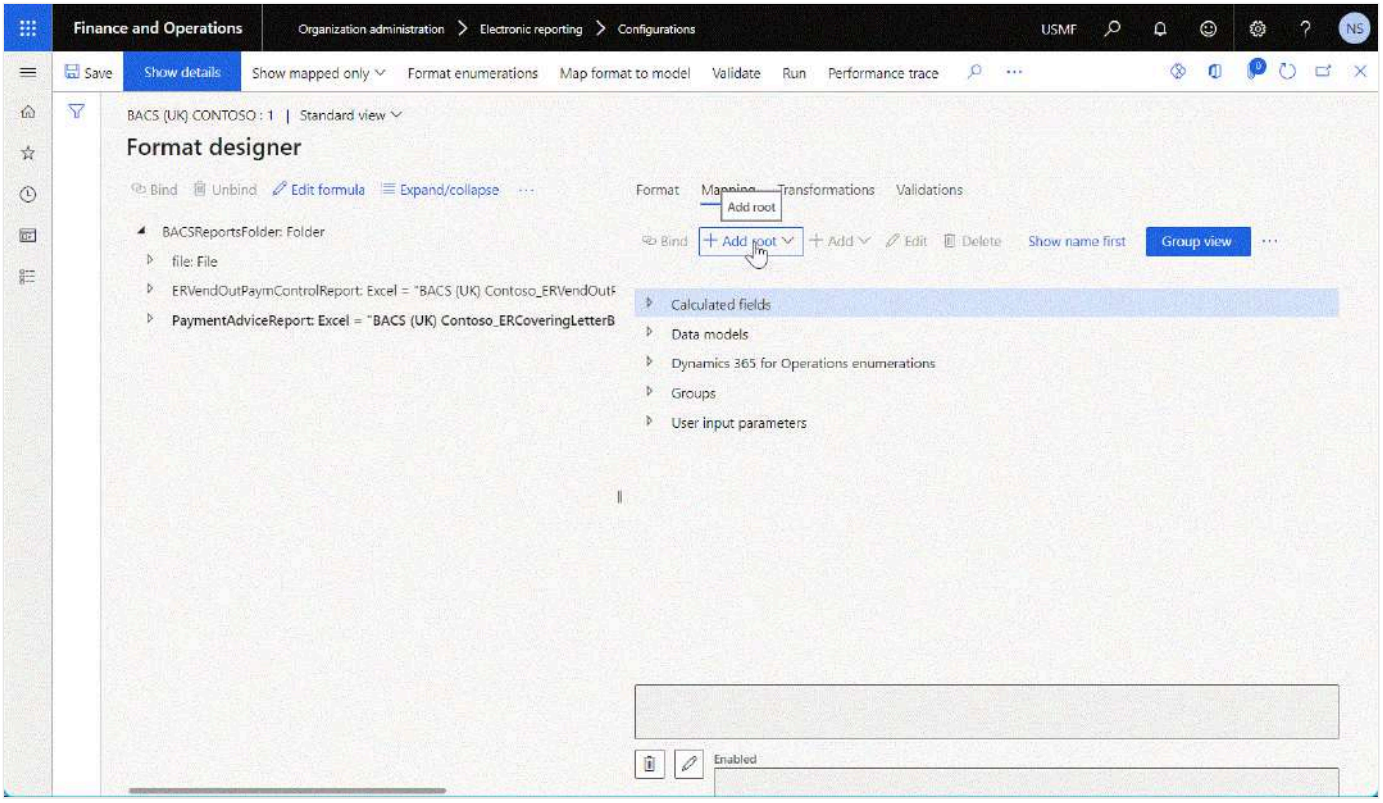


Format designer

The **Mapping** tab of the **Format designer** page shows the data sources that you already added to the current format. Use the **Add root** and **Add** buttons to add a new data source entry.

- To add a new top-level data source, select **Add root**. Then, in the **Add data source** dialog box, select the desired data source type.
- To add a new child data source, select an existing data source as the parent node to add the new data source to, and select **Add**. Then, in the **Add data source** dialog box, select the desired data source type.

The following illustration shows the addition of a new top-level data source of the *Data model* > *Enumeration* type.



> **Note**
>
> The following data source types are available for selection only when you turn on the **Show details** toggle button on the **Format designer** page:
>
> - Class
> - Object
> - Table
> - Table records

Common properties of ER data sources

You can specify the properties described in this section for any data source type.

Name property

Because data source names must be unique in an ER component, you must provide the **Name** property. Use this property to uniquely identify the added data source in the configured ER component.

Label property

The **Label** property is optional. Use it to specify an alternative name for the data source. To specify language-dependent text for the label of the editable data source, select **Translate**. When you translate the label, the **Model mapping designer** or **Format designer** page presents it in the preferred language of the current user.

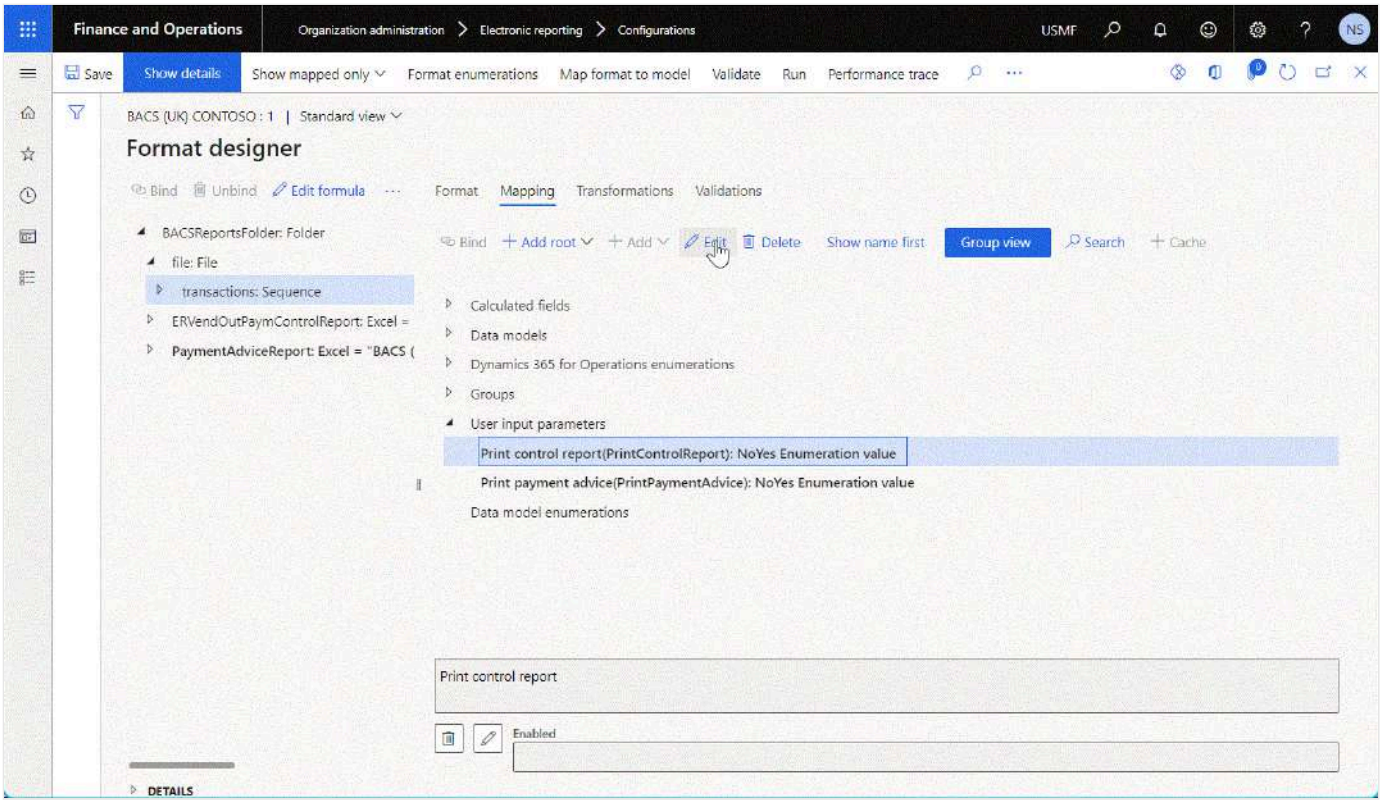
> **Tip**
>
> Turn the **Show name first** toggle button on the **Model mapping designer** or **Format designer** page on or off to sort data sources by name or label.

When you specify this property for a data source that lets you enter information in a data entry field, the specified label is the prompt text for that data entry field. When you translate the label, the prompt text for the data entry field appears in your preferred language, or the preferred language of the current user.

Help property

The **Help** property is optional. Use it to specify a description of the data source. To specify language-dependent text for the description of the editable data source, select **Translate**. When you translate the description, the **Model mapping designer** or **Format designer** page presents it in the preferred language.

The following illustration shows the entry of data source properties on the **Format designer** page.



Data model group

You can configure data sources of different types that represent a data model that you select as the basis for the editable ER model mapping or ER format component. This section provides a summary of the properties that are common to all types of ER data sources that belong to the **Data model** group.

Model property

The mandatory **Model** property references the ER data model component that specifies the structure of this data source.

Definition property

The optional **Definition** property points to a single root element of the selected ER data model component to specify what part of the referenced ER data model is used in this data source.

> **Tip**
>
> You can leave the **Definition** property blank if the default root definition is specified in the referenced data model.

Version property

The optional **Version** property specifies the revision of the data model component for this data source. To review the list of data model revisions that are available in the current Finance instance, expand the **Versions** FastTab on the **Configurations** page for the appropriate data model configurations.

> **Tip**
>
> Leave this property blank to use a data model component from the configuration **version** that's in the **Draft** status. In this way, you can simultaneously edit your ER model mapping or ER format and its base data model.

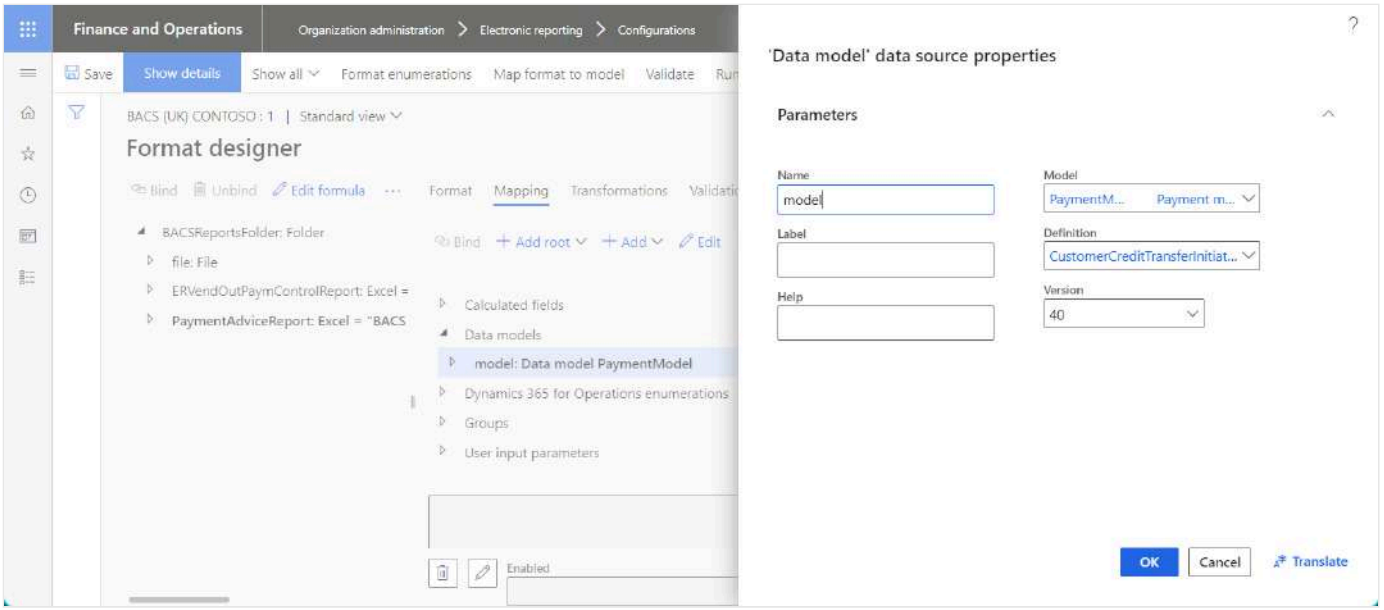
> **Important**
>
> You must specify this property when you change the status of the editable configuration from **Draft** to **Completed**. If you change the structure of the draft data model and use your changes in the edited ER model mapping or ER format, change the status of the edited base data model configuration version from **Draft** to **Completed** before you make the same change for the edited configuration version of the ER model mapping or ER format. Otherwise, a Path not found exception is thrown when you try to complete the draft version of the edited ER model mapping or ER format configuration.

Data model

The **Data model** data source represents the ER data model component that's filled in by actual data at runtime when a data consumer request occurs.

> **Tip**
>
> This data source is automatically added for any ER format component that you create to generate an outbound document.

The following illustration shows the properties for a data source of the *Data model* type in the **Data source properties** dialog box.

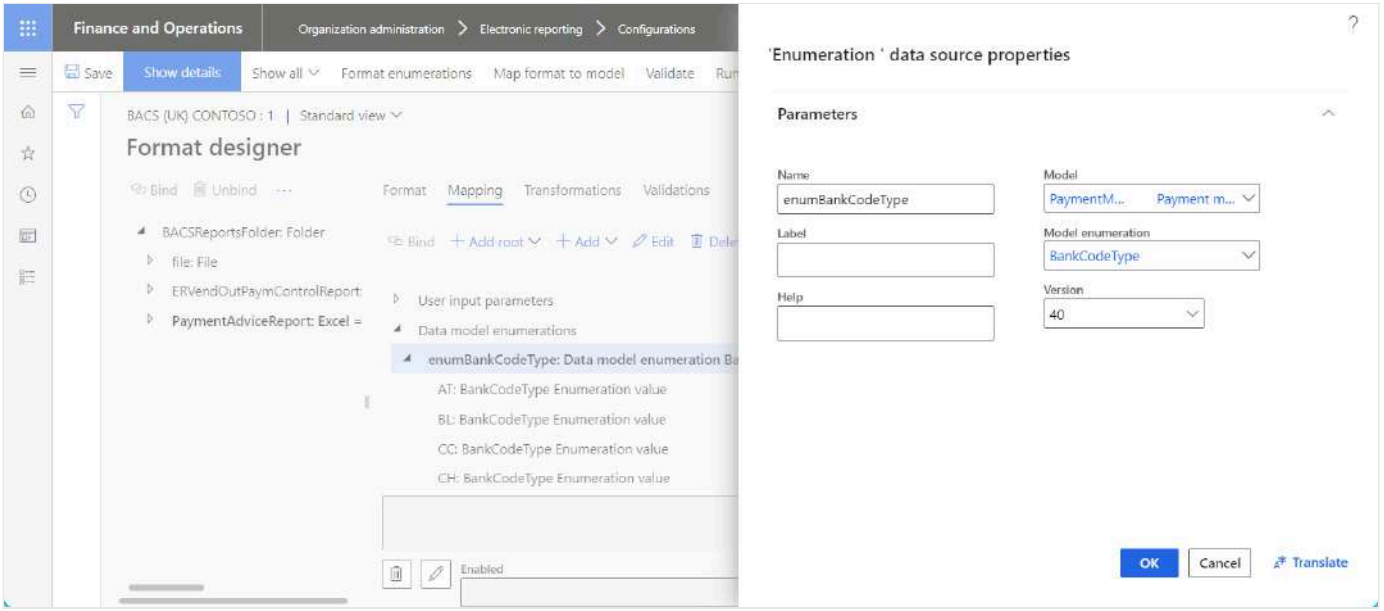


Model enumeration

The **Data model enumeration** data source represents the enumeration of the base data model. You usually need this data source when you configure an ER expression to compare the value of a data model field with a specific enumeration value.

The mandatory **Model enumeration** property points to a data model enumeration of the selected ER data model component. It specifies which values of the referenced ER data model enumeration are used in this data source.

The following illustration shows the properties for a data source of the *Model enumeration* type in the **Data source properties** dialog box.



Model enumeration user input parameter

The **Model enumeration user input parameter** data source represents the enumeration of the base data model. You usually need this data source when you want the value of the referenced enumeration that's specified in the related data entry field in the dialog box at runtime, before the ER format runs.

The mandatory **Model enumeration** property points to a data model enumeration of the selected ER data model component. It specifies what values of the referenced ER data model enumeration this data source returns.

The **Allow multiple selection** property identifies whether you can specify a single value or multiple values of the referenced enumeration.

Use the **Read only** property to configure an ER expression and specify whether the appropriate data entry field in the dialog box is editable at runtime.

Use the **Default value** property to configure an ER expression that specifies the default value for the appropriate data entry field in the dialog box at runtime.

The **Always reset to default value** property identifies whether the value that's returned by the **Default value** ER expression should always be used as the default value, regardless of the previously used value.

Use the **Edit visibility** function to configure an ER expression that specifies, at runtime, whether the appropriate data entry field should be shown in the dialog box at runtime.

- If this expression is configured and returns *False* at runtime, the appropriate data entry field in the dialog box is hidden.
- Otherwise, the appropriate data entry field is visible in the dialog box at runtime.

For more information, see Use USER INPUT PARAMETER data sources to specify parameters for a report.

Model enumeration lookup

Use the **Model enumeration lookup** data source to configure an ER data source of the *Lookup* type that returns the values of an ER data model enumeration.

> ⓘ **Note**
>
> You can only configure the **Model enumeration lookup** data source for an ER format component.

Configure a data source of the *Model enumeration lookup* type to filter data in an ER format so that it's based on a set of abstract rules. You can then specify real rules outside the ER component designers by using the user interface (UI) that's automatically generated based on the settings of the **Lookup** data source of the corresponding ER format and the current legal entity data. When you run this ER format, the ER format's **Lookup** data source accesses the specified rules.

The mandatory **Model enumeration** property of the **Model enumeration lookup** data source points to a data model enumeration of the base ER data model component to specify what values of the referenced ER data model enumeration this data source returns.

The **Cross-company** property identifies whether you plan to use the configured data source to evaluate the data of multiple companies at runtime.

The **Extended** property reveals more methods for accessing values of the configured data source.

For more information, see Configure Lookup data sources to use ER application-specific parameters.

Format enumeration group

You can configure different data source types that represent the editable format component and return values of an enumeration of that format. This section provides a summary of the properties that are common to all types of ER data sources that belong to the **Format enumeration** group.

> ⓘ **Note**
>
> You can only configure data sources of the **Format enumeration** group for an ER format component.

The mandatory **Enumeration** property references an ER format enumeration whose value the configured data source returns.

Format enumeration

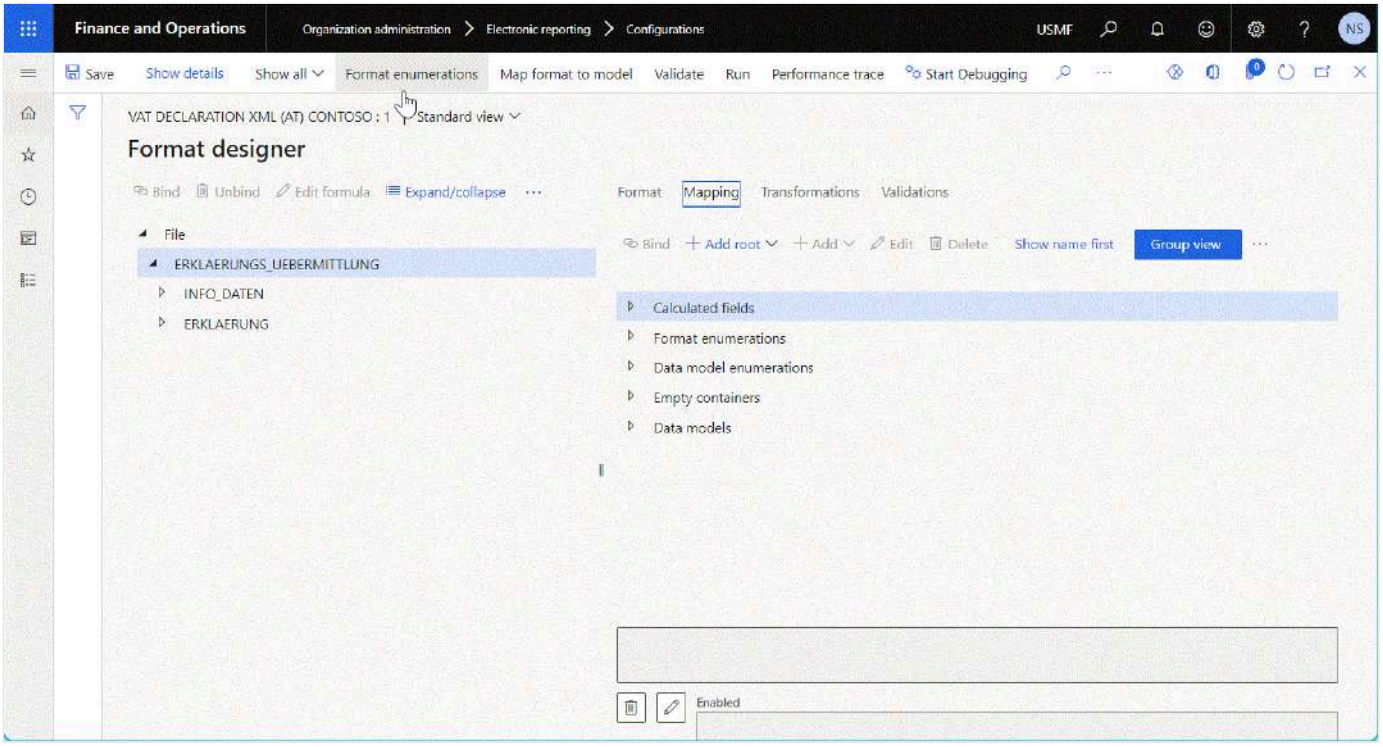
The **Format enumeration** data source represents the enumeration of the editable format.

- On the **Format enumeration** FastTab, select **Add** to add a new format enumeration.

- On the **Format enumeration values** FastTab, select **Add** to add a new value for the selected format enumeration.

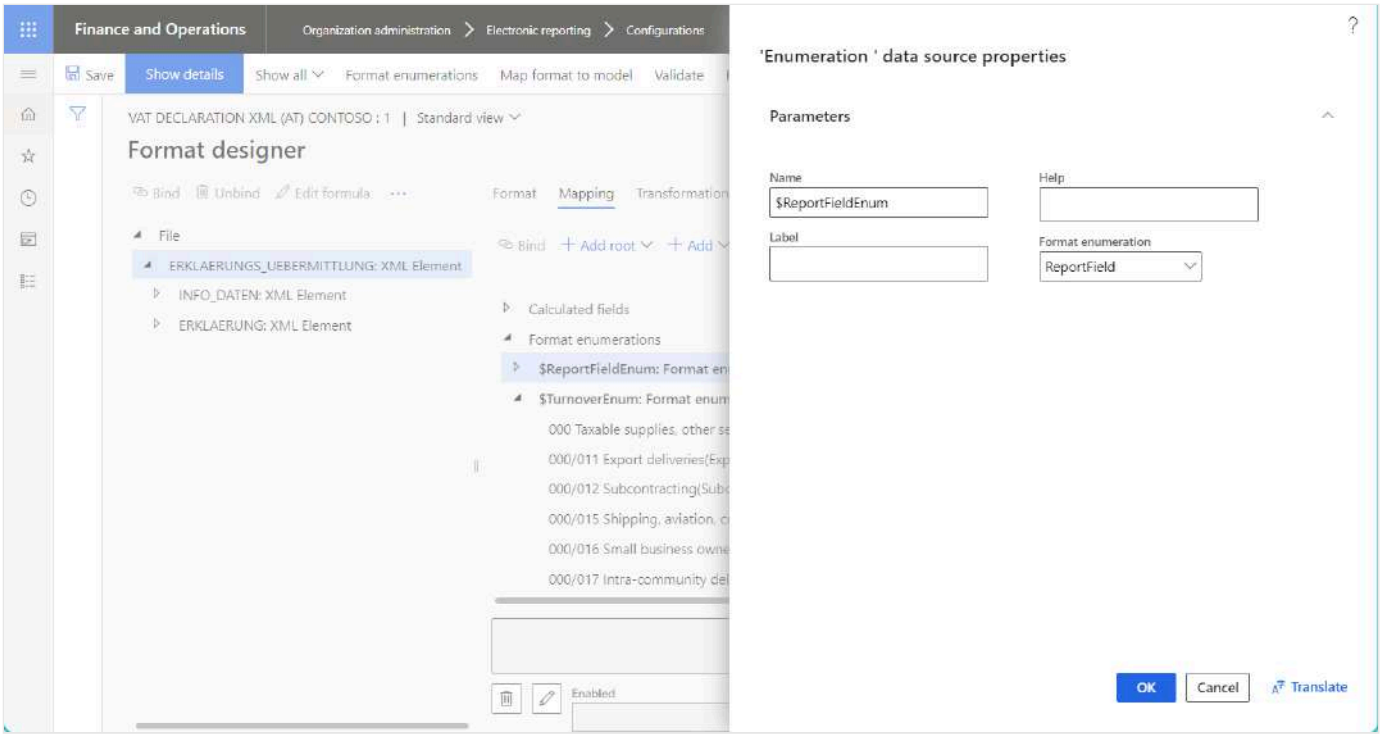
> **Tip**
>
> The **Label** and **Help** properties of format enumerations and format enumeration values are translatable.

The following illustration shows a format enumeration that you configured for the editable format component.



You usually need this data source when you configure an ER expression to compare a specific format enumeration value with a value of the relevant enumeration that another data source returns.

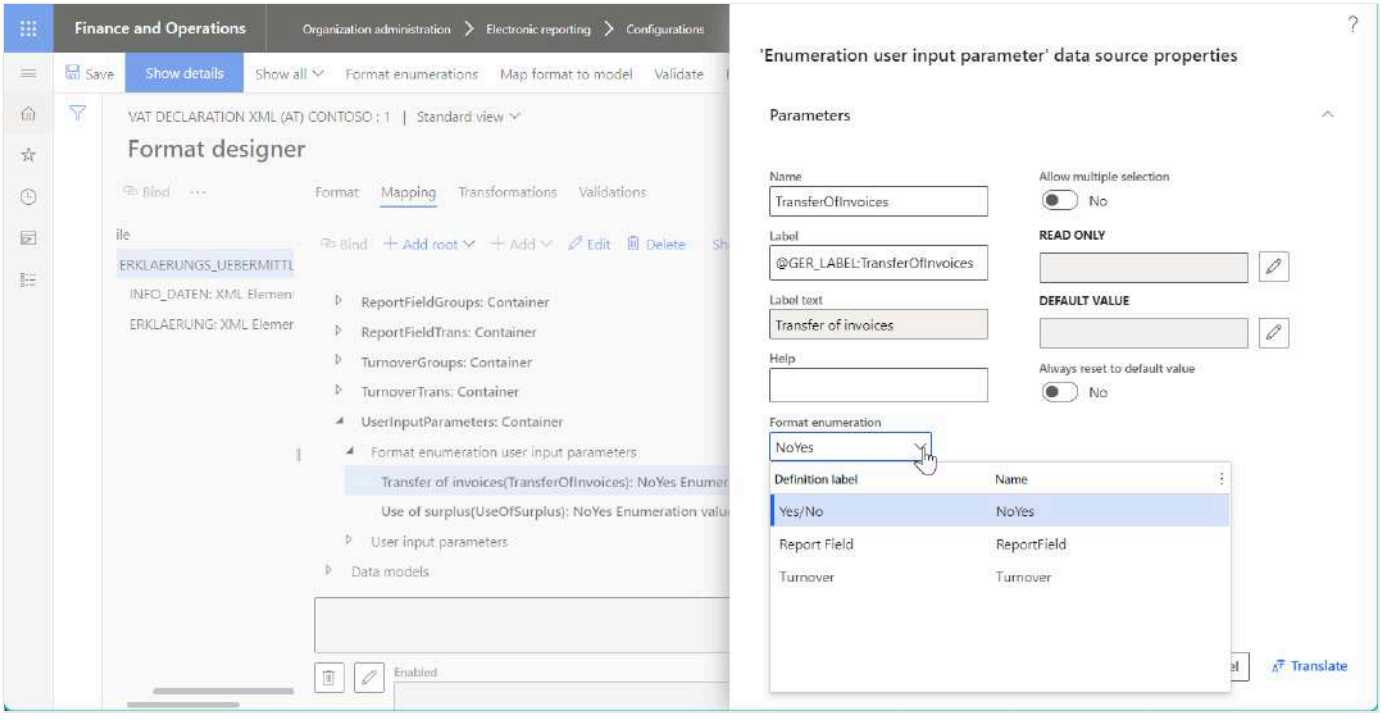
The following illustration shows the properties for a data source of the *Format enumeration* type in the **Data source properties** dialog box.



Format enumeration user input parameter

The **Format enumeration user input parameter** data source represents the enumeration of the editable format. You usually need this data source when you want to specify a value of the referenced enumeration in the related data entry field in the dialog box at runtime, before an ER format runs.

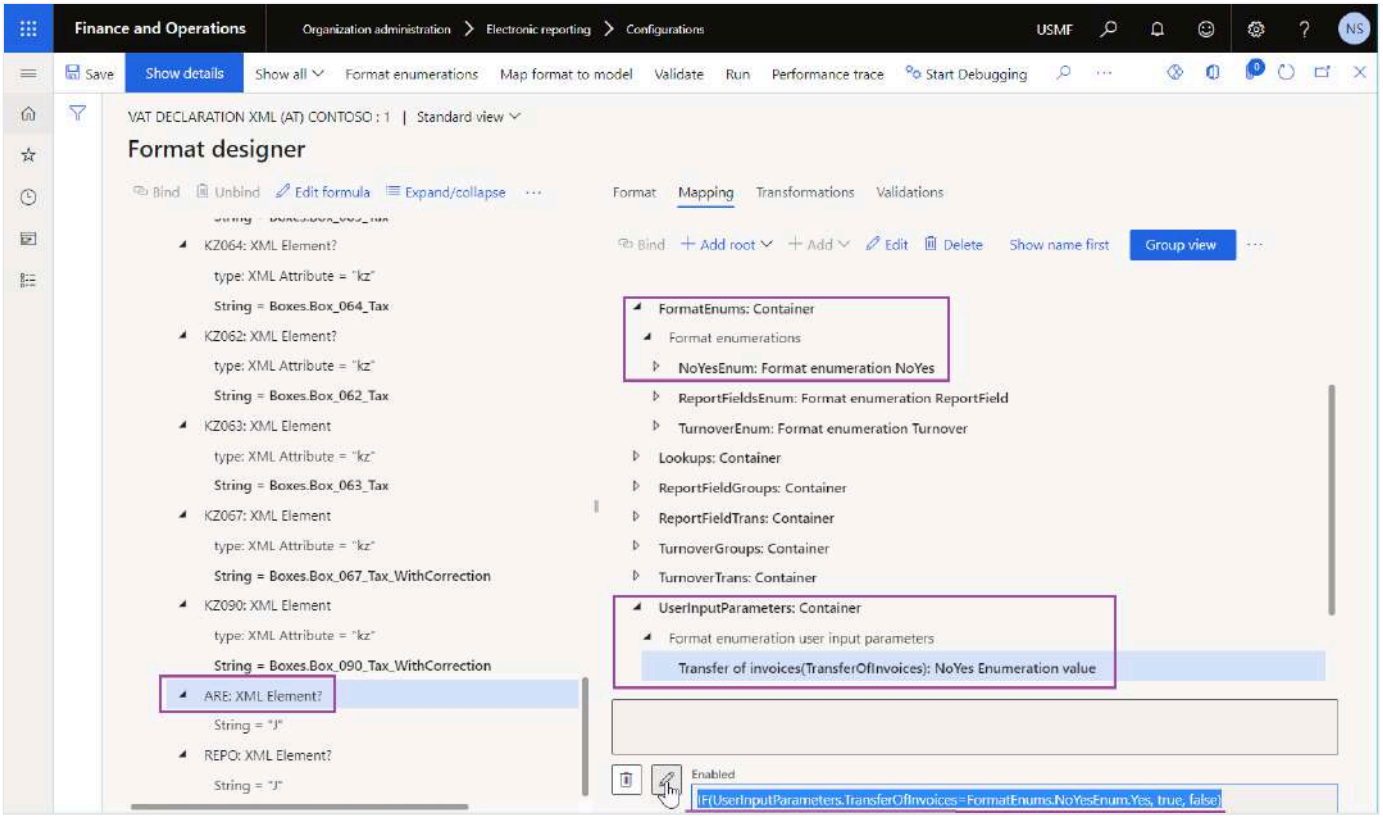
The mandatory **Format enumeration** property of the **Format enumeration user input parameter** data source points to an enumeration of the editable format to specify what values of the referred format enumeration this data source returns.



Set the **Allow multiple selection**, **Read only**, **Default value**, and **Always reset to default value** properties as described earlier for the *Model enumeration user input parameter* data source type.

> **Tip**
>
> If you leave the **Label** or **Help** property blank for a data source of the *Format enumeration user input parameter* type, the appropriate property of the referenced format enumeration is used, if it's configured.

The following illustration shows an ER expression that's configured to enable an ER format element, depending on the result of comparison of values of data sources of the *Format enumeration user input parameter* and *Format enumeration* types.



Format enumeration lookup

Use the **Format enumeration lookup** data source to configure an ER data source of the *Lookup* type to return the values of an ER format enumeration.

Configure a data source of the *Format enumeration lookup* type to filter data in an ER format so that it's based on a set of abstract rules. You can then specify real rules outside the ER component designers by using the UI that's automatically generated based on the settings of the **Lookup** data source of the corresponding ER format and the current legal entity data. When you run this ER format, the specified rules are accessed by the ER format's **Lookup** data source.

The mandatory **Format enumeration** property of the **Format enumeration lookup** data source points to a format enumeration of the editable format to specify what values of the referenced format enumeration this data source returns.

Set the **Cross-company** and **Extended** properties as described earlier for the *Model enumeration lookup* data source type.

Format group

Export format

Use the **Export format** data source to run another ER format during the execution of the editable format. The execution results of the nested ER format serve as a data source for the execution of the editable ER format.

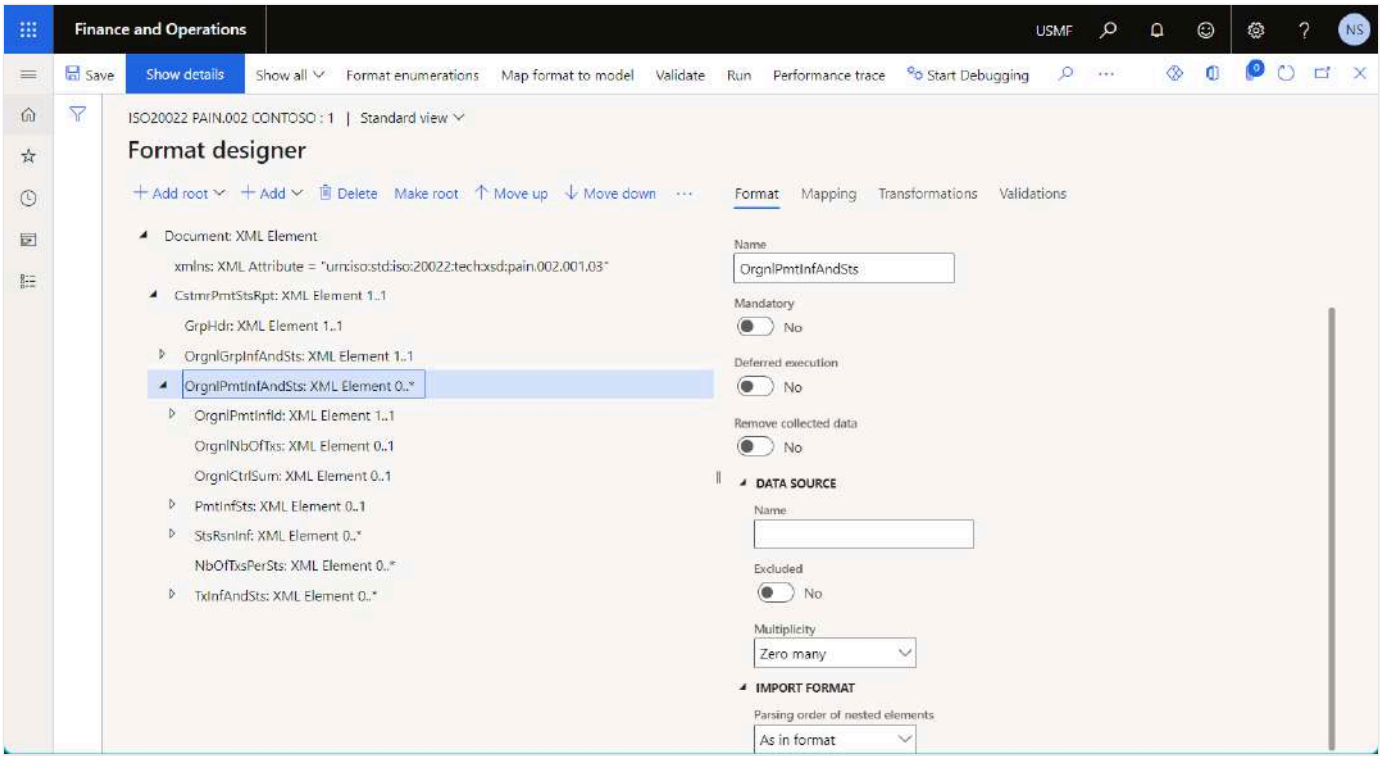
Use the mandatory **Format** property to specify an ER format that must run during the execution of the editable format.

Import format

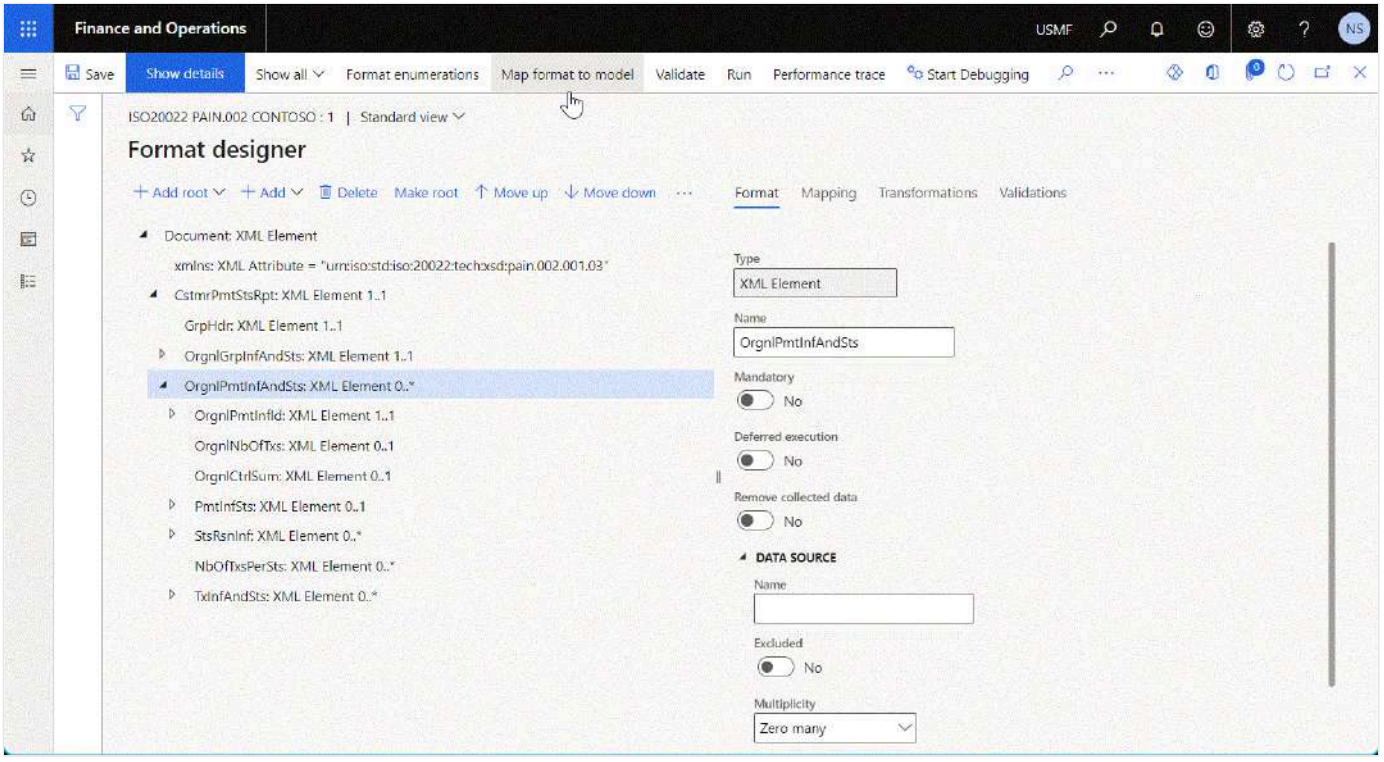
Use the **Import format** data source to parse an inbound business document. The results of the inbound document parsing can then be used in the format mapping to fill a data model.

Use the mandatory **Format** property to specify an ER format that must be used for inbound document parsing.

The following illustration shows the ER format that's configured to parse an inbound document in XML format.



The following illustration shows the model mapping that contains a data source of the *Import format* type to expose data of a parsed inbound document and then use that data to fill a data model.



For more information, see Parse incoming documents.

Dynamics 365 Finance group

Class

Use the **Class** data source to call a static method of a public class from your ER solution. You can dynamically define argument values for calling classes at runtime. To invoke a class, configure a data source of the *Calculated field* type with an expression that references the desired class of application source code. For more information, see Design ER expressions to call application class methods.

You can add a data source of the *Class* type in the editable **Model mapping** component. If you identify the editable model mapping as the preferred one for execution, set the **Integration point** option of the **Class** data source to **Yes**. For more information about this option, see API to run a format mapping for the generation of outbound documents.

Object

Use the **Object** data source to call a public method of a class instance from your ER solution. You can dynamically define argument values for calling classes at runtime. To invoke a class, configure a data source of the *Calculated field* type with an expression that references the desired class of application source code.

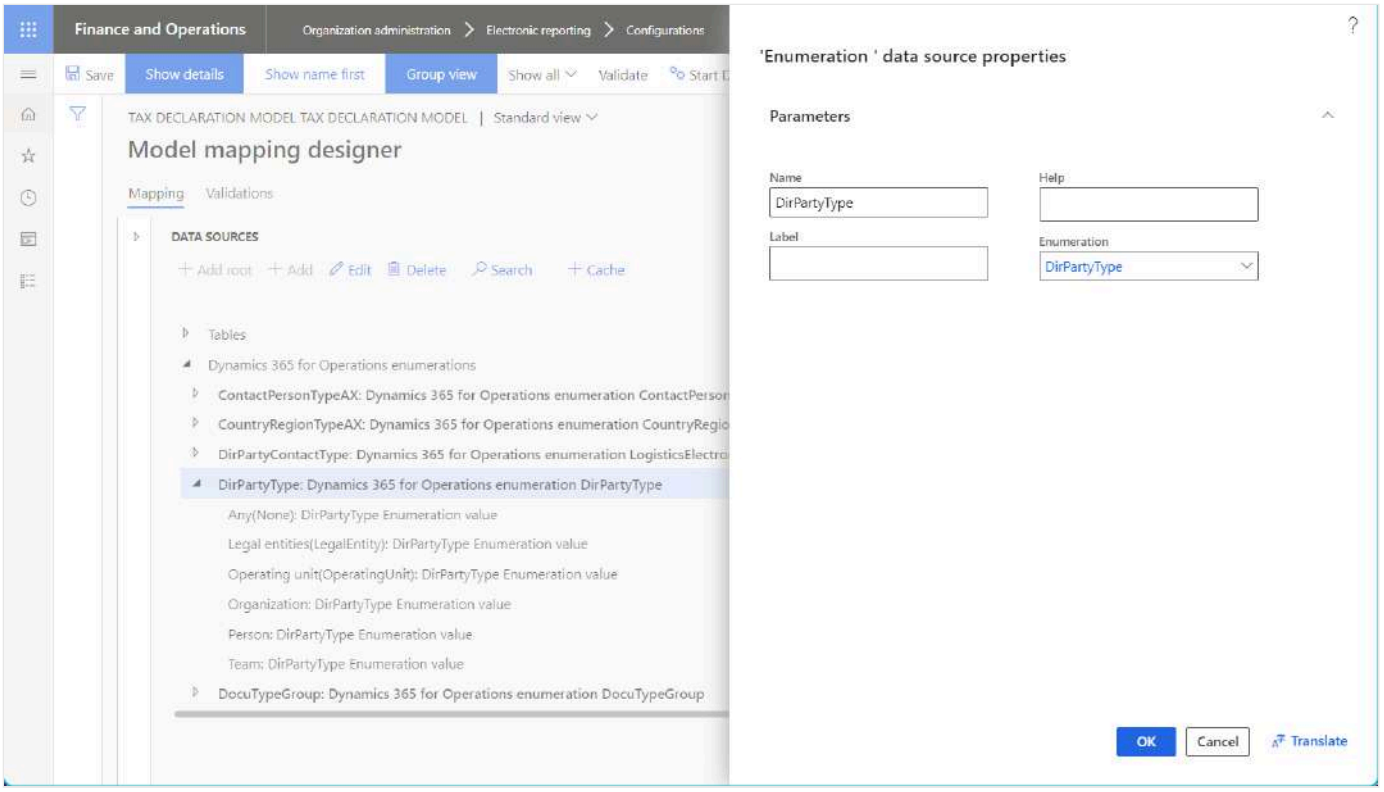
Add a data source of the *Object* type in the editable **Model mapping** component. If you identify the editable model mapping as the preferred one for execution at runtime, set the **Integration point** option of this **Object** data source to **Yes**.

Enumeration

The **Enumeration** data source represents the application enumeration. You usually need this data source when you configure an ER expression to compare a specific application enumeration value with a value of the relevant enumeration that another data source returns.

Use the mandatory **Enumeration** property to specify an application enumeration.

The following illustration shows the properties for a data source of the *Application enumeration* type in the **Data source properties** dialog box.



Application enumeration lookup

Use the **Application enumeration lookup** data source to configure an ER data source of the *Lookup* type to return the values of an application enumeration.

Configure a data source of the *Application enumeration lookup* type to filter data in an ER format so that it's based on a set of abstract rules. You can then specify real rules outside the ER component designers by using the UI that's automatically generated based on the settings of the **Lookup** data source of the corresponding ER format and the current legal entity data. When you run this ER format, the specified rules are accessed by the ER format's **Lookup** data source.

The mandatory **Operations data type name (EDT, enum)** property of the **Application enumeration lookup** data source points to an application enumeration or an application extended data type (EDT) to specify what values are returned by this data source.

Set the **Cross-company** and **Extended** properties as described earlier for the *Model enumeration lookup* data source type.

Number sequence

Use the **Number sequence** data source to return a value from the referenced number sequence for the current application instance. When a data consumer calls this data source, the referenced number sequence increments and returns the received value returned.

You must specify the mandatory **Number sequence code** property to identify the required number sequence.

In addition to **Number sequence** data sources, you can use the built-in ER **NUMSEQVALUE** function.

Table

Use the **Table** data source to call static methods of an application table, entity, or view. You call these static methods in the same way that you call static methods of an application class, as described earlier.

You must specify the mandatory **Table** property to identify the required table, entity, or view.

Table records

Use the **Table records** data source to fetch records from an application table, entity, or view.

You must specify the mandatory **Table** property to identify the required table, entity, or view.

If the table, entity, or view that you reference in the **Table** property keeps records company-specific, specify the **Cross-company** property.

- Set this property to **No** to fetch records only for the company that an ER solution runs in scope of.
- Set this property to **Yes** to fetch records for all companies of the current application instance.

Set the **Ask for query** option to **Yes** to enable the system query dialog box at runtime, so that users can filter data for the configured data source. For more information, see Cross-company data sources in Electronic reporting (ER).

If you identify the editable model mapping as the preferred one for execution, set the **Integration point** option to **Yes**.

Use the **Select fields** function to limit the list of fields whose values are fetched at runtime. For more information, see Improve performance of ER solutions by reducing the number of table fields that are fetched at runtime.

Use the **Refill table** function whenever you add or update Application Object Tree (AOT) artifacts. This function resembles the **Rebuild table references** function.

General group

Empty container

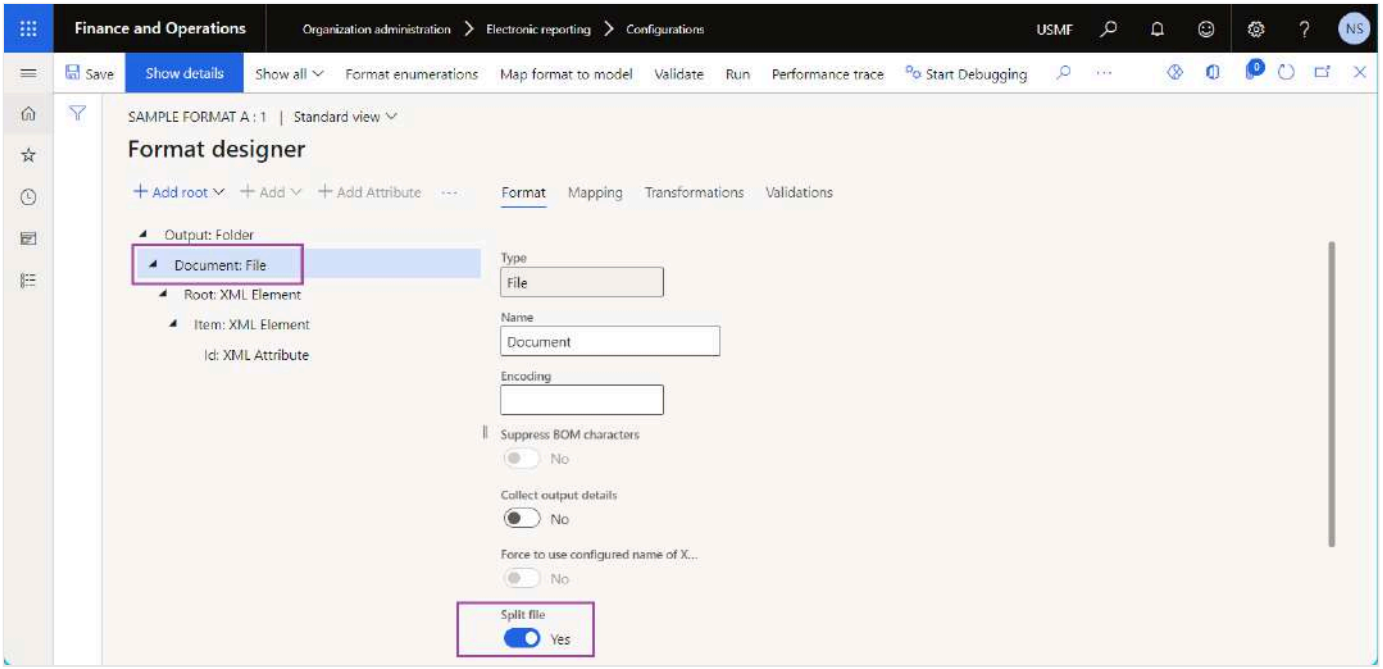
Use the **Empty container** data source as the container for other data sources. Use it to organize your data sources or to make groups of data sources of different types for specific purposes.

In addition, you can use an **Empty container** data source as the mockup of the desired record. Then, by using the LIST function, you can limit the list of fields for the final list of records.

Endless list

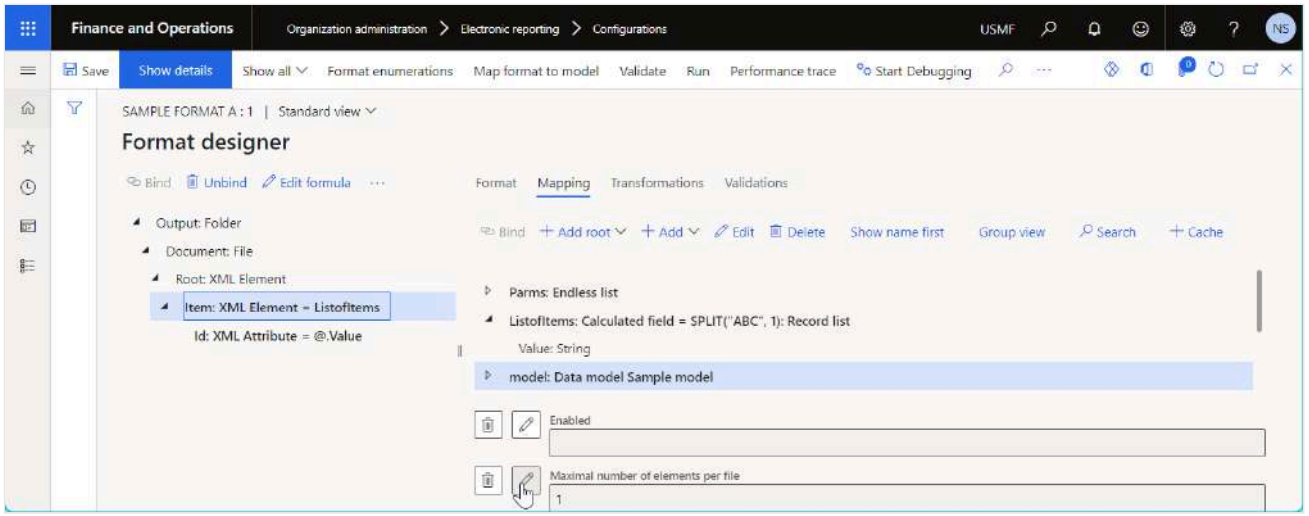
You can configure an ER format to split generated XML output into multiple files whenever specific limits are exceeded. Use the **Endless list** data source to uniquely name those outbound files.

The following illustration shows a sample ER format that's configured to generate zipped XML output that must be split into multiple files.

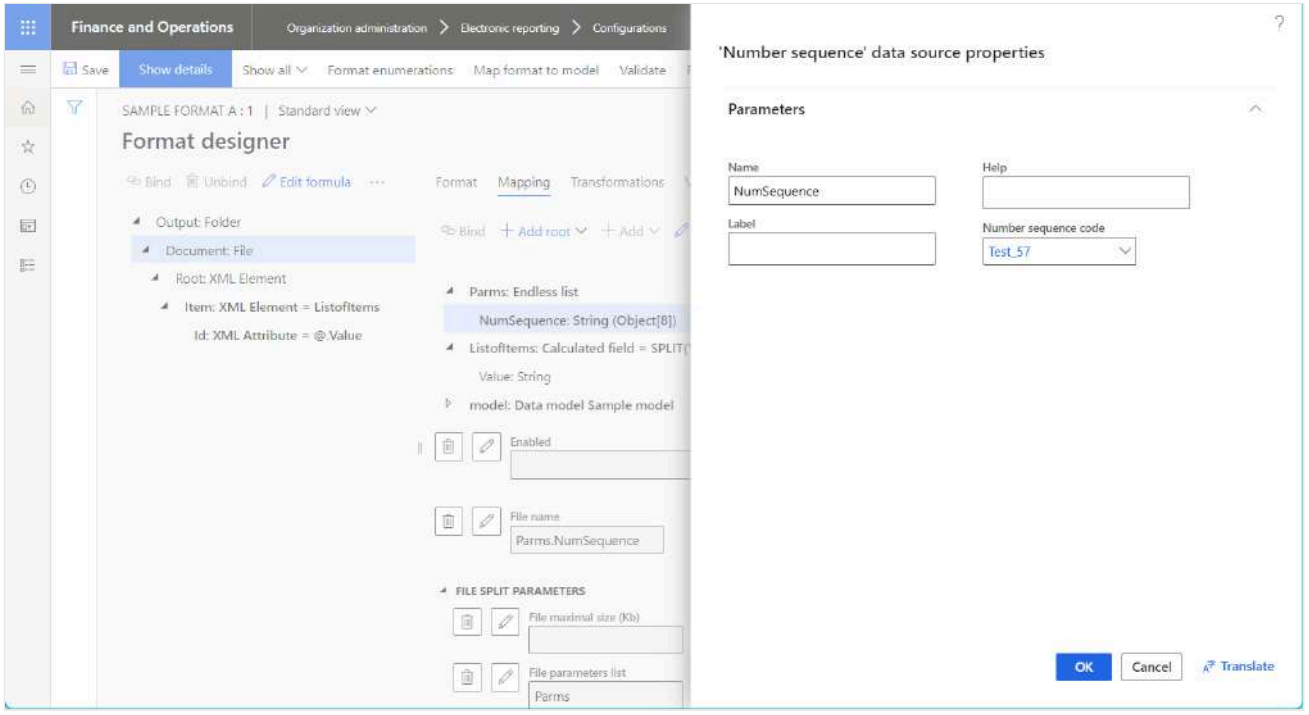


The following illustrations show the bindings of the sample ER format:

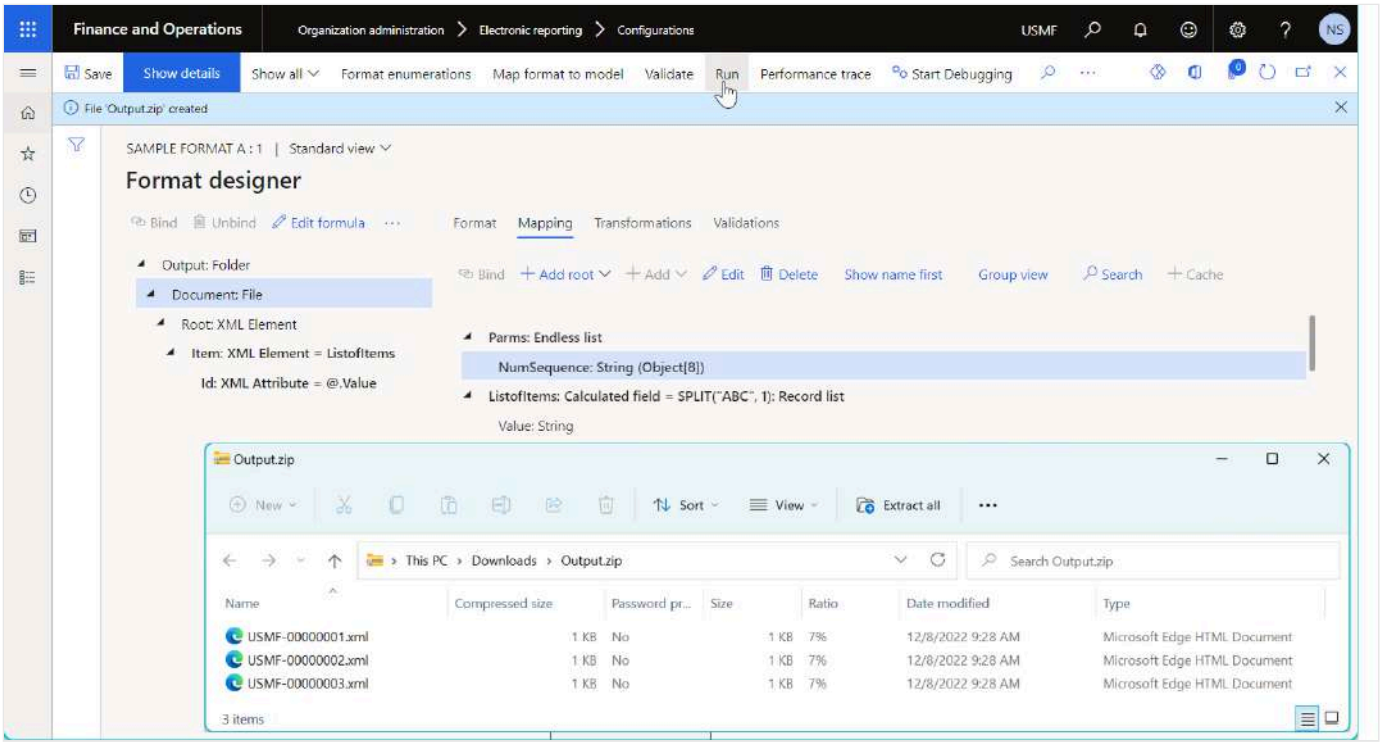
- The **Item** format element is bound to the `ListofItems` data source that returns three records. The **Maximal number of elements per file** property of this format element is configured to split generated output into multiple XML files, each of which must contain only one `Item` XML node.



- The **File parameters list** property of the **File** format element references the `Parms` data source of the *Endless list* type to ensure that this data source is invoked whenever the output split occurs. Because the `Parms` data source contains the nested `NumSequence` data source of the *Number sequence* type, the application number sequence that's referenced in `NumSequence` is also iterated for each split. Therefore, the `Parms.NumSequence` ER expression that's configured in the **File name** property of the **File** component generates a unique name for each output file, based on the current value of the referenced number sequence.



The following illustration shows the result of running the previously described sample ER format. The result represents a zip file that contains XML output that's split into three uniquely named XML files.



For more information, see Split generated XML files based on file size and content quantity.

User input parameter

Use a data source of the *User input parameter* type to let users specify a value of the referenced application enumeration or application EDT in the related data entry field in the dialog box at runtime, before an ER format runs.

The mandatory **Operations data type name (EDT, enum)** property of the **User input parameter** data source points to an application enumeration or an application EDT to specify what values this data source returns.

Set the **Allow multiple selection**, **Read only**, **Default value**, and **Always reset to default value** properties as described earlier for the *Model enumeration user input parameter* data source type.

Use the **Edit visibility** function for the *Model enumeration user input parameter* data source type.

Functions group

Barcode

Use a data source of the *Barcode* type to generate an image that represents the bar code for specified text.

The mandatory **Barcode format** property of the **Barcode** data source specifies the bar code type. The following bar code formats are currently supported:

- One-dimensional bar codes:
  - Codabar
  - Code 39
  - Code 93
  - Code 128
  - EAN-8
  - EAN-13
  - ITF-14
  - Intelligent Mail
  - MSI
  - Plessey
  - PDF417
  - UPC-A
  - UPC-E
- Two-dimensional bar codes:
  - Aztec
  - Data Matrix
  - QR Code

The optional **Width** property specifies the bar code's width in pixels. A value of **0** (zero) indicates that the default width is used. The meaning can vary for different formats.

The optional **Height** property specifies the bar code's height in pixels. A value of **0** (zero) indicates that the default height is used. The meaning can vary for different formats.

The optional **Margin** property specifies the size of the bar code's margin in pixels. The margin is the area on each side of a bar code that must be kept clear (quiet zone). A value of **0** (zero) indicates that the default margin is used. The meaning can vary for different formats.

The **Output content** option specifies whether a bar code image contains the encoded information as text. Set this option to **Yes** to generate a bar code image that contains the encoded information as text. The default value is **No**.

The mandatory **Encoding** property specifies the type of characters that are encoded in the generated bar code image. By default, the **UTF-8** encoding is used.

> **Important**

When you add a new **Barcode** data source, place it under another item (container) as a nested element. The **Barcode** data source appears in the configured ER component as a function that has the **Value** parameter of the ***String*** type. Provide the bar code text as the argument of this parameter.

To learn more, see Use Barcode data sources to generate bar code images.

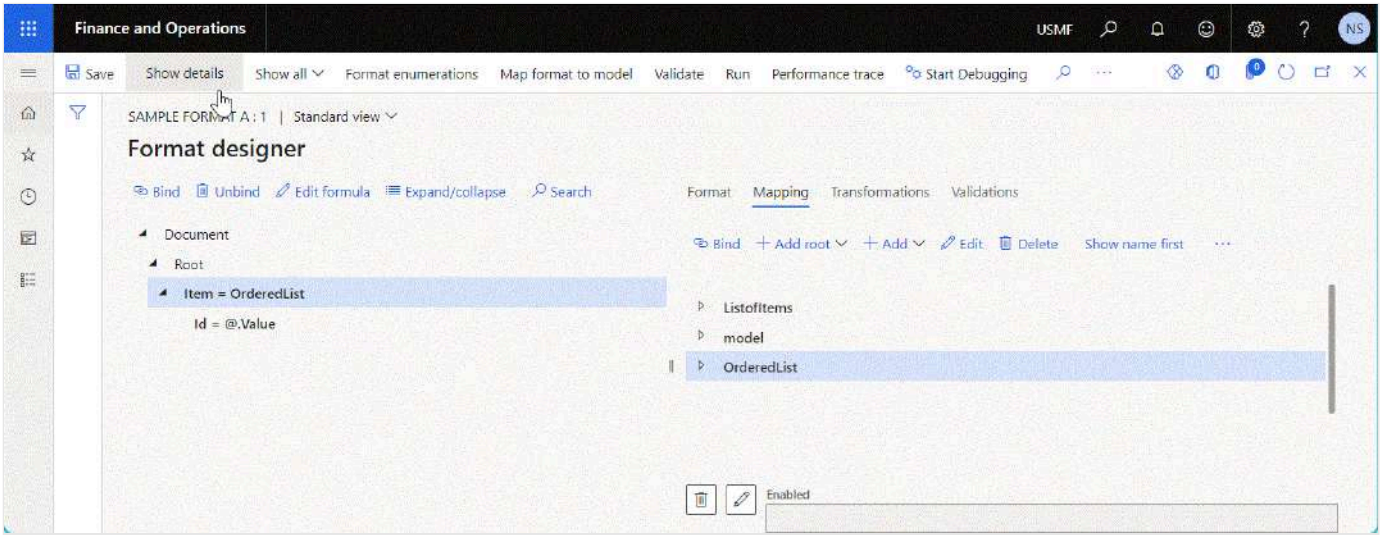
Calculated field

Use a data source of the *Calculated field* type to configure an ER expression for transforming values of other data sources.

Use the **Edit formula** function to configure an ER expression of the editable data source of the *Calculated field* type.

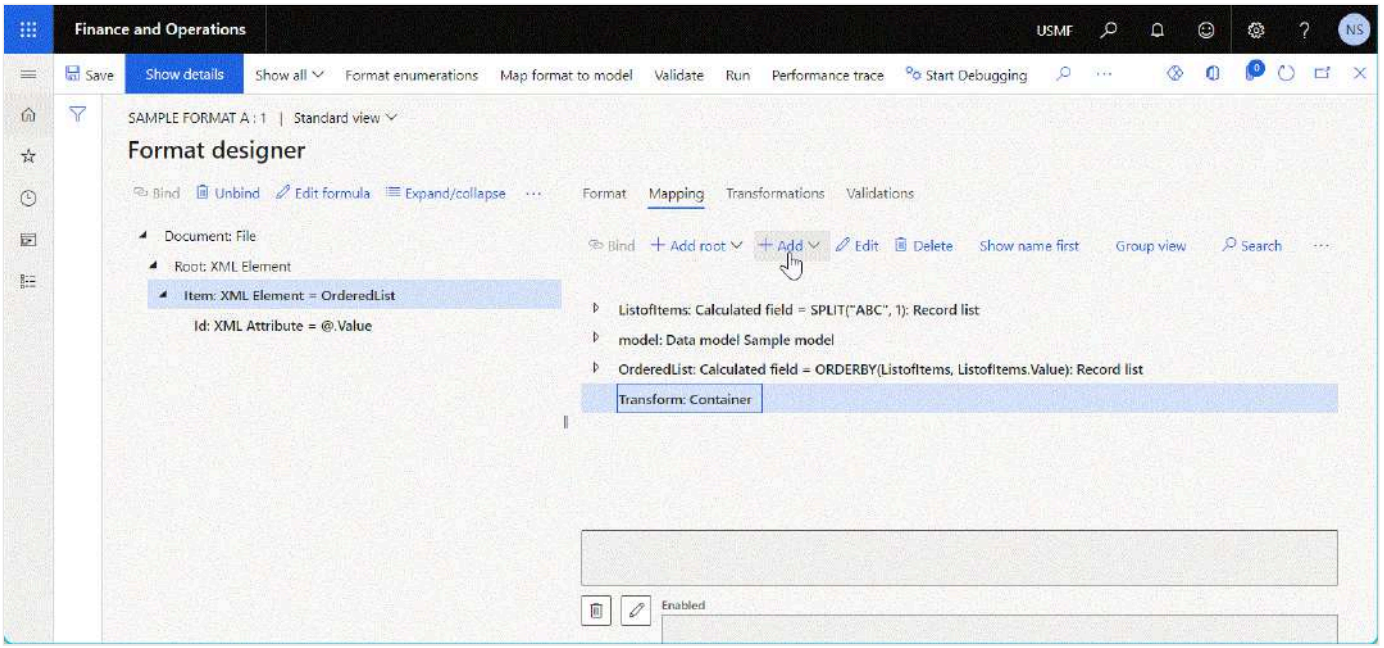
> **Tip**
>
> Turn on the **Show details** toggle button to preview configured expressions for data sources of the *Calculated field* type in the **Data sources** pane of the **Model mapping designer** page and on the **Mapping** tab of the **Format designer** page.

The following illustration shows the **Calculated field** data source that sorts the initially provided list of records in alphabetic order.

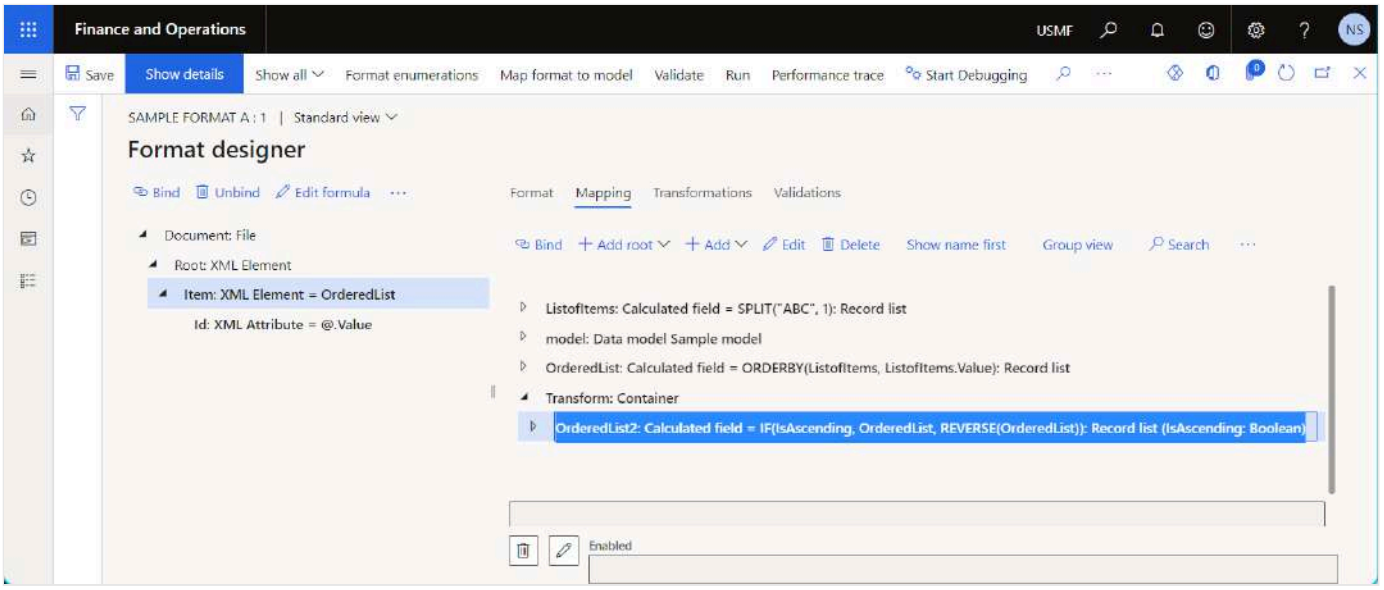


When you add a new **Calculated field** data source by placing it under another item as a nested element, you can specify multiple parameters that you can then reference in the configured ER expression. You can also configure other formulas to call this data source. In this way, you can control the values of arguments of those parameters. Therefore, you can reuse a single data

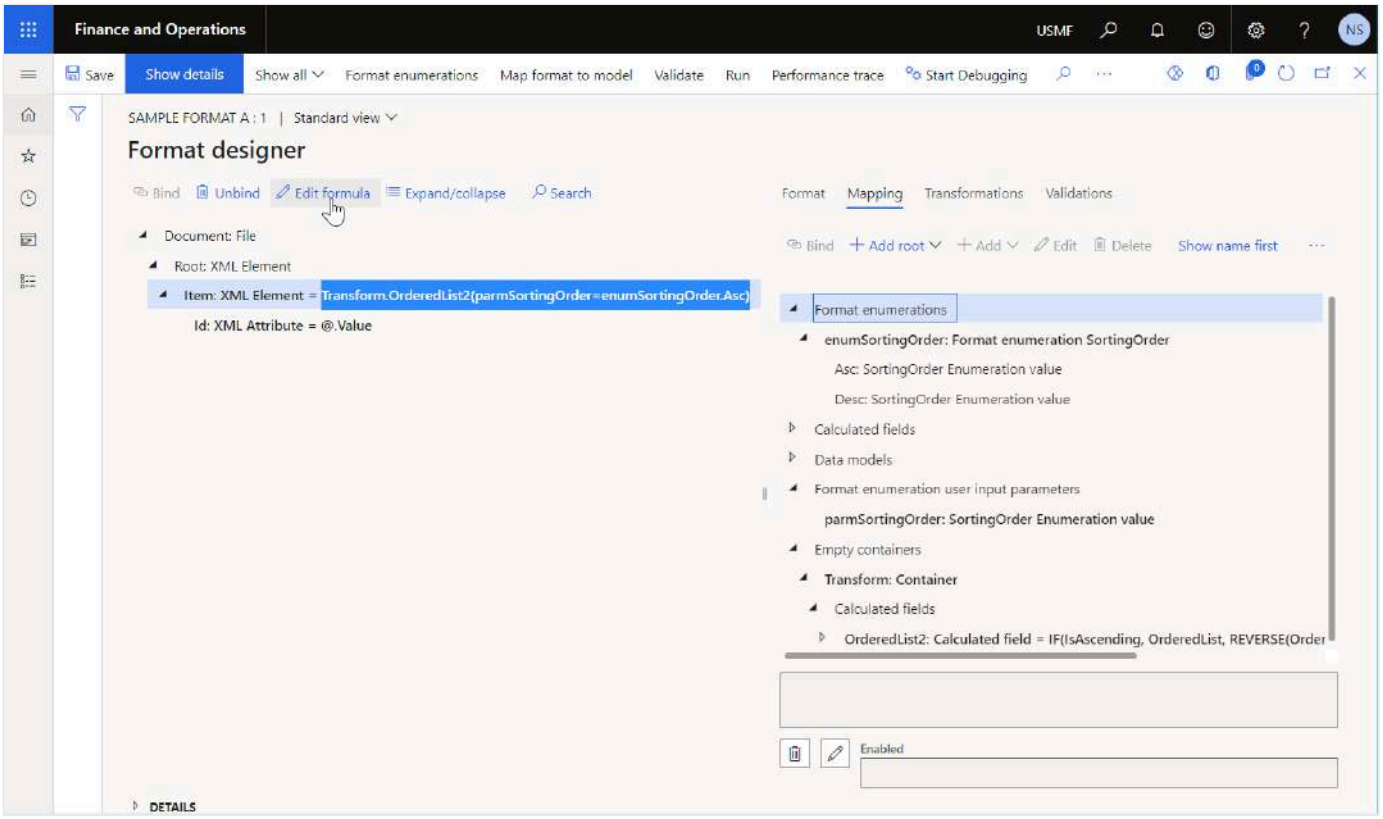
source in many bindings and reduce the total number of data sources that you must configure in an ER model mapping or ER format component.



The following illustration shows the **Calculated field** data source that sorts the initially provided list of records according to the sort direction that's specified at runtime.



The sort order of this data source is specified by using the value of the argument of the data source parameter.



For more information, see Support parameterized calls of ER data sources of the Calculated field type.

Data collection

You can configure an ER model mapping or an ER format to process specific elements, such as records of a model mapping data source or format elements, in a specific order. Additionally, you can configure a data source of the *Data collection* type to collect, during element processing at runtime, values of data model fields or values of bindings of the processed format elements, and then sum those values. The data source then uses the collected values to fill in a generated document or perform other calculations.

The mandatory **Item type** property of the **Data collection** data source specifies the type of collected data. The following data types are currently supported:

- *Boolean*
- *Date*
- *DateTime*
- *GUID*
- *Int64*
- *Integer*
- *Real*
- *String*

- *Time*

By default, a **Data collection** data source collects only unique values. To access the list of collected values, use the **Result** property of a **Data collection** data source. This property returns a record list. The records of the record list contain the **Value** field that you can use to access collected values.

To force a data source of the *Data collection* type to collect **all** values, follow these steps:

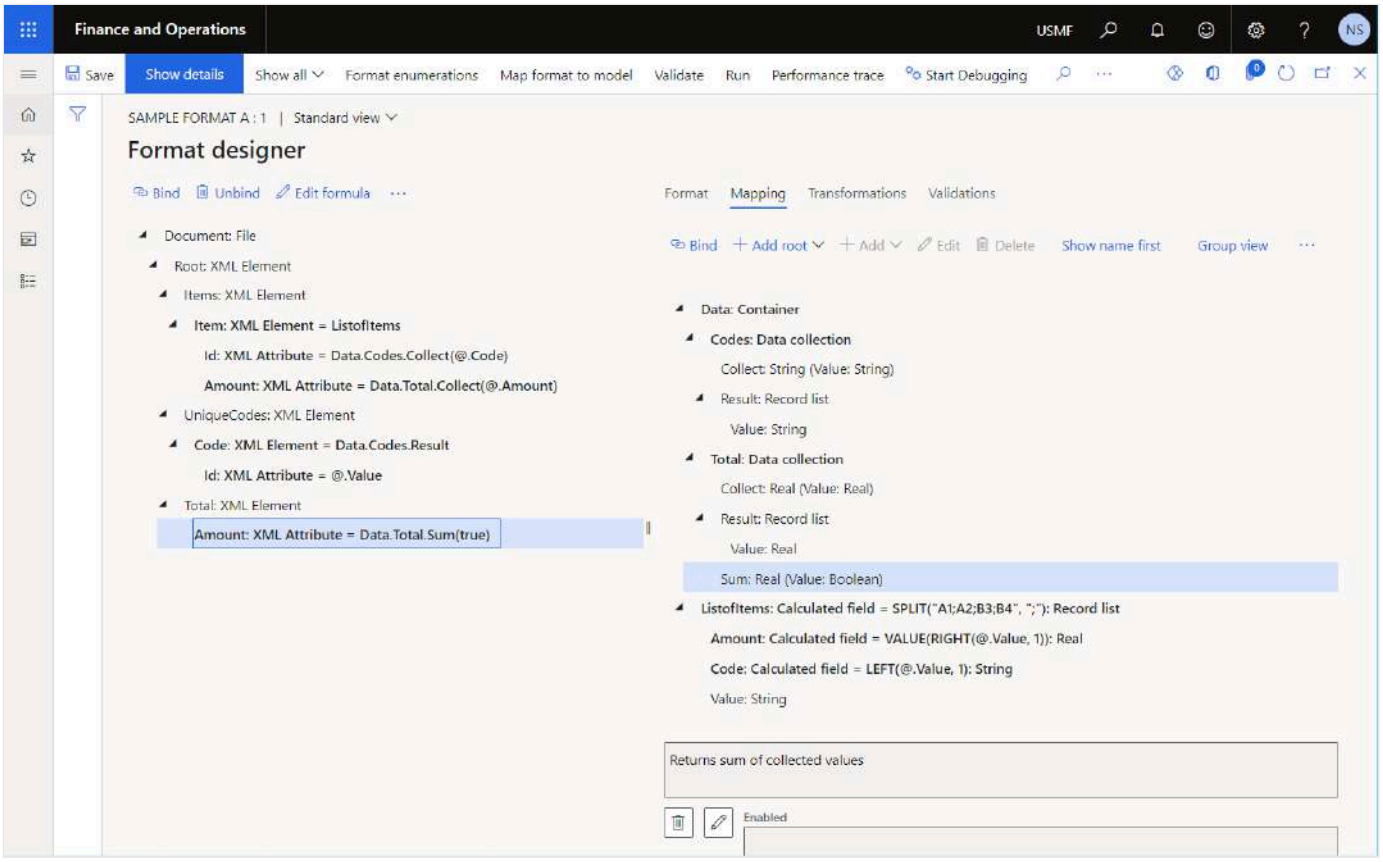
1. Select one of the following data types for the **Item type** property: *Int64*, *Integer*, or *Real*.
2. Set the **Collect all values** option of the configured **Data collection** data source to **Yes**.

When you set the **Collect all values** option to **Yes**, the **Sum(Flag)** parameterized property becomes available. Use this property to get the total amount of all currently collected values. In this property, the **Flag** argument is a *Boolean* value that indicates whether the total value must be reset.

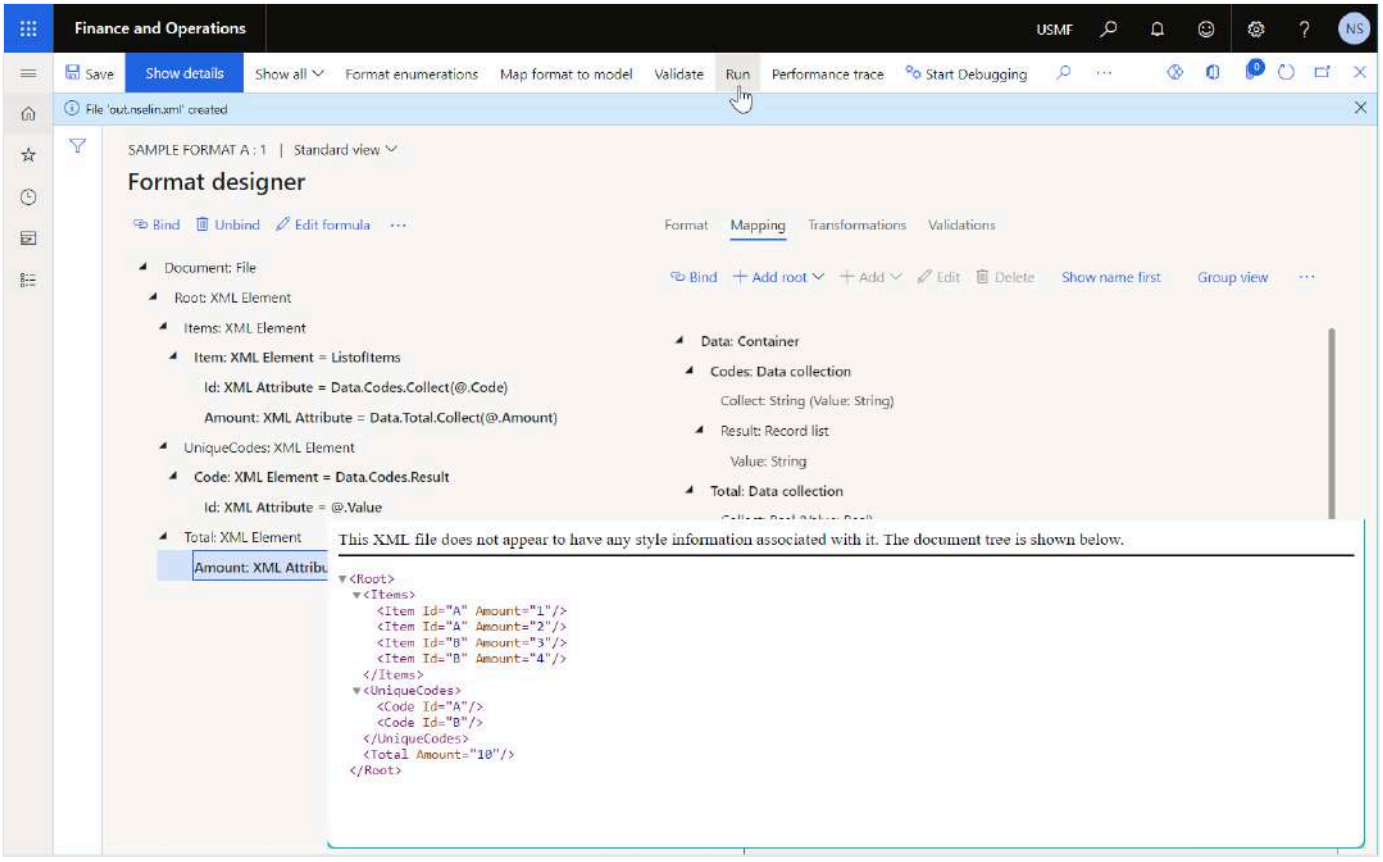
- If the value *False* is provided, summation continues from the previously collected amount.
- If the value *True* is provided, a new summation starts.

The following illustration shows the sample ER format that has two data sources of the *Data collection* type:

- The `Data.Codes` data source is configured to collect unique codes that are put in a generated document. The configured `Data.Codes.Result` binding is then used to put the list of unique codes in the footer of the generated document.
- The `Data.Total` data source is configured to calculate the total of values that are put in a generated document. The configured `Data.Total.Sum(true)` binding is then used to put this total value in the footer of the generated document.



The following illustration shows the result of running the previously described sample ER format that has two data sources of the *Data collection* type.



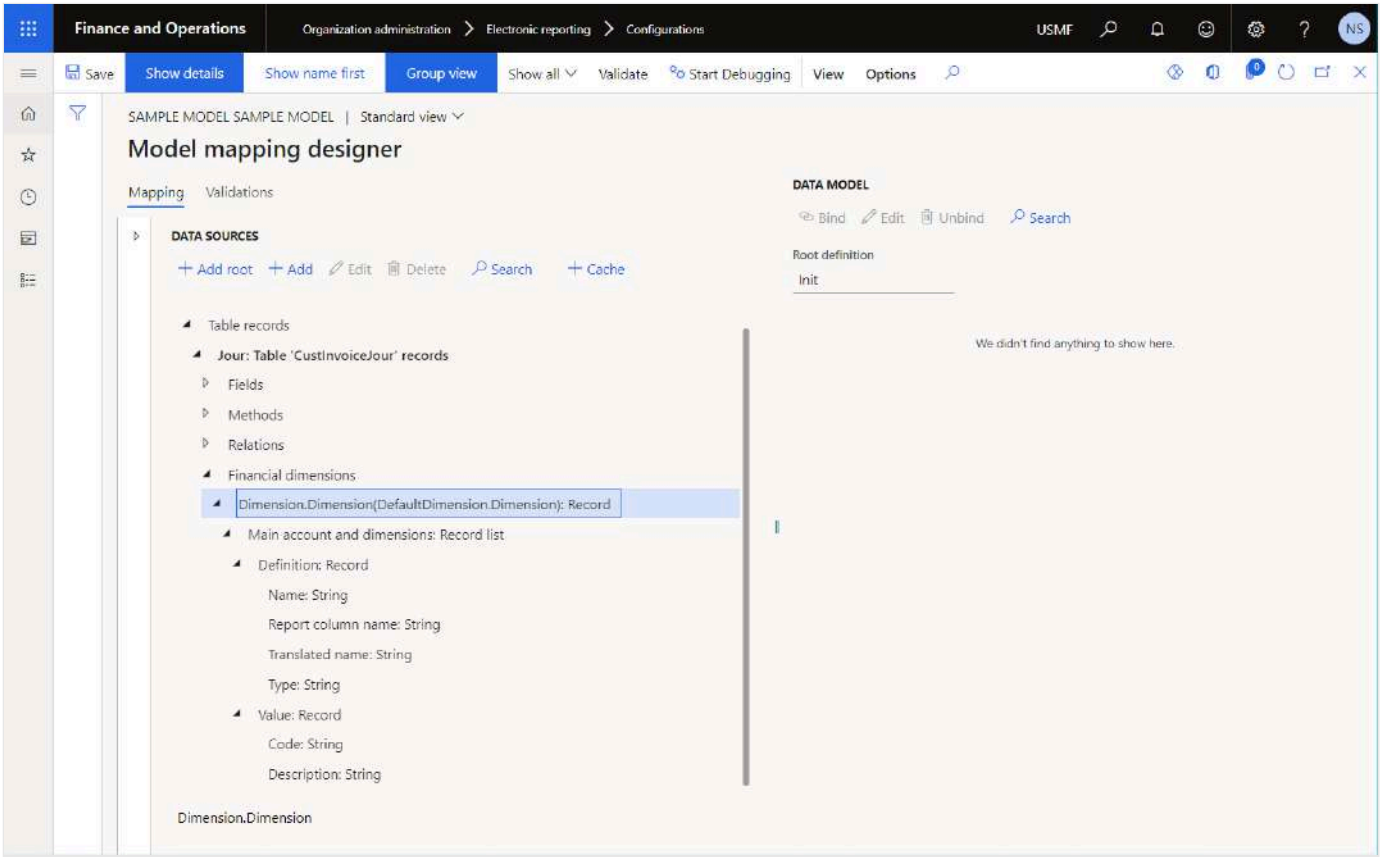
For more information, see Use DATA COLLECTION data sources in Electronic reporting formats.

Financial dimensions details

When you configure a data source of the *Table record* type that references an application table that supports the relation to financial dimensions, you see that this ER data source offers a field of the *Financial dimensions* type for every financial dimension relation. This field exposes the **Main account and dimensions** record list that enables access to financial dimensions as the list of records. Every record in this list represents a single dimension.

- The **Definition** record lets you access financial dimension metadata.
  - The **Name** field exposes the name of a financial dimension.
  - The **Report column name** field exposes the report alias of a financial dimension.
  - The **Translated name** field exposes the name of a financial dimension in the language that's specified by the language context of the ER solution that's running.
- The **Value** record lets you access a financial dimension value.
  - The **Code** field returns a financial dimension code.
  - The **Description** field returns a financial dimension name.

The following illustration shows a field of the *Financial dimensions* type of the **Table record** data source that you can use to access default financial dimensions for every record in the **CustInvoiceJour** application table.



Use the **Financial dimensions details** data source in the configured ER component to specify how the scope of financial dimensions is defined for any report that uses this component when a data consumer accesses a field of the *Financial dimensions* type. If you don't configure the **Financial dimensions details** data source in the editable ER component, the report uses all financial dimensions of the current application instance.

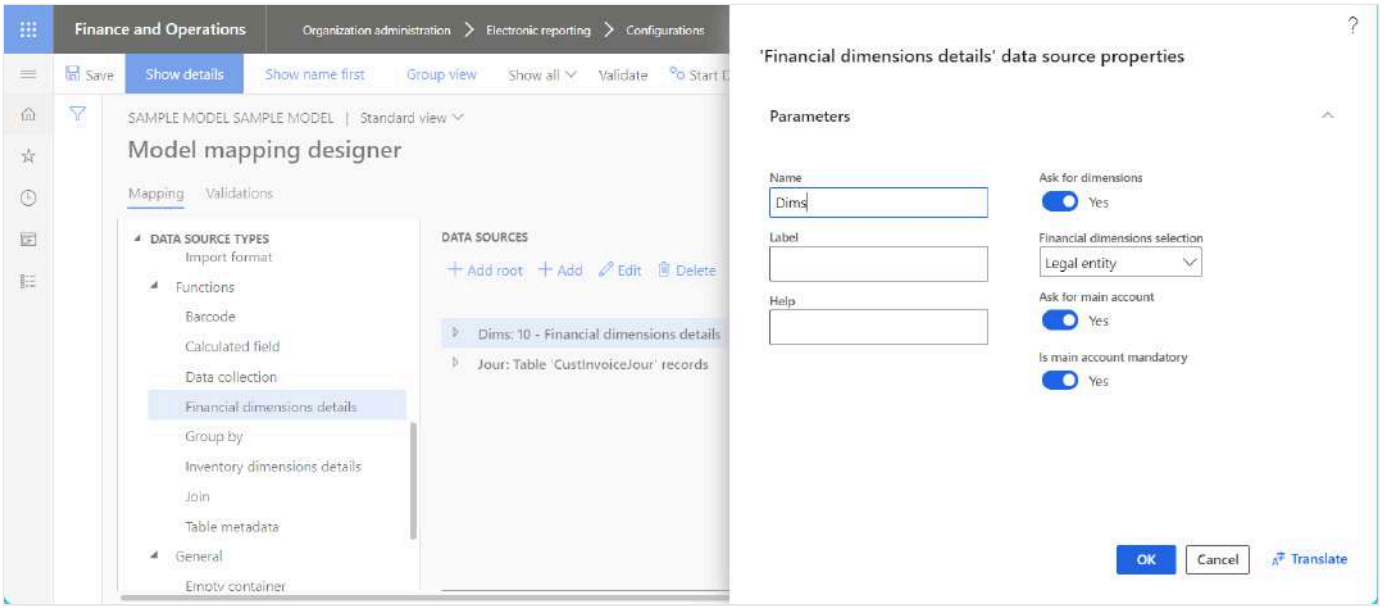
Set the **Ask for dimensions** option of the configured **Financial dimensions details** data source to **Yes** to let the user select dimensions in the dialog box at runtime. If you set the option to **No**, the report uses all financial dimensions of the current application instance by default.

When you set the **Ask for dimensions** option to **Yes**, the **Financial dimensions selection** option is enabled, and you can specify the scope of financial dimensions. The following options are available:

- Select **All** to use all financial dimensions of the current application instance.
- Select **Legal entity** to use only the financial dimensions of the company that an ER solution runs in the scope of.
- Select **Dimension set** to use only the financial dimensions of the dimension set that the user specifies in the dialog box at runtime.

Set the **Ask for main account** option to **Yes** to let the user select the main account as part of the list of dimensions in the dialog box at runtime. If you set the option to **No**, the main account isn't included in the list of dimensions, and the **Is main account mandatory** option is enabled. If you set the **Is main account mandatory** option to **Yes**, the main account is included in the list of dimensions, regardless of the user's selection.

The following illustration shows the data source of the *Financial dimensions details* type that you can use to specify the scope of financial dimensions for fields of the *Financial dimensions* type when the configured model mapping is used at runtime.



To learn more, complete the procedure in the following "ER Use financial dimensions as a data source" articles:

- Part 1 - Design data model
- Part 2 - Model mapping
- Part 3 - Design the report
- Part 4 - Run the report

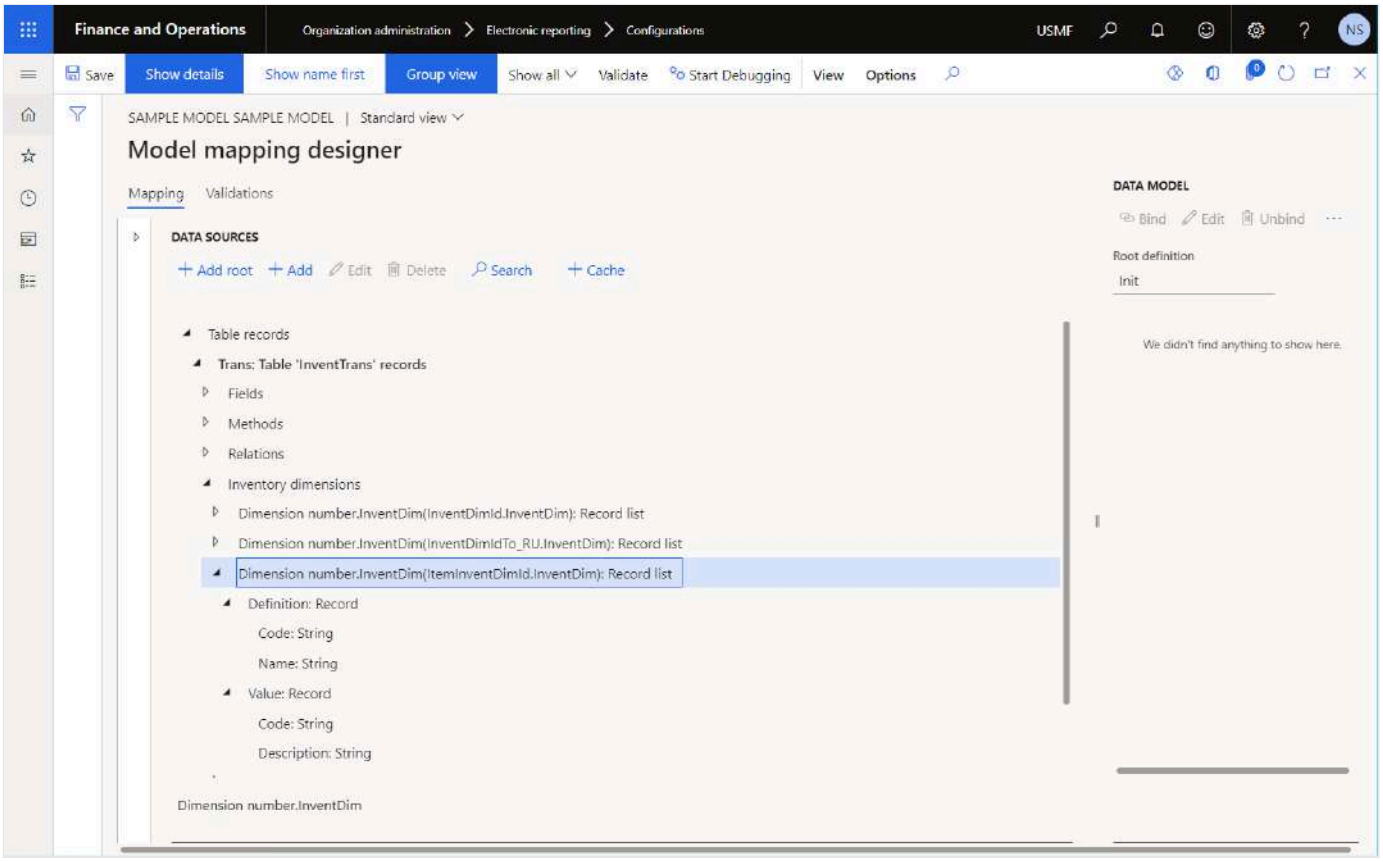
Inventory dimensions details

When you configure a data source of the *Table record* type that references an application table that supports the relation to inventory dimensions, you see that this ER data source offers a field of the *Inventory dimensions* type for every inventory dimension relation. This field exposes the **InventDim** record list that enables access to inventory dimensions as the list of records. Every record in this list represents a single dimension.

- The **Definition** record lets you access inventory dimension metadata.
  - The **Code** field exposes the code of an inventory dimension.
  - The **Name** field exposes the name of an inventory dimension.

- The **Value** record lets you access an inventory dimension value.
  - The **Code** field returns an inventory dimension code.
  - The **Description** field returns an inventory dimension name.

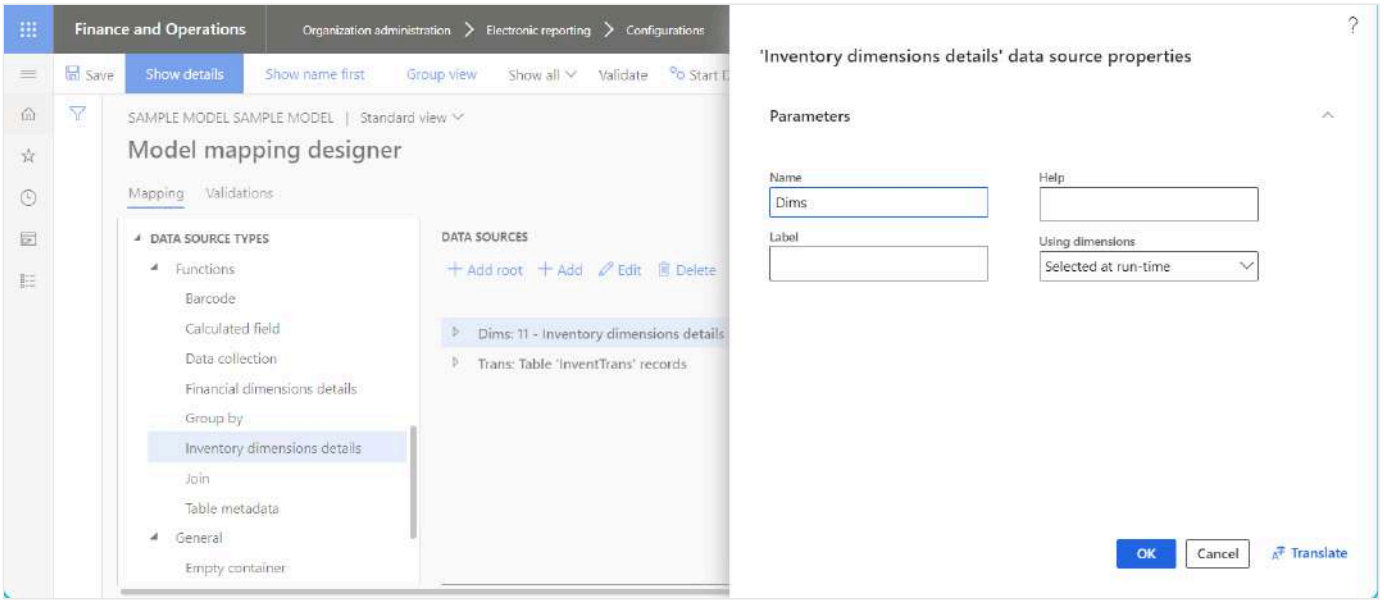
The following illustration shows a field of the *Inventory dimensions* type of the **Table record** data source that you can use to access several sets of inventory dimensions for every record in the **InventTrans** application table.



Use the **Inventory dimensions details** data source in the configured ER component to specify how the scope of inventory dimensions is defined for any report that uses this component when a field of the *Inventory dimensions* type is accessed by a data consumer. Set the **Using dimensions** property to specify the scope of inventory dimensions. The following options are available:

- Select the **All supported** option to use all inventory dimensions of the current application instance.
- Select the **Selected at run-time** option to use only the inventory dimensions that the user specifies in the dialog box at runtime.

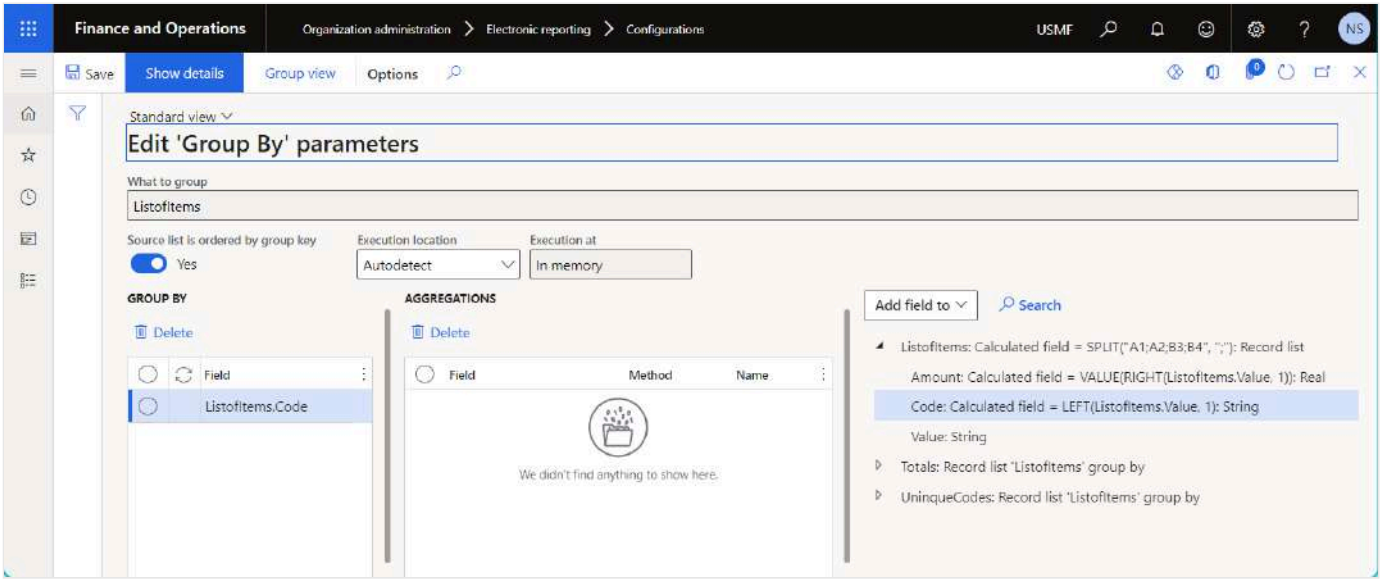
The following illustration shows the data source of the *Inventory dimensions details* type that you can use to specify the scope of inventory dimensions for the **Inventory dimensions* fields when the configured model mapping is used at runtime.



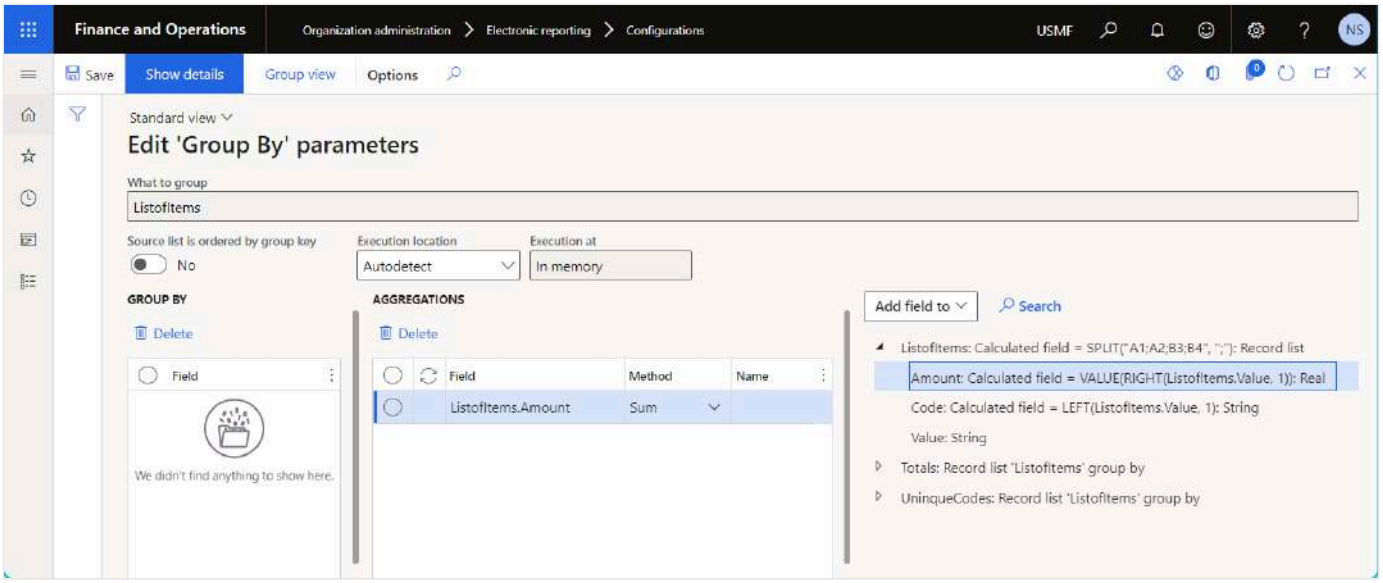
Group by

You can configure the **Group by** data source to group records of the base data source of the *Record list* type. For every generated group of records, this data source can calculate different aggregate functions.

The following illustration shows a data source of the *Group by* type that's set up to group records by code value.



The following illustration shows a data source of the *Group by* type that's set up to calculate the total amount for the initial list of records.



Follow these steps to configure grouping parameters on the **Edit Group By parameters** page.

- To specify the base data source for grouping, select the desired data source on the right side of the page, then select **Add field** > **What to group**.
- To specify a field for grouping, select the desired field of the specified base data source on the right side of the page, then select **Add field to** > **Grouped fields**.
- To specify a field for calculating the aggregated value, select the desired field of the specified base data source on the right side of the page, then select **Add field to** > **Aggregation fields**.
- Set the **Source list is ordered by group key** option to **Yes** to sort the group of records based on the values of fields that you select for grouping.

The following aggregate functions are currently supported.

Expand table

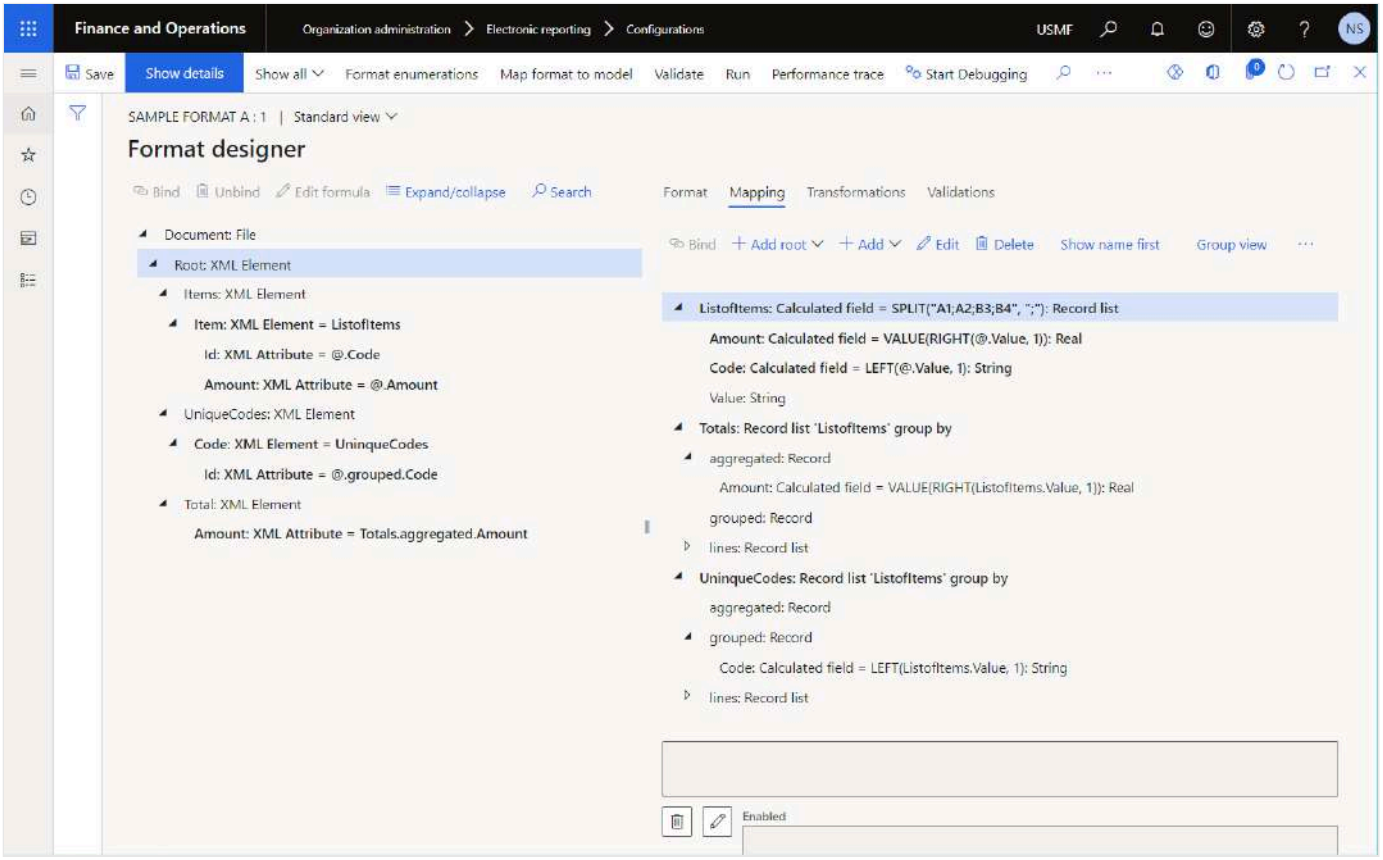
Name	Description	Applicability
AVG	This function returns the average of the values in a group.	This function can be used only with numeric fields.
COUNT	This function returns the number of items that were found in a group.	
MIN	This function returns the minimum value among the values in a group.	
MAX	This function returns the maximum value among the values in a group.	
SUM	This function returns the sum of all the values in a group.	This function can be used only with numeric fields.

Depending on the nature of the base data source, the grouping and aggregation can be done either at the database level or in memory. To specify the execution location, select the desired option for the **Execution location** property of the configured data source:

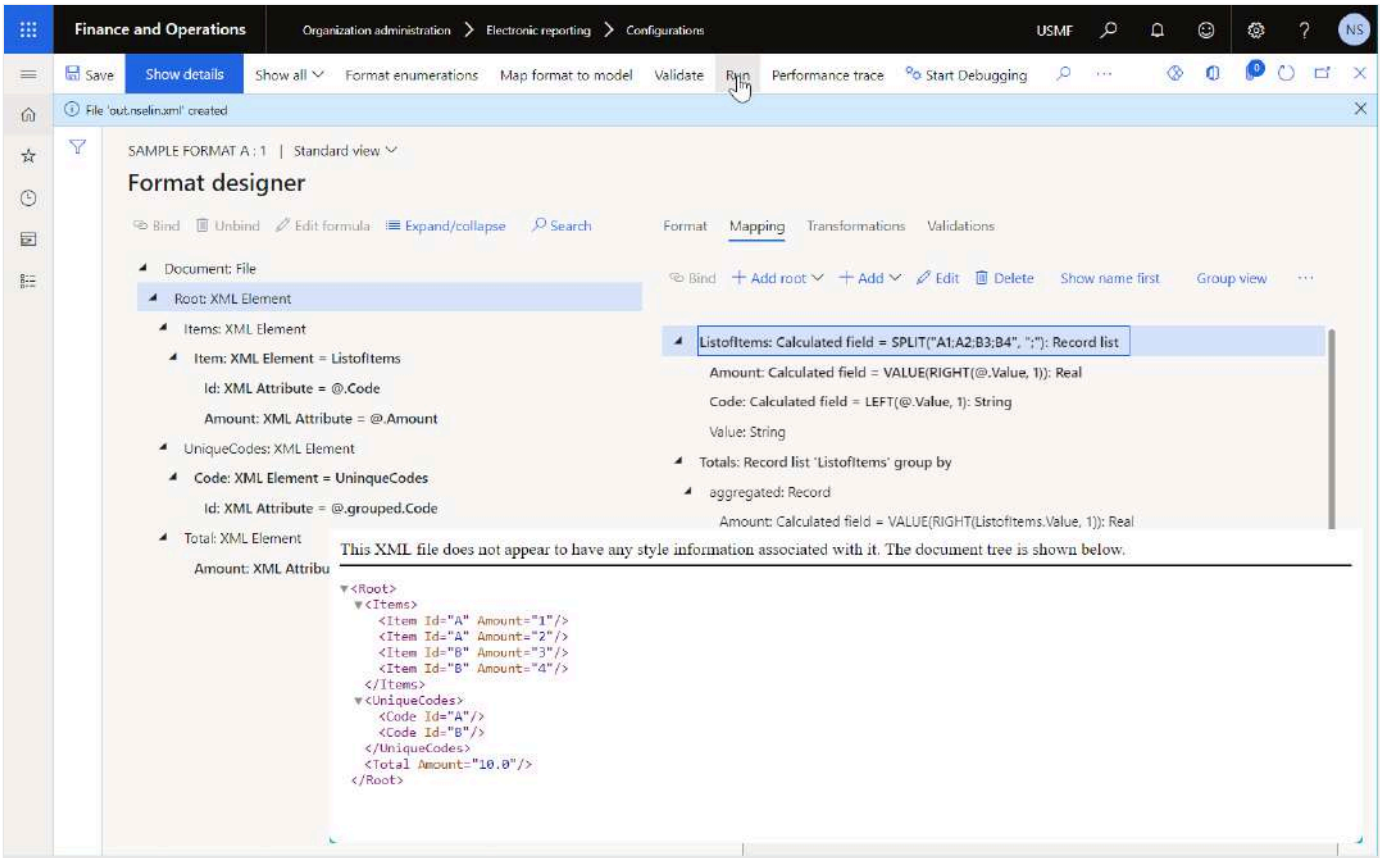
- Select the **In memory** option to do grouping and aggregation in application memory.
- Select the **Query** option to do grouping and aggregation in the application database when applicable.
- Leave the default **Autodetect** option to let ER identify the most appropriate execution location. If the base data source is queryable, the **Query** option is applied when you save changes to the configured data source. Otherwise, the **In memory** option is applied.

The configured **Group by** data source exposes a single record for every group of records of the base data source. This **Group by** data source is structured to expose the results of data grouping and aggregation for each group of records at runtime.

- The **aggregated** record exposes the value of each configured aggregation.
- The **grouped** record exposes the value of each grouping field.
- The **lines** record list exposes records of the base data source that belongs to the current group.



The following illustration shows the result of running the previously described sample ER format that has two data sources of the *Group by* type.



For more information, see Group records and aggregate calculations by using GROUPBY data sources.

Join

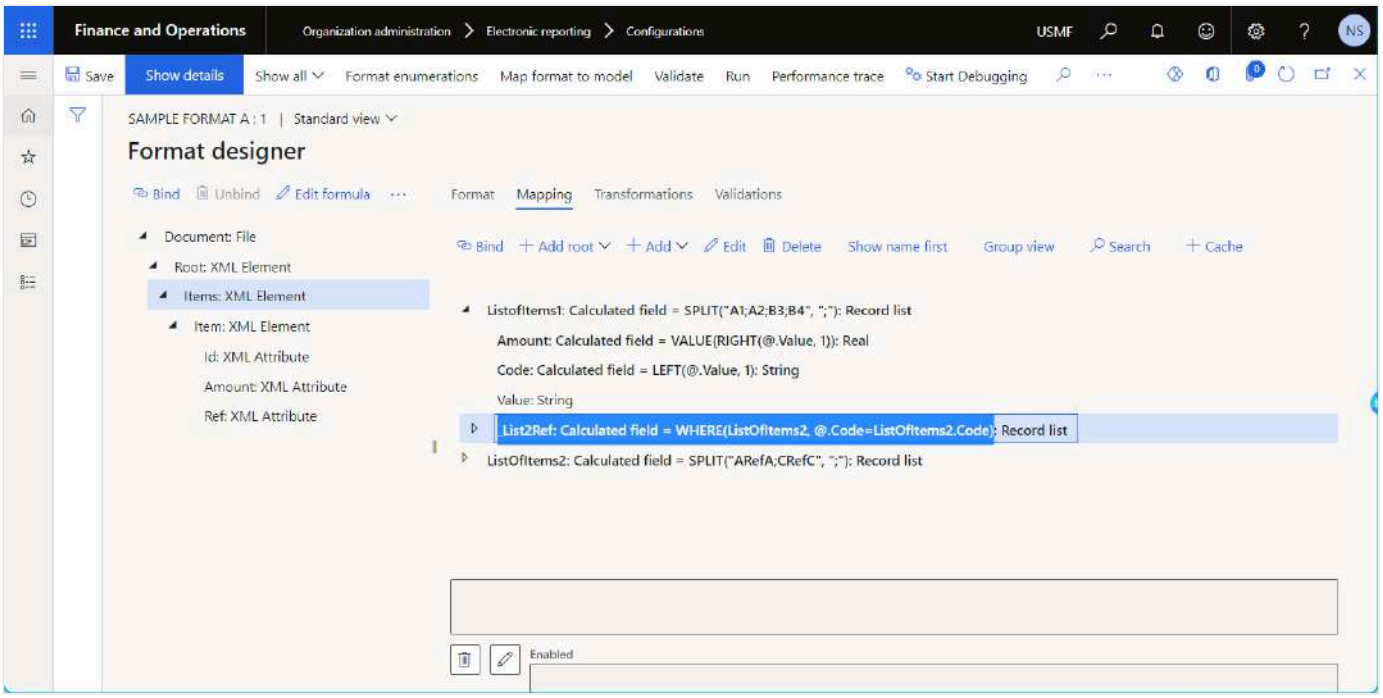
You can configure the **Join** data source to fetch records from several base data sources and return a joined list of records that contains fields from the records of the base data sources.

> **Tip**
>
> Because you can join many data sources that have multiple fields, use the **Select fields** function for any base data source of the configured **Join** data source to limit the list of fields whose values are fetched at runtime. For more information, see **Improve performance of ER solutions by reducing the number of table fields that are fetched at runtime**.

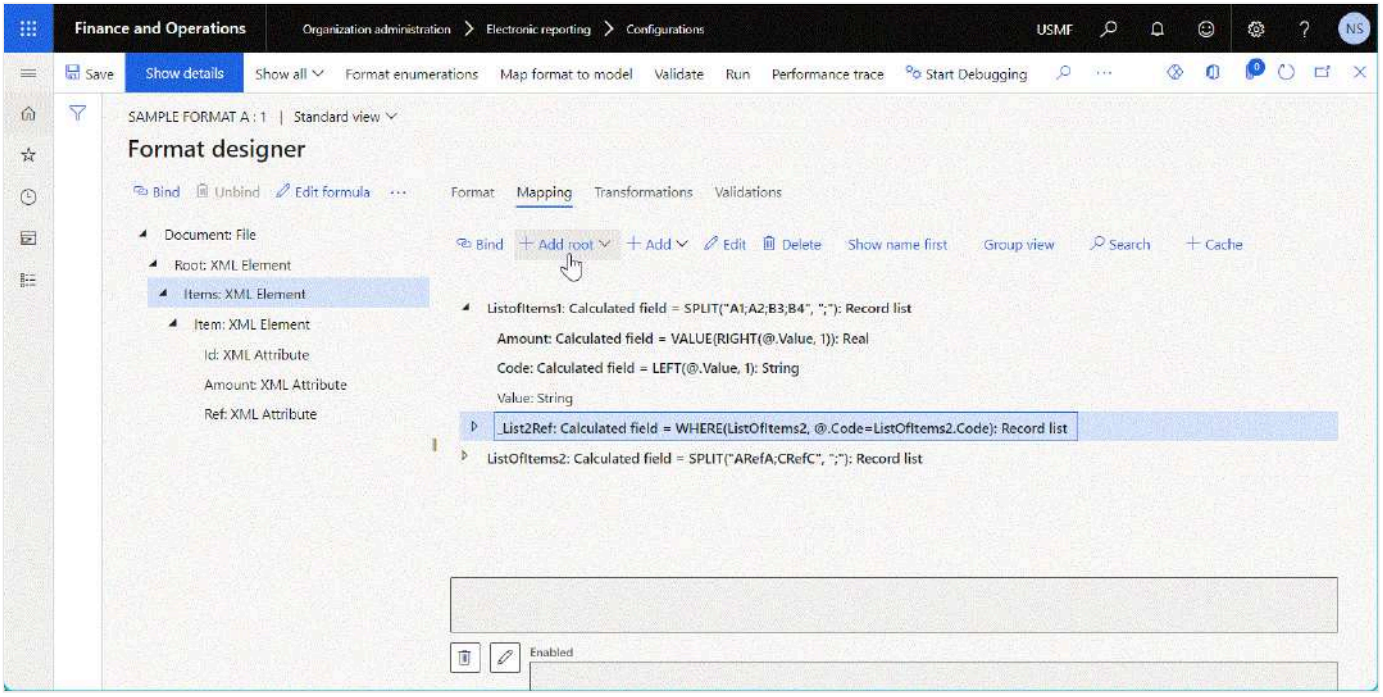
The following types of joins are currently supported:

- **Outer (left)** – Join all records of the first (leftmost) data source and then any records of the second (rightmost) data source that match in accordance with the configured conditions.
- **Inner (right)** – Join only those records of the first (leftmost) and second (rightmost) data sources that match each other in accordance with the configured conditions.

> **Note**
>
> You must configure the data sources that you want to join as nested fields of the *Calculated field* type, and you must specify the join criteria for every configured base data source.



The following illustration shows the configuration of a data source of the *Join* type on the **Join designer** page. To add a data source to the joined list, select the data source on the right side of the page, then use the **Add** button above the **Joined lists** grid.

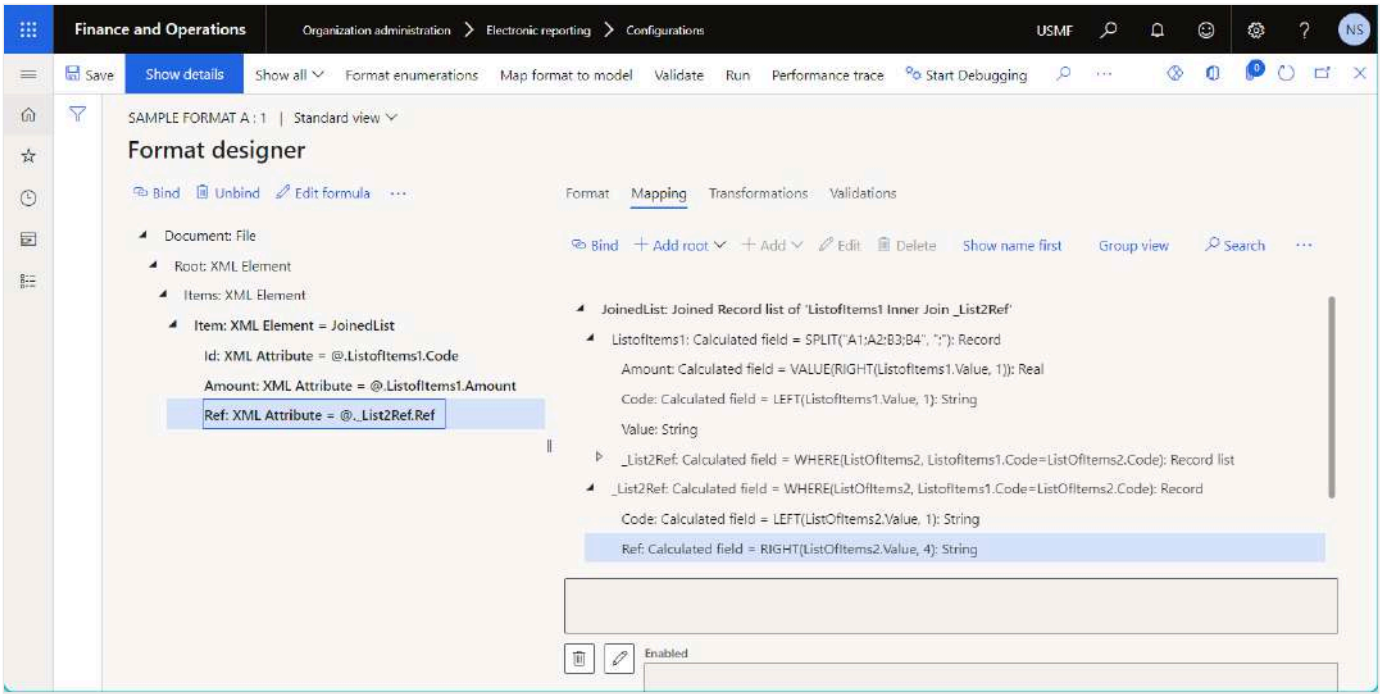


Depending on the nature of the base data sources, the join can be done either at the database level or in memory. To specify the execution location, select the desired option for the **Execute**

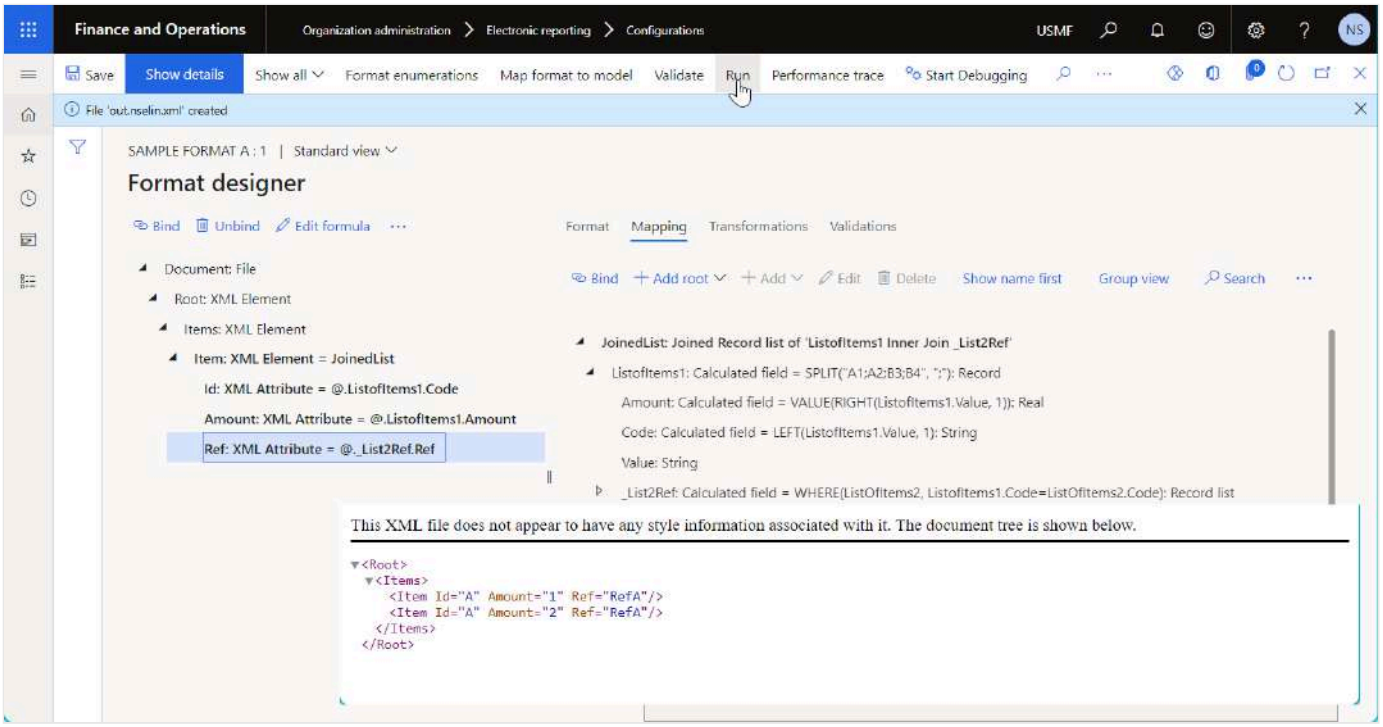
property of the configured **Join** data source:

- Select the **In memory** option to do the join in application memory.
- Select the **Query** option to do the join in the application database when applicable.

This **Join** data source includes several base data sources that you configure under each other as nested fields of the *Calculated field* type. The expression of every configured calculated field includes the condition that's used to associate records of the base data source with records of the nested data source.



The following illustration shows the result of running the previously described sample ER format that has a data source of the *Join* type.

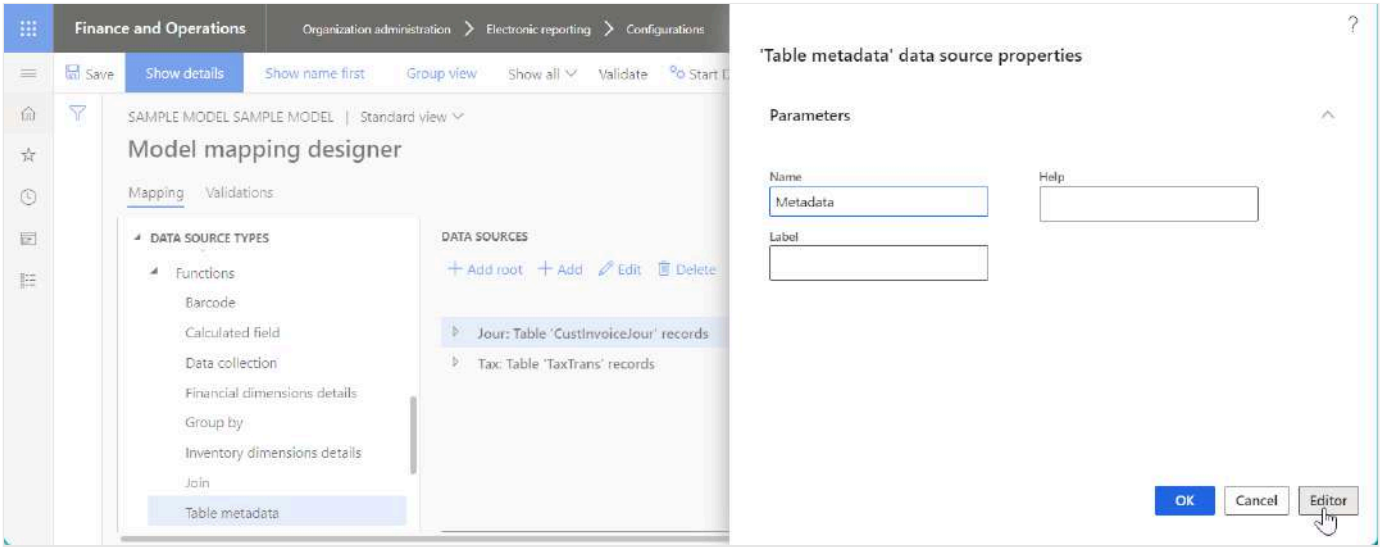


For more information, see Use JOIN data sources to get data from multiple application tables in Electronic reporting (ER) model mappings.

Table metadata

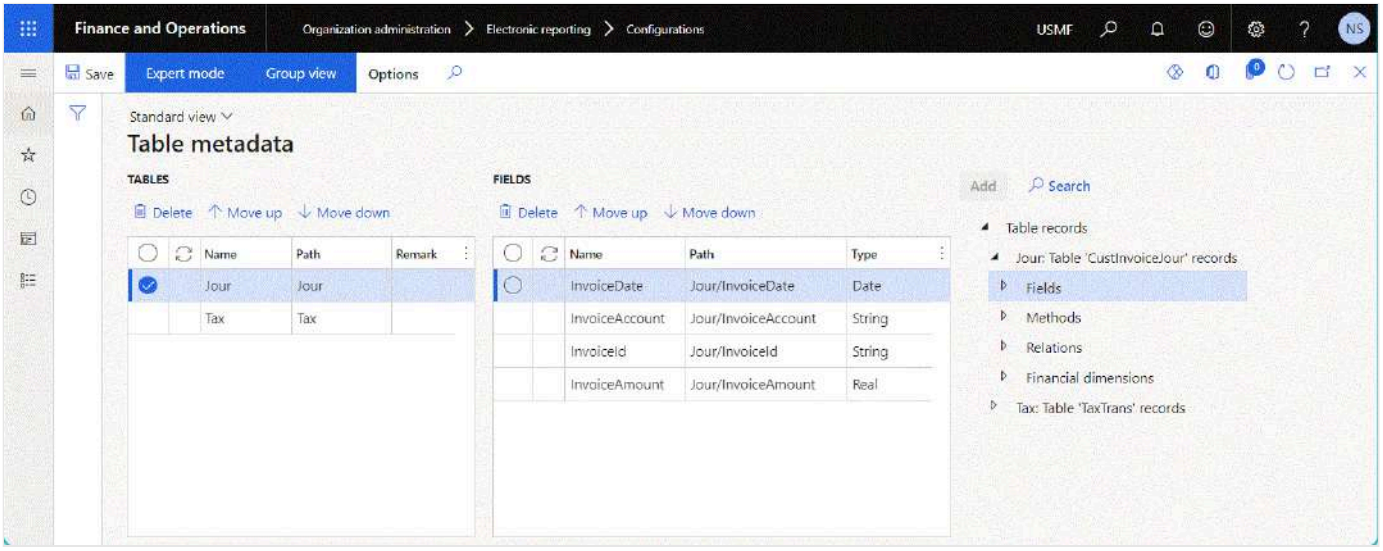
You can configure a **Table metadata** data source to simultaneously access the metadata and data of one or many ER data sources that you configured to return data of the *Record list* type.

When you add a new **Table metadata** data source, use the **Editor** button in the **Data source properties** dialog box to access the **Table metadata** page, where you can configure the added data source.

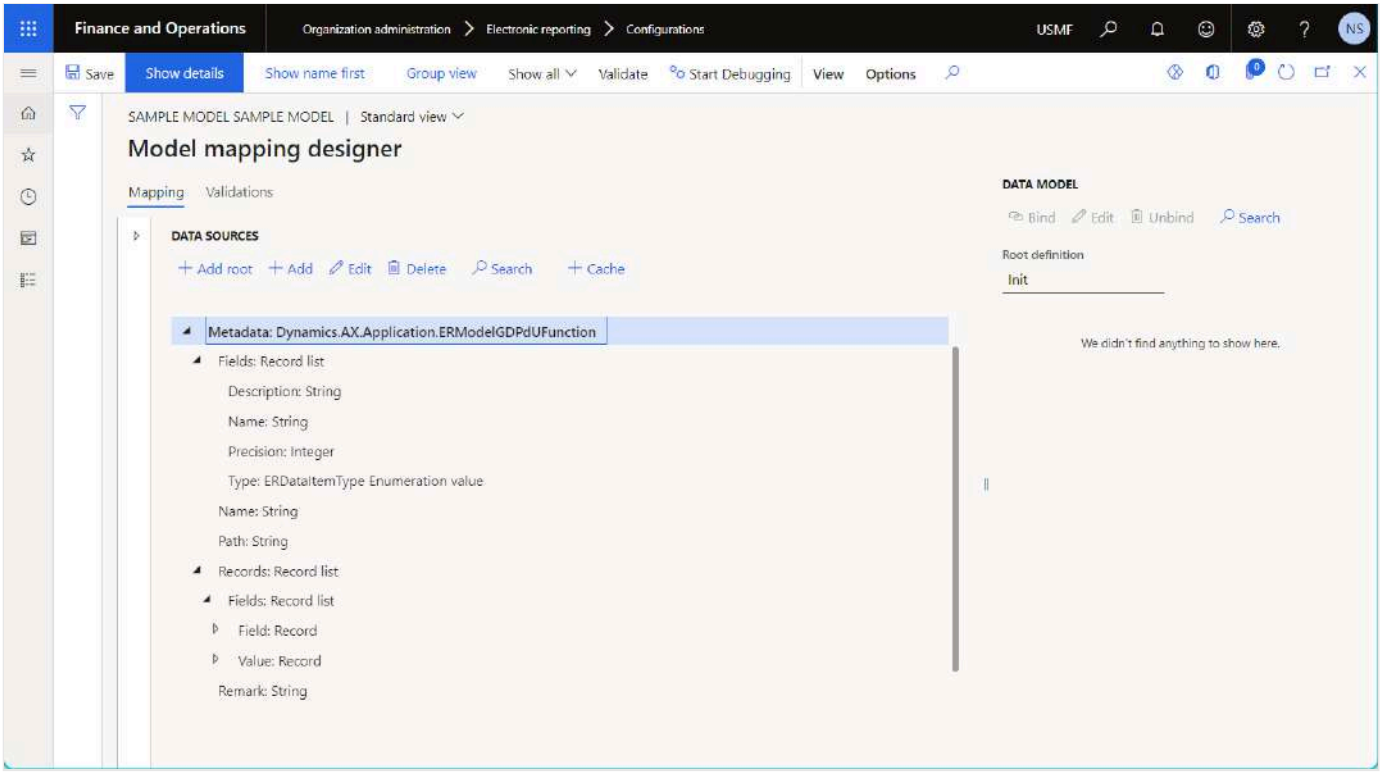


You can add the following items to the editable **Table metadata** data source:

- A data source that returns *Record list* data. Select the desired data source on the right side of the **Table metadata** page, then select **Add**.
- A field of the added data source. Select the desired field on the right side of the **Table metadata** page, then select **Add**.



The following illustration shows the configured data source of the *Table metadata* type.

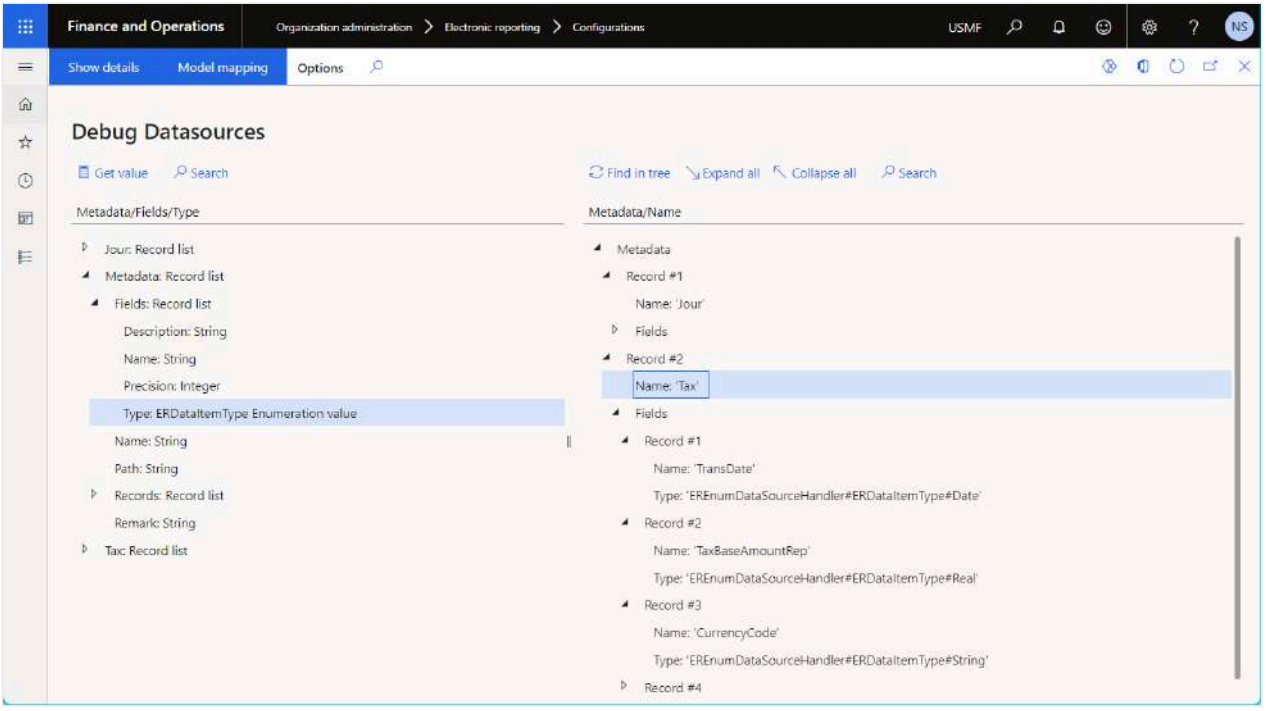


The configured data source of the *Table metadata* type returns a single record for each added ER data source that returns *Record list* data.

- **Name** returns the title of the appropriate data source.
- **Path** returns the path of the appropriate data source in the editable ER component (model mapping).

- **Remark** returns the description of the appropriate data source.
- **Fields** returns the list of fields of the current data source.
    - **Fields.Name** returns the title of the appropriate field.
    - **Fields.Description** returns the description of the appropriate field.
    - **Fields.Type** returns the type of the appropriate field as a value of the **ERDataItemType** enumeration.
    - **Fields.Precision** returns the precision of the appropriate field if this field returns a numeric value.

      The following illustration shows results of metadata debugging for the configured data source of the *Table metadata* type.



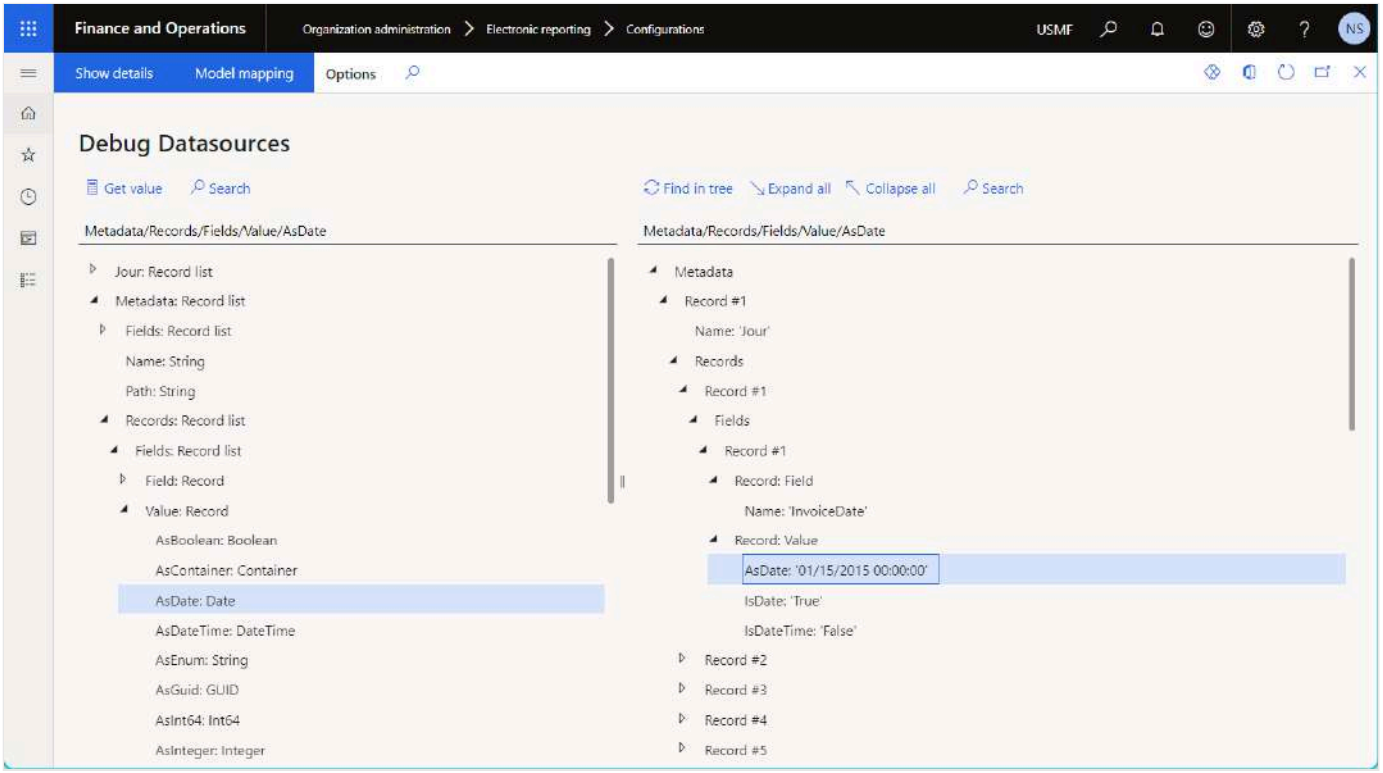
- **Records** returns the records of the appropriate data source.
    - **Records.Fields** represents fields of the current record.
        - **Records.Fields.Field.Name** returns the title of the appropriate field.
        - **Records.Fields.Field.Description** returns the description of the appropriate field.
        - **Records.Fields.Field.Type** returns the type of the appropriate field as a value of the **ERDataItemType** enumeration.

- **Records.Fields.Field.Precision** returns the precision of the appropriate field if this field returns a numeric value.

- **Records.Fields.Value** represents the value of the current field of the current record.
  - **Records.Fields.Value.AsBoolean** returns the value of the current field when the type of this field is *Boolean*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Boolean* type.
  - **Records.Fields.Value.AsContainer** returns the value of the current field when the type of this field is *Container*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Container* type.
  - **Records.Fields.Value.AsDate** returns the value of the current field when the type of this field is *Date*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Date* type.
  - **Records.Fields.Value.AsDateTime** returns the value of the current field when the type of this field is *DateTime*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *DateTime* type.
  - **Records.Fields.Value.AsEnum** returns the value of the current field when the type of this field is *Enumeration*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Enumeration* type.
  - **Records.Fields.Value.AsGuid** returns the value of the current field when the type of this field is *Guid*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Guid* type.
  - **Records.Fields.Value.AsInt64** returns the value of the current field when the type of this field is *Int64*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Int64* type.
  - **Records.Fields.Value.AsInteger** returns the value of the current field when the type of this field is *Integer*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Integer* type.
  - **Records.Fields.Value.AsReal** returns the value of the current field when the type of this field is *Real*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Real* type.
  - **Records.Fields.Value.AsString** returns the value of the current field when the type of this field is *String*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *String* type.
  - **Records.Fields.Value.AsTime** returns the value of the current field when the type of this field is *Time*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Time* type.

- **Records.Fields.Value.AsVoid** returns the value of the current field when the type of this field is *Void*. An exception is thrown at runtime if you try to fetch this property for a field that isn't of the *Void* type.
- **IsBoolean** returns **True** for a field of the *Boolean* type. Otherwise, it returns **False**.
- **IsContainer** returns **True** for a field of the *Container* type. Otherwise returns **False**.
- **IsDate** returns **True** for a field of the *Date* type. Otherwise, it returns **False**.
- **IsDateTime** returns **True** for a field of the *DateTime* type. Otherwise, it returns **False**.
- **IsEnum** returns **True** for a field of the *Enumeration* type. Otherwise, it returns **False**.
- **IsGuid** returns **True** for a field of the *Guid* type. Otherwise, it returns **False**.
- **IsInt64** returns **True** for a field of the *Int64* type. Otherwise, it returns **False**.
- **IsInteger** returns **True** for a field of the *Integer* type. Otherwise, it returns **False**.
- **IsReal** returns **True** for a field of the *Real* type. Otherwise, it returns **False**.
- **IsString** returns **True** for a field of the *String* type. Otherwise, it returns **False**.
- **IsTime** returns **True** for a field of the *Time* type. Otherwise, it returns **False**.
- **IsVoid** returns **True** for a field of the *Void* type. Otherwise, it returns **False**.

The following illustration shows the results of data debugging for the configured data source of the *Table metadata* type.



To learn more about data sources of the *Table metadata* type, download and review the **German audit file output** ER format configuration from the Global repository. Notice that the **Data export model** configuration that you download with the selected ER format contains the **German audit file - default groups** model mapping that's configured to use the *Table metadata* data source to

access different application tables. The downloaded **German audit file output** ER format configuration consumes this model mapping to generate country/region-specific audit reports.

Frequently asked questions

Question: I'm trying to add a new data source of the *Table records* type that references a custom table. However, I can't find that table in the lookup of the **Table** field in the **Data source properties** dialog box.

Answer: The ER metadata of your application instance is obsolete. Use either the **Refill table** function or the **Rebuild table references** function to refresh the ER metadata and align it with your source code base.

Formula designer in Electronic reporting (ER)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to use the formula designer in Electronic reporting (ER). When you design a format for a specific electronic document in ER, use formulas to transform data so that it meets the requirements for the document's fulfillment and formatting. These formulas resemble formulas in Microsoft Excel. The formulas support various types of functions, including text, date and time, mathematical, logical, information, and data type conversion functions, as well as other business domain–specific functions.

Formula designer overview

ER supports the formula designer. At design time, you can configure expressions that can be used for the following tasks at runtime:

- Transform data that you receive from an application database and that you enter in an ER data model designed to be a data source for ER formats. For example, these transformations might include filtering, grouping, and data type conversion.
- Format data that you must send to a generating electronic document in accordance with the layout and conditions of a specific ER format. For example, the formatting might be done in accordance with the requested language or culture, or the encoding.
- Control the process of creating electronic documents. For example, the expressions can enable or disable the output of specific elements of the format, depending on processing data. They can also interrupt the document creation process or throw messages to users.

Open the **Formula designer** page when you perform any of the following actions:

- Bind data source items to data model components.
- Bind data source items to format components.

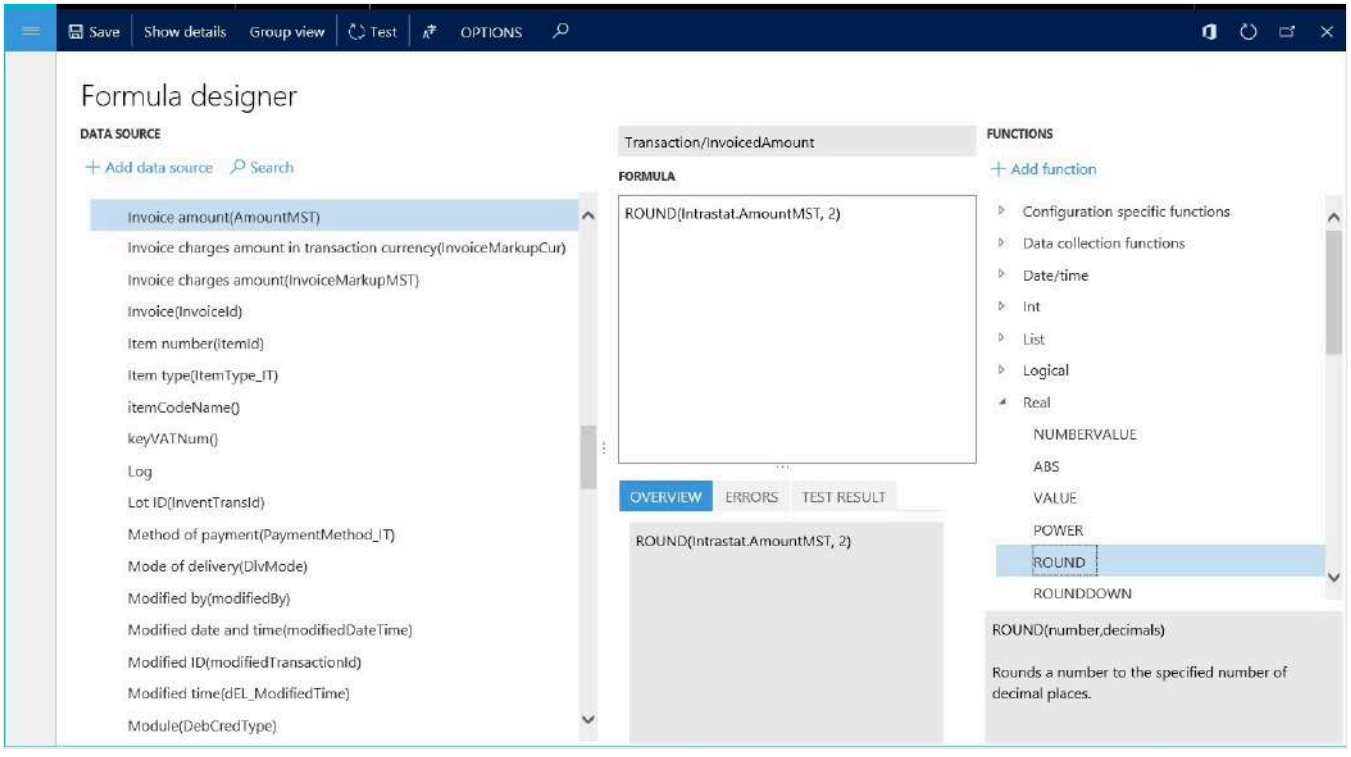
- Complete maintenance of calculated fields that are part of data sources.
- Define the visibility and editability conditions for user input parameters.
- Define the default values for user input parameters.
- Design a format's transformations.
- Define the enabling conditions for the format's components.
- Define the file names for the format's FILE components.
- Define the conditions for process control validations.
- Define the message text for process control validations.

Data binding

Use the ER formula designer to define an expression that transforms data received from data sources. At runtime, enter the data in the data consumer in the following ways:

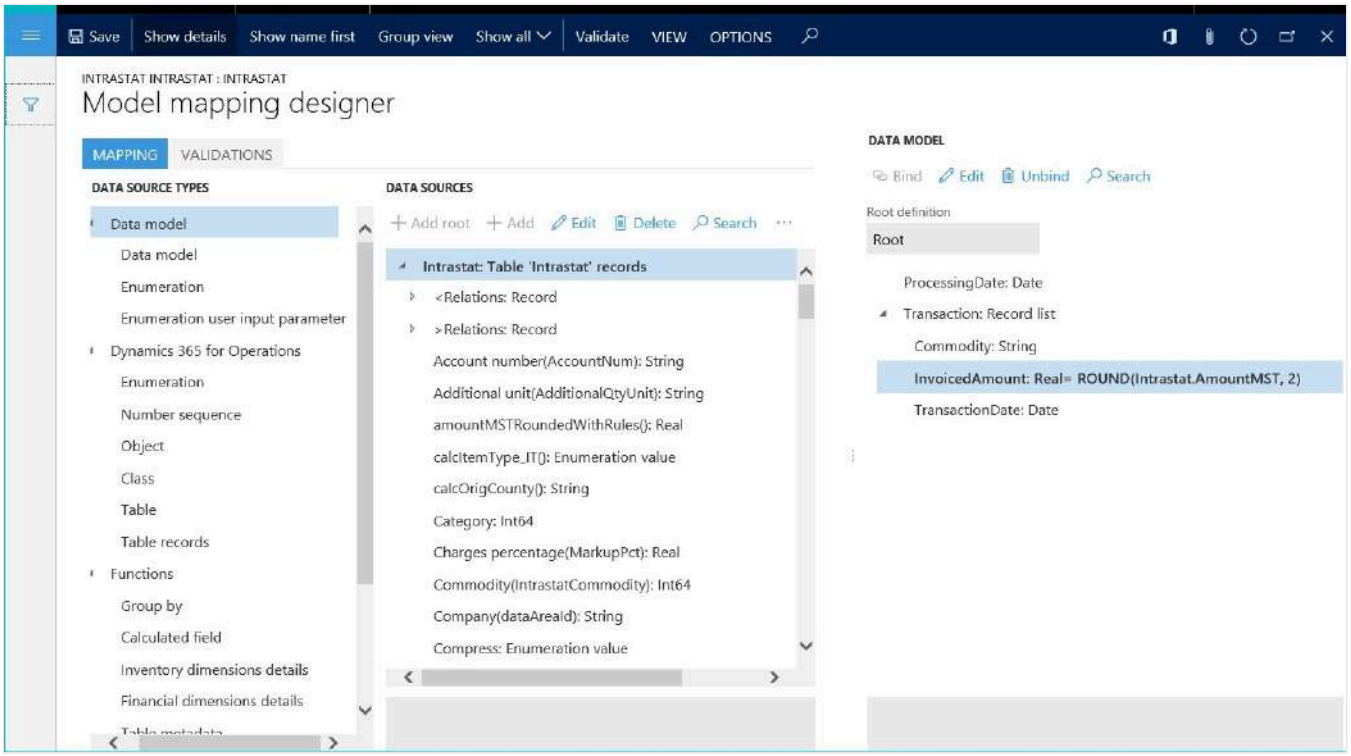
- From application data sources and runtime parameters to an ER data model
- From an ER data model to an ER format
- From application data sources and runtime parameters to an ER format

The following illustration shows the design of an expression of this type. In this example, the expression rounds the value of the **Intrastat.AmountMST** field in the Intrastat table to two decimal places and then returns the rounded value.



The following illustration shows how you can use an expression of this type. In this example, the result of the designed expression is entered in the **Transaction.InvoicedAmount**

component of the **Tax reporting model** data model.

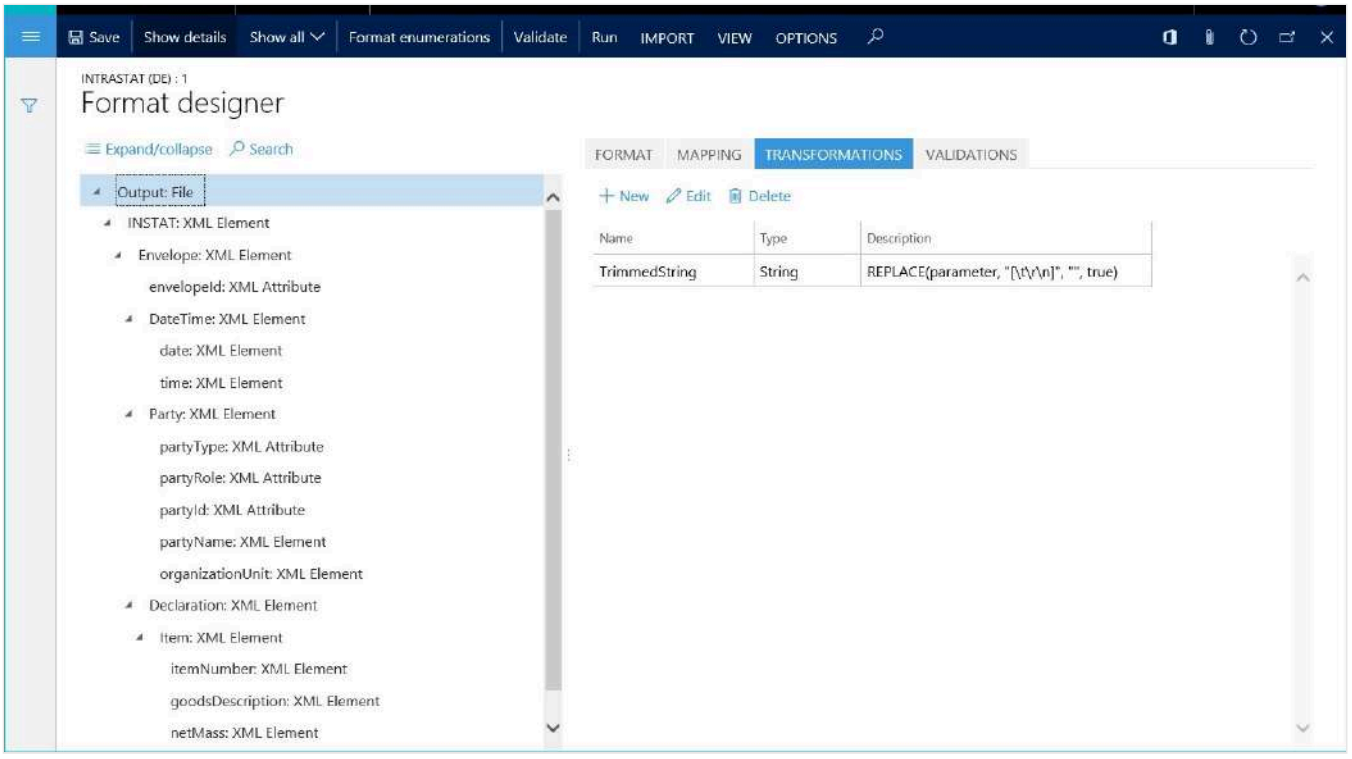


At runtime, the designed formula, `ROUND (Intrastat.AmountMST, 2)`, rounds the value of the **AmountMST** field for each record in the Intrastat table to two decimal places. It then enters the rounded value in the **Transaction.InvoicedAmount** component of the **Tax reporting** data model.

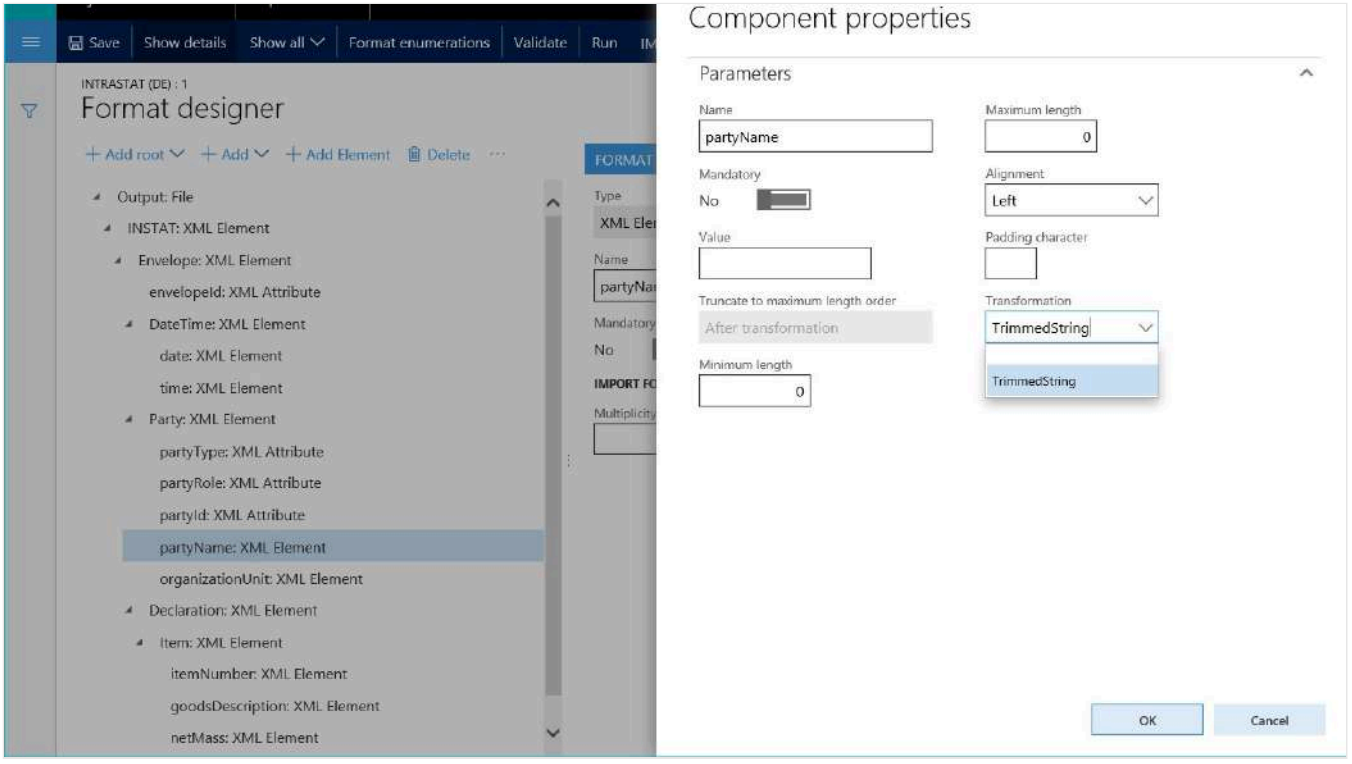
Data formatting

Use the ER formula designer to define an expression that formats data received from data sources. You can send the formatted data as part of the generating electronic document. If you have formatting that you want to apply as a typical rule and reuse for a format, introduce that formatting one time in the format configuration as a named transformation that has a formatting expression. You can link this named transformation to many format components where the output must be formatted according to the formatting expression that you created.

The following illustration shows the design of a transformation of this type. In this example, the **TrimmedString** transformation truncates incoming data of the *String* data type by removing leading and trailing spaces. It then returns the truncated string value.

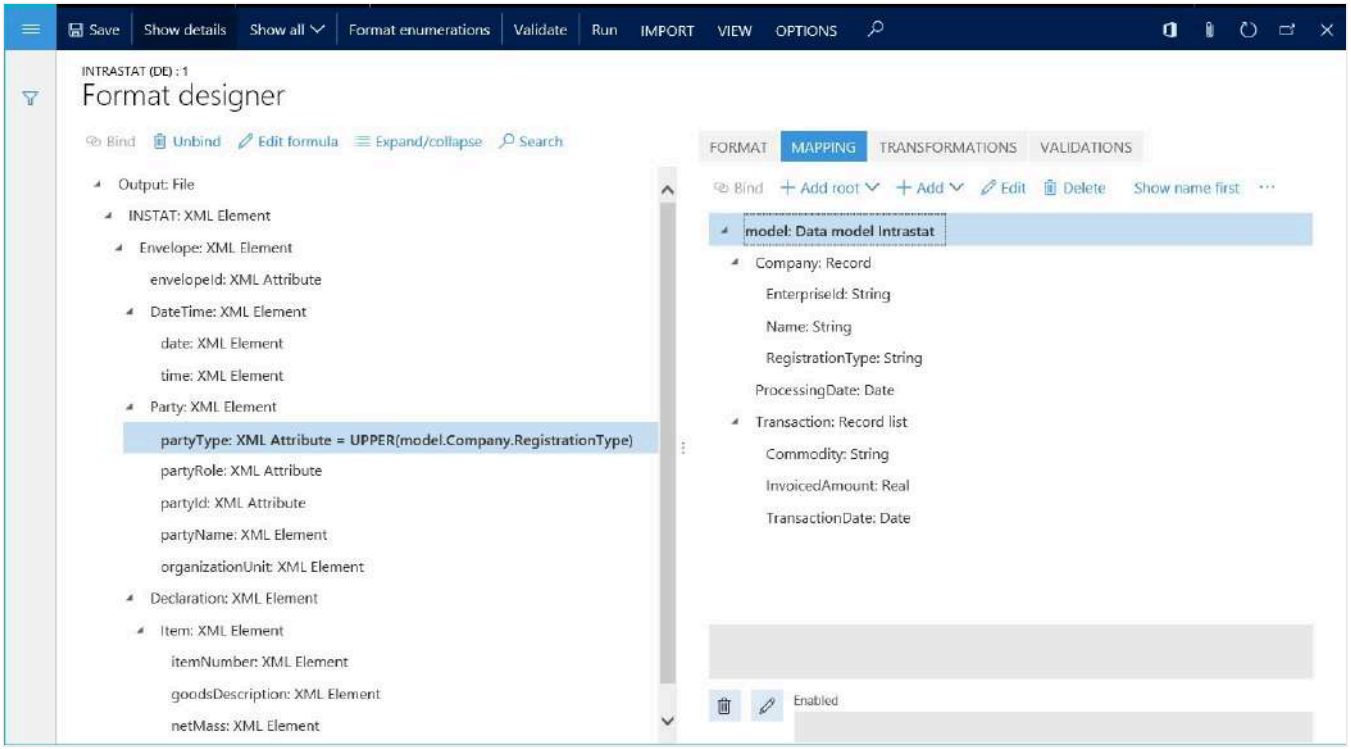


The following illustration shows how you can use a transformation of this type. In this example, several format components send text as output to the generating electronic document at runtime. All these format components refer to the **TrimmedString** transformation by name.



When format components, such as the **partyName** component in the preceding illustration, refer to the **TrimmedString** transformation, the transformation sends text as output to the generating electronic document. This text doesn't include leading and trailing spaces.

If you have formatting that you must apply individually, introduce that formatting as an individual expression of a binding of a specific format component. The following illustration shows an expression of this type. In this example, the **partyType** format component is bound to the data source via an expression that converts incoming data from the **Model.Company.RegistrationType** field in the data source to uppercase text. The expression then sends that text as output to the electronic document.



Process flow control

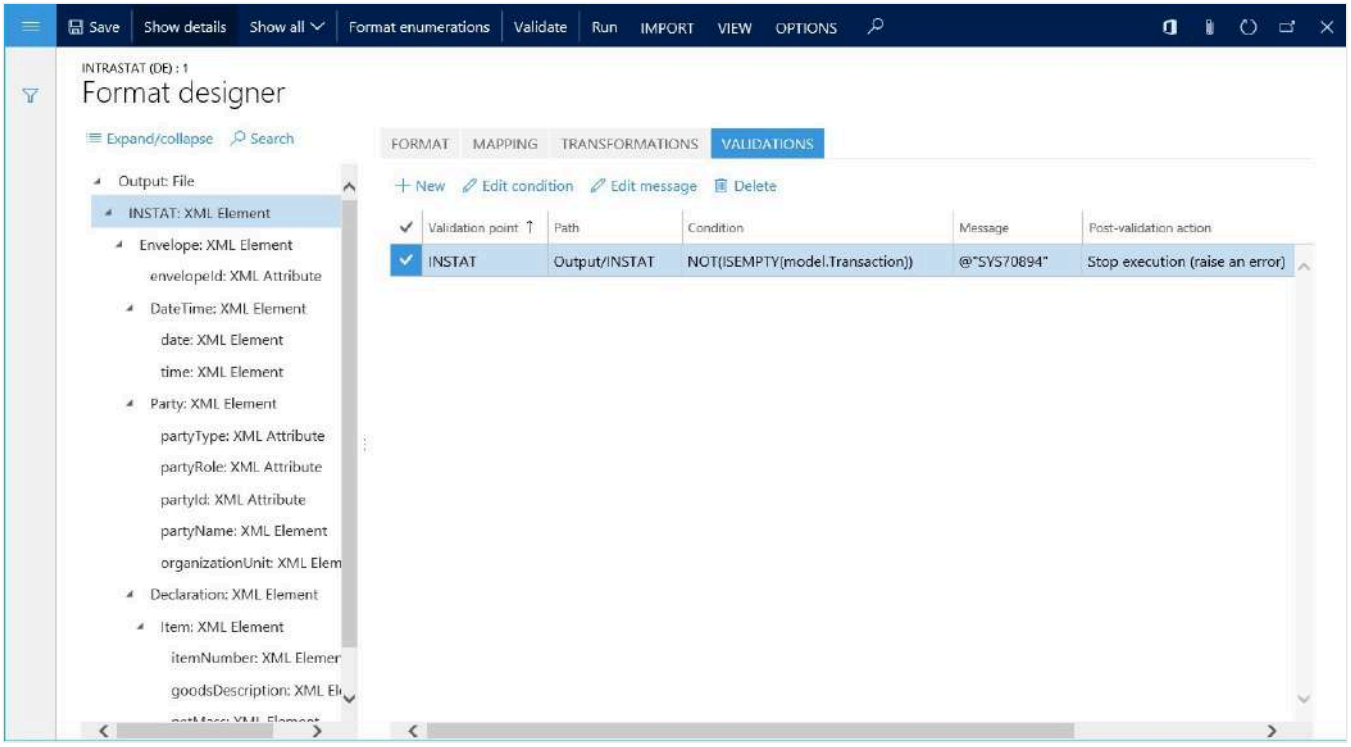
Use the ER formula designer to define expressions that control the process flow of generating electronic documents. You can perform the following tasks:

- Define conditions that determine when to stop a document creation process.
- Specify expressions that either create messages for the user about stopped processes or throw execution log messages about the continuing process of report generation.
- Specify the file names of generating electronic documents, and control the conditions of their creation.

Each rule of the process flow control is designed as an individual validation. The following illustration shows a validation of this type. Here's an explanation of the configuration in this example:

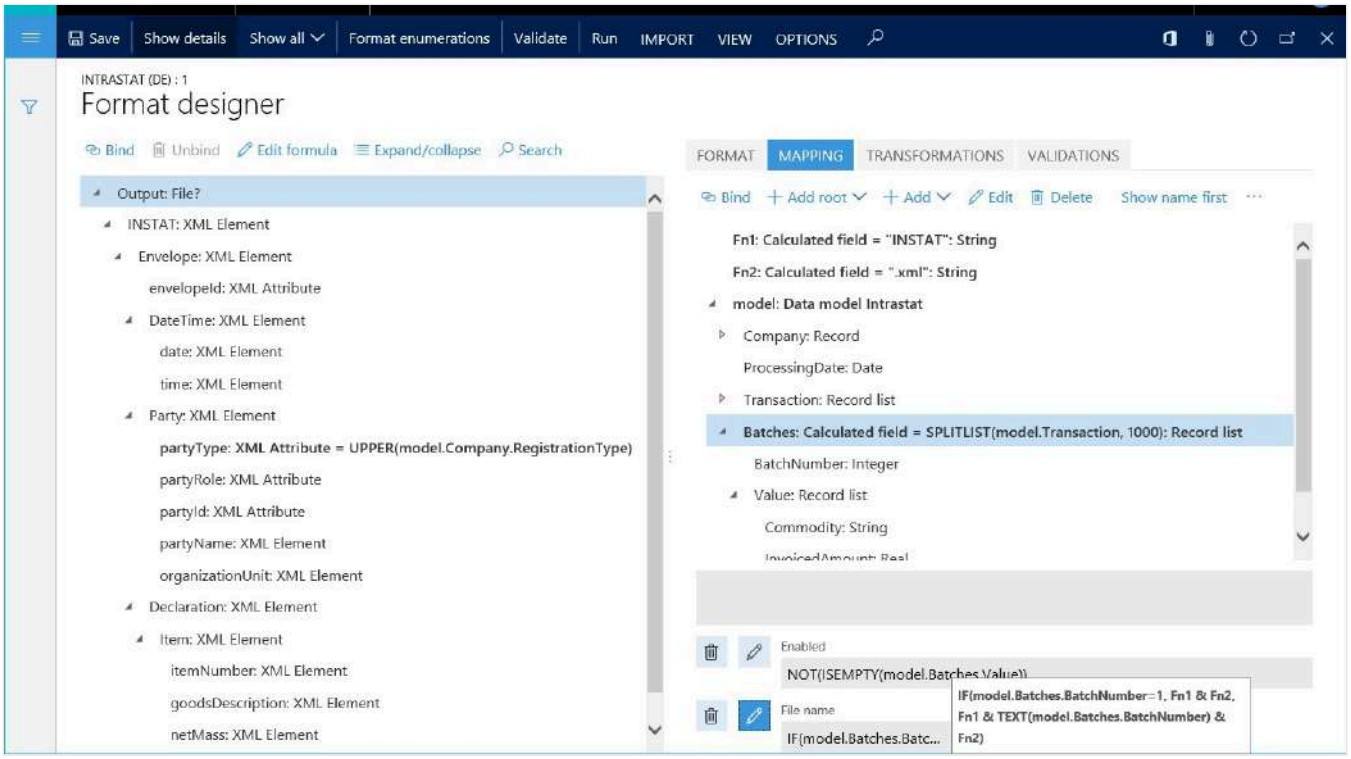
- The validation is evaluated when the **INSTAT** node is created during generation of the XML file.

- If the list of transactions is empty, the validation stops the execution process and returns **FALSE**.
- The validation returns an error message that includes the text of label SYS70894 in the user's preferred language.



Use the ER formula designer to generate a file name for a generating electronic document and to control the file creation process. The following illustration shows the design of a process flow control of this type. Here's an explanation of the configuration in this example:

- The list of records from the **model.Intrastat** data source is divided into batches. Each batch contains up to 1,000 records.
- The output creates a zip file that contains one file in XML format for every batch that was created.
- An expression returns a file name for generating electronic documents by concatenating the file name and the file name extension. For the second batch and all subsequent batches, the file name contains the batch ID as a suffix.
- An expression enables (by returning **TRUE**) the file creation process for batches that contain at least one record.



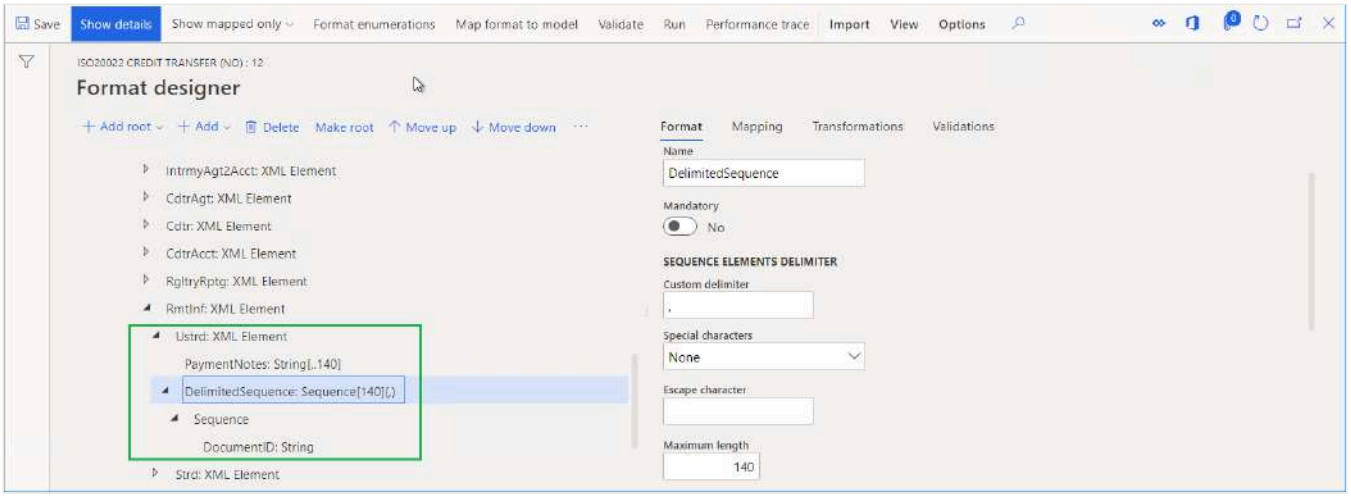
Document content control

Use the ER formula designer to configure expressions that control what data goes into generated electronic documents at runtime. These expressions can enable or disable the output of specific elements of the format, depending on processing data and configured logic. Enter these expressions for a single format element in the **Enabled** field on the **Mapping** tab of the **Operations designer** page. Enter the expressions as a logic condition that returns a *Boolean* value:

- If the condition returns **True**, the current format element runs.
- If the condition returns **False**, the current format element is skipped.

The following illustration shows expressions of this type. (Version 11.12.11 of the **ISO20022 Credit transfer (NO)** format configuration that Microsoft provides is used as an example.) The **XMLHeader** format component describes the structure of the credit transfer message according to the ISO 20022 XML message standards. The **XMLHeader/Document/CstmrCdtTrfInitn/PmtInf/CdtTrfTxInf/RmtInf/Ustrd** format component adds the **Ustrd** XML element to the generated message and puts the remittance information in an unstructured format as text of the following XML elements:

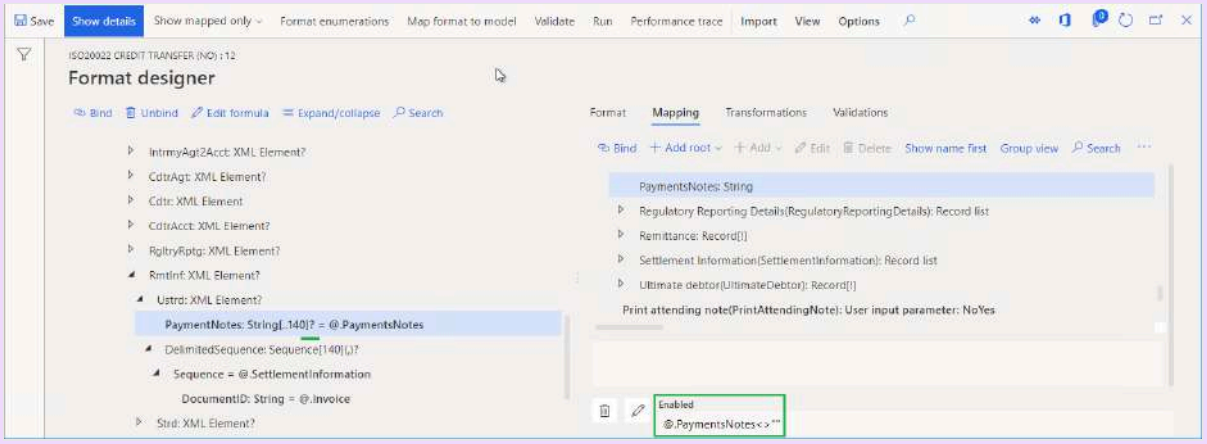
- The **PaymentNotes** component generates the text of payment notes.
- The **DelimitedSequence** component generates comma-separated invoice numbers that settle the current credit transfer.



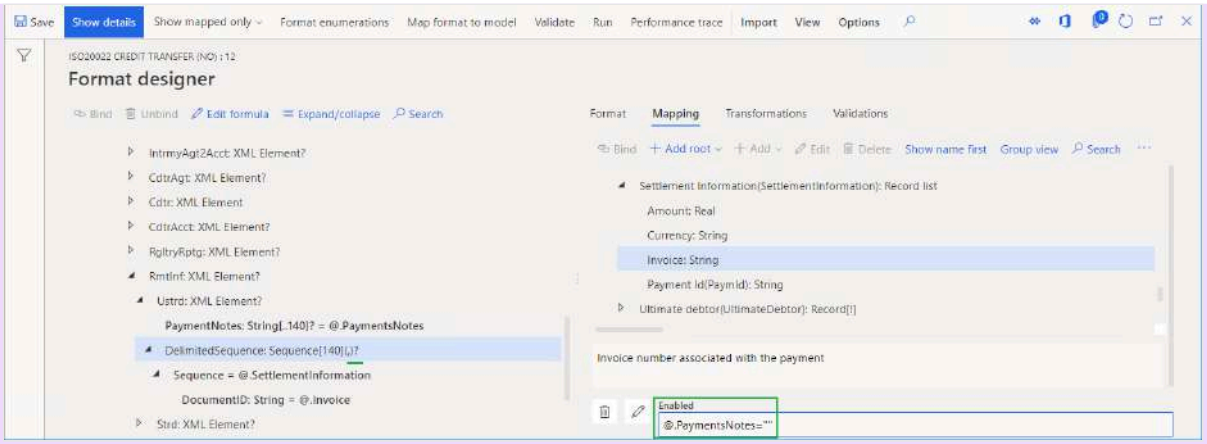
ⓘ Note

The **PaymentNotes** and **DelimitedSequence** components are labeled by using a question mark. A question mark indicates that the use of a component is conditional. In this case, use of the components is based on the following criteria:

- The `@.PaymentsNotes <> ""` expression that you define for the **PaymentNotes** component enables (by returning **TRUE**) the **Ustrd** XML element to be filled with the text of payment notes, if that text isn't blank for the current credit transfer.



- The `@.PaymentsNotes = ""` expression that you define for the **DelimitedSequence** component enables (by returning **TRUE**) the **Ustrd** XML element to be filled with a comma-separated list of the invoice numbers that settle the current credit transfer, if the text of payment notes for that credit transfer is blank.

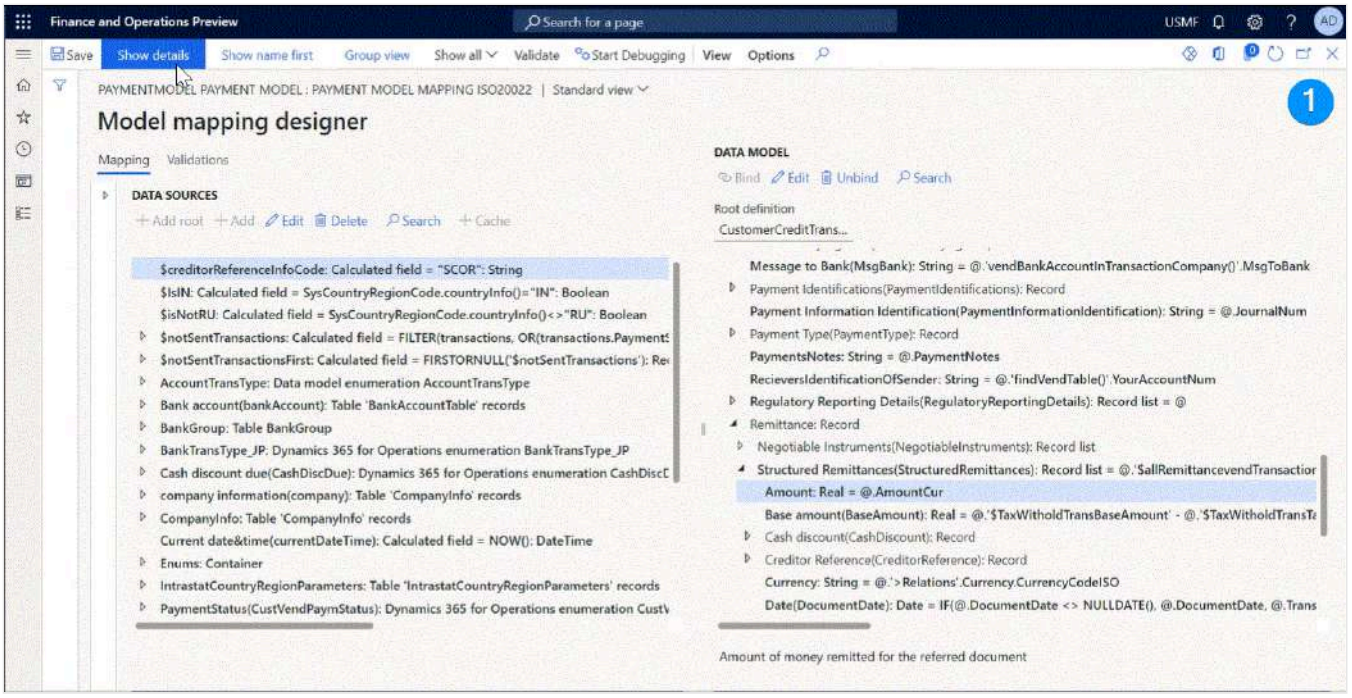


Based on this setup, the message that is generated for each debtor payment, the **Ustrd** XML element, contains either the text of payment notes or, when that text is blank, a comma-separated list of the invoice numbers that settle the payment.

Assistance in writing formulas

Data sources navigator

You can edit a formula that represents an element of a structured data source. When you configure your ER parameters to present the path to an element of a structured data source as the relative path, the formula shows the "at" (@) sign instead of the remaining part of the absolute path of the hierarchical tree structure. This remaining part of the absolute path points to a parent element of the editable one. In Finance version **10.0.30 and later**, on the **Formula designer** page, in the **Data sources** pane, you can select the **Go to @** option to position the cursor of the data sources tree to an element that is the parent of the editable one. The structure of all collapsed ascending elements is automatically and recursively expanded when required. This expansion helps you quickly visualize the base element of the editable one, observe siblings of the editable element in the data sources tree, and use each of them in the editable formula if needed.



Data sources picker

On the **Formula designer** page, in the **Data sources** pane on the left, select an element of a data source that you want to bring into the editable formula. Then select **Add data source**. The selected element is added to the text of the editable formula.

> **Tip**
>
> When you use the **Add data source** option in the default formula editor, the selected element is always added to the end of the formula text. When you use the same option in the Advanced formula editor, the selected element is inserted to the formula text at the current cursor position.

Built-in functions picker

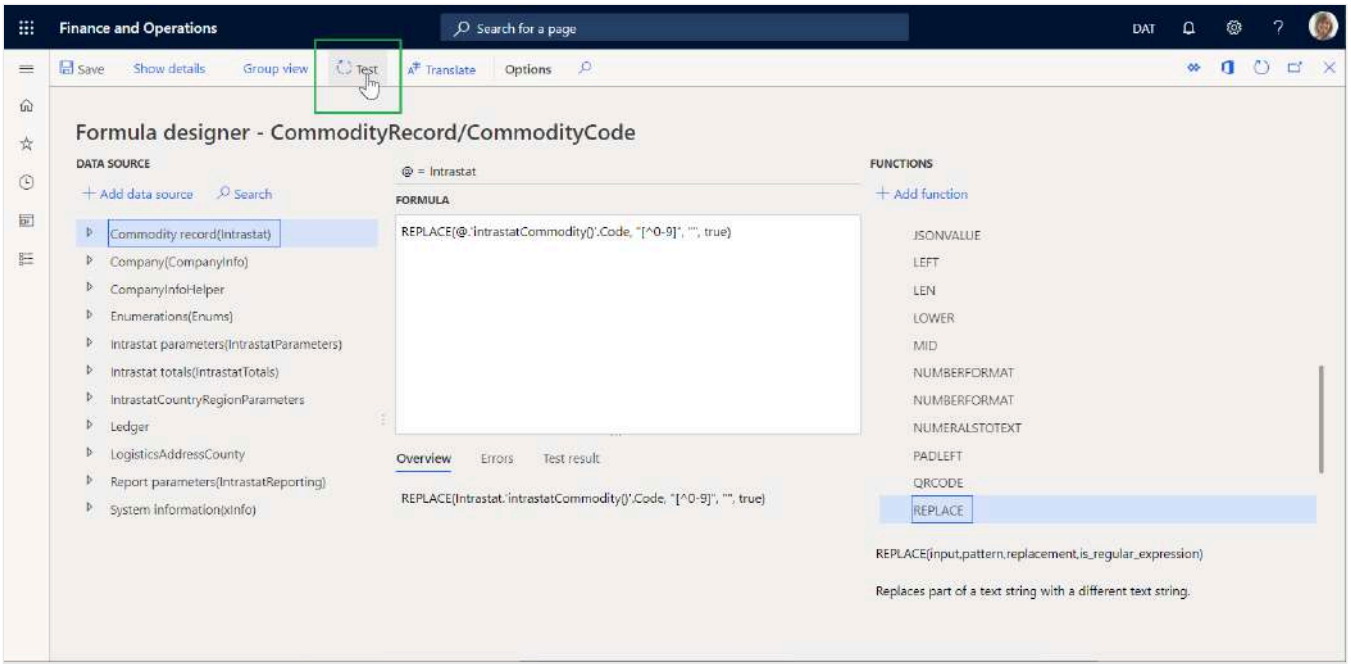
On the **Formula designer** page, in the **Functions** pane on the right, select an ER built-in function that you want to bring into the editable formula. Then, select **Add function**. The selected function is added to the text of the editable formula.

> **Tip**
>
> When you use the **Add function** option in the default formula editor, the selected function is always added to the end of the formula text. When you use the same option in the

Advanced formula editor, the selected function is inserted to the formula text at the current cursor position.

Validation of configured formulas

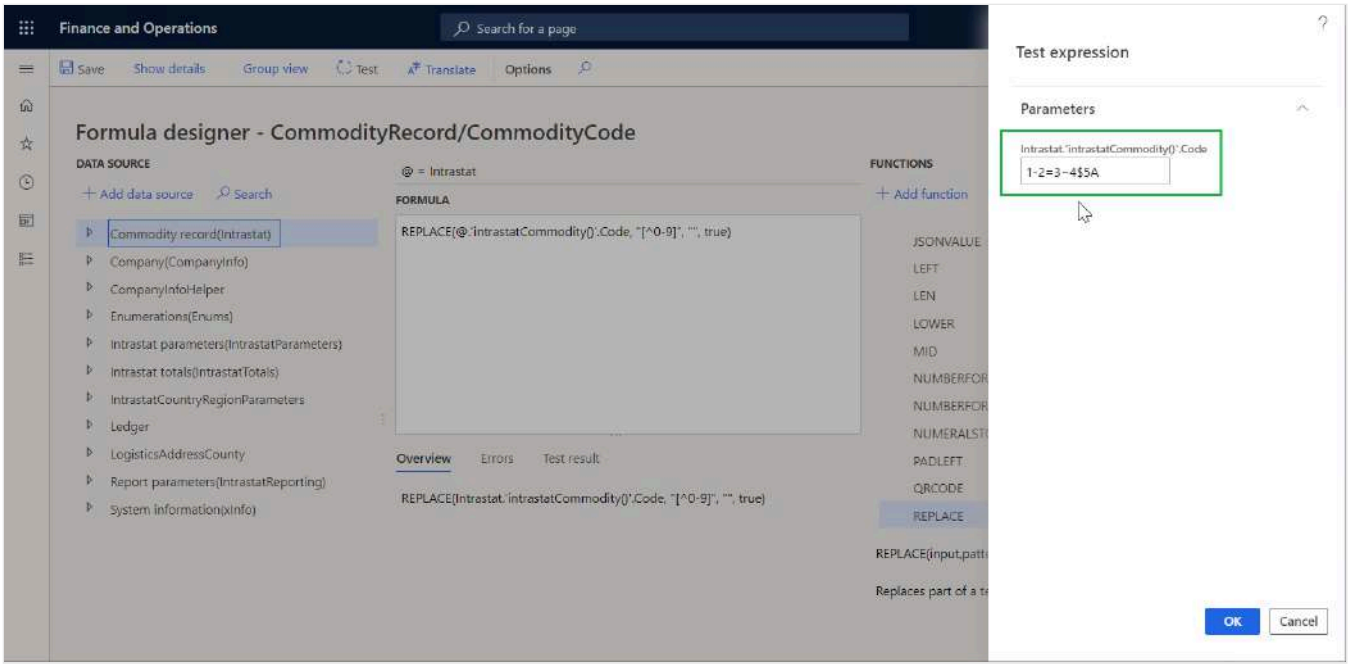
On the **Formula designer** page, select **Test** to validate how the configured formula works.



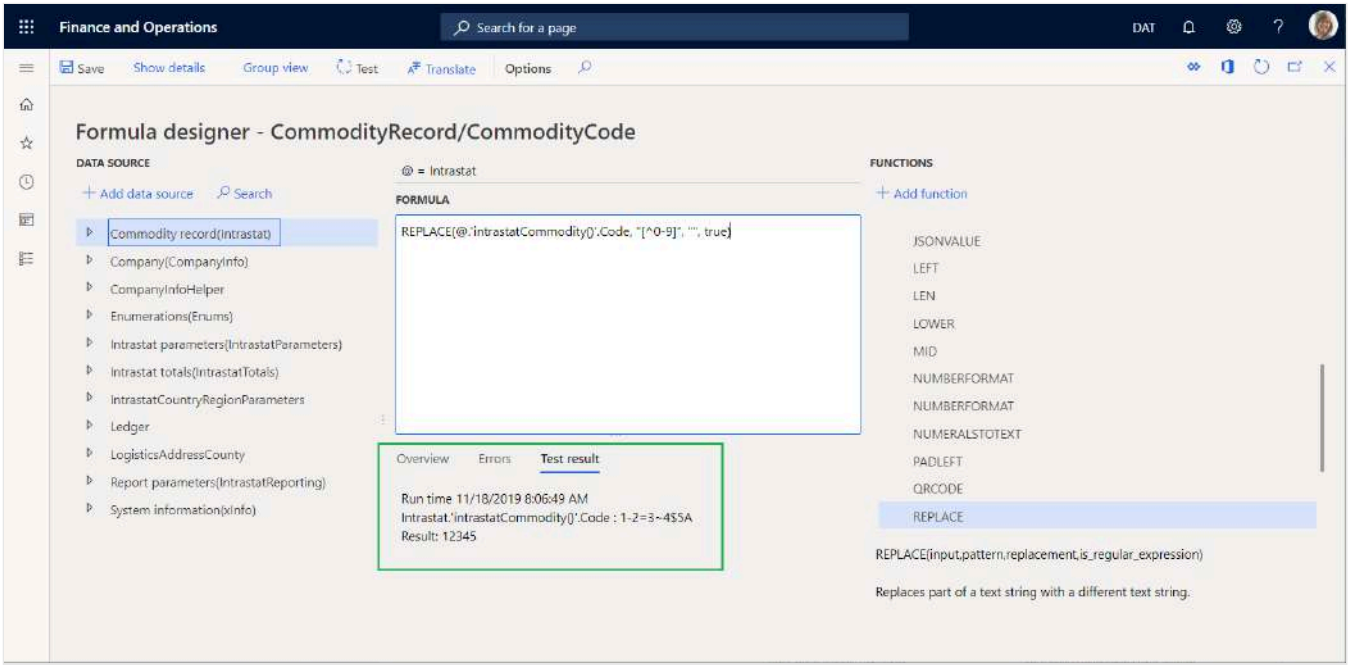
When the formula needs values for arguments, open the **Test expression** dialog box from the **Formula designer** page. In most cases, you must manually define these arguments because the configured bindings don't run at design time. The **Test result** tab on the **Formula designer** page shows the result from execution of the configured formula.

The following example shows how you can test the formula that you configured for the foreign trade domain to make sure that the Intrastat commodity code contains only digits.

When you test this formula, use the **Test expression** dialog box to specify the value of the Intrastat commodity code for testing.



After you specify the Intrastat commodity code and select **OK**, the **Test result** tab on the **Formula designer** page shows the result of execution of the configured formula. You can then evaluate whether the result is acceptable. If the result isn't acceptable, you can update the formula and test it again.



Some formulas can't be tested at design time. For example, a formula might return a result of a data type that can't be shown on the **Test result** tab. In this case, you receive an error message that states that the formula can't be tested.

Electronic reporting advanced formula editor

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

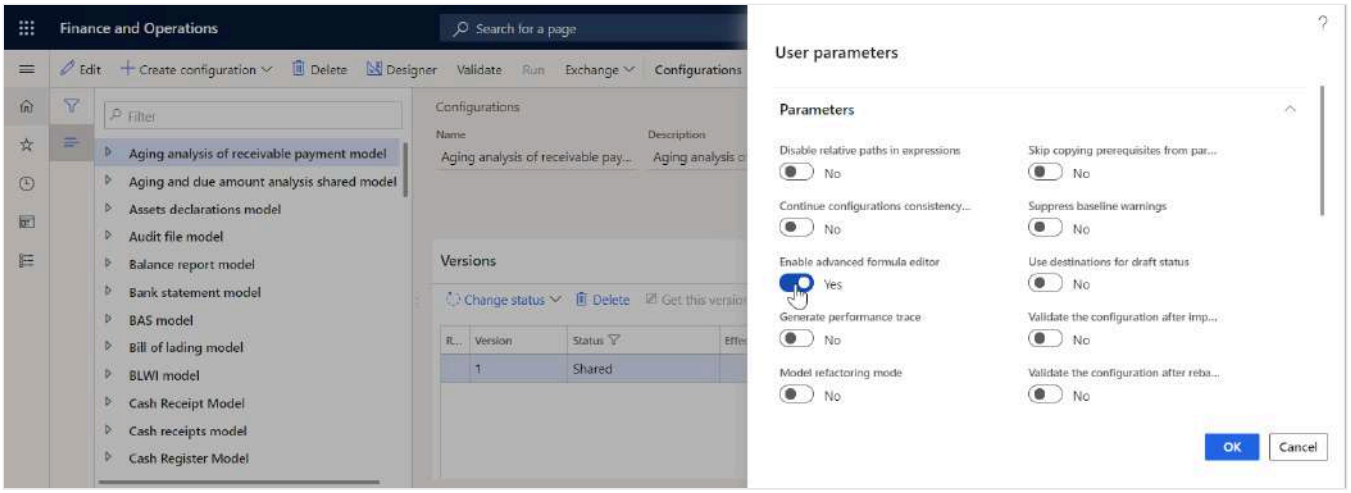
In addition to the Electronic reporting formula editor, you can use the advanced Electronic reporting formula editor to improve the experience of configuring Electronic reporting (ER) expressions. The advanced editor is browser-based and powered by the Monaco editor. This article describes the most commonly used advanced editor features:

- Code autoformatting
- IntelliSense
- Code completion
- Code navigation
- Code structuring
- Find and replace
- Data pasting
- Syntax colorization

Activate the advanced formula editor

Complete the following steps to start using the advanced formula editor in your instance of Microsoft Dynamics 365 Finance.

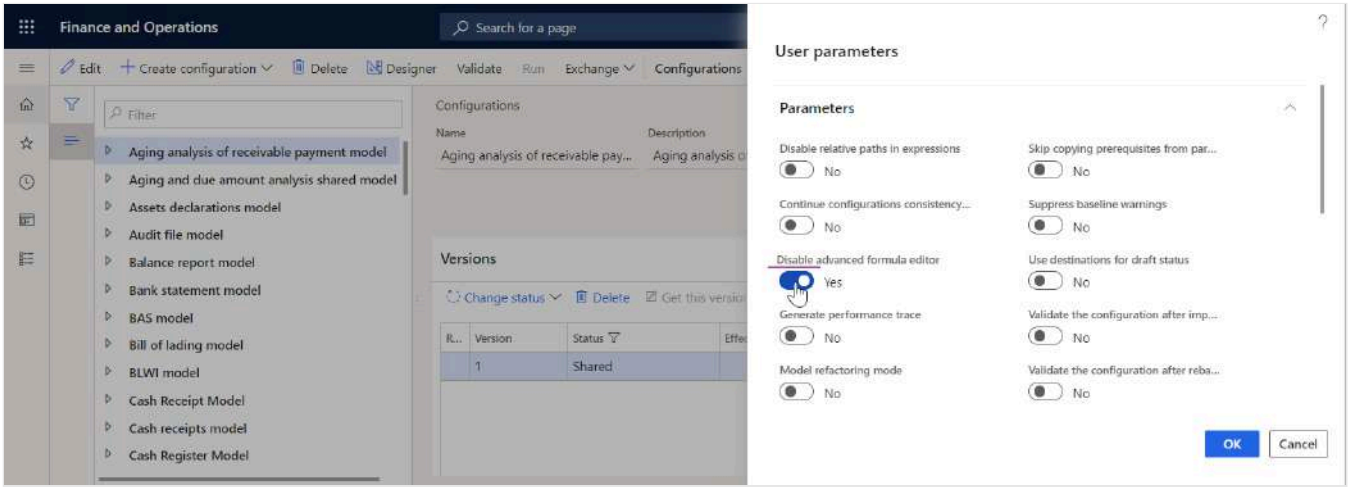
1. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
2. On **Configurations**, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
3. In **User parameters**, in the **Execution tracing** section, set the **Enable advanced formula editor** parameter to **Yes**.



> **Note**
>
> This parameter is user specific and company specific.

Starting in Microsoft Dynamics 365 Finance version 10.0.19, you can control which ER formula editor is offered by default. Complete the following steps to enable the advanced formula editor for all users and companies of the current Finance instance.

1. Open the **Feature management** workspace.
2. Find and select the feature **Set the ER advanced formula editor as the default one for all users** in the list, and then select **Enable now**.
3. Go to **Organization administration** > **Electronic reporting** > **Configurations**.
4. On **Configurations**, on the Action Pane, on the **Configurations** tab, in the **Advanced settings** group, select **User parameters**.
5. In **User parameters**, find the **Disable advanced formula editor** parameter and verify that it's set to **No**.

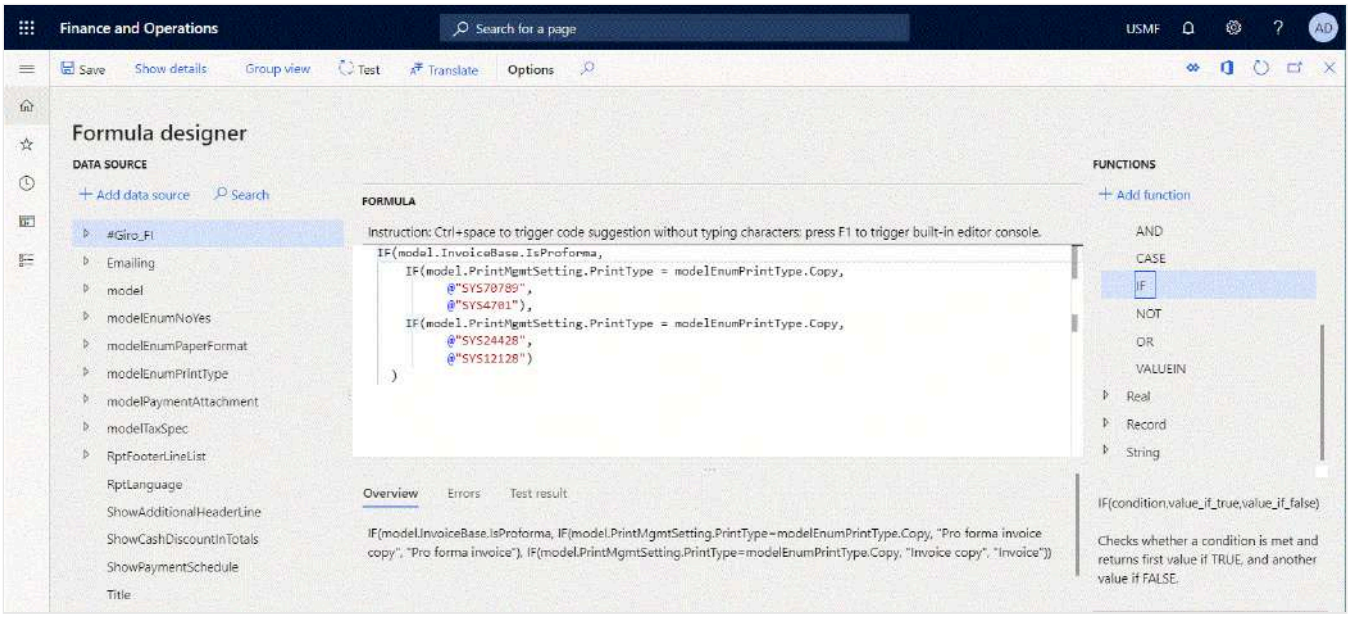


> **Note**

The values of the parameters **Enable advanced formula editor** and **Disable advanced formula editor** are kept separate for each user. The **User parameters** dialog box displays these parameters depending on the status of the **Set the ER advanced formula editor as the default one for all users** feature.

Code autoformatting

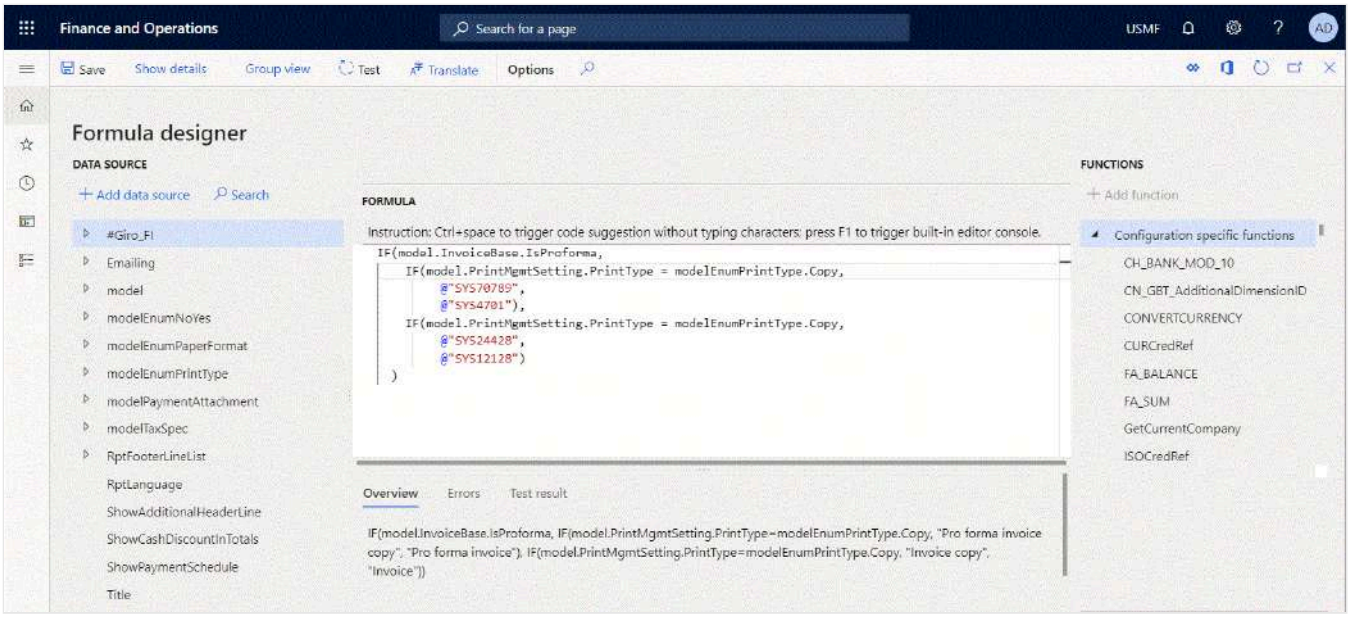
When you write a complex expression that consists of multiple rows of code, the editor automatically indents a new line based on the indentation of the previous row. You can select lines and change their indentation by typing **Tab** or **Shift+Tab**.



Autoformatting helps you keep the entire expression well formatted, which makes further maintenance easier and simplifies understanding of the configured logic.

IntelliSense

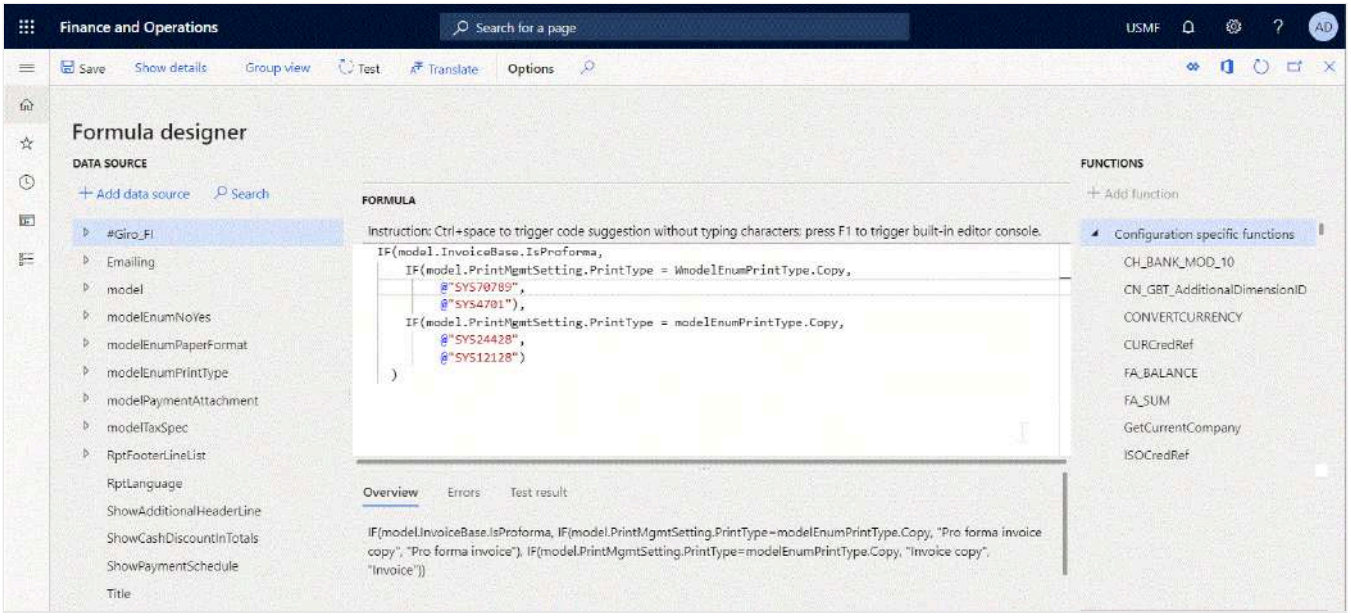
The editor provides word completion to help you write expressions faster and avoid typos. When you start adding new text, the editor automatically offers a list of functions supported in ER functions that contain the characters you entered. You can also trigger IntelliSense in any place of a configured expression by typing **Ctrl+Space**.



Code completion

The editor automatically provides code completion by:

- Inserting a closing bracket when you enter an opening bracket, and keeping the cursor inside the brackets.
- Inserting the second quotation mark when you enter the first one, and keeping the cursor inside the quotations.
- Inserting the second double quotation mark when you enter the first one, and keeping the cursor inside the quotations.



When you point to a typed bracket, the editor automatically highlights the second bracket of this pair to show the construct that they support.

Code navigation

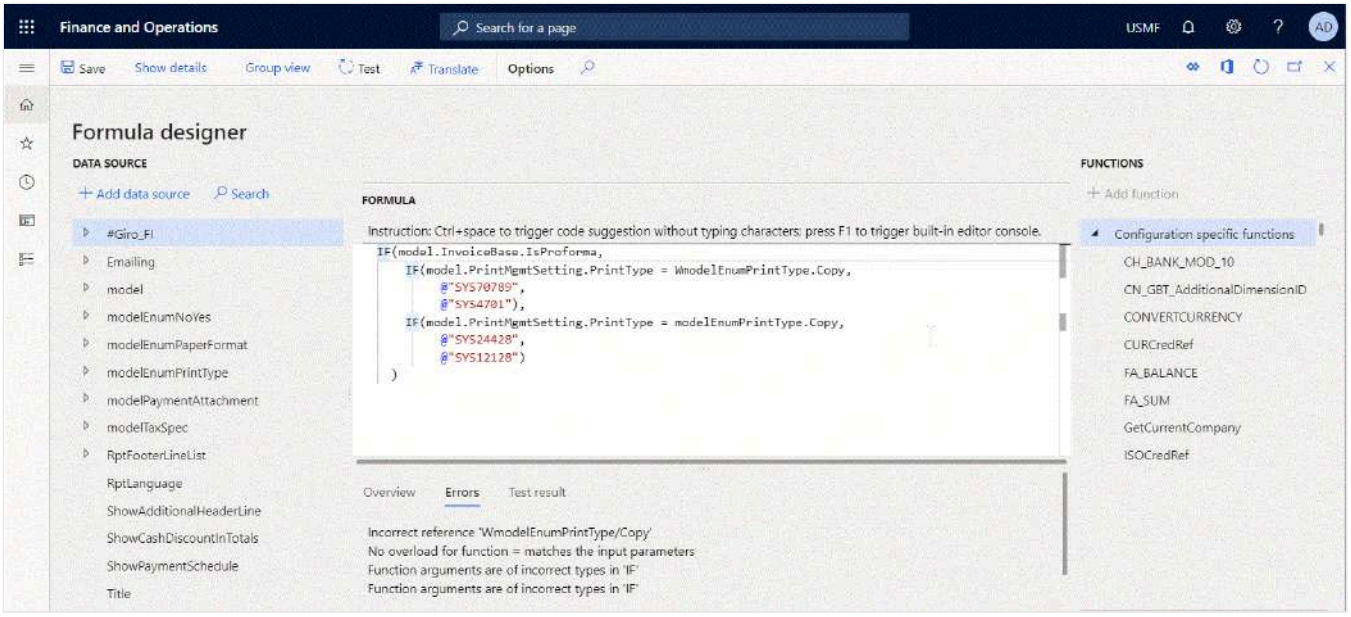
You can find required symbols or lines in your expression by using the **Go to** command from the command palette or the context menu.

For example, to jump to line **8**, use one of the following methods:

- Press **Ctrl+G**, enter the value **8**, and then press **Enter**.

  -or-

- Press **F1**, type **G**, select **Go to line**, enter the value **8**, and then press **Enter**.



Code structuring

The code for some functions, such as IF or CASE, is automatically structured. You can expand and collapse any or all of the folding regions of this code to reduce the editable part of an expression so you can focus on only the piece of code that requires your attention. Use the toggle fold and unfold commands for that task.

For example, to fold all regions, use one of the following methods:

- Press **Ctrl+K**

  -or-

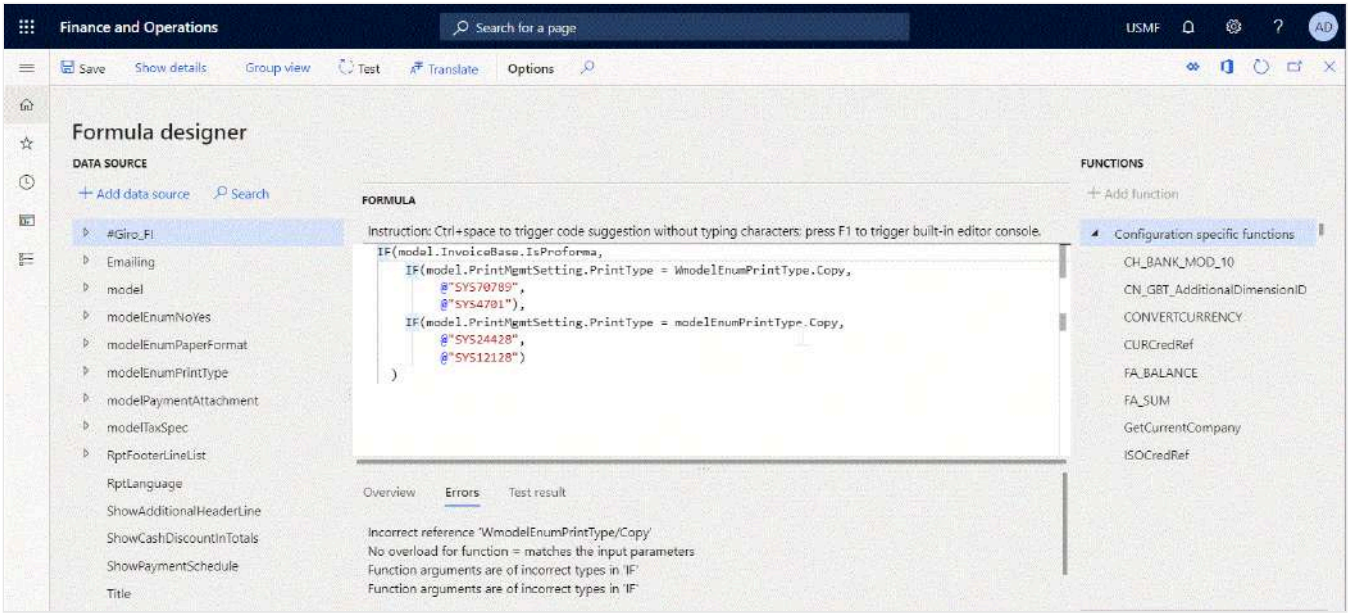
- Press **F1**, press **FO**, select **Fold all**, and then press **Enter**.

To unfold all regions, use one of the following methods:

- Press **Ctrl+J**

-or-

- Press **F1**, type **UN**, select **Unfold all**, and then press **Enter**.



Find and replace

To find occurrences of certain text, select the text in your expression, and do the following steps:

- Press **Ctrl+F** and then press **F3** to find the next occurrence of the selected text, or press **Shift+F3** to find the previous occurrence.

  -or-

- Press **F1**, type **F**, and then select the required option to find the selected text.

To replace occurrences of certain text, select the text in your expression, and do the following steps:

- Press **Ctrl+H**. Enter the alternative text and select the replacement option to replace either the selected text or all occurrences of this text in the current expression.

  -or-

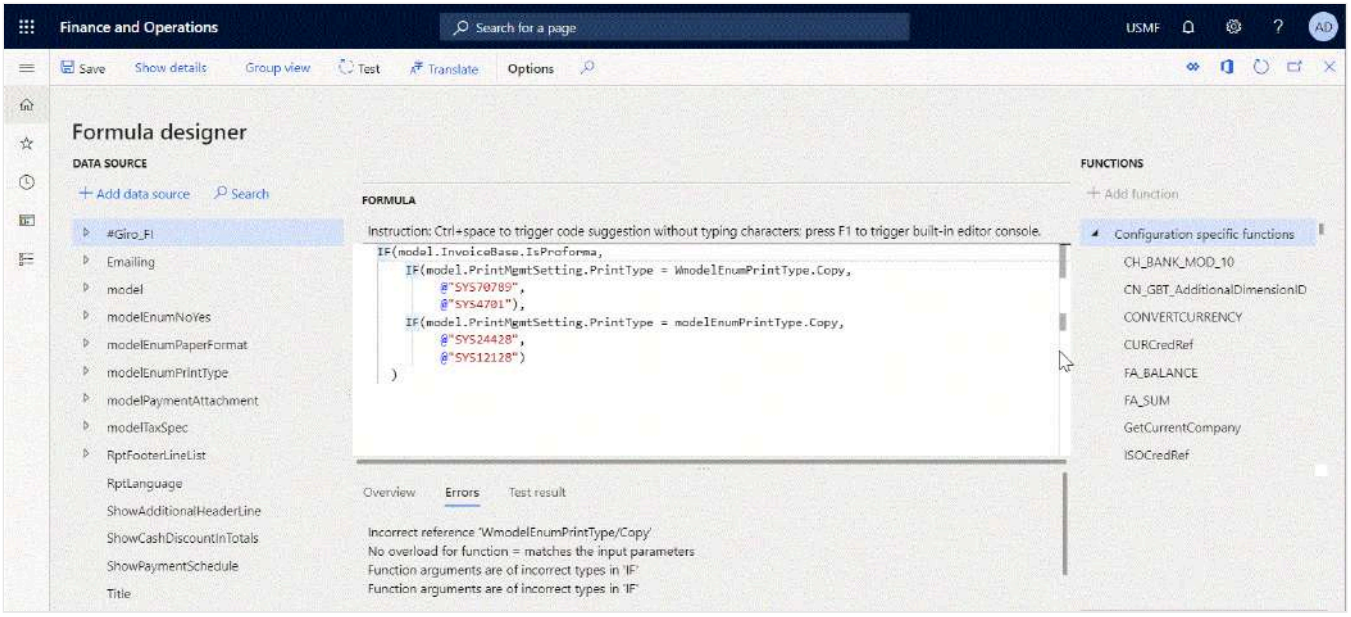
- Press **F1**, type **R**, and then select the required option to replace the selected text. Enter the alternative text and select the replacement option to replace either the selected text or all occurrences of this text in the current expression.

To change all occurrences of certain text, select the text in your expression, and do the following steps:

- Press **Ctrl+F2** and then enter the alternative text.

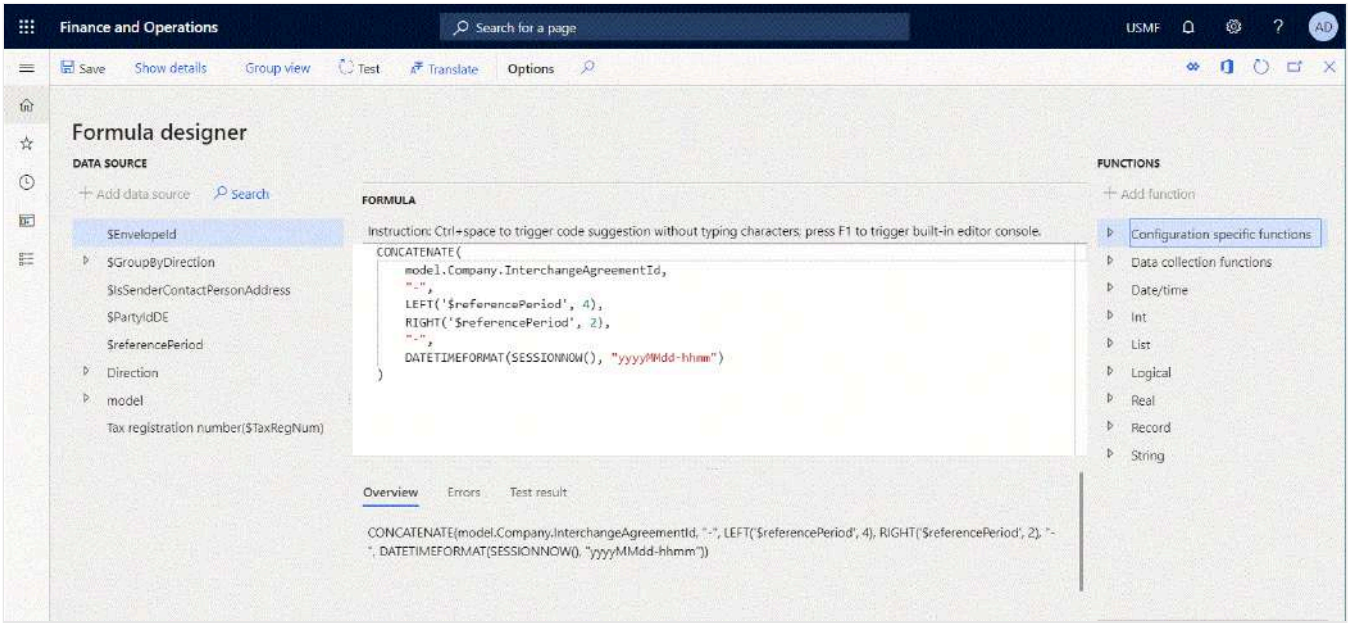
  -or-

- Press **F1**, type **C**, and then select the required option to change the selected text. Enter the alternative text.



Data sources and functions pasting

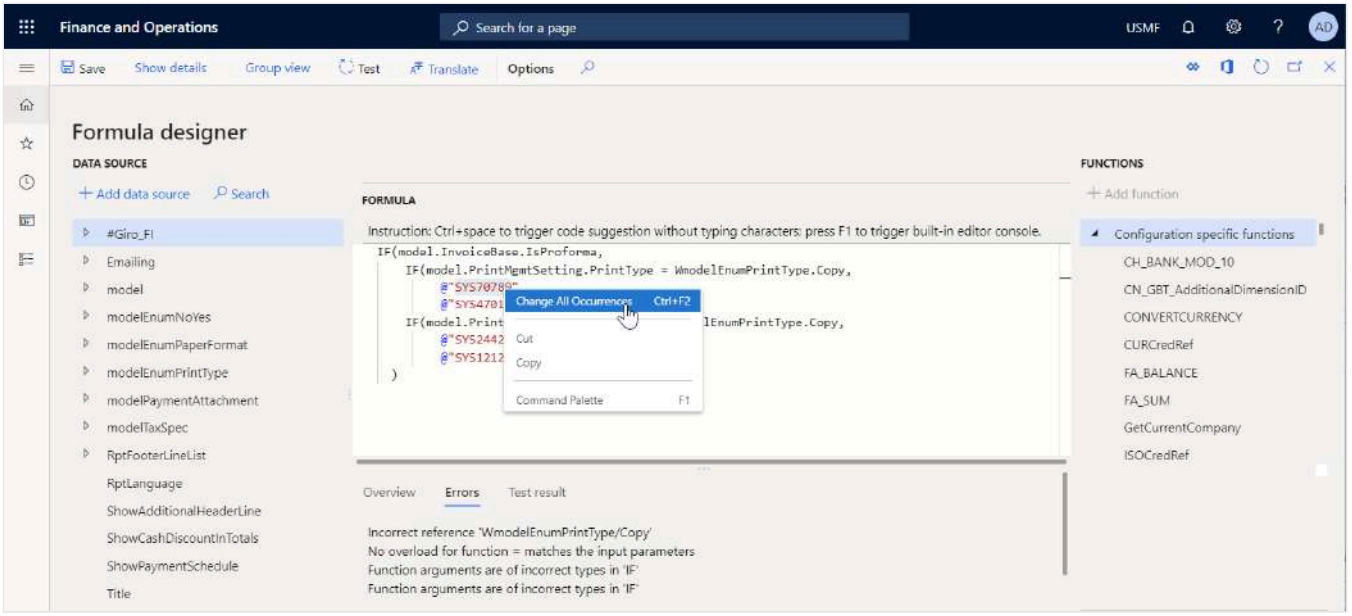
Select **Add data source** to paste a data source from the **Data source** left panel into the current expression. Select **Add function** to paste a function from the **Functions** right panel into the current expression. If you use the ER formula editor, the selected function or data source is always added to the end of the configured expression. When you use the advanced ER formula editor, you can add the selected function or data source to any part of the configured expression. Use the cursor to specify where you want to paste the data.



Syntax colorization

Currently, the editor uses different colors to highlight the following parts of expressions:

- The text in double brackets that can represent a label ID of a text constant.



Limitations

The editor currently supports the following web browsers:

- Chrome
- Edge
- Firefox
- Opera
- Safari

Electronic reporting formula language

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) provides a powerful data transformation experience. The language that you use to express the required data manipulations in the ER formula designer resembles the formula language in Microsoft Excel.

Basic syntax

ER expressions can contain any or all of the following elements:

- Constants
- Operators
- References
- Paths
- Functions

Constants

When you design expressions, use text and numeric constants (that is, values that aren't calculated). For example, the expression `VALUE ("100") + 20` uses the numeric constant **20** and the string constant **"100"**, and it returns the numeric value **120**.

The ER formula designer supports escape sequences. Therefore, you can specify an expression string that should be handled differently. For example, the expression `"Leo Tolstoy ""War and Peace"" Volume 1"` returns the text string **Leo Tolstoy "War and Peace" Volume 1**.

Operators

The following table shows the arithmetic operators that you can use to do basic mathematical operations, such as addition, subtraction, multiplication, and division.

Expand table

Operator	Meaning	Example
+	Addition	`1+2`
-	Subtraction, negation	`5-2`, `-1`
*	Multiplication	`7\*8`
/	Division	`9/3`

The following table shows the comparison operators that are supported. You can use these operators to compare two values.

Expand table

Operator	Meaning	Example
=	Equal	`X=Y`
>	Greater than	`X>Y`
<	Less than	`X<Y`
>=	Greater than or equal to	`X>=Y`
<=	Less than or equal to	`X<=Y`
<>	Not equal to	`X<>Y`

Additionally, you can use an ampersand (&) as a text concatenation operator. In this way, you can join, or concatenate, one or more text strings into a single piece of text.

Expand table

Operator	Meaning	Example
&	Concatenate	`"Nothing to print:" & " " & "no records found"`

Operator precedence

The order in which the parts of a compound expression are evaluated is important. For example, the result of the expression `1 + 4 / 2` varies, depending on whether the addition or division operation is done first. You can use parentheses to explicitly define how an expression is evaluated. For example, to indicate that the addition operation should be done first, you can

change the preceding expression to `(1 + 4) / 2`. If you don't explicitly indicate the order of operations in an expression, the order is based on the default precedence that is assigned to the supported operators. The following table shows the precedence that is assigned to each operator. Operators that have a higher precedence (for example, 7) are evaluated before operators that have a lower precedence (for example, 1).

Expand table

Precedence	Operators	Syntax
7	Grouping	(...)
6	Member access	... .
5	Function call	... (...)
4	Multiplicative	... * ... ... / ...
3	Additive	... + ... - ...
2	Comparison	... < ... ... <= ... ... => ... ... > ... ... = ... <> ...
1	Separation	... , ...

If an expression includes multiple consecutive operators that have the same precedence, those operations are evaluated from left to right. For example, the expression `1 + 6 / 2 \* 3 > 5` returns **true**. Use parentheses to explicitly indicate the desired order of operations in expressions, so that the expressions are easier to read and maintain.

References

You can use all data sources of the current ER component that are available during the design of an expression as named references. The current ER component can be either a model mapping or a format. For example, the current ER model mapping contains the **ReportingDate** data source, which returns a value of the *DateTime* data type. To correctly format that value in the generating document, reference the data source in the expression as `DATETIMEFORMAT (ReportingDate, "dd-MM-yyyy")`.

Precede all characters in the name of a referencing data source that don't represent a letter of the alphabet with a single quotation mark ('). If the name of a referencing data source contains at least one symbol that doesn't represent a letter of the alphabet, enclose the name in single quotation marks. For example, these non-alphabetic symbols can be punctuation marks or other written symbols. Here are some examples:

- Refer to the **Today's date & time** data source in an ER expression as `'Today''s date & time'`.
- Refer to the **name()** method of the **Customers** data source in an ER expression as `Customers.'name()'`.

If the methods of application data sources have parameters, use the following syntax to call those methods:

- If the **isLanguageRTL** method of the **System** data source has an **EN-US** parameter of the *String* data type, refer to this method in an ER expression as `System.isLanguageRTL("EN-US")`.
- Quotation marks aren't required when a method name contains only alphanumeric symbols. However, they're required for a method of a table if the name includes brackets.

When you add the **System** data source to an ER mapping that refers to the **Global** application class, the expression `System.isLanguageRTL("EN-US ")` returns the *Boolean* value **FALSE**. The modified expression `System.isLanguageRTL("AR")` returns the *Boolean* value **TRUE**.

You can limit the way that values are passed to the parameters of this type of method:

- Only constants can be passed to methods of this type. Define the values of the constants at design time.
- Only primitive (basic) data types are supported for parameters of this type. The primitive data types include *Integer*, *Real*, *Boolean*, and *String*.

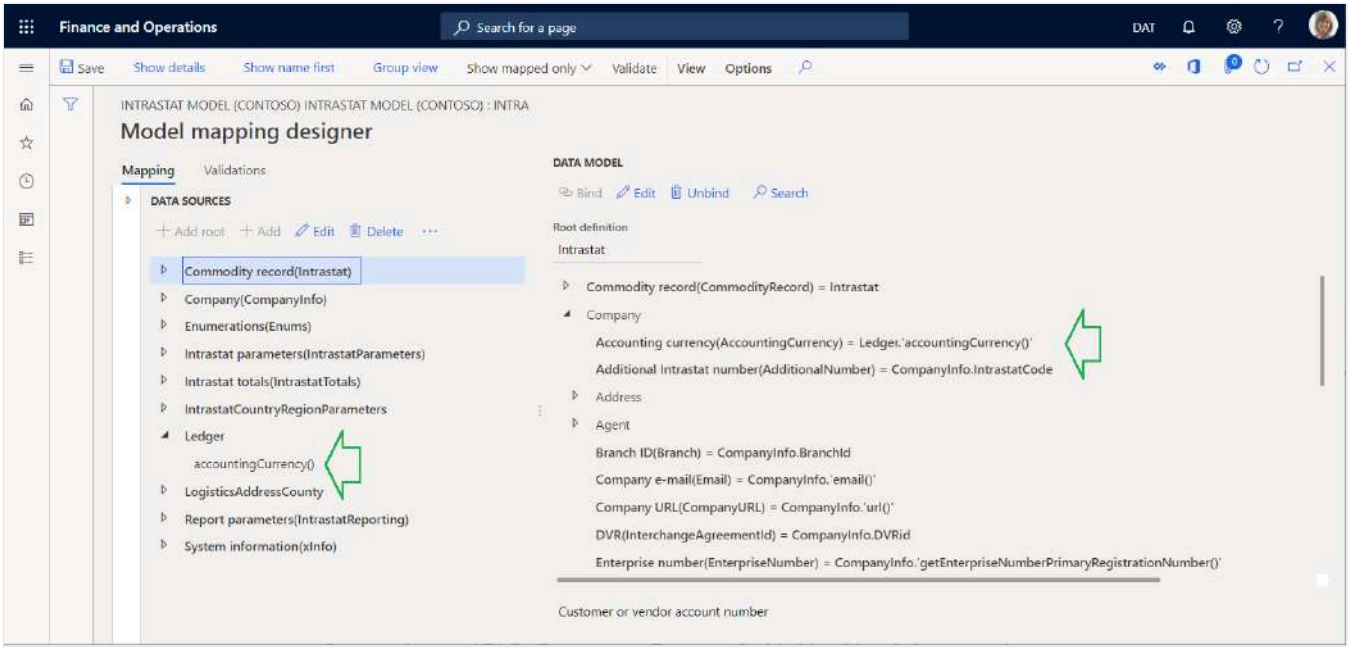
Paths

When an expression references a structured data source, use the path definition to select a specific primitive element of that data source. Use a dot character (.) to separate individual elements of a structured data source. For example, the current ER model mapping contains the **InvoiceTransactions** data source, and this data source returns a list of records. The **InvoiceTransactions** record structure contains the **AmountDebit** and **AmountCredit** fields, and both these fields return numeric values. Therefore, you can design the following expression to calculate the invoiced amount: `InvoiceTransactions.AmountDebit -`

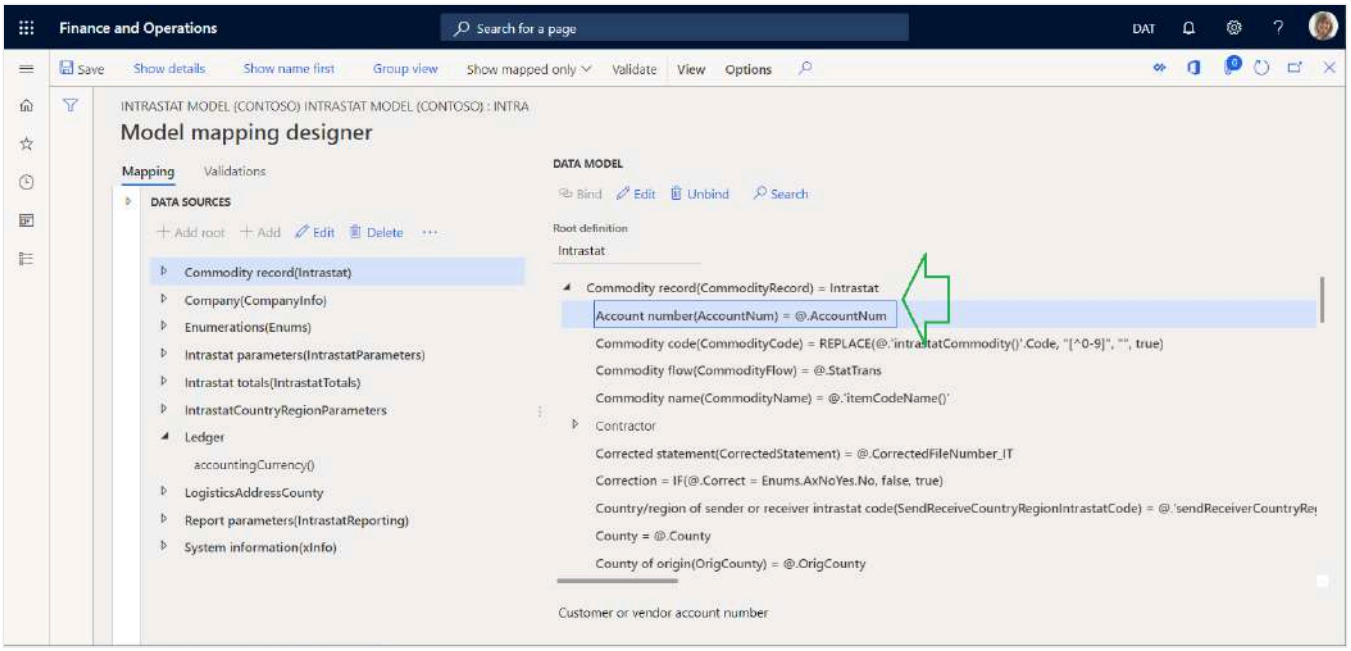
`InvoiceTransactions.AmountCredit`. The `InvoiceTransactions.AmountDebit` construction in this expression is the path that is used to access the **AmountDebit** field of the **InvoiceTransactions** data source of the *Record list* type.

Relative path

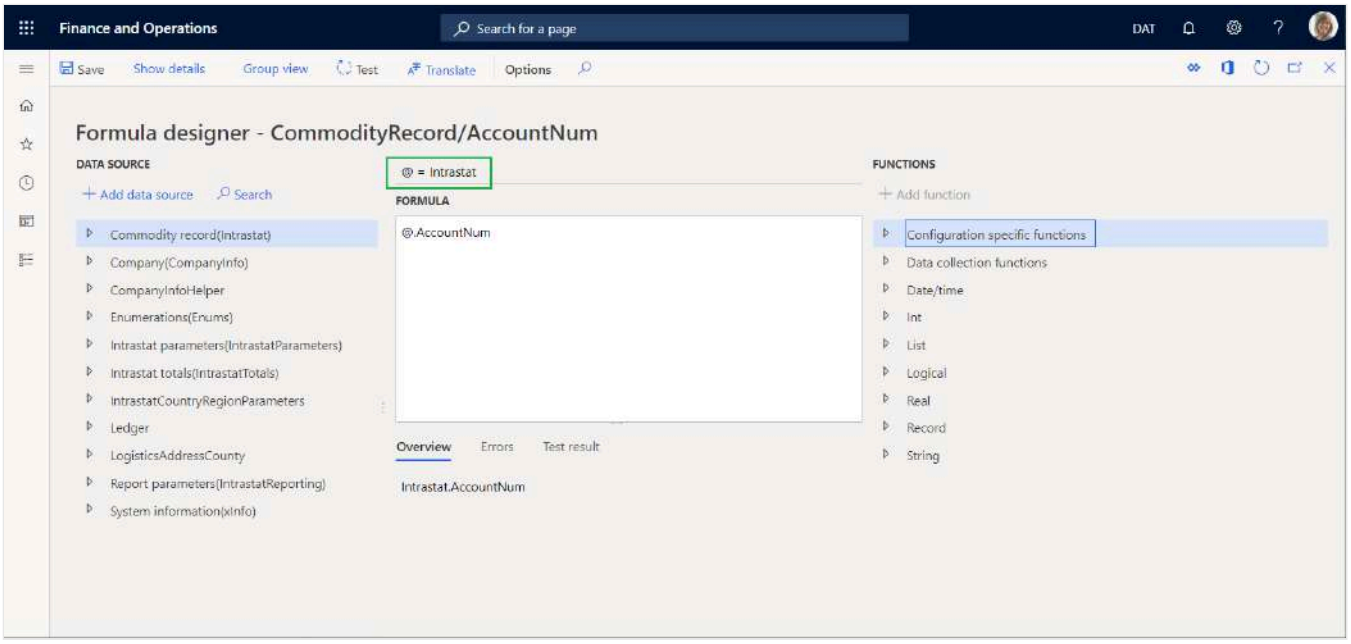
If the path of a structured data source starts with an `@` sign, it's a relative path. The `@` sign represents the remaining part of the absolute path of the hierarchical tree structure that the relative path uses. The following illustration shows an example. In this example, the absolute path `Ledger.'accountingCurrency()'` indicates that the accounting currency value from the **Ledger** data source is entered in the **AccountingCurrency** field of the data model.



The example in the following illustration shows how a relative path is used. The relative path `@.AccountNum` indicates that the **AccountNum** field of the **Intrastat** data source (which appears one level above the **AccountNum** field in the data model's hierarchical tree) is used to enter the customer or vendor account number in the data model's **AccountNum** field.



The ER formula editor also shows the remaining part of the absolute path.



For more information, see Use a relative path in data bindings of ER models and formats.

Functions

Use ER built-in functions in ER expressions. You can use all data sources of the expression context (that is, the current ER model mapping or ER format) as parameters when calling functions, as long as they follow the list of arguments for calling functions. You can also use constants as parameters. For example, the current ER model mapping contains the **InvoiceTransactions** data source, and this data source returns a list of records. The **InvoiceTransactions** record structure contains the **AmountDebit** and **AmountCredit** fields, and both these fields return numeric values. To calculate the invoiced amount, you can design the

following expression that uses the built-in ER rounding function: `ROUND(InvoiceTransactions.AmountDebit - InvoiceTransactions.AmountCredit, 2)`.

When you design ER model mappings and ER reports, use ER functions from the following categories:

- Date and time functions
- List functions
- Logical functions
- Mathematical functions
- Record functions
- Text functions
- Data collection functions
- Other (business domain–specific) functions
- Type conversion functions

Functions list extension

ER lets you extend the list of functions that you use in ER expressions. Some engineering effort is required. For detailed information, see Extend the list of Electronic reporting (ER) functions.

Compound expressions

You can create compound expressions that use functions from different categories, as long as the data types match. When you use functions together, match the data type of the output from one function to the input data type that another function requires. For example, to avoid a possible "list-is-empty" error in a binding of a field to an ER format element, combine functions from the List category with a function from the Logical category, as the following example shows. Here, the formula uses the IF function to test whether the **IntrastatTotals** list is empty before it returns the value of the required aggregation from that list. If the **IntrastatTotals** list is empty, the formula returns **0** (zero).

VB

```
IF(ISEMPTY(IntrastatTotals), 0.0, IntrastatTotals.aggregated.'$AmountMSTRounded')
```

Multiple solutions

Often, you can get the same data transformation result in multiple ways, by using functions from different categories or different functions from the same category. For example, the previous expression can also be configured by using the COUNT function from the List category.

VB

```
IF(COUNT (IntrastatTotals)=0, 0.0, IntrastatTotals.aggregated.'$AmountMSTRounded')
```

Supported primitive data types for Electronic reporting formulas

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides information about the primitive data types that are supported in Electronic reporting (ER) expressions. Here is a list of the primitive data types:

- boolean
- date
- datetime
- enumeration
- guid
- integer
- int64
- real
- string

Boolean

The *boolean* primitive data type contains a value that is either *true* or *false*. Use the reserved literal keywords **True** and **False** wherever a *boolean* expression is expected. The default value is *false*.

The internal representation of a *boolean* is an *integer*. The *integer* value 0 (zero) represents *false*, and all other *integer* values represent *true*. When you validate a configured expression that returns a *boolean* in the ER formula designer, the test result pane shows *0* (zero) when an expression returns *false*. Otherwise, the test result pane shows *1*.

A *boolean* has no implicit conversions. However, you can use the TEXT function to explicitly convert a *boolean* to a *string*:

- The *false* value converts to the text string **False**.
- The *true* value converts to the text string **True**.

> ⓘ **Note**
>
> This conversion doesn't depend on the provided language and culture **context**.

Comparison operators are the only type of operator that you can use with the *boolean* data type. The following operators can compare two *boolean* values: <> and =.

Date

The *date* primitive data type contains the day, month, and year. Use the following functions to create dates:

- DATEVALUE
- NULLDATE
- SESSIONTODAY
- TODAY

The *date* data type holds dates between January 1, 1900, and December 31, 2154. The default value is **null**, and the internal representation is the date January 1, 1900.

A *date* has no implicit conversions. However, you can use the following explicit conversion functions:

- DATEFORMAT
- DATETODATETIME
- TEXT

The ADDDAYS function adds and subtracts days from dates. By using this function, you can move the date a specific number of days into the future or the past. The DAYS function subtracts dates from each other and calculates the difference in days. For more information about the transformation of *date* values, see List of ER functions in the Date and time category.

Comparison operators are the only type of operator that you can use with the *date* data type. Use the following operators to compare two *date* values: <>, <, <=, =, >, and >=.

Datetime

The *datetime* primitive data type combines the *date* type and a value that represents the time that has passed since midnight. The time is expressed in hours, minutes, seconds, and fractions of a second. A *datetime* value also holds information about the time zone.

The *datetime* data type can hold dates between January 1, 1900 (1900-01-01T00:00:00.0000000+00:00 in the round-trip format) and December 31, 2154 (2154/12/31T11:59:59.9999999+00:00 in the round-trip format). The smallest unit of time in a *datetime* is one ten millionth of a second.

> ⓘ **Note**
>
> When you use the **hh** specifier for hours, time values that go beyond 12:59:59.9999999 aren't valid times.
>
> When you use the **HH** specifier for hours, time values that go beyond 23:59:59.9999999 aren't valid times.

The default value is **null**, and the internal representation is the date January 1, 1900 (1900-01-01T00:00:00.0000000+00:00 in the round-trip format).

Initiate datetimes by using the following functions:

- DATETIMEVALUE
- NULNULLDATETIMELDATE
- SESSIONNOW
- NOW

A *datetime* has no implicit conversions. However, you can use the following explicit conversion functions:

- DATETIMEFORMAT
- TEXT

For more information about the transformation of *datetime* values, see List of ER functions in the Date and time category.

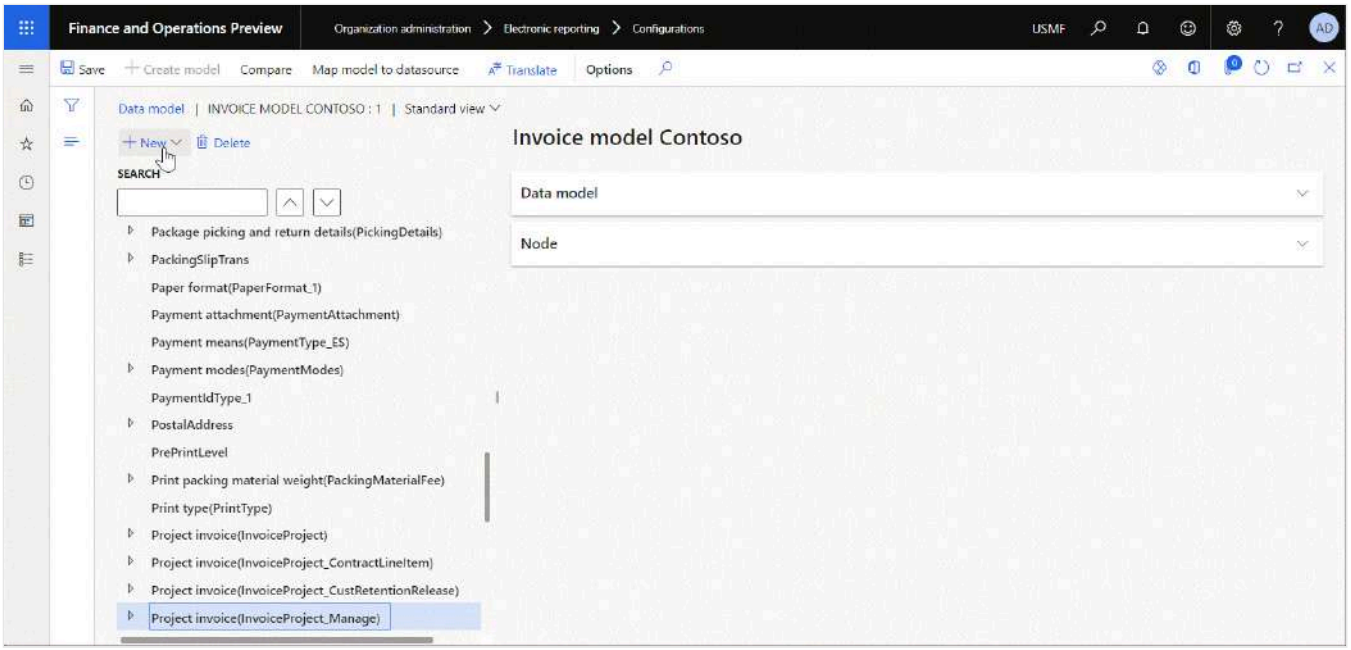
Comparison operators are the only type of operator that you can use with the *datetime* data type. The following operators can compare two *datetime* values: <>, <, <=, =, >, and >=.

Enumeration

The *enumeration* primitive data type is a list of literals. You can use enumerations that are defined in the application source code. You can also introduce your own enumerations in the ER data model and ER format components.

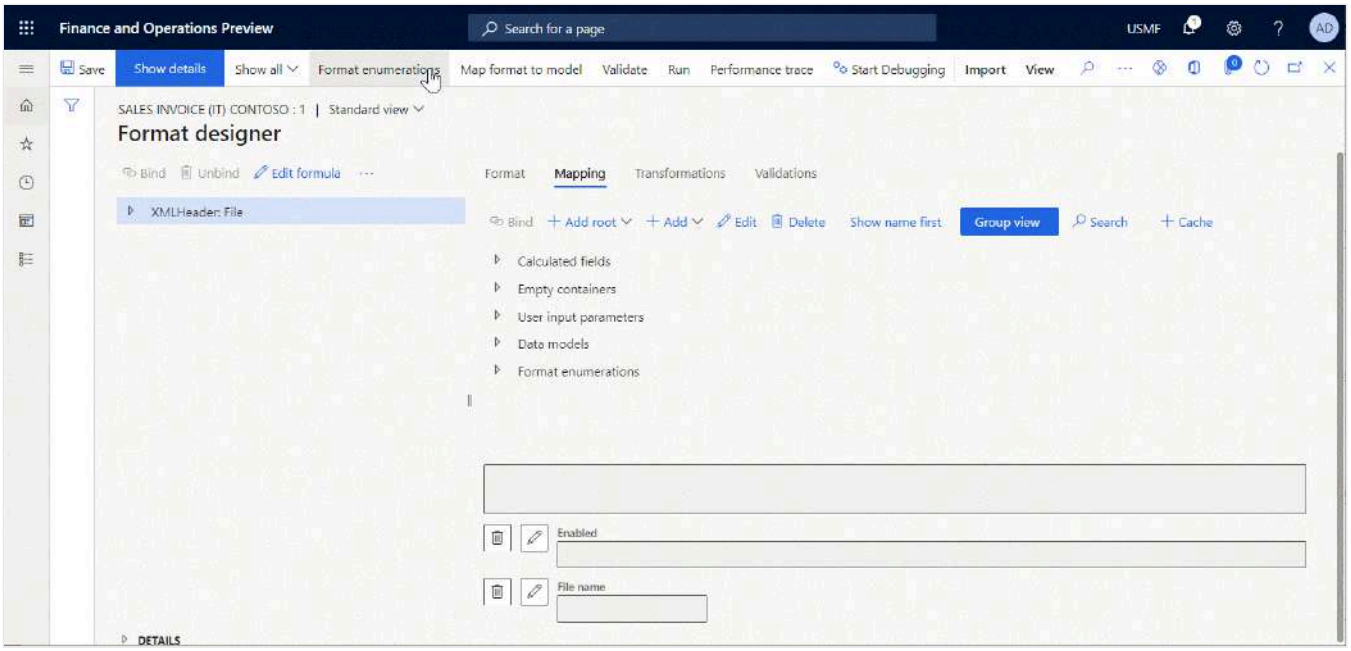
You can use an application *enumeration* in expressions of any ER model mapping and ER format.

The following illustration shows how you can add the **CustVendCorrectiveReasonCode** model enumeration to the editable ER data model.



You can use a model *enumeration* in expressions of any ER model mapping and ER format that you create under a data model where you introduced the *enumeration*.

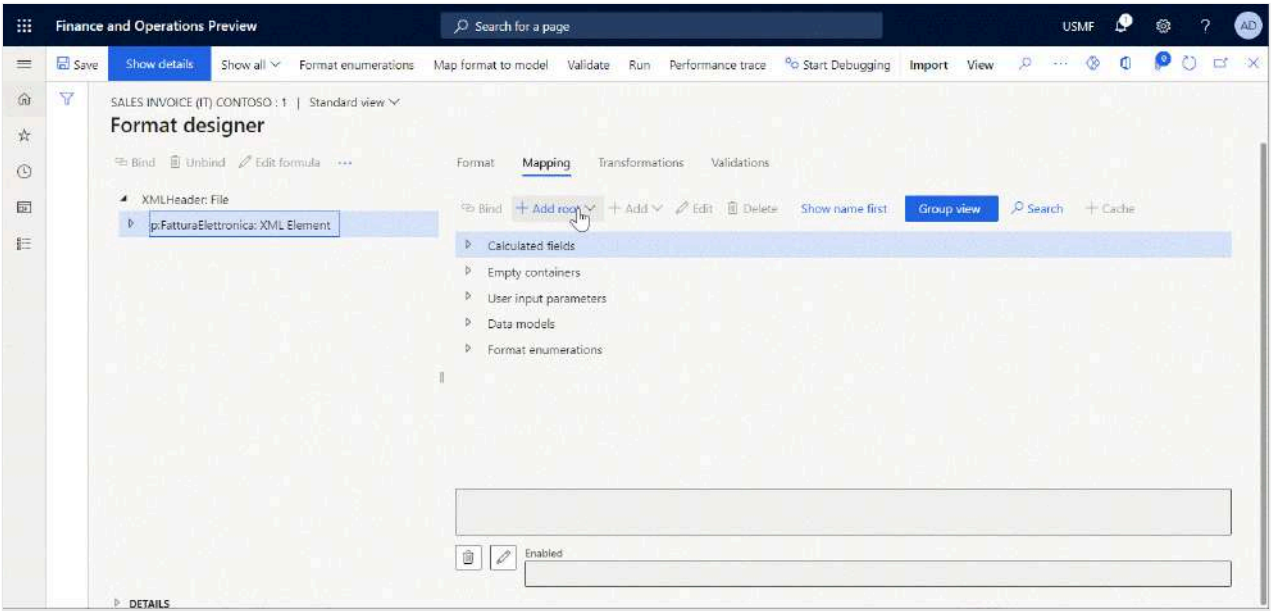
The following illustration shows how you can add the **List of Natura reverse charge subcategories** format enumeration to the editable ER format.



You can use a format *enumeration* only in expressions of the ER format where you introduced the *enumeration*.

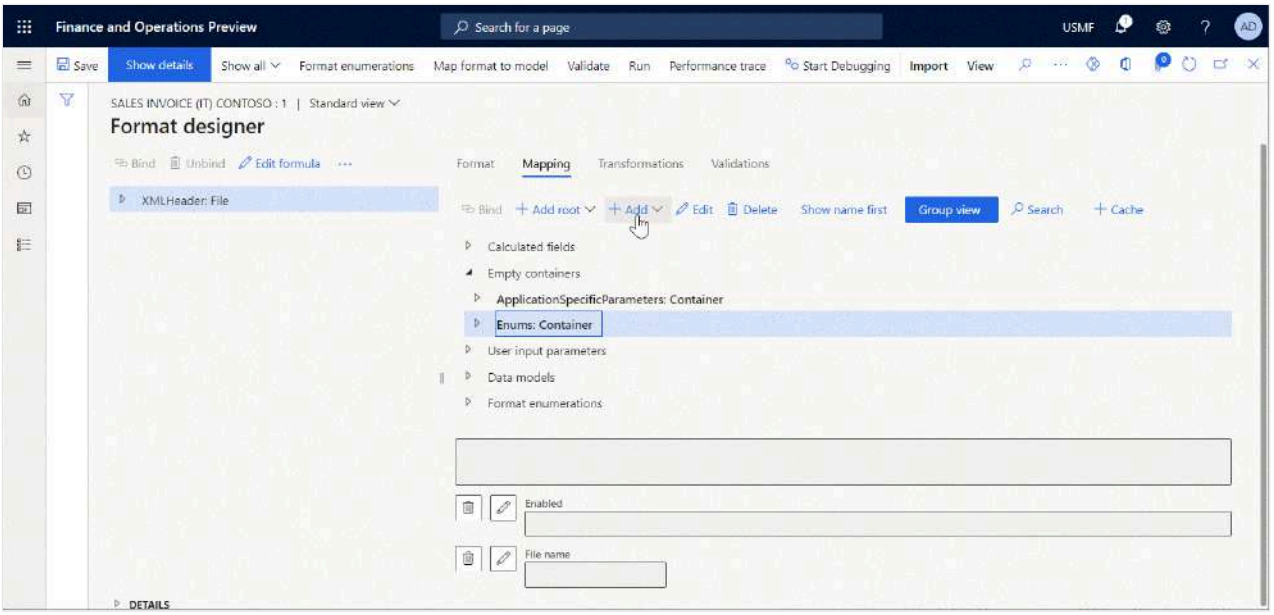
Use the appropriate type of ER data sources to bring a specific enumeration to a configured ER component as a constant or as a value that the user running an ER solution defined in the dialog box at runtime.

- Access application enumerations by using the **Dynamics 365 for Operations \ Enumeration** and **General \ User input parameters** data sources. The following illustration shows how you can add to the editable ER format the **appenumNoYes** and **uipNoYes** data sources that refer to the **NoYes** application enumeration.

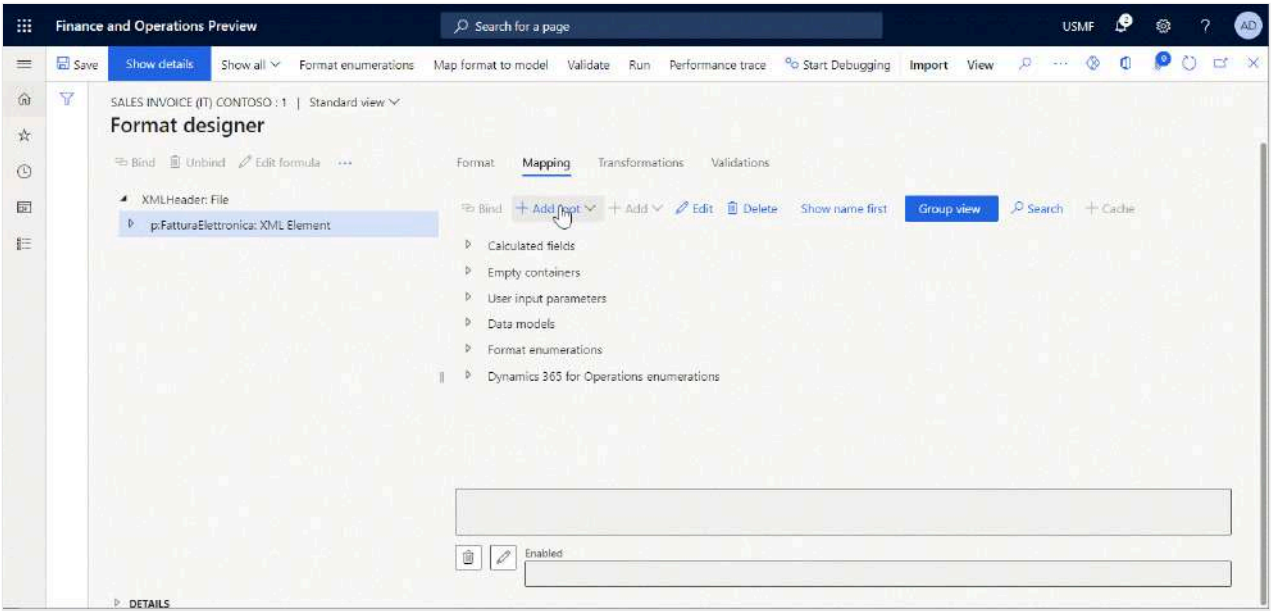


- Access data model enumerations by using the **Data model \ Enumeration** and **Data model \ Enumeration user input parameters** data sources. The following illustration

shows how you can add to the editable ER format the **CustVendCorrectiveReasonCode** data source that refers to the **CustVendCorrectiveReasonCode** data model enumeration.



- Access format enumerations by using the **Format \ Enumeration** and **Format \ Enumeration user input parameters** data sources. The following illustration shows how you can add to the editable ER format the **NaturaReverseCharge** data source that refers to the **Natura reverse charge subcategories** format enumeration.



An *enumeration* has no implicit conversions. However, you can use the TEXT conversion function to convert an *enumeration* to a text string. This conversion isn't language dependent. To learn how you can associate an *enumeration* value with the appropriate language-specific labels, see the usage examples for the LISTOFFIELDS and GETENUMVALUEBYNAME functions.

Comparison operators are the only type of operator that you can use with the *enumeration* data type. The following operators can be used to compare two *enumeration* values: <> and =.

Guid

The *guid* primitive data type holds a globally unique identifier (GUID) value. A GUID is a value that you can use across all computers and networks, wherever a unique identifier is required. It's unlikely that the number is duplicated. A valid GUID meets all the following specifications:

- It has 32 hexadecimal digits.
- It has four dash characters that are embedded at the following locations: 8-4-4-4-12.
- You can add optional braces {} at the beginning and end of the string. For example, both **{2CDB0FE7-D7B3-4938-A0F0-FE28FB8FE212}** and **2CDB0FE7-D7B3-4938-A0F0-FE28FB8FE212** are valid GUID strings.
- It has a total of 36 or 38 characters, depending on whether you add braces.
- The letters that are used as hexadecimal digits can be uppercase (A–F), lowercase (a–f), or mixed.

Use the following explicit conversion functions:

- GUIDVALUE
- TEXT

Comparison operators are the only type of operator that you can use with the *guid* data type. Use the following operators to compare two *guid* values: <> and =.

Integer

The *integer* primitive data type represents a number that has no decimal places. Use integers as control variables in repetitive statements or as indexes in record lists.

An *integer* literal is the integer as it's entered directly in an ER expression (formula), such as **12345**. An *integer* is 32 bits wide. The default value is **0**, and the internal representation is a long number. An *integer* is automatically converted to a *real*.

Additionally, use the following explicit conversion functions:

- INTVALUE
- NUMBERFORMAT
- TEXT

The range of an *integer* is [-2,147,483,647 : 2,147,483,647]. You can use all integers in this range as literals.

Use all comparison and mathematical operators with the *integer* data type.

Int64

The *int64* primitive data type represents a number that has no decimal places. Use *Int64* values as control variables in repetitive statements or as record identifiers.

An *int64* is 64 bits wide. The default value is **0**, and the internal representation is a long number. An *int64* automatically converts to a *real*.

Additionally, use the following explicit conversion functions:

- INT64VALUE
- NUMBERFORMAT
- TEXT

The range of an *int64* is [-9,223,372,036,854,775,807 : 9,223,372,036,854,775,807].

You can use all comparison and mathematical operators with the *int64* data type.

Real

The *real* primitive data type can hold decimal values in addition to integers. You can use decimal literals anywhere that a *real* is expected. A decimal literal is the decimal as it's entered directly in code, such as **2.19**.

> ⓘ **Note**
>
> In ER expressions, a period (.) is always used as the decimal separator.

You can use reals in all expressions, and you can use them with both comparison and arithmetic operators. A *real* has a precision of 16 significant digits. The default value for a *real* is **0.0**, and the internal representation is a binary-coded digital (BCD) number. The BCD encoding enables exact representations of values that are multiples of 0.1. The range of a *real* variable is $-(10)^{127}$ through $(10)^{127}$. All reals in this range can be used as literals in ER expressions.

A *real* has no implicit conversions. However, you can use the following functions to explicitly convert a *real* to other data types and other data types to a *real*:

- INTVALUE

- INT64VALUE
- NUMBERFORMAT
- TEXT
- VALUE

You can use all comparison and mathematical operators with the *real* data type.

String

The *string* primitive data type represents a sequence of characters that are used as texts, account numbers, addresses, and telephone numbers.

String literals are characters that are enclosed in quotation marks (""). *String* literals can be used wherever *string* values are expected in ER expressions. You can use strings in logical expressions, such as comparisons. You can also concatenate *string* values by using the **&** operator or the CONCATENATE function.

> ⓘ **Note**
>
> If you concatenate two *string* values, and you want the resulting *string* to span more than one line, use the line break separator between the values. For the TEXT output, this separator can be a character that is generated by using the CHAR(10) or CHAR(13) expression. For HTML, it can be the **
** tag.

The default value for a *string* is a blank text string that has no characters, and the internal representation is a list of characters.

There are no automatic conversions for strings. However, you can use the following explicit conversion functions:

- CHAR
- FORMAT
- LEFT
- LEN
- MID
- PADLEFT
- REPLACE
- RIGHT
- TEXT

- TRANSLATE
- TRIM
- UPPER

For more information about the transformation of *string* values, see List of ER functions of the text category.

A *string* can hold an indefinite number of characters.

All comparison operators can be used with the *string* data type.

Supported composite data types for Electronic reporting formulas

This article provides information about the composite data types that are supported in Electronic reporting (ER) expressions. The composite data types are class, container, record, record list, and object.

Class

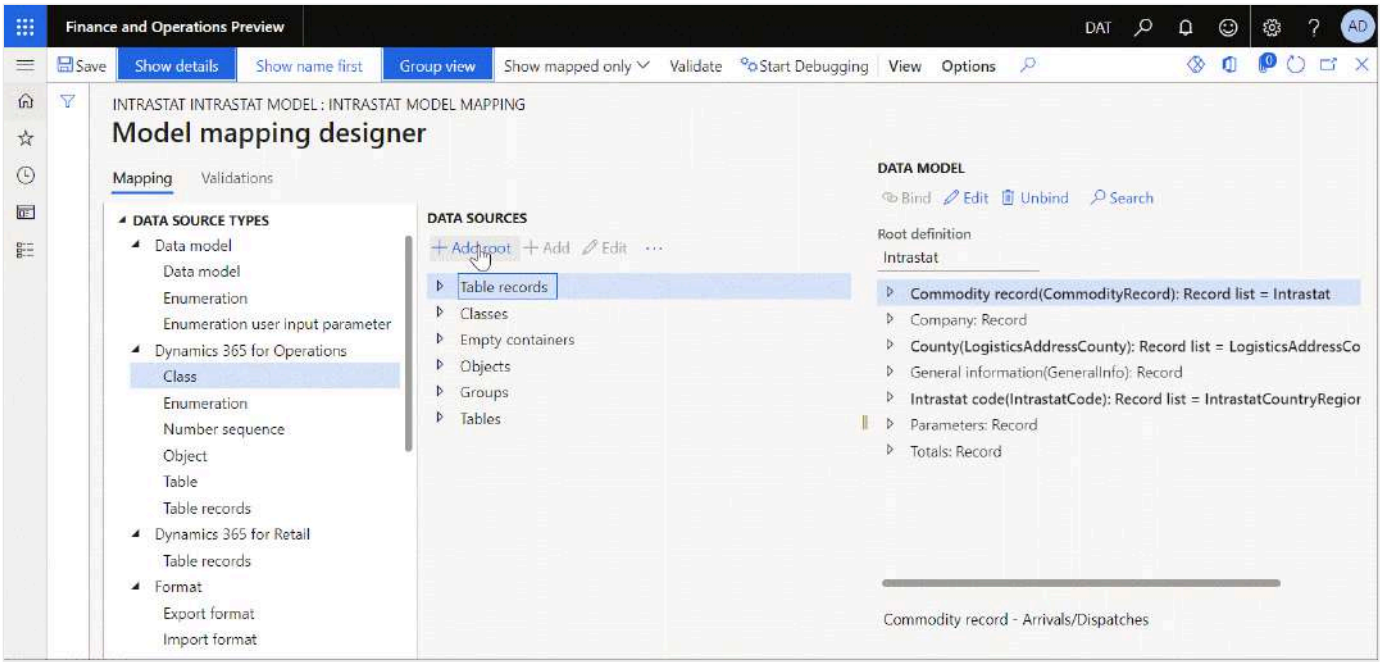
The *class* data type refers to a public application class. In ER, it's represented as a *record* that contains a separate field for every public method of the referenced class. When the call of the method is parameterized, you must also specify the required arguments of the appropriate types in an ER expression that is configured to call the method.

In ER mapping and format components, you can add the **Class** data source that is presented as a data source and that returns a value of the *class* type. This data source exposes public methods of the class that you can call at runtime.

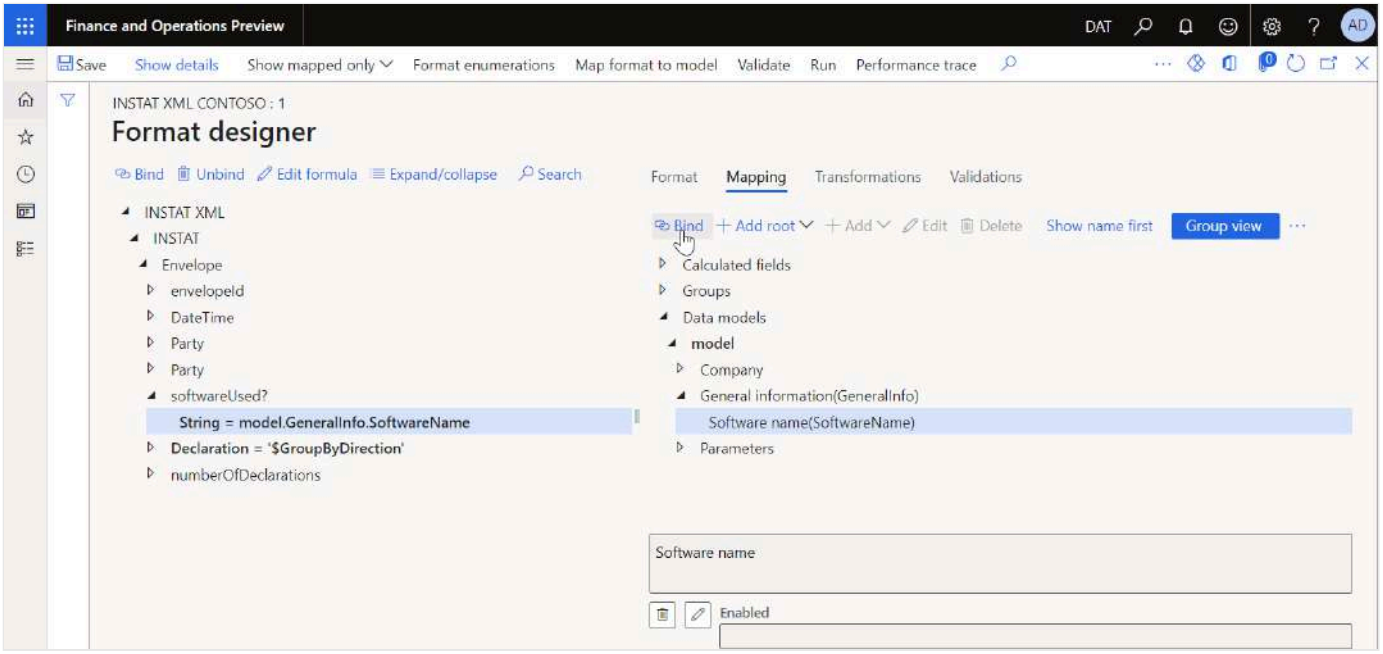
> ⓘ **Note**
>
> Only methods that return a value can be called from ER expressions.
>
> Only methods that have a range of zero to eight arguments can be called from ER expressions.

The default value of a *class* is **null**.

The following illustration shows how the **System information(xInfo)** data source of the **Class** type is added to make the instance of the **xInfo** application class and call its **productName()** method to receive the name of the current application. The name of the current application is fetched at runtime by execution of the `xInfo.productName` binding that you configured for the **Software name(SoftwareName)** field of the ER data model. This binding calls the `productName()` method of the **xInfo** application class that is represented in the current model mapping as the **System information(xInfo)** data source.



The following illustration shows how the ER format is configured to put the provided application name in generated documents. The **Software name(SoftwareName)** field of the used data model is bound to the **String** component that is nested under the **softwareUsed** XML element of the ER format. So, the name of the current application is placed at runtime to the **softwareUsed** XML element of a generated document in XML format.



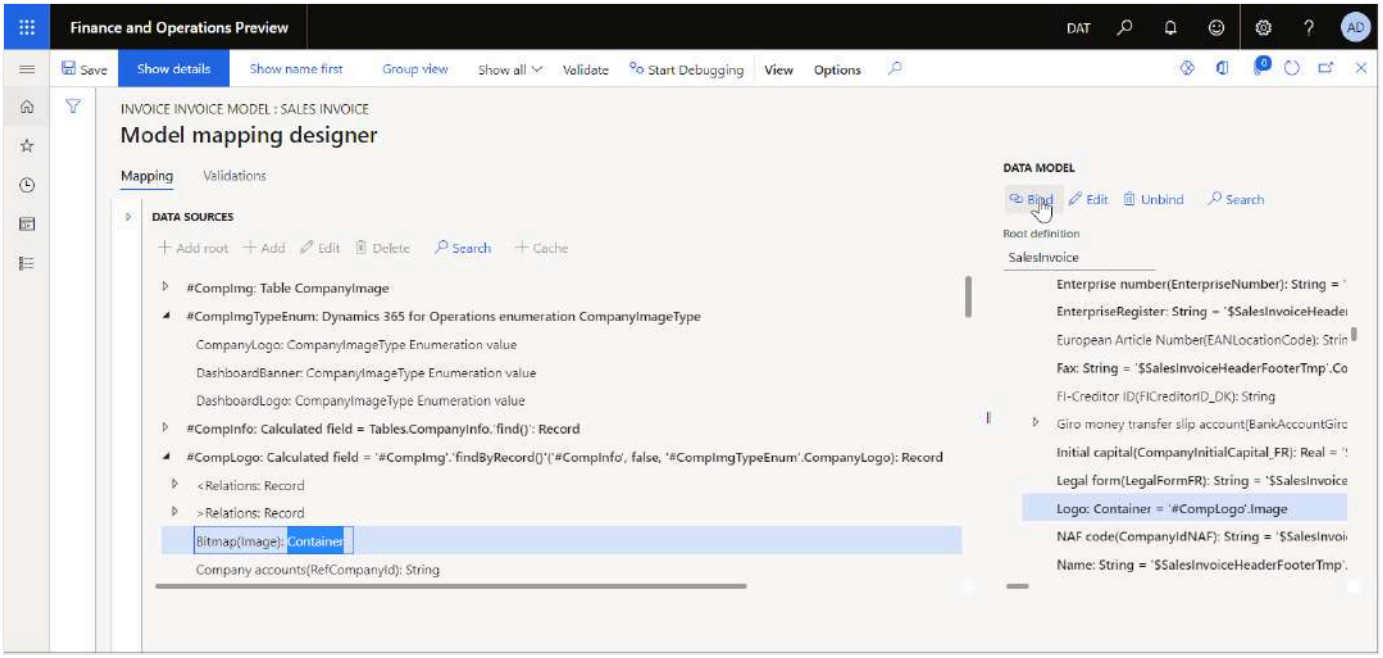
Container

The *container* data type holds binary content. Use a *container* value to pass specific information from storage to a generated document. In the ER framework, use this data type to include media content such as a company logo in generated documents.

> **Note**
>
> Although you can represent every media item as a *container* value, not every *container* value represents a media item. Therefore, if you configure an ER format to use a *container* to include an image in generated documents, but the referenced *container* doesn't return media content, an exception might be thrown. The exception resembles the following example: "Error executing code: Binary (object), method constructFromContainer called with invalid parameters."

The default value of a *container* is **null**.

The following illustration shows how the **Bitmap(Image)** field of the *Container* type is bound to the data model **Logo** field of the **Container** type in the **Sales invoice** model mapping. This binding makes the company logo available to any ER format that is designed for the **SalesInvoice** root definition and that uses this model mapping at runtime.



Record

A *record* is a collection of named fields, each associated with a value of either a primitive data type or a composite data type. Usually, you use a *record* to represent a single record in a record list. In this case, every item represents individual fields, methods, and relations.

The default value of a *record* is **empty**.

> **Note**

When you get the value of a field in an empty *record*, the default value of the appropriate data type is returned.

You can get a *record* by using the following functions:

- FIRST
- FIRSTORNULL
- EMPTYRECORD
- NULLCONTAINER

For more information about the transformation of *record* values, see List of ER functions in the list category.

Record list

A *record list* is a list of items of the *record* type. Usually, you use a *record list* to represent the list of records that you fetch from a database table.

By default, you access records in a *record list* sequentially. To access a specific record, use the INDEX function and specify the *integer* index.

The default value of a *record list* is **empty**. Use the ISEMPTY function to check whether a *record list* is empty.

> ⓘ **Note**
>
> If a *record list* is empty, any attempt to get a field value for a *record* in it causes an exception to be thrown at runtime. To learn how you can help prevent runtime exceptions of this type, see **Consideration of empty list cases**.

Initiate a *record list* by using the following functions:

- ALLITEMS
- ALLITEMSQUERY
- EMPTYLIST
- LIST
- LISTDISTINCT

For more information about the transformation of *record list* values, see List of ER functions in the list category. To learn how to introduce *record list* items, fill them with application data, and then

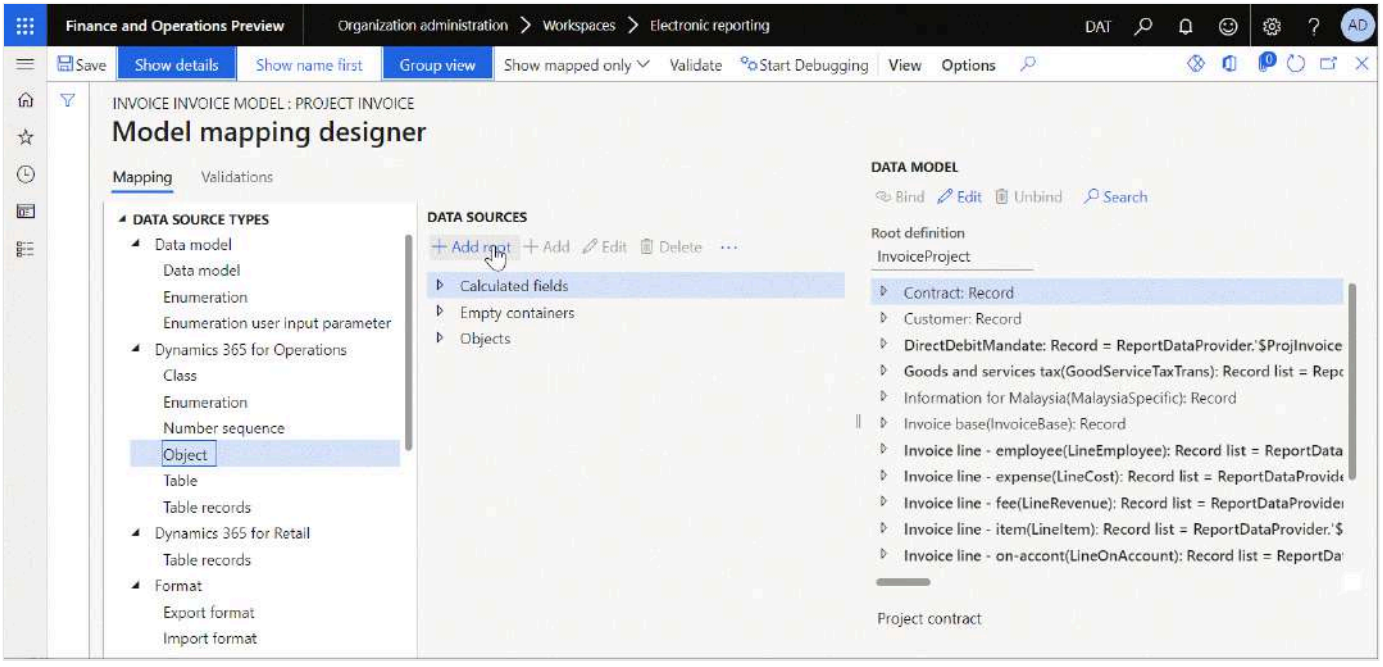
use the data to generate business documents, see Design a new ER solution to print a custom report.

Object

An *object* is a stateful instance of a *class*. You usually create an *object* in source code. You then pass the *object* to an ER model mapping, where it provides details about the execution context.

The default value of an *object* is **null**.

The following illustration shows how you add the **ReportDataContract** data source of the *Object* type to pass information about a generated invoice from source code to the **Project invoice** model mapping. For example, the invoice instance text is part of the execution context. The execution context text comes from source code at runtime by execution of the `ReportDataContract.parmInvoiceInstanceText` binding that you configured for the **Note** field of the ER data model. This binding calls the `parmInvoiceInstanceText()` method of the **PSAProjInvoiceContract** application class that the current model mapping represents as the **ReportDataContract** data source.



To learn how to pass details of the execution context from source code to the running ER solution, see Develop application artefacts to call the designed report.

> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) container functions can be used to perform operations that involve data sources of the *Container* data type. These operations occur when the processing data represents a collection of binary data in binary large object (BLOB) format. This article provides a summary of these functions.

List of supported functions

Expand table

Function	Description
Base64StringToContainer	This function returns a *Container* value that consists of binary content that is decoded from the specified ASCII string that represents a Base64 group of binary-to-text encoding schemes.

Base64StringToContainer ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `BASE64STRINGTOCONTAINER` function converts the specified input of the *String* type to a data item of the *Container* type.

Syntax

VB

```
BASE64STRINGTOCONTAINER (input)
```

Arguments

`input`: *String*

The valid path of a data source of the *String* type.

Return values

Container

The resulting binary value in binary large object (BLOB) format.

Usage notes

The "Parameter is not valid" exception is thrown if the input string doesn't provide a correct Base64 group of binary-to-text encoding schemes.

Example

You define the following data sources in your model mapping:

- The root **DocuTypeGroupEnum** data source of the *Dynamics 365 for Operations / Enumeration* type that refers to the **DocuTypeGroup** application enumeration
- The root **Customer** data source of the *Dynamics 365 for Operations / Table records* type that refers to the **CustTable** application table
- The **#Media** data source of the *Calculated field* type that is configured in the following way:
  - It's added as a child data source of the **Customer** data source.
  - It contains the expression `WHERE(@.'<Relations'.'<Documents', @.'<Relations'.'<Documents'.'docuType()'.TypeGroup = DocuTypeGroupEnum.Image)`.
- The **#MediaAsBase64String** data source of the *Calculated field* type that is configured in the following way:
  - It's added as a child data source of the **Customer.'#Media'** data source.
  - It contains the expression `Customer.'#Media'.'getFileContentAsBase64String()'`.
- The **#BlobFomBase64** data source of the *Calculated field* type that is configured in the following way:
  - It's added as a child data source of the **Customer.'#Media'** data source.
  - It contains the expression `Base64StringToContainer(Customer.'#Media'.'#MediaAsBase64String')'`.

In this example, the **#MediaAsBase64String** data source encodes the binary content of the current media attachment as text that represents a Base64 group of binary-to-text encoding schemes. The **#BlobFomBase64** data source decodes the Base64 string and returns a binary value in BLOB format.

List of ER functions in the Date and time category

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) date and time functions can be used to extract information from date and time values, and to perform operations on them. This article provides a summary of these functions.

List of supported functions

Expand table

Function	Description
AddDays	This function returns a *DateTime* value that is the specified number of days before or after a specified start date.
ChangeTimeZone	This function returns a *DateTime* value that is converted from a given date/time value in one time zone to a date/time value in another time zone.
DateFormat	This function returns a *String* value that presents a given date value as text in the specified format and in an optionally specified culture.
DateTimeFormat	This function returns a *String* value that presents a given date/time value as text in the specified format and in an optionally specified culture.
DateTimeValue	This function returns a *DateTime* value that is converted from a given text value in the specified format and in an optionally specified culture to a date/time value.
DateToDateTime	This function returns a *DateTime* value that is converted from a given date value to a date/time value in Coordinated Universal Time (Greenwich Mean Time [GMT]).
DateValue	This function returns a *Date* value that is converted from a given text value in the specified format and in an optionally specified culture to a date value.

Function	Description
DayOfYear	This function returns an *Integer* value that represents the number of days between January 1 and the specified date.
Days	This function returns an *Integer* value that represents the number of days between one specified date and a second specified date.
Now	This function returns a *DateTime* value that represents the current application server date and time.
NullDate	This function returns a *Date* value that represents the **null** date (January 1, 1900).
NullDateTime	This function returns a *DateTime* value that represents the **null** date/time value (January 1, 1900) in Coordinated Universal Time.
SessionNow	This function returns a *DateTime* value that represents the current application session date and time.
SessionToday	This function returns a *Date* value that represents the current application session date.
Today	This function returns a *Date* value that represents the current application server date.
WeekNum	This function returns an *Integer* value that represents the week of the year.

ADDDAYS ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ADDDAYS` function calculates a *DateTime* value that is the specified number of days before or after a specified start date.

Syntax

```
VB

ADDDAYS (datetime, days)
```

Arguments

`datetime`: *DateTime*

A date/time value that represents the start date.

`days`: *Integer*

The number of days before or after `datetime`.

Return values

DateTime

The resulting date/time value.

Usage notes

A positive value for `days` yields a future date. A negative value yields a past date.

Example 1

`ADDDAYS (NOW(), 7)` returns the date and time seven days in the future.

Example 2

`ADDDAYS (NOW(), -3)` returns the date and time three days in the past.

Additional resources

Date and time functions

Last updated on 04/08/2026

CHANGETIMEZONE ER function

The `CHANGETIMEZONE` function returns a *DateTime* value in Coordinated Universal Time (Greenwich Mean Time [GMT]) that is converted from a given date/time value in one time zone to a date/time value in another time zone.

Syntax

VB

```
CHANGETIMEZONE (datetime, base time zone, target time zone)
```

Arguments

`datetime`: *DateTime*

A date/time value in the Coordinated Universal Time time zone that represents the date/time value to convert.

`base time zone`: *String*

The name of the time zone that a given date/time value is shifted to before conversion.

`target time zone`: *String*

The name of the time zone that a converted date/time value is shifted to during conversion.

Return values

DateTime

The resulting date/time value in the Coordinated Universal Time time zone.

Usage notes

To specify source and target time zones, you can use time zone names that are provided by the Internet Assigned Numbers Authority (IANA) or that are supported by Microsoft Windows.

At runtime, the exception "Time zone '<time zone name>' does not exist" is thrown if the provided name isn't found in the IANA list or in the Windows registry.

For time zones where daylight saving time is observed, the conversion considers the Coordinated Universal Time daylight saving time offset. The latest available information about this offset is used during conversion.

Example 1

In this example, the time zone names for Windows are used.

You configure the **DSX** data source of the **Calculated field** type. It contains the following expression.

VB

```
CONCATENATE(
    DATETIMEFORMAT( DSY, "O"),
    " -> ",
    DATETIMEFORMAT( CHANGETIMEZONE(DSY, "E. Europe Standard Time", "Hawaiian Standard Time"), "O")
)
```

If you configure the expression of the **DSY** data source of the **Calculated field** type as `DATETIMEVALUE ("01-Jun-2021 12:55:00", "dd-MMM-yyyy HH:mm:ss", "EN")`, the **DSX** data source returns the text **2021-06-01T12:55:00.0000000+00:00 -> 2021-05-31T23:55:00.0000000+00:00**. This text shows that the time difference between the two provided time zones on June 1 is more than 24 hours. Therefore, the converted date/time value is one day earlier than the given date/time value, because the base time zone is ahead of the target time zone.

If you configure the expression of the **DSY** data source of the **Calculated field** type as `DATETIMEVALUE ("01-Dec-2021 12:55:00", "dd-MMM-yyyy HH:mm:ss", "EN")`, the **DSX** data source returns the text **2021-12-01T12:55:00.0000000+00:00 -> 2021-12-01T00:55:00.0000000+00:00**. This text shows that the time difference between the two provided time zones on December 1 is less than 24 hours. Therefore, the converted date/time value equals the given date/time value.

> ⓘ **Note**
>
> The same expression returns a different variance between the provided and converted date/time values for the same pair of time zones because a different Coordinated Universal Time daylight saving time offset is observed for the provided time zones on a given date/time.

Example 2

In this example, the IANA time zone names are used.

You configure the **DSX** data source of the **Calculated field** type. It contains the following expression.

VB

```
CONCATENATE(
    DATETIMEFORMAT( DSY, "O"),
    " -> ",
    DATETIMEFORMAT( CHANGETIMEZONE(DSY, "Europe/Athens", "US/Hawaii"), "O")
)
```

If you configure the expression of the **DSY** data source of the **Calculated field** type as `DATETIMEVALUE ("01-Jun-2021 12:55:00", "dd-MMM-yyyy HH:mm:ss", "EN")`, the **DSX** data source returns the text **2021-06-01T12:55:00.0000000+00:00 -> 2021-05-31T23:55:00.0000000+00:00**. This text shows that the time difference between the two provided time zones on June 1 is more than 24 hours. Therefore, the converted date/time value is one day earlier than the given date/time value, because the base time zone is ahead of the target time zone.

If you configure the expression of the **DSY** data source of the **Calculated field** type as `DATETIMEVALUE ("01-Dec-2021 12:55:00", "dd-MMM-yyyy HH:mm:ss", "EN")`, the **DSX** data source returns the text **2021-12-01T12:55:00.0000000+00:00 -> 2021-12-01T00:55:00.0000000+00:00**. This text shows that the time difference between the two provided time zones on December 1 is less than 24 hours. Therefore, the converted date/time value equals the given date/time value.

Example 3

You configure the **DSX** data source of the **Calculated field** type. It contains the following expression.

VB

```
CONCATENATE(
    DATETIMEFORMAT( DSY, "O"),
    " -> ",
    DATETIMEFORMAT( CHANGETIMEZONE(DSY, "US/Hawaii", "Europe/Athens"), "O")
)
```

If you configure the expression of the **DSY** data source of the **Calculated field** type as `DATETIMEVALUE ("01-Jun-2021 12:55:00", "dd-MMM-yyyy HH:mm:ss", "EN")`, the **DSX** data source returns the text **2021-06-01T12:55:00.0000000+00:00 -> 2021-06-02T01:55:00.0000000+00:00**'. This text shows that the time difference between the two provided time zones on June 1 is more than 24 hours. Therefore, the converted date/time value is one day later than the given date/time value, because the target time zone is ahead of the base time zone.

Example 4

You might receive a date and time stamp from an external source as text that contains no time zone information. However, you might know the time zone that the source operates in. For example, you receive the date and time stamp **01/12/2025 12:55:00** from a service that operates in Spain. To correctly save this date and time value to the database, complete the following conversion steps:

- Configure the **DSY** data source of the **Calculated field** type to convert a date/time stamp from text to the Coordinated Universal Time date/time value.

  ```
  DATETIMEVALUE ("01/12/2025 12:55:00", "dd/MM/yyyy HH:mm:ss", "ES")
  ```

- Configure the **DSX** data source of the **Calculated field** type to shift the converted date/time value to Coordinated Universal Time as the date/time value of the time zone of the external source.

  ```
  CHANGETIMEZONE(DSY, "Romance Standard Time", "GMT Standard Time")
  ```

> **Note**
>
> When you use the `CHANGETIMEZONE` function for date/time conversion, be aware that any date/time value is stored in the database as the value in the Coordinated Universal Time time zone. Before this value can be presented on application pages, it's transformed. The transformation considers the time zone that is **set** as a preferred zone for the currently signed-in application user.

DATEFORMAT ER function

The `DATEFORMAT` function returns a *String* value that presents a given date value as text in the specified format and in an optionally specified culture. For information about the supported formats, see standard and custom.

Syntax 1

VB

```
DATEFORMAT (date, format)
```

Syntax 2

VB

```
DATEFORMAT (date, format, culture)
```

Arguments

`date`: *Date*

A date value that represents the date to format.

`format`: *String*

The format of the output string. For information about the supported formats, see standard and custom.

> ⓘ Note
>
> The format string is case-sensitive when you use either a standard format or a custom format. For example, the **standard** "d" format specifier returns the date by using the short date pattern, whereas the standard "D" format specifier returns the date by using the long date pattern. Additionally, the **custom** "M" format specifier returns the month from 1 through 12, whereas the custom "m" format specifier returns the minute from 0 through 59.

`culture`: *String*

The culture to use for formatting. For information about the supported cultures, see culture.

Return values

String

The resulting string value.

Usage notes

If the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATEFORMAT` function is called by using syntax 1 in an Electronic reporting (ER) format for a **FILE** element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

Example 1

`DATEFORMAT (TODAY (), "dd-MM-yyyy")` returns the current application server date, December 24, 2025, as the string "**24-12-2025**", based on the specified custom format.

Example 2

`DATEFORMAT (SESSIONTODAY (), "d", "DE")` returns the current application session date, December 24, 2025, as the string "**24-12-2025**", based on the selected German culture and the specified format.

Date and time functions

Last updated on 08/04/2026

DATETIMEFORMAT ER function

The `DATETIMEFORMAT` function returns a *String* value that presents a given date/time value as text in the specified format and in an optionally specified culture. For information about the supported formats, see standard and custom.

Syntax 1

VB

```
DATETIMEFORMAT (datetime, format)
```

Syntax 2

VB

```
DATETIMEFORMAT (datetime, format, culture)
```

Arguments

`datetime`: *DateTime*

A date/time value that represents the date and time to format.

`format`: *String*

The format of the output string. For information about the supported formats, see standard and custom.

> ⓘ Note
>
> The format string is case-sensitive when you use either a standard format or a custom format. For example, the **standard** "d" format specifier returns the date by using the short date pattern, whereas the standard "D" format specifier returns the date by using the long date pattern. Additionally, the **custom** "M" format specifier returns the month from 1 through 12, whereas the custom "m" format specifier returns the minute from 0 through 59.

`culture`: *String*

The culture to use for formatting. For information about the supported cultures, see culture.

Return values

String

The resulting string value.

Usage notes

If the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATETIMEFORMAT` function is called by using syntax 1 in an Electronic reporting (ER) format for a **FILE** element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

When the `DATETIMEFORMAT` function converts a given date/time value, it considers the time zone setting of the application user who is running the ER format that the function is called in the context of.

Example 1

`DATETIMEFORMAT (NOW(), "dd-MM-yyyy")` returns the current application server date/time value, December 24, 2025, as "**24-12-2025**", based on the specified custom format.

Example 2

`DATETIMEFORMAT (SESSIONNOW(), "d", "DE")` returns the current application session date/time value, December 24, 2025, as "**24.12.2025**", based on the selected German culture and the specified format.

Example 3

`DATETIMEFORMAT (DATETIMEVALUE( "2019-11-12T09:00:00.0000000-07:00", "O"), "O")` returns the string value **2024-11-12T08:00:00.0000000-08:00** when the function is called during a process that an application user initiates who has the time zone value **(GMT-08:00) Pacific Time (US & Canada)** in the **Language and country/region preferences** section.

DATETIMEVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `DATETIMEVALUE` function returns a *DateTime* value that is converted from a given text value in the specified format and in an optionally specified culture to a date/time value. For information about the supported formats, see standard and custom.

Syntax 1

```
VB

DATETIMEVALUE (text, format)
```

Syntax 2

```
VB

DATETIMEVALUE (text, format, culture)
```

Arguments

`text`: *String*

Text that represents the value to format.

`format`: *String*

The format of the given text. For information about the supported formats, see standard and custom.

`culture`: *String*

The culture that is used for formatting of the given text. For information about the supported cultures, see culture.

Return values

DateTime

The resulting date/time value.

Usage notes

When the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATETIMEVALUE` function is called by using syntax 1 in an Electronic reporting (ER) format for a **FILE** element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

Example 1

`DATETIMEVALUE ("21-Dec-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss")` returns **2:55:00 AM on December 21, 2016**, based on the specified custom format and the default application's **EN-US** culture.

Example 2

`DATETIMEVALUE ("21-Gen-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss", "IT")` returns **2:55:00 AM on December 21, 2016**, based on the specified custom format and culture.

However, `DATETIMEVALUE ("21-Gen-2016 02:55:00", "dd-MMM-yyyy hh:mm:ss", "EN-US")` throws an exception to inform the user that the specified string isn't recognized as a valid date/time value for the specified culture.

DATETODATETIME ER function

The `DATETODATETIME` function returns a *DateTime* value that is converted from a given date value to a date/time value in Coordinated Universal Time (Greenwich Mean Time [GMT]).

Syntax

VB

```
DATETODATETIME (date)
```

Arguments

`date`: *Date*

A date value that represents the date to convert.

Return values

DateTime

The resulting date/time value.

Example 1

`DATETODATETIME (CompInfo. 'getCurrentDate()')` returns the date of the current Microsoft Dynamics 365 Finance session, December 24, 2025, as **12/24/2025 12:00:00 AM**. In this example, **CompInfo** is an Electronic reporting (ER) data source of the **finance and operations/Table** type, and it refers to the CompanyInfo table.

Example 2

`DATETODATETIME (DATEVALUE ("2024-11-12T16:00:00.0000000-07:00", "O"))` returns the date and time value **11/12/2024 12:00:00 AM**.

DATEVALUE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `DATEVALUE` function returns a *Date* value that is converted from a given text value in the specified format and in an optionally specified culture to a date value. For information about the supported formats, see standard and custom.

Syntax 1

```
VB

DATEVALUE (text, format)
```

Syntax 2

```
VB

DATEVALUE (text, format, culture)
```

Arguments

`text`: *String*

Text that represents the value to format.

`format`: *String*

The format of the given text. For information about the supported formats, see standard and custom.

`culture`: *String*

The culture that is used for formatting of the given text. For information about the supported cultures, see culture.

Return values

Date

The resulting date value.

Usage notes

When the culture isn't defined as an argument of the called function, the value of `culture` is defined by the calling context. For example, if the `DATEVALUE` function is called by using syntax 1 in an Electronic reporting (ER) format for a **FILE** element that is configured to use the German culture, the conversion will be done by using the German culture. The default `culture` value is **EN-US**.

Example 1

`DATEVALUE ("21-Dec-2016", "dd-MMM-yyyy")` returns the date value **December 21, 2016**, based on the specified custom format and the default application's **EN-US** culture.

Example 2

`DATEVALUE ("21-Gen-2016", "dd-MMM-yyyy", "IT")` returns the date value **January 21, 2016**, based on the specified custom format and culture.

However, `DATEVALUE ("21-Gen-2016", "dd-MMM-yyyy", "EN-US")` throws an exception to inform the user that the specified string isn't recognized as a valid date for the specified culture.

DAYOFYEAR ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `DAYOFYEAR` function returns an *Integer* value that represents the number of days between January 1 and the specified date.

Syntax

VB

```
DAYOFYEAR (date) as Integer
```

Arguments

`date`: *Date*

A date value that represents the date to use for the calculation of the number of days.

Return values

Integer

The resulting numeric value.

Example 1

`DAYOFYEAR (DATEVALUE ("01-03-2016", "dd-MM-yyyy"))` returns **61**.

Example 2

`DAYOFYEAR (DATEVALUE ("01-01-2016", "dd-MM-yyyy"))` returns **1**.

DAYS ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `DAYS` function returns an *Integer* value that represents the number of days between one specified date and a second specified date.

Syntax

VB

```
DAYS (date 1, date 2) as Integer
```

Arguments

`date 1`: *Date*

A date value that represents the start date for the calculation of the number of days.

`date 2`: *Date*

A date value that represents the end date for the calculation of the number of days.

Return values

Integer

The resulting numeric value.

Usage notes

The `DAYS` function returns a positive value when the first date is later than the second date, it returns **0** (zero) when the first date equals the second date, and it returns a negative value

when the first date is earlier than the second date.

Example

```
DAYS (TODAY (), DATEVALUE( DATETIMEFORMAT( ADDDAYS ( NOW(), 1), "yyyyMMdd"), "yyyyMMdd"))
```

returns **-1**.

Date and time functions

Last updated on 04/08/2026

NOW ER function

The `NOW` function returns a *DateTime* value that represents the current application server date and time.

Syntax

```VB
NOW ()
```

Return values

DateTime

The resulting date/time value.

Example

`DATETIMEFORMAT (NOW(), "dd-MM-yyyy")` returns the current application server date/time value, December 24, 2025, as "**24-12-2025**", based on the specified custom format.

NULLDATE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `NULLDATE` function returns a *Date* value that represents the **null** date (January 1, 1900).

Syntax

VB

```
NULLDATE () as
```

Return values

Date

The resulting date value.

Example 1

`DATEFORMAT (NULLDATE(), "yyyy-MM-dd")` returns the **null** date, January 1, 1900, as **"1900-01-01"**, based on the specified custom format.

Example 2

The expression `IF( Invoice.DocumentDate = NULLDATE(), true, false)` returns **True** when the value of the **DocumentDate** field equals the **null** date. In this example, **Invoice** is an Electronic reporting (ER) data source of the **Finance/Table records** type, and it refers to the CustInvoiceJour table.

NULLDATETIME ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `NULLDATETIME` function returns a *DateTime* value that represents the **null** date/time value (January 1, 1900) in Coordinated Universal Time (Greenwich Mean Time [GMT]).

Syntax

VB

```
NULLDATETIME ()
```

Return values

DateTime

The resulting date/time value.

Example

`DATETIMEFORMAT( NULLDATETIME(), "O")` returns the string value **1900-01-01T00:00:00.0000000+00:00** when it's called during a process that was initiated by an application user who has the time zone value **(GMT) Coordinated Universal Time** in the **Language and country/region preferences** section.

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `SESSIONNOW` function returns a *DateTime* value that represents the current application session date and time.

Syntax

VB

```
SESSIONNOW ()
```

Return values

DateTime

The resulting date/time value.

Example

`DATETIMEFORMAT (SESSIONNOW(), "d", "DE")` returns the current application session date/time value, December 24, 2015, as "**24.12.2015**", based on the selected German culture and the specified format.

SESSIONTODAY ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `SESSIONTODAY` function returns a *Date* value that represents the current application session date.

Syntax

VB

```
SESSIONTODAY ()
```

Return values

Date

The resulting date value.

Example

`DATEFORMAT (SESSIONTODAY (), "d", "DE")` returns the current application session date, December 24, 2015, as the string **"24-12-2015"**, based on the selected German culture and the specified format.

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `TODAY` function returns a *Date* value that represents the current application server date.

Syntax

```
X++
TODAY ()
```

Return values

Date

The resulting date value.

Example

`DATEFORMAT (TODAY (), "dd-MM-yyyy")` returns the current application server date, December 24, 2015, as the string **"24-12-2015"**, based on the specified custom format.

WEEKNUM ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `WEEKNUM` function returns an *Integer* value that represents the week of the year that includes a specified *Date* value. The calculation is based on culture-dependent rules that define a calendar week and the first day of the week.

Syntax

VB

```
WEEKNUM (date, culture) as Integer
```

Arguments

`date`: *Date*

A date value that represents the date to use to calculate the week of the year.

`culture`: *String*

The culture to use for the calculation. You can use culture codes that are supported in accordance with .NET standards.

Return values

Integer

The resulting numeric value.

Usage notes

The week of the year is calculated based on the ISO 8601 standard, if this standard has been adopted by a country or region that the locale is provided for at runtime. Otherwise, the calculation is based on country/region-specific national standards.

If an unsupported culture code is provided as an argument of the `WEEKNUM` function at runtime, an exception is thrown. If the blank string is provided as a culture code, the English country/region-neutral calendar is used to calculate the week number.

Examples

`WEEKNUM (DATEVALUE ("01-01-2020", "de"))` returns **1**.

`WEEKNUM (DATEVALUE ("01-01-2021", "de"))` returns **53**.

`WEEKNUM (DATEVALUE ("01-01-2022", "de"))` returns **52**.

`WEEKNUM (DATEVALUE ("01-01-2022", "ar"))` returns **21**.

List of ER functions in the list category

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) list functions can be used to extract information from, and perform operations on, data sources of the *Record list* and *Container (record)* data types. This article provides a summary of these functions.

List of supported functions

Expand table

Function	Description
AllItems	This function runs as an in-memory selection. It returns a new flattened *Record list* value that consists of a list of records that represents all items that match the specified path.
AllItemsQuery	This function runs as a joined SQL query. It returns a new flattened *Record list* value that consists of a list of records that represents all items that match the specified path.
Count	This function returns an *Integer* value that represents the number of records in the specified list, if the list isn't empty. If the list is empty, this function returns **0** (zero).
EmptyList	This function returns an empty *Record list* value by using the specified list as a source for the list structure.
Enumerate	This function returns a new *Record list* value that consists of enumerated records of the specified list.
Filter	This function returns the specified list as a *Record list* value after the query has been changed so that it filters for the specified condition.
First	This function returns the first record of the specified list as a *Container (record)* value, if that list isn't empty. If the list is empty, this function throws an exception.
FirstOrNull	This function returns the first record of the specified list as a *Container (record)* value, if that record isn't empty. If the record is empty, this function returns a null *Container (record)* value.

Function	Description
Index	This function returns a *Container (record)* value that is selected by using the specified numeric index in the specified list. If the index is out of range for the records in the specified list, this function throws an exception.
IsEmpty	This function returns a *Boolean* value of **TRUE** if the specified list contains no records. Otherwise, it returns a *Boolean* value of **FALSE**.
List	This function returns a *Record list* value that consists of a new list that is created from the specified arguments.
ListDistinct	This function calculates the specified expression as a selector for every record of the specified list. It returns a new *Record list* value that contains a single record for each unique selector value.
ListJoin	This function returns a *Record list* value that represents a new joined list that is created from the specified arguments.
ListOfFields	This function returns a *Record list* value that is created based on the structure of the specified argument of the *Enumeration* or *Container (record)* type.
ListOfFirstItem	This function returns a *Record list* value that consists of only the first record of the specified list.
OrderBy	This function returns the specified list as a *Record list* value after it has been sorted according to the specified arguments. These arguments can be defined as expressions.
Repeat	This function builds a record that contains the field that has a value that matches the specified input. It then returns a new *Record list* of a record that is repeated a specified number of times.
Reverse	This function returns the specified list as a *Record list* value in reversed sort order.
Split	This function splits the specified input string into substrings and returns the result as a new *Record list* value.
SplitList	This function splits the specified list into sublists (or batches), each of which contains the specified number of records. It then returns the result as a new *Record list* value that consists of the batches.
SplitListByLimit	This function splits the specified list into a new list of sublists (batches). The number of records in each batch is dynamically calculated. The function then returns the result as a new *Record list* value that consists of the batches.
StringJoin	This function returns a *String* value that consists of concatenated values of the specified field from the specified list. The values can be separated by the specified delimiter.
Where	This function returns the specified list as a *Record list* value after it has been filtered according to the specified condition.

ALLITEMS ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ALLITEMS` function runs as an in-memory selection and returns a new flattened *Record list* value as a list of records that represents all items that match the specified path.

Syntax

VB

```
ALLITEMS (path)
```

Arguments

`path`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

Usage notes

The path must be defined as a valid data source path of a data source element of the *Record list* data type. Data elements such as the path string and date should raise an error in the Electronic reporting (ER) expression builder at design time.

We don't recommend that you use this function for transactional data sources that might contain a large volume of data. Instead, consider using the ALLTEMSQUERY function.

Example 1

If you enter `SPLIT("abcdef" , 2)` as data source **DS**, the expression `COUNT( ALLITEMS (DS))` returns **3**.

Example 2

If you enter **Vend** as the data source of the *Record list* data type that refers to the VendTable application table, the expression `ALLITEMS (Vend.'<Relations'.ContactPerson)` returns a flattened list of records that has the **ContactPerson** table structure and contains all contact persons that can be accessed by using the **ContactPerson.ContactForParty == VendTable.Party** relation, and that is available for all vendors from the referenced vendor table.

List functions

Last updated on 04/08/2026

ALLITEMSQUERY ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ALLITEMSQUERY` function runs as a joined SQL query. It returns a new flattened *Record list* value that consists of a list of records that represent all items that match the specified path.

Syntax

VB

```
ALLITEMSQUERY (path)
```

Arguments

`path`: *Record list*

The valid path of a data source of the *Record list* data type. It must contain at least one relation.

Return values

Record list

The resulting list of records.

Usage notes

The specified path must be defined as a valid data source path of a data source element of the *Record list* data type. It must also contain at least one relation. Data elements such as the path *String* and *Date* should raise an error in the Electronic reporting (ER) expression builder at design time.

When this function is applied to data sources of the *Record list* data type that refer to an application object that can be directly called by using SQL (for example, an table, entity, or query), it runs as a joined SQL query. Otherwise, it runs in memory as the ALLITEMS function.

Example

You define the following data sources in your model mapping:

- A **CustInv** data source of the *Table records* type that refers to the CustInvoiceTable table
- A **FilteredInv** data source of the *Calculated field* type that contains the expression `FILTER (CustInv, CustInv.InvoiceAccount = "US-001")`
- A **JourLines** of the *Calculated field* type that contains the expression `ALLITEMSQUERY ( FilteredInv.'<Relations'.CustInvoiceJour.'<Relations'.CustInvoiceTrans)`

When you run the model mapping to call the **JourLines** data source, the following SQL statement is run:

SQL

```
SELECT ... FROM CUSTINVOICETABLE T1 CROSS JOIN CUSTINVOICEJOUR T2 CROSS JOIN
CUSTINVOICETRANS T3 WHERE...
```

COUNT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `COUNT` function returns an *Integer* value that represents the number of records in the specified list, if the list isn't empty. If the list is empty, this function returns **0** (zero).

Syntax

VB

```
COUNT (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Integer

The resulting numeric value.

Example

`COUNT (SPLIT("abcd" , 3))` returns **2**, because the `SPLIT` function that is used in this example creates a list that consists of two records.

EMPTYLIST ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `EMPTYLIST` function returns an empty *Record list* value by using the specified list as a source for the list structure.

Syntax

```
VB

EMPTYLIST (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

Example

`EMPTYLIST (SPLIT ("abc", 1))` returns a new empty list that has the same structure as the list that is returned by the `SPLIT` function that is used.

Additional resources

List functions

Last updated on 04/08/2026

ENUMERATE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ENUMERATE` function returns a new *Record list* value that consists of enumerated records of the specified list.

Syntax

VB

```
ENUMERATE (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

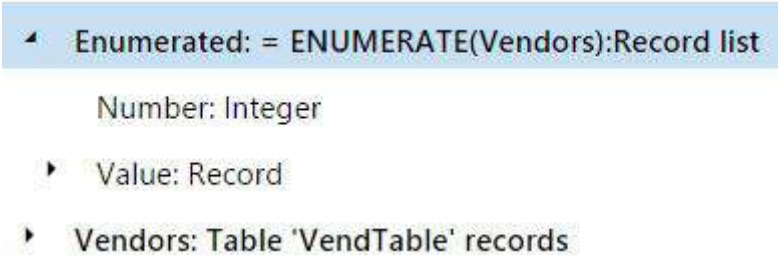
Usage notes

The list of enumerated records that is returned exposes the following additional elements:

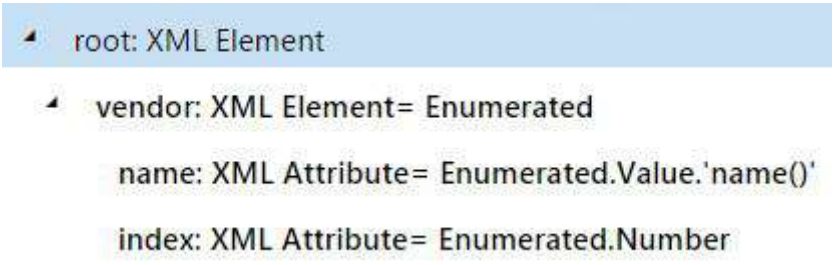
- The record of fields (**Value** component)
- The current record index (**Number** component)

Example

In the following illustration, an **Enumerated** data source is created as an enumerated list of vendor records from the **Vendors** data source that refers to the VendTable table.



The following illustration shows the Electronic reporting (ER) format. In this format, data bindings are created to generate output in XML format. This output presents individual vendors as enumerated nodes.



The following illustration shows the result when the designed format is run.

FILTER ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `FILTER` function returns the specified list as a *Record list* value after the query has been changed so that it filters for the specified condition.

Syntax

```
VB

FILTER (list, condition)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`condition`: *Boolean*

A valid conditional expression that is used to filter records of the specified list.

Return values

Record list

The resulting list of records.

Usage notes

This function differs from the WHERE function, because the specified condition is applied to any Electronic reporting (ER) data source of the *Table records* type at the database level. The list

and condition can be defined by using tables and relations.

If one or both arguments that are configured for this function (`list` and `condition`) don't allow this request to be translated to the direct SQL call, an exception is thrown at design time. This exception informs the user that either `list` or `condition` can't be used to query the database.

> ⓘ **Note**
>
> The `FILTER` function behaves differently than the `WHERE` function when the **VALUEIN** function is used to specify the selection criteria.
>
> - If the `VALUEIN` function is used in scope of the `WHERE` function, and the second argument of `VALUEIN` refers to a data source that returns no records, the Boolean ***False*** value that `VALUEIN` returns is considered. Therefore, the expression `WHERE(Vendors, VALUEIN(Vendors.VendGroup, VendGroups, VendGroups.VendGroup))` returns no vendor records if the **VendGroups** data source returns no vendor group records.
> - If the `VALUEIN` function is used in scope of the `FILTER` function, and the second argument of `VALUEIN` refers to a data source that returns no records, the Boolean ***False*** value that `VALUEIN` returns is ignored. Therefore, the expression `FILTER(Vendors, VALUEIN(Vendors.VendGroup, VendGroups, VendGroups.VendGroup))` returns all vendor records of the **Vendors** data source, even if the **VendGroups** data source returns no vendor group records.

Example 1

If **Vendor** is configured as an ER data source that refers to the VendTable table, the expression `FILTER (Vendors, Vendors.VendGroup = "40")` returns a list of only vendors that belong to vendor group 40.

Example 2

If **Vendor** is configured as an ER data source that refers to the VendTable table, and if **parmVendorBankGroup** is configured as an ER data source that returns a value of the *String* data type, the expression `FILTER ( Vendor.'<Relations'.VendBankAccount, Vendor.'<Relations'.VendBankAccount.BankGroupID = parmVendorBankGroup)` returns a list of only vendor accounts that belong to a specific bank group.

Example 3

You enter data source **DS** of the *Calculated field* type, and it contains the expression `SPLIT ("A,B,C", ",")`. You then enter another expression, `FILTER( DS, DS.Value = "B")`. When you try to save this expression in the ER formula designer, the following exception is thrown: "Validation error: The list expression of FILTER function is not queryable."

FIRST ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `FIRST` function returns the first record of the specified list as a *Container (record)* value, if that list isn't empty. If the list is empty, this function throws an exception.

Syntax

VB

```
FIRST (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Container (record)

The resulting record value.

Example 1

The expression `FIRST(SPLIT("ABC",1)).Value` returns the text value "**A**".

Example 2

The expression `FIRST(SPLIT("",1)).Value` throws an exception at runtime.

FIRSTORNULL ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `FIRSTORNULL` function returns the first record of the specified list as a *Container (record)* value, if that record isn't empty. If the record is empty, this function returns a null *Container (record)* value.

Syntax

```
VB

FIRSTORNULL (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Container (record)

The resulting record value.

Example

The expression `FIRSTORNULL(SPLIT("",1)).Value` returns an empty string ("").

Additional resources

List functions

INDEX ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `INDEX` function returns a *Container (record)* value that is selected by using the specified numeric index in the specified list. If the index is out of range for the records in the specified list, an exception is thrown.

Syntax

```
VB

INDEX (list, index)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`index`: *Integer*

A numeric index that indicates the position of the desired record in the specified list.

> **Note**
>
> Because one-based numbering is used for this function, specify the value **1** to return the first record of the specified list.

Return values

Container (record)

The resulting record value.

Example 1

If you enter data source **DS** of the *Calculated field* type, and it contains the expression `SPLIT ("A|B|C", "|")`, the expression `DS.Value` returns the text value "**B**" for the second record of this record list. The expression `INDEX (SPLIT ("A|B|C", "|"), 2).Value` also returns the text value "**B**".

Example 2

If you enter data source **DS** of the *Calculated field* type, and it contains the expression `SPLIT ("A|B|C", "|")`, the expression `INDEX (SPLIT ("A|B|C", "|"), 4).Value` throws an exception at runtime.

ISEMPTY ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ISEMPTY` function returns a *Boolean* value of **TRUE** if the specified list contains no records. Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

VB

```
ISEMPTY (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Boolean

The resulting *Boolean* value.

Example 1

If you enter data source **DS** of the *Calculated field* type, and it contains the expression `SPLIT ("A|B|C", "|")`, the expression `ISEMPTY(DS)` returns **FALSE**.

Example 2

The expression `ISEMPTY (SPLIT ("",1))` returns **TRUE**.

LIST ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `LIST` function returns a *Record list* value that consists of a new list of records that is created from the specified arguments.

Syntax

VB

```
LIST (record 1 [, record 2, …, record N])
```

Arguments

`record 1`: *Container (record)*

A reference to a data source of the *Record* data type. This argument is required.

`record N`: *Container (record)*

A reference to a data source of the *Record* data type. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Usage notes

The structure of the list that is created contains only the fields that are presented in the structure of every record that is mentioned in the arguments.

Example

You enter data source **Record 1** of the *Container* type. This data source contains the following nested fields of the *Calculated field* type:

- **Code:** This field contains an expression that returns a value of the *String* type.
- **Amount:** This field contains an expression that returns a value of the *Real* type.

You then enter data source **Record 2** of the *Container* type. This data source contains the following nested fields of the *Calculated field* type:

- **Amount:** This field contains an expression that returns a value of the *Real* type.
- **IsValid:** This field contains an expression that returns a value of the *Boolean* type.

In this case, the expression `LIST('Record 1', 'Record 2')` returns a new list that contains two records. The structure of this list consists of a single **Amount** field of the *Real* type, because this field is the only field that is presented in every argument of the called function.

Additional resources

List functions

Last updated on 04/08/2026

LISTDISTINCT ER Function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `LISTDISTINCT` function calculates the specified expression as a selector for every record of the specified list. It returns a new *Record list* value that contains a single record for each unique selector value.

Syntax

```
LISTDISTINCT (list, selector)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`selector`: *Primitive data type*

A valid expression that is used to calculate a selector value for every record in the specified list.

The following data types are supported for this parameter:

- Boolean
- Date
- DateTime
- GUID
- Integer
- Int64
- Real

- String

Return values

Record list

The resulting list of records.

Usage notes

The structure of the list that is created matches the structure of the specified list.

The same selector value might be calculated for multiple records in the specified list. In this case, field values of the corresponding record in the created list equal the values of the first record from the specified list that the selector value is calculated for.

The execution of this function is done on any Electronic reporting (ER) data source of the *Record list* type that is present in memory.

The **GROUPBY** data source can also be used to generate the list of records that the selector that has distinct values is calculated for. However, from a performance and memory consumption perspective, it's better to use the `LISTDISTINCT` function than the **GROUPBY** data source, because the execution of the function is done in memory.

Example

The following example shows how you can get the list of unique customer account numbers that at least one sales invoice or project invoice has been issued to during a specific period.

1. Enter the **SalesInvoice** data source of the `Record list` type that refers to the **CustInvoiceJour** application table and filters sales invoices for specific periods.

   The `InvoiceAccount` field of this data source returns the account number of an invoiced customer.

2. Enter the **ProjectInvoice** data source of the `Record list` type that refers to the **ProjInvoiceJour** application table and filters project invoices for specific periods.

   The `InvoiceAccount` field of this data source returns the account number of an invoiced customer.

3. Configure the **AllInvoices** data source of the `Calculated field` type that contains the expression `LISTJOIN(SalesInvoice, ProjectInvoice)`.

   This data source returns the joined list of sales invoices and project invoices.

4. Configure the **InvoicedCustomer** data source of the `Record list` type that contains the expression `LISTDISTINCT(AllInvoices, AllInvoices.InvoiceAccount)`.

   This data source returns a new list that contains a single record for every unique customer that has been invoiced during the defined period. The `InvoiceAccount` field of this list contains a customer account number.

List functions

Last updated on 04/08/2026

LISTJOIN ER function

Article • 08/12/2022

The `LISTJOIN` function returns a *Record list* value that represents a new joined list of records that is created from the specified arguments.

Syntax

```
VB

LISTJOIN (list 1 [, list 2, …, list N])
```

Arguments

`list 1`: *Record list*

A reference to a data source of the *Record list* data type. This argument is mandatory.

`list N`: *Record list*

A reference to a data source of the *Record list* data type. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Usage notes

The structure of the list that is created contains only the fields that are present in the structure of every record list that is referenced in the arguments.

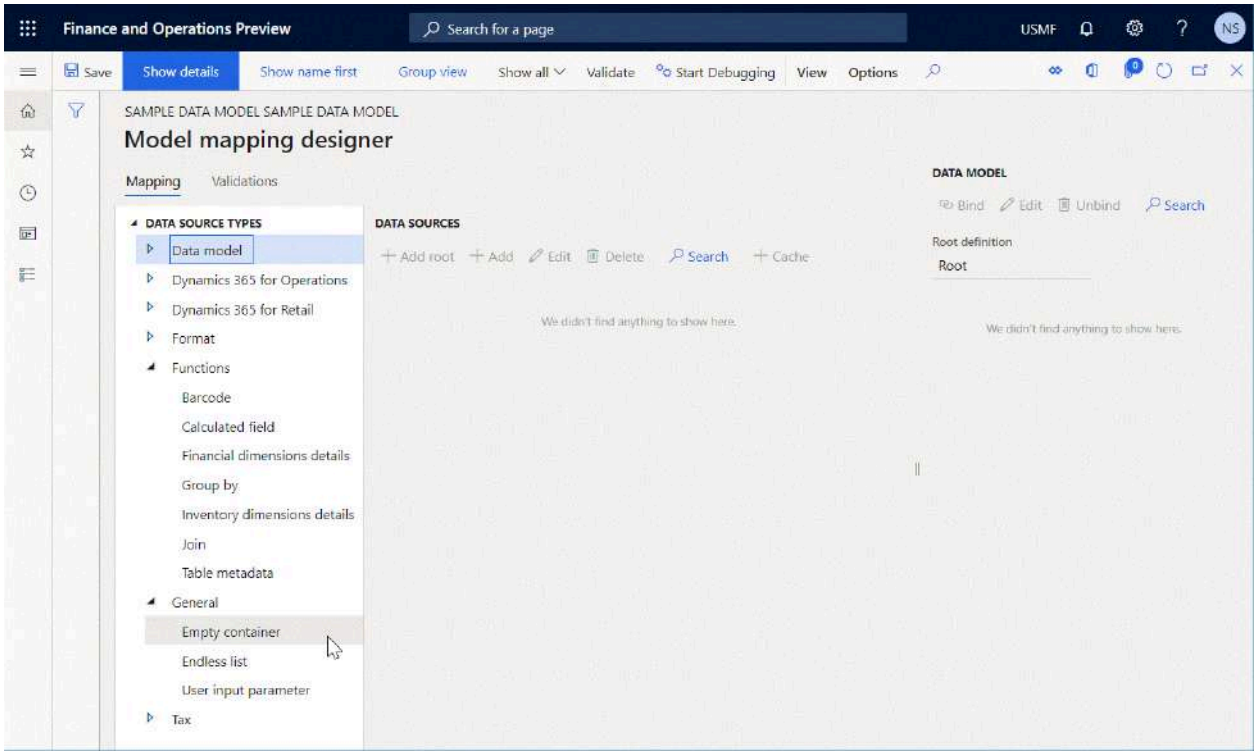
Example

You enter data source **Record 1** of the `Container` type. This data source contains the following nested fields of the `Calculated field` type:

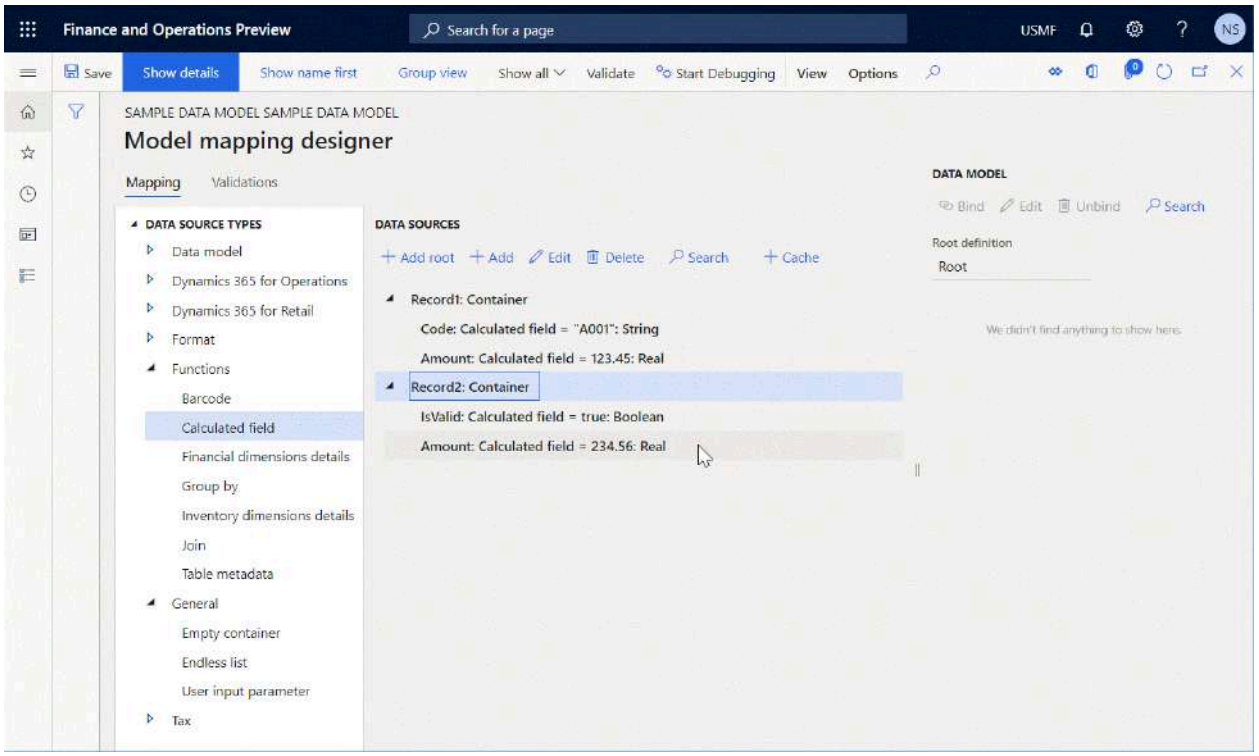
- **Code**: This field contains an expression that returns a value of the `String` type.
- **Amount**: This field contains an expression that returns a value of the `Real` type.

You then enter data source **Record 2** of the `Container` type. This data source contains the following nested fields of the `Calculated field` type:

- **Amount**: This field contains an expression that returns a value of the `Real` type.
- **IsValid**: This field contains an expression that returns a value of the `Boolean` type.



In this case, the expression `LISTJOIN(LIST('Record 1'), LIST('Record 2'))` returns a new list that contains two records.



The structure of this list consists of a single **Amount** field of the `Real` type, because this field is the only field that is presented in every argument of the called function.

LISTOFFIELDS ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `LISTOFFIELDS` function returns a *Record list* value that is created based on the structure of the specified argument of the *Enumeration* or *Container (record)* type.

Syntax 1

```
VB

LISTOFFIELDS (path)
```

Syntax 2

```
VB

LISTOFFIELDS (path, language)
```

Arguments

`path`: Data source reference

The valid reference path of a data source of one of the following data types:

- Model enumeration
- Format enumeration
- Application enumeration
- Container (record)

`language`: *String*

Text that represents a language code.

Return values

Record list

The resulting list of records.

Usage notes

The list that is created consists of records that have the following fields:

- **Name** (*String* data type)
- **Label** (*String* data type)
- **Description** (*String* data type)
- **IsTranslated** (*Boolean* data type)

If the `path` argument refers to a data source of the *Container (Record)* type, for every field of the referenced container record, a new record is added to the list that is created. For every record that is created, the **Name** field returns the name of the field of the referenced container record that the current record was created for.

If the `path` argument refers to a data source of one of the *Enumeration* types, for every enumeration value of the referenced enumeration, a new record is added to the list that is created. For every record that is created, the **Name** field returns the value of the referenced enumeration that the current record was created for, the **Description** field returns the description of that enumeration, and the **Label** field returns the label of that enumeration.

At runtime, when syntax 1 is used, the **Label** and **Description** fields must return values that are based on the language settings of the Electronic reporting (ER) format that is running:

- If the labels and descriptions for the requested language are available, the **Label** and **Description** fields return values that are based on that language, and the **IsTranslated** field returns **True**.
- If the labels and descriptions for the requested language aren't available, the **Label** and **Description** fields return values that are based on the default **EN-US** language, and the **IsTranslated** field returns **False**.

At runtime, when syntax 2 is used, the **Label** and **Description** fields must return values that are based on the language that is defined as the second argument of the called function:

- If the labels and descriptions for the requested language are available, the **Label** and **Description** fields return values that are based on that language, and the **IsTranslated**

field returns **True**.

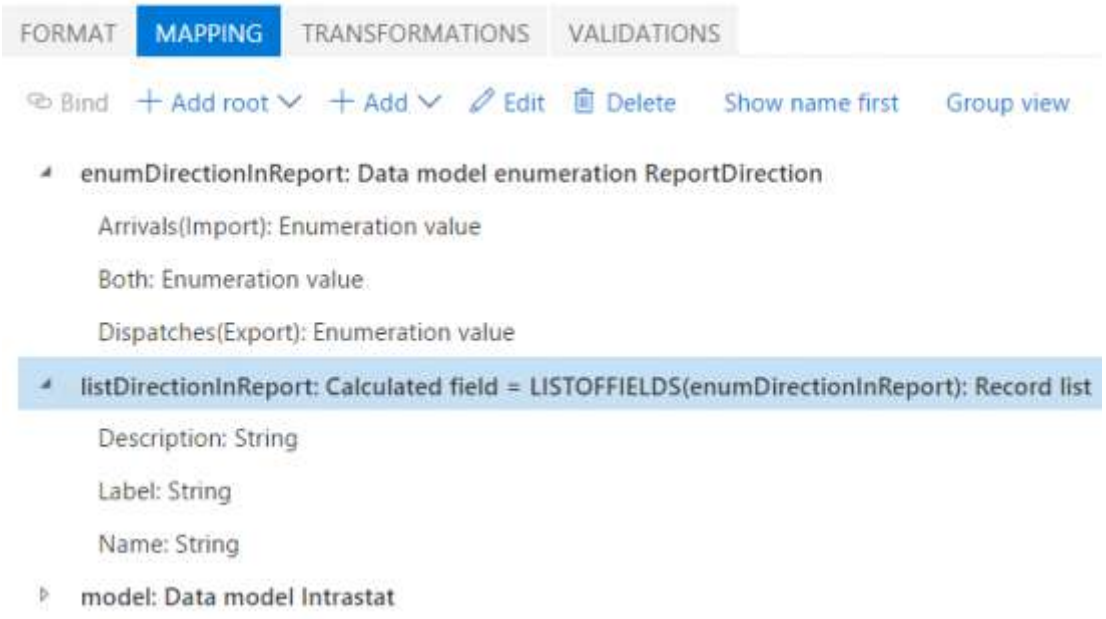
- If the labels and descriptions for the requested language aren't available, the **Label** and **Description** fields return values that are based on the **EN-US** language, and the **IsTranslated** field returns **False**.

Example 1

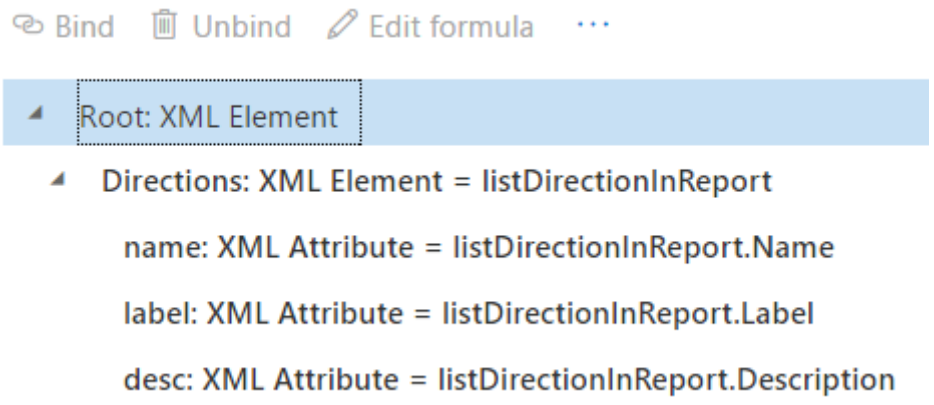
In the following illustration, an enumeration is introduced in an ER data model.

The following illustration shows these details:

- The model enumeration is inserted into a report as a data source.
- An ER expression uses the model enumeration as a parameter of the `LISTOFFIELDS` function.
- A data source of the *Record list* type is inserted into a report by using the ER expression that is created.



The following example shows the ER format elements that are bound to the data source of the *Record list* type that was created by using the `LISTOFFIELDS` function.



The following illustration shows the result when the designed format is run.

```
<?xml version="1.0" encoding="UTF-8"?>
- <Root>
    <Directions desc="" label="Both" name="Both"/>
    <Directions desc="" label="Dispatches" name="Export"/>
    <Directions desc="" label="Arrivals" name="Import"/>
  </Root>
```

> ⓘ Note
>
> Based on the language settings of the parent **FILE** and **FOLDER** format elements, translated text for labels and descriptions is entered in the output of the ER format.

Example 2

You use the *Calculated field* data source type to configure **enumType_de** and **enumType_deCH** data sources for the **enumType** data model enumeration:

- **enumType_de** = `LISTOFFIELDS (enumType, "de")`
- **enumType_deCH** = `LISTOFFIELDS (enumType, "de-CH")`

In this case, you can use the following expression to get the label of the enumeration value in Swiss German, if that translation is available. If the Swiss German translation isn't available, the label is in German.

VB

```
IF (NOT (enumType_deCH.IsTranslated), enumType_de.Label, enumType_deCH.Label)
```

LISTOFFIRSTITEM ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `LISTOFFIRSTITEM` function returns a *Record list* value that consists of only the first record of the specified list.

Syntax

VB

```
LISTOFFIRSTITEM (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

Example

The expression `FIRST( LISTOFFIRSTITEM ( SPLIT ("ABC",1))).Value` returns the text value "**A**".

Additional resources

List functions

Last updated on 04/08/2026

ORDERBY ER function

The `ORDERBY` function returns the specified list as a *Record list* value after it has been sorted according to the specified arguments. These arguments can be defined as expressions.

Syntax 1

```
VB
ORDERBY (list, expression 1[, expression 2, …, expression N])
```

Syntax 2

```
VB
ORDERBY (location, list, expression 1[, expression 2, …, expression N])
```

> **Note**
>
> This syntax is supported for Microsoft Dynamics 365 Finance version 10.0.25 and later.

Arguments

`location`: *String*

The location where sorting should be run. The following options are valid:

- "Query"
- "InMemory"

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`expression 1`: *Field*

The valid path of a field of the data source that is referenced by the `list` argument of the called function. The referenced field must be a field of the primitive data type. This argument is required.

`expression N`: *Field*

The valid path of a field of the data source that is referenced by the `list` argument of the called function. The referenced field must be a field of the primitive data type. These additional arguments are optional.

Return values

Record list

The resulting list of records.

Usage notes

Syntax 1

Data sorting is always done in the memory of the application server. For more details, see example 1.

Syntax 2

Sorting in memory

When the `location` argument is specified as **InMemory**, data sorting is done in the memory of an application server. For more details, see example 2.

Sorting in database

When the `location` argument is specified as **Query**, data sorting is done at the database level. In this case, the `list` argument must point to one of the following Electronic reporting (ER) data sources that specifies the application source that a direct database query can be established for:

- Data source of the *Table records* type
- Relation of a data source of the *Table records* type
- Data source of the *Calculation field* type

The `expression 1` and `expression N` arguments must point to fields of an ER data source that specifies the relevant fields of the application source that a direct database query can also be established for.

If a direct database query can't be established, a validation error occurs in the ER model mapping designer. The message that you receive states that the ER expression that includes the `ORDERBY` function can't be run at runtime.

For better performance, we recommend that you use the **Query** option when the sorting is configured for application data sources that might contain the large number of records (for example, for transactional application tables).

> **Note**
>
> The `ORDEBY` function itself can't be translated to a direct database query. Therefore, an ER data source that contains this function isn't queryable. It also can't be used in the scope of ER functions such as **FILTER** and **ALLITEMSQUERY**, where only queryable data sources can be used.

For more details, see example 3 and example 4.

Comparability

Because the SQL database engine and Finance application server can use a different ranking value for a single character, the sorting result of the same list of records can differ when a String field is used for sorting. For more details, see example 5.

Example 1: In-memory default execution

If you enter data source **DS** of the *Calculated field* type, and it contains the expression `SPLIT ("C|B|A", "|")`, the expression `FIRST( ORDERBY( DS, DS. Value)).Value` returns the text value "**A**".

Example 2: In-memory explicit execution

If **Vendor** is configured as an ER data source of the *Table records* type that refers to the **VendTable** table, both the expression `ORDERBY (Vendor, Vendor.'name()')` and the expression `ORDERBY ("InMemory", Vendor, Vendor.'name()')` return a list of vendors that is sorted by name in ascending order.

When you configure the expression `ORDERBY ("Query", Vendor, Vendor.'name()')` in the ER model mapping designer, a validation error occurs at design time, because the `Vendor.'name()'`

path refers to an application method that has logic that can't be translated to a direct database query.

Example 3: Database query

If **TaxTransaction** is configured as an ER data source of the *Table records* type that refers to the **TaxTrans** table, the expression `ORDERBY ("Query", TaxTransaction, TaxTransaction.TaxCode)` sorts records at the application database level and returns a list of tax transactions that is sorted by tax code in ascending order.

Example 4: Queryable data sources

If **TaxTransaction** is configured as an ER data source of the *Table records* type that refers to the **TaxTrans** table, the **TaxTransactionFiltered** ER data source can be configured so that it contains the expression `FILTER(TaxTransaction, TaxCode="VAT19")` that will fetch transactions for a specified tax code. Because the configured **TaxTransactionFiltered** ER data source is queryable, the expression `ORDERBY ("Query", TaxTransactionFiltered, TaxTransactionFiltered.TransDate)` can be configured to return the list of filtered tax transactions that is sorted by transaction date in ascending order.

If you configure **TaxTransactionOrdered** as an ER data source of the *Calculated field* type that contains the expression `ORDERBY ("Query", TaxTransaction, TaxTransaction.TransDate)` and an ER data source of the *Calculated field* type that contains the expression `FILTER(TaxTransactionOrdered, TaxCode="VAT19")`, a validation error occurs at design time in the ER model mapping designer. This error occurs because the first argument of the FILTER function must refer a queryable ER data source, but the **TaxTransactionOrdered** data source that contains the `ORDERBY` function isn't queryable.

Example 5: Comparability

Prerequisites

1. Enter data source **DS1** of the *Calculated field* type that contains the expression `SPLIT ("D1|_D2|D3", "|")`.
2. Open the **Financial dimension values** page, and select the **CostCenter** dimension.
3. Enter the following dimension values: **D1**, **_D2**, and **D3**.

Sorting in memory

1. Configure data source **DS2** of the *Calculated field* type that contains the expression `ORDERBY("InMemory", DS1, DS1.Value)`.
2. Notice that the expression `FIRST(DS2).Value` returns the text value "**D1**", the expression `INDEX(DS2, COUNT(DS2)).Value` returns the text value "**_D2**", and the expression `STRINGJOIN(DS2, DS2.Value, "|")` returns the text value "**D1|D3|_D2**".

Sorting in database

1. Enter data source **DS3** of the *Table records* type that refers to the **FinancialDimensionValueEntity** entity.
2. Configure data source **DS4** of the *Calculated field* type that contains the expression `FILTER(DS3, DS3.FinancialDimension="CostCenter")`.
3. Configure data source **DS5** of the *Calculated field* type that contains the expression `ORDERBY(DS4, DS4.DimensionValue)`.
4. Notice that the expression `FIRST(DS5).Value` returns the text value "**_D2**", the expression `INDEX(DS5, COUNT(DS5)).Value` returns the text value "**D3**", and the expression `STRINGJOIN(DS5, DS5.Value, "|")` returns the text value "**_D2|D1|D3**".

REPEAT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `REPEAT` function builds a record that contains the field with a value that matches the specified input. It then returns a new *Record list* of a record that repeats a specified number of times.

Syntax

```
VB
REPEAT (item, number)
```

Arguments

`item`: Any supported primitive or composite data type

The value to repeat.

`number`: *Integer*

The number of repeats.

Return values

Record list

The resulting list of records.

Usage notes

The list of repeated records that the function returns exposes the following fields:

- The specified value (`Item` field)

- The current record index (`Number` field)

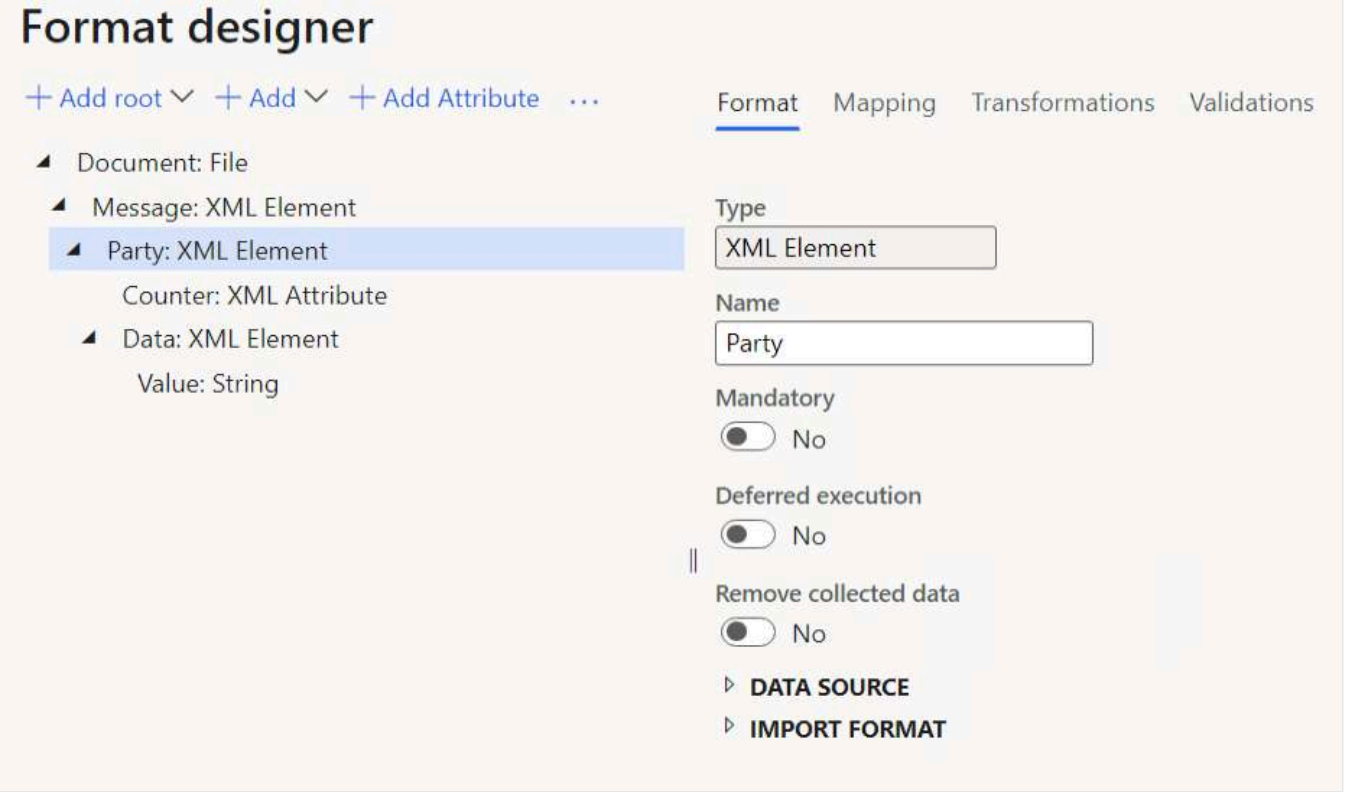
> **Note**
>
> Because this function uses one-based numbering, the `Number` field has the value **1** for the first record of the resulting list.

Use this function to multiply existing data so that you can do performance and volume testing of Electronic reporting (ER) solutions by using the Regression suite automation tool (RSAT).

Example

You want to generate a document in XML format that contains as many `Party` XML elements as you specify in a data entry field in the dialog box at runtime, before the execution of an ER format begins.

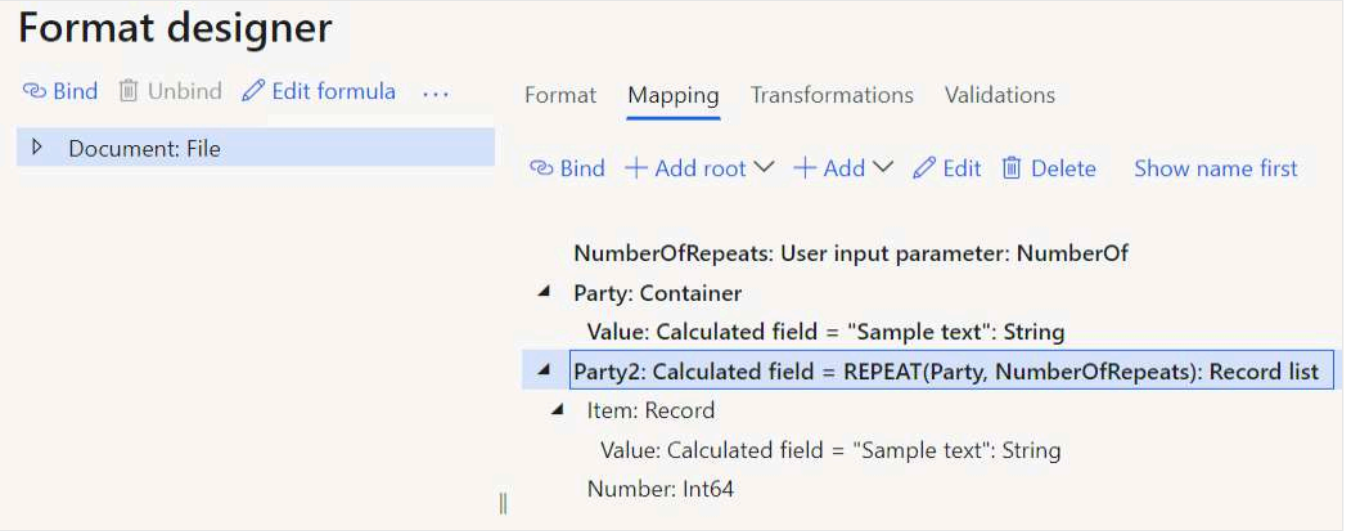
The following illustration shows the ER format. In this format, the single `Party` XML element is added to expose the properties of a single party.



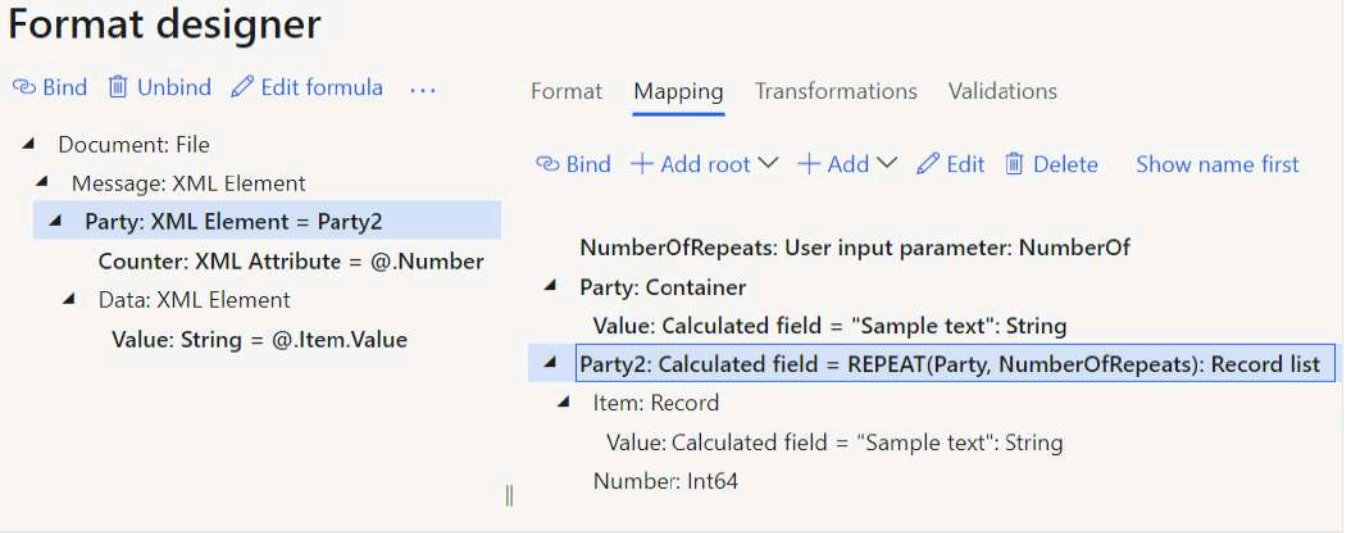
The next illustration shows the following configured data sources:

- The `Party` data source that represents a single party. The `Party.Value` field exposes a single text value.

- The `NumberOfRepeats` data source that offers a data entry field in the dialog box at runtime, so that you can specify the number of parties that should be entered in the generated document.
- The `Party2` data source that repeats the `Party` record the number of times that you specified in the `NumberOfRepeats` data source.



The next illustration shows data bindings of the editable ER format that are created to generate output in XML format. This output presents individual parties as enumerated nodes.



The following illustration shows the result when you run the designed format and specify the value of the `NumberOfRepeats` data source as **5**.

REVERSE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `REVERSE` function returns the specified list as a *Record list* value in reversed sort order.

Syntax

```
VB

REVERSE (list)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

Return values

Record list

The resulting list of records.

Example 1

If you enter data source **DS** of the *Calculated field* type, and it contains the expression `SPLIT ("C|B|A", "|")`, the expression `FIRST( REVERSE( ORDERBY( DS, DS. Value))).Value` returns the text value "**C**".

Example 2

If **Vendor** is configured as an Electronic reporting (ER) data source that refers to the VendTable table, the expression `REVERSE (ORDERBY (Vendors, Vendors.'name()'))` returns a list of vendors that is sorted by name in descending order.

SPLIT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `SPLIT` function splits the specified input string into substrings and returns the result as a new *Record list* value.

Syntax 1

```
VB

SPLIT (input, length)
```

This syntax is used to split the specified input string into substrings, each of which has the specified length.

Syntax 2

```
VB

SPLIT (input, delimiter)
```

This syntax is used to split the specified input string into substrings, based on the specified delimiter.

Arguments

`input`: *String*

The text to split.

`length`: *Integer*

The maximum length of a single substring.

`delimiter`: *String*

A delimiter that is used to separate substrings.

Return values

Record list

The resulting list of records.

Usage notes

The record structure of the list that is returned consists of the **Value** field of the *String* type. Every record of the list that is returned contains generated substrings in this field.

If the `delimiter` argument is empty, the new list that is returned consists of one record that has the **Value** field of the *String* type. This field contains the input text.

If the `input` argument is empty, a new empty list is returned. If either the `input` or `delimiter` argument is unspecified (null), an application exception is thrown.

Example 1

`SPLIT ("abcd", 3)` returns a new list that consists of two records that have the **Value** field of the *String* type. The **Value** field in the first record contains the text "**abc**", and the **Value** field in the second record contains the text "**d**".

Example 2

`SPLIT ("XAb aBy", "aB")` returns a new list that consists of three records that have the **Value** field of the *String* type. The **Value** field in the first record contains the text "**X**", the **Value** field in the second record contains the text " ", and the **Value** field in the third record contains the text "**y**".

Example 3

Yo can use the INDEX function to access individual elements of the specified input string. If you enter the **MyList** data source of the **Calculated field** type and configure for it the `SPLIT("abc", 1)` expression, the expression `INDEX(MyList,2).Value` returns the text "**b**".

Example 4

The ENUMERATE function can also help you access individual elements of the specified input string. If you first enter the **MyList** data source of the **Calculated field** type and configure for it the `SPLIT("abc", 1)` expression, and then enter the **EnumeratedList** data source of the **Calculated field** type and configure for it the `ENUMERATE(MyList)` expression, the expression `FIRSTORNULL(WHERE(EnumeratedList, EnumeratedList.Number=2)).Value` returns the text "**b**".

SPLITLIST ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `SPLITLIST` function splits the specified list into sublists (or batches), each of which contains the specified number of records. It then returns the result as a new *Record list* value that consists of the batches.

Syntax 1

```
VB

SPLITLIST (list, number)
```

Syntax 2

```
VB

SPLITLIST (list, number, on-demand reading flag)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`number`: *Integer*

The maximum number of records per batch.

`on-demand reading flag`: *Boolean*

A *Boolean* value that specifies whether elements of sublists should be generated on demand.

Return values

Record list

The resulting list of records.

Usage notes

The list of batches that is returned contains the following elements:

- **Value:** *List*

  The list of records that belong to the current batch.

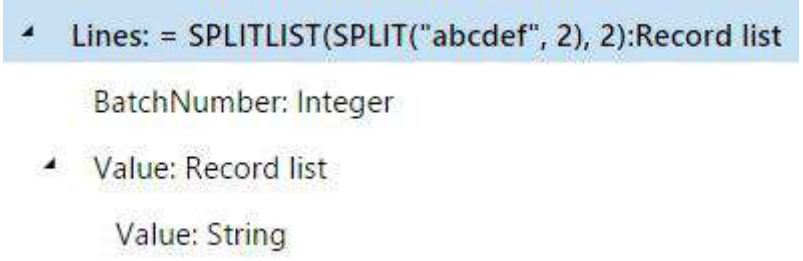
- **BatchNumber:** *Integer*

  The number of the current batch in the returned list.

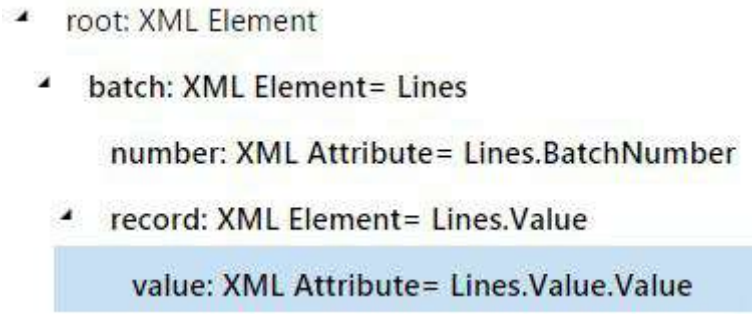
When the on-demand reading flag is set to **True**, sublists are generated upon request which allows for a reduction in memory consumption but may cause performance degradation if elements aren't used sequentially.

Example

In the following illustration, a **Lines** data source is created as a record list that has three records. This list is divided into batches, each of which contains up to two records.



The following illustration shows the designed format layout. In this format layout, bindings to the **Lines** data source are created to generate output in XML format. This output presents individual nodes for each batch and the records in it.



The following illustration shows the result when the designed format is run.

```
<?xml version="1.0" encoding="UTF-8"?>
- <root>
  - <batch number="1">
        <record value="ab"/>
        <record value="cd"/>
    </batch>
  - <batch number="2">
        <record value="ef"/>
    </batch>
</root>
```

SPLITLISTBYLIMIT ER function

Article • 08/12/2022

The `SPLITLISTBYLIMIT` function splits the specified list into a new list of sublists (batches). The number of records in each batch is dynamically calculated. The function then returns the result as a new *Record list* value that consists of the batches.

Syntax

```
VB
```

```
SPLITLISTBYLIMIT (list, limit value, limit source)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`limit value`: *Integer* or *Real*

The maximum value of the limit that is used to split the original list into batches.

`limit source`: *Field*

The valid path of a field of the *Integer* or *Real* type in the specified list. The value of this field defines the step that the total sum is increased on.

Return values

Record list

The resulting list of records.

Usage notes

The list of batches that is returned contains the following elements:

- **Value**: *List*

  The list of records that belong to the current batch.

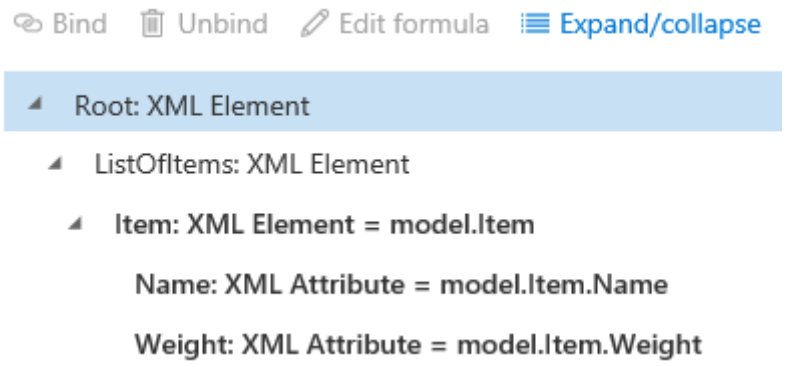
- **BatchNumber**: *Integer*

  The number of the current batch in the returned list.

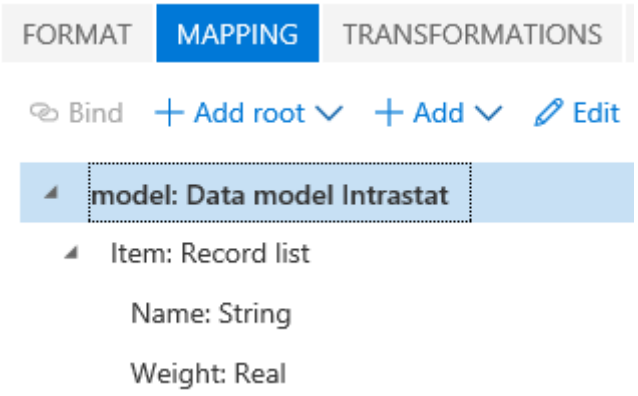
The limit isn't applied to a single item of the original list if the limit source exceeds the defined limit.

Example

The following illustration shows an Electronic reporting (ER) format.



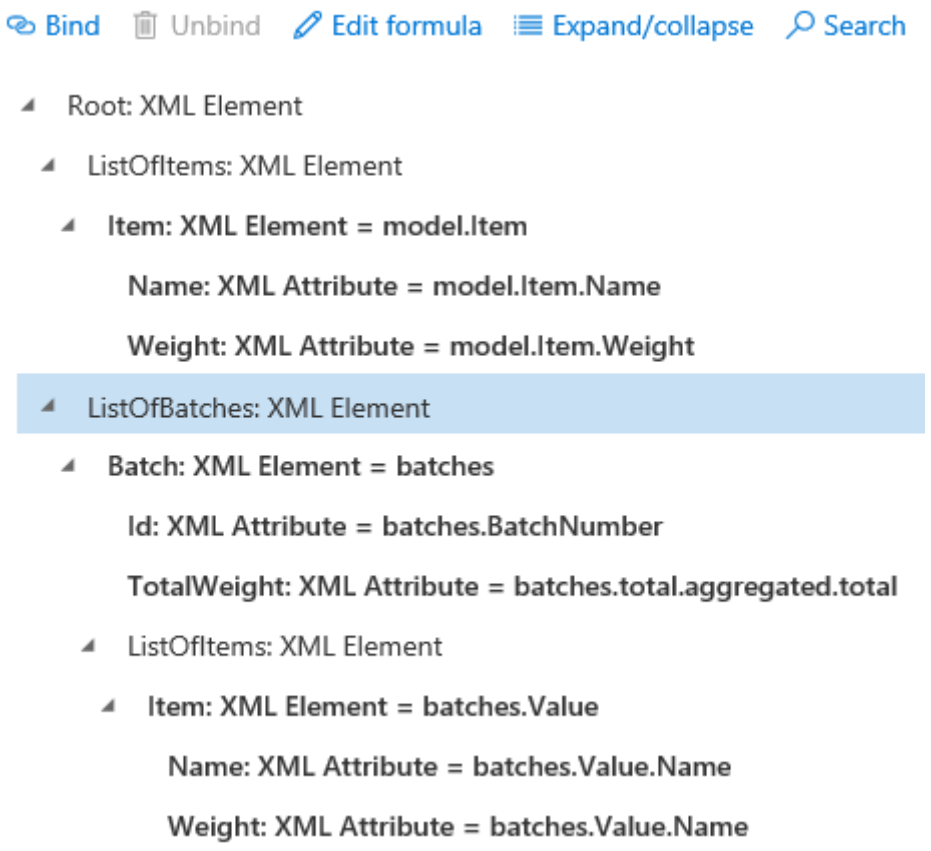
The following illustration shows the data sources that are used for the format.

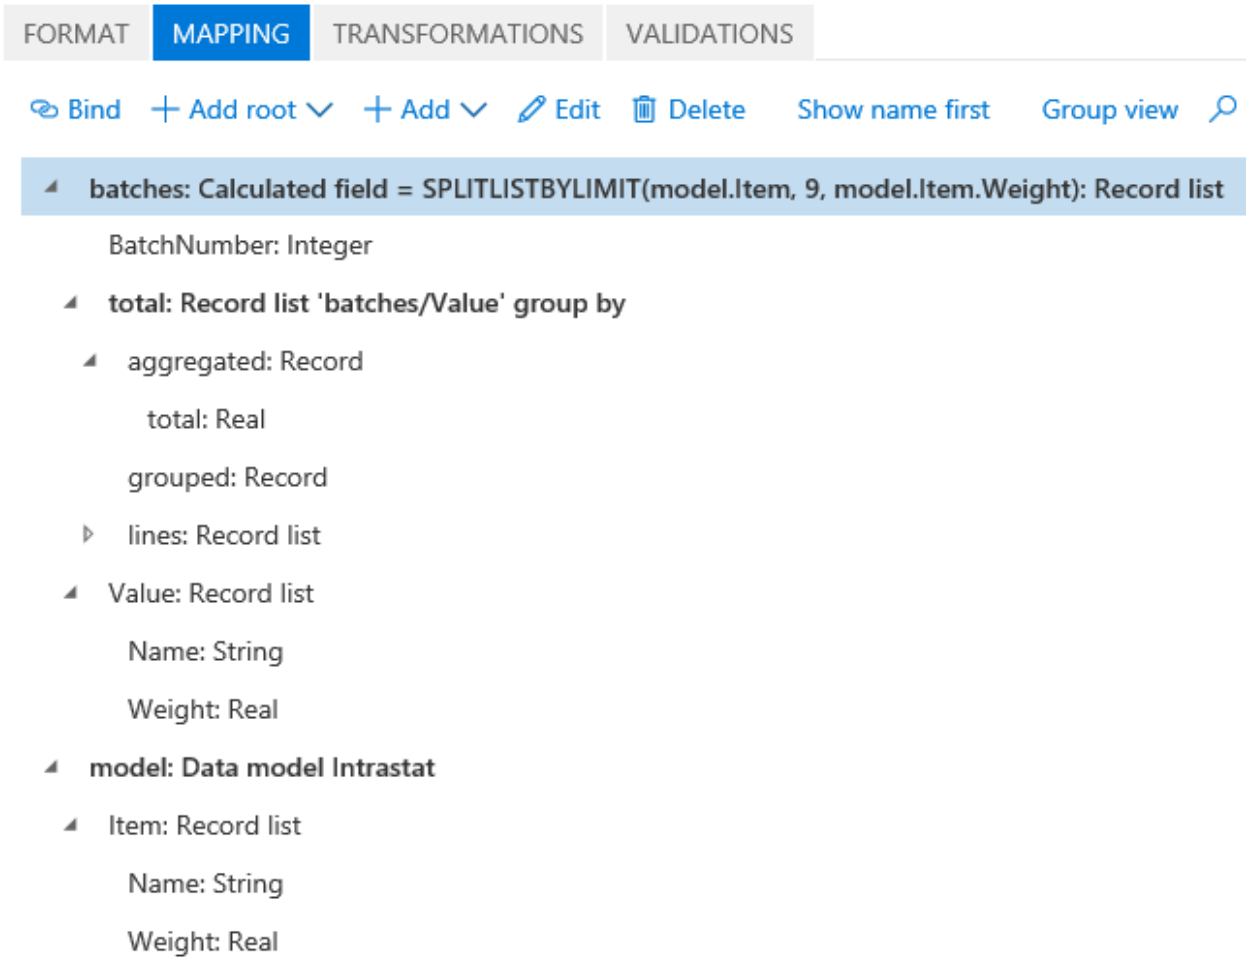


The following illustration shows the result when the format is run. In this case, the output is a flat list of commodity items.

```
<?xml version="1.0" encoding="UTF-8"?>
- <Root>
  - <ListOfItems>
      <Item Weight="1" Name="Speaker"/>
      <Item Weight="2" Name="Projector"/>
      <Item Weight="3" Name="Radio receiver"/>
      <Item Weight="4" Name="Monitor"/>
      <Item Weight="5" Name="Transmitter or receiver"/>
      <Item Weight="6" Name="Parts and components"/>
      <Item Weight="11" Name="Hardware"/>
    </ListOfItems>
</Root>
```

In the following illustrations, the same format has been adjusted so that it presents the list of commodity items in batches if a single batch must include commodities and the total weight should not exceed a limit of 9.





The following illustration shows the result when the adjusted format is run.

```
<?xml version="1.0" encoding="UTF-8"?>
- <Root>
  - <ListOfItems>
      <Item Weight="1" Name="Speaker"/>
      <Item Weight="2" Name="Projector"/>
      <Item Weight="3" Name="Radio receiver"/>
      <Item Weight="4" Name="Monitor"/>
      <Item Weight="5" Name="Transmitter or receiver"/>
      <Item Weight="6" Name="Parts and components"/>
      <Item Weight="11" Name="Hardware"/>
    </ListOfItems>
  - <ListOfBatches>
    - <Batch TotalWeight="6.0" Id="1">
      - <ListOfItems>
          <Item Weight="Speaker" Name="Speaker"/>
          <Item Weight="Projector" Name="Projector"/>
          <Item Weight="Radio receiver" Name="Radio receiver"/>
        </ListOfItems>
      </Batch>
    - <Batch TotalWeight="9.0" Id="2">
      - <ListOfItems>
          <Item Weight="Monitor" Name="Monitor"/>
          <Item Weight="Transmitter or receiver" Name="Transmitter or receiver"/>
        </ListOfItems>
      </Batch>
    - <Batch TotalWeight="6.0" Id="3">
      - <ListOfItems>
          <Item Weight="Parts and components" Name="Parts and components"/>
        </ListOfItems>
      </Batch>
    - <Batch TotalWeight="11.0" Id="4">
      - <ListOfItems>
          <Item Weight="Hardware" Name="Hardware"/>
        </ListOfItems>
      </Batch>
    </ListOfBatches>
</Root>
```

> ⓘ Note
>
> The limit isn't applied to the last item of the original list, because the value (**11**) of the limit source (**weight**) exceeds the defined limit (**9**). To ignore sublists during report generation, use either the `WHERE` function or the **Enabled** expression of the corresponding format element, as you require.

STRINGJOIN ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `STRINGJOIN` function returns a *String* value that consists of concatenated values of the specified field from the specified list. The values can be separated by the specified delimiter.

Syntax

```
VB

STRINGJOIN (list, field, delimiter)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`field`: *Field*

The valid path of a field of the *String* data type in the specified list.

`delimiter`: *String*

A delimiter that is used to separate substrings.

Return values

String

The resulting text value.

Example

If you enter `SPLIT("abc" , 1)` as data source **DS**, the expression `STRINGJOIN (DS, DS.Value, "-")` returns "**a-b-c**".

List functions

Last updated on 04/08/2026

WHERE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `WHERE` function returns the specified list as a *Record list* value after it has been filtered according to the specified condition.

Syntax

```VB
WHERE (list, condition)
```

Arguments

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`condition`: *Boolean*

A valid conditional expression that is used to filter records of the specified list.

Return values

Record list

The resulting list of records.

Usage notes

This function differs from the FILTER function, because the specified condition is applied to any Electronic reporting (ER) data source of the *Record list* type that is present in memory.

If the arguments that are configured for this function (`list` and `condition`) allow this request to be translated to the direct SQL call, a warning message is thrown at design time. This message informs the user that performance might be improved if the FILTER function is used instead of `WHERE`.

Example 1

If **Vendor** is configured as an ER data source that refers to the VendTable table, the expression `WHERE (Vendors, Vendors.VendGroup = "40")` returns a list of only vendors that belong to vendor group 40.

Example 2

If you enter data source **DS** of the *Calculated field* type, and it contains the expression `SPLIT ("A|B|C", "|")`, the expression `WHERE( DS, DS.Value = "B")` returns a list of only one record that contains the text **"B"** in the **Value** field.

List of ER functions in the logical category

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) logical functions can be used to work with logical values to perform more than one comparison in a single expression or test multiple conditions. This article provides a summary of these functions.

List of supported functions

Expand table

Function	Description
And	This function returns a *Boolean* value of **TRUE** if all the specified conditions are true. Otherwise, it returns a *Boolean* value of **FALSE**.
Case	This function evaluates the value of the specified expression against the specified alternative options and returns the result of the first option that equals the value of the specified expression. Otherwise, it returns an optional default result, if a default result is specified as the last argument of the called function that isn't preceded by an option. The value that is returned can be a value of any of the supported data types.
Contains	This function determines whether the specified input contains the specified text. It returns a *Boolean* value of **TRUE** if the specified input contains the specified text. Otherwise, it returns a *Boolean* value of **FALSE**.
EndsWith	This function determines whether the specified input ends with the specified text. It returns a *Boolean* value of **TRUE** if the specified input ends with the specified text. Otherwise, it returns a *Boolean* value of **FALSE**.
If	This function returns the first specified value if the specified condition is met. Otherwise, it returns the second specified value. The value that is returned can be a value of any of the supported data types.
Not	This function returns the reversed logical value of the specified condition as a *Boolean* value.

Function	Description
Or	This function returns a *Boolean* value of **FALSE** if all the specified conditions are false. If any specified condition is true, the function returns a *Boolean* value of **TRUE**.
StartsWith	This function determines whether the specified input starts with the specified text. It returns a *Boolean* value of **TRUE** if the specified input starts with the specified text. Otherwise, it returns a *Boolean* value of **FALSE**.
ValueIn	This function determines whether the specified input matches any value of a specified item in the specified list. It returns a *Boolean* value of **TRUE** if the specified input matches the result of running the specified expression for at least one record of the specified list. Otherwise, it returns a *Boolean* value of **FALSE**.
ValueInLarge	This function determines whether the specified input of the *Int64* or *Integer* type matches any value of a specified item in the specified list. It returns a *Boolean* value of **TRUE** if the specified input matches the result of running the specified expression for at least one record of the specified list. Otherwise, it returns a *Boolean* value of **FALSE**.

AND ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `AND` function returns a *Boolean* value of **TRUE** if all the specified conditions are true. Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

```
VB
AND (condition 1[, condition 2, …, condition N])
```

Arguments

`condition 1`: *Boolean*

A valid conditional expression that must be tested. This argument is required.

`condition N`: *Boolean*

A valid conditional expression that must be tested. These additional arguments are optional.

Return values

Boolean

The resulting *Boolean* value.

Usage notes

In the arguments of logical functions, you can use data source references, numeric and text values, Boolean values, comparison operators, and other Electronic reporting (ER) functions.

However, all the arguments must be evaluated to a *Boolean* value of **TRUE** or **FALSE**.

Example

`AND (1=1, "a"="a")` returns **TRUE**.

`AND (1=2, "a"="a")` returns **FALSE**.

Additional resources

Logical functions

Last updated on 04/08/2026

CASE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `CASE` function evaluates the value of the specified expression against the specified alternative options and returns the result of the first option that equals the value of the specified expression. Otherwise, it returns the optional default result, if a default result is specified as the last argument of the called function that isn't preceded by an option. The value that is returned can be a value of any of the supported data types.

Syntax

VB

```
CASE (expression, option 1, result 1[, option 2, result 2, …, option N, result N,
default result])
```

Arguments

`expression`: *Primitive data type* (Boolean, numeric, or text)

A valid expression that returns a value of the primitive data type.

`option 1`: *Primitive data type* (Boolean, numeric, or text)

A valid expression that returns a value of the same primitive data type as the `expression` argument of the called function. This argument is required.

`result 1`: *Any of the supported data types*

The returned result that corresponds to the preceding option. This argument is required.

`option N`: *Primitive data type* (Boolean, numeric, or text)

A valid expression that returns a value of the same primitive data type as the `expression` argument of the called function. This argument is optional.

`result N`: *Any of the supported data types*

The returned result that corresponds to the preceding option. This argument is optional.

`default result`: *Any of the supported data types*

The result that should be returned if there is no match. This argument is optional.

Return values

Any of the supported data types

The resulting value of any of the supported data types.

Usage notes

An exception is thrown at runtime if there is no match and an optional default result isn't defined.

All results must be specified by using the same data type. An exception is thrown at design time if the data types of the configured results don't match.

If the first result value and the *N*th result value are values of the *Container (record)* or *Record list* data type, the result has only the fields that exist in both values.

Example

`CASE( DATETIMEFORMAT( NOW(), "MM"), "10", "WINTER", "11", "WINTER", "12", "WINTER", "")` returns the string "**WINTER**" if the current application session date is between October and December. Otherwise, it returns a blank string.

CONTAINS ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `CONTAINS` function determines whether the specified input contains the specified text. It returns a *Boolean* value of **TRUE** if the specified input contains the specified text. Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

VB

```
CONTAINS (input, search text)
```

Arguments

`input`: *String*

The valid path of an item of a data source of the *String* type or a string constant, the value of which might contain the second argument.

`search text`: *String*

The valid path of a data source of the *String* data type or a string constant, the value of which might be contained in the first argument.

Return values

Boolean

The resulting *Boolean* value.

Usage notes

This function can be used to specify a condition expression of the FILTER function only when the relevant mapping is configured in Regulatory Configuration Services to access Microsoft Dataverse. Otherwise, an exception is thrown at design time. The message that you receive recommends that you use the WHERE function instead of the `FILTER` function.

Example 1

The expression `CONTAINS ("abc", "d")` returns **FALSE**, whereas the expression `CONTAINS ("abc", "C")` returns **TRUE**.

Example 2

The expression `CONTAINS (model.InvoiceBase.Customer.PostalAddress.Address, "DEU")` returns **TRUE** if the value of the **Address** field of the **model** data source contains the string **DEU**. Otherwise, it returns **FALSE**.

Additional resources

Logical functions

ENDSWITH ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ENDSWITH` function determines whether the specified input ends with the specified text. It returns a *Boolean* value of **TRUE** if the specified input ends with the specified text. Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

```
VB

ENDSWITH (input, end text)
```

Arguments

`input`: *String*

The valid path of an item of a data source of the *String* type or a string constant, the value of which might end with the second argument.

`start text`: *String*

The valid path of a data source of the *String* data type or a string constant, the value of which might be at the end of the first argument.

Return values

Boolean

The resulting *Boolean* value.

Usage notes

This function can be used to specify a condition expression of the FILTER function only when the relevant mapping is configured in Regulatory Configuration Services to access Microsoft Dataverse. Otherwise, an exception is thrown at design time. The message that you receive recommends that you use the WHERE function instead of the `FILTER` function.

Example 1

The expression `ENDSWITH ("abc", "d")` returns **FALSE**, whereas the expression `ENDSWITH ("abc", "C")` returns **TRUE**.

Example 2

The expression `ENDSWITH (model.InvoiceBase.Customer.PostalAddress.Address, "USA")` returns **TRUE** if the value of the **Address** field of the **model** data source ends with the string **USA**. Otherwise, it returns **FALSE**.

Additional resources

Logical functions

IF ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `IF` function returns the first specified value if the specified condition is met. Otherwise, it returns the second specified value. The value that is returned can be a value of any of the supported data types.

Syntax

```VB
IF (condition, first value, second value) as any of the supported data types
```

Arguments

`condition`: *Boolean*

A valid conditional expression that must be tested.

`first value`: *Any of the supported data types*

The result that is returned if the condition is met.

`second value`: *Any of the supported data types*

The result that is returned if the condition isn't met.

Return values

Any of the supported data types

The resulting value of any of the supported data types.

Usage notes

The `first value` and `second value` arguments must be specified by using the same data type. An exception is thrown at design time if the data types of the configured values don't match.

If the first value and the second value are values of the *Container (record)* or *Record list* data type, the result has only the fields that exist in both values.

Example

`IF (1=2, "condition is met", "condition is not met")` returns the string "**condition is not met**".

NOT ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `NOT` function returns the reversed logical value of the specified condition as a *Boolean* value.

Syntax

VB

```
NOT (condition)
```

Arguments

`condition`: *Boolean*

A valid conditional expression that must be reversed.

Return values

Boolean

The resulting *Boolean* value.

Example

`NOT (TRUE)` returns **FALSE**.

Additional resources

Logical functions

Last updated on 04/08/2026

OR ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `OR` function returns a *Boolean* value of **FALSE** if all the specified conditions are false. If any specified condition is true, the function returns a *Boolean* value of **TRUE**.

Syntax

VB

```
OR (condition 1[, condition 2, …, condition N])
```

Arguments

`condition 1`: *Boolean*

A valid conditional expression that must be tested. This argument is required.

`condition N`: *Boolean*

A valid conditional expression that must be tested. These additional arguments are optional.

Return values

Boolean

The resulting *Boolean* value.

Example

`OR (1=2, "a"="a")` returns **TRUE**.

STARTSWITH ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `STARTSWITH` function determines whether the specified input starts with the specified text. It returns a *Boolean* value of **TRUE** if the specified input starts with the specified text. Otherwise, it returns a *Boolean* value of **FALSE**.

Syntax

VB

```
STARTSWITH (input, start text)
```

Arguments

`input`: *String*

The valid path of an item of a data source of the *String* type or a string constant, the value of which might start with the second argument.

`start text`: *String*

The valid path of a data source of the *String* data type or a string constant, the value of which might be at the beginning of the first argument.

Return values

Boolean

The resulting *Boolean* value.

Usage notes

This function can be used to specify a condition expression of the FILTER function only when the relevant mapping is configured in Regulatory Configuration Services to access Microsoft Dataverse. Otherwise, an exception is thrown at design time. The message that you receive recommends that you use the WHERE function instead of the `FILTER` function.

Example 1

The expression `STARTSWITH ("abc", "d")` returns **FALSE**, whereas the expression `STARTSWITH ("abc", "A")` returns **TRUE**.

Example 2

The expression `STARTSWITH (model.InvoiceBase.Customer.PostalAddress.Address, "123 Coffee Street")` returns **TRUE** if the value of the **Address** field of the **model** data source starts with the string **123 Coffee Street**. Otherwise, it returns **FALSE**.

Last updated on 04/08/2026

VALUEIN ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `VALUEIN` function checks whether the specified input matches any value of a specified item in the specified list. It returns **TRUE** if the specified input matches the result of running the specified expression for at least one record of the specified list. Otherwise, it returns **FALSE**.

Syntax

VB

```
VALUEIN (input, list, list item expression)
```

Arguments

`input`: *Field*

The valid path of an item of a data source of the *Record list* type. The value of this item is matched.

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`list item expression`: *Boolean*

A valid conditional expression that either points to or contains a single field of the specified list that you use for the matching.

Return values

Boolean

The resulting *Boolean* value.

Usage notes

In general, the `VALUEIN` function translates to a set of **OR** conditions. If the list of **OR** conditions is large and the maximum total length of an SQL statement might be exceeded, consider using the VALUEINLARGE function.

VB

```
(input = list.item1.value) OR (input = list.item2.value) OR …
```

In some cases, the function translates to a database SQL statement by using the `EXISTS JOIN` operator.

> ⓘ **Note**
>
> Depending on whether you use the `VALUEIN` function to specify the selection criteria for the **FILTER** function or the **WHERE** function, the value that the `VALUEIN` function returns is **used differently**.

Example 1

In your model mapping, you define the **List** data source of the *Calculated field* type. This data source contains the expression `SPLIT ("a,b,c", ",")`.

When you call a data source, if you configure it as the `VALUEIN ("B", List, List.Value)` expression, it returns **TRUE**. In this case, the `VALUEIN` function translates to the following set of conditions: `(("B" = "a") or ("B" = "b") or ("B" = "c"))`, where `("B" = "b")` equals **TRUE**.

When you call a data source, if you configure it as the `VALUEIN ("B", List, LEFT(List.Value, 0))` expression, it returns **FALSE**. In this case, the `VALUEIN` function translates to the following condition: `("B" = "")`, which doesn't equal **TRUE**.

The upper limit for the number of characters in the text of such a condition is 32,768 characters. Therefore, don't create data sources that might exceed this limit at runtime. If the limit is exceeded, the application stops running, and an exception is thrown. For example, this situation can occur if the data source is configured as `WHERE (List1, VALUEIN (List1.ID, List2, List2.ID)`, and the **List1** and **List2** lists contain a large volume of records.

In some cases, the `VALUEIN` function translates to a database statement by using the `EXISTS JOIN` operator. This behavior occurs when the FILTER function is used and the following conditions are met:

- The **ASK FOR QUERY** option is turned off for the data source of the `VALUEIN` function that refers to the list of records. No additional conditions are applied to this data source at runtime.
- No nested expressions are configured for the data source of the `VALUEIN` function that refers to the list of records.
- A list item of the `VALUEIN` function refers to a field of the specified data source, not to an expression or method of that data source.

Consider using this option instead of the WHERE function that is described earlier in this example.

Example 2

You define the following data sources in your model mapping:

- The **In** data source of the *Table records* type. This data source refers to the Intrastat table.
- The **Port** data source of the *Table records* type. This data source refers to the IntrastatPort table.

When you call a data source that you configured as the `FILTER (In, VALUEIN(In.Port, Port, Port.PortId))` expression, the system generates the following SQL statement to return filtered records of the Intrastat table.

VB

```
select … from Intrastat
exists join TableId from IntrastatPort
where IntrastatPort.PortId = Intrastat.Port
```

For **dataAreaId** fields, the final SQL statement uses the `IN` operator.

Example 3

You define the following data sources in your model mapping:

- The **Le** data source of the *Calculated field* type. This data source contains the expression `SPLIT ("DEMF,GBSI,USMF", ",")`.

- The **In** data source of the *Table records* type. This data source refers to the Intrastat table, and the **Cross-company** option is turned on for it.

When you call a data source that you configured as the `FILTER (In, VALUEIN (In.dataAreaId, Le, Le.Value))` expression, the final SQL statement contains the following condition.

VB

```
Intrastat.dataAreaId IN ('DEMF', 'GBSI', 'USMF')
```

Logical functions

VALUEINLARGE functions

Last updated on 04/13/2026

VALUEINLARGE ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `VALUEINLARGE` function determines whether the specified input of the *Int64* or *Integer* type matches any value of a specified item in the specified list. The function returns a *Boolean* value of **TRUE** if the specified input matches the result of running the specified expression for at least one record of the specified list. Otherwise, it returns a *Boolean* value of **FALSE**. To understand the difference with the `VALUEIN` function, see the Usage note section later in this article.

Syntax

VB

```
VALUEINLARGE (input, list, list item expression)
```

Arguments

`input`: *Field*

The valid path of a data source item of the *Record list* type. The value of this item will be matched.

`list`: *Record list*

The valid path of a data source of the *Record list* data type.

`list item expression`: *Expression*

A valid conditional expression that either points to or contains a single field of the specified list that should be used for the matching.

Return values

Boolean

The resulting *Boolean* value.

Usage notes

When the specified input represents an *Int64* or *Integer* type of a data source item, the call to which is translatable to a direct SQL statement, the specified list is converted to a temporary SQL table and matching is performed in the database by executing a single `EXISTS JOIN` query. Otherwise, this function works as the VALUEIN function.

When the specified input represents a data source item that is designed as an item other than *Int64* and *Integer* type, an error occurs at design time informing you that the `VALUEINLARGE` function is not applicable for the configured ER expression.

When the `VALUEINLARGE` function expression is executed and more than one temporary table is used in scope of this execution, a runtime error occurs.

Example

You define the following data sources in your model mapping:

- The **In** data source of the *Table records* type.
  - This data source refers to the **Intrastat** table.
  - The **Cross-company** option is set to **No**.
- The **InMemory** data source of the *Calculated field* type.
  - This data source contains the expression `WHERE (In, In.Port <> "")`.
- The **InFiltered** data source of the *Calculated field* type.
  - This data source contains the expression `FILTER (In, VALUEINLARGE(In.RecId, InMemory, InMemory.RecId)`.

When the data source **InFiltered** is called under the context of the company **DEMF**, a new temporary table is created in the application database, the collected in memory list of record identification codes are inserted to this table, and the following SQL statement is generated to return filtered records of the **Intrastat** table.

X++

```
SELECT … from Intrastat T1
WHERE ((T1.PARTITION=?) AND (T1.DATAAREAID IN (N'DEMF'))) AND
```

```
EXISTS (SELECT 'x' FROM tempdb."DBO".? T2 WHERE ((T2.PARTITION=?) AND
(T1.RecId=T2.RecId)))
```

List of ER functions in the mathematical category

Electronic reporting (ER) mathematical functions can be used to do many common mathematical calculations. This article provides a summary of these functions.

List of supported functions

Expand table

Function	Description
Abs	This function returns the absolute value (modulus) of the specified number as a *Real* value. In other words, it returns the number without its sign.
DIV	This function returns the integer division of two integers. The result is the quotient of the division of `dividend` by `divisor`, rounded down to the nearest integer.
MOD	This function returns the remainder after a number is divided by another number. In other words, it returns the modulus of the specified numbers.
Power	This function returns a *Real* value that represents the result of raising the specified positive number to the specified power.
Round	This function returns the specified number as a *Real* value after it has been rounded to the specified number of decimal places.
RoundDown	This function returns the specified number as a *Real* value after it has been rounded down to the specified number of decimal places.
RoundUp	This function returns the specified number as a *Real* value after it has been rounded up to the specified number of decimal places.

ABS ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ABS` function returns the absolute value (modulus) of the specified number as a *Real* value. In other words, it returns the number without its sign.

Syntax

VB

```
ABS (number)
```

Arguments

`number`: *Real*

A numeric value that you want the modulus of.

Return values

Real

The resulting numeric value.

Example

`ABS (-1)` returns **1**.

Additional resources

Mathematical functions

Last updated on 04/08/2026

DIV ER function

The `DIV` function is available in Dynamics 365 Finance **10.0.49** and later.

The `DIV` function returns the integer division of two integers. The result is the quotient of the division of `dividend` by `divisor`, rounded down to the nearest integer.

Syntax

VB

```
DIV (dividend, divisor)
```

Arguments

`dividend`: *Integer*

The dividend, or the number to be divided.

`divisor`: *Integer*

The divisor, or the number by which `dividend` is divided.

Return values

Integer

The resulting numeric value.

Example

`DIV (5, 2)` returns **2**.

Additional resources

Mathematical functions

Last updated on 07/22/2026

MOD ER function

The `MOD` function is available for Finance and Operations **10.0.49** and later.

The `MOD` function returns the remainder after a number is divided by another number. In other words, it returns the modulus of the specified numbers.

Syntax

VB

```
MOD (dividend, divisor)
```

Arguments

`dividend`: *Real* or *Integer*

The dividend, or the number to be divided.

`divisor`: *Real* or *Integer*

The divisor, or the number by which `dividend` is divided.

Return values

Real or *Integer*

The resulting numeric value.

Example

`MOD (5, 2)` returns **1**.

Example 2

`MOD (6.6, 3.1)` returns **0.4**.

POWER ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `POWER` function returns a *Real* value that represents the result of raising the specified positive number to the specified power.

Syntax

VB

```
POWER (number, power)
```

Arguments

`number`: *Real* or *Integer*

A numeric value that must be raised to the specified power.

`power`: *Real* or *Integer*

A numeric value that represents the specific power.

Return values

Real

The resulting numeric value.

Example 1

`POWER (10, 2)` returns **100**.

Example 2

`POWER (4, 0.5)` returns 2.

Additional resources

Mathematical functions

ROUND ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ROUND` function returns the specified number as a *Real* value after it has been rounded to the specified number of decimal places.

Syntax

VB

```
ROUND (number, decimals)
```

Arguments

`number`: *Real*

A numeric value that must be rounded.

`decimals`: *Integer*

A numeric value that represents the number of decimal places.

Return values

Real

The resulting numeric value.

Usage notes

If the value of the `decimals` argument is more than 0 (zero), the specified number is rounded to that many decimal places.

If the value of the `decimals` argument is **0** (zero), the specified number is rounded to the nearest even integer.

If the value of the `decimals` argument is less than 0 (zero), the specified number is rounded to the left of the decimal point.

Example 1

`ROUND (1200.767, 2)` rounds to two decimal places and returns **1200.77**.

Example 2

`ROUND (1200.767, -3)` rounds to the nearest multiple of 1,000 and returns **1000**.

Example 3

`ROUND (1200.5, 0)` rounds to the nearest even integer and returns **1200**, while `ROUND (1201.5, 0)` does the same and returns **1202**.

Additional resources

Mathematical functions

ROUNDDOWN ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ROUNDDOWN` function returns the specified number as a *Real* value after it has been rounded down to the specified number of decimal places.

Syntax

VB

```
ROUNDDOWN (number, decimals)
```

Arguments

`number`: *Real*

A numeric value that must be rounded down.

`decimals`: *Integer*

A numeric value that represents the number of decimal places.

Return values

Real

The resulting numeric value.

Usage notes

This function behaves like ROUND, but it always rounds the specified number down (toward zero).

Example 1

`ROUNDDOWN (1200.767, 2)` rounds down to two decimal places and returns **1200.76**.

Example 2

`ROUNDDOWN (1700.767, -3)` rounds down to the nearest multiple of 1,000 and returns **1000**.

Additional resources

Mathematical functions

Last updated on 04/08/2026

ROUNDUP ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `ROUNDUP` function returns the specified number as a *Real* value after it has been rounded up to the specified number of decimal places.

Syntax

VB

```
ROUNDDOWN (number, decimals)
```

Arguments

`number`: *Real*

A numeric value that must be rounded up.

`decimals`: *Integer*

A numeric value that represents the number of decimal places.

Return values

Real

The resulting numeric value.

Usage notes

This function behaves like ROUND, but it always rounds the specified number up (away from zero).

Example 1

`ROUNDUP (1200.763, 2)` rounds up to two decimal places and returns **1200.77**.

Example 2

`ROUNDUP (1200.767, -3)` rounds up to the nearest multiple of 1,000 and returns **2000**.

EMPTYRECORD ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `EMPTYRECORD` function returns a null *Container (record)* value that has the same structure as the specified record list or record.

Syntax

VB

```
EMPTYRECORD (list)
```

Arguments

`list`: *Record list* or *Container (record)*

The valid path of a data source of either the *Record list* or *Container (record)* type.

Return values

Container (record)

The resulting record value.

Usage notes

> **Note**
>
> A null record is a record where all fields have an empty value. An empty value is **0** (zero) for numbers, an empty string for strings, and so on.

Example

`EMPTYRECORD (SPLIT ("abc", 1))` returns a new empty record that has the same structure as the list that is returned by the `SPLIT` function. For more information, see SPLIT.

Additional resources

Record functions

Last updated on 04/08/2026

NULLCONTAINER ER function

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The `NULLCONTAINER` function returns a null *Container (record)* value that has the same structure as the specified record list or record.

Syntax

VB

```
NULLCONTAINER (list)
```

Arguments

`list`: *Record list* or *Container (record)*

The valid path of a data source of either the *Record list* or *Container (record)* type.

Return values

Container (record)

The resulting record value.

Usage notes

> **Note**
>
> This function is obsolete. Use the `EMPTYRECORD` function instead. For more information, see EMPTYRECORD.

Example

`NULLCONTAINER (SPLIT ("abc", 1))` returns a new empty record that has the same structure as the list that is returned by the `SPLIT` function. For more information, see SPLIT.

List of ER functions of the text category

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Electronic reporting (ER) text functions can be used to perform operations on data sources of the *String* data type. This article provides a summary of these functions.

List of supported functions

Expand table

Function	Description
Char	This function returns a *String* value that presents a single character that is referenced by the specified Unicode number.
Concatenate	This function returns all the specified text strings as a *String* value after they have been joined into one string.
Format	This function returns the specified string a *String* value after it has been formatted by substituting any occurrences of **%N** with the *N*th argument.
GetEnumValueByName	This function searches for a specific *Enum* value in the specified enumeration data source by using the enumeration name that is specified as a *String* value. If the *Enum* value is found, the function returns it.
GetLabelText	This function searches for a specific label to return a *String* value that represents the translation of the specified label in the specified language.
GuidValue	This function converts the specified input of the *String* type to a data item of the *GUID* type.
JsonValue	This function parses data in JavaScript Object Notation (JSON) format that is accessed at the specified path, and it extracts a scalar value that is based on the specified ID. It then returns the extracted scalar value as a *String* value.
Left	This function returns a *String* value that presents the specified number of characters from the start of the specified string.

Function	Description
Len	This function returns an *Integer* value that presents the number of characters in the specified string.
Lower	This function returns the specified text string as a *String* value after it has been converted to lowercase letters.
Mid	This function returns a *String* value that presents the specified number of characters from the specified string, starting at the specified position.
NewGUID	This function returns a newly generated *GUID* value.
NumberFormat	This function returns a *String* value that presents the specified number in the specified format and in an optionally specified culture.
NumeralsToText	This function returns the specified number as a *String* value after it has been spelled out (that is, converted to text strings) in the specified language.
PadLeft	This function returns a *String* value of the specified length, where the start of the specified string is padded with one or more instances of the specified characters.
QrCode	This function returns a *Container* value that presents the Quick Response code (QR code) image for the specified string in binary format.
