This procedure shows how to change the owner of consignment inventory from the vendor to your legal entity when there's demand for the inventory in production. This change of ownership is done by creating and posting an inventory ownership change journal. The ownership change journal lines can be created manually or, as shown in this recording, based on existing production demand. Typically, a shop floor supervisor performs this task. You can use this procedure in the USMF demo data company or on your own data. If you're using your own data, make sure that you have the following prerequisites: an inventory journal name that has been set up for inventory ownership change, physically recorded vendor-owned on-hand items, and one or more production order lines for the material. This procedure is for a feature that was added in Dynamics 365 for Operations, version 1611.

> **Note**
>
> Outbound consignment processes aren't supported out-of-the-box and automatic ownership journal processing isn't supported.

Create an inventory ownership journal

1. Go to **Inventory management** > **Journal entries** > **Items** > **Inventory ownership change**.
2. Select **New**. The inventory ownership change journal is used to change the owner of consignment inventory from the vendor to the current legal entity. This change of ownership is done by releasing the on-hand inventory that is owned by the vendor and then receiving that inventory in the current legal entity.
3. In the **Name** field, enter or select a value. You can select only inventory journal names that have a journal type of *Ownership change*.
4. Select **OK**.
5. Select **Functions**.

6. Select **Create journal lines from production orders**. You can start the change of ownership process by querying all the production lines that have demand for consumption of raw material.
7. In the **Inventory issue statuses to include** field, select an option. This option lets you filter by the issue status of the inventory transactions. For example, you can create journal lines for inventory that has the *Picked* and *Reserved physical* statuses.
8. Expand the **Records to include** section. This section lets you apply additional filtering. For example, you can select a specific raw material date.
9. Select **OK**.

Post the inventory ownership change journal

1. Select **Post**. When the journal is posted, the vendor-owned inventory is released by using an *Ownership change* reference. The inventory is then received as on-hand by using an inventory transaction that is updated with a purchase order product receipt. Only transactions that are related to the posted journal are created. No expected inventory transactions are created.
2. Select **OK**.
3. Close the page.

Create a consignment replenishment order

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to create a consignment replenishment order where you can track the expected delivery from a vendor into your consignment inventory. It also shows how to record a receipt of products so that the consignment inventory is registered as on-hand inventory owned by the vendor. This procedure would typically be done by a procurement professional. You can use this guide in demo data company USMF. This procedure is for a feature that was added in Dynamics 365 for Operations, version 1611.

Create a consignment replenishment order

1. Go to **Procurement and sourcing** > **Consignment** > **Consignment replenishment orders**.
2. Select **New**.
3. In the **Vendor account** field, select vendor **US-104** (you must select a vendor that's registered as an owner on the **Inventory owners** page).
4. Select **OK**.
5. Select **Add line**.
6. In the **Item number** field, type *M9211CI* (you must select an item that is set up for consignment inventory).
7. In the **Quantity** field, enter a number.
8. In the **Requested delivery date** field, enter a date. The requested and confirmed dates are used by the MRP engine for the expected arrival of the goods.
9. In the **Confirmed delivery date** field, enter a date.
10. Expand the **Line details** section.
11. Select the **Inventory dimensions** tab.
12. To show the owner in the **Inventory dimensions owner** field, refresh the page. Vendor US-104 is now listed as the owner.

Check the inventory transaction status

1. Select **Inventory**.
2. Select **Transactions**.

3. In the desired row, notice that the **Receipt** field is set to *Ordered*.
4. Close the page.

Receive items

1. Select **Product receipt**.
2. In the **External product receipt** field, type a value.
3. In the **Quantity** field, enter a number that's lower than the number that's shown there.
4. Select **OK**.

Check the on-hand inventory

1. Select **Inventory**.
2. Select **On-hand**.
3. Select **Overview**. The items that have been received as consignment inventory owned by the vendor are available on-hand. The remaining quantity on the consignment replenishment order is shown in the **Ordered in total** field.
4. Close the page.

Last updated on 04/10/2025

Monitor consignment inventory using vendor collaboration

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure shows how to use vendor collaboration to see information about the stock level of product that you placed in consignment with a customer. You can also monitor the consumption of the stock when the customer takes ownership of the inventory.

View consumed inventory

To view the inventory that the customer has consumed from the consignment stock, follow these steps:

1. Go to **Vendor collaboration** > **Consignment inventory** > **Products received from consignment inventory**. The list shows the product receipt lines that were generated when ownership of the consignment inventory changed from the vendor to the customer. You might have to scroll to the right to see quantities and other information. You can use the information in this list to generate invoices for your customer. You can also export the data to Microsoft Excel.
2. Select **View purchase order**.
3. Expand the **Line details** section. The line is marked as *Consignment*, and the header section shows that the purchase order has a status of *Received*.
4. Close the page.

View on-hand inventory

To view on-hand inventory, go to **Vendor collaboration** > **Consignment inventory** > **On-hand consignment inventory**. The **On-hand consignment inventory** page shows the stock that you own at the customer's warehouse. You can show additional dimensions, such as the site and warehouse, by selecting the Display dimensions tab.

Item and raw material tracing in inventory, production, and sales

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how you can use item tracing to identify where items or raw materials have been used, are being used, or will be used in production and sales processes.

Item tracing functionality is available on the **Item tracing** page. The following sections describe how you can use item tracing, and what the options and limitations are.

What is item tracing?

Item tracing is a business intelligence (BI) tool that provides visibility into the source and destination of items and raw materials in the supply chain. Manufacturers can trace items, raw materials, or ingredients back to the vendor, and forward through the production and sale of the finished product. Item tracing helps manufacturers comply with regulatory requirements, and also helps quality officers and production managers analyze and take action to address variances in the quality of products and materials. Here are some examples of the ways that manufacturers can use item tracing:

- Identify the amount of an item or raw material that is currently in inventory, and where it's stored.
- Determine how much of the item or raw material is shipped, and which customers it was shipped to.
- Identify any planned shipments that include the item or raw material.
- Locate production orders that use the item or raw material, and that are planned, in progress, or reported as finished.
- Find out where the item or raw material was purchased.
- Investigate where an item or raw material was consumed in the production of another item.

What can I trace, and are there any limitations?

You can trace historical inventory transactions for items and raw materials, based on an item number and a tracking dimension, such as a serial number, batch number, or vendor batch number. You can trace an item or raw material only if you assign a tracking dimension to it. Because tracing is based on inventory transactions, some limitations exist when you trace items. For example, some limitations relate to transactions for projects, fixed assets, and commerce. Additionally, co-products appear in the trace details, but by-products aren't included. The trace includes all warehouse transactions from one location to another. Therefore, users might find the amount of information overwhelming. The trace displays for one legal entity at a time. The trace doesn't include cross-company capabilities in an intercompany context. You must start a new trace for each company where an item is received or issued.

What criteria can I specify for an item trace?

To perform an item trace, you need to provide the item number, a tracking dimension (such as a batch number or serial number), and the direction. The following table describes the criteria that you can use in an item trace.

Expand table

Field group	Description
Item number	Enter the identifier for the item or raw material that you're tracing.
Product dimensions	Optional: Trace specific aspects of the product definition, such as a configuration, size, color, or style.
Tracking dimensions	Enter a batch number, vendor batch number, or serial number tracking dimension. When you use the batch number as a criterion, the vendor batch number is displayed if you captured that information.
Storage dimensions	Optional: Trace items that are stored in a specific location.
Period	Optional: Enter dates to limit the trace to a specific period. The trace details show only documents and transactions that were created between these dates.
Forward or backward	Select the direction for the trace. You can trace forward or backward: • **Backward** – Trace downstream to identify the source, the quantity that remains on hand, and any production orders that are at least partially reported as finished.

Field group	Description
	• **Forward** – Trace upstream to identify the destination. You can find the sales orders, and the customers that the traced item or raw material is at least partially shipped to.

What information is included in the trace details?

The results of a trace appear in chronological order in the tree on the **Details** FastTab of the **Item tracing** page. The order varies, depending on the trace direction. The details include all transactions from the purchase of the item from the vendor to the sale of the item to the customer. Trace results also include interim products that are related to the item or the tracking dimension specified in the trace criteria. The top node shows the quantity of the item, in the inventory unit, that remains on hand, based on the storage dimensions specified in the trace criteria.

> **Note**
>
> The trace details provide a snapshot of the information that was available when the trace was done. The trace details aren't updated if the information changes after the trace is done.

Why don't some nodes contain any details?

To reduce the amount of information in the trace details, only the node for the first instance of the item or raw material includes details. If a selected node doesn't contain details, you can view the node that does contain details by selecting **Go to traced line**. You can then return to the node that you left by selecting **Go back**.

Can I view only a particular type of document? For example, can I view only production orders, customers, or vendors?

Yes, from the trace details, you can open list pages that include only a particular type of document or transaction. You can access these pages from the **Tracing** menu item on the Action Pane, in the **Item**, **Sales**, **Purchase**, **Production**, and **Quality** groups. For example, to view a list of the vendors in the trace details, select **Tracing** > **Purchase** > **Vendors**. The list pages summarize the documents or transactions from the trace details. The **Pending transactions**, **Pending orders**, and **Not shipped sales orders** list pages also show other information that isn't included in the

trace details. Additionally, they always show results as of the current date, even if a date range was specified. The following table describes the additional details that these pages can include.

Expand table

Lists	Description
Not shipped sales orders	View sales order lines that aren't picked, and that therefore aren't shown in the trace details.
Pending orders	View all pending production orders for the traced item, regardless of the tracking dimensions that the trace criteria used. You can also view pending production orders where the traced item is an ingredient, and where no registrations exist and no transactions are reported as finished for the order.
Pending transactions	View pending inventory transactions for the traced item that include the specified tracking dimensions or a blank tracking dimension. You can also view pending inventory transactions for items and tracking dimension combinations, or a blank value, in the trace details.

How many levels can I trace up or down in a BOM or formula?

You can trace one level up or down in a bill of materials (BOM) or formula. For example, if you run a trace on raw materials, you can see the finished product and any co-products. However, if you trace a co-product, the trace details don't include the finished product.

How can I view more details about a document or transaction in the trace details?

On the **Details** FastTab, there are two ways to view more information about a selected document or transaction in the trace details:

- When you select a node in the trace details on the **Details** FastTab, the other FastTabs on the page display information about the document or transaction in the node.
- Open the details page for the document in a selected node by selecting **View details**. For example, if you select a node that describes a production order, and you select **View details**, the **Production orders details** page appears.

Some FastTabs give you access to additional information about the selected node. For example, on the **Non conformances** FastTab, you can select **Inquiries** to investigate whether there's a history of non-conformance. On the **Batch** FastTab, you can select **On-hand list** to view the

amount of physical inventory that is currently on hand and any inventory transactions that involve the batch.

Can I run more than one trace and then compare the details?

After you run the trace, use the following options on the **Trace from node** button to run a new trace on the transaction in the selected node:

- **Backward** or **Forward** – Start a new trace for the selected node, and overwrite the details of the current trace.
- **New backward** or **New forward** – Start a new trace in a new window, and keep the details of the current trace.

To use the **New backward** or **New forward** option, use the **Open in a new window** functionality to have a new trace appear in a new window.

Can I save the trace details?

You can save the information on the **Details** tab as an XML file by selecting **Export** under the **Tracing** action on the Action Pane. In addition to the trace details, the XML file includes the trace criteria, parent node, and on-hand quantity. The capability to save the details of a trace is useful if, for example, you want to attach the information to a quality order or other compliance documentation. You can specify where the file is saved. To view the file immediately, select the **Show document** option.

> ⓘ **Note**
>
> The file is always saved, even if you only want to view it. By default, the XML file opens in a browser window. However, you can right-click the file, select **Open with**, and then select the program to use to display the contents.

Can I calculate a balance for a particular item or ingredient?

You can export the information from the summary pages to Microsoft Excel. Open the relevant page, select the **Open in Microsoft Office** icon, and then select **Export to Microsoft Excel**. This functionality is especially useful when you want to calculate a mass balance for an item or

ingredient from the **Transactions summary** page. On the **Transactions summary** page, you can filter on the item or ingredient, and optionally on the batch, and then export the information to Excel. In Excel, you can isolate, for example, the on-hand quantity, the quantity that was sold, and the amount that was used in production.

Can I investigate whether there's a history of issues with items or raw materials?

The trace details include information about quality orders and nonconformances that involve the item or raw material. To view a summary of quality orders and nonconformances, select **Quality orders** or **Non conformances** on the Action Pane.

> **Note**
>
> Destructive quality orders can appear more than one time in the trace details. When a destructive quality order is created for a document, such as a purchase order, it appears for each transaction for that document.

Are there any reporting capabilities that are related to item tracing?

You can generate the **Shipped to customers** report to identify the amount of the item or raw material that's shipped and the customers that it was shipped to. For an inquiry that's related to compliance, you can generate the report for all customers. For an inquiry that's related to customer service, you can generate the report for a selected customer. If the product was a raw material used in the production of a finished item, the finished item is also included.

> **Note**
>
> If you're using the features for deleting or archiving sales orders, the report results also include any sales orders that are deleted or archived.

Can I trace co-products and by-products?

You can trace co-products, but you can't trace a by-product, because tracking dimensions aren't typically assigned to by-products. When you trace an item, the trace details include any related co-products. A node that contains a co-product includes the word "co-product" in the details.

You can also view details about a co-product by selecting the node in the trace details and then selecting the **Production** FastTab.

Last updated on 05/22/2026

Trace an item or raw material

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure demonstrates how to use item tracing to identify where items or raw materials have been used or are being used. With this procedure, you can identify an item, trace it back to the source, and then trace forward through the production and sale of the finished product. The process can be used to investigate the customers impacted, the sales orders affected, and more. This procedure uses demo data company USP2.

Trace an item backwards using a known batch number

1. Go to **Inventory management** > **Inquiries and reports** > **Tracking dimensions** > **Item tracing**.
2. In the **Item number** field, select *P9100*.
3. In the list, select the link in the selected row.
4. In the **Forward or backward** field, select *Backward*.
5. In the **Batch number** field, select *as-12-344-01*.
6. In the list, select the link in the selected row.
7. Select **OK**.

Identify an item, trace it forward, and make an analysis

The top node of the tree represents the on hand quantity of the selected item and batch. You need to expand the nodes of the tree to find the item that the forward trace should be executed on.

1. In the tree, expand the following nodes and then select the last node.

   Expand: *P9100 / 1 / 10 / as-12-344-01 ● 2 keg ● 7.00 gal \P9100 ● Picked ● Sales order 000072 ● 12/22/2015 ● -1 keg ● -4.00 gal ● Site=1, Warehouse=10, Batch number=as-12-344-01 \P9100 ● Production B-000050 ● 12/9/2015● 7 keg ● 27.00 gal ●*

Site=1,Warehouse=10,Batch number=as-12-344-01 ● Co-products: P9101 and then select that node.

2. In the tree, expand the following node and then select that node.

   Starting from the node that you just selected, expand *M9103 ● Production line B-000050 ● 12/9/2015 ● -160.00 lb ● Size=70, Color=OK, Site=1, Warehouse=10, Batch number=App01* and then select that node.

3. Select **Trace from node**.

4. Select **Forward**.

5. On the Action Pane, select **Tracing**.

   There are several tracing options which provide information about the customers impacted by the item that you're tracing, and the sales orders related to the item which have and haven't been shipped.

6. Select **Customers**.

7. Close the page.

8. On the Action Pane, select **Tracing**.

9. Select **Shipped sales orders**.

10. Close the page.

Last updated on 04/10/2025

Merge inventory batches

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides information about how to consolidate two or more inventory batches into a merged batch.

When you merge batches, calculations can help optimize the characteristics and batch attributes of the merged batch. After you select the source batches, you can review and change the merged batch before you post it. You can also transfer the batch merge to an inventory journal for approval. Inventory can then be reserved or posted directly from that inventory journal. When you post a merged batch, the inventory is adjusted for the source batches and the merged batch.

Are there any prerequisites?

Yes, there are some things that you must set up before you can use the merge batch tools. The following table describes the prerequisites.

Expand table

Page	Description
Journal names, inventory	You must create a journal name of the type BOM that is used by default when you post batch merges in inventory journals. Optional but recommended: You can specify that reservations should be made automatically when the batch merge is transferred to the inventory journal. Otherwise, there's a risk that the on-hand inventory might be changed after the batch merge details are set up and the journal is posted. To enable automatic reservations for the journal name, select **Automatic** in the **Reservation** field.
Inventory and warehouse management parameters	You must specify the default journal name for the inventory journal.
Released products	Here are the recommended settings for the item:

Page	Description

	• To automatically generate batch numbers for merged batches, you must assign the released product to a batch number group. You can also enter a batch number manually when you create a merged batch, or select an existing batch number. If you select an existing batch number, make sure that the selected batch hasn't been included in any inventory transactions.
	• If you're using shelf life or best-before dates for the released product, the dates for a merged batch are calculated based on the selection in the **Batch merge date calculation** field. The following options are available:
	  ◦ **Earliest** – The calculation is based on the earliest date that is specified for a source batch that is selected for the batch merge.
	  ◦ **Latest** – The calculation is based on the latest date that is specified for a source batch that is selected for the batch merge.
	  ◦ **Manual** – No calculation is done. If a date is the same on all source batches, a date is suggested. You can change that date. If a date isn't the same on the source batches, you can manually enter the date.

Batch number group	Optional: To generate a batch number when you create a merged batch, you must assign a batch number group to the released product. Otherwise, you can enter a batch number manually.

When might I want to merge batches of inventory?

Here are some examples of scenarios where it might be useful to merge batches:

- Walking through the warehouse, Sammy notices that several batches of the same item have low quantities. Sammy is expecting to receive several new shipments, and realizes that some floor space can be freed by merging the odd quantities into a new batch.
- Sammy is receiving inventory, and wants to combine the new batch with one that has already been received, to improve the batch attribute value of the existing batch. By doing so, you create a new batch.

Can I merge batches across sites and legal entities?

No, you can merge only batches that have the same site and warehouse storage dimensions in one legal entity. However, you can specify a different location and pallet ID for the merged batch.

Can I merge partial quantities?

No, you can merge only the full quantity of batches. The batch merge functionality is intended as an inventory feature, not a production feature.

What if the batches have different batch attribute values?

When you select the source batches to combine in the merged batch, Supply Chain Management verifies whether all the batches have the characteristics or attribute values. When an attribute value is the same, a value is suggested for the merged batch. You can change that value. Attribute values that aren't the same are left blank for the merged batch, and you can enter those values manually. If the batch attribute type for the attribute value is an integer or a fraction, and the values aren't the same for all the source batches, the value is calculated by using a weighted average calculation. The calculated value is rounded up or down to the nearest increment. If the value is blank for a source batch, the batch and its quantity aren't included in the calculation. **Example** The following example shows a weighted average calculation for a merged batch. Two of the source batches have a blank value for a batch attribute type that is an integer. The following attribute is assigned to the source batches.

Expand table

Attribute	Minimum	Increment	Maximum
Grade	3	3	30

The source batches have the following attribute values for the **Grade batch** attribute.

Expand table

Batch	Quantity	Attribute	Attribute value
B1	10	Grade	Blank
B2	15	Grade	15

Batch	Quantity	Attribute	Attribute value
B3	20	Grade	20
B4	25	Grade	Blank
B5	30	Grade	25

When you add these batches as source batches, the following values are assigned to the merged batch.

Expand table

Batch	Quantity	Attribute	Attribute value
B6	100	Grade	21

The values and quantities for batches B1 and B4 aren't included in the weighted average calculation. Therefore, here's how the value for the merged batch is calculated.

Expand table

Value	Quantity (weight)	Relative weight	Relative weight × Value
15	15	0.230769231	3.461538462
20	20	0.307692308	6.153846154
25	30	0.461538462	11.53846154
	Total: 65, which is the sum of the weights		**Total:** 21.5384615, which is rounded to 21 (the nearest increment)

What if the batches have different batch dates?

If the batches have different batch dates, some of the dates are calculated based on the values in the **Batch dates** group on the **Merged batch** FastTab of the **Batch merge** page. The system calculates values for the fields in the **Batch dates** group. These values include the manufacturing date, expiration date, shelf advice date, and best-before date. The dates are calculated based on settings for the item in the **Item data** field group of the **Released product details** page. You can change the values or enter them manually. For all other dates, no calculation is done. The same principle is used for batch attribute values. If a date is the same for all the source batches, that date is suggested for the merged batch. If the date isn't the

same for all source batches, the date is blank on the merged batch, and you can enter it manually.

What if the dimensions are different on the batches that I want to merge?

Here's how product dimensions, tracking dimensions, and storage dimensions are handled:

- **Product dimensions** – All product dimensions for the selected item must be the same. You can't merge batches across product dimensions.
- **Tracking dimensions** – A new batch number is automatically generated if a batch number group is specified for the item. If a batch number group isn't assigned to an item, you can select an existing batch or enter the number manually. Serial numbers are transferred from the source batch to the inventory journal lines for the merged batch.
- **Storage dimensions** – The site and warehouse storage dimensions must be the same for all the source batches and the merged batch. However, you can specify a new location and pallet ID for the merged batch.

How does posting work?

Posting works in two ways, depending on whether you use an approval process for journals. You can use the **Transfer to journal** and **Post the batch merge** actions to transfer the batch merge to a journal where it can be verified and posted, or you can post the batch merge directly. The main difference between the two actions is that a transfer to a journal doesn't post the batch merge. Both actions create a new batch if an existing batch isn't selected, update all batch details and attribute values, and create an inventory journal.

- **Transfer to journal** – Transfer the batch merge details to a new inventory journal. If you've set up automatic reservations, the quantities in the source batches are reserved. The details of the batch merge can't be changed. To modify the batch merge, you must delete the journal. The journal can be used as a task that another employee must perform later. The reservation of the batch quantity to the journal line is secured. This allocation lets a quality planner or a warehouse manager create tasks for their employees.
- **Post the batch merge** – Post the batch merge directly. This action can be performed after the physical merge has occurred.

You can approve the inventory journal for the batch merge from the **All batch merges** list page. Select **Journal** > **Post**. After a journal is posted, you can't change the details in the merged batch. After you transfer a batch merge to an inventory journal, you can change the details only if the journal is deleted.

After I merged a catchweight item, why can’t I see the catchweight information in the inventory journal?

You can merge batches of catch-weight items just like all other items. However, the catch-weight information doesn't appear in the inventory journal. We recommend that you verify the catch-weight information before you transfer the batch merge to the inventory journal.

Correct inventory tracking information

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure walks you through the process of creating and posting an inventory transfer journal to correct inventory tracking information. In this example, you update the information of a batch-controlled item by changing an incorrectly registered batch to another batch. You can walk through this procedure in demo data company *USPI*, or use your own data. If you use your own data, you need to have an item that's batch-enabled, and it must not be location-controlled. You also need to have an inventory journal name set up for inventory transfers. These tasks are normally carried out by a warehouse employee.

Create an inventory transfer journal

To create an inventory transfer journal, follow these steps:

1. Go to **Transfer**.
2. Select **New**.
3. In the **Name** field, enter or select a value.
4. Select **OK**.

Create journal lines

To create journal lines, follow these steps:

1. Select **New**.
2. In the **Item number** field, enter or select a value. If you're using *USPI* demo data, select item *M5003*.
3. In the **Quantity** field, enter a number.
4. Select the **Inventory dimensions** tab.
5. In the **Batch number** field, enter or select a value.
6. In the **Site** field, enter or select a value.
7. In the **Warehouse** field, enter or select a value.
8. In the **Batch number** field, enter or select a value.

Post the journal

To post the journal, follow these steps:

1. Select **Post**.
2. Select **OK**.

Check tracing information

To check tracing information, follow these steps:

1. Select **Inventory**.
2. Select **Trace**.
3. Select **OK**. With this tracing information, you can trace back to the batch you corrected inventory from. You can also use the Item tracing page to see this information.
4. Close the page.

Check inventory transactions

To check inventory transactions, follow these steps:

1. Select **Inventory**.
2. Select **Transactions**. Here you can see the transactions that were created when you posted your journal.

Last updated on 11/20/2025

Working with serialized items

> **Note**
>

This article explains how to register serial numbers on packing slips or invoices during the sales process. This functionality is useful if a company wants to capture serial numbers for service and warranty purposes, but doesn't need to maintain serial numbers in inventory from receipt to issue.

Many companies just want to capture serial numbers for service and warranty purposes, and don't need to maintain serial numbers in inventory from receipt to issue. In these scenarios, you can register the serial numbers on the packing slips or invoices when products are sold. If products are later returned, you can trace each product to an invoice to determine whether you sold the product, and whether the service or warranty obligations are valid.

You must enable serial numbers for the sales process by selecting the **Active in sales process** option on the **Tracking dimension groups** page. The following events then occur in Supply Chain Management:

- On the **Serial numbers** FastTab, the **Serial number control** option is set to *Yes*. When you select this option, you must register one serial number for each item on the packing slip or invoice.
- All selections on the tracking dimension group for serial numbers are cleared, except the **Blank issue allowed** option. You can select the **Blank issue allowed** option to override the serial number control, and allow products to be packed and invoiced without registering serial numbers.

> **Important**
>
> When the **Physical inventory** option for the **Serial number** dimension is cleared, including the automatic clearing that occurs when you select **Active in sales process**, on-hand

inventory isn't tracked per serial number. This change can cause discrepancies between received and issued serial numbers for the same item.

When do I register serial numbers during the sales process?

You can register serial numbers either on the packing slip for a sales order or on the invoice. When you prepare an invoice for a serialized item that was shipped together with a packing slip, you can select which serial numbers on the packing slip to invoice. The number of registered serial numbers must not exceed the quantity of items that were shipped. If you're creating a partial invoice, you can select fewer serialized items than were registered on the packing slip. When you print a packing slip or an invoice, the serial numbers that were registered are included.

Can I enter serial numbers by scanning them, or do I have to type them?

You can either scan or type serial numbers. When you use a scanner, the scan mode determines whether the serial numbers are added to or removed from the list of serial numbers on the invoice or packing slip. If you want to scan serial numbers by using, for example, a hand-held bar code scanner, configure the scanner to send an Enter or TAB command after the serial number. This command indicates the end of the data stream. Otherwise, you must press Enter or TAB on the keyboard after you scan each serial number.

If I enable serial numbers for the sales process, do I have to register all serial numbers for all items?

The setup of the tracking dimension group that is assigned to the product determines whether serial numbers must be registered for all items on a packing slip or invoice. When you enable serial numbers for the sales process, the **Serial number control** option is automatically selected. You must then register one serial number, or register a blank registration for an unreadable number, for each item on the packing slip or invoice. If you don't want to require a serial number for each item, select the **Blank issue allowed** option on the tracking dimension group that is assigned to the item. You can then register fewer serial numbers than the quantity of items that are being shipped. If you register more serial numbers than the quantity of items that are being shipped, you won't be able to post the packing slip or invoice.

Can I register serial numbers for partial invoices and partial shipments?

You can create partial invoices and packing slips for sales orders, and register serial numbers only for the items that those invoices and packing slips include. If you want to create a partial invoice and you have more than one packing slip for the sales order, you can include serial numbers from more than one packing slip. However, there can be only one packing slip that doesn't include all serial numbers. For example, if you have three packing slips, and each packing slip includes two serialized items, you can't create a partial invoice for one item from each packing slip.

What do I do when a serial number isn't readable?

If a serial number can't be read or scanned, you can create a blank line for the item by selecting **Not readable** on the **Serial numbers** page. If the serial number becomes available later, you can update the invoice or packing slip. For more information, see the next section, "Can I correct or change the serial numbers that I registered for a sales order?"

Can I correct or change the serial numbers that I registered for a sales order?

Yes, you can correct serial numbers if the following conditions are met:

- **Invoices** – You can change the serial numbers for items that you didn't yet invoice. The packing slip is then also updated. However, if you corrected a sales order line by registering a negative quantity, you can't change serial numbers for the sales order line.
- **Packing slips** – You can't partially correct a packing slip line that contains serialized items. You must reverse the full quantity for the line. If you canceled or corrected a packing slip, you don't have to register the reversed serial numbers again when you create a new packing slip for the same serialized items. The numbers that you registered are used.

Can I view the serial numbers that shipped together with a specific packing slip, or that were included on an invoice?

Yes, you can run an inquiry on the packing slip journal line or invoice journal line to view a list of all serial numbers that the document includes.

Can I view the serialized items that I have on hand?

No, you can't view the serialized items that you have on hand, because serial numbers aren't registered for items until the items are sold.

Can I register serial numbers for catchweight items?

No, you can't register serial numbers for catch-weight items during the sales process. Additionally, if a product is set up as a catch-weight item, you can't assign the product to a tracking dimension group that is set up to use serial numbers only during the sales process.

Can I register serial numbers at the retail POS?

Yes, the retail point of sale (POS) prompts the user to enter a serial number when the user sells an item that is assigned a tracking dimension group that is set up to use serial numbers only during the sales process.

What security roles are required to register serial numbers during the sales process?

All roles that can maintain sales packing slips and sales invoices can use this functionality. The following duties let workers correct serial numbers and register blank entries for serial numbers that can't be read or scanned:

- Maintain serial number corrections
- Maintain registration of non-readable serial numbers

Outbound process overview

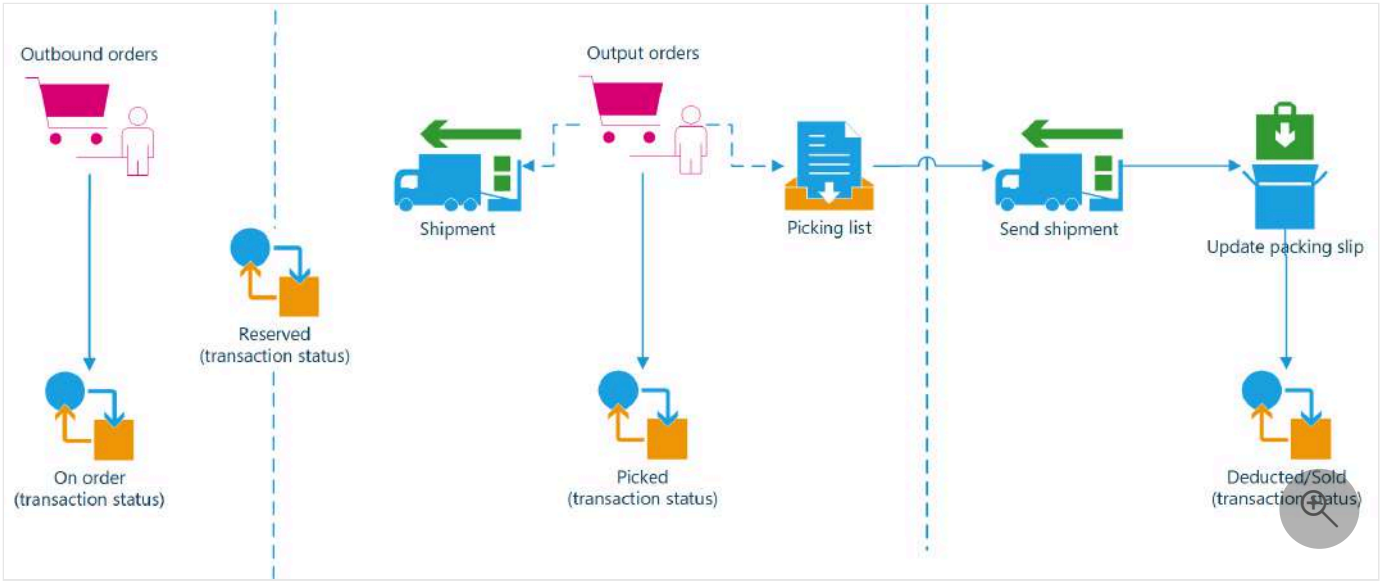
This article provides an overview of the outbound process in Inventory management.

Output orders

Use output orders to link sales order lines and transfer order lines with the outbound picking processes that use picking lists.

When picking lists are generated from either sales orders or transfer orders, output orders and shipments are automatically created. A picking list has a one-to-one relationship with a shipment. The transfer order shipment or the sales order packing slip can be processed from the shipment.

The following diagram shows an overview of the process for outbound orders.



Set up outbound rules to define how the program should handle the outbound process. Use these rules to control the shipment process. In particular, use the rules to control which stage in the process a shipment can be sent during. The following settings define how the outbound processes are handled.

Picking route status for sales and transfer orders

Go to **Account receivable** > **Setup** > **Account receivable parameters**, and then, on the **Updates** tab, select a value in the **Picking route status** field.

If the **Picking route status** field is set to **Completed**, the picking process occurs automatically as part of the process of generating picking lists. If the field is set to *Activated*, the picking list lines

must be manually updated.

The same setup applies to transfer orders. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**, and then, on the **Transport** tab, select a value in the **Picking route status** field.

End output inventory orders

Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**. On the **General** tab, set the **End output inventory order** option.

When the warehouse worker reduces the picking list quantities, the corresponding inventory order quantities are removed from the shipment. When the picking list is updated at a point in time, the remaining quantities are reported back to the order if the **End output inventory order** option is set to *Yes*. If the **End output inventory order** option is set to *No*, the remaining quantities stay as an open output order quantity. They must be added to a new picking list as part of the **Open output orders** functionality.

Reduce quantity

Use the **Reduce quantity** parameter as part of the process of generating picking lists. The setting of this parameter works together with the **Reservation** setting that triggers a reservation process as part of the release to the warehouse.

Example of an outbound process for a sales order

For this example, there's a sales order for two items. During picking list generation, you select the **Reduce quantity** parameter. Therefore, you release and create picking lines only for available on-hand inventory. You must report the picking via a registration process for picking lists (**Picking route status** = *Activated*).

The inventory, which isn't already reserved, is reserved during picking list generation. The unavailable inventory can be either removed from the sales order or released to the warehouse for outbound processing later, when inventory is available for picking.

As soon as you pick all the picking lines on the **Picking list registration** page, the associated shipment is completed. The process for sales order packing slips can then be initialized based on the picked inventory.

Reserve inventory quantities

08/29/2025

This article describes the different options that are available for reserving inventory.

You can automatically reserve inventory quantities for a specific sales order. This reservation means that you can't withdraw reserved inventory from the warehouse for other orders unless you cancel the inventory reservation or part of the inventory reservation.

There are several reasons for reserving inventory:

- First ordered, first delivered, which means that customers get available items in the same order in which they place their orders.
- Shortage of items due to a long or unknown delivery time from the vendor. You might want to make sure that certain customers or orders get delivery of the first-available items.
- Certain customers and certain types of orders have first priority for delivery.
- Items with serial or batch numbers. You can mark certain items that are or will be delivered to specific orders.
- Specially ordered items that are reserved for certain orders.
- Production orders. For example, you can mark items that are produced for and adjusted to specific orders.

Inventory can be reserved automatically when you create a new order line, or you can reserve inventory manually on the individual orders. You can also reserve inventory at different stages in a production process. Only stocked products can be reserved. You can't reserve services because there's no on-hand inventory. You can reserve both physical on-hand inventory and ordered but not yet received inventory. If you reserve a larger quantity than what the on-hand inventory contains, a message displays that you can't reserve such a large quantity. You can then either reserve the quantity anyway or change the ordered quantity. The quantity can be either reserved or changed. If you reserve more items than are available, the shortage is covered the next time that items are available for delivery.

Inventory reservation policies

Set inventory reservation policies on the **Item model groups** page, the **Inventory and warehouse management parameters** page, or the **Production parameters** page.

Policies on the Item model groups page

The **Inventory policies** section contains the following reservation policies.

Expand table

Reservation policy	Description
FIFO date-controlled	If you select the **FIFO date-controlled** option, the inventory reservation is controlled by a sorting date according to the FIFO principle. Batches are reserved based on the earliest date of receipt of items, according to the principle of first in, first out (FIFO).
Backward from ship date	This option becomes available if you select the **FIFO date-controlled** option. If you select **Backward from ship date**, and if you're reserving available physical inventory, then the inventory reservation is controlled by the last update physical date according to the FIFO rule. If you're reserving available ordered inventory, the inventory is reserved backward from the desired ship date according to the principle of last in, first out (LIFO). If no receipts are available before the ship date, the reservation follows the LIFO rule using the transaction ship date.
Item sales reservation	Determines whether item reservation is manual or automatic. If a reservation is automatic, inventory is reserved when order lines are created. You can make reservations at the item number level for BOMs (**Automatic** option), or for the individual elements of a BOM (**Explosion** option). The default value for **Item sales reservation** might be inherited from **Accounts receivable parameters.** On that page, set the value in the Reservation field in the **Sales default values section** on the **General** tab.
Same batch selection	Same batch reservation lets you reserve inventory for a sales order line against a single batch of inventory. To use this option, you must also set the **Consolidate requirement** option to **Yes**. Additional settings are required for the tracking dimension group and storage dimension group. Learn more in Reserve the same batch for a sales order.
Consolidate requirement	This option is similar to the **Same batch selection** option, and it consolidates inventory that's reserved for sales order lines into a single requirement.
FEFO date-controlled	This option allows you to reserve batches that are close to their expiration date or best before date. You also need to set the **Pick criteria** field to select either **Expiration date** or **Best before date**.

Example for FIFO date-controlled and Backward from ship date

In this example, on-hand inventory for item number A exists for three different batch numbers.

Expand table

Item number	Batch number	Quantity	Date
A	1000	5	February 2, 2016
A	1001	3	January 1, 2016
A	1002	7	March 3, 2016

A sales order that should be automatically reserved and delivered on April 4, 2016, reserves the following batch:

- If both the **FIFO date-controlled** and **Backward from ship date** check boxes are cleared, batch 1000 is reserved because it's the batch with the lowest number.
- If the **FIFO date-controlled** check box is selected and the **Backward from ship date** check box is cleared, batch 1001 is reserved because it's the batch with the first date of receipt (FIFO).
- If both the **FIFO date-controlled** and **Backward from ship date** check boxes are selected, batch 1002 is reserved because it's the batch receipt closest to the sales order ship date.

Policies on the Inventory and warehouse management parameters page

The **Inventory and warehouse management parameters** page has two options related to reservations:

- The **Reserve ordered items** option on the **General** tab lets you reserve item receipts that you ordered against item issues in Accounts receivable, Project management and accounting, and Production control. If you clear this option, you can only reserve items that you physically received. If you set up a particular item to accept negative inventory, this field isn't relevant.
- The **Reserve items automatically** option on the **Transfer** tab determines the default setting for automatically reserving items for transfer orders. You can override the default setting on individual transfer orders.

Inventory reservation policies on the Production parameters page

The value of the **Reservation** field on the **General** tab on the **Production parameters** page determines the default point in the production process at which inventory should be reserved. For example, you can reserve inventory when work is scheduled or when work is started.

Reserve the same batch for a sales order

Article • 09/29/2021

This article explains how to set up a product to allow reservation of inventory against a single batch of inventory.

Same batch reservation lets you reserve inventory for a sales order line against a single batch of inventory. For example, a customer who orders wallpaper can request that the whole order be filled from the same batch or lot, to avoid inconsistencies among the rolls. To set up a product to use same batch reservation, the following settings must be active in the item model group, tracking dimension group, and storage dimension group that you assign to the product:

- **Item model groups** – The item model group must have the **Same batch selection** and **Consolidate requirement** fields selected in the **Reservation** field group for inventory policies.
- **Tracking dimensions groups** – The tracking dimension group must have the **Coverage plan by dimension** field selected for the batch number.
- **Storage dimensions groups** – The storage dimension group must have the **Coverage plan by dimension** field selected for **Site** and **Warehouse**.

When you reserve inventory for a product on a sales order line that is set up for same batch selection, the system tries to reserve the ordered quantity from a single inventory batch. Any specific batch attribute requirements are also considered. If the quantity can't be filled from a single batch, the **Same batch reservation conflict** page appears. This page describes the issues and also the actions that you can take to continue with the reservation. The following conditions might prevent the batch from being reserved:

- The batch disposition code has **Block reservation** for sales flagged as **Blocked**.
- The batch has expired, based on the expiration date and any applicable customer sellable days. The item can still be considered for reservation if the item model group for the item is First Expiry First Out (FEFO) date–controlled, and if the best-before date is selected as the pick criterion.
- The batch doesn't have enough shelf-life days remaining, based on the expiration date and best-before date, plus any customer sellable days.

For items associated with a storage dimension group that has **Use warehouse management processes** enabled, you can reserve specific batch numbers by using a reservation hierarchy where the batch number inventory dimension is defined above the location dimension. This type of reservation hierarchy is also known as a *Batch-above [location]* reservation hierarchy. The **Batch reservation** page for sales and transfer order

lines also lets you select and reserve multiple lines based on the available batch numbers. For more information about what to do if you are using a reservation hierarchy that has the batch number dimension below the location (*Batch-below [location]*), see Flexible warehouse-level dimension reservation policy.

Inventory close

As part of the process to settle issue transactions with receipt transactions, you can also choose to have the general ledger updated to reflect the adjustments that have been made.

The inventory close process settles issue transactions to receipt transactions, based on the inventory valuation method that is selected in the item's item model group. As part of the settlement process, you can specify that the general ledger should be updated, so that it reflects the adjustments that have been made. However, until inventory close or recalculation has been run, issue transactions are posted at the calculated running average cost price.

After inventory close, you can no longer post in periods that are before the inventory closing date that you set, unless you reverse a completed inventory close process. For example, if inventory close is run for the period that ends on January 31, you can't post transactions that have a date that is earlier than January 31.

Items in inventory are assigned to one of two inventory types: item or service. Inventory close performs the same functions for both types. However, for service items, inventory close still settles issues to receipts.

How often the inventory close process is run varies by company. However, transaction volume should help determine how often you decide to run inventory close. In general, most companies run inventory close as part of their month-end close and reconciliation procedures.

Inventory recalculation and the general ledger

If adjustments to inventory and the general ledger are required during a month or other inventory period, you can run inventory recalculation instead of inventory close. Inventory recalculation makes adjustments but doesn't make settlements to inventory transactions.

During inventory recalculation, on-hand inventory is adjusted, inventory transactions are adjusted, and inventory recalculations and inventory closes are run. These tasks affect any ledger account that is linked to the original inventory transaction.

Example

When you create a purchase order from a sales order, the general ledger accounts that are used for the original sales order are updated. Even if the ledger accounts for the item group that is

assigned to the item were changed after the sales order was posted, and an inventory recalculation created an adjustment amount, the adjustment amount is posted to the original ledger accounts. The adjusted amount isn't posted to the new ledger accounts that are assigned to the item.

After the update is completed, you can review the ledger voucher that is posted because of one of these tasks.

1. On the **Closing and adjustment** page, on the **Overview** tab, select the update to review.
2. Select **Details**, and then select **Voucher**.

Effects of the inventory close process on the general ledger

Several of the tasks that you can perform on the **Closing and adjustment** page cause an update to general ledger. For example, the general ledger is updated when you make inventory on-hand adjustments, make inventory transaction adjustments, run inventory recalculation, and run inventory close.

The ledger accounts that are updated because of these tasks are linked to the original inventory transaction. For example, if a sales order is settled to a purchase order, the general ledger accounts that were used for the original sales order are adjusted. This behavior occurs even if the ledger accounts for the item group that is assigned to the item have changed since the sales order was posted. After inventory close creates a settlement amount, the settlement amount is still posted to the original ledger accounts, not to the new ledger accounts that are assigned to the item. The general ledger might also be updated if you reverse an inventory close.

> ⓘ **Note**
>
> - Inventory close is a required step in the month-end closing procedure for all inventory models except moving average. You'll be warned if you try to close a financial period without first performing the inventory close as of the period end date.
> - Before you run the closing procedure, you can view a list of items that can't be settled during the update.
> - We recommend that you run inventory close during off-peak hours, to distribute computing resources more evenly.

The inventory close log

After the inventory close process has been completed, a message in the message center might inform you that a unit cost price might be incorrect because a transaction couldn't be fully settled.

Before this message is shown, the system reports the item number and the affected transaction. The message informs you that the cost amount that is used for this transaction wasn't updated because of the inventory close. This message appears when a transaction of the issue type can't be settled.

During the inventory close process, the system checks each financial dimension to see whether there are more issues than receipts up to the specified closing date. This type of imbalance can occur when an inventory transaction from a purchase order isn't fully posted financially, either because the vendor invoice hasn't been received, or because bill of materials (BOM) components that are included in a production on a higher level aren't financially posted. (The subproduction isn't cost-calculated.) In this case, the subsequent close won't adjust all issues to the correct cost price, because not enough receipt information is available.

For each run of the closing procedure, the system indicates whether a log that contains the warnings is stored and can be viewed.

If you receive many warnings in the message, we recommend that you perform the following actions:

- Update receipts financially.
- Advance the closing date.
- Reevaluate the business procedures.

In some circumstances, you might not be able to do anything about the warnings. For example, if marking is used, and the marked purchase order has a financial date that is after the closing date, the closing date can't be changed.

Reversing a completed inventory close

Occasionally, you might have to reverse a completed inventory close to return settlements to the state that they had before adjustments were made. When you reverse a completed inventory close, inventory is reopened to enable posting in the period that the inventory close covers. Related changes might also be made in the general ledger. After you've finished making adjustments, you can run inventory close again for the period that you're working with.

> ⓘ **Note**

Only the last inventory period that was closed can be reopened. To reverse an earlier inventory close, you must reverse each subsequent inventory close one at a time, starting with the most recent close.

Last updated on 11/26/2025

Running average cost price

The inventory close process settles issue transactions to receipt transactions, based on the inventory valuation method that is selected in the item's item model group. However, before inventory close is run, the system calculates a running average cost price that is typically used when issue transactions are posted.

The system estimates this running average cost price for an item by using the following formula:

Estimated price = (Physical amount + Financial amount) ÷ (Physical quantity + Financial quantity)

Default item cost

The default item cost for a released product can be configured in one of two ways on the **Released product details** page:

- Create a standard cost by selecting **Item price** in the **Set up** group on the **Manage costs** tab of the Action Pane. If you use this method, you must use a standard cost costing version, and the cost must be activated.
- Define a default item cost price for a released product by entering a value in the **Price** field on the **Manage costs** FastTab.

In addition to entering or creating a price, you can select the **Use latest cost price** checkbox on the **Manage costs** FastTab of the **Released product details** page. In this case, the system automatically updates the **Price** field when you post a financial update. For example, if you post a purchase order invoice, the field is set to the purchase price from that invoice.

If you have a cost price in an active costing version, and you enter a price on the **Manage costs** FastTab, the system uses the price from the active costing version before it uses the price that is defined on the **Manage costs** FastTab.

Using the running average cost price

The following table shows when the system posts inventory transactions by using the running average cost price, and when it uses the cost price that is defined on the item master record instead.

Expand table

Condition	The system uses the estimated running average cost price	The system uses the default item cost price
Both the numerator* and denominator** are positive.	Yes	No
The numerator*, denominator**, or both are negative.	No	Yes
The denominator** is 0 (zero).	No	Yes

* Numerator = (Physical amount + Financial amount)

** Denominator = (Physical quantity + Financial quantity)

> **Note**
>
> If the **Include physical value** option isn't selected for an item, the system uses 0 (zero) for both the physical amount and the physical quantity. For information about this option, see Options for including physical value in cost calculations.

Avoiding pricing amplification

On rare occasions, the system prices several issues before it has enough receipts to base the price on. This scenario can cause estimates of the running average cost price to be overly inflated. However, there are steps that you can take to avoid pricing amplification, or to reduce its impact when it does occur.

Scenario: The following transactions occur for an item where the **Include physical value** option is selected:

1. You financially receive a quantity of 100 at USD 100.00.
2. You financially issue a quantity of 200.
3. You physically receive a quantity of 101 at USD 202.00.

When you examine the estimated running average cost price for the item, you expect a cost price of USD 1.51. Instead, you find an estimated running average of USD 102.00, which is based on the following formula:

Estimated price = [202 + (-100)] ÷ [101 + (-100)] = 102 ÷ 1 = 102

This pricing amplification occurs because, when 200 items are financially issued in step 2, the system must price 100 of the items before it has any corresponding receipts. This situation causes

negative inventory. The system then estimates a unit price of USD 1.00, as you might expect. However, when the corresponding 100 receipts arrive, they are at a unit price of USD 2.00 each.

> **Note**
>
> Although the issues create negative inventory, inventory is positive when the issue price is calculated. Therefore, the running average cost price is used instead of the price on the item master. At this point, the system has an inventory value offset of USD 100.00. Although that offset was built up over 100 pieces, where there was a unit offset of USD 1.00 each, you now have only one piece in inventory. Therefore, the offset of USD 100.00 is allocated to this one piece. The result is the overly inflated estimated cost price.
>
> For comparison, notice that if steps 2 and 3 are reversed in the scenario, 200 items will be issued at a unit price of USD 1.51, and one piece will remain at a unit price of USD 1.51. Because this pricing amplification scenario can occur when negative inventory is involved, it's difficult to avoid in the following cases:
>
> - You must estimate issue prices on the on-hand value and quantity.
> - You must adjust the on-hand value and quantity on issues and receipts.
> - Your business model allows you to send out, or price, more pieces than you have.
> - You must accept any receipt value and quantity that are submitted to you.

However, if your business model allows for the following practices, they can help you avoid the negative quantities that make the pricing amplification scenario possible:

- If you select the **Include physical value** option for an item, clear the **Physical negative inventory** checkbox on the **Item model groups** page.
- If you do **not** select the **Include physical value** option for an item, clear the **Financial negative inventory** option on the **Item model groups** page.

Additionally, consider that the maximum offset in your physical inventory value is limited by the number of physical transactions, and the difference between physical and financial prices. If all physical transactions are eventually updated financially, the physical value can't rise to extreme levels. The amplification effect decreases significantly when the accumulated offset is spread out over several on-hand pieces instead of just one.

Avoid a zero cost price on issues

When the **Include physical value** option isn't selected on the **Item model group** page, an issue from inventory can have a zero cost price if there are no financially updated receipts in inventory. To help avoid this scenario, consider the following options:

- Select the **Include physical value** option on the **Item model group** page. This option prevents a zero cost price on an issue, provided that the receipt is physically updated. If you don't allow negative physical inventory, issues calculate the running average from the physically updated transactions.
- Create a default item cost price by activating a costing version that has a standard cost, or enter the price on the **Manage costs** FastTab of the **Released product details** page. This option is best when the **Include physical value** option isn't selected on the **Item model group** page, because the system will always have a fallback price to use.
- Select the **Use latest cost price** option on the **Manage costs** FastTab of the **Released product details** page. This option keeps the **Price** field up to date each time that you financially update a receipt. If you select this option, but you don't enter a default price or activate a cost in a standard costing version, you can still have a zero cost on an issue.

If you have issue transactions that have zero cost, the *Inventory close and adjustment* process will correct the cost price by creating an adjustment after the receipts are financially updated. Keep in mind that the financial period when this update occurs might differ from the financial period when the items were physically received or issued.

Last updated on 11/26/2025

Adjust on-hand inventory cost values

Use the **Adjustment of on-hand inventory** page to adjust the cost value of the on-hand inventory quantities after running an inventory close process. To open the **Adjustment of on-hand inventory** page, start on the **Closing and adjustment** page, select the record of a completed inventory close process, and then select **Adjustment** > **On-hand**.

For example, suppose you have the following transactions in February:

- February 1: An inventory financial receipt for a quantity of 2 at a cost of USD 10.00
- February 5: An inventory financial receipt for a quantity of 1 at a cost of USD 13.00
- February 19: An inventory financial issue for a quantity of 1 at a running average cost of USD 11.00

This item was set up with the first in, first out (FIFO) inventory model, and inventory close was performed as of February 28. The financial issue transaction of USD 11.00 is settled against the financial receipt that is dated February 1, and an adjustment of USD 1.00 is made. The following inventory receipts then contain open inventory quantities:

- February 1: A quantity of 1 at a cost of USD 10.00
- February 5: A quantity of 1 at a cost of USD 13.00

To set the cost of these two items to USD 15.00, use the on-hand adjustment option to adjust the open on-hand quantities as of the last inventory close period.

> **Note**
>
> The posting date of the on-hand adjustment transaction is the date of the last inventory close. You can't modify this date.

Last updated on 07/01/2026

Track running average cost per inventory dimension

An inventory dimension group is attached to every inventory item. Therefore, the running average cost price of an item is calculated based on the selected inventory dimensions that are being tracked financially.

There are three types of inventory dimensions: product, storage, and tracking. Product dimensions include configuration, size, and color. Product dimensions are always tracked financially. Storage and tracking dimensions include site, warehouse, location, inventory status, license plate, batch number, and serial number. You can decide which storage and tracking dimensions are tracked financially.

Example 1

If the storage dimension group that is attached to the item is financially tracked by warehouse, the running average cost price is calculated per warehouse. The following purchase orders have been invoiced:

- A purchase order for a quantity of 2 at a cost price of USD 10.00 has been invoiced for warehouse GW.
- A purchase order for a quantity of 3 at a cost price of USD 12.00 has been invoiced for warehouse GW.
- A purchase order for a quantity of 5 at a cost price of USD 15.00 has been invoiced for warehouse MW.

The running average cost price for warehouse GW is USD 11.20, and the running average cost price for warehouse MW is USD 15.00. A sales order invoice is posted for warehouse GW. The value of the inventory and the cost of goods sold (before inventory close is run and without marking) is USD 11.20. Another sales order is posted for warehouse MW. The value of the inventory and the cost of goods sold (before inventory close is run and without marking) is USD 15.00.

Example 2

If the storage dimension group that is attached to the item is financially tracked by warehouse, and the tracking dimension group is financially tracked by batch number, the running average

cost price is calculated for each batch. The following purchase orders have been invoiced:

- A purchase order for a quantity of 2 at a cost price of USD 10.00 has been invoiced for warehouse GW and batch AAA.
- A purchase order for a quantity of 3 at a cost price of USD 12.00 has been invoiced for warehouse GW and batch AAA.
- A purchase order for a quantity of 2 at a cost price of USD 15.00 has been invoiced for warehouse GW and batch BBB.

The running average cost price for warehouse GW and batch AAA is USD 11.20, and the running average cost price for warehouse GW and batch BBB is USD 15.00.

> **Note**
>
> We recommend that you always view the cost price for all financial dimensions that are being tracked.

Last updated on 11/26/2025

Configure and manage financial dimension links to sites

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

To enable the system to calculate profit and loss figures for each site for your legal entity, link a financial dimension to the site inventory dimension and assign a financial dimension value to each site.

Set up a financial dimension link to a site

When you set up a financial dimension link to a site, you:

- Associate a financial dimension with the site inventory dimension.
- Associate a financial dimension value with each site.

To set up a financial dimension link to a site, follow these steps:

1. Go to **Inventory management** > **Setup** > **Posting** > **Dimension link**.
2. On the Action Pane, select **Edit**.
3. In the **Select the dimension to be linked to the storage dimension, Site** field, select the financial dimension to link to the site inventory dimension.
4. On the Action Pane, select **Sites** to open the **Sites** page.
5. On the list pane, select the site you want to link the financial dimension to.
6. Expand the **Financial dimensions** FastTab. The financial dimension that you selected in the previous page appears under the **Default financial dimensions** heading.
7. From the drop-down list under the **Default financial dimensions** heading, select the financial dimension value that you want to associate with the selected site.
8. Repeat steps 5 to 7 for each site.
9. When you're done, select **Save**.

Activate a financial dimension link

Activating a financial dimension link has the following effects:

- When you create new transactions that use both inventory dimensions and financial dimensions, the system uses the dimension value that you specify for the site as the dimension value for the linked financial dimension.
- You can post transactions that use both inventory dimensions and financial dimensions, even if the dimension value for the linked financial dimension doesn't match the value that you specified for the site.
- You can change the dimension value for the linked financial dimension on open transactions that use both inventory dimensions and financial dimensions.

> ⓘ **Note**
>
> You must assign a financial dimension value to each site before you can complete this procedure.

To activate a financial dimension link, follow these steps:

1. Go to **Inventory management** > **Setup** > **Posting** > **Dimension link**.
2. On the Action Pane, select **Activate link**.
3. The **Linked dimension update** dialog opens. Select **OK** to activate the link.
4. The **Current status** field updates to show that the *Dimension link is active* and the **Select the dimension to be linked to the storage dimension, Site** field becomes inactive.

Lock a financial dimension link

When you lock a financial dimension link, the following effects take place:

- New inventory transactions that use both inventory dimensions and financial dimensions get a financial dimension value based on the value specified for the site.
- You can post transactions that use both inventory dimensions and financial dimensions only when the dimension value of the linked financial dimension matches the value specified for the site.
- You can't change the dimension value of the linked financial dimension on transactions that use both inventory dimensions and financial dimensions.
- You can't modify the financial dimension value that's associated with a site.

You must set up a financial dimension link before you can lock it.

To lock a financial dimension link, follow these steps:

1. Go to **Inventory management** > **Setup** > **Posting** > **Dimension link**.
2. On the Action Pane, select **Lock link**.

3. The **Linked dimension update** dialog opens. Select **OK** to lock the link. The system updates all open transactions accordingly.
4. The **Current status** field updates to show that the *Dimension link is locked*.

Unlock a financial dimension link

You can unlock locked financial dimension links. When you unlock a link, you can complete these tasks:

- Post transactions that use both inventory dimensions and financial dimensions, even if the dimension value of the linked financial dimension doesn't match the value that is specified for the site.
- Modify the dimension value of the linked financial dimension on open transactions that use both financial dimensions and inventory dimensions.
- Modify the financial dimension values on the **Sites** page.

1. Go to **Inventory management** > **Setup** > **Posting** > **Dimension link**.
2. On the Action Pane, select **Unlock link**.
3. The **Current status** field updates to show that the *Dimension link is active*.

Deactivate a financial dimension link

When you deactivate a financial dimension link, the following changes occur:

- The link between the site inventory dimension and the financial dimension is removed.
- The linked financial dimension isn't assigned the dimension value specified for each site.
- You can choose a different financial dimension to link to the site inventory dimension.

To deactivate a financial dimension link, follow these steps:

1. Go to **Inventory management** > **Setup** > **Posting** > **Dimension link**.
2. On the Action Pane, select **Deactivate link**.
3. The **Current status** field updates to show that the *Dimension link is inactive*.

Run an on-hand consistency check

The on-hand consistency check is a corruption-recovery tool that rebuilds the on-hand inventory tables (`InventSum` and, for warehouse management items, `WHSInventReserve`) from the inventory transactions table (`InventTrans`). Use it when you have confirmed on-hand data corruption—not as a periodic maintenance task.

This article explains when to run the check, how to run it safely, the performance characteristics you should plan for, and how the **Skip on-hand aggregation and clean up in on-hand consistency check** parameter interacts with the standard on-hand database cleanup jobs.

> **ⓘ Important**
>
> If Inventory Visibility is enabled on your system, complete the additional preparation steps described in Run on-hand consistency checks while Inventory Visibility is enabled before you run the on-hand consistency check as described in this article.

When to run an on-hand consistency check

Run an on-hand consistency check when you observe symptoms such as the following for one or more items:

- The **On-hand list** shows a quantity that doesn't match the sum of the related inventory transactions for the same dimensions.
- Inventory close or recalculation fails with an error referencing negative on-hand for an item whose item model group doesn't allow negative inventory (for example, *Inventory closing can't proceed because available physical on-hand inventory on item <Item> is currently negative*).
- Negative on-hand quantities exist that can't be explained by posted transactions.
- Physical inventory or available quantity doesn't match the sum of posted inventory transactions.

These symptoms typically indicate that the `InventSum` or `WHSInventReserve` tables are out of sync with `InventTrans`. The most common cause is a data inconsistency introduced by a script, external process, or user action that updated `InventTrans` directly without recalculating the summary tables. Running the consistency check in *Fix error* mode rebuilds the summary tables from the transactions, which resolves the discrepancy.

If none of these conditions apply, don't run the check. The dedicated on-hand entries cleanup jobs are the correct tool for routine maintenance.

When not to run the check

Here are some rules that illustrate when not to run the on-hand consistency check:

- Don't schedule the on-hand consistency check as a recurring batch job. It isn't a maintenance routine.
- Don't run the check across all items during business hours. The check replays the entire `InventTrans` history per item and takes locks on `InventSum` and `WHSInventReserve`.
- Don't run the check with **Check/Fix** set to *Fix error* as your first action. Always run it in *Check* mode first and review the log.
- Don't run the check as a precaution before or after upgrades, cleanup jobs, or routine close. None of those operations corrupt on-hand data.

How to run the check safely

To run the on-hand consistency check, follow these steps:

1. Go to **System administration** > **Periodic tasks** > **Database** > **Consistency check**.
2. Set **Module** to *Inventory management*.
3. Expand the **Item** tree, and select the **On-hand** check box. If you suspect transaction-level corruption, select the **Inventory transactions** checkbox too.
4. Click on the text in the **Item** row (not the check box) so that the entire row has a blue background.
5. Open the **More** menu (**...**) and select **Dialog**.
6. Use the dialog box to filter the run to the specific item or item range that's affected. Running on *all items* is rarely the right choice.

   > **Tip**
   >
   > Scope the check to a single item, or to as few items as possible, whenever you can. Running an on-hand consistency check for all items processes the entire `InventTrans`

table and can take a long time on large datasets. Limiting the scope through the **Dialog** filter makes the check finish much faster and reduces the risk of timeouts.

7. Select **OK** to close the filter dialog.
8. In the **Consistency check** dialog, set **Check/Fix** to *Check* and then select **OK** to run the check. Review the log when it completes.
9. Select **Show messages** (bell icon at the top-right of the page) to open the **Action center** and review the messages for any errors or warnings.
10. If errors are confirmed, repeat this procedure with **Check/Fix** set to *Fix error*, ideally as a batch job outside business hours.

If the *Fix error* run doesn't resolve the discrepancy, contact Microsoft Support or your partner.

Performance considerations

The run time of the on-hand consistency check scales with the volume of `InventTrans` history for the items in scope, not with the current on-hand quantity. An item with a long posting history takes longer to rebuild than an item with few transactions, even if both currently have similar on-hand values.

To keep the run predictable:

- **Filter by item** – Use the dialog filter to scope the run to the affected items. Running on *all items* should be reserved for documented disaster recovery scenarios.
- **Run in batch and outside business hours** – The fix run takes exclusive locks on `InventSum` and `WHSInventReserve` rows for each item it touches. Concurrent posting against the same item can deadlock or be blocked.
- **Be aware of the cleanup side effect** – With the default parameter setting, the fix run also runs the equivalent of an on-hand cleanup job for each item in scope, which adds time to the run. Set the **Skip on-hand aggregation and clean up in on-hand consistency check** parameter to *Yes* if you want the fix run to focus only on rebuilding the on-hand tables. Learn more about this option in Choose whether to apply on-hand aggregation and clean up.

Choose whether to apply on-hand aggregation and clean up

You can choose to either run or skip on-hand cleanup when the on-hand consistency check runs in *Fix error* mode.

For very large datasets, you can shorten the run time of the consistency check by skipping the aggregation and clean-up steps that the check performs alongside the core recalculation. The recalculation that recreates `InventSum` records still runs; only the non-essential clean up is skipped.

To set this option, follow these steps:

1. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**.
2. Open the **General** tab.
3. In the **On-hand consistency check clean up** field group, set **Skip on-hand aggregation and clean up in on-hand consistency check** to one of the following values:

    - *Yes* – The consistency check skips the on-hand cleanup side effect and focuses solely on rebuilding the on-hand tables. This choice results in a faster run, but zero-quantity rows aren't cleaned up.
    - *No* – The consistency check includes the on-hand cleanup side effect. It also aggregates and deletes zero-quantity rows for the items in scope. This choice results in a longer run time, but it tidies up the on-hand tables. This value is the default setting.

What the check does in fix mode

When you run the on-hand consistency check with **Check/Fix** set to *Fix error*, the system performs the following steps for each item in scope:

1. **Always** – The system rebuilds `InventSum` (and `WHSInventReserve` for warehouse management items) from `InventTrans`. This is the corruption fix itself.
2. **Only when the parameter is *No* (default)** – The system also performs the following on-hand cleanup work for that item:

    - **On-hand entries aggregation by financial dimensions** – Aggregates zero-quantity `InventSum` rows up to the financial inventory dimension level. This operation uses the same logic as the standalone *On-hand entries aggregation by financial dimensions* cleanup job, scoped to the item.
    - **On-hand cleanup** – For warehouse management items, runs the same logic as the *Warehouse management on-hand entries cleanup* job to delete zero-quantity rows in

`InventSum` and `WHSInventReserve` for the item. For non-warehouse-management items, the system runs the same logic as the *On-hand entries cleanup* job for the item's tracking-dimension rows.

If the aggregation or cleanup step fails for a specific item, the system logs a warning (*On-hand clean up is failed for item <Item> in consistency check*) and continues with the next item. The recalculation work for that item is still completed—only the cleanup operation is skipped.

When to skip on-hand aggregation and clean up

Set **Skip on-hand aggregation and clean up in on-hand consistency check** to *Yes* in any of the following situations:

- You already scheduled the on-hand cleanup jobs and want the consistency check to focus only on rebuilding the on-hand tables.
- You want the fix run to finish faster, because the per-item cleanup work is skipped.
- You need to preserve zero-quantity rows that downstream historical reporting depends on, such as *Physical inventory by inventory dimension* with **As of date** set, or *On-hand list* with **Closed transactions** selected.
- You're running the fix on a tight maintenance window and can't accept the additional runtime of the inline cleanup.

When not to skip on-hand aggregation and clean up

Set **Skip on-hand aggregation and clean up in on-hand consistency check** to *No* in either of the following situations:

- The on-hand cleanup jobs aren't yet scheduled in the environment and you want the fix run to also tidy up zero-quantity rows for the affected items.
- The scope of the fix run is small (a few items) and the additional cleanup time isn't a concern.

Relationship to the standalone cleanup jobs

The standalone on-hand cleanup jobs are the correct tool for ongoing database maintenance. The consistency check, even with the cleanup side effect enabled, isn't a substitute for them.

Expand table

Job	Path	Purpose
On-hand entries cleanup	**Inventory management** > **Periodic tasks** > **Clean up** > **On-hand entries cleanup**	Deletes closed and unused on-hand entries for items with tracking dimensions.
Warehouse management on-hand entries cleanup	**Inventory management** > **Periodic tasks** > **Clean up** > **Warehouse management on-hand entries cleanup**	Deletes zero-quantity rows in `InventSum` and `WHSInventReserve` for warehouse management items.
On-hand entries aggregation by financial dimensions	**Inventory management** > **Periodic tasks** > **Clean up** > **On-hand entries aggregation by financial dimensions**	Aggregates zero-quantity `InventSum` rows up to the financial inventory dimension level.

Learn more in Cleanup routines in Dynamics 365 Finance and Dynamics 365 Supply Chain Management and Warehouse management on-hand entries cleanup job.

Reports that can be affected by cleanup

The cleanup process removes zero-quantity rows from the on-hand tables. This removal happens both when you run the standalone cleanup jobs and when you run the on-hand consistency check in *Fix error* mode with the **Skip on-hand aggregation and clean up in on-hand consistency check** parameter set to *No*. These rows don't contribute to current on-hand values, but several historical and "as of date" reports read them directly. After cleanup, those reports might return incomplete or missing data for periods where on-hand rows are removed.

Reports that depend on zero-quantity on-hand rows include those listed in the following table.

Expand table

Report	Impact when rows are deleted
Inventory aging report	"As of date" snapshots and aging buckets might be missing rows for inventory dimensions that have since dropped to zero quantity.
Historical inventory financial calculation (Russia)	Historical inventory value calculations rely on the full on-hand row history. Deleted zero-quantity rows can cause incorrect financial snapshots for past dates.
Physical quantity summary engine (China)	Physical quantity summaries that aggregate by inventory dimension might be missing closed or zero-quantity rows after cleanup.
Physical inventory by inventory dimension	When the **As of date** parameter is set, or when **Closed transactions** is selected, deleted rows no longer appear in

Report	Impact when rows are deleted
	the report output.
On-hand list (with the **Quantity <> 0** filter cleared or **Closed transactions** selected in **Dimensions display**)	Closed or zero-quantity dimensions no longer appear at the level (for example, license plate) where they were deleted.

How to mitigate the impact on reports

To mitigate the impact of cleanup on historical and "as of date" reports, use the following approaches:

- **Don't run the consistency check in *Fix error* mode with the default parameter setting if you rely on these reports for the items in scope** – Set **Skip on-hand aggregation and clean up in on-hand consistency check** to *Yes* for that run, so the recalculation doesn't also delete zero-quantity rows.
- **Run the historical reports before you schedule the cleanup jobs in environments where the reports are business-critical** – Reports that are already generated aren't affected retroactively.
- **Weigh the trade-off per environment** – The cleanup jobs and the inline cleanup in the consistency check exist for performance reasons. The performance gains are real, and the lost dimension-level visibility is usually acceptable. However, it isn't acceptable in environments where the reports listed earlier are part of statutory or business-critical reporting.

Recommended workflow when corruption is suspected

If you suspect on-hand data corruption, use the following workflow to investigate and resolve it:

1. **Identify the affected item** – Use the original error message, the **On-hand list**, and **Inventory transactions** to confirm which item has corrupted on-hand data.
2. **Back up if you're in a position to do so** – The fix is set-based and not easily reversible.
3. **Run the check in *Check* mode for that item only** – Use the dialog filter to scope the run. Review the log.
4. **Decide on the parameter setting** – If the environment has scheduled cleanup jobs that already manage on-hand rows, set **Skip on-hand aggregation and clean up in on-hand consistency check** to *Yes* for this run. Otherwise, leave it at *No* so the fix also tidies up zero-quantity rows.
5. **Rerun in *Fix error* mode as a batch job** outside business hours.

6. **Verify** – After the fix completes, re-check the **On-hand list** and the original error condition.

Inventory On-hand mobile app

08/28/2025

> **Important**
>
> The Inventory On-hand mobile app (preview) is no longer available on the Power Platform Admin Center and is instead being provided as a sample app that you can download from the scmsamples-InventoryOnHand repository on GitHub. The sample app is identical to the previously available first-party app, but is now distributed through GitHub rather than through the Power Platform Admin Center. You can fork the GitHub repository so you can customize it as needed for your scenarios. Previously installed instances of the first-party mobile app will continue to work. Learn more in Removed or deprecated features in Dynamics 365 Supply Chain Management.

The Inventory On-hand mobile app lets you query and view product inventory in Microsoft Dynamics 365 Supply Chain Management by using a mobile device. It was built by using Power Apps.

The app lets you perform the following tasks:

- Search product inventory by entering a product ID or name.
- Filter products and inventory by site, warehouse, location, batch, and default product dimensions.
- Filter products and inventory by inventory status and inventory quantity range.
- Specify your regular sites and locations to prioritize the search range.
- Switch among legal entities to check cross-organization inventory.

This article describes how administrators can prepare your Supply Chain Management and Dataverse environments to support the Inventory On-hand mobile app. It also describes how to install the app on your mobile devices.

Prerequisites

Before you can start to onboard the Inventory On-hand mobile app, you must meet the requirements that are outlined in this section.

System requirements

To run the latest Inventory On-hand mobile app, you must be using Supply Chain Management version 10.0.40 or later.

Set up Dataverse for your Supply Chain Management environment

The mobile app uses Dataverse virtual tables that are connected to Supply Chain Management. Therefore, a Dataverse environment must be integrated with your Supply Chain Management environment. If Dataverse isn't already set up for your environment, follow the instructions in Microsoft Power Platform integration with finance and operations apps.

When you create the Dataverse environment where you want to install the Inventory On-hand mobile app, be sure to enable Dynamics 365 apps.

The Power Apps component framework feature must be enabled for your environment.

Install the mobile app in Dataverse

For complete details about how to download, customize, install, and set up the app, go to the scmsamples-InventoryOnHand repository on GitHub.

Share the mobile app and assign security roles

After the mobile app solution is installed in your Dataverse environment, you must share it with your users. The Inventory On-hand mobile app is a canvas app. To share it, follow the instructions in Share an app.

The security roles that can access and query on-hand inventory through the mobile app are inherited from your Supply Chain Management setup. Therefore, any user (such as a sales manager, warehouse manager, or production manager) that has the security roles required to access the on-hand inventory list in Supply Chain Management can also query and view that data in the Inventory On-hand mobile app. For more information about how to set up roles and security in Supply Chain Management, see Security roles.

Open the Inventory On-hand mobile app

Follow these steps to use the Inventory On-hand mobile app on a mobile device.

1. Open the Power Apps mobile app, and sign in by using the same corporate account that you use to sign in to Supply Chain Management.
2. Use the **Search** field to search for *Inventory on-hand mobile app*. Because the app is a canvas app, you can add it to your favorites list in Power Apps by swiping left on it after you find it.
3. Open the Inventory On-hand mobile app, and start to use it.

4. The first time that you open the app, you can go to the settings and select a legal entity. You can also set the default site and warehouse where you usually work. These settings are especially useful for store managers.
5. When you search for products and inventory, the app first searches in the default site and warehouse. On the result page, you can easily switch between a full search and a search in the default site and warehouse.

Clear the Power Apps cache on a mobile device after an update of the back-end setup

If the back-end setup is updated in Supply Chain Management after you install the Power Apps mobile app on a mobile device (for example, if the legal entity setup is changed), you might have to clear the cache in Power Apps to update the local setup data. Power Apps then reloads the settings that otherwise might not take effect until the cache is cleared.

Follow these steps to clear the Power Apps cache on a mobile device.

1. Sign in to the Power Apps mobile app.
2. In the upper left of the page, select the image for your user account to open the settings menu.
3. Select **Clear cache** to open the **Clear cache** dialog box.
4. Select **Confirm**.

Frequently asked questions

What platforms and mobile devices are supported?

The Inventory On-hand mobile app runs within the Power Apps mobile app. All platforms supported by the Power Apps mobile app can also run the Inventory On-hand mobile app. Learn more in System requirements, limits, and configuration values for Power Apps.

Why don't I see anything when I sign in to the app?

If you don't see any features in the app, you probably lack the permissions required to access them. Access is controlled by the security roles assigned to your user account in Supply Chain Management. The roles you need are the same as those required to access the on-hand inventory list in Supply Chain Management. Learn more in Security roles.

Can I customize and extend the app?

Yes. You can customize and extend the app by working with the source code provided on GitHub.

Does the app support offline mode?

No, the Inventory On-hand mobile app doesn't currently support offline mode.

Is there multi-language support?

Yes, the Inventory On-hand mobile app is available in all the same languages as Supply Chain Management. The language is set according to your mobile device settings.

Consolidate inventory transactions

> **Important**
>
> Some or all of the functionality noted in this article is available as part of a preview release. The content and the functionality are subject to change. For more information about preview releases, see One version service updates FAQ.

Over time, the inventory transaction table (`InventTrans`) grows and consumes more database space. This article describes how to consolidate data about inventory transactions to help improve system performance and reduce storage consumption.

> **Note**
>
> Only financially updated inventory transactions can be consolidated in a selected closed ledger period. To be consolidated, financially updated outbound inventory transactions must have an issue status of *Sold*, and inbound inventory transactions must have a receipt status of *Purchased*.

When you consolidate inventory transactions, the system moves all related transactions to the `InventTransArchive` table. It then creates summary transactions in the `InventTrans` table, grouped by `ItemId` and `InventDimId`. If the combined quantity and cost fields for a group equal zero, the system doesn't create a new summary transaction.

If an `itemId` and `inventDimId` combination contains only one receipt or issue transaction, the transaction isn't consolidated.

> **Note**
>
> After consolidating your inventory transactions, you can further optimize storage and system performance by using the *Archive with Dataverse long term retention* feature to move `InventTransArchive` records to a Microsoft Azure data lake. Learn more in Archive inventory transaction data in Dynamics 365 Supply Chain Management.

Considerations before consolidating inventory transactions

Before you consolidate inventory transactions, consider the following impacts on your business processes:

- **Transaction auditing** – When you audit inventory transactions from related documents (such as purchase order lines), you can view the consolidated transactions under **Archived transactions** until they're moved to long-term storage by using the *Archive with Dataverse Long term retention* feature. To review all consolidated transactions, go to **Inventory management** > **Periodic tasks** > **Clean up** > **Inventory transaction consolidation**.
- **Inventory closing** – You can't cancel inventory closing for periods that are consolidated.
- **Cost conversion** – You can't perform standard cost conversion for periods that are consolidated.
- **Inventory reports** – Reports that rely on detailed inventory transaction data show consolidated values instead of individual transactions. Affected reports include the inventory aging report and inventory value reports.
- **Inventory forecasts** – Forecasts that run during consolidated periods might produce different results because they use summary data rather than detailed transaction history.
- **Transaction-dependent operations** – You can't perform business processes that require the original inventory transactions, such as creating return orders and adjustments, after a period is consolidated.

Prerequisites

Version requirements

To consolidate inventory transactions, you must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.49 or later.

Feature management requirements

To consolidate inventory transactions, the feature named *(Preview) Optimized inventory transaction consolidation* must be turned on in feature management.

Configure a number sequence for the consolidation process

Before you start the first inventory transaction consolidation job, configure a number sequence for the consolidation process. Configure this number sequence under **Inventory management** >

Inventory and warehouse management parameters > **Number sequences** and assign a number sequence to the **Inventory transaction consolidation voucher** reference.

Conditions for consolidating inventory transactions

You can consolidate inventory transactions only for periods that meet all of the following conditions:

- The ledger period is on hold or permanently closed.
- The period is at least one year before the current system date.
- Inventory closing ran on or after the end date of the consolidation period.
- The period length is less than 365 days from the last consolidation or from the earliest transaction date.
- No inventory recalculations are currently running or pending.
- No license plate cleanup jobs, cost conversion jobs, or inventory recalculations are currently running.
- All inventory transactions and related data pass the validation checks described in the next section.

Validate inventory transactions

The system performs the following validations during the consolidation process to ensure data integrity and prevent inconsistencies:

- **Open issue transactions** – Settle all issue transactions through inventory closing before consolidation.
- **Physically updated transactions that aren't financially posted** – Financially post all transactions before consolidation to prevent downstream process issues.
- **Inconsistent inventory settlements** – Inventory settlements must sum to zero in the selected period.

> ⓘ **Note**
>
> The validation phase duration depends on the number of inventory transactions in your system. In environments with a high volume of inventory transactions, expect the validation to take considerable time.

Allow inventory transaction consolidation without inventory closing

To allow inventory transaction consolidation without inventory closing, follow these steps:

1. Go to **Inventory management** > **Setup** > **Inventory and warehouse management parameters**.
2. Open the **General** tab.
3. Set **Allow inventory transaction consolidation without inventory closing** to one of the following values:
    - *No* – The system can only consolidate inventory transactions for closed inventory.
    - *Yes* – The system can also consolidate inventory transactions on unclosed inventory for items that use the *Standard cost* or *Moving average* inventory model.

    By default, this setting is permanently set to *No*. If you want to change it to *Yes*, contact Microsoft Technical Support for assistance.

> **Important**
>
> After you consolidate an inventory transaction, you can no longer close that inventory period.

Consolidate your inventory transactions

To consolidate inventory transactions, follow these steps:

1. Go to **Inventory management** > **Periodic tasks** > **Clean up** > **Inventory transaction consolidation**.

    The **Inventory transaction consolidation** page appears and shows a list of consolidated process records.
2. On the Action Pane, select **Inventory transaction consolidation** to create an inventory transaction consolidation.
3. In the **Inventory transaction consolidation** dialog box, on the **Parameters** FastTab, set the following fields:

- **To date in closed ledger period** – Select the end date of the consolidation period. The system consolidates all eligible transactions up to and including this date. Previously unconsolidated transactions before this date are included if they now meet the consolidation requirements.

> ⓘ **Note**
>
> Only periods that meet the conditions for consolidating inventory transactions are available for selection.

4. On the **Run in the background** FastTab, set up batch processing details as you require. Follow the usual steps for batch jobs in Microsoft Dynamics 365 Supply Chain Management.

5. Select **OK**.

6. You receive a message that prompts you to confirm that you want to continue. Read the message carefully, and then select **Yes** if you want to continue.

   You receive a message that states that your inventory transaction consolidation job is added to the batch queue. The job starts to consolidate inventory transactions from the selected period. You can find the batch job under **System administration** > **Inquiries** > **Batch jobs**, where you can also review any logs generated by the batch tasks.

View consolidated inventory transactions

The **Inventory transaction consolidation** page shows your full consolidating history. Each row in the grid shows information such as the date when the consolidation was created, the user who created it, and its status.

Filter the list of consolidations

In the drop-down list at the top of the page, select one of the following values to filter the consolidations that appear in the grid:

- *Active* – Show only active consolidations.
- *All* – Show all consolidations.

You can also filter and sort the grid by using the column headers.

Information shown in the grid

For each consolidation in the grid, the following information is provided:

- **Active** – A check mark indicates that the consolidation is active.
- **To date** – The date of the newest transaction that can be included in the consolidation.
- **Voucher** - The voucher for the consolidation session, generated by the configured number sequence.
- **Scheduled by** – The user account that created the consolidation.
- **Executed** – The date when the consolidation was created.
- **Stop current update** – A check mark indicates that the consolidation is in progress, but it has been paused.
- **State** – The processing status of the consolidation. The possible values are *Waiting*, *In progress*, and *Finished*.

The grid toolbar

The toolbar above the grid provides the following buttons that you can use to work with a selected consolidation:

- **Consolidated transactions** – View the full details of the selected consolidation. The **Consolidated transactions** page shows all the transactions in the consolidation. To view more information about a specific transaction on the **Consolidated transactions** page, select it in the grid. On the Action Pane, select **Consolidated transaction details**. The **Consolidated transaction details** page shows information such as the ledger posting, related subledger references, and financial dimensions.
- **Pause** – Pause a selected consolidation that is currently being processed. The pause takes effect only after the archiving task is generated. Therefore, there might be a short delay before the pause takes effect. If a consolidation is paused, a check mark appears in its **Stop current update** field.
- **Resume** – Resume processing for a selected consolidation that is currently paused.
- **Progress details** – Open a log that shows the progress of your inventory consolidation jobs.

Extend your code to support custom fields

If your `InventTrans` table contains one or more custom fields, you might need to extend the code to support them, depending on how they are named.

- If the custom field has the same name in both `InventTrans` and `InventTransArchive`, add it to the `InventoryArchiveFields` field group on `InventTrans`. No code is required—the engine automatically resolves the matching field on `InventTransArchive`.

- If the field names differ between the two tables, use the field mapper extension described in this section.

> **Important**
>
> The pattern for mapping custom field names changed in Supply Chain Management version 10.0.47. In version 10.0.46 and earlier, you mapped custom fields by extending the `InventTransArchiveProcessTask` and `InventTransArchiveSqlStatementHelper` classes. In version 10.0.47 and later, you map custom fields by extending the `InventTransArchiveFieldMapper` class. If your customizations still use the legacy extension pattern, you must migrate them to use the new pattern. You can't run inventory transaction consolidation until you migrate your customizations to use the new extension pattern.

In Supply Chain Management version 10.0.47 and later, custom field mapping is done through a dedicated `InventTransArchiveFieldMapper` class. Create a Chain of Command (CoC) extension and override the two list methods. Each method returns a `List` of field IDs that the consolidation engine adds to the source query (`InventTrans`) and the destination insert (`InventTransArchive`).

The following sample code includes the `CreatedBy` field from `InventTrans` and writes it to a custom `InventTransCreatedBy` field on `InventTransArchive`.

X++

```
[ExtensionOf(classStr(InventTransArchiveFieldMapper))]
final class InventTransArchiveFieldMapper_Foundation_Extension
{
    public List getInventTransFields()
    {
        List inventTransFields = next getInventTransFields();

        inventTransFields.addEnd(fieldNum(InventTrans, CreatedBy));

        return inventTransFields;
    }

    public List getInventTransArchiveFields()
    {
        List inventTransArchiveFields = next getInventTransArchiveFields();

        inventTransArchiveFields.addEnd(fieldNum(InventTransArchive,
InventTransCreatedBy));

        return inventTransArchiveFields;
    }
}
```

Keep the following points in mind when you write the extension:

- **The engine pairs the two lists positionally.** The first field returned by `getInventTransFields()` is paired with the first field returned by `getInventTransArchiveFields()`, and so on. The lists must contain the same number of entries in the same order.
- **Always call `next` and append to the returned list.** This step preserves the contributions of any other extensions and keeps your code forward-compatible.

Consolidate inventory transactions FAQ (preview)

[This article is prerelease documentation and is subject to change.]

This article provides answers to frequently asked questions about inventory transaction consolidation in Microsoft Dynamics 365 Supply Chain Management.

Why are there more rows in the InventTransOrigin table after consolidation?

This result is expected. The *Inventory transactions consolidation* job creates new inventory transaction (`InventTrans`) and inventory transactions originator (`InventTransOrigin`) records.

For transactions that aren't warehouse management process (WMS) transactions, the job creates a new record with reference category `InventTransArchive` in the `InventTransOrigin` table. This new record links to the new consolidating inventory transaction.

For WMS transactions, the job creates a new record with reference category `WHSInventTransArchiveOnlyAffectsLocationAndBelow` in the `InventTransOrigin` table. This type of record affects only location and below in the inventory reservation hierarchy. In other words, it's used only for transactions that affect specific locations in the warehouse. Here are some examples:

- `WHSWork` – Transactions related to warehouse work orders.
- `WHSContainer` – Transactions that involve containers in the warehouse.
- `WHSOrderCommittedReservation` – Transactions for orders that have committed reservations.
- `WHSWarehouseInventoryBlocking` – Transactions that block inventory in the warehouse.

Reduce the consolidation frequency to help minimize the increase in the `InventTransOrigin` table.

Why aren't some transactions moved to the InventTransArchive table during consolidation?

This result is expected. In the following scenarios, the system keeps transactions in the `InventTrans` table after inventory transaction consolidation:

- When the *Inventory transactions consolidation* job creates new inventory transactions that consolidate the archived inventory transactions, the job keeps these new transactions in the `InventTrans` table. Learn more in the previous section.
- If an `ItemId` and `InventDimId` combination contains only one receipt or issue transaction in the archive period, the job doesn't consolidate that transaction. Instead, it keeps the transaction in the `InventTrans` table.
- Inventory transactions are only included in the consolidation if all transactions for a given document can be consolidated. If, for example, not all inventory transactions for a sales order can be consolidated, no transactions for the sales order are consolidated. These transactions are automatically included in future consolidations when the prerequisites are met.

The following examples illustrate these aggregation rules.

Aggregation rule example 1

Before consolidation

Expand table

ID	Item number	Inventory dimension ID	Financial date	Reference	Receipt	Issue	Quantity
A1	WMS item A	Dim_1	January 10, 2020	Purchase order	Purchased		10
A2	WMS item A	Dim_1	January 15, 2020	Counting		Sold	-3
A3	WMS item A	Dim_1	January 20, 2020	Work		Sold	-7
A4	WMS item A	Dim_2	January 20, 2020	Work	Purchased		7
A5	WMS item A	Dim_2	January 20, 2020	Work		Sold	-7
A6	WMS item A	Dim_3	January 20, 2020	Work	Purchased		7
A7	WMS item A	Dim_3	January 25, 2020	Sales order		Sold	-7

After consolidation until January 31, 2020

Expand table

ID	Item number	Inventory dimension ID	Financial date	Reference	Receipt	Issue	Quantity
B1	WMS item A	Dim_1	January 31, 2020	Archived inventory transaction	Purchased		7
A3	WMS item A	Dim_1	January 20, 2020	Work		Sold	-7
B3	WMS item A	Dim_2	January 31, 2020	Archived warehouse transaction type that affects only location and below		Sold	0
A6	WMS item A	Dim_3	January 20, 2020	Work	Purchased		7
A7	WMS item A	Dim_3	January 25, 2020	Sales order		Sold	-7

Result summary

Note the following results of the consolidation:

- Line B1 consolidates line A1 and line A2, because A1 and A2 both have the same inventory dimension (Dim_1), and they aren't a warehouse transaction type that affects only location and below.
- Line B3 consolidates line A4 and line A5, because A4 and A5 both have the same inventory dimension (Dim_2), and they are a warehouse transaction type that affects only location and below. Typically, if the cost amount and quantity are 0, line B3 isn't inserted into the inventory transactions table.
- Line A3 isn't consolidated with line B1, because it's a warehouse transaction type that affects only location and below.

Inventory Visibility Add-in overview

08/14/2025

The Inventory Visibility Add-in (also referred to as the *Inventory Visibility service*) provides an independent and highly scalable microservice that enables real-time on-hand inventory change postings and visibility tracking across all your data sources and channels. It provides a platform that lets you manage your global inventory by using functionality that includes (but isn't limited to) the following list:

- Centrally track the latest inventory status (such as on-hand, ordered, purchased, in-transit, returned, and quarantined) across all your data sources, warehouses, and locations by connecting your Supply Chain Management or third-party logistics data sources (such as order management systems, third-party enterprise resource planning [ERP] systems, point of sale [POS] systems, and warehouse management systems) to the Inventory Visibility service.
- Query on-hand stock availability and shortages, and obtain immediate responses by calling the Inventory Visibility service directly.
- Avoid overselling, especially when your demand comes from different channels, by making real-time soft reservations in the Inventory Visibility service.
- Better manage promised orders and customer expectations by providing accurate current or next-available dates, so that the omnichannel available-to-promise (ATP) feature can calculate expected order fulfillment dates.

Extensibility

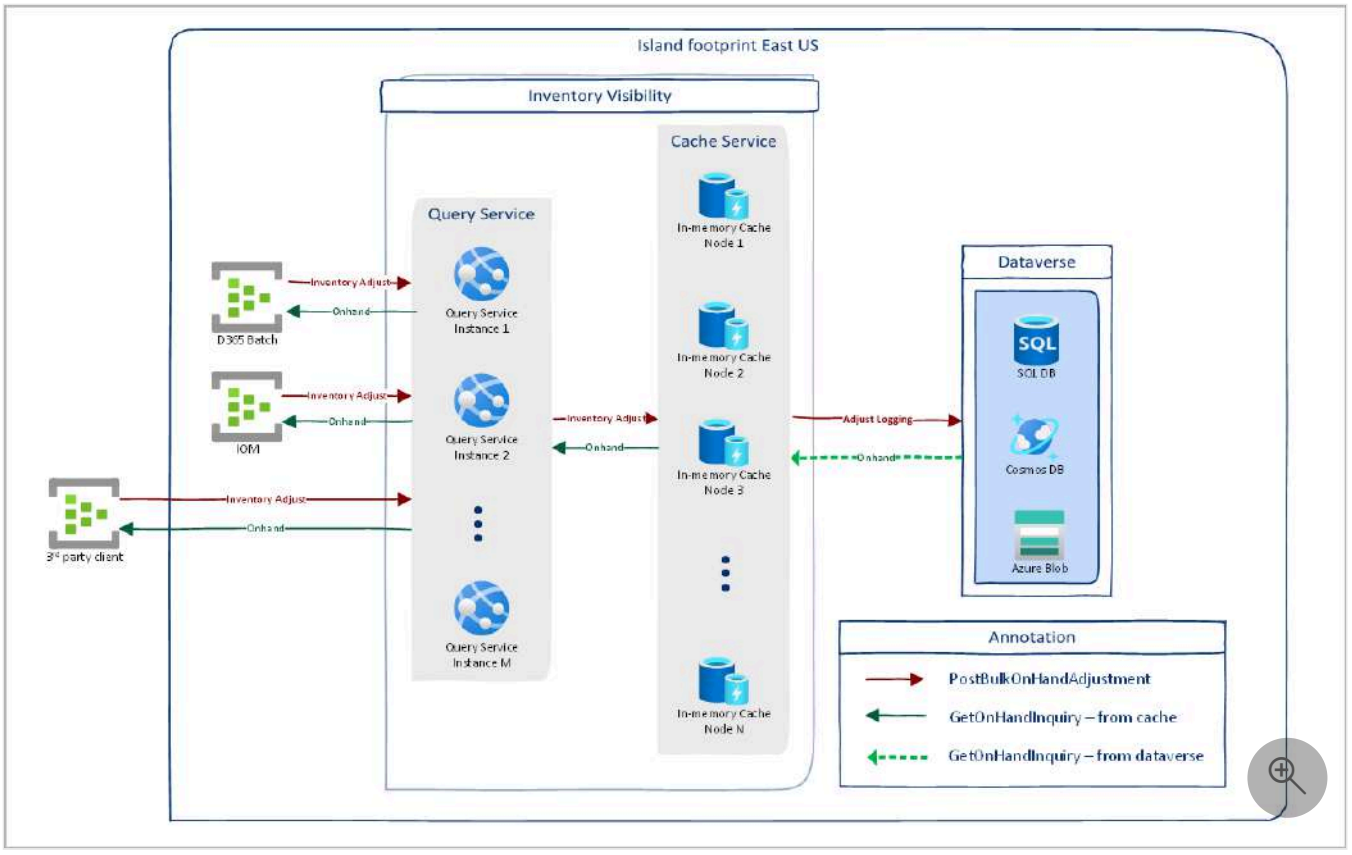
The Inventory Visibility service is highly extensible because data input and output aren't restricted to Microsoft applications. External systems can access the service through RESTful application programming interfaces (APIs). In addition to using the out-of-box mappings that are provided for the Supply Chain Management data source and dimensions, you can integrate Inventory Visibility with multiple third-party systems by setting up additional data sources, inventory statuses measures (referred to as *physical measures* in Inventory Visibility service), and inventory dimensions via the configuration app. In this way, you can flexibly query and change your multiple data sources and predefined inventory dimensions.

Additionally, because Inventory Visibility is built on Microsoft Dataverse, its data can be used to build and integrate with Power Apps. You can also use Power BI to create customized dashboards that meet your business requirements.

Scalability

The Inventory Visibility service can be scaled up or down, depending on your data volume. The scalability experience is mostly seamless and is conducted by the Microsoft platform team, based on automatic detection and assessment of your transaction data volume.

The following illustration shows the Inventory Visibility architecture.



Feature highlights

Get a global view of real-time inventory

Inventory Visibility ensures that you have access to the most up-to-date inventory quantities at all times, across all your channels, locations, and warehouses. You'll benefit most from using it to support your daily operational business whenever you must obtain inventory records. Physical on-hand inventory, quantities sold, and quantities purchased are all available out of the box. You can also configure other physical inventory measures (such as returned, quarantined, and posted data) as you require, to obtain those details in real time. Inventory Visibility can efficiently process millions of inventory change posts. This data can be aggregated and reflected in the latest inventory quantities in the service immediately, per second, or per minute, depending on the interval that data is posted at. Learn more in Inventory Visibility public APIs.

Central inventory adjustment

Inventory Visibility allows external systems to call its API to post inventory changes. The changes will immediately take effect in Inventory Visibility. Therefore, on-hand inventory is instantly deducted.

Soft reservation to avoid overselling across all order channels

A *soft reservation* lets you assign or flag specific quantities to fulfill an order or demand. A soft reservation doesn't affect physical inventory, but it does deduct from the *available for reservation* inventory quantity and provides an updated quantity for future order fulfillment. This feature will be useful if sales requests or orders come into your business from one or more channels or data sources that are outside your system-of-record enterprise resource planning (ERP) system.

If you don't use soft reservations in the Inventory Visibility service, you must wait until the order is synced to, and processed by, your ERP system to get a physical inventory quantity update. This process typically has huge latency. However, soft reservations take immediate effect each time that a sales request or order is generated in your sales channels. Therefore, they help prevent oversell situations by ensuring that your omnichannel orders won't interfere with each other when they eventually reach the ERP system. Soft reservations also ensure that you can fulfill all the orders that you've promised. Therefore, they help you meet customer expectations and maintain customer loyalty. Learn more in Inventory Visibility reservations.

Immediate response of ATP quantity and dates

Visibility into your near-future projected inventory (including supply, demand, and projected on-hand details) is important, because it helps your company achieve the following goals:

- Minimize inventory levels to reduce inventory management costs.
- Facilitate internal order processing, so that salespeople can calculate shipment and delivery dates, based on the availability of the products that are ordered.
- Provide transparency about when customers can expect an out-of-stock item to become available, by providing the next-available date.

The ATP feature is easy to adopt into your daily order fulfillment process. Most importantly, like other Inventory Visibility offerings, the ATP feature is *global and real-time*. Therefore, you can set up multiple ATP calculation formulas to have full inventory availability queries that cover all your business channels and data sources. Learn more in Inventory Visibility on-hand change schedules and available to promise.

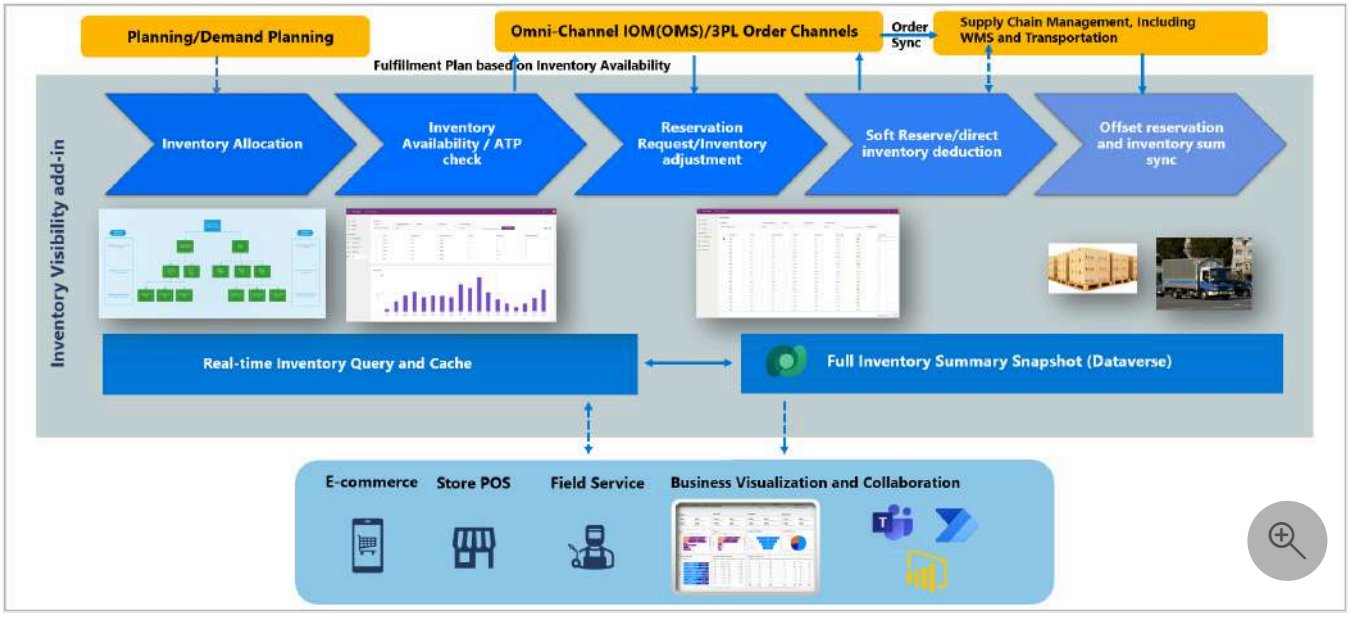
Preallocate your stock to important channels or customers with Inventory Allocation

The Inventory Visibility allocation feature lets you protect and ring-fence your valuable on-hand stock for important channels, customer groups, or locations. After stock is allocated, inventory consumption is restricted to the allocated pool, and the quantities that are left in the pool will be deducted in near-real time to reflect the quantity that is still available for consumption. Learn more in Inventory Visibility inventory allocation.

Compatibility with WMS items

Microsoft aims to provide out-of-box integration with warehouse management processes (WMS), so that WMS customers can also enjoy the benefits of the Inventory Visibility service. Per the 2022 Wave 1 release (public preview in March), inventory service supports WMS item on-hand queries and ATP. The soft reservation and allocation feature will be supported for WMS customers in the next wave. Learn more in Inventory Visibility support for WMS items.

The following illustration shows a high-level summary of existing features and how they can be positioned in the data flow.



Licensing, API Usage, and Storage for Inventory Visibility Service

The Inventory Visibility Service (IVS) is a first-party microservice available in two versions, which are described in the following subsections.

Inventory Visibility Add-in for Microsoft Dynamics 365 Supply Chain Management

The *Inventory Visibility Add-in for Microsoft Dynamics 365 Supply Chain Management* version is for companies that have a valid Supply Chain Management license (which always includes Inventory Visibility).

There's no throttling on how frequently you can call IVS APIs. Most on-hand inventory queries are served from an in-memory cache and therefore don't trigger Dataverse API calls. However, operations such as *inventory adjustments (post on-hand change)*, *soft reservations, or *ATP (scheduled on-hand change) queries* via IVS *do* result in Dataverse API calls. These Dataverse calls are subject to Dataverse service protection API limits, which are enforced *per web server*. These limits accumulate across web servers, and Microsoft automatically scales web server capacity based on your usage and performance needs. While the exact number of web servers isn't fixed or user-configurable, the platform scales to meet high-volume enterprise workloads as needed.

In terms of storage, IVS usually stores aggregated inventory data in Dataverse. However, there are two exceptions:

- **Transaction logging** – When enabled, this feature logs successful inventory API posts and stores them in Dataverse for audit and traceability.
- **Sync external inventory adjustments to Supply Chain Management** – This feature stores detailed omnichannel inventory transactions in Dataverse before syncing them to Supply Chain Management.

Even for these two exceptions, you can archive the transactions if you don't need them anymore.

For most use cases, therefore, the data footprint is typically small and is usually covered by the Dataverse storage included with your Supply Chain Management licenses. Each full-access user license for a Microsoft finance and operations app (such as Supply Chain Management) contributes additional Dataverse storage capacity, which accumulates across all licensed users (typically at 250 MB of database storage and 2 GB of file storage per user).

Your actual storage usage might vary depending on your configuration and transaction volume. Learn more in Dataverse capacity-based storage details. If you need to estimate your usage, you can enable Inventory Visibility on a sandbox environment, load a small subset of your data, and check the Dataverse usage. If your estimated API and storage usage exceeds the standard allocation, you can contact your Microsoft sales representative.

Inventory Visibility Service component for IOM

The *Inventory Visibility Service component for Intelligent Order Management (IOM)* version is for companies that use IOM or companies that aren't using Supply Chain Management as their

ERP system. The license is included in the Intelligent Order Management bundle. Learn more in Intelligent Order Management overview.

Inventory Visibility terminology

It's important that you understand the following concepts and terms when you're working with the Inventory Visibility Add-in:

- **Data source** – A data source represents the system that your data is from.
- **Dimensions** – Dimensions identify product characteristics. They can be storage dimensions (such as site or warehouse) or product dimensions (such as color, size, or style).
- **Physical measures** – Physical measures are quantities that measure different inventory statuses, such as on-hand, purchased, on order, or sold.
- **Calculated measures** – Calculated measures are quantitative measures that are calculated from a set of physical measures. For example, the *Total available* calculated measure is calculated as *On-hand* + *Purchased* – *On order* – *Sold*.
- **Partition** – A partition defines a hierarchy for how inventory visibility will distribute received data. Currently, the default partition is site and location.
- **Index hierarchy** – An index hierarchy further defines how you want to query inventory and obtain results that have more granularity.

For more information about these terms and concepts, see Configure Inventory Visibility.

Install and set up Inventory Visibility

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Human Resources, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

This article describes how to install the Inventory Visibility Add-in for Microsoft Dynamics 365 Supply Chain Management.

> **Tip**
>
> If you're a feature consultant or solution consultant, join the D365 SCM Inventory Management and Inventory Visibility community on Microsoft Viva Engage. Read about the latest developments, exchange tips with other consultants and developers, and discuss features.
>
> For useful code samples and troubleshooting guides, visit the Inventory Visibility GitHub repo.
>
> If you're experiencing technical issues or running into exceptions, get help by contacting Microsoft Support through Microsoft Dynamics Lifecycle Services or the Power Platform admin center. Be sure to include your Supply Chain Management environment ID when you contact them.

Inventory Visibility prerequisites

Before you install Inventory Visibility, complete the following tasks:

- Get a Supply Chain Management environment that's linked to a Dataverse environment.
- Make sure that you complete the prerequisites for setting up add-ins. For information about these prerequisites, see Add-ins overview. Inventory Visibility doesn't require dual-write linking.

The following table lists the countries/regions where Inventory Visibility is currently supported.

Expand table

Azure region	Region short name
Asia East	eas
Asia Southeast	seas
Australia East	eau
Australia Southeast	seau
Brazil South	sbr
Canada Central	cca
Canada East	eca
China East 2	cne2
China East 3	cne3
China North 2	cnn2
China North 3	cnn3
Europe North	neu
Europe West	weu
France Central	cfr
France South	sfr
India Central	cin
India South	sin
Italy North	nit

Azure region	Region short name
Japan East	ejp
Japan West	wjp
Norway East	eno
Norway West	wno

US East 2	eus2
US West	wus

Install the Inventory Visibility Add-in

Before you install the add-in, register an application and add a client secret to Microsoft Entra under your Azure subscription. For instructions, see Register an application and Add a client secret. Make sure to note the **Application (client) ID**, **Client secret**, and **Tenant ID** values, because you'll need them later.

> **Important**
>
> If you have more than one environment, create a different Microsoft Entra application for each environment. If you use the same application ID and tenant ID to install the Inventory

Visibility Add-in for different environments, a token issue occurs for older environments. As a result, only the latest installation is valid.

You can install the Inventory Visibility Add-in from either of two places:

- **Microsoft Dynamics Lifecycle Services** – Lifecycle Services is a collaboration portal that provides a unified collaborative environment together with a set of regularly updated services that help you manage the application lifecycle of your implementations.
- **Power Platform admin center** – The Power Platform admin center provides a unified portal where administrators can manage environments and settings for Power Apps, Power Automate, Power Pages, and Microsoft Copilot Studio.

Install the Inventory Visibility Add-in from Lifecycle Services

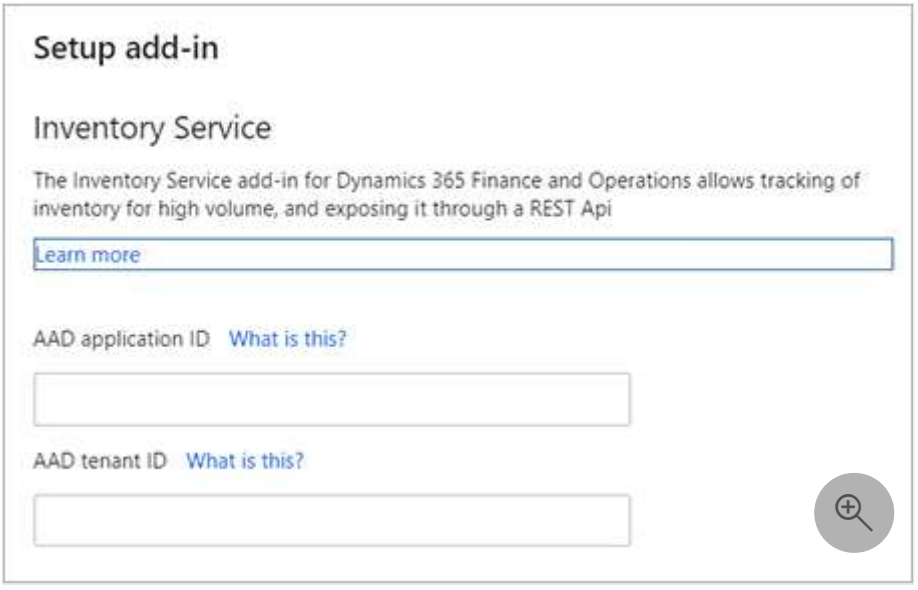
After you register an application and add a client secret to Microsoft Entra ID, follow these steps to install the Inventory Visibility Add-in.

1. Sign in to Lifecycle Services.
2. On the home page, select the project where your environment is deployed.
3. On the project page, select the environment where you want to install the add-in.
4. On the environment page, scroll down until you find the **Environment add-ins** section in the **Power Platform integration** section. There, you can find the Dataverse environment name. Confirm that the Dataverse environment name is the one that you want to use for Inventory Visibility.

   > **Important**
   >
   > Before you start the installation, you should check for linking mismatch warnings in Lifecycle Services. To do so, open the details page for your environment in Lifecycle Services and look for a warning that resembles the following example: "Microsoft has detected that your environment is linked via dual-write to a different destination than specified in Power Platform Integration, which isn't recommended." If you see this warning, it's possible that your dual-write environment is linked to a Dataverse instance, but Lifecycle Services isn't set up for Power Platform integration. This linking mismatch can cause unexpected behavior. For information about how to fix this issue,

see Linking mismatch. After the linking mismatch is fixed, you can install Inventory Visibility.

5. In the **Environment add-ins** section, select **Install a new add-in**.
6. Select the **Install a new add-in** link. A list of available add-ins appears.
7. In the list, select **Inventory Visibility**.
8. Set the following fields for your environment:
    - **Microsoft Entra application (client) ID** – Enter the Microsoft Entra application ID that you created and noted earlier.
    - **Microsoft Entra tenant ID** – Enter the tenant ID that you noted earlier.



9. Agree to the terms and conditions by selecting the **Terms and conditions** checkbox.
10. Select **Install**. The status of the add-in is shown as **Installing**. When the installation is completed, refresh the page. The status should change to **Installed**.
11. In Dataverse, select the **Apps** section in the left navigation, and verify that the **Inventory Visibility** Power Apps is installed successfully.

> ⓘ **Note**
>
> If the system warns you that you don't have permission to install Inventory Visibility on Lifecycle Services, contact the administrator to modify your permission.

If it takes more than an hour to install from the Lifecycle Services page, your user account probably lacks permission to install solutions in the Dataverse environment. Follow these steps to resolve the issue:

1. Cancel the Inventory Visibility Add-in installation process from the Lifecycle Services page.
2. Install the Inventory Visibility Add-in from the Power Platform admin center.
3. After the installation is completed, go back to the Lifecycle Services page, and check the status of the Inventory Visibility Add-in.

Install the Inventory Visibility Add-in from the Power Platform admin center

After you register an application and add a client secret to Microsoft Entra ID, you must install the Inventory Visibility Add-in.

Important

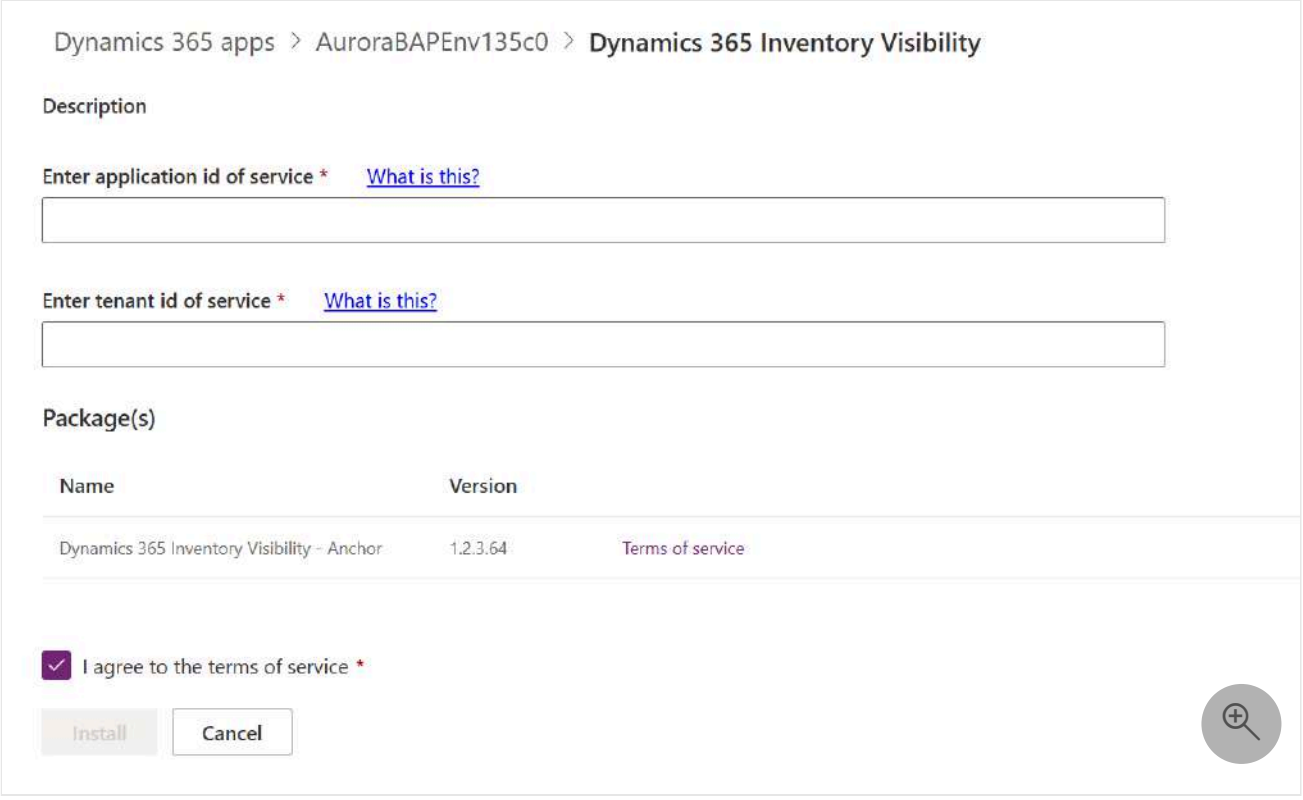
Unless you're using the unified developer experience, check for linking mismatch warnings in Lifecycle Services before you install Inventory Visibility. To do so, open the details page for your environment in Lifecycle Services and look for a warning that resembles the following example: "Microsoft has detected that your environment is linked via dual-write to a different destination than specified in Power Platform Integration, which isn't recommended." If you see this warning, it's possible that your dual-write environment is linked to a Dataverse instance, but Lifecycle Services isn't set up for Power Platform integration. This linking mismatch can cause unexpected behavior. For information about how to fix this issue, see Linking mismatch. After you fix the linking mismatch, you can install Inventory Visibility.

Follow these steps to install the Inventory Visibility Add-in.

1. Sign in to the Microsoft 365 admin center.
2. Make sure that the *Dynamics 365 Unified Operations Plan* license is assigned to the user account that you want to use to install the add-in. If the license isn't assigned, assign it.
3. Sign in to the Power Platform admin center by using the same user account.
4. Select the environment where you want to install the add-in.

5. On the top bar, select **Resources** > **Dynamics 365 apps**.
6. Select **Install App**.
7. Select the *Dynamics 365 Finance and Operations Platform Tools* app. This app provides platform support for registering Inventory Visibility. If you have more than one license that provides access to this app, there might be multiple entries for it. In this case, select any entry that has a status of **Enabled**. Then select **Next**.
8. Agree to the terms of service and select **Install**. Wait for the installation to finish before you move on to the next step. When the installation finishes, the value in the **Status** column changes from *Installing* to *Installed*.
9. Select **Install App**.
10. Find *Dynamics 365 Inventory Visibility* in the list, and select **Next**.
11. Set the following fields for your environment:

    - **Enter application id of service** – Enter the Microsoft Entra application ID that you created and made a note of earlier.
    - **Enter tenant id of service** – Enter the tenant ID that you made a note of earlier.



12. Agree to the terms of service.

13. Select **Install**. During the installation, the status of the add-in is shown as *Installing*. After the installation is completed, refresh the page. The status should change to *Installed*.

Set up Inventory Visibility in Supply Chain Management

Set up Inventory Visibility integration

After you install the add-in, prepare your Supply Chain Management system to work with it by following these steps.

1. In Supply Chain Management, open the **Feature management** workspace, and turn on the *Inventory Visibility integration* feature. As of Supply Chain Management version 10.0.45, it's mandatory and can't be turned off.

2. Go to **Inventory Management** > **Set up** > **Inventory Visibility Integration parameters**.

3. Open the **General** tab and make the following settings:

    - **Inventory Visibility endpoint** – Enter the URL of the environment where you're running Inventory Visibility. Learn more in Find your service endpoint and read the configuration.
    - **Maximum number of records in a single request** – Set the maximum number of records to include in a single request. Enter a positive integer that's less than or equal to 1,000. The default value is 512. Keep the default value unless Microsoft Support advises you to change it or you're otherwise certain that you need to change it.

4. The following optional features enhance the functionality of Inventory Visibility. Decide whether you want to use any of these features. If you do, set them up. (You can also set them up later.)

    - **Soft reservations and offsets** – Soft reservations help organizations achieve a single source of truth for available inventory, especially during the order fulfillment process. For information about how to enable and set up this feature, see Inventory Visibility reservations.
    - **Support for warehouse management processes (WMS) items** – This feature lets you use WMS items with Inventory Visibility. For information about how to enable and set up this feature, see Inventory Visibility support for WMS items.
    - **Inventory summary** – This feature provides an inventory summary for products together with all dimensions. For information about how to enable and set up this feature, see Inventory summary.

- **Preload a streamlined on-hand query** – This feature provides an aggregated inventory summary for products by configured dimensions. For information about how to enable and set up this feature, see Preload a streamlined on-hand query.
- **Track time-series inventory in Inventory Visibility** – This feature enables Supply Chain Management to send its on-hand change schedule to Inventory Visibility to support available-to-promise (ATP) calculations. For information about how to enable and set up this feature, see Track time-series inventory in Inventory Visibility.

5. After you finish setting up the optional features you selected, go to **Inventory Management** > **Periodic tasks** > **Inventory Visibility Integration**, and enable the job. All inventory change events from Supply Chain Management are now posted to Inventory Visibility.

> **Note**
>
> When you enable the Inventory Visibility integration job, if you receive an error that states that you must update the partition schema, see the **Update partition schema to two if you get an error when enabling the Inventory Visibility integration job** section of this article for instructions.

Inventory Visibility integration hotfixes

For a list of the latest hotfixes available for Inventory Visibility integration features in Supply Chain Management, see Recent Dynamics 365 SCM hotfixes.

Update partition schema to two if you get an error when enabling the Inventory Visibility integration job

When you try to enable the Inventory Visibility integration batch job from Supply Chain Management, you might receive the following error:

> Cannot sync more than 500000 records in the same warehouse. To mitigate this issue, update partition schema to 2 in Inventory Visibility Add-in.

If you receive this error, follow these steps to update your partition schema to help prevent out-of-memory issues. If you don't receive this error, you can skip this procedure.

1. In Power Apps, delete all inventory data.
2. Set up a system to send API requests to Inventory Visibility.

3. After data is deleted, call the `Get` API with a body of `none` to get all partition IDs (by using `/api/environment/{environmentId}/allpartitionids`). Review the response to confirm that data is completely cleared. The result should be empty.
4. Call the `Post` API with a body of `none` to change the partition schema (by using `/api/environment/{environmentId}/updatePartitionSchema?newversion=2`).
5. In Power Apps, enable the advanced warehouse inventory feature, and update the configuration.
6. In Power Apps, review the runtime configuration. The `CachePartitonIdVersion` field should show a value of `ByLocationAndProductIdMod64`.
7. In Supply Chain Management, go to **Inventory Management** > **Periodic tasks** > **Inventory Visibility Integration**, and enable the job.

Update the Inventory Visibility Add-in

To update an installed version of the Inventory Visibility Add-in to the latest version, follow these steps:

1. Sign in to the Power Platform admin center.
2. On the navigation pane, select **Environments**.
3. Open the environment where you want to update the Inventory Visibility Add-in.
4. In the **Resources** section, select **Dynamics 365 apps**.
5. In the list, find the row where **Name** is *Dynamics 365 Inventory Visibility*. Check the value in the **Status** column for this row.
    - If the **Status** is *Installed*, then you're already running the latest version so you can skip the rest of this procedure.
    - If the **Status** is *Update available*, then an update is available. Continue with the next step.

    > **Tip**
    >
    > To see which version of the add-in you're currently running, regardless of the status, open the **More application actions** menu (ellipsis button), and then select **Details**.

6. If the page shows that an update is available, open the **More application actions** menu (ellipsis button), and then select **Update**.

7. In the dialog box that appears, select the **I agree to the terms of service** checkbox, and then select **Update**.

8. A pop-up window prompts you to confirm the action. To proceed, enter the name of your environment in the field provided, and then select **Update**.

Uninstall the Inventory Visibility Add-in

To uninstall the Inventory Visibility Add-in, follow these steps:

1. Sign in to Supply Chain Management.

2. Go to **Inventory Management** > **Periodic tasks** > **Inventory Visibility Integration**, and disable the job.

3. Go to Lifecycle Services and open the page for the environment where you want to uninstall the add-in (see also the Install the Inventory Visibility Add-in section).

4. Select **Uninstall**.

> ⓘ **Note**
>
> Uninstalling from the Power Platform admin center isn't officially supported.

The uninstall process terminates the Inventory Visibility Add-in, unregisters the add-in from Lifecycle Services, and deletes any temporary data that's stored in the Inventory Visibility Add-in data cache. Primary inventory data that was synced to your Dataverse subscription isn't deleted.

> ⓘ **Important**
>
> If you want to continue to use Inventory Visibility in the current environment, don't delete all solutions from your Dataverse environment. If you want to delete all inventory data in Dataverse, use the delete all inventory data option.

> ⓘ **Note**
>
> If you must delete all solutions that are related to Inventory Visibility, follow these steps:
>
> 1. Open Power Apps.

2. Use the environment picker in the upper right to select the target Dataverse environment.

3. Go to **Solutions**, and delete solutions in the following order:
   a. Dynamics 365 Inventory Visibility – Anchor
   b. Dynamics 365 Inventory Visibility – Copilot
   c. Dynamics 365 Inventory Visibility – Application
   d. Dynamics 365 Inventory Visibility – Controls
   e. Dynamics 365 Inventory Visibility – Plugins
   f. Dynamics 365 Inventory Visibility – Base
   g. Dynamics 365 Product Search - Anchor
   h. Dynamics 365 Product Search Core

Inventory Visibility data that's stored in tables is deleted together with the solutions.

Move data between Supply Chain Management databases and Dataverse environments

You can migrate data between Supply Chain Management databases and Dataverse environments in several ways. For instructions, see the Inventory Visibility GitHub repo.

Last updated on 04/24/2026

Set up product search for Inventory Visibility

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

The *product search* feature lets users search for products and on-hand inventory information based on specific attributes, such as size and color. It provides the following benefits:

- **Time savings** – Users can quickly find products that meet their exact requirements without having to do extensive browsing. Therefore, the feature helps improve the user experience and save valuable time.
- **Higher confidence** – Attribute-based search ensures that users get exactly what they're looking for. Therefore, user confidence increases.
- **Increased product visibility** – Attribute-based search can highlight products that are less often searched for but still potentially relevant. Therefore, users are exposed to a broader range of options that they might not have considered.

This feature is accessible both through the Inventory Visibility app in Microsoft Power Apps and through the API.

Prerequisites

Before you can use the product search service, your system must meet the following requirements:

- You must be running Dynamics 365 Supply Chain Management 10.0.36 or later.
- Inventory Visibility version 1.2.2.54 or later must be installed and set up as described in Install and set up Inventory Visibility.

Install the product search service

New Inventory Visibility installations

The product search service is included in the current version of the Inventory Visibility Add-in. Therefore, you don't have to install it separately if you haven't already installed the add-in for your environment. For information about how to install Inventory Visibility for the first time, see Install and set up Inventory Visibility.

Existing Inventory Visibility installations

If your system is running Inventory Visibility version 1.2.2.53 or earlier, you must update Inventory Visibility in your Microsoft Dynamics Lifecycle Services project and then install the newest version. Learn more in Install and set up Inventory Visibility.

Configure the product search service

Follow these steps to configure product search for Inventory Visibility.

1. If dual-write isn't already enabled for your Lifecycle Services project, enable it as described in Dual-write setup from Lifecycle Services.
2. In Supply Chain Management, go to **System administration** > **Workspaces** > **Data management**, and select the **Framework parameters** tile.
3. On the **Data import/export framework parameters** page, on the **Entity settings** tab, select **Refresh entity list**.
4. The *Refresh entity list* job is added to the batch queue. Wait for the job to be completed.
5. Go back to **System administration** > **Workspaces** > **Data management**, and select the **Dual-write** tile.
6. On the Action Pane, select **Apply solution**.
7. In the **Apply solution** dialog box, select **Dynamics 365 Product Search Core**, and then select **Apply**.
8. Wait for the process to be completed. It might take several minutes. When it's completed, the **Dual-write** page is updated and shows all the table maps that were added. Select all the table maps, and then select **Run** on the Action Pane.
9. The **Initial writes and related table map(s)** dialog box appears. For each table map, select the **Initial sync** checkbox, and set the **Master for initial sync** field to *Finance and*

Operations apps. Then select **Run**.

Troubleshooting

If some table maps fail to do an initial synchronization because of a permission issue, follow these steps to check your team roles.

1. Sign in to your Dataverse environment, go to **Settings** > **Security**, and select **Teams**.
2. Open your team, and select **Manage Roles**.
3. Make sure that the following role is assigned to your team:

    - *System Administrator*

For more information about how to set up dual-write security roles, see Set up dual-write security roles and permissions.

Search for products using the API

After you set up the product search service, you can search for products either by using the Inventory Visibility app in Power Apps or by using the Inventory Visibility API. For details about how to search for products by using the Inventory Visibility API, see Query with product search.

Search for products using the Inventory Visibility app in Power Apps

After you set up the product search service, you can search for products either by using the Inventory Visibility app in Power Apps or by using the Inventory Visibility API. For details about how to search for products by using the Inventory Visibility app in Power Apps, see Search for products using the Inventory Visibility app.

Last updated on 03/10/2026

Enable Inventory Visibility for Commerce

This article describes how to set up Inventory Visibility for Microsoft Dynamics 365 Commerce Scale Units (CSUs) so that e-commerce, point of sale (POS), or other applications on CSUs can use it for real-time inventory lookup, reservation, and adjustments.

Inventory Visibility for Commerce

Accurate inventory information is crucial for any retailer that runs an omnichannel business. Discrepancies between system-recorded inventory and physical inventory can lead to lost revenue or reduced customer satisfaction. Retailers require an accurate, holistic view of inventory across all channels and locations, and throughout all sales and supply chain processes. They must be able to query, reserve, and adjust on-hand inventory in near-real time.

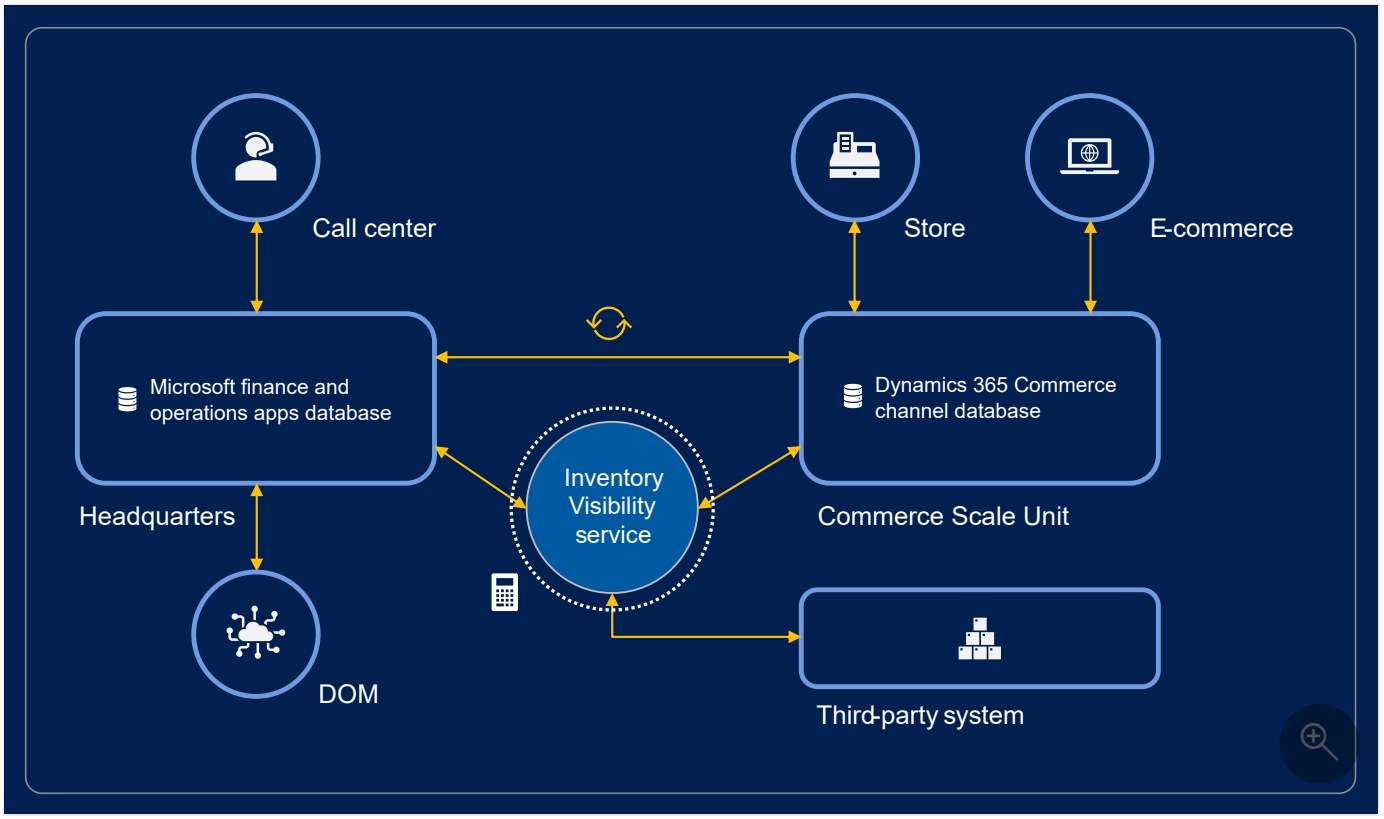
Dynamics 365 Commerce works asynchronously with inventory data. It relies on scheduled back-end jobs to exchange data between Commerce headquarters and CSU components. Because the inventory data that's available to headquarters at any given time might not reflect the latest inventory snapshot, it can't reliably support omnichannel scenarios.

If your company runs any or all of the following scenarios, we recommend that you enable Inventory Visibility so that Commerce can provide real-time inventory data across all channels:

- You're running both Dynamics 365 Commerce and Dynamics 365 Supply Chain Management.
- Your POS or e-commerce business runs on multiple CSUs.
- You have third-party systems that also update inventory.

The Inventory Visibility add-in (also referred to as the *Inventory Visibility service*) for Supply Chain Management is an independent and highly scalable microservice for posting on-hand inventory changes and tracking inventory across data sources in real time. It provides a set of RESTful APIs and includes native support for integrating with Commerce directly out of the box. Whenever a Commerce channel requests real-time inventory data, Inventory Visibility provides it in real time. Whenever an event that changes inventory occurs in the system (such as order creation, editing, cancellation, return, or fulfillment), the event is immediately posted to Inventory Visibility to update its inventory snapshot.

The following illustration shows a system that implements most of the previously mentioned integration scenarios (but just a single CSU).



For more information about Inventory Visibility, see Inventory Visibility Add-in overview.

Prerequisites

Before you can use the features that this article describes, your system must meet the following requirements:

- You must have licenses for both Supply Chain Management and Commerce.
- You must be running Supply Chain Management version 10.0.36 or later.
- The Inventory Visibility add-in must be installed and set up as described in Install and set up Inventory Visibility. Be sure to make a note of the following information from the setup, because you'll need it when you set up the integration with Commerce:
  - Application ID (Client ID)
  - Client secret
  - Tenant ID
- The following features must be turned on in Feature management:
  - *Inventory Visibility integration with inventory adjustment posting* (As of Supply Chain Management version 10.0.45, this feature is mandatory and can't be turned off.)
  - *Inventory Visibility integration with inventory adjustment offset* (As of Supply Chain Management version 10.0.45, this feature is mandatory and can't be turned off.)

- *Enable warehouse items in Inventory Visibility* (As of Supply Chain Management version 10.0.45, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.)

- Inventory Visibility support for WMS items must be enabled for your environment.

Enable adjustments in Supply Chain Management

To enable adjustments in Supply Chain Management, follow these steps:

1. Sign in to Supply Chain Management.
2. Go to **Inventory Management** > **Inventory Visibility** > **Inventory Visibility integration**.
3. On the **Adjustment** tab, on the **Manage inventory adjustment posting and retry** FastTab, on the toolbar, select **Enable adjustment**.

Create a key vault to hold the client secret for Inventory Visibility

To create a key vault to hold the client secret for Inventory Visibility, follow these steps:

1. Sign in to the Azure portal.
2. Search for or select **Key vaults** to open the **Key vaults** page.
3. On the toolbar, select **Create**.
4. Work through the **Create key vault** wizard to create a key vault.
5. Open the key vault that you just created.
6. On the navigation pane, select **Overview**.
7. Copy the **Vault URI** value, and paste it into a temporary text file. Label the value so that you can identify it later.
8. While your key vault is still open, on the navigation pane, select **Object** > **Secrets**.
9. On the toolbar, select **Generate/Import**.
10. On the **Create a secret** page, set the following fields:

    - **Upload options** – Select *Manual*.

- **Name** – Enter a name for the secret (for example, *commerce-iv-01-secret*). Copy the value, paste it into your temporary text file, and label it.
- **Secret value** – Enter the client secret value that you used when you installed the Inventory Visibility add-in (as mentioned in the Prerequisites section).
- **Content type** – This field is optional. The suggested value is *application/vnd.ms-StorageConnectionString*.
- **Set activation date** – Select this checkbox, and then enter the first date when this secret should be valid.
- **Set expiration date** – Select this checkbox, and then enter the last date when this secret should be valid.
- **Enabled** – Set this option to *Yes*.

> **Important**
>
> If the client secret value that you used when you installed the Inventory Visibility add-in expires, then the **Secret value** in this step also becomes invalid. If this happens, then you must create a new client secret value for the Inventory Visibility application registration and update the **Secret value** mentioned in this step accordingly.

11. Select **Create** to create and save the secret.

Register a Microsoft Entra application to provide access to the key vault

To register a Microsoft Entra application to enable Supply Chain Management and Commerce to access the key vault, follow these steps:

1. In the Azure portal, return to the home page.
2. Search for or select **App registrations** to open the **App registrations** page.
3. On the toolbar, select **New registration**.
4. On the **Register an application** page, set the following fields:

    - **Name** – Enter a name.
    - **Supported account types** – Specify who can use the new application. For more information about this setting, see Identity and account types for single- and multitenant apps.

- **Redirect URI** – Leave this field blank.

5. Select **Register** to register the application.
6. The new app registration is opened. On the navigation pane, select **Manage** > **Certificates & secrets**.
7. On the **Client secrets** tab, select **New client secret**.
8. In the **Add a client secret** dialog box, select an expiration date that meets your needs, and then select **Add**.
9. The **Certificates & secrets** page now shows details about the new client secret. These details are shown only once and will be hidden when the page is reloaded. Therefore, you must copy them now. Copy the **Value** value, paste it into your temporary text file, and label it.
10. On the navigation pane, select **Overview**. Copy the following values, paste them into your temporary text file, and label them:

    - **Application (client) ID**
    - **Directory (tenant) ID**

After the application is registered, create an access policy to enable it to access the key vault.

1. Open the key vault you created in Create a key vault to hold the client secret for Inventory Visibility.
2. On the navigation pane, select **Access policies**.
3. On the toolbar, select **Create** to open the **Create an access policy** page.
4. On the **Permissions** tab, under **Secret permissions** > **Secret Management Operations**, Select the **Get** checkbox. A template isn't required.
5. Select **Next**.
6. On the **Principal** tab, select the application you just registered in this section.
7. Select **Next**.
8. The **Application** tab is optional.
9. Select **Next**.
10. On the **Review + create** tab, review your settings and then select **Create**.

Set up Supply Chain Management to access the new key vault

To set up Supply Chain Management to access the new key vault through the new application, follow these steps:

1. Sign in to Supply Chain Management.
2. Use the company picker to select the same company (legal entity ID) as your Dynamics 365 Commerce channel.
3. Go to **System administration** > **Setup** > **Key Vault parameters**.
4. On the Action Pane, select **New** to add a record. Set the following fields for it:
    - **Name** – Enter a name for the Key Vault record.
    - **Description** – Enter a short description.
    - **Key Vault URL** – Paste the **Vault URI** value that you copied when you created the key vault. (See step 7 in the Create a key vault to hold the client secret for Inventory Visibility section.)
    - **Key Vault client** – Enter the **Application (client) ID** value that you copied when you created the app registration. (See step 10 in the Register a Microsoft Entra application to provide access to the key vault section.)
    - **Key Vault secret key** – Enter the secret **Value** value that you copied when you created the app registration. (See step 9 in the Register a Microsoft Entra application to provide access to the key vault section.)
5. On the **Secrets** FastTab, on the toolbar, select **Add** to add a row to the grid. Set the following fields for it:
    - **Name** – Enter a name to identify the secret. You'll need this value later. Therefore, copy it, paste it into your temporary text file, and label it.
    - **Description** – Enter a short description.
    - **Secret** – Enter a value using the following format:

      vault://<KeyVaultName>/<SecretName>/<SecretVersion>

      The *<KeyVaultName>* and *<SecretVersion>* attributes are optional. However, the *<SecretName>* attribute is required, and is the **Name** value that you copied when you created the secret for the key vault (see step 10 in the Create a key vault to hold the client secret for Inventory Visibility section). If the secret version isn't defined in the Key Vault secret key, the system retrieves the active secret that has the latest expiration date. In most cases, you can define a Key Vault secret key in the following format:

vault://<SecretName>

For example, if the name of your key vault secret is *commerce-iv-01-secret*, enter *vault://commerce-iv-01-secret*.

- **Secret type** – Select *Manual*.

After filling in all the necessary fields, you can click the **Validate** button to verify your secret.

6. On the **Secrets** FastTab, on the toolbar, select **Validate**. If you correctly entered all the values, you receive the following informational message: "Validation successful." If you receive an error message, double-check your settings, and try again.

7. On the Action Pane, select **Save**. Be patient, because the save operation takes about two minutes.

For more information about the settings that are mentioned in this procedure, see Set up the Azure Key Vault client.

Set up the integration between Inventory Visibility and Commerce

To set up the integration between Inventory Visibility and Commerce, follow these steps:

1. Sign in to Supply Chain Management.

2. Go to **Retail and Commerce** > **Headquarters setup** > **Parameters** > **Commerce shared parameters**.

3. On the **Inventory** tab, set the following fields:

   - **Microsoft Entra tenant ID** – Enter the **Directory (tenant) ID** value that you used when you installed the Inventory Visibility add-in (as mentioned in the Prerequisites section).
   - **Microsoft Entra app ID** – Enter the **Application (client) ID** value that you used when you installed the Inventory Visibility add-in (as mentioned in the Prerequisites section).
   - **Microsoft Entra client secret** – Select the **Name** value that you copied when you specified the secret for the key vault on the **Key Vault parameters** page in Supply Chain Management. (See step 5 in the Set up Supply Chain Management to access the new key vault section.)
   - **Use Inventory Visibility as inventory data provider** – Set this option to *Yes*.

4. On the Action Pane, select **Save**.

Run the global configuration job

To run the global configuration job, follow these steps:

1. Go to **Retail and Commerce** > **Retail and Commerce IT** > **Distribution schedule**.
2. In the list pane, select the record that's named *1110 Global configuration*.
3. On the Action Pane, select **Run now**.

Last updated on 07/27/2026

Inventory Visibility app user interface version

The Inventory Visibility app runs in Microsoft Power Apps. The current version of the app supports two versions of the user interface. You can choose which version you prefer to use. The following versions are available:

- User interface version 2, which is referred to as *UI version 2* in this article
- User interface version 1, which is referred to as *UI version 1* in this article

This article describes the differences between the two versions, the new operations that are supported in UI version 2, and how to migrate from UI version 1 to UI version 2.

> **Note**
>
> User interface version 1 will be deprecated in a future release. Users are suggested to switch to UI version 2 when possible.

Features and configurations supported by each version

The following settings and features are accessible only from the configuration page for UI version 1:

- Cleanup of preloaded on-hand results
- Operations that are related to inventory allocation

> **Note**
>
> Most of the features for setting up and viewing preloaded on-hand results are supported by both versions of the user interface. Only the cleanup of existing preloaded on-hand results requires UI version 1.

The following settings and features are accessible only from the pages for UI version 2:

- Support for 180-day available-to-promise (ATP) calculations
- Inventory adjustments via the user interface

The following settings are accessible on the pages for both UI version 1 and UI version 2. Changes are synced between versions:

- Index hierarchy setup

All other features and settings can be accessed in both versions of the user interface. However, changes aren't synced between versions.

Switch between UI versions 1 and UI version 2

New installations of Inventory Visibility use UI version 2 by default. If you first installed an older version, the app continues to use UI version 1 by default, even after updates. However, you can switch to UI version 2 when you're ready.

Follow these steps to switch between UI versions.

1. In Power Apps, open the **Inventory Visibility** app.
2. On the navigation pane, select **UI Version Control**.
3. Select **Configuration entity version**.
4. Set the **Entity version** field to *2* or *1*, depending on the version of the UI (and Dataverse configuration entities) that you want to use.

If you're switching to UI version 2, you'll probably want to migrate your UI version 1 settings as described in the next section.

Migrate configuration settings from UI version 1 to UI version 2

When you switch from UI version 1 to UI version 2, Inventory Visibility is updated and uses only configuration values from the Dataverse entities that correspond to UI version 2. You can still read and update the old (legacy) Dataverse entities by using the pages from UI version 1. However, changes to the settings have no effect unless you switch the whole app back to UI version 1. While UI version 2 is active, only the settings that you configure on the UI version 2 pages are used. To view and edit the legacy settings from UI version 1, open the Inventory Visibility menu at the bottom of the navigation pane, and then select **Legacy UI**.

After you switch to UI version 2, you can migrate your previous UI version 1 settings to the new Dataverse entities that are used by UI version 2. Although you can switch back to UI version 1 at any time, you can't migrate settings from UI version 2 to UI version 1. If you switch back to UI version 2 after you've been working in UI version 1 for a while, you can remigrate your UI version

1 settings. However, only newly created records are migrated. Updated and deleted records aren't replicated. Therefore, all your previous UI version 2 settings are kept.

To migrate your settings from UI version 1 to UI version 2, follow these steps:

1. In Power Apps, open the **Inventory Visibility** app.
2. On the navigation pane, select **Admin settings**.
3. On the **Migrate entities to V2** tile, select **Manage**.
4. In the dialog box that appears, enter the credentials that you used when you installed the Inventory Visibility service, and then select **Login**.
5. The system copies your existing settings from UI version 1 to UI version 2.

For a more detailed migration guide with screenshots and troubleshooting tips, see Migrate Configuration Settings from UI Version 1 to UI Version 2 in the Inventory Visibility Add-in Examples repo on GitHub.

Use the Inventory Visibility app UI version 2

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to use the Inventory Visibility app, which runs in Microsoft Power Apps.

The Inventory Visibility app offers two versions of a model-driven user experience for visualization. Users can now choose between the new user interface (referred to as *UI version 2* in this article) and the old (legacy) user interface (referred to as *UI version 1* in this article).

Prerequisites

To use UI version 2 with the Inventory Visibility app, complete the following prerequisites:

- Install and set up Inventory Visibility.
- Turn on Inventory Visibility UI version 2.

Authenticate with the Inventory Visibility service

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Admin settings**.
3. On the **Set tokens** tile, select **Manage**.
4. In the dialog box, enter the **Client ID**, **Tenant ID**, and **Client secret** values. These values were defined when the Inventory Visibility Add-in was installed.
5. Select **Login**. The system generates a new bearer token for your sessions. This token expires after one hour.

Switch between user interface versions

Regardless of which version of the user interface is active, you can switch to the other version at any time. However, only the settings that you apply in the active version of the UI have any effect. To switch between the two versions, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select one of the following options:
    - **Inventory Visibility** – The navigation pane shows the pages for UI version 2.
    - **Legacy UI** – The navigation pane shows the pages for UI version 1.

Find your service endpoint and read the configuration

The Inventory Visibility service is deployed on Azure Service Fabric in multiple geographies and multiple regions. Currently, there's no central endpoint to automatically redirect your requests to the appropriate geography and region. Therefore, the service endpoint uses the following pattern, which includes the required information:

`https://inventoryservice.<RegionShortName>-il<IsLandNumber>.gateway.prod.island.powerapps.com`

To obtain your service endpoint and runtime configuration, follow these steps:

1. On the UI version 2 navigation pane, select **Admin settings**.
2. On the **Show service details** tile, select **Manage**.
3. In the dialog box, find your service endpoint and configuration details.

Update the configuration

Any time that you modify the configuration and save your changes, the system saves the new configuration settings only temporarily. The changes don't take effect until you commit the new settings to the service. Follow these steps to commit new configuration settings to the service.

1. On the UI version 2 navigation pane, select **Admin settings**.
2. On the **Update Configuration** tile, select **Manage**.
3. Review your modifications in the dialog box.

> **ⓘ Important**
>
> Be sure to verify all the important modifications that are about to be made to your data sources, physical measures, and dimension mappings.

4. Select **Confirm Update** to apply your configuration change.

Data partition rule

Inventory Visibility can distribute and store inventory data in either of the following ways:

- *By location* – Choose this option if you always know site and warehouse information when you make on-hand queries, inventory adjustments, inventory reservations or inventory allocations through Inventory Visibility.
- *By product ID* – Choose this option if you often don't know site or warehouse information when calling Inventory Visibility. For example, when making e-commerce in-basket reservations, the fulfillment warehouse might be unknown when online orders are initially placed. In this case, you need to call Inventory Visibility to query on-hand inventory and make reservations without providing warehouse information.

To change the data partition rule, follow these steps:

1. Open the Inventory Visibility app
2. Select **Data partition rule** and choose the rule you want to use.
3. Clear all inventory data.
4. Update the configuration to apply your changes. (The update-configuration operation fails if you don't clear the data first.)

The data partition rule controls how data is distributed. Operations that are performed inside the same partition provide better performance, at lower cost, than operations that cross partitions. Use the *By product ID* option if you often query across different locations. However, use the *By location* option if you more often query for multiple products at the same location.

When using the *By location* partition rule, the rule in the following table is included in the solution by default and can't be changed (this becomes set 0 of the index hierarchy). When using *By product ID*, the rule has no effect on Inventory Visibility APIs.

Expand table

Base dimension	Hierarchy
SiteId	1
LocationId	2

Important

Don't customize the partition configuration. If you delete or change the configuration without official guidance, you're likely to encounter an unexpected error.

On-hand index configuration

In many cases, on-hand inventory is queried not only at the most detailed level but also at some aggregated levels, based on the inventory dimensions.

For frequently used query patterns, you can help improve query performance by setting up *indexes*.

An index is composed of a *set number*, *dimensions*, and a *hierarchy*.

Expand table

Name	Description
Set number	Dimensions under the same set number belong to the same set (index) and are grouped together.
Dimensions	The dimensions are base dimensions that query results are aggregated on.
Hierarchy	The hierarchy determines the specific combinations of dimensions that can take advantage of an index query. For example, you set up an index that has the following dimensions and hierarchy: *(ColorId, SizeId, StyleId)*. In this case, only queries that use the following four dimension combinations for their filter and group-by fields are enhanced: • **First combination:** Empty • **Second combination:** *(ColorId)* • **Third combination:** *(ColorId, SizeId)* • **Fourth combination:** *(ColorId, SizeId, StyleId)* (The filter field isn't order-restricted.) The index doesn't speed up queries that use other dimension combinations.

The default on-hand index configuration includes a standard set of indexes.

Tip

These tips can help when you set up your on-hand index configuration:

- Base dimensions that are reserved in the partition configuration (set number *0*) shouldn't be included in other on-hand index configurations.

- If you aren't interested in querying specific dimension combinations, set up an index that has only one base dimension, *Empty*.

Set up the on-hand index configuration

1. On the UI version 2 navigation pane, select **Index Configuration**.
2. Add and remove lines in the grid as you require to define your index. For more information, see the introduction to this section and the example in the next subsection.
3. Update the configuration to apply your changes.

On-hand index configuration example

This section provides an example that shows how an on-hand index works.

The following table shows a list of available inventory.

Expand table

Item	ColorId	SizeId	StyleId	Quantity
D0002	Black	Small	Wide	1
D0002	Black	Small	Regular	2
D0002	Black	Large	Wide	3
D0002	Black	Large	Regular	4
D0002	Red	Small	Wide	5
D0002	Red	Small	Regular	6
D0002	Red	Large	Regular	7

The following table shows an on-hand index configuration.

Expand table

Set Number	Dimension	Hierarchy
1	*ColorId*	1
1	*SizeId*	2
1	*StyleId*	3

This index helps improve the performance of the following on-hand inventory queries:

- *()* – Grouped by all
  - D0002, 28
- *(ColorId)* – Grouped by *ColorId*
  - D0002, Black, 10
  - D0002, Red, 18
- *(ColorId, SizeId)* – Grouped by the combination of *ColorId* and *SizeId*
  - D0002, Black, Small, 3
  - D0002, Black, Large, 7
  - D0002, Red, Small, 11
  - D0002, Red, Large, 7
- *(ColorId, SizeId, StyleId)* – Grouped by the combination of *ColorId*, *SizeId*, and *StyleId*
  - D0002, Black, Small, Wide, 1
  - D0002, Black, Small, Regular, 2
  - D0002, Black, Large, Wide, 3
  - D0002, Black, Large, Regular, 4
  - D0002, Red, Small, Wide, 5
  - D0002, Red, Small, Regular, 6
  - D0002, Red, Large, Regular, 7

Feature management

The following table shows the features that Inventory Visibility offers. Each of these features can be turned on or off for your environment.

Expand table

Feature name	Description
Available to promise	Track your available to promise (ATP) across all data sources and channels.
Inventory allocation	Allocate your valuable on-hand stock to your most important channels, customers, or predefined groups, and track the consumption of each allocated pool.
Advanced warehouse inventory	Sync and view advanced warehouse item inventory by using warehouse hierarchies.

Feature name	Description
Soft reservation	Post your omnichannel reservations to Inventory Visibility soft reservations for real-time inventory availability checks and updates.
Inventory log history	Enable Inventory Visibility to store your successful transaction logs. You can query the log history for details about the organization, product, date range, site, and warehouse.
Inventory summary	Periodically sync your raw inventory summary from the cache to Dataverse. This feature isn't compatible with advanced warehouse items. Enable either this feature or the *Preloaded on-hand* feature. Don't enable both features.
Preload on-hand	Periodically preload the inventory summary to Dataverse from a query result. The query result can be configured with the dimensions that are most relevant to your business. This feature is compatible with advanced warehouse items. Enable either this feature or the *Inventory summary* feature. Don't enable both features.

By default, all these features are disabled. To turn a feature on or off, and to make related configuration settings, follow these steps:

1. On the UI version 2 navigation pane, select **Feature management**.
2. Find the tile for the feature that you want to turn on or off, and then select **Manage**.
3. Turn on and set up the feature as you require. Each feature provides different settings. For more information, see the documentation for the feature that you're setting up.
4. Update the configuration to commit your changes.

Delete all configurations

If necessary, you can delete all configurations except those in the *fno* and *@iv* Inventory Visibility data sources. Deleted configurations can't be restored.

1. On the UI version 2 navigation pane, select **Admin Settings**.
2. On the **Delete all configurations** tile, select **Manage**.
3. You're prompted to confirm the deletion. Select **OK** to continue.

Delete all inventory data

If necessary, you can delete all Inventory Visibility data, except configurations, in both the cache and Dataverse. Deleted data can't be restored, and users are blocked until deletion completes.

1. On the UI version 2 navigation pane, select **Admin Settings**.
2. On the **Delete all inventory data** tile, select **Manage**.
3. You're prompted to confirm the deletion. Select **OK** to continue.

Inventory queries and updates

On the navigation pane, the **Operational visibility** group provides access to pages where you can perform real-time on-hand inventory queries and updates. When the soft reservation feature is enabled, you can also post reservation requests to the API. For more information about API requests, see Inventory Visibility public APIs.

The following elements are common to all the pages:

- A **Post** or **Query** button on the toolbar lets you send API requests to the Inventory Visibility service. This button becomes available only after you enter all the content that's required for the API call on the page.
- A **Product** section lets you enter a product ID, an organization ID, and dimension values for the API request. Select the **Edit Dimensions** button in this section to choose which of the available dimensions to include in the request.
- A **Settings** section (the exact name varies) lets you enter API-specific settings, such as whether to query ATP contents for an on-hand query.
- A **Developer reference** button on the toolbar lets you view the raw contents of your API request (read-only).
- A **Settings** button on the toolbar lets you view and edit the authentication details that are used to access the Inventory Visibility service.

The following subsections provide details about how to set up and use each type of operation.

On-hand query

Use the **On hand query** page in the **Operational visibility** group to query real-time on-hand inventory. Follow these steps to set up and run a query.

1. On the UI version 2 navigation pane, select **On hand query**.

2. In the **Product** section, enter the **Organization ID**, **Site ID**, and **Location ID** values of the products that you want to find.

3. In the **Product ID** field, enter one or more product IDs to get an exact match for your query. Alternatively, leave the field blank to include all products at the specified site and location.

4. Select **Edit Dimensions** to choose which dimensions to include in the query body. Then enter values for the selected dimensions in the **Product** section.

> **Note**
>
> If you plan to make an ATP query, ensure that every dimension that is included in the ATP index is also listed in the **Product** section. For example, if your ATP index includes `ColorId` and `SizeId`, both those dimensions must be listed in the **Product** section. If any dimensions are missing, select **Edit Dimensions** to add them. In the search form, you can leave some of the dimension values blank. However, the dimensions must be included in the query body if they're included in the ATP index.

5. For each field that you want to include in the query, but without filtering on any specific value, select **Use all values**.

6. In the **Query Settings** section, set the following options:

    - **Query ATP** – Select this checkbox to include ATP information.
    - **Include negative quantities** – Select this checkbox to include negative quantities for calculated measure results.

7. Select **Query** on the toolbar to send the request.

Inventory adjustment

Use the **Inventory Adjustment** page in the **Operational visibility** group to make real-time updates to inventory. Follow these steps to set up and submit an update.

1. On the UI version 2 navigation pane, select **Inventory Adjustment**.
2. In the **Product** section, enter the **Product ID**, **Organization ID**, **Site ID**, and **Location ID** values of the products that you want to update.
3. Select **Edit Dimensions** to choose which dimensions to include in the request body. Then enter values for the selected dimensions in the **Product** section.
4. In the **Measures to update** section, select **Add** to add a row for the measure that you want to update. For the new row, select a data source, physical measure, and quantity to update. You must specify at least one measure. You can add multiple measures.
5. Select **Post** on the toolbar to send the request.

Soft reserve

Use the **Soft reserve** page in the **Operational visibility** group to make soft reservations of inventory.

> **Important**
>
> Use the capability to make soft reservations through the user interface only to test the feature. Every soft reservation request must be associated with a transaction order line change (create, modify, delete, and so on). Therefore, make only soft reservations that are linked to back-end orders. Learn more in Inventory Visibility soft reservations.

Follow these steps to set up and submit a soft reservation.

1. On the UI version 2 navigation pane, select **Soft reserve**.
2. In the **Product** section, enter the **Product ID**, **Organization ID**, **Site ID**, and **Location ID** values of the products that you want to update.
3. Select **Edit Dimensions** to choose which dimensions to include in the request body. Then enter values for the selected dimensions in the **Product** section.
4. In the **Reservation settings** section, set the following fields:
    - **Enable negative inventory to support oversell** – Select this checkbox to skip the available-for-reservation check. Clear it to enforce the check.
    - **Reserve on measure** – Select the data source and physical measure to perform the soft reservation on.
    - **Quantity** – Specify the quantity to reserve.
5. Select **Post** on the toolbar to send the request.

Change a schedule

Use the **Post on hand change schedule** page in the **Operational visibility** group to post inventory changes with dates to the Inventory Visibility service. Follow these steps to set up and submit a schedule change.

1. On the UI version 2 navigation pane, select **Change schedule**.
2. In the **Product** section, enter the dimension values of the products that you want to update.
3. In the **Change schedule measure, quantity and date** section, select **Add** to specify the date, data source, physical measure, and quantity for the change.
4. Select **Post** on the toolbar to send the request.

Search for products in the Inventory Visibility app

The *product search* feature lets users search for products and on-hand inventory information based on specific attributes, such as size and color. For details about how to set up this feature, see Set up product search for Inventory Visibility. For details about how to use it in the Inventory Visibility app, see Search for products using the Inventory Visibility app.

Last updated on 06/22/2026

Use the Inventory Visibility app UI version 1

Article • 01/02/2024

This article describes how to use the Inventory Visibility app, which runs in Microsoft Power Apps.

The Inventory Visibility app offers two versions of a model-driven user experience for visualization. Users can now choose between the new user interface (referred to as *UI version 2* in this article) and the old (legacy) user interface (referred to as *UI version 1* in this article).

This article describes how to work with UI version 1. For information about how to work with UI version 2, see Use the Inventory Visibility app UI version 2.

Prerequisites

Before you can use UI version 1 to work with the Inventory Visibility app, the following prerequisites must be in place:

- Install and set up Inventory Visibility.
- Turn on Inventory Visibility UI version 1.

Authenticate with the Inventory Visibility service

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.
3. On the navigation pane, select **Operational Visibility**.
4. Select **Settings** at the top of the page.
5. In the dialog box, enter the **Client ID**, **Tenant ID**, and **Client secret** values. You should have found these values when you installed the Inventory Visibility Add-in.
6. Select the **Refresh** button on the right side of the **Bearer Token** field. The system generates a new bearer token for your sessions. This token expires after one hour.

Switch between user interface versions

Regardless of which version of the user interface is active, you can switch to the other version at any time. However, only the settings that you apply in the active version of the UI have any effect. To switch between the two versions, follow these steps.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select one of the following options:
    - **Inventory Visibility** – The navigation pane shows the pages for UI version 2.
    - **Legacy UI** – The navigation pane shows the pages for UI version 1.

Find your service endpoint and read the configuration

The Inventory Visibility service is deployed on Azure Service Fabric in multiple geographies and multiple regions. Currently, there's no central endpoint to automatically redirect your requests to the appropriate geography and region. Therefore, the service endpoint uses the following pattern, which includes the required information:

```
https://inventoryservice.<RegionShortName>-
il<IsLandNumber>.gateway.prod.island.powerapps.com
```

To obtain your service endpoint and runtime configuration, follow these steps.

1. On the UI version 1 navigation pane, select **Configuration**.
2. Select **Show Service Details** in the upper-right corner.
3. In the dialog box, you can find your service endpoint and configuration details.

Update the configuration

Any time that you modify the configuration and save your changes, the system saves the new configuration settings only temporarily. The changes don't take effect until you commit the new settings to the service. Follow these steps to commit new configuration settings to the service.

1. On the UI version 1 navigation pane, select **Configuration**.
2. On the navigation pane, select **Configuration**.
3. Select **Update Configuration** in the upper-right corner.

4. In the dialog box, set the **Client ID**, **Tenant ID**, and **Client secret** fields. You should have found the values for these fields when you installed the Inventory Visibility Add-in.

5. Select **Login**.

6. Review your modifications in the dialog box.

   > **Important**
   >
   > Be sure to verify all the important modifications that are about to be made to your data sources, physical measures, and dimension mappings.

7. Select **Confirm Update** to apply your configuration changes.

Partition configuration

Partition configuration controls how data is distributed. Operations that are performed inside the same partition provide better performance, at lower cost, than operations that cross partitions. The following partition configuration is included in the solution by default. Therefore, *you don't have to set it up yourself*.

Expand table

Base dimension	Hierarchy
SiteId	1
LocationId	2

> **Important**
>
> Don't customize the partition configuration. If you delete or change the configuration without official guidance, you're likely to encounter an unexpected error.

Set up the on-hand index configuration

The on-hand index configuration has the same purpose and functionality, regardless of which version of the user interface is active. For an overview of the on-hand index configuration and examples that show how it works, see On-hand index configuration.

This section describes only how to find the on-hand index configuration settings in UI version 1.

1. On the UI version 1 navigation pane, select **Configuration**.
2. On the **Product Index Hierarchy** tab, add sets and dimensions as you require. Add dimensions in order, according to the hierarchy that you want to create. For information about what the settings mean and how they work, including some examples, see On-hand index configuration. Set and dimensions numbers are automatically generated as you make modifications.
3. Update the configuration to apply your changes.

Feature management

The following table shows the features that Inventory Visibility offers. Each of these features can be turned on or off for your environment.

Expand table

Feature name	Description
Available to promise	Track your available to promise (ATP) across all data sources and channels.
Inventory allocation	Allocate your valuable on-hand stock to your most important channels, customers, or predefined groups, and track the consumption of each allocated pool.
Advanced warehouse inventory	Sync and view advanced warehouse item inventory by using warehouse hierarchies.
Soft reservation	Post your omnichannel reservations to Inventory Visibility soft reservations for real-time inventory availability checks and updates.
Inventory log history	Enable Inventory Visibility to store your successful transaction logs. You can query the log history for details about the organization, product, date range, site, and warehouse.
Inventory summary	Periodically sync your raw inventory summary from the cache to Dataverse. This feature isn't compatible with advanced warehouse items. Enable either this feature or the *Preloaded on-hand* feature. Don't enable both features.
Preload on-hand	Periodically preload the inventory summary to Dataverse from a query result. The query result can be configured with the dimensions that are most relevant to your business. This feature is compatible with advanced warehouse items. Enable either this feature or the *Inventory summary* feature. Don't enable both features.

By default, all these features are disabled. To turn a feature on or off, and to make related configuration settings, follow these steps.

1. On the UI version 1 navigation pane, select **Configuration**.
2. Find the tile for the feature that you want to turn on or off, and then select **Manage**.
3. On the **Feature management & settings** tab, use the option for each feature that's listed to turn it on or off. More fields might be added to the page when some features are turned on. For more information, see the documentation for the feature that you're setting up.
4. Update the configuration to commit your changes so that they take effect.

Delete all configurations

If necessary, you can delete all configurations except those in the *fno* and *@iv* Inventory Visibility data sources. Deleted configurations can't be restored.

1. On the UI version 1 navigation pane, select **Configuration**.
2. Select the **More** menu (three dots) in the upper-right corner, and then select **Delete all configurations**.

Delete all inventory data

If necessary, you can delete all Inventory Visibility data, except configurations, in both the cache and Dataverse. Deleted data can't be restored, and users are blocked until deletion is completed.

1. On the UI version 1 navigation pane, select **Configuration**.
2. Select the **More** menu (three dots) in the upper-right corner, and then select **Delete all inventory data**.

Inventory queries and updates

The **Operational visibility** page provides tabs where you can perform real-time on-hand inventory queries and updates. When the soft reservation or inventory allocation feature is turned on, you can also post reservation or allocation requests. For more information about API requests, see Inventory Visibility public APIs.

The following subsections provide details about how to set up and use each tab.

On-hand query

Use the **Onhand query** tab of the **Operational visibility** page to query real-time on-hand inventory. Follow these steps to set up and run a query.

1. On the UI version 1 navigation pane, select **Operational visibility**.
2. On the **Onhand query** tab, enter the **Organization ID**, **Site ID**, and **Location ID** values of the products that you want to find.
3. In the **Product ID** field, enter one or more product IDs to get an exact match for your query. Alternatively, leave the field blank to include all products in the specified organization, site, and location.
4. To get a more granular result (for example, a view that's grouped by dimensions such as color and size), select the dimensions to group by in the **Group result by** field.
5. To filter items that have a specific dimension value (for example, color = red), select the dimension in the **Filter dimensions** field, and then enter the value.
6. To include ATP information, select the **Query ATP** checkbox.
7. Select **Query** to send the request.

Reservation posting

Use the **Reservation posting** tab of the **Operational visibility** page to make soft reservations of inventory.

> **Important**
>
> The capability to make soft reservations through the user interface should be used only to test the feature. Every soft reservation request should be associated with a transaction order line change (create, modify, delete, and so on). Therefore, we recommend that you make only soft reservations that are linked to back-end orders. Learn more in Inventory Visibility soft reservations.

Follow these steps to set up and submit a soft reservation.

1. On the UI version 1 navigation pane, select **Operational visibility**.
2. On the **Reservation posting** tab, in the **Quantity** field, enter the quantity that you want to soft reserve.
3. Select the **Enable negative inventory to support oversell** checkbox to skip the available-for-reservation check, or clear it to enforce the check.
4. In the **Operator** field, select the data source and physical measure to make the soft reservation on.
5. Enter the **Organization ID**, **Site ID**, **Location ID**, and **Product ID** values that you want to soft reserve.

6. In the **Dimension** field, select a data source. Then add dimensions from that data source, and enter values for each of the selected dimensions.
7. Select **Post** to send the request.
8. Select **Show details** to view a detailed response, including the `reservationId` value.

Inventory allocation

The inventory allocation feature lets sales planners or key account managers manage and preallocate important stock across allocation groups (such as channels, regions, and customer groups). It also supports real-time tracking, adjustment, and analytics of consumption against allocated quantities, to ensure that replenishment or reallocation can be done on time. The ability to have real-time visibility into allocation, consumption, and allocation balance is especially important at fast-sale or promotion events.

For more information about inventory allocation, including information about how to work with it in the Inventory Visibility app, see Inventory Visibility inventory allocation

Search for products in the Inventory Visibility app

The *product search* feature lets users search for products and on-hand inventory information based on specific attributes, such as size and color. For information about how to set up this feature, see Set up product search for Inventory Visibility. For information about how to use it in the Inventory Visibility app, see Search for products using the Inventory Visibility app.

Feedback

Was this page helpful? Yes No

Provide product feedback

Search for products using the Inventory Visibility app

The *product search* feature lets users search for products and on-hand inventory information based on specific attributes, such as size and color. It provides the following benefits:

- **Time savings** – Users can quickly find products that meet their exact requirements without having to do extensive browsing. Therefore, the feature helps improve the user experience and save valuable time.
- **Higher confidence** – Attribute-based search ensures that users get exactly what they're looking for. Therefore, user confidence increases.
- **Increased product visibility** – Attribute-based search can highlight products that are less often searched for but still potentially relevant. Therefore, users are exposed to a broader range of options that they might not have considered.

This feature is accessible both through the Inventory Visibility app in Microsoft Power Apps and through the API. This article describes how to search for products by using the Inventory Visibility app in Power Apps.

Prerequisites

Before you can search for products in the Inventory Visibility app, your system must meet the following requirements:

- You must be running Dynamics 365 Supply Chain Management 10.0.36 or later.
- Inventory Visibility version 1.2.2.54 or later must be installed and set up as described in Install and set up Inventory Visibility.
- The Inventory Visibility search service must be installed and set up as described in Set up product search for Inventory Visibility.

Search for products using attribute filters

When you search by using attribute filters, you select one or more specific product attributes (such as product number, color, and brand). You also specify the value that you're looking for in each attribute. The search results include all products that match all the specified values.

To search for products by using attribute filters in the Inventory Visibility app, follow these steps:

1. Sign in to your Power Apps environment.
2. Open the **Inventory Visibility** app.
3. Open the **Product search** page from the left pane.
4. In the **Attribute filters** pane, find and select the attribute that you want to filter by. A **Find attribute** field is provided to help you find the attribute that you're looking for.
5. A dropdown dialog box appears, where you can select a logical operator (such as *Is exactly*, *Contains*, or *Begins with*), and then enter or select the value that you're looking for. When you've finished, select **OK**.
6. Your new criterion is added to the **Filtered by** list at the top of the **Attribute filters** pane. You can remove any filter that's listed here by selecting its **Close** (**X**) button.
7. Repeat steps 4 through 6 to add more filters as you require. If you include more than one criterion in the filter, the search results include only products that match *all* the criteria. (The criteria are combined by using an *AND* operator.)
8. When you're ready to run the search, select **Apply** at the bottom of the **Attribute filters** pane.
9. The main part of the page lists all matching products. For each product, the list shows the product name, a short description, and the total quantity that's available in inventory.
10. To view more inventory details about a product, select its checkbox in the list. You can select more than one product. When you've finished selecting products, select **View inventory**.

> ⓘ **Note**
>
> You can't combine attribute search criteria with quick search criteria. If you do one type of search and then do the other type of search, the first search results are cleared.

Search for products using quick search

Quick search provides a single search field that matches products based only on their product number or product name. It doesn't support searching by other attributes. The search results include all products that include the specified value in their product number, their product name, or both.

To search for products by using only a product number or product name, follow these steps:

1. Sign in to your Power Apps environment.
2. Open the **Inventory Visibility** app.
3. Open the **Product search** page from the left pane.

4. In the main part of the page, in the field under the **What do you want to search?** heading, enter a product name or number. Then select the search button next to the field.
5. The main part of the page lists all matching products. For each product, the list shows the product name, a short description, and the total quantity that's available in inventory.
6. To view more inventory details about a product, select its checkbox in the list. You can select more than one product. When you've finished selecting products, select **View inventory**.

> **Note**
>
> You can't combine attribute search criteria with quick search criteria. If you do one type of search and then do the other type of search, the first search results are cleared.

Configure Inventory Visibility data sources

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article offers a comprehensive overview of data source configuration for Inventory Visibility. It covers the essential steps for setting up and optimizing data source configurations to enhance your inventory management processes.

Each data source configuration includes the following components:

- Data source name
- Dimensions (dimension mapping)
- Physical measures
- Calculated measures

> **Note**
>
> If you recently transitioned from UI version 1 to UI version 2, see the Differences between Inventory Visibility UI version 1 and UI version 2 section of this article to learn what has changed.
>
> For new installations, use UI version 2 from the start. If you're still using UI version 1, test the new version, and then upgrade to UI version 2 as soon as possible.

Prerequisites

Before you begin, install and set up the Inventory Visibility Add-in as described in Install and set up Inventory Visibility.

Differences between Inventory Visibility UI version 1 and UI version 2

The Inventory Visibility app in Microsoft Power Apps supports two versions of the user interface: UI version 1 and UI version 2. Each version uses a different and independent collection of configuration settings. Therefore, you must choose which version to use.

When you're setting up data sources, UI version 2 differs from UI version 1 in the following ways:

- **Physical measures** – In UI version 2, you no longer have to specify the data source for a physical measure. By default, UI version 2 uses the current data source.
- **Calculated measures** – In UI version 2, you specify calculated measures in two steps:
    1. Set up calculated measure metadata to specify the name and data source for a calculated measure.
    2. Add calculated measure lines. Each line consists of a physical measure name and an operator (addition or subtraction) that's used to combine the line with the other lines during the calculation.

Add data sources (data source names)

Each data source represents a system that provides your data. Example data source names include *fno* (which corresponds to Dynamics 365 Supply Chain Management) and *pos* (which stands for "point of sale"). By default, Supply Chain Management is set up as a default data source (*fno*) in Inventory Visibility.

> ⓘ **Note**
>
> The *fno* data source is reserved for Supply Chain Management. If your Inventory Visibility Add-in is integrated with a Supply Chain Management environment, don't delete configurations related to *fno* in the data source.

> ⓘ **Important**
>
> When you add a data source, be sure to validate the data source name, physical measures, and dimension mappings before you update the configuration for the Inventory Visibility service. You can't modify these settings after you select **Update Configuration**.

Add a data source in UI version 2

This section applies when you're using Inventory Visibility UI version 2.

To add a data source in UI version 2, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature management**.
3. On the **Data source settings** tile, select **Manage**.
4. On the **Data source settings** page, select **New** on the toolbar to add a data source. Enter a name for the new data source (for example, *ecommerce* or another meaningful data source ID).
5. Select **Save**.

Add a data source in UI version 1

This section applies when you're using Inventory Visibility UI version 1.

To add a data source in UI version 1, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.
3. On the navigation pane, select **Configuration**.
4. On the **Data Source** tab, select **New data source** to add a data source. Enter a name for the new data source (for example, *ecommerce* or another meaningful data source ID).

> **Note**
>
> When you add a data source, be sure to validate the data source name, physical measures, and dimension mappings before you update the configuration for the Inventory Visibility service. You can't modify these settings after you select **Update Configuration**.

Dimensions (dimension mapping)

Dimension configuration standardizes multi-system integration for posting events and queries based on dimension combinations. Inventory Visibility provides a list of base dimensions that can be mapped from the dimensions of your data source. Thirty-three dimensions are available for mapping.

- If you're using Supply Chain Management as one of your data sources, 13 dimensions are already mapped to the Supply Chain Management standard dimensions by default. The other 12 dimensions (*inventDimension1* through *inventDimension12*) are also mapped to custom dimensions in Supply Chain Management. The remaining eight dimensions

(*ExtendedDimension1* through *ExtendedDimension8*) are extended dimensions that you can map to external data sources.

- If you don't use Supply Chain Management as one of your data sources, you can freely map the dimensions. The following table shows the full list of available dimensions.

> **Note**
>
> If you use Supply Chain Management, and you change the default dimension mappings between Supply Chain Management and Inventory Visibility, the changed dimension doesn't sync data. Therefore, if your dimension isn't on the default dimension list and you're using an external data source, use *ExtendedDimension1* through *ExtendedDimension8* for the mapping.

Expand table

Dimension type	Base dimension
Product	*ColorId*
Product	*SizeId*
Product	*StyleId*
Product	*ConfigId*
Tracking	*BatchId*
Tracking	*SerialId*
Location	*LocationId*
Location	*SiteId*
Inventory status	*StatusId*
Warehouse specific	*WMSLocationId*
Warehouse specific	*WMSPalletId*
Warehouse specific	*LicensePlateId*
Others	*VersionId*
Inventory (custom)	*InventDimension1* through *InventDimension12*
Extension	*ExtendedDimension1* through *ExtendedDimension8*

Dimension type	Base dimension
System	*Empty*

> **Note**
>
> The dimension types that are listed in the preceding table are for your reference only. You don't have to define them in Inventory Visibility.
>
> The inventory (custom) dimensions might be reserved for Supply Chain Management. In that case, use the extended dimensions instead.

External systems can access Inventory Visibility through its RESTful APIs. For the integration, Inventory Visibility lets you configure the *external data source* and the mapping from the *external dimensions* to the *base dimensions*. Here's an example of a dimension mapping table.

Expand table

External dimension	Base dimension
MyColorId	*ColorId*
MySizeId	*SizeId*
MyStyleId	*StyleId*
MyDimension1	*ExtendedDimension1*
MyDimension2	*ExtendedDimension2*

By configuring a dimension mapping, you can send the external dimensions directly to Inventory Visibility. Inventory Visibility then automatically converts external dimensions to base dimensions.

Add dimension mappings in UI version 2

This section applies when you're using Inventory Visibility UI version 2.

To add a dimension mapping in UI version 2, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature management**.
3. On the **Data source settings** tile, select **Manage**.

4. On the **Data source settings** page, select the data source where you want to set up a dimension mapping.

5. In the **Dimension mappings** section, select **New Dimension Mapping** on the toolbar.

6. On the **New Dimension Mapping** page, set the following fields:

    - **Customer dimension** – Enter the name of the source dimension.
    - **Base Dimension** – Select the dimension in Inventory Visibility that you want to map to.

    For example, you've already created a data source that's named *ecommerce*, and it includes a product color dimension. In this case, to do the mapping, first add *ProductColor* to the **Dimension Name** field for the *ecommerce* data source. Then select *ColorId* in the **To Base Dimension** field.

7. On the toolbar, select **Save**.

Add dimension mappings in UI version 1

To add a dimension mapping in UI version 1, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.

2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.

3. On the navigation pane, select **Configuration**.

4. On the **Data source** tab, expand the data source where you want to set up a dimension mapping.

5. In the **Dimension Mappings** section, select **Add** to add a dimension mapping row. Then set the following fields for the new row:

    - **Dimension Name** – Enter the name of the source dimension.
    - **To Base Dimension** – Select the dimension in Inventory Visibility that you want to map to.

6. Select the **Save** link for the new row.

Physical measures

When a data source posts an inventory change to Inventory Visibility, it posts that change by using *physical measures*. Physical measures modify the quantity and reflect the inventory status.

You can define your own physical measures based on your requirements. Queries can be based on the physical measures.

Inventory Visibility provides a list of default physical measures that are mapped to Supply Chain Management (the *fno* data source). These default physical measures are taken from the inventory transaction statuses on the **On-hand list** page in Supply Chain Management (**Inventory Management** > **Inquiries and Report** > **On-hand list**). The following table provides an example of physical measures.

Expand table

Physical measure name	Description
NotSpecified	Not specified
Arrived	Arrived
AvailOrdered	Available ordered
AvailPhysical	Available physical
Deducted	Deducted
OnOrder	OnOrder
Ordered	Ordered
PhysicalInvent	Physical inventory
Picked	Picked
PostedQty	Posted quantity
QuotationIssue	Quotation issue
QuotationReceipt	Quotation receipt
Received	Received
Registered	Registered
ReservOrdered	Ordered reserved
ReservPhysical	Physical reserved
OrderedSum	Ordered in total

If your data source is Supply Chain Management, you don't have to recreate the default physical measures. However, for external data sources, you can create new physical measures as you

require.

Add physical measures in UI version 2

This section applies when you're using Inventory Visibility UI version 2.

To add a physical measure in UI version 2, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature management**.
3. On the **Data source settings** tile, select **Manage**.
4. On the **Data source settings** page, select the data source where you want to do the dimension mapping. Then, in the **Physical Measure** section, select **New physical measure** on the toolbar.
5. On the **New physical measure** page, set the following fields for the new physical measure:
    - **Display name** – Enter a name that's unique not only within the new measure's own data source but also across all data sources. The recommended format is *<Data source>.<Physical measure name>* (for example, *ecommerce.returned*). This format ensures that the display name is distinct and unique across all data sources.
    - **Physical measure name** – Enter the name of the physical measure.
6. On the toolbar, select **Save**.

Add physical measures in UI version 1

This section applies when you're using Inventory Visibility UI version 1.

To add a physical measure in UI version 1, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.
3. On the navigation pane, select **Configuration**.
4. On the **Data source** tab, expand the data source where you want to set up a physical measure.
5. In the **Physical measure** section, select **Add** to add a physical measure row. Then, in the **Measure name** field for the new row, enter the name of the measure. For example, enter *Returned* if you want to record returned quantities in this data source for Inventory Visibility.

6. Select the **Save** link for the new row.

Extended dimensions

If you're using external data sources, you can take advantage of the extensibility that the solution offers by creating class extensions for the `InventOnHandChangeEventDimensionSet` and `InventInventoryDataServiceBatchJobTask` classes.

Synchronize with the database after creating the extensions so that the custom fields are added to the `InventSum` table. You can then refer to the "Dimensions" section earlier in this article, to map your custom dimensions to any of the eight extended dimensions in `BaseDimensions` in Inventory.

> **Note**
>
> For additional details about creating extensions, see Extensibility home page.

Calculated measures

Inventory Visibility lets you query both inventory physical measures and *custom calculated measures*. Calculated measures provide a customized computation formula that consists of a combination of physical measures. This functionality lets you define a set of physical measures that are added, and/or a set of physical measures that are subtracted, to form the customized measurement.

> **Important**
>
> A calculated measure is a composition of physical measures. Its formula can include only physical measures without duplicates, not calculated measures.

The configuration lets you define a set of calculated measure formulas that includes modifiers of addition or subtraction to get the total aggregated output quantity.

Add calculated measures in UI version 2

This section applies when you're using Inventory Visibility UI version 2.

To add a calculated measure in UI version 2, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature management**.
3. On the **Data source settings** tile, select **Manage**.
4. On the **Data source settings** page, select the data source where you want to do the dimension mapping. Then, in the **Calculated measures** section, select **New calculated measure** on the toolbar.
5. On the **New calculated measure** page, set the following fields for the new calculated measure:
    - **Calculated measure display name** – Enter a name that's unique not only within the new measure's own data source but also across all data sources. The recommended format is *<Data source>.<Calculated measure name>* (for example, *iv.TotalAvailable*). This format ensures that the display name is distinct and unique across all data sources.
    - **Calculated measure name** – Enter the name of the calculated measure.
6. On the toolbar, select **Save & close**. The page is refreshed and now includes the **Calculated measure details** section.
7. In the **Calculated measure details** section, select **New calculated measure details V2** on the toolbar to add a modifier row for the calculated measure.
8. On the **New calculated measure detail** page, set the following fields for the new modifier:
    - **Calculated measure formula description** – Enter a detailed explanation of the significance and purpose of the formula in the calculated measure.
    - **+/- to result** – Select the modifier type (*Addition* or *Subtraction*).
    - **Physical measure name reference** – Select the name of the measure (from the selected data source) that provides the value for the modifier.
9. On the toolbar, select **Save & close**.
10. Repeat steps 7 through 9 until you've added all the modifiers that are required to complete the formula for your calculated measure.
11. On the toolbar, select **Save**.

Add calculated measures in UI version 1

This section applies when you're using Inventory Visibility UI version 1.

To add a calculated measure in UI version 1, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.
3. On the navigation pane, select **Configuration**.
4. On the **Calculated measure** tab, select **New Calculate Measure** to add a calculated measure.
5. Set the following fields for the new calculated measure:
    - **New calculated measure name** – Enter the name of the calculated measure.
    - **Data source** – Select the data source to include the new calculated measure in. The querying system is a data source.
6. A new, blank modifier line is automatically included for the new calculated measure. Set the following fields for it:
    - **Modifier** – Select the modifier type (*Addition* or *Subtraction*).
    - **Data source** – Select the data source where the measure that provides the modifier value is found.
    - **Measure** – Select the name of the measure (from the selected data source) that provides the value for the modifier.
7. Select **Save measure** to save your settings so far.
8. If you must add another modifier line, select **Add** to add a row, and then set the fields as you did for the first row. When you finish, select the **Save** link for the row.
9. Repeat the previous step until you've added all the required modifiers and completed the formula for your calculated measure.
10. Select **Save**.

Work with calculated measures in Inventory Visibility

For example, a fashion company operates across three data sources:

- `pos` – Corresponds to the store channel.

- `fno` – Corresponds to Supply Chain Management.
- `ecommerce` – Corresponds to your web channel.

Without calculated measures, when you query for product D0002 (Cabinet) under site 1, warehouse 11, and a `ColorID` dimension value of `Red`, you might get the following query result, which shows inventory quantities under each preconfigured physical measure. However, you don't have visibility into the total available for reservation quantities across your data sources.

JSON

```
[
    {
        "productId": "D0002",
        "dimensions": {
            "SiteId": "1",
            "LocationId": "11",
            "ColorId": "Red"
        },
        "quantities": {
            "pos": {
                "inbound": 80.0,
                "outbound": 20.0
            },
            "fno": {
                "availphysical": 100.0,
                "orderedintotal": 50.0,
                "orderedreserved": 10.0
            },
            "ecommerce": {
                "received": 90.0,
                "scheduled": 30.0,
                "issued": 60.0,
                "reserved": 40.0
            }
        }
    }
]
```

You then configure a calculated measure that's named `MyCustomAvailableforReservation`, as shown in the following table. This calculated measure is consumed by the consumption system.

Expand table

Consumption system	Calculated measure	Data source	Physical measure	Calculation type
`CrossChannel`	`MyCustomAvailableforReservation`	`fno`	`availphysical`	`Addition`

Consumption system	Calculated measure	Data source	Physical measure	Calculation type
`CrossChannel`	`MyCustomAvailableforReservation`	`fno`	`orderedintotal`	`Addition`
`CrossChannel`	`MyCustomAvailableforReservation`	`fno`	`orderedreserved`	`Subtraction`
`CrossChannel`	`MyCustomAvailableforReservation`	`pos`	`inbound`	`Addition`
`CrossChannel`	`MyCustomAvailableforReservation`	`pos`	`outbound`	`Subtraction`
`CrossChannel`	`MyCustomAvailableforReservation`	`ecommerce`	`received`	`Addition`
`CrossChannel`	`MyCustomAvailableforReservation`	`ecommerce`	`scheduled`	`Addition`
`CrossChannel`	`MyCustomAvailableforReservation`	`ecommerce`	`issued`	`Subtraction`
`CrossChannel`	`MyCustomAvailableforReservation`	`ecommerce`	`reserved`	`Subtraction`

When you use this computation formula, the new query result includes the customized measurement.

JSON

```
[
    {
        "productId": "D0002",
        "dimensions": {
            "SiteId": "1",
            "LocationId": "11",
            "ColorId": "Red"
        },
        "quantities": {
            "pos": {
                "inbound": 80.0,
                "outbound": 20.0
            },
            "fno": {
                "availphysical": 100.0,
                "orderedintotal": 50.0,
                "orderedreserved": 10.0
            },
            "ecommerce": {
                "received": 90.0,
                "scheduled": 30.0,
                "issued": 60.0,
                "reserved": 40.0
            },
            "CrossChannel": {
                "MyCustomAvailableforReservation": 220.0
            }
        }
```

```
    }
]
```

The `MyCustomAvailableforReservation` output, based on the calculation setting in the custom measurements, is 100 + 50 – 10 + 80 – 20 + 90 + 30 – 60 – 40 = 220.

The default data source configuration

This section provides details about the default data source configuration that's set up when you install Inventory Visibility. You can modify this configuration as needed.

> **ⓘ Important**
>
> The default configuration has evolved through various version iterations. It's possible that your sandbox environment was initially set up with an outdated default configuration, while your production environment was initialized with the latest version of the default configuration. If you've customized your third-party system based on an outdated default configuration, it might encounter issues when your production environment goes live, especially if you haven't reviewed and adjusted the configuration. To prevent this scenario, thoroughly review and update your draft and runtime configurations before transitioning your production environment.

Data source configuration

Configuration of the iv data source

This section describes how the *iv* data source is configured.

Physical measures configured for the "iv" data source

The following physical measures are configured for the *iv* data source:

- *Ordered*
- *Softreserved*

AvailableToReserve calculated measure

The *AvailableToReserve* calculated measure is configured for the *iv* data source as shown in the following table.

Expand table

Calculation type	Data source	Physical measure
Addition	*fno*	*PhysicalInvent*
Addition	*fno*	*Ordered*
Addition	*fno*	*Arrived*
Addition	*pos*	*Inbound*
Addition	*iv*	*Ordered*
Subtraction	*fno*	*ReservPhysical*
Subtraction	*iv*	*Softreserved*
Subtraction	*pos*	*Outbound*
Subtraction	*fno*	*Softreserved*

TotalAvailable calculated measure

The *TotalAvailable* calculated measure is configured for the *iv* data source as shown in the following table.

Expand table

Calculation type	Data source	Physical measure
Addition	*fno*	*AvailOrdered*
Subtraction	*iv*	*Softreserved*
Subtraction	*@iv*	*@allocated*

TotalOnHand calculated measure

The *TotalOnHand* calculated measure is configured for the *iv* data source as shown in the following table.

Expand table

Calculation type	Data source	Physical measure
Addition	*fno*	*PhysicalInvent*

Configuration of the "fno" data source

This section describes how the *fno* data source is configured.

Dimension mappings for the "fno" data source

The dimension mappings that are listed in the following table are configured for the *fno* data source.

Expand table

External dimension	Base dimension
InventBatchId	*BatchId*
InventColorId	*ColorId*
InventLocationId	*LocationId*
InventSerialId	*SerialId*
InventSiteId	*SiteId*
InventSizeId	*SizeId*
InventStatusId	*StatusId*
InventStyleId	*StyleId*
LicensePlateId	*LicensePlateId*
WMSLocationId	*WMSLocationId*
WMSPalletId	*WMSPalletId*
ConfigId	*ConfigId*
InventVersionId	*VersionId*
InventDimension1	*CustomDimension1*
InventDimension2	*CustomDimension2*
InventDimension3	*CustomDimension3*
InventDimension4	*CustomDimension4*
InventDimension5	*CustomDimension5*
InventDimension6	*CustomDimension6*

External dimension	Base dimension
InventDimension7	*CustomDimension7*
InventDimension8	*CustomDimension8*
InventDimension9	*CustomDimension9*
InventDimension10	*CustomDimension10*
InventDimension11	*CustomDimension11*
InventDimension12	*CustomDimension12*

Physical measures configured for the "fno" data source

The following physical measures are configured for the *fno* data source:

- *Arrived*
- *PhysicalInvent*
- *ReservPhysical*
- *onorder*
- *notspecified*
- *availordered*
- *availphysical*
- *picked*
- *postedqty*
- *quotationreceipt*
- *received*
- *ordered*
- *ReservOrdered*
- *OrderedSum*
- *SoftReserved*

Configuration of the "pos" data source

This section describes how the data source *pos* is configured.

Physical measures for the "pos" data source

The following physical measures are configured for the *pos* data source:

- *Inbound*

- *Outbound*

AvailQuantity calculated measure

The *AvailQuantity* calculated measure is configured for the *pos* data source as shown in the following table.

Expand table

Calculation type	Data source	Physical measure
Addition	*fno*	*AvailPhysical*
Addition	*pos*	*Inbound*
Subtraction	*pos*	*Outbound*

Configuration of the "iom" data source

The following physical measures are configured for the *iom* (Intelligent Order Management) data source:

- *OnOrder*
- *OnHand*

Configuration of the "erp" data source

The following physical measures are configured for the *erp* (enterprise resource planning) data source:

- *Unrestricted*
- *QualityInspection*

Inventory Visibility support for WMS items

This article describes Inventory Visibility support for items that are enabled for warehouse management processes (WMS). The feature that adds this capability to Inventory Visibility is named *Advanced WMS*.

WMS items

A WMS item is an item that's enabled for WMS and processed at a warehouse that's also WMS enabled.

For more information about WMS and the **Warehouse management** module in Microsoft Dynamics 365 Supply Chain Management, see Warehouse management overview.

Scope of the feature

The Advanced WMS feature for Inventory Visibility focuses on on-hand quantity calculations that are based on on-hand queries. The feature isn't intended to let you use Inventory Visibility to manage warehouse processing activities in general. Inventory Visibility doesn't expose warehouse-specific concepts to its users. Here are some examples of these concepts:

- Reservation hierarchy
- Whether an item or warehouse is WMS enabled
- Unit sequence group ID
- Warehouse-specific processes, such as shipments, loads, waves, and work

Inventory Visibility infers this information, based on the data that's sent from Supply Chain Management. The WMS-specific data (in other words, data from the `WHSInventReserve` table) isn't visible to users.

When you use the Advanced WMS feature for Inventory Visibility, all query results will be identical to the results from queries that are made directly in Supply Chain Management. However, they won't be identical to the results from queries that are made by using the Warehouse Management mobile app, because the mobile app uses slightly different calculation logic.

When to use the feature

We recommend that you use the WMS feature for Inventory Visibility in scenarios where all the following conditions are met:

- You're syncing Supply Chain Management data with Inventory Visibility.
- You're using WMS in Supply Chain Management.
- Users make reservations for WMS items at levels below the warehouse level (for example, at the license plate level because you're processing warehouse work).

In other scenarios, on-hand query results will be the same, regardless of whether the Advanced WMS feature for Inventory Visibility is enabled. Additionally, performance will be better if you don't enable the feature in these scenarios, because there are fewer calculations and less overhead.

Enable the WMS feature for Inventory Visibility

To enable the WMS feature for Inventory Visibility, follow these steps:

1. Sign in to Supply Chain Management as an admin.

2. Open the Feature management workspace, and enable the following features in this order:
   a. *Inventory Visibility integration* (As of Supply Chain Management version 10.0.45, this feature is turned on by default.)
   b. *Enable warehouse items in Inventory Visibility* (As of Supply Chain Management version 10.0.45, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.)

3. Go to **Inventory Management** > **Setup** > **Inventory Visibility integration parameters**.

4. On the **Enable WMS items** tab, set the **Enable WMS items sync** option to *Yes*. Then save the setup.

5. Select **Sync WMS data** to sync the WMS data to Inventory Visibility. This step is required because, when you first enable the synchronization of WMS items, only subsequent changes to on-hand quantities of WMS items will be synced to Inventory Visibility. When you select **Sync WMS data**, the system syncs all available WMS data to Inventory Visibility. This synchronization might take a long time, depending on your data volume. Therefore, we recommend that you complete this step during off-peak hours.

If you're using the new user interface for the Inventory Visibility app (UI version 2), the WMS feature is turned on by default. Therefore, you're ready to query on-hand quantities of WMS items. If you're using the old user interface (UI version 1), you must turn on the *Advanced*

warehouse inventory feature in the Inventory Visibility app in Power Apps before you can query for WMS items. Follow these steps to turn on the feature.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.
3. On the navigation pane, select **Configuration**.
4. On the **Feature management & settings** tab, turn on the *Advanced warehouse inventory* feature.

Choose whether to truncate unused dimensions

This section applies when you're using Inventory Visibility UI version 2. If you want to use the feature that's described here, but you're still using UI version 1, consider updating to UI version 2.

When you use the WMS feature, you can choose to truncate dimensions that you aren't using. The system can then accept queries that exclude specific dimensions. This functionality helps increase query performance and reduce the amount of storage that's required for the feature. Unused dimensions are truncated by default when you sync WMS data from Supply Chain Management, unless one or more of the following dimensions are included in your index hierarchy:

- Batch ID
- Serial ID
- License plate ID
- WMS Location ID

If you're using any of the preceding dimensions, but you haven't added them to your index hierarchy, you should disable the **Truncate unused dimensions** option by following these steps.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature management**.
3. On the **Advanced warehouse inventory** tile, select **Manage**.
4. Set the **Truncate unused dimensions** option to *No*.
5. On the toolbar, select **Save & close**.
6. On the navigation pane, select **Admin settings**.
7. On the **Update configuration** tile, select **Manage**.

8. Review your modifications in the dialog box.

> **Important**
>
> Be sure to verify all the important modifications that are about to be made to your data sources, physical measures, and dimension mappings.

9. Select **Confirm Update** to apply your configuration changes.

> **Important**
>
> If you turn off the **Truncate unused dimensions** option after you've already synced some WMS item data from Supply Chain Management, you must sync WMS data to ensure that all the previously truncated dimension data is re-synced to Inventory Visibility.

Query on-hand quantities of WMS items

To query for WMS items, you use the same application programming interface (API) and message syntax that you use for non-WMS items. You don't have to specify whether an item is a WMS item or a non-WMS item. Inventory Visibility automatically distinguishes items, based on the data that's stored.

The results from queries for WMS items are essentially the same as the results for non-WMS items. The only difference is that the following physical measures from the `fno` data source are calculated based on WMS logic in Supply Chain Management:

- `AvailOrdered`
- `AvailPhysical`
- `ReservOrdered`
- `ReservPhysical`

All other physical measures are calculated just as they are when the WMS feature for Inventory Visibility is disabled.

You can find detailed information about how on-hand calculations for WMS items work in Reservations in Warehouse management.

On-hand list view and data entity for WMS items

The **Preload the Inventory Visibility Summary** page provides a view for the *On-hand Index Query Preload Results* entity. Unlike the *Inventory summary* entity, the *On-hand Index Query Preload Results* entity provides an on-hand inventory list for products together with selected dimensions. Inventory Visibility syncs the preloaded summary data every 15 minutes.

If you use Inventory Visibility with WMS items and want to view the on-hand list for WMS items, we recommend that you enable the *Preload the Inventory Visibility Summary* feature. (Learn more in Preload a streamlined on-hand query.) A corresponding data entity in Dataverse stores your preloaded query result, which is updated every 15 minutes. The name of the data entity is *Onhand Index Query Preload Result*.

> **Important**
>
> The Dataverse entity is read-only. You can view and export the data in the Inventory Visibility entities, but **don't modify it**.

Changes to WMS item quantities that are stored in the Supply Chain Management data source (`fno`) are prohibited. This behavior matches the behavior of other features of Inventory Visibility. This restriction is enforced to help prevent conflicts.

WMS item compatibility for other functions in Inventory Visibility

Soft reservations and inventory allocation of WMS items are supported. You can include WMS-related physical measures in soft reservation and allocation calculations.

Calculate available-to-promise quantities

The solution fully supports available to promise (ATP) for WMS items. You can define ATP calculations without worrying about WMS-specific details.

Last updated on 07/27/2026

Inventory Visibility inventory summary

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The **Inventory summary** page is a customized view for the *Inventory OnHand Sum* entity. It provides an inventory summary for products together with all dimensions. Inventory summary data is periodically synced from Inventory Visibility.

The **Inventory summary** feature isn't compatible with items enabled for warehouse management processes (WMS).

> **Note**
>
> The inventory summary feature tracks only on-hand inventory changes that occur after you turn on the feature. Data for products that haven't changed since you turned on the feature isn't synced from the Inventory Visibility cache to the Microsoft Dataverse environment.
>
> If you change the settings for a calculated measure, data on the **Inventory summary** page isn't automatically updated until the related product data is modified.
>
> If the **Inventory summary** page doesn't show all the on-hand information that you expect, open Dynamics 365 Supply Chain Management, go to **Inventory Management** > **Periodic tasks** > **Inventory Visibility integration**, disable the batch job, and then reenable it to do the initial push. All data is synced to the *Inventory OnHand Sum* entity immediately after the initial push. If you want to use the inventory summary feature, turn it on before you create any on-hand changes and enable the **Inventory Visibility integration** batch job.

Turn on the inventory summary feature in UI version 2

This section applies when you're using Inventory Visibility UI version 2.

To enable the **Inventory summary** page and set the synchronization frequency in UI version 2, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature management**.
3. On the **Inventory summary** tile, select **Manage**.
4. Set the following fields:
    - **Enable feature** – Set this option to *True*.
    - **Synchronize frequency** – Set the frequency (in minutes) that inventory summary data should be synced at. The minimum frequency is five minutes.
5. On the toolbar, select **Save & close**.
6. On the navigation pane, select **Admin Settings**.
7. On the **Update configuration** tile, select **Manage**.
8. Review your modifications in the dialog box.

    > ⓘ **Important**
    >
    > Be sure to verify all the important modifications that are about to be made to your data sources, physical measures, and dimension mappings.

9. Select **Confirm Update** to apply your configuration changes.

Turn on the inventory summary feature in UI version 1

To enable the **Inventory summary** page and set the synchronization frequency in UI version 1, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.
3. On the navigation pane, select **Configuration**.
4. On the **Feature management & settings** tab, turn on the option for the *Inventory summary* feature.
5. After the feature is enabled, the **Service Configuration** section becomes available. It includes a row that you can use to configure the *OnHandMostSpecificBackgroundService*

feature. To set the frequency that inventory summary data is synced at, use the **Up** and **Down** buttons in the **Value** field to change the interval between synchronizations. The minimum interval is five minutes. When you finish, select **Save**.

6. Select **Update configuration** to save and apply your new settings.

Filter and browse the inventory summaries

Follow these steps to open the **Inventory summary** page, where you can filter and browse your inventory summaries.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Inventory Visibility**.
3. On the navigation pane, select **Inventory summary**.

    - On the **Inventory summary** page, there are three fields above the grid: **Default dimension**, **Custom dimension**, and **Measure**. Use these fields to control which columns are visible. You can also select any column header in the grid to filter or sort the current result by that column.
    - Use the **Edit filters** button in the upper right of the page to create a personal view that shows the rows that are important to you. The filter options let you create a wide range of views, from simple to complex. They also let you add grouped and nested conditions to the filters. For more information about how to use the advanced filter, see Edit or create personal views using advanced grid filters.
    - The lower left of the page shows information such as *2 records (2 selected)* or *50 records*. This information refers to the records that are currently loaded from the **Edit filters** result. The text *2 selected* refers to the number of records that have been selected by using the column header filters for the loaded records. There's a **Load More** button that you can use to load more records from Dataverse. By default, 50 records are loaded. When you select **Load More**, the next 1,000 available records are loaded into the view. The numbers on the **Load More** button indicate the number of currently loaded records and the total number of records that the **Edit filters** result found. For example, the text *(5/5)* indicates that all five of the records from the **Edit filters** result are currently loaded into the view.

The following illustration highlights the dimension, filtering, result count, and "load more" fields on the **Inventory summary** page.

Preload a streamlined on-hand query

06/17/2025

Microsoft Dynamics 365 Supply Chain Management stores lots of information about your current on-hand inventory and makes it available for a wide range of purposes. However, many everyday operations and third-party integrations require just a small subset of the stored details. If the system is queried for all of them, the result can be large data sets that take time to assemble and transfer. Therefore, the Inventory Visibility service can periodically fetch and store a streamlined set of on-hand inventory data to make that optimized information continuously available. The stored on-hand inventory details are filtered based on configurable business criteria, to ensure that only the most relevant information is included. Because the filtered on-hand inventory lists are stored locally in the Inventory Visibility service and regularly updated, they support quick access, on-demand data exports, and streamlined integration with external systems.

Preloaded on-hand queries provide the following benefits:

- A cleaner view that stores an inventory summary that includes only the dimensions that are relevant to your daily business
- An inventory summary that's compatible with items that are enabled for warehouse management processes (WMS)

> **Important**
>
> We recommend that you use either the *Preloaded onhand* feature or the *Inventory summary* feature, but not both. If you enable both features, performance will be affected.

The **Onhand index query preload results** page provides a view for the *On-hand Index Query Preload Results* entity. Unlike the *Inventory summary* entity, the *On-hand Index Query Preload Results* entity provides an on-hand inventory list for products together with selected dimensions. Inventory Visibility syncs the preloaded summary data every 15 minutes.

> **Note**
>
> Like the *Inventory summary* feature, the *Preloaded onhand* feature tracks only on-hand inventory changes that occur after you turn on the feature. Data for products that haven't changed since you turned on the feature isn't synced from the inventory service cache to the Dataverse environment.
>
> If you change the settings for a calculated measure, data on the **Onhand index query preload results** page isn't automatically updated until the related product data is

modified.

If the **Onhand index query preload results** page doesn't show all the on-hand information that you expect, go to **Inventory management** > **Periodic tasks** > **Inventory Visibility integration**, disable the batch job, and then reenable it to do the initial push. All data will be synced to the *On-hand Index Query Preload Results* entity within 15 minutes. If you want to use this feature, we recommend that you turn it on before you create any on-hand changes and enable the **Inventory Visibility integration** batch job.

Turn on and configure preloaded on-hand queries in UI version 2

This section applies when you're using Inventory Visibility UI version 2.

To turn on and configure preloaded on-hand queries in UI version 2, follow these steps.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature management**.
3. On the **Preloaded onhand** tile, select **Manage**.
4. Set the **Enable feature** option to *True*.
5. In the **Preload group by dimensions** section, add a row for each dimension that you want to use for preloaded on-hand queries. The dimensions that you add here are used to group the preloaded on-hand data.
    - To add a row, select **New onhand index query preload configuration** on the toolbar. Set the **Group by value** field to the dimension that you want to group by, and then assign an order. Preloaded on-hand queries use only dimensions from set number *0* as group-by values. Other sets are ignored. When you've finished, select **Save & Close** on the toolbar.
    - To modify a row, select the **Preload set number** link to open the row settings, edit the fields as you require, and then select **Save & Close** on the toolbar.
    - To remove a row, select the **Preload set number** link to open the row settings, and then select **Delete** on the toolbar.
6. If you changed the group-by configuration, select **Admin settings** on the navigation pane, and then, on the **Delete preloaded onhand data** tile, select **Manage**. This step cleans up the database and makes it ready to accept your new group-by settings.

7. On the navigation pane, select **Admin settings**. Then, on the **Update configuration** tile, select **Manage** to update the configuration and activate your changes.

Turn on and configure preloaded on-hand queries in UI version 1

This section applies when you're using Inventory Visibility UI version 1.

To turn on and configure preloaded on-hand queries in UI version 1, follow these steps.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.
3. On the navigation pane, select **Configuration**.
4. On the **Feature Management & Settings** tab, if the *Preloaded onhand query results* feature is already enabled, we recommend that you use the option to turn it off for now, because the cleanup process might take a long time. You'll turn the feature on again later in this procedure.
5. On the **Preload Setting** tab, in the **Step 1: Clean up preload storage** section, select **Clean** to clean up the database and make it ready to accept your new group-by settings.
6. In the **Step 2: Set up group by values** section, in the **Group result by** field, enter a comma-separated list of field names to group your query results by. After you have data in the preload storage database, you won't be able to change this setting until you clean the database as described in the previous step.
7. On the **Feature Management & Settings** tab, use the option to turn on the *Preload on-hand query results* feature.
8. Select **Update configuration** in the upper-right corner of the page to commit your changes.

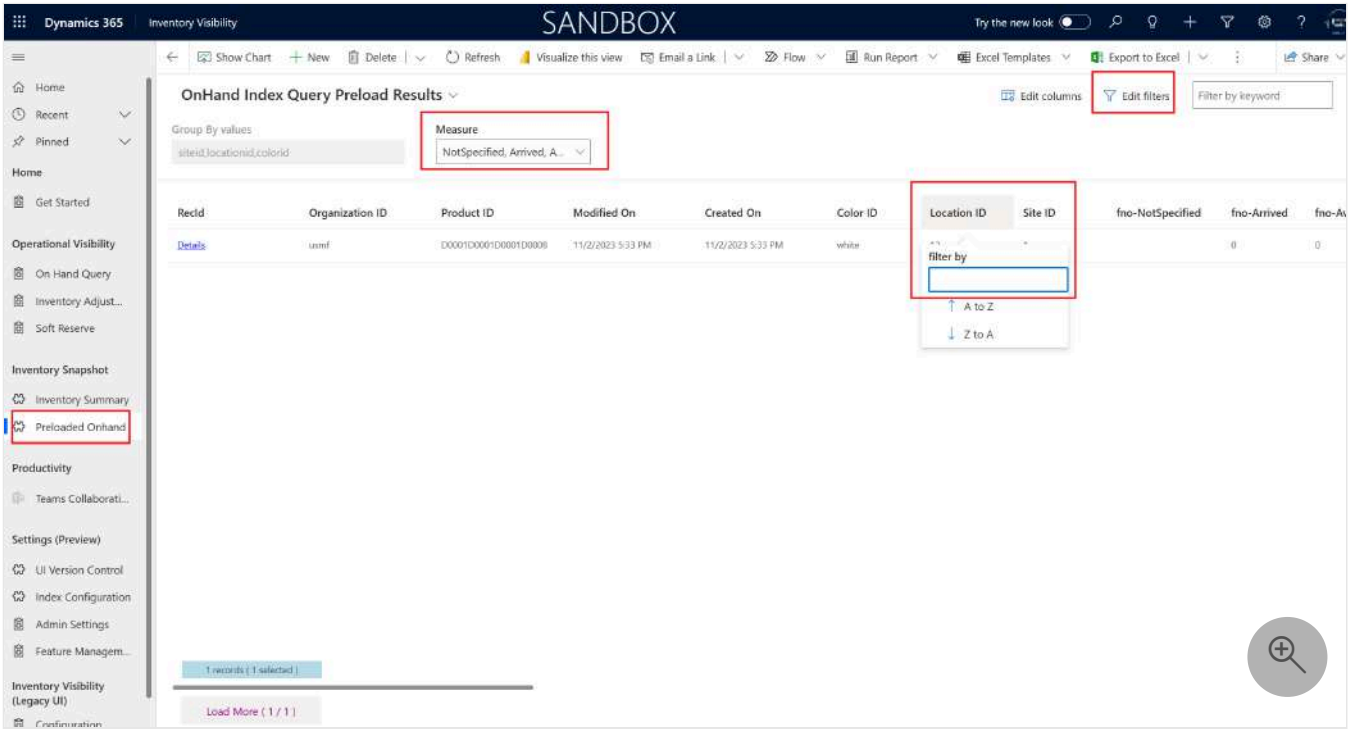
Filter and browse the preloaded query

To filter and browser the preloaded query, follow these steps.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Inventory visibility**.
3. On the navigation pane, select **Preloaded onhand**.
4. On the **Onhand index query preload results** page, you can filter and browse your preloaded summary.

- Use the **Edit filters** button to create a personal view that shows the rows that are important to you. These filter options let you create a wide range of views, from simple to complex. They also let you add grouped and nested conditions to the filters. For more information about how to use the advanced filter, see Edit or create personal views using advanced grid filters.
- Because you've predefined the dimensions that are used to load summary data, the **Onhand index query preload results** page shows dimension-related columns. *The dimensions aren't customizable. The system supports only site and location dimensions for preloaded on-hand lists.* The page provides filters that are similar to the filters on the **Inventory summary** page. However, the dimensions are already selected.
- The bottom of the page shows information such as *50 records (29 selected)* or *50 records*. This information refers to the records that are currently loaded from the **Edit filters** result. The text *29 selected* refers to the number of records that have been selected by using the column header filters for the loaded records. There's a **Load More** button that you can use to load more records from Dataverse. By default, 50 records are loaded. When you select **Load More**, the next 1,000 available records are loaded into the view. The numbers on the **Load More** button indicate the number of currently loaded records and the total number of records that the **Edit filters** result found.

The following illustration highlights the filtering fields that are available on the **Onhand index query preload results** page.



Run on-hand consistency checks while Inventory Visibility is enabled

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Microsoft Dynamics 365 Supply Chain Management provides an on-hand consistency check tool that you can use to recalculate inventory on-hand list data based on inventory transactions for selected items or all items. The tool analyzes the inventory transactions (`InventTrans`) table and then reconstructs the `InventSum` and `WHSInventReserve` tables.

> **Note**
>
> This article describes only the additional preparation that's required when the *Inventory Visibility integration* batch job is enabled. For general guidance about when and how to run an on-hand consistency check, see Run an on-hand consistency check.

If you run an on-hand consistency check on *all items* while the *Inventory Visibility integration* batch job is enabled, the following conditions apply:

- The tool usually takes longer to finish running than it does when the *Inventory Visibility integration* batch job isn't enabled.
- The tool uses API calls to sync the changes in the `InventSum` and `WHSInventReserve` tables to the Inventory Visibility service. Therefore, if the *Inventory Visibility integration* batch job is enabled, the consistency check might fail if the external calls result in unexpected errors.

For these reasons, disable the *Inventory Visibility integration* batch job before you run an on-hand consistency check on all items.

Prepare for and run an on-hand consistency check on all items

Before you run an on-hand consistency check on all items, follow these steps:

1. Go to **Inventory Management** > **Periodic Tasks** > **Inventory Visibility integration**.
2. Check the **Status** value to determine whether the job is enabled.
    - If the **Status** value is *Disabled*, you can skip the rest of this procedure and just run the on-hand consistency check.
    - If the **Status** value is *Enabled*, disable the job by selecting **Disable** on the Action Pane.
3. Run the on-hand consistency check.
4. When the check is completed, go to **Inventory Management** > **Setup** > **Inventory Visibility integration parameters**.
5. On the **General** tab, set the **Resync before initial push** option to *Yes*.
6. On the Action Pane, select **Save**.
7. Go to **Inventory Management** > **Periodic Tasks** > **Inventory Visibility integration**.
8. On the Action Pane, select **Enable** to reenable the batch job.

The initial push with the `Resync` action first cleans up legacy Supply Chain Management data in Inventory Visibility service. It then resyncs the `InventSum` and `WHSInventReserve` tables to the Inventory Visibility Service.

> **Important**
>
> The Inventory Visibility service resumes delivering correct query results after the reenabled *Inventory Visibility integration* batch job completes its initial push work.

Prepare for and run an on-hand consistency check on selected items

If you want to run an on-hand consistency check on only a few selected items, you don't need to complete the extra steps that are described in the previous section. Instead, just run the check.

Inventory Visibility adjustment offset

08/13/2025

This article describes how to offset inventory adjustments that were updated through Inventory Visibility and then also updated in Microsoft Dynamics 365 Supply Chain Management. To prevent inventory quantities from being updated twice, you must offset the previously adjusted inventory from Supply Chain Management to Inventory Visibility.

For example, you have an external sales system, such as a point of sale (POS) or e-commerce system, that makes external sales transactions. You have a data source that's named *POS* in Inventory Visibility. You also have a physical measure, *Sold*, that captures externally sold quantities. Your external system registers a sale of 10 units of item ID A0001, including all relevant dimensions. When you re-create the transaction in Supply Chain Management, if the re-created transaction is a sales order, you must set up sales order offset mappings. If you use an inventory adjustment journal to post inventory changes that are registered through your POS systems, you must set up inventory adjustment journal offset mappings.

When you sync or import external sales orders and inventory adjustment journals from Inventory Visibility into Supply Chain Management, notice that the relevant tables include two new columns: `OFFSETDATASOURCE` and `OFFSETPHYSICALMEASURE`. Be sure to fill in these two columns with the data source and physical measure values that you set up in your inventory offset configuration (as described later in this article). When sales orders and inventory adjustment journals are created in Supply Chain Management, you can view the data source and physical measure mappings on the sales order or journal lines.

> **Note**
>
> Supply Chain Management transaction lines that must be offset are added to the regular data synchronization batch job between Supply Chain Management and Inventory Visibility. Therefore, you should expect a delay of about one minute before you can view the data being offset in Inventory Visibility.

Prerequisites

Before you can use the features that are described in this article, your system must meet the following requirements:

- You must be running Supply Chain Management version 10.0.39 or later.
- The feature that's named *Inventory Visibility integration with inventory adjustment offset* must be turned on in Feature management. As of Supply Chain Management version

10.0.45, this feature is mandatory and can't be turned off.

- Inventory Visibility must be installed, and the basic integration between Supply Chain Management and Inventory Visibility must be set up, as described in Install and set up Inventory Visibility.
- You must be using the **/api/environment/{environmentId}/onhand** and/or **/api/environment/{environmentId}/onhand/bulk** API to make inventory adjustments and post on-hand change events to Inventory Visibility. For information about these two APIs, see Create one on-hand change event and Create multiple change events.

Enable and set up the feature

Follow these steps to enable and set up the Inventory Visibility adjustment offset feature.

1. Go to **Inventory management** > **Inventory Visibility** > **Inventory Visibility integration parameters**.

2. The **Inventory adjustment offset** tab includes two FastTabs: **Sales order** and **Inventory adjustment journal**. Each FastTab represents a type of transaction that you can set up automatic adjustment offsets for. On the appropriate FastTab, set the following fields:

    - **Inventory Visibility offset data source** – Specify the data source that you use Inventory Visibility to post inventory adjustments to (for example, *POS*).

    - **Inventory Visibility offset physical measure** – Specify the physical measure that you use to record the adjustment quantity changes in Inventory Visibility (for example, *Sold*).

    - **Offset trigger** – Select the Supply Chain Management record status that should trigger the offset. For sales orders, you can select *Create* or *Invoice*. For inventory adjustment journals, you can select *Create* or *Post*.
        - **Example 1:** You have a POS system that registers external sales order transactions by using the *POS* data source and the *Sold* physical measure. Each transaction represents inventory that was consumed and paid for in the store. Therefore, you trigger the offset when the sales order reaches *Invoiced* status in Supply Chain Management.
        - **Example 2:** You have an e-commerce website that posts inventory adjustments to Inventory Visibility by using the *Ecommerce* data source and the *On order* physical measure. When you create a new sales order in Supply Chain Management, you trigger the offset at the *Created* status.

    - **Site**, **Warehouse**, **Inventory status**, **Location**, **License plate**, **Batch number**, and **Serial number** – Each of these checkboxes represents a storage or tracking

dimension. Select the checkbox for each dimension that the system should match when it offsets back to Inventory Visibility. Clear the checkbox for each dimension that should be *excluded* when the system matches records. For product and inventory dimensions that aren't listed here (such as color, size, and style), the system exactly matches the values that are specified on the sales order or journal line when it offsets back to Inventory Visibility. *Make sure that only the relevant storage and tracking dimensions are selected*.

- **Example 1:** An external system makes inventory adjustments or on-hand changes through Inventory Visibility by specifying the item ID, color, size, site, and warehouse. Later, when you create a matching sales order in Supply Chain Management, you enter matching item and inventory dimensions, but *you also add a batch number*, which isn't known to the external system. In this case, you should clear the **Batch number** and **Serial number** checkboxes, because batch number and serial number values aren't submitted by the external system and shouldn't be matched when the offset is done.
- **Example 2:** Your process allows site or warehouse information to be changed when an inventory adjustment transaction is re-created in Supply Chain Management. An external system adjusts inventory for item A0001 in site 1 without specifying a warehouse. (In e-commerce, the fulfillment warehouse often isn't known when an order is first submitted.) The fulfillment warehouse (warehouse 13) is specified later in Supply Chain Management. To enable this type of offset to work correctly, you should clear the **Warehouse** checkbox for the appropriate line.

3. If you must set up more offsets for sales order or inventory adjustment journals, select **Add line** on the toolbar of the appropriate FastTab, and repeat the previous steps for each new line.

Inventory Visibility reservations

This article describes a typical use case for soft reservations and explains how to set them up in Inventory Visibility. It includes information about how to create soft reservations, offset them upon physical consumption, and adjust or unreserve specified inventory quantities.

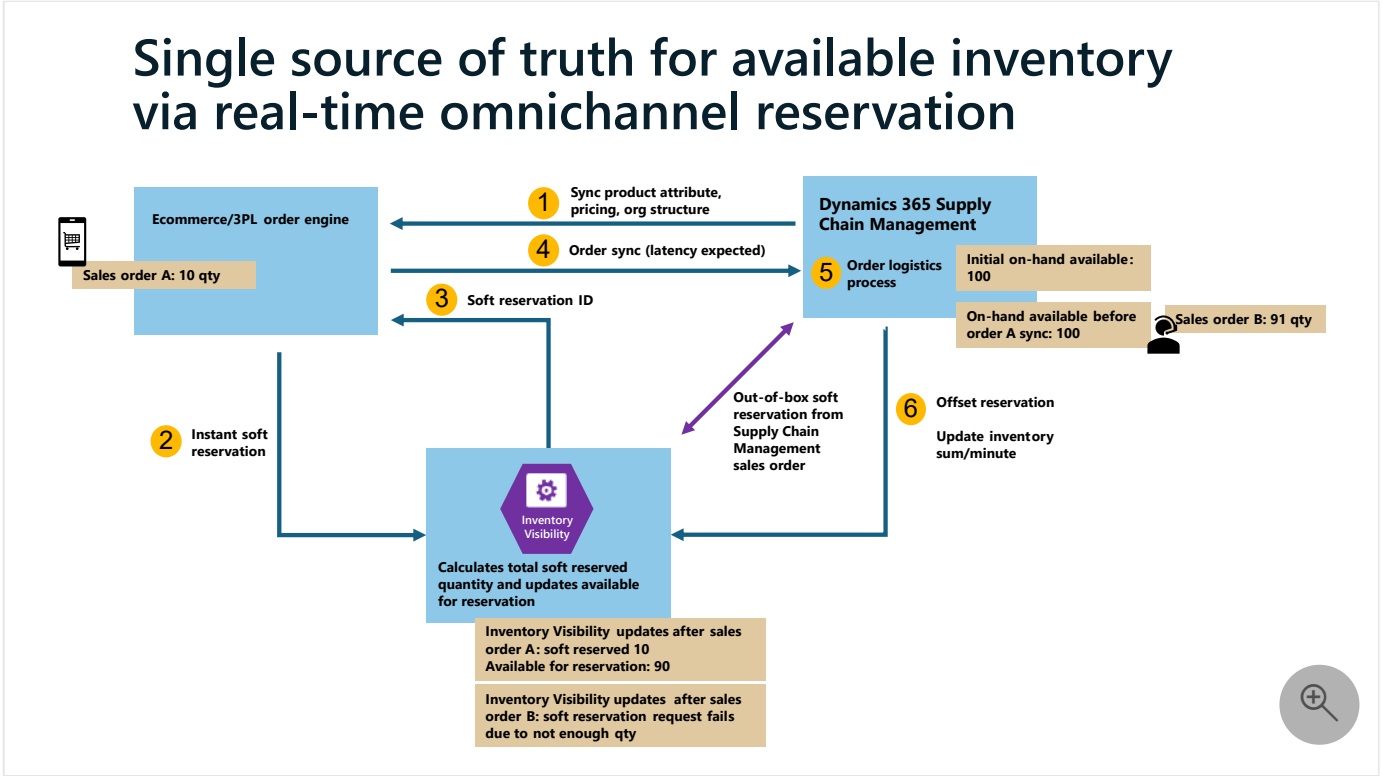
In Microsoft Dynamics 365 Supply Chain Management version 10.0.33 or later, you can make soft reservations from sales orders. When you soft reserve from sales orders, the reservation requests are posted to Inventory Visibility, and the available-for-reservation quantities are validated in Inventory Visibility.

> **Important**
>
> The default soft reservation configuration has evolved through various version iterations. Therefore, it's possible that your sandbox environment was initially set up with an outdated default configuration, whereas your production environment was initialized with the latest version of the default configuration. If you've customized your third-party system based on an outdated default configuration, it might encounter issues when your production environment goes live, especially if you haven't reviewed and adjusted the configuration. To help prevent this scenario, thoroughly review and update your draft and runtime configurations before you transition your production environment.

Sample use case for soft reservation

Soft reservations help organizations achieve a single source of truth for available inventory, especially during the order fulfillment process. This functionality is useful for organizations where the following conditions exist:

- The organization has at least two different systems that are directly taking outbound orders.
- The organization is very strict and wants to prevent double-booking of product inventory, which can happen if multiple systems are able to overbook the last piece of stock. This situation is prevented when all order systems can make instant soft reservation API calls to Inventory Visibility, which provides a single source of truth for inventory availability.



The previous illustration shows how soft reservation works and highlights the following operations:

- Your initial inventory level is synced to Inventory Visibility from Microsoft Dynamics 365 Supply Chain Management.
- You have two order-taking systems running in parallel (an e-commerce system and Supply Chain Management). In an actual case, you could have more systems.
- Soft reservations are posted from each of your order channels or systems to Inventory Visibility. Inventory Visibility validates inventory availability and tries to make a soft reservation. If soft reservation succeeds, Inventory Visibility adds to the soft reserved quantity, deducts from the available for reservation (AFR) quantity, and responds with a soft reservation ID.
- When sales order A is soft reserved in Inventory Visibility, your physical inventory quantity remains the same in Supply Chain Management because sales order A hasn't been synced to Supply Chain Management.
- Now, the call center enters sales order B directly in Supply Chain Management, which makes a soft reservation call to Inventory Visibility. Even though Supply Chain Management still shows 100 pieces available, Inventory Visibility knows there's only 90 pieces available, so the soft reservation request fails. Nevertheless, the call center user can still choose to block or continue processing sales order B in Supply Chain Management (if overselling is allowed).
- Then sync either single or aggregated soft-reserved orders (order lines) into Supply Chain Management to make hard reservations and release to the warehouse or update the final inventory quantity.

- You can set the system to offset soft reservations when physical inventory is updated in Supply Chain Management.

Soft reservations are usually created, consumed, and canceled by using API calls to the Inventory Visibility service.

> **Note**
>
> You can optionally set up Supply Chain Management (and other third-party systems) to automatically offset the quantity that has been reserved by using Inventory Visibility. The offset quantity is deleted from the reservation records in Inventory Visibility.
>
> By default, the offset function is automatically turned on when you enable the soft reservation feature.

Turn on and set up the reservation feature in UI version 2

This section and its subsections apply when you're using Inventory Visibility UI version 2.

Turn on the reservation feature

Follow these steps to turn on the reservation feature in UI version 2.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature Management**.
3. On the **Soft Reservation** tile, select **Manage**.
4. Set the **Enable feature** option to *True*.
5. The **Filter unconfigured dimensions** option controls how the system behaves if a user submits reservation requests that include dimensions that aren't specified on the **Reservation dimensions** FastTab. (Learn more in the Configure reservation mappings and dimensions section of this article.) Select one of the following values:
    - *True* – Reservation requests that include dimensions that aren't defined on the **Reservation dimensions** FastTab succeed, but undefined dimensions are ignored.
    - *False* – Reservation requests that include dimensions that aren't defined on the **Reservation dimensions** FastTab fail.

> **Important**
>
> If you've enabled the *Inventory Visibility integration with soft reservation on sales order lines* feature in Supply Chain Management, you must set the **Filter unconfigured dimensions** option to *True*. Learn more in the Integrate soft reservations and offsets with Supply Chain Management section.

6. On the toolbar, select **Save**.

7. If you changed the setting of the **Filter unconfigured dimensions** option, you must reverse all existing reservations to preserve data consistency. Use the clean up reservation data API to clean up existing soft reservation records.

Configure reservation mappings and dimensions

When you make a reservation, you might want to know whether on-hand inventory is currently available for reservation. The validation is linked to a calculated measure that represents a computation formula of a combination of physical measures.

By setting up the mapping from a physical measure to a calculated measure, you enable the Inventory Visibility service to automatically validate reservation availability based on the physical measure.

> **Important**
>
> All the physical measures and calculated measures that you plan to map for each data source must already be defined for your system. For information about how to configure measures and data sources, see Configure Inventory Visibility.

Default reservation mappings are provided out of the box. You can review and use these mappings directly. You can also add your own mappings by following these steps.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.

2. Define all the data sources, physical measures, and calculated measures that you plan to use with the soft reservations feature. For instructions, see Configure Inventory Visibility. Here are some guidelines for the setup of typically required measures:

- Define the physical measure that serves as the soft reservation measure (for example, *SoftReservPhysical*).
- Define the *available for reservation* calculated measure that contains the available-for-reservation computation formula that you map to the physical measure. For example, you might set up *AvailableToReserve* (available for reservation) so that it's mapped to the previously defined *SoftReservPhysical* physical measure. This setup lets you find which quantities that have the *SoftReservPhysical* inventory status are available for reservation.

The following table shows the available-for-reservation computation formula.

Expand table

Calculation type	Data source	Physical measure
Addition	*fno*	*AvailPhysical*
Addition	*pos*	*Inbound*
Subtraction	*pos*	*Outbound*
Subtraction	*iv*	*SoftReservPhysical*

Set up the physical measure that the reservation measure is based on as a component of the calculated measure. In this way, the calculated measure quantity is affected by the reservation quantity. For example, use the *SoftReservPhysical* physical measure of the *iv* data source as a component of the *AvailableToReserve* calculated measure of the *iv* data source.

3. In the **Reservation mapping** section, set up the mapping from the physical measure to the calculated measure. For the previous example, you might use the following settings to map *AvailableToReserve* to the previously defined *SoftReservPhysical* physical measure:

   - **Physical measure data source:** *iv*
   - **Physical measure:** *SoftReservPhysical*
   - **Available for reservation data source:** *iv*
   - **Available for reservation calculated measure:** *AvailableToReserve*

   Now, when you reserve *SoftReservPhysical*, Inventory Visibility automatically finds *AvailableToReserve* and its related computation formula to validate the reservation.

4. In the **Reservation dimensions** section, set up all the product dimensions that might be specified when a reservation is made. *Each reservation dimension must contain a partition*

configuration.

Here's an example of reservation dimensions.

Expand table

Key	Hierarchy
SiteId	1
LocationId	2
ColorId	3
SizeId	4
StyleId	5

In this example, the partition schema is *ByLocation*, and the basic partition dimension is *(SiteId, LocationId)*.

5. On the toolbar, select **Save**.

Example available-for-reservation calculation

The following example shows how the Inventory Visibility API might report on-hand inventory information.

JSON

```
{
    "productId": "D0002",
    "dimensions": {
        "SiteId": "1",
        "LocationId": "11",
        "ColorId": "Red"
    },
    "quantities": {
        "iv": {
            "SoftReservPhysical": 90
        },
        "fno": {
            "availphysical": 70.0,
        },
        "pos": {
            "inbound": 50.0,
            "outbound": 20.0
        }
```

```
    }
}
```

In this case, the following available-for-reservation calculation applies:

`AvailableToReserve` = `fno.availphysical` + `pos.inbound` – `pos.outbound` – `iv.SoftReservPhysical`
= 70 + 50 – 20 – 90
= 10

Therefore, if you try to make reservations on `iv.SoftReservPhysical`, and the quantity is less than or equal to `AvailableToReserve` (*10*), the soft reservation request succeeds.

Turn on and set up the reservation feature in UI version 1

This section applies when you're using Inventory Visibility UI version 1.

To turn on and set up the reservation feature UI version 1, follow these steps:

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.
3. On the navigation pane, select **Configuration**.
4. On the **Feature management & settings** tab, use the option to turn on the *Soft reservation* feature.
5. Select the **Soft reservation** tab.
6. Open the **Configuration** page.
7. If you plan to receive soft reservation data from Supply Chain Management, select the **Use soft reservation for sales order in FinOps** checkbox.
8. On the **Soft Reservation** tab, review the default soft reservation hierarchy. Add new dimensions to the hierarchy as you require. For more information about how to work with the soft reservation hierarchy, see the Configure reservation mappings and dimensions section.
9. In the **Set Soft Reservation Mapping** section, review the default settings. For more information about soft reservation mappings and the required measures, see the Configure reservation mappings and dimensions section.

Create soft reservations using the Inventory Visibility API

When you call the reservation API, the system marks the reservation of the specified goods and quantities.

For example, the company Contoso sells product D0002 (Cabinet) from its e-commerce website. A customer places a sales order for a small red cabinet via the website. Contoso decides to fulfill this order by using the following dimensions:

- Organization ID = usmf
- Site = 1
- Warehouse = 11
- Product = D0002
- Color = red
- Size = small

Contoso has already set up an API connection to Inventory Visibility from its own e-commerce system. When the order is received, the system instantly triggers an API call to make a soft reservation for the cabinet in Inventory Visibility.

Reservations are made in the Inventory Visibility service by submitting a POST request to the service's URL, such as `/api/environment/{environmentId}/onhand/reserve`.

For a reservation, the request body must contain an organization ID, a product ID, reserved quantities, and dimensions.

When you call the reservation API, you can control the reservation validation by specifying the Boolean `ifCheckAvailForReserv` parameter in the request body. A value of `True` means that the validation is required, whereas a value of `False` means that the validation isn't required. The default value is `True`.

If you want to cancel a reservation or unreserve specified inventory quantities, set the quantity to a negative value, and set the `ifCheckAvailForReserv` parameter to `False` to skip the validation.

Here's an example of the request body that references the sales order in the previous context.

JSON

```
# Url

# Replace {endpoint} with your system endpoint.
    {endpoint}/api/environment/{environmentId}/onhand/reserve

# Method
Post
```

```
# Header
# replace {access_token} with the one get from security service
Api-version: "1.0"
Content-Type: "application/json"
Authorization: "Bearer {access_token}"

# Body
{
    "id": "Testrequest",
    "organizationId": "usmf",
    "productId": "D0002",
    "dimensions": {
        "SiteId": "1",
        "LocationId": "11",
        "ColorId": "red",
        "SizeId": "small"
    },
    "quantityDataSource": "iv",
    "modifier": "softreserved",
    "quantity": 1,
    "ifCheckAvailForReserv": true
}
```

All dimensions must be defined in your reservation dimensions configuration and must contain the partition for the product. Here are examples of feasible dimension combinations that use the default configuration:

- `(SiteId, LocationId)`
- `(SiteId, LocationId, SizeId)`
- `(SiteId, LocationId, ColorId, SizeId)`
- `(SiteId, LocationId, ColorId, SizeId, StyleId)`

> **Note**
>
> Reservations on different *dimension levels* are independent. For example, your defined reservation dimensions are `(SiteId, LocationId, ColorId, SizeId)`. If you reserve some quantity for one product at dimension level `(SiteId, LocationId, ColorId)`, reservations at other levels, such as `(Site , Location , Color , Size)` or `(Site , Location)`, aren't affected.

A successful soft reservation request returns a *soft reservation ID* for each reservation record. The soft reservation ID isn't a unique identifier for an individual soft reservation record, but a combination of the product ID and dimension values that are associated with the soft reservation request. You can record the soft reservation ID on the order line when you sync the successfully reserved orders to Supply Chain Management or another ERP system for offset.

Integrate soft reservations and offsets with Supply Chain Management

You can trigger a soft reservation from a Supply Chain Management sales order and then make an offset back to Inventory Visibility when the order lines are hard reserved (that is, changed to a status of *Reserve physical*, *Reserve ordered*, *Picked*, and so on). The process differs slightly, depending on the soft reservation feature that you're using (*Inventory Visibility integration with reservation offset* or *Inventory Visibility integration with soft reservation on sales order lines*).

- *Inventory Visibility integration with soft reservation on sales order lines* – This feature lets you avoid double booking by making a soft reservation after you create a sales order line in Supply Chain Management. The soft reservation automatically offsets when this line reaches a status of *Reserve ordered*, *Reserve physical*, *Pick*, and so on.

- *Inventory Visibility integration with reservation offset* – This feature lets you offset soft reservations that were made outside of Supply Chain Management. You can soft reserve directly from the soft reservation API (or another customization channel) and then enter the reservation ID into the corresponding sales order line in Supply Chain Management. This feature automatically offsets the soft reservation once the line status fulfills the conditions established by your settings.

Turn on the feature in Supply Chain Management

Sign in to Supply Chain Management and make sure that you've enabled the following two features in Feature management.

- *Inventory Visibility integration with reservation offset* – This feature requires Supply Chain Management version 10.0.22 or later. As of Supply Chain Management version 10.0.45, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.
- *Inventory Visibility integration with soft reservation on sales order lines* – This feature is recommended if you're running Supply Chain Management version 10.0.33 or later. As of Supply Chain Management version 10.0.45, this feature is turned on by default.

These features are compatible with each other as of build 10.0.1591.98 of Supply Chain Management version 10.0.34 and build 10.0.1627.63 of Supply Chain Management version 10.0.35 (and all builds of versions 10.0.36 and higher). Prior to these versions, the features aren't compatible with each other, so enable only the one you want to use. Upgrade to a newer version if you require both features.

Configure additional settings if the "Inventory Visibility integration with soft reservation on sales order lines" feature is enabled

If you enabled the *Inventory Visibility integration with soft reservation on sales order lines* feature, follow these steps to configure additional settings.

1. In Supply Chain Management, go to **Inventory Management** > **Setup** > **Inventory Visibility integration parameters**.

2. On the **Enable soft reservation** tab, in the **Default soft reserve block level** field, select one of the following values to specify how the system should behave if you try to process sales order lines that no soft reservation exists for in Inventory Visibility:

    - *Block* – You can't process a sales order line to a hard reservation (reserve physical) or further unless Inventory Visibility has already recorded a successful soft reservation for the line.
    - *Warning* – You receive a warning message if you try to process a sales order line to a hard reservation (reserve physical) but no matching soft reservation has been made in Inventory Visibility.
    - *Ignore* – The system doesn't check for a soft reservation in Inventory Visibility when you try to process order lines in Supply Chain Management.

> **Tip**
>
> You don't have to enable or set up the offset modifier, because offset for soft reservation is always enabled and triggers when a sales line proceeds to hard reservation status (or further, if the hard reservation step is skipped).

Configure additional settings if the "Inventory Visibility integration with reservation offset" feature is enabled

If you enabled the *Inventory Visibility integration with reservation offset* feature, follow these steps to configure additional settings.

1. In Supply Chain Management, go to **Inventory Management** > **Setup** > **Inventory Visibility integration parameters**.

2. On the **Reservation offset** tab, set the following fields:

- **Enable reservation offset** – Set this option to *Yes* to enable the functionality.
- **Reservation offset modifier** – Select one of the following values to specify the inventory transaction status that offsets reservations that are made in Inventory Visibility. This setting determines the order processing stage that triggers offsets. The stage is traced by the order's inventory transaction status.
  - *On order* – Orders that have a status of *On order* send an offset request when they're created. The offset quantity is the quantity of the created order (line).
  - *Reserve* – Orders that have a status of *Reserve* send an offset request when they're either order reserved or physically reserved. When you offset at the *Reserve* status, the order sends an offset request at any new inventory status that's closest to reserved picked (for example, pick, packing slip posted, or invoiced). This behavior occurs even if you skip the reservation in Supply Chain Management and continue to another inventory status (for example, if you skip from release to warehouse to pick and pack). The request is triggered only once. If it's triggered at pick, the offset isn't duplicated when a packing slip is posted. The offset quantity is the same as the quantity of the inventory transaction status when the offset was triggered (in other words, *Reserved ordered/Reserve Physical*, or a later status, on the corresponding order line).

Create soft reservations and offsets when you use the Inventory Visibility integration with soft reservation on sales order lines feature

When you use the *Inventory Visibility integration with soft reservation on sales order lines* feature, you can post soft reservations and also offset soft reservations from sales order lines in Supply Chain Management. The offset capabilities in this feature support both *internally* and *externally* created sales lines.

1. Sign in to Supply Chain Management
2. Go to **Sales and marketing** > **Sales Orders** > **All Sales Orders**.
3. On the Action Pane, select **New** to create a sales order.
4. Fill in the **Create sales order** dialog box in the usual way, and then select **OK** to finish creating the new order.
5. The new order is opened. Enter a sales line. Be sure to specify **Product ID**, **Site**, **Warehouse**, and **Quantity** values. Specify any other inventory dimension values that are applicable.

6. There are two ways to make a soft reservation from a sales order. Follow one of these steps:

    - *To soft reserve the whole order, including all lines*, select **Inventory Visibility integration** > **Soft reservation** on the Action Pane. Then select one of the following options:
        - **Reserve entire order directly** – Make an instant soft reservation API call to Inventory Visibility.
        - **Reserve entire order by batch** – Add the reservation requests to a batch queue that's associated with a batch job that syncs Supply Chain Management with Inventory Visibility about once per minute.

    - *To soft reserve a specific order line*, select the sales line, and then select **Inventory** > **Inventory Visibility integration** > **Soft reserve** on the toolbar of the FastTab toolbar to open the **Inventory service reservation details** dialog box. Then select either to reserve directly or to add the reservation as a batch job. The following information is shown:
        - **Unreserved** – The quantity that wasn't soft reserved.
        - **Soft reserve success** – The quantity that was successfully soft reserved.
        - **Batch reserve in progress** – The quantity that was added to the soft reservation batch queue.
        - **Direct reserve in progress** – The quantity that triggered an instant soft reservation API call to Inventory Visibility.
        - **Failed - not enough stock** – The quantity that couldn't be soft reserved because of unavailable stock.
        - **Failed - other reason** – The quantity that couldn't be soft reserved for another reason, such as a failed API call, connection issues, or other issues.
        - **Offset quantity** – The total offset quantity, including both offset success and in-progress quantities.
        - **Pending to offset quantity** – The quantity that skipped soft reservation and proceeded directly to hard reservation or further physical inventory consumption.

7. To view and edit the soft reservation blocking level of a sales line, select the relevant line on the **Sales order lines** FastTab. Then, expand the **Line details** FastTab and open its **General** tab. The **Soft reservation blocking level** field indicates the blocking level for the selected sales line. The default setting for all new order lines is set on the **Inventory visibility integration parameters** page, but you can edit it for individual sales lines as needed. The following values are possible:

    - *Ignore* – You aren't blocked or given a warning if you reserve physical or reserve ordered without a soft reservation.

- *Warning* – You receive a warning, but you aren't blocked, if you reserve physical or reserve ordered without a soft reservation.
- *Blocking* – You must have a soft reservation before you can reserve physical or reserve ordered.

If a line is set to block or warn when a soft reservation couldn't be made, you might see a block notice here. To help avoid the risk of overselling, don't choose to override the soft reservation validation unless overrides are permitted in your business.

When a soft reservation is successfully made, a soft reservation ID is automatically returned and recorded for each sales line.

By default, the soft reservation offset is triggered when the line reaches a hard reservation status (*Reserve physical* or *Reserve ordered*) or later. Sales lines that show a valid soft reservation ID and a qualifying trigger status are automatically added to the offset batch queue.

8. To view the soft reservation status of a sales order line, select the relevant line on the **Sales order lines** FastTab. Then, expand the **Line details** FastTab and open its **General** tab. The **Soft reservation status** field shows the stage of the soft reservation process for the selected sales order line. The following values are possible:

    - *Not started* – The soft reservation process is waiting to start.
    - *Unfinished* – A soft reservation was attempted, but not all quantities were successfully posted. Some or all quantities might have failed to post, or some quantities might have been successfully soft reserved with other reservations still waiting to finish.
    - *Succeeded* – All quantities were successfully soft reserved.

> ⓘ **Note**
>
> If you must reverse a successful soft reservation, open the relevant sales order, and then select **Revert reservation directly** or **Revert reservation by batch** at the sales order or sales line level.

Import sales orders that have been soft reserved externally

It's likely that your company has other order channels that also post soft reservation to Inventory Visibility. Sales orders that have been soft reserved externally might need to be imported into

Supply Chain Management if you're using it as your system of record. Follow these steps to import sales orders that have been soft reserved externally.

1. Sign in to Supply Chain Management.
2. Go to **System Administration** > **Work spaces** > **Data management**.
3. Select the **Framework parameters** tile.
4. On the **Data import/export framework parameters** page, on the **Entity settings** tab, select **Refresh entity list**.
5. Go back to **System Administration** > **Work spaces** > **Data management**.
6. Select the **Export** tile.
7. On the **New Record** page, in the **Group name** field, enter a name.
8. On the **Selected entities** FastTab, select **Add entity** on the toolbar, and then, in the drop-down dialog box, set the following values:
    - **Entity name** – Select *Sales order lines V2*.
    - **Target data format** – Select *Excel*.
    - **Select fields** – Select *Importable fields*.
9. Select **Add** to apply your settings, and then select **Close** to close the dialog box.
10. A new line is added to the grid. On the new line, select the button in the **Filter** column.
11. In the **Inquiry** dialog box, the grid on the **Range** tab should already have one row. Edit the row so that it has the following values:
    - **Table** – Select *Sales order lines V2*.
    - **Derived table** – Select *Sales order lines V2*.
    - **Field** – Select *Sales order*.
    - **Criteria** – Select any sales order number.
12. Select **OK** to apply your settings and close the dialog box.
13. On the Action Pane, select **Export**.
14. On the **Execution summary** page, on the **Entity processing status** FastTab, select **Download file** on the toolbar.

15. Open the downloaded file in Excel, and remove all the data rows. Leave only the header row.

16. Add new rows that include the sales order line details that you want to import into Supply Chain Management.

17. For each row, in addition to the usual order data, be sure to include soft reservation details in the following columns:

    - **INVENTORYSERVICERESERVATIONID** – Enter the soft reservation ID from the external reservation.
    - **ISSOFTRESERVEDEXTERNALLY** – Enter *Yes*.

18. Import the completed Excel file. You can check import status after completion.

19. After the file is successfully imported, you can confirm that the new sales orders have soft reservation details by opening those orders in Supply Chain Management.

> ⓘ **Note**
>
> After you import sales orders that include soft reservation details, you can't modify the soft reservation or revert it from Supply Chain Management. If the data that you imported isn't correct, delete the affected sales line, and then reimport it.

Create soft reservations and offsets when you use the Inventory Visibility integration with reservation offset feature

When you use the *Inventory Visibility integration with reservation offset* feature, you can't trigger soft reservation directly from Supply Chain Management. Instead, this feature supports only the offset of sales order lines that were created *externally* from Supply Chain Management. When externally created soft-reserved sales lines are replicated into Supply Chain Management, offsets might be required from Supply Chain Management to Inventory Visibility.

You can offset a soft-reserved quantity after the quantity on an order is physically deducted in Supply Chain Management or another ERP system. Inventory Visibility offers out-of-box soft reservation offset integration with Supply Chain Management.

Follow these steps to offset a soft reservation.

1. Sign in to Supply Chain Management.

2. Go to **Sales and marketing** > **Sales Orders** > **All Sales Orders**.

3. On the Action Pane, select **New**. Create a new order and a new sales line.

4. Re-create the external sales order, and add a sales line that uses the same product ID, organization, site, warehouse, and dimensions values.

5. On the **Sales order lines** FastTab, select the sales line that you just entered, and then, on the toolbar, select **Inventory** > **Reservation ID**.

6. Follow one of these steps:

    - Copy the soft reservation ID in your soft reservation request response, and paste it into the **Reservation ID** field.
    - Leave the **Reservation ID** field blank, but select the **Inventory service auto offset** checkbox. The system automatically determines which product and product dimensions to offset, based on the item ID and dimension values entered on the selected line.

7. Select **OK**.

8. While the same sales line is still selected, physically reserve the ordered quantity by selecting **Inventory** > **Reservation** on the toolbar of the **Sales order lines** FastTab.

9. If you've previously set the **Reservation offset modifier** field to *Reserved*, the offset is triggered when the order line has a status of *Reserve physical* or *Reserve ordered*. A batch job runs once a minute to sync offset requests from Supply Chain Management to Inventory Visibility.

> ⓘ **Note**
>
> For transaction statuses that include a specified reserve offset modifier, the transaction update offsets the corresponding reservation record when all the following conditions are met:
>
> - The reservation ID on the inventory transaction matches the reservation ID of the reservation record in Inventory Visibility.
> - The dimensions of the inventory transaction match the dimensions of the reservation record in Inventory Visibility.
> - Changes in inventory transaction status trigger offsets for reservations when the inventory transaction status reflects the fact that an order process has been completed

or skipped.

Offset quantities follow the inventory quantities that are specified on the relevant inventory transactions. An offset takes effect only if reserved quantity remains in Inventory Visibility.

Check for failed reservation offsets

To check for failed reservation offsets, go to **Inventory Management** > **Periodic tasks** > **Inventory Visibility integration**. A failed offset might be caused by an incorrect soft reservation ID, an internet issue, a broken system connection, and so on.

Cancel or revert a soft reservation

If an original order line is canceled or deleted, and you must revert the corresponding soft reservation, take one of the following actions:

- Post a soft reservation event with a negative quantity that has the same exact information in your API query body.
- Post an unreserve request with the same quantity and reservation ID. Learn more in Reverse reservation events.

Inventory Visibility inventory allocation

08/13/2025

Business background and purpose

Organizations often have to preallocate their on-hand stock to their most important sales channels, customer groups, regions, and promotional events to ensure that the preallocated stock is protected against any other use and can be consumed only via sales transactions that are relevant to the allocation. Inventory allocation in Inventory Visibility is a component of the sales operational planning process, and is done before any actual sales activities occur or a sales order is created.

For example, a company that's named Contoso produces a popular bike. Unfortunately, because a recent supply chain disruption has affected all in-transit stock of that bike, Contoso has only limited on-hand stock and must make best use of it. Contoso operates both online and in-store sales. In each sales channel, the company has a few important corporate partners (marketplaces and large retailers) that demand that a specific portion of the bike's available inventory be saved for them. Therefore, the bicycle company must be able to balance stock distribution across channels and also manage the expectations of its VIP partners. The best way to achieve both goals is to use inventory allocation, so that each channel and retailer can receive specific allocated quantities that can be sold to consumers later.

Inventory allocation has two basic business purposes:

- **Inventory protection (ring fencing)** – Organizations want to preallocate restricted or limited stock to prioritized channels, regions, VIP customers, and subsidiary companies. The Inventory Visibility allocation feature aims to protect the allocated inventory, so that the other allocations, reservations, or other sales demands won't affect the previously allocated inventory.
- **Oversell control** – The Inventory Visibility allocation feature aims to put a restriction on the previously allocated quantities, so that the receiving party (for example, a channel or customer group) won't over-consume them when the actual sales transaction that's based on a soft reservation goes into effect.

Allocation definition in Inventory Visibility Service

Allocation virtual pool

Although the allocation feature in Inventory Visibility doesn't set aside physical inventory quantities, it does refer to the available physical inventory quantity to define its initial *available to allocate* virtual pool quantity. Inventory allocation in Inventory Visibility is a soft allocation. It's done before actual sales transactions occur and doesn't depend on sales orders. For example, you can allocate stock to your most important sales channels or large corporate retailers before any end customers visit the sales channel or retail store to purchase it.

Difference between inventory allocation and soft reservation

Soft reservations are often linked to actual sales transactions (sales order lines). Both allocation and soft reservation can be used independently, but if you want to use them together, soft reservation should be done after allocation. We recommend that you do inventory allocation first and then soft reserve against the allocated quantities to achieve near-real-time consumption against allocation. Learn more in the Consume as a soft reservation section of this article.

The inventory allocation feature lets sales planners or key account managers manage and preallocate important stock across allocation groups (such as channels, regions, and customer groups). It also supports real-time tracking, adjustment, and analytics of consumption against allocated quantities, to ensure that replenishment or reallocation can be done on time. This ability to have real-time visibility into allocation, consumption, and allocation balance is especially important at fast-sale or promotion events.

Terminology

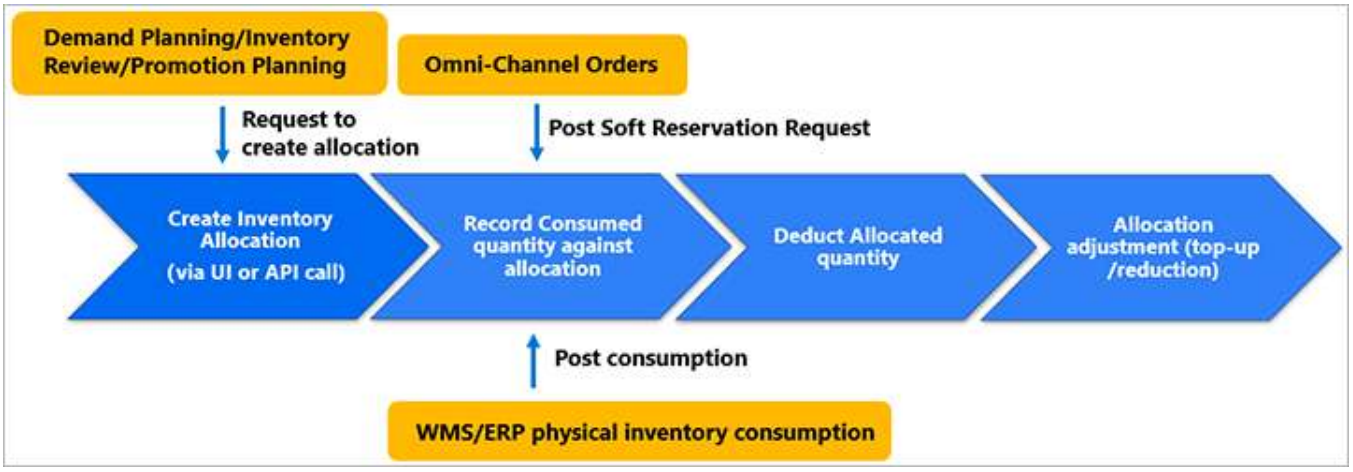
The following terms and concepts are useful in discussions of inventory allocation:

- **Allocation group** – The group that owns the allocation, such as a sales channel, customer group, or order type.
- **Allocation group name** – The name of each allocation group. For example, *web* or *store* might be the name of the sales channel allocation group, whereas *VIP* or *normal* might be the name of the customer allocation group.
- **Allocation hierarchy** – A means to combine allocation groups in a hierarchical manner. A maximum of eight levels of hierarchy are supported. For example, you could define *Channel* as hierarchy level 0, *Region* as level 1, and *Customer group* as level 2. During inventory allocation, you must follow the allocation hierarchy sequence when you specify the value of the allocation group. For example, you could create an allocation of 200 red bikes to the *Web* channel, the *London* region, and the *VIP* customer group.
- **Available to allocate** – The *virtual common pool* that indicates the quantity that's available for further allocation. It's a calculated measure that you can freely define by

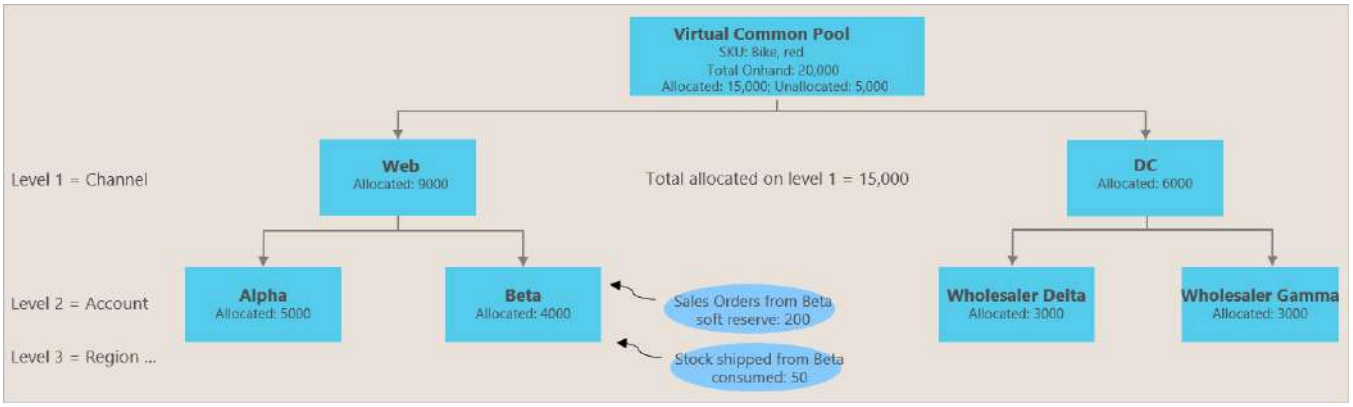
using your own formula. If you're also using the soft reservation feature, we recommend that you use the same formula to calculate available-to-allocate and available-to-reserve.

- **Allocated** – A physical measure that shows the allocated quota that can be consumed by the allocation groups. It's deducted at the same time that the consumed quantity is added.
- **Consumed** – A physical measure that indicates the quantities that have been consumed against the original allocated quantity. As numbers are added to this physical measure, the Allocated physical measure is automatically reduced.

The following illustration shows the business workflow for inventory allocation.



The following illustration shows the allocation hierarchy and allocation groups. The *virtual common pool* shown here is the available-to-allocate quantity.



Turn on and set up inventory allocation in UI version 2

This section applies when you're using Inventory Visibility UI version 2.

To set up inventory allocation, you must complete the following tasks, which are described in the subsections of this section:

- Enable the allocation feature, and update the configuration to initialize it.

- Set up the *available to allocate* calculated measure (and include the *allocated* physical measure in the calculation).
- Set up your allocation groups.
- Update the configuration to activate your new settings.

Enable the inventory allocation feature

Follow these steps to enable the inventory allocation feature.

1. In Power Apps, open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature Management**.
3. On the **Inventory allocation** tile, select **Manage**.
4. Set the **Enable feature** option to *Yes*.
5. On the toolbar, select **Save**.
6. On the navigation pane, select **Admin Settings**.
7. On the **Update configuration** tile, select **Manage**.
8. Review your modifications in the dialog box.

   > **ⓘ Important**
   >
   > Be sure to verify all the important modifications that are about to be made to your data sources, physical measures, and dimension mappings.

9. Select **Confirm Update** to apply your configuration change.

Set up the available to allocate calculated measure

When you enable the inventory allocation feature and update the configuration as described in the previous section, Inventory Visibility creates one predefined data source and several initial measures.

The data source is named *@iv*. It includes the following set of default physical measures:

- *@allocated*
- *@cumulative_allocated*
- *@consumed*
- *@cumulative_consumed*

To use allocation, you must correctly set up the formula for the *available to allocate* calculated measure (*@iv.@available_to_allocate*). For example, you have the *onordered* physical measure in the *fno* data source and the *inbound* physical measure in the *pos* data source. You can then allocate on-hand stock for the sum of *fno.onordered* and *pos.inbound*. In this case, *@iv.@available_to_allocate* should contain *pos.inbound* and *fno.onordered* in the formula. Here's an example calculation:

@iv.@available_to_allocate = fno.onordered + pos.inbound – @iv.@allocated

> **Note**
>
> The *@iv* data source is a predefined data source, and the physical measures in *@iv* that have an at sign (@) as a prefix are predefined measures. These measures are the predefined configuration for the allocation feature. Therefore, don't change or delete them. Otherwise, you're likely to encounter unexpected errors when you use the allocation feature.
>
> You can add new physical measures to the predefined *@iv.@available_to_allocate* calculated measure. However, you must not change its name.

Follow these steps to set up the *available to allocate* calculated measure:

1. In the Inventory Visibility app, select **Feature Management** on the navigation pane.
2. On the **Data source settings** tile, select **Manage**.
3. Open the data source that's named *@iv*.
4. In the **Calculated Measures** section, open the record that's named *@available_to_allocate* if it exists. Otherwise, create a record where the **Calculated measure name** value is *@available_to_allocate*, and **Save** the new record.
5. In the **Calculated measure details** section, add the physical measures that you want to use to calculate your available-to-allocate quantities. Be sure to include the *@iv.@allocated* physical measure in the formula.

Set up your allocation groups and hierarchy

Every allocation that's created in Inventory Visibility must be assigned to a specific *allocation group*. You can create up to eight allocation groups, each of which has a name and a level. A level is required to establish a group hierarchy.

Each level is defined as an integer from *0* (zero) through *7*, representing the order in which the groups are used in the allocation hierarchy. The group that's assigned to level *0* is the highest level in the hierarchy, and the group that's assigned to level *7* is the lowest level in the hierarchy.

When you create an allocation, you must specify hierarchies in order from the highest level to the lowest level. For example, your configuration has *Country/region* for group level 0, *State* for group level 1, and *City* for group level 2. In this case, both *Country/region* and *State* are required when *City* is specified. However, an allocation can be created by using only *Country/region* and *State*, or by using only *Country/region*.

Follow these steps to set up your allocation groups and hierarchy.

1. In the Inventory Visibility app, select **Feature Management** on the navigation pane.
2. On the **Inventory allocation** tile, select **Manage**.
3. In the **Allocation group** section, use the **New allocation group** button on the toolbar to add a row for each allocation group that you need. Assign a level between *0* and *7*. To edit an existing group, select its name in the **Allocation group name** column.
4. On the toolbar at the top of the page, select **Save**.

> **Important**
>
> Be careful when you delete or change the allocation hierarchy. For guidance, see the Tips for using allocation section.

Update the configuration to activate your new settings

After you've finished changing your configuration, you must apply the changes to activate them.

1. In the Inventory Visibility app, select **Admin Settings** on the navigation pane.
2. On the **Update configuration** tile, select **Manage**.
3. Review your modifications in the dialog box.

   > **Important**
   >
   > Be sure to verify all the important modifications that are about to be made to your data sources, physical measures, and dimension mappings.

4. Select **Confirm Update** to apply your configuration changes.

Turn on and set up inventory allocation in UI version 1

This section applies when you're using Inventory Visibility UI version 1.

Follow these steps to enable inventory allocation and set up allocation groups if you're using UI version 1.

1. Enable the inventory allocation feature.
   a. Go to **Legacy UI** > **Configuration**.
   b. On the **Feature Management & Settings** tab, turn on the feature that's named *Inventory Allocation*.
   c. Select **Update configuration** in the upper-right corner to apply the new setting.

2. Configure the *available to allocate* calculated measure and the *allocated* physical measure.
   a. On the **Calculated Measure** tab, review the initial calculated measure, which is named *@iv.@available_to_allocate*.
   b. Edit the formula to meet your business needs by adding and removing physical measures. Be sure to include the *@iv.@allocated* physical measure in the formula.

3. Set up your allocation groups and hierarchy.
   a. Select the **Allocation** tab.
   b. In the default allocation configuration, there are four levels of hierarchy. These levels, from highest to lowest, are *Channel* (group level 0), *customerGroup* (group level 1), *Region* (group level 2), and *OrderType* (group level 3). You can edit the groups by working in the **Edit configuration** field. To remove an existing allocation group, select the **X** next to its name. To add an allocation group, enter the name directly in the **Edit configuration** field.
   c. When you've finished editing the groups, select **Save**.

4. Update the configuration to activate your new settings.

   - When you've finished configuring the allocation group and hierarchy settings, select **Save**, and then select **Update Configuration** in the upper-right corner.

The values of the configured allocation groups will be updated when you create an allocation by using either the user interface or API POST (`/api/environment/{environmentId}/allocation/allocate`). Details about both approaches are provided later in this article. If you use four group names and set them to [`channel`, `customerGroup`, `region`, `orderType`], these names will be valid for allocation-related requests after you call the configuration update API.

> ⓘ **Note**

Settings that are applied for the enabled status of the allocation feature and for allocation groups in UI version 1 don't affect the corresponding settings in UI version 2. Likewise, settings for the enabled status and allocation groups in UI version 2 don't affect the corresponding settings in UI version 1. Only those settings that are applied in the **active UI version** apply.

> **Important**
>
> Be careful when you delete or change the allocation hierarchy. For guidance, see the Tips for using allocation section.

Tips for using allocation

- For every product, the allocation function must use the same *dimension level* according to the on-hand index configuration that's set up in the on-hand index configuration. For example, your index hierarchy is [`Site`, `Location`, `Color`, `Size`]. You allocate some quantity for one product at the [`Site`, `Location`, `Color`] dimension level. In this case, the next time that you want to allocate the same product, you must allocate at the same level. If you use the [`Site`, `Location`, `Color`, `Size`] level or the [`Site`, `Location`] level, the data will be inconsistent.
- When you modify allocation groups and the hierarchy, if allocation data already exists in the system, deletion of existing allocation groups or a shift in the allocation group hierarchy will corrupt the existing mapping between the allocation groups. Therefore, be sure to use the `Unallocate` API to remove all old data before you update the configuration. However, you don't have to clean up the data if you're just adding new allocation groups to the lowest hierarchy.
- Allocation will succeed only for products that have a positive `available_to_allocate` quantity.
- To allocate products from a high allocation hierarchy group to a subgroup, use the `Reallocate` API. For example, your allocation group hierarchy is [`channel`, `customerGroup`, `region`, `orderType`], and you want to allocate some product from the [`Online`, `VIP`] allocation group to the [`Online`, `VIP`, `EU`] allocation subgroup. In this case, use the `Reallocate` API to move the quantity. When you use the `Allocate` API, it will allocate the quantity from the virtual common pool.
- To view overall product availability (the common pool), use the query on-hand API to request the inventory amount that's *available to allocate*. You can then make allocation decisions based on this information.

Use the allocation APIs

The following table lists the allocation APIs that are available.

Expand table

Method	API	Description
POST	`/api/environment/{environmentId}/allocation/allocate`	Create an allocation
POST	`/api/environment/{environmentId}/allocation/unallocate`	Revert or remove allocated records
POST	`/api/environment/{environmentId}/allocation/reallocate`	Move allocated quantities from an existing allocation to other allocation groups
POST	`/api/environment/{environmentId}/allocation/consume`	Deduct (use) the allocated quantity
POST	`/api/environment/{environmentId}/allocation/query`	Check existing allocation records against the allocation groups and hierarchy

Allocate

Call the `Allocate` API to allocate a product that has specific dimensions. Here's the schema for the request body.

JSON

```
{
    "id": "string",
    "productId": "string",
    "dimensionDataSource": "string",
    "groups": {
        "groupA": "string",
        "groupB": "string",
        "groupC": "string"
    },
    "quantity": decimal,
    "organizationId": "string",
    "dimensions": {
        "dimension1": "string",
        "dimension2": "string",
        "dimension3": "string"
    }
}
```

For example, you want to allocate a quantity of 10 for product *Bike*, site *1*, location *11*, color *red*, channel *Online*, customer group *VIP*, and region *US*. To do this allocation, you can make a call that has the following body content.

JSON

```
{
    "id": "test101",
    "productId": "Bike",
    "groups": {
        "channel": "Online",
        "customerGroup": "VIP",
        "region": "US"
    },
    "quantity": 10,
    "organizationId": "usmf",
    "dimensions": {
        "siteId": "1",
        "locationId": "11",
        "colorId": "red"
    }
}
```

The quantity must always be more than 0 (zero).

Unallocate

Use the `Unallocate` API to reverse the `Allocate` operation. Negative quantity isn't allowed in an `Allocate` operation. The body of `Unallocate` is identical to the body of `Allocate`.

Reallocate

Use the `Reallocate` API to move some allocated quantity to another group combination. Here's the schema for the request body.

JSON

```
{
    "id": "string",
    "productId": "string",
    "dimensionDataSource": "string",
    "sourceGroups": {
        "groupA": "string",
        "groupB": "string",
        "groupC": "string"
    },
    "groups": {
        "groupD": "string",
```

```
        "groupE": "string",
        "groupF": "string"
    },
    "quantity": decimal,
    "organizationId": "string",
    "dimensions": {
        "dimension1": "string",
        "dimension2": "string",
        "dimension3": "string"
    }
}
```

For example, you can move two bikes that have the dimensions [site=1, location=11, color=red] from allocation group [Online, VIP, US] to allocation group [Online, VIP, EU] by calling the `Reallocate` API and providing the following body text.

JSON

```
{
    "id": "test102",
    "productId": "Bike",
    "sourceGroups": {
        "channel": "Online",
        "customerGroup": "VIP",
        "region": "US"
    },
    "groups": {
        "channel": "Online",
        "customerGroup": "VIP",
        "region": "EU"
    },
    "quantity": 2,
    "organizationId": "usmf",
    "dimensions": {
        "siteId": "1",
        "locationId": "11",
        "colorId": "red"
    }
}
```

Consume

Use the `Consume` API to post the consumption quantity against allocation. For example, you could use this API to move allocated quantity to some real measures. Here's the schema for the request body.

JSON

```
{
    "id": "string",
    "productId": "string",
    "dimensionDataSource": "string",
    "groups": {
        "groupA": "string",
        "groupB": "string",
        "groupC": "string"
    },
    "quantity": decimal,
    "organizationId": "string",
    "dimensions": {
        "dimension1": "string",
        "dimension2": "string",
        "dimension3": "string"
    },
    "physicalMeasures": {
        "datasource1": {
            "measure": "string" // Addition or Subtraction
        }
    }
}
```

For example, there are eight allocated bikes that have the dimensions [site=1, location=11, color=red] for allocation group [Online, VIP, US]. The following available-to-allocate formula is used:

`@iv.@available_to_allocate` = `fno.onordered` + `pos.inbound` − `@iv.@allocated`

The eight bikes are allocated from the `pos.inbound` measure.

Now, three bikes are sold, and they're taken from the allocation pool. To register this move, you can make a call that has the following request body.

JSON

```
{
    "id": "test103",
    "organizationId": "usmf",
    "productId": "Bike",
    "dimensions": {
        "siteId": "1",
        "locationId": "11",
        "colorId": "red"
    },
    "groups": {
        "channel": "Online",
        "customerGroup": "VIP",
        "region": "US"
    },
```

```
    "quantity": 3,
    "physicalMeasures": {
        "pos": {
            "inbound": "Subtraction"
        }
    }
}
```

After this call, the allocated quantity for the product will be reduced by 3. In addition, Inventory Visibility will generate an on-hand change event where `pos.inbound` = *-3*. Alternatively, you can keep the `pos.inbound` value as is, and just consume the allocated quantity. However, in this case, you must either create another physical measure to keep the consumed quantities or use the predefined measure `@iv.@consumed`.

In this request, notice that the physical measure you use in the consume request body should use the opposite modifier type (Addition or Subtraction), compared with the modifier type used in the calculated measure. So in this consume body, `iv.inbound` has the value `Subtraction`, not `Addition`.

The `fno` data source can't be used in the consume body as we always claimed that Inventory Visibility can't change any data for the `fno` data source. The data flow is one-way, which means that all quantity changes for the `fno` data source must come from your Supply Chain Management environment.

Consume as a soft reservation

The `Consume` API can also consume the allocated quantity as a soft reservation. In this case, the `Consume` operation will reduce the allocated quantity and then create a soft reservation for that quantity. To use this approach, you must also be using the soft reservation feature of Inventory Visibility.

For example, you've set a soft reservation physical measure as `iv.softreserved`. The following formula is used for the available-to-reserve calculated measure:

`iv.available_to_reserve` = `fno.onordered` + `pos.inbound` – `iv.softreserved`

To use this setup with the allocation feature, add `@iv.@allocated` to `iv.available_to_reserve` to produce the following formula:

`iv.available_to_reserve` = `fno.onordered` + `pos.inbound` – `iv.softreserved` – `@iv.@allocated`

Then update `@iv.@available_to_allocate` to the same value.

When you want to consume a quantity of 3 and directly reserve this quantity, you can make a call that has the following request body.

JSON

```
{
    "id": "???",
    "organizationId": "usmf",
    "productId": "Bike",
    "dimensions": {
        "siteId": "1",
        "locationId": "11",
        "colorId": "red"
    },
    "groups": {
        "channel": "Online",
        "customerGroup": "VIP",
        "region": "US"
    },
    "quantity": 3,
    "physicalMeasures": {
        "iv": {
            "softreserved": "Addition"
        }
    }
}
```

In this request, notice that `iv.softreserved` has the value `Addition`, not `Subtraction`.

Query

Use the `Query` API to retrieve allocation related information for some products. You can use dimension filters and allocation group filters to narrow down the results. *The dimensions must match exactly the one you want to retrieve*, for example, [site=1, location=11] will have unrelated results compared with [site=1, location=11, color=red].

JSON

```
{
    "productId": "string",
    "organizationId": "string",
    "dimensions": {
        "dimension1": "string",
        "dimension2": "string",
        "dimension3": "string"
    },
    "groups": {
        "additionalProp1": "string",
        "additionalProp2": "string",
```

```
        "additionalProp3": "string"
    },
}
```

For example, use [site=1, location=11, color=red] and empty groups field to get all allocation records:

JSON

```
{
    "organizationId": "usmf",
    "productId": "Bike",
    "dimensions": {
        "siteId": "1",
        "locationId": "11",
        "colorId": "red"
    },
    "groups": {},
}
```

Use [site=1, location=11, color=red] and groups [channel=Online, customerGroup=VIP, region=US] to get allocation records for this group:

JSON

```
{
    "organizationId": "usmf",
    "productId": "Bike",
    "dimensions": {
        "siteId": "1",
        "locationId": "11",
        "colorId": "red"
    },
    "groups": {
        "channel": "Online",
        "customerGroup": "VIP",
        "region": "US"
    },
}
```

Use the allocation user interface

You can manually manage allocations by using the Inventory Visibility app in Power Apps.

> ⓘ **Important**

In the current version of the Inventory Visibility app, you can manage allocations only when you're using Inventory Visibility UI version 1. If you're using UI version 2, you must use the APIs to manage allocations. For more information about the two UI versions and how to switch between them, see Inventory Visibility app user interface versions.

Open the allocation user interface

The **Allocation** tab on the **Operational visibility** page serves as the user interface where you can create, consume, reallocate, and query allocations, as described in later subsections.

To open the allocation user interface, follow these steps.

1. Sign in to your Power Apps environment, and open the **Inventory Visibility** app.
2. On the **Change area** menu at the bottom of the navigation pane, select **Legacy UI**.
3. On the navigation pane, select **Operational visibility**.
4. Select the **Allocation** tab.

Create an allocation

Follow these steps to create an allocation in the Inventory Visibility app.

1. On the toolbar of the **Allocation** tab, select **Allocate**.
2. Set the **Base fields**, **Dimensions**, and **Target allocation groups** values. When you're selecting values in the **Dimensions** section, first select a data source, then select a dimension from that data source, and then enter dimension values in the fields that appear each time you add a dimension.
3. Select **Submit**.

Consume an allocation

On the toolbar of the **Allocation** tab, select **Consume** to consume an allocation. To ensure that you consume within the correct allocation group and hierarchy, enter the same sets of organization and dimension details that you specified when you created the allocation.

Reallocate an allocation

On the toolbar of the **Allocation** tab, select **Reallocate** to move existing allocated quantity from one set of allocation groups to another.

Query existing allocations

On the toolbar of the **Allocation** tab, select **Query**, and then enter product, organization, dimension, and allocation group values to obtain query results of existing allocations.

Inventory Visibility on-hand change schedules and ATP

06/17/2025

This article describes how to set up the *On-hand change schedule* feature to schedule future on-hand changes and calculate available-to-promise (ATP) quantities. ATP is the quantity of an item that's available and can be promised to a customer in the next period. Use of this calculation can greatly increase your order fulfillment capability.

For many manufacturers, retailers, or sellers, it isn't enough just to know what's currently on hand. They must have full visibility into future availability. This future availability should consider future supply, future demand, and ATP.

Calculated measures for ATP quantities

The *ATP calculated measure* is a predefined calculated measure that's typically used to find the on-hand quantity that's currently available. The *supply quantity* is the sum of quantities for those physical measures that have a modifier type of *addition*, and the *demand quantity* is the sum of quantities for those physical measures that have a modifier type of *subtraction*.

You can add multiple calculated measures to calculate multiple ATP quantities. However, the total number of distinct physical measures across all ATP calculated measures should be less than nine.

> **Important**
>
> A calculated measure is a composition of physical measures. Its formula can include only physical measures without duplicates, not calculated measures.

For example, you set up the following calculated measure:

On-hand-available = (*PhysicalInvent* + *OnHand* + *Unrestricted* + *QualityInspection* + *Inbound*) – (*ReservPhysical* + *SoftReservePhysical* + *Outbound*)

The sum (*PhysicalInvent* + *OnHand* + *Unrestricted* + *QualityInspection* + *Inbound*) represents supply, and the sum (*ReservPhysical* + *SoftReservePhysical* + *Outbound*) represents demand. Therefore, the calculated measure can be understood in the following way:

On-hand-available = *Supply – Demand*

You can add another calculated measure to calculate the **On-hand-physical** ATP quantity.

On-hand-physical = (*PhysicalInvent* + *OnHand* + *Unrestricted* + *QualityInspection* + *Inbound*) – (*Outbound*)

There are eight distinct physical measures across those two ATP calculated measures: *PhysicalInvent*, *OnHand*, *Unrestricted*, *QualityInspection*, *Inbound*, *ReservPhysical*, *SoftReservePhysical*, and *Outbound*.

For more information about calculated measures, see Calculated measures.

Turn on and set up on-hand change scheduling and ATP in UI version 2

This section applies when you're using Inventory Visibility UI version 2.

Before you can use ATP, you must set up one or more calculated measures to calculate the ATP quantities. You must also turn on the feature and configure ATP settings in Microsoft Power Apps.

Follow these steps to turn on the *On-hand change schedule* feature in Power Apps and configure the ATP settings.

1. Sign in to Power Apps, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Feature management**.
3. On the **Available to promise** tile, select **Manage**.
4. Set the **Enable feature** option to *True* to turn on the ATP feature.
5. Set the **Max schedule period (days)** field to the number of days that users can view and submit scheduled on-hand changes. Users who query for stock information will get the on-hand quantity, scheduled on-hand changes, and ATP for each day in the defined period, starting from the current date. The maximum value for this field is 180 days. By default, it's set to 30 days. Therefore, you can schedule changes for up to 30 days from today.

   > **ⓘ Important**
   >
   > The schedule period includes the current date. Therefore, users can schedule on-hand changes to occur any time from the current date (the day when the change is submitted) through (schedule period – 1) days in the future.

6. In the **Schedule Measures** section, set up schedule measures. You can use existing calculated measures as schedule measures, or you can create new ones. When you query Inventory Visibility, the ATP value is provided for defined calculated measures, based on the scheduled changes of component physical measures. In the **Schedule Measures** section, select **New OnHand Change Schedule Configuration V2** on the toolbar to add a new calculated measure binding for ATP. The calculated measure is what you want to use to find the currently available on-hand quantity. For information about how to create a calculated measure, see Calculated measures.

   > **Important**
   >
   > The default ATP calculated formula is for reference. You can modify and add other data sources and physical measures to set up the correct ATP calculation for your business.

7. In the **ATP Index Set Configuration** section, set up your ATP index. The ATP index resembles the *product index hierarchy* that lets you group query results by specific dimensions. For example, if you set *ColorId* and *SizeId* as your ATP index set, query results will be grouped by color and size. You can have multiple index sets.

   > **Important**
   >
   > The default *ColorId* and *SizeId* index is for reference. You can remove dimensions and add other dimensions.

8. Select **Save**.

9. When you've finished configuring all the required settings, select **Update Configuration** under **Admin Settings** on the navigation pane.

Learn more in Complete and update the configuration.

How the on-hand change schedule and ATP calculations work

An *on-hand change schedule* establishes expected dates and quantities of scheduled on-hand changes. You can submit an on-hand change schedule to Inventory Visibility, provided that the dates are within the period that's defined by the **Schedule period** setting (see the Enable and set up the features section of this article). Users who query for stock information will get the on-hand quantity, scheduled on-hand changes, and ATP for each day in that period.

Scheduled changes are initially uncommitted and therefore don't affect your actual on-hand quantities in the system. To commit the changes, you must submit an *on-hand change event*, which updates the actual available on-hand quantity. You must then revert the scheduled change by submitting an on-hand change schedule for a matching negative quantity.

For example, you place an order for 10 bikes and expect it to arrive tomorrow. Therefore, you submit an on-hand change schedule that has an inbound quantity of 10 and is dated for tomorrow. When the order arrives the next day, you add the bikes to your physical on-hand inventory. You must then commit the change to your system to update the actual on-hand quantity. To commit the change, you submit an on-hand change event that has an inbound quantity of 10. You then revert the scheduled change by submitting an on-hand change schedule that has an inbound quantity of -10.

When you query Inventory Visibility for on-hand and ATP quantities, it returns the following information for each day in the schedule period:

- **Date** – The date that the result applies to. The time zone is Coordinated Universal Time (UTC).
- **On-hand quantity** – The actual on-hand quantity for the specified date. This calculation is made according to the ATP calculated measure that's configured for Inventory Visibility.
- **Scheduled supply** – The sum of all scheduled inbound quantities that haven't become physically available for immediate consumption or shipment as of the specified date.
- **Scheduled demand** – The sum of all scheduled outbound quantities that haven't been consumed or shipped as of the specified date.
- **ATP quantity** – The minimum projected on-hand quantity that's available from the specified date through the end of the schedule period. This quantity includes all scheduled quantity adjustments. It's the maximum quantity that can be promised on the current date for delivery or consumption on that day.

For example, if the current date is February 1, 2022, and the schedule period is 7, users can submit scheduled on-hand changes that are expected to occur from February 1 through February 7, 2022. In this case, the ATP quantity for February 3, for example, is calculated based on the on-hand quantity for that day and the scheduled quantities from February 3 through February 7.

Example

The following example shows how a series of scheduled quantity changes affects the on-hand and ATP quantities that Inventory Visibility reports. It also shows how to commit a scheduled change, how a committed schedule change affects the results, and what can occur if you don't commit a scheduled change.

The results in this example show a *projected on-hand* value. This value incorporates all scheduled updates for illustration purposes but isn't actually reported when you query Inventory Visibility.

1. The following settings are configured for your system on the **ATP setting** page of the Inventory Visibility app in Power Apps:

    - **Schedule measures** – A calculated measure that's named *On-hand* is added here. It's calculated as *On-hand = Supply – Demand*.
    - **Max schedule period (days)** – The value is set to *7*.
    - **ATP index set configuration** – *ColorId* and *SizeId* are added here.

2. The following conditions also apply:

    - The current date is February 1, 2022.
    - The current on-hand quantity is 20.

3. For the current date (February 1, 2022), you submit a scheduled demand quantity of 3 to Inventory Visibility. Therefore, the projected on-hand quantity is 17. The following table shows the result.

Expand table

Date	On-hand	Scheduled supply	Scheduled demand	Projected on-hand	ATP
2022-02-01	20		3	17	17
2022-02-02	20			17	17
2022-02-03	20			17	17
2022-02-04	20			17	17
2022-02-05	20			17	17
2022-02-06	20			17	17
2022-02-07	20			17	17

4. On the current date (February 1, 2022), you submit a scheduled supply quantity of 10 for February 3, 2022. The following table shows the result.

Expand table

Date	On-hand	Scheduled supply	Scheduled demand	Projected on-hand	ATP
2022-02-01	20		3	17	17

Date	On-hand	Scheduled supply	Scheduled demand	Projected on-hand	ATP
2022-02-02	20			17	17
2022-02-03	20	10		27	27
2022-02-04	20			27	27
2022-02-05	20			27	27
2022-02-06	20			27	27
2022-02-07	20			27	27

5. On the current date (February 1, 2022), you submit the following scheduled quantity changes:

   - Demand quantity of 15 for February 4, 2022
   - Supply quantity of 1 for February 5, 2022
   - Supply quantity of 3 for February 6, 2022

   The following table shows the result.

Expand table

Date	On-hand	Scheduled supply	Scheduled demand	Projected on-hand	ATP
2022-02-01	20		3	17	12
2022-02-02	20			17	12
2022-02-03	20	10		27	12
2022-02-04	20		15	12	12
2022-02-05	20	1		13	13
2022-02-06	20	3		16	16
2022-02-07	20			16	16

6. On the current date (February 1, 2022), you ship the scheduled demand quantity of 3. Therefore, you must commit this change so that it's reflected in your actual on-hand quantity. To commit the change, you submit an on-hand change event that has an outbound quantity of 3. You then revert the scheduled change by submitting an on-hand change schedule that has an outbound quantity of -3. The following table shows the result.

Expand table

Date	On-hand	Scheduled supply	Scheduled demand	Projected on-hand	ATP
2022-02-01	17		0	17	12
2022-02-02	17			17	12
2022-02-03	17	10		27	12
2022-02-04	17		15	12	12
2022-02-05	17	1		13	13
2022-02-06	17	3		16	16
2022-02-07	17			16	16

7. On the next day (February 2, 2022), the schedule period shifts forward by one day. The following table shows the result.

Expand table

Date	On-hand	Scheduled supply	Scheduled demand	Projected on-hand	ATP
2022-02-02	17			17	12
2022-02-03	17	10		27	12
2022-02-04	17		15	12	12
2022-02-05	17	1		13	13
2022-02-06	17	3		16	16
2022-02-07	17			16	16
2022-02-08	17			16	16

8. However, two days later (February 4, 2022), the supply quantity of 10 that was scheduled for February 3 still hasn't arrived. The following table shows the result.

Expand table

Date	On-hand	Scheduled supply	Scheduled demand	Projected on-hand	ATP
2022-02-04	17		15	2	2
2022-02-05	17	1		3	3

Date	On-hand	Scheduled supply	Scheduled demand	Projected on-hand	ATP
2022-02-06	17	3		6	6
2022-02-07	17			6	6
2022-02-08	17			6	6
2022-02-09	17			6	6
2022-02-10	17			6	6

As you see, the scheduled (but not committed) on-hand changes don't affect the actual on-hand quantity.

Submit change schedules, change events, and ATP queries through the API

You can use the following application programming interface (API) URLs to submit on-hand change schedules, change events, and queries.

Expand table

Path	Method	Description
`/api/environment/{environmentId}/onhand/changeschedule`	`POST`	Create one scheduled on-hand change.
`/api/environment/{environmentId}/onhand/changeschedule/bulk`	`POST`	Create multiple scheduled on-hand changes.
`/api/environment/{environmentId}/onhand`	`POST`	Create one on-hand change event.
`/api/environment/{environmentId}/onhand/bulk`	`POST`	Create multiple change events.
`/api/environment/{environmentId}/onhand/indexquery`	`POST`	Query by using the `POST` method.
`/api/environment/{environmentId}/onhand`	`GET`	Query by using the `GET` method.
`/api/environment/{environmentId}/onhand/exactquery`	`POST`	Exact query by using the `POST` method.

Learn more in Inventory Visibility public APIs.

Create one on-hand change schedule

An on-hand change schedule is created by submitting a `POST` request to the relevant Inventory Visibility service URL. You can also submit bulk requests.

An on-hand change schedule can be created only if the scheduled date is between the current date and the end of the current schedule period. The datetime format should be *year-month-day* (for example, **2022-02-01**). The time format must be accurate only to the day.

This API creates a single on-hand change schedule.

txt

```
Path:
    /api/environment/{environmentId}/onhand/changeschedule

        },
        quantitiesByDate: {
            [datetime:datetime]: {
                [dataSourceName:string]: {
                    [key:string]: number,
                },
            },
        },
    }
```

The following example shows sample body content without `dimensionDataSource`.

JSON

```
{
    "id": "id-bike-0001",
    "organizationId": "usmf",
    "productId": "Bike",
    "dimensions": {
        "SiteId": "1",
```

```
        "LocationId": "11",
        "ColorId": "Red",
        "SizeId": "Small"
    },
    "quantitiesByDate": {
        "2022-02-01": {
            "pos": {
                "inbound": 10
            }
        }
    }
}
```

Create multiple on-hand change schedules

This API can create multiple records at the same time. The only differences between this API and the single-event API are the `Path` and `Body` values. For this API, `Body` provides an array of records. The maximum number of records is 512. Therefore, the on-hand change schedule bulk API can support up to 512 scheduled changes at a time.

txt

```
Path:
    /api/environment/{environmentId}/onhand/changeschedule/bulk
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    [
        {
            id: string,
            organizationId: string,
            productId: string,
            dimensionDataSource: string,
            dimensions: {
                [key:string]: string,
            },
            quantityDataSource: string, # optional
            quantitiesByDate: {
                [datetime:datetime]: {
                    [dataSourceName:string]: {
                        [key:string]: number,
                    },
                },
            },
        },
```

```
        ...
    ]
```

The following example shows sample body content.

JSON

```
[
    {
        "id": "id-bike-0001",
        "organizationId": "usmf",
        "productId": "Bike",
        "dimensions": {
            "SiteId": "1",
            "LocationId": "11",
            "ColorId": "Red",
            "SizeId": "Small"
        },
        "quantitiesByDate": {
            "2022-02-01": {
                "pos": {
                    "inbound": 10
                }
            }
        }
    },
    {
        "id": "id-car-0002",
        "organizationId": "usmf",
        "productId": "Car",
        "dimensions": {
            "SiteId": "1",
            "LocationId": "11",
            "ColorId": "Red",
            "SizeId": "Small"
        },
        "quantitiesByDate": {
            "2022-02-05": {
                "pos": {
                    "outbound": 10
                }
            }
        }
    }
]
```

Create on-hand change events

On-hand change events are made by submitting a `POST` request to the relevant Inventory Visibility service URL (see the start of the Submit change schedules, change events, and ATP

queries through the API section).

> **Note**
>
> On-hand change events aren't unique to the ATP functionality but are part of the standard Inventory Visibility API. This example has been included because events are relevant when you work with ATP. On-hand change events resemble on-hand change reservations, but event messages must be sent to a different API URL, and events use `quantities` instead of `quantityByDate` in the message body. For more information about the on-hand change events and other features of the Inventory Visibility API, see Inventory Visibility public APIs.

The following example shows a request body that contains a single on-hand change event.

JSON

```
{
    "id": "id-bike-0001",
    "organizationId": "usmf",
    "productId": "Bike",
    "dimensions": {
        "SiteId": "1",
        "LocationId": "11",
        "SizeId": "Big",
        "ColorId": "Red"
    },
    "quantities": {
        "pos": {
            "inbound": 10.0
        }
    }
}
```

Query the scheduled on-hand changes and ATP results

You can query scheduled on-hand changes and ATP results by submitting either a `POST` request or a `GET` request to the appropriate API URL (see the Submit change schedules, change events, and ATP queries through the API section).

In your request, set `QueryATP` to *true* if you want to query scheduled on-hand changes and ATP results. By default, the query returns all ATP-related data from today. You can specify `ATPFromDate` and `ATPToDate` to narrow the results. (The "to" and "from" dates just filter the

result. They don't affect how ATP is calculated.) The value of the `groupByValues` parameter must exactly match one of your ATP index sets.

- If you're submitting the request by using the `GET` method, set these parameters in the URL.
- If you're submitting the request by using the `POST` method, set these parameters in the request body.

> **Note**
>
> Regardless of whether the `returnNegative` parameter is set to *true* or *false* in the request body, the result will include negative values when you query for scheduled on-hand changes and ATP results. These negative values will be included because, if only demand orders are scheduled, or if supply quantities are less than demand quantities, the scheduled on-hand change quantities will be negative. If negative values weren't included, the results would be confusing. For more information about this option and how it works for other types of queries, see Inventory Visibility public APIs.

> **Important**
>
> Scheduled on-hand changes are stored exclusively in Dataverse, which means that queries for scheduled on-hand changes and ATP results are subject to Dataverse's performance and data access limits. To avoid exceeding these limits and ensure optimal performance, apply targeted filters to your queries to minimize the volume of data retrieved.

Query by using the POST method

txt

```
Path:
    /api/environment/{environmentId}/onhand/indexquery
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    {
        dimensionDataSource: string, # Optional
        filters: {
            organizationId: string[],
```

```
            productId: string[],
            siteId: string[],
            locationId: string[],
            [dimensionKey:string]: string[],
        },
        groupByValues: string[],
        returnNegative: boolean,
    }
```

The following example shows how to create an index query request body that can be submitted to Inventory Visibility by using the `POST` method.

JSON

```
{
    // OnHand Index Query fields
    "filters": {
        "organizationId": ["usmf"],
        "productId": ["Bike"],
        "SiteId": ["1"],
        "LocationId": ["11"]
    },
    "groupByValues": ["ColorId", "SizeId"],
    "returnNegative": true,

    // ATP related fields
    "QueryATP":true,
    "ATPFromDate": "2022-02-01",
    "ATPToDate": "2022-02-10",
}
```

Query by using the GET method

txt

```
Path:
    /api/environment/{environmentId}/onhand
Method:
    Get
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Query(Url Parameters):
    groupBy
    returnNegative
    [Filters]
```

The following example shows how to create an index query request URL as a `GET` request.

txt

```
https://inventoryservice.{RegionShortName}-
il301.gateway.prod.island.powerapps.com/api/environment/{EnvironmentId}/onhand?
organizationId=usmf&productId=Bike&SiteId=1&LocationId=11&groupBy=ColorId,SizeId&r
eturnNegative=true&QueryATP=true&ATPToDate=2022-02-01&ATPToDate=2022-02-10
```

The result of this `GET` request is exactly the same as the result of the `POST` request in the previous example.

Exact query by using the POST method

To set up an exact query, add ATP-related fields to the query body. Learn more in Exact query by using the post method.

JSON

```
{
    // Exact query fields
    // ...

    // ATP related fields
    "QueryATP":true,
    "ATPFromDate": "2022-02-01",
    "ATPToDate": "2022-02-10",
}
```

Query result example

Any of the previous query examples might produce the following reply. For this example, the system is configured with the following settings:

- **ATP calculated measure:** *iv.onhand = pos.inbound – pos.outbound*
- **Schedule period:** *7*

Here's an example of the reply body.

JSON

```
[
    {
        "quantitiesByDate": {
            "2022-02-02T00:00:00": {
                "pos": {
```

```
                    "outbound": 5,
                    "inbound": 0,
                },
                "iv": {
                    "onhand": -5,
                },
            },
            "2022-02-06T00:00:00": {
                "pos": {
                    "inbound": 7,
                    "outbound": 0,
                },
                "iv": {
                    "onhand": 7,
                },
            }
        },
        "atpQuantities": {
            "2022-02-01T00:00:00Z": {
                "iv": {
                    "onhand": 5.0
                }
            },
            "2022-02-02T00:00:00Z": {
                "iv": {
                    "onhand": 5.0
                }
            },
            "2022-02-03T00:00:00Z": {
                "iv": {
                    "onhand": 5.0
                }
            },
            "2022-02-04T00:00:00Z": {
                "iv": {
                    "onhand": 5.0
                }
            },
            "2022-02-05T00:00:00Z": {
                "iv": {

                }
            },
            "2022-02-06T00:00:00Z": {
                "iv": {
                    "onhand": 12.0
                }
            },
            "2022-02-07T00:00:00Z": {
                "iv": {
                    "onhand": 12.0
                }
            }
        },
        "productId": "Bike ",
```

```
        "dimensions": {
            "ColorId": "Red",
            "SizeId": "Big",
            "siteid": "1",
            "locationid": "11"
        },
        "quantities": {
            "pos": {
                "inbound": 10.0,
                "outbound": 0,
            },
            "iv": {
                "onhand": 10.0,
            }
        }
    }
]
```

Track time-series inventory in Inventory Visibility

The Inventory Visibility service enables external systems to query Microsoft Dynamics 365 Supply Chain Management for inventory changes that will occur up to 180 days in the future. In this way, users who work in an external system can view future inventory availability details and make accurate projections about when orders can be delivered.

The Inventory Visibility service can import information about planned inbound and outbound inventory changes together with the related dates. Available-to-promise (ATP) functionality in Inventory Visibility can then query those time-series based inventory changes and calculate your omnichannel ATP. External systems can query and retrieve this information from Inventory Visibility in near-real time by calling its API.

The *Inventory Visibility integration with ATP* feature that is described in this article adds support for out-of-box ATP integration between Supply Chain Management and Inventory Visibility. Therefore, you can easily bring expected inventory issue and receipts together with time-series information from Supply Chain Management into Inventory Visibility. You can also post updated scheduling information back to Supply Chain Management.

Prerequisites

Before you can use the feature that is described in this article, your system must meet the following requirements:

- You must be running Supply Chain Management version 10.0.41 or later.
- The feature named *Inventory Visibility integration with ATP* must be turned on in Feature management. As of Supply Chain Management version 10.0.45, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.
- You must be running the latest version of Inventory Visibility. Learn how to install Inventory Visibility, view version information, and check for updates in Install and set up Inventory Visibility.

Enable Inventory Visibility integration with ATP in Supply Chain Management

To configure Supply Chain Management to exchange ATP information with Inventory Visibility, follow these steps:

1. Sign in to Supply Chain Management.
2. Go to **Inventory Management** > **Inventory Visibility** > **Inventory Visibility integration with ATP**.
3. On the Action Pane, select **Enable** to enable the integration. (If you must ever disable the integration, you can select **Disable** here.)

Default calculated measure for ATP in Supply Chain Management

Inventory Visibility includes a default calculated measure that is named `@iv.@atp`. This calculated measure includes all expected issues and receipts from Supply Chain Management. You typically use it to query Supply Chain Management ATP information in Inventory Visibility. You can customize it as you require. Learn how to work with calculated measures in Calculated measures.

Set up ATP in Inventory Visibility

When ATP in Inventory Visibility is integrated with Supply Chain Management, it works just as it does when it's integrated with other systems. Learn how to set up and use ATP in Inventory Visibility in Inventory Visibility on-hand change schedules and available to promise.

Work with ATP data in the Inventory Visibility app in Power Apps

When you use the Inventory Visibility app in Power Apps, you can query and post ATP information.

- To query ATP information, go to **Operational visibility** > **On hand query**. Be sure to enable the **Query ATP** option.
- To post ATP information, go to **Operational visibility** > **Change schedule**. There, you can specify and submit updated schedule information.

Learn more in Use the Inventory Visibility app UI version 2.

Query and post ATP data using the Inventory Visibility API

You can use the Inventory Visibility API to query and post ATP information. Learn more in Submit change schedules, change events, and ATP queries through the API.

Inventory Visibility Power BI dashboard

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Microsoft provides a sample Microsoft Power BI dashboard file that you can download and connect to your Inventory Visibility instance and other data sources. In this way, you can visualize your inventory levels across regions, entities, and channels. Use the dashboard to track inventory movement, compare supply and demand portions, view the most popular and least popular products, and drive decisions about inventory risk mitigation.

The dashboard lets you perform the following tasks:

- Filter on inventory dimensions to focus on the regions and products that matter most to you.
- Identify out-of-stock, understocked, and overstocked products for timely inventory replenishment or reduction.
- View inventory key performance indicators (KPIs), such as on-hand quantity, supply, and demand, to quickly monitor your inventory status.
- Tailor the sample dashboard to your organization's business needs.

License requirements

Because the dashboard is a standard Power BI file (.pbix file), you must have a Power BI license to use it. Learn more in Power BI licensing guide.

Download the dashboard and connect it to Inventory Visibility

1. Download the Inventory Visibility dashboard file from Inventory Visibility samples folder on GitHub.

2. For all the data that you plan to view by using the Power BI dashboard, configure *preloaded on-hand queries* in Inventory Visibility. For instructions, see Preload a streamlined on-hand query.

3. Connect the Power BI report to your Dataverse environment by following these steps:
   a. Open the downloaded report in Power BI desktop.
   b. Expand the **Data** pane. Select and hold (or right-click) the **Query Preload Results** table, and then select **Edit query** to open the Power Query editor.
   c. Replace the value of the `EnvironmentURL` parameter with the base URL of your Dataverse environment (for example, `example.crm.dynamics.com`).
   d. Refresh the query to update the results.

4. To load data from your entities, create a new data source, and name it *pbi* to indicate that it's your Power BI data source. (Learn more in Configure Inventory Visibility.) To reduce the size of the response body, information from this data source is excluded from results.

Default KPIs

To use the visuals and KPIs provided in the sample dashboard, define the following calculated measures in the `pbi` data source. Add the relevant physical measures from your data sources to these calculated measures.

- `Totalonhand` – The total physical inventory stock that you have in your warehouses.
- `Totalavailablephysical` – The total available physical inventory quantities.
- `Totalavailable` – The total quantities that are available. This total includes both available physical inventory and available ordered inventory, minus the on-order quantity that hasn't been promised.
- `Totalordered` – The total quantity that has been purchased or produced, or that's otherwise inbound.
- `totalonorder` – The total quantities that are on order.
- `Hardreserved` The total hard-reserved quantities. This total includes both reserve physical quantities and reserve ordered quantities.
- `Returned` – The total returned quantities. Make sure that one of your data sources includes a physical measure for returns, and that this physical measure is added to the `Returned` calculated measure.
- `Totalsold` – The total quantities that have been sold.
- `Othersupply` – Supply quantities from other user-specified sources that aren't included in the previously mentioned measures.

- `Otherdemand` – Demand quantities from other user-specified sources that aren't included in the previously mentioned measures.
- `Totalsoftreserved` – The total soft-reserved quantities.
- `Received` – The total inventory quantity received into your warehouses.

These sample calculated measures are included in the following formulas on the Power BI report:

- On the **Supply by Product** dashboard: *Total supply* = `Totalonhand` + `Totalordered` + `Othersupply`
- On the **Demand by Product** dashboard: *Total demand* = `Totalonorder` + `Totalsoftreserved` + `Totalreserved` + `Otherdemand`

Customize the dashboard

Customize the sample dashboard by directly editing the visuals. You can also edit the query to show different measures from different data sources.

To add a new data source, follow these steps:

1. Open the dashboard in Power BI desktop, and expand the **Data** pane. Select and hold (or right-click) the **Query Preload Results** table, and then select **Edit query** to open the Power Query editor.
2. On the ribbon of the Power Query editor, on the **Home** tab, select **Refresh Preview**.
3. In the **Query Settings** pane, in the **Applied Steps** section, select and hold (or right-click) the **Expanded is_quantities** step, and then select **Edit settings**.
4. Search for or select the data source that you want to add to the report.

To add, modify, or delete a column for an existing data source, follow these steps:

1. Open the dashboard in Power BI desktop, and expand the **Data** pane. Select and hold (or right-click) the **Query Preload Results** table, and then select **Edit query** to open the Power Query editor.
2. On the ribbon of the Power Query editor, on the **Home** tab, select **Refresh Preview**.
3. In the **Query Settings** pane, in the **Applied Steps** section, find the **Expanded is_quantities.<data-source>** step, where **<data-source>** is the data source that the new column belongs to.
4. Select and hold (or right-click) the step, and then select **Edit settings**.
5. Search for or select the name of the column that you want to add to the report.

You can also define new columns, based on the retrieved entity. In the sample report, the columns for total supply and total demand are calculated columns that are defined in Power BI.

If you're familiar with Power Query, directly edit the query by using the Power Query language. On the ribbon of the Power Query editor, on the **Home** tab, select **Advanced Editor** to open the advanced editor.

Inventory Visibility public APIs

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

This article describes the public APIs that are provided by Inventory Visibility.

The public REST API of the Inventory Visibility Add-in presents several specific endpoints for integration. It supports four main interaction types:

- Posting on-hand inventory changes to the add-in from an external system
- Setting or overriding on-hand inventory quantities in the add-in from an external system
- Posting reservation events to the add-in from an external system
- Querying current on-hand quantities from an external system

The following table lists the APIs that are currently available:

Expand table

Path	Method	Description
`/api/environment/{environmentId}/onhand`	Post	Create one on-hand change event
`/api/environment/{environmentId}/onhand/bulk`	Post	Create multiple change events
`/api/environment/{environmentId}/setonhand/{inventorySystem}/bulk`	Post	Set/override on-hand quantities

Path	Method	Description
`/api/environment/{environmentId}/onhand/reserve`	Post	Create one soft reservation event
`/api/environment/{environmentId}/onhand/reserve/bulk`	Post	Create multiple soft reservation events
`/api/environment/{environmentId}/onhand/unreserve`	Post	Reverse one soft reservation event
`/api/environment/{environmentId}/onhand/unreserve/bulk`	Post	Reverse multiple soft reservation events
`/api/environment/{environmentId}/onhand/reserve/resyncjob`	Post	Clean up reservation data
`/api/environment/{environmentId}/getJobProgress`	Get	Get job execution progress
`/api/environment/{environmentId}/onhand/changeschedule`	Post	Create one scheduled on-hand change
`/api/environment/{environmentId}/onhand/changeschedule/bulk`	Post	Create multiple on-hand changes with dates
`/api/environment/{environmentId}/onhand/indexquery`	Post	Query by using the post method (recommended)
`/api/environment/{environmentId}/onhand`	Get	Query by using the get method
`/api/environment/{environmentId}/onhand/exactquery`	Post	Exact query by using the post method
`/api/environment/{environmentId}/allocation/allocate`	Post	Create one allocate event
`/api/environment/{environmentId}/allocation/unallocate`	Post	Create one unallocate event
`/api/environment/{environmentId}/allocation/reallocate`	Post	Create one reallocate event
`/api/environment/{environmentId}/allocation/consume`	Post	Create one consume event
`/api/environment/{environmentId}/allocation/query`	Post	Query allocation result

Path	Method	Description
`/api/environment/{environmentId}/onhand/productsearch/indexquery`	Post	Post index query with product search
`/api/environment/{environmentId}/onhand/productsearch/exactquery`	Post	Post exact query with product search
`/api/environment/{environmentId}/transaction/adjustment/bulk`	Post	Sync external inventory changes through Inventory Visibility

> **Note**
>
> The {environmentId} part of the path is the environment ID of Microsoft Dynamics 365 Supply Chain Management. This ID is the one stated for Supply Chain Management in Microsoft Dynamics Lifecycle Services, not the ID of the Power Platform environment that is linked to the Supply Chain Management environment.
>
> The bulk API can return a maximum of 512 records for each request.

Authentication

The platform security token is used to call the Inventory Visibility public API. Therefore, you must generate a *Microsoft Entra token* by using your Microsoft Entra application. You must then use the Microsoft Entra token to get the *access token* from the security service.

To get a security service token, follow these steps:

1. Sign in to the Azure portal, and use it to find the `clientId` and `clientSecret` values for your Dynamics 365 Supply Chain Management app.
2. Fetch a Microsoft Entra token (`aadToken`) by submitting an HTTP request that has the following properties:
   - **URL:** `https://login.microsoftonline.com/${aadTenantId}/oauth2/v2.0/token`
   - **Method:** `GET`
   - **Body content (form data):**

Expand table

Key	Value
client_id	${aadAppId}
client_secret	${aadAppSecret}
grant_type	client_credentials
scope	0cdb527f-a8d1-4bf8-9436-b352c68682b2/.default

You should receive a Microsoft Entra token (`aadToken`) in response. It should resemble the following example.

JSON

```
{
    "token_type": "Bearer",
    "expires_in": "3599",
    "ext_expires_in": "3599",
    "access_token": "eyJ0eX...8WQ"
}
```

3. Formulate a JavaScript Object Notation (JSON) request that resembles the following example.

JSON

```
{
    "grant_type": "client_credentials",
    "client_assertion_type": "aad_app",
    "client_assertion": "${Your_Microsoft_EntraToken}",
    "scope": "https://inventoryservice.operations365.dynamics.com/.default",
    "context": "${fno_environment_id}",
    "context_type": "finops-env"
}
```

Note the following points:

- The `client_assertion` value must be the Microsoft Entra token (`aadToken`) that you received in the previous step.
- The `context` value must be the Supply Chain Management environment ID where you want to deploy the add-in.
- Set all the other values as shown in the example.

4. Fetch an access token (`access_token`) by submitting an HTTP request that has the following properties:

- **URL:** `https://securityservice.operations365.dynamics.com/token`
- **Method:** `POST`
- **HTTP header:**

Expand table

Key	Value
Api-Version	1.0
Content-Type	application/json

- **Body content:** Include the JSON request that you created in the previous step.

You should receive an access token (`access_token`) in response. You must use this token as a bearer token to call the Inventory Visibility API. Here's an example.

JSON

```
{
    "access_token": "${Returned_Token}",
    "token_type": "bearer",
    "expires_in": 3600
}
```

> **Note**
>
> If you receive a response with status code 307, use the value of the `Location` header to resend the token request to the new URL. Most HTTP libraries handle redirects automatically.

Create on-hand change events

There are two APIs for creating on-hand change events:

- Create one record: `/api/environment/{environmentId}/onhand`
- Create multiple records: `/api/environment/{environmentId}/onhand/bulk`

The following table summarizes the meaning of each field in the JSON body.

Expand table

Field ID	Description
`id`	A unique ID for the specific change event. If a resubmission occurs due to a service failure, this ID is used to ensure the same event won't be counted twice in the system.
`organizationId`	The identifier of the organization that's linked to the event. This value is mapped to an organization or data area ID in Supply Chain Management.
`productId`	The identifier of the product.
`quantities`	The quantity that the on-hand quantity must be changed by. For example, if 10 new books are added to a shelf, this value will be `quantities:{ shelf:{ received: 10 }}`. If three books are removed from the shelf or sold, this value will be `quantities:{ shelf:{ sold: 3 }}`.
`dimensionDataSource`	The data source of the dimensions that are used in the posting change event and query. If you specify the data source, you can use the custom dimensions from the specified data source. Inventory Visibility can use the dimension configuration to map the custom dimensions to the general default dimensions. If no `dimensionDataSource` value is specified, you can use only the general base dimensions in your queries.
`dimensions`	A dynamic key-value pair. The values are mapped to some of the dimensions in Supply Chain Management. However, you can also add custom dimensions (for example, *Source*) to indicate whether the event is coming from Supply Chain Management or an external system.

> **Note**
>
> If your data partition rule is set to *By product ID*, `siteId` and `locationId` are optional dimensions. Otherwise, they're required dimensions. This rule also applies to the allocation, soft reserve, and change schedule APIs.

The following subsections provide examples that show how to use these APIs.

Create one on-hand change event

This API creates a single on-hand change event.

txt

```
Path:
    /api/environment/{environmentId}/onhand
Method:
    Post
Headers:
```

```
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    {
        id: string,
        organizationId: string,
        productId: string,
        dimensionDataSource: string, # Optional
        dimensions: {
            [key:string]: string,
        },
        quantities: {
            [dataSourceName:string]: {
                [key:string]: number,
            },
        },
    }
```

The following example shows sample body content. In this example, the company has a point-of-sale (POS) system that processes in-store transactions and therefore inventory changes. The customer has returned a red T-shirt to your store. To reflect the change, you post a single change event for the *T-shirt* product. This event will increase the quantity of the *T-shirt* product by 1.

JSON

```
{
    "id": "Test201",
    "organizationId": "usmf",
    "productId": "T-shirt",
    "dimensionDataSource": "pos",
    "dimensions": {
        "siteId": "1",
        "locationId": "11",
        "posMachineId": "0001",
        "colorId": "red"
    },
    "quantities": {
        "pos": {
            "inbound": 1
        }
    }
}
```

The following example shows sample body content without `dimensionDataSource`. In this case, `dimensions` will be the base dimensions. If `dimensionDataSource` is set, `dimensions` can be either the data source dimensions or the base dimensions.

JSON

```
{
    "id": "Test202",
    "organizationId": "usmf",
    "productId": "T-shirt",
    "dimensions": {
        "siteId": "1",
        "locationId": "11",
        "colorId": "red"
    },
    "quantities": {
        "pos": {
            "inbound": 1
        }
    }
}
```

Create multiple change events

This API can create change events, just as the single-event API can. The only difference is that this API can create multiple records at the same time. Therefore, the `Path` and `Body` values differ. For this API, `Body` provides an array of records. The maximum number of records is 512. Therefore, the on-hand change bulk API can support up to 512 change events at a time.

For example, a retail store POS machine processed the following two transactions:

- One return order of one red T-shirt
- One sales transaction of three black T-shirts

In this case, you can include both inventory updates in one API call.

txt

```
Path:
    /api/environment/{environmentId}/onhand/bulk
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    [
        {
            id: string,
            organizationId: string,
            productId: string,
            dimensionDataSource: string, # Optional
```

```
            dimensions: {
                [key:string]: string,
            },
            quantities: {
                [dataSourceName:string]: {
                    [key:string]: number,
                },
            },
        },
        ...
    ]
```

The following example shows sample body content.

JSON

```
[
    {
        "id": "Test203",
        "organizationId": "usmf",
        "productId": "T-shirt",
        "dimensionDataSource": "pos",
        "dimensions": {
            "SiteId": "Site1",
            "LocationId": "11",
            "posMachineId": "0001"
            "colorId": "red"
        },
        "quantities": {
            "pos": { "inbound": 1 }
        }
    },
    {
        "id": "Test204",
        "organizationId": "usmf",
        "productId": "T-shirt",
        "dimensions": {
            "siteId": "1",
            "locationId": "11",
            "colorId": "black"
        },
        "quantities": {
            "pos": { "outbound": 3 }
        }
    }
]
```

Set/override on-hand quantities

The *Set on-hand* API overrides the current data for the specified product. This functionality is typically used to do inventory counting updates. For example, during its daily inventory counting, a store might find that the actual on-hand inventory for a red T-shirt is 100. Therefore, the POS inbound quantity must be updated to 100, regardless of what the previous quantity was. You can use this API to override the existing value.

txt

```
Path:
    /api/environment/{environmentId}/setonhand/{inventorySystem}/bulk
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    [
        {
            id: string,
            organizationId: string,
            productId: string,
            dimensionDataSource: string, # Optional
            dimensions: {
                [key:string]: string,
            },
            quantities: {
                [dataSourceName:string]: {
                    [key:string]: number,
                },
            },
            modifiedDateTimeUTC: datetime,
        },
        ...
    ]
```

The following example shows sample body content. The behavior of this API differs from the behavior of the APIs that are described in the Create on-hand change events section earlier in this article. In this sample, the quantity of the *T-shirt* product will be set to 1.

JSON

```
[
    {
        "id": "Test204",
        "organizationId": "usmf",
        "productId": "T-shirt",
        "dimensionDataSource": "pos",
        "dimensions": {
```

```
            "SiteId": "1",
            "LocationId": "11",
            "posMachineId": "0001"
            "colorId": "red"
        },
        "quantities": {
            "pos": {
                "inbound": 100
            }
        }
    }
]
```

Create reservation events

To use the *Reserve* API, you must turn on the reservation feature and complete the reservation configuration. For more information (including a dataflow and sample scenario), see Inventory Visibility reservations.

Create one reservation event

A reservation can be made against different data source settings. To configure this type of reservation, first specify the data source in the `dimensionDataSource` parameter. Then, in the `dimensions` parameter, specify dimensions according to the dimension settings in the target data source.

When you call the reservation API, you can control the reservation validation by specifying the Boolean `ifCheckAvailForReserv` parameter in the request body. A value of `True` means that the validation is required, whereas a value of `False` means that the validation isn't required. The default value is `True`.

If you want to reverse a reservation or unreserve specified inventory quantities, set the quantity to a negative value, and set the `ifCheckAvailForReserv` parameter to `False` to skip the validation. There's also a dedicated unreserve API to do the same. The difference is only in the way the two APIs are called. It's easier to reverse a specific reservation event by using `reservationId` with the *unreserve* API. Learn more in Unreserve one reservation event section.

txt

```
Path:
    /api/environment/{environmentId}/onhand/reserve
Method:
    Post
Headers:
    Api-Version="1.0"
```

```
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    {
        id: string,
        organizationId: string,
        productId: string,
        dimensionDataSource: string,
        dimensions: {
            [key:string]: string,
        },
        quantityDataSource: string, # optional
        quantities: {
            [dataSourceName:string]: {
                [key:string]: number,
            },
        },
        modifier: string,
        quantity: number,
        ifCheckAvailForReserv: boolean,
    }
```

The following example shows sample body content.

JSON

```
{
    "id": "reserve-0",
    "organizationId": "SCM_IV",
    "productId": "iv_contoso_product",
    "quantity": 1,
    "quantityDataSource": "iv",
    "modifier": "softReservOrdered",
    "ifCheckAvailForReserv": true,
    "dimensions": {
        "siteId": "iv_contoso_site",
        "locationId": "iv_contoso_location",
        "colorId": "red",
        "sizeId": "small"
    }
}
```

The following example shows a successful response.

JSON

```
{
    "reservationId": "RESERVATION_ID",
    "id": "ohre~id-822-232959-524",
    "processingStatus": "success",
    "message": "",
```

```
    "statusCode": 200
}
```

Create multiple reservation events

This API is a bulk version of the single-event API.

txt

```
Path:
    /api/environment/{environmentId}/onhand/reserve/bulk
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    [
        {
            id: string,
            organizationId: string,
            productId: string,
            dimensionDataSource: string,
            dimensions: {
                [key:string]: string,
            },
            quantityDataSource: string, # optional
            quantities: {
                [dataSourceName:string]: {
                    [key:string]: number,
                },
            },
            modifier: string,
            quantity: number,
            ifCheckAvailForReserv: boolean,
        },
        ...
    ]
```

Reverse reservation events

The *Unreserve* API serves as the reverse operation for *Reservation* events. It provides a way to reverse a reservation event specified by `reservationId` or to decrease the reservation quantity.

Reverse one reservation event

When a reservation is created, a `reservationId` will be included in the response body. You must provide the same `reservationId` to cancel the reservation, and include the same `organizationId`, `productId`, and `dimensions` used for the reservation API call. Finally, specify an `OffsetQty` value that represents the number of items to be freed from the previous reservation. A reservation can either be fully or partially reversed depending on the specified `OffsetQty`. For example, if *100* units of items were reserved, you can specify `OffsetQty: 10` to unreserve *10* of the initial reserved amount.

txt

```
Path:
    /api/environment/{environmentId}/onhand/unreserve
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    {
        id: string,
        organizationId: string,
        productId: string,
        reservationId: string,
        dimensions: {
            [key:string]: string,
        },
        OffsetQty: number
    }
```

The following code shows an example of body content.

JSON

```
{
    "id": "unreserve-0",
    "organizationId": "SCM_IV",
    "productId": "iv_contoso_product",
    "reservationId": "RESERVATION_ID",
    "dimensions": {
        "siteid":"iv_contoso_site",
        "locationid":"iv_contoso_location",
        "ColorId": "red",
        "SizeId": "small"
    },
    "OffsetQty": 1
}
```

The following code shows an example of a successful response body.

JSON

```
{
    "reservationId": "RESERVATION_ID",
    "totalInvalidOffsetQtyByReservId": 0,
    "id": "ohoe~id-823-11744-883",
    "processingStatus": "success",
    "message": "",
    "statusCode": 200
}
```

> **Note**
>
> In the response body, when `OffsetQty` is less than or equal to the reservation quantity, `processingStatus` will be "*success*" and `totalInvalidOffsetQtyByReservId` will be *0*.
>
> If `OffsetQty` is greater than the reserved amount, `processingStatus` will be "*partialSuccess*" and `totalInvalidOffsetQtyByReservId` will be the difference between `OffsetQty` and the reserved amount.
>
> For example, if the reservation has a quantity of *10*, and `OffsetQty` has a value of *12*, `totalInvalidOffsetQtyByReservId` would be *2*.

Reverse multiple reservation events

This API is a bulk version of the single-event API.

txt

```
Path:
    /api/environment/{environmentId}/onhand/unreserve/bulk
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    [
        {
            id: string,
            organizationId: string,
            productId: string,
```

```
            reservationId: string,
            dimensions: {
                [key:string]: string,
            },
            OffsetQty: number
        }
        ...
    ]
```

Clean up reservation data

The *clean up reservation data* API is used to clean up historical reservation data. The body should be a list of data sources. If the list is empty, all data sources will be cleaned up.

txt

```
Path:
    /api/environment/{environmentId}/onhand/reserve/resyncjob
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    [
        "iv",
        "pos"
    ]
```

If the cleanup job is successfully created, a job ID will be returned in the response, which can be used to get job execution progress.

Get job execution progress

Use the *get job execution progress* API to obtain the execution progress of a job. A job ID is required to identify the job.

txt

```
Path:
    /api/environment/{environmentId}/getJobProgress
Method:
    Get
Headers:
    Api-Version="1.0"
```

```
    Authorization="Bearer $access_token"
ContentType:
    application/json
Query(Url Parameters):
    jobId
```

Here's a sample get URL.

txt

```
/api/environment/{environmentId}/getJobProgress?jobId=SomeJob:xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxxx
```

Query on-hand

Use the *Query on-hand* API to fetch current on-hand inventory data for your products. You can use this API whenever you must know the stock, such as when you want to review product stock levels on your e-commerce website, or when you want to check product availability across regions or in nearby stores and warehouses. The API currently supports querying up to 5,000 individual items by `productID` value. Multiple `siteID` and `locationID` values can also be specified in each query. When your data partition rule is set to *By location*, the maximum limit is defined by the following equation:

NumOf(SiteID) × NumOf(LocationID) <= 10,000.

Query by using the post method

The query by post API is available in two versions. The following table outlines the differences.

Expand table

API version 1.0	API version 2.0
Can only query one organization ID.	Can query multiple organization IDs.
Can query up to 10,000 combinations of sites and warehouses.	Can query more than 10,000 combinations of organization IDs, sites, and warehouses. Can return results in multiple pages.

The following subsections show how to use each API version.

Query by post API version 1.0

txt

```
Path:
    /api/environment/{environmentId}/onhand/indexquery
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    {
        dimensionDataSource: string, # Optional
        filters: {
            organizationId: string[],
            productId: string[],
            siteId: string[],
            locationId: string[],
            [dimensionKey:string]: string[],
        },
        groupByValues: string[],
        returnNegative: boolean,
    }
```

In the body part of this request, `dimensionDataSource` is an optional parameter. If it isn't set, `filters` will be treated as *base dimensions*.

The `returnNegative` parameter controls whether the results contain negative entries.

Query data stored by location

This section applies when your data partition rule is set to *By location*.

- `organizationId` should be an array containing exactly one value.
- `productId` can contain one or more values. If it's an empty array, the system will return all products for the specified sites and locations. In this case, `siteId` and `locationId` shouldn't be empty.
- `siteId` and `locationId` are used for partitioning. You can specify more than one `siteId` and `locationId` value in a *Query on-hand* request. If both arrays are empty, the system will return all sites and locations for the specified products. In this case, `productId` shouldn't be empty.

We recommend to use the `groupByValues` parameter in a way that's consistent with your index configuration. Learn more in On-hand index configuration.

Query data stored by product ID

This section applies when your data partition rule is set to *By product ID*. In this case, two `filters` fields are required: `organizationId`, `productId`.

- `organizationId` should be an array containing exactly one value.
- `productId` should be an array with at least one value.

Unlike when storing data by location, if you don't specify values for `siteId` and `locationId`, inventory information for each product ID will be aggregated across all sites and/or locations.

> **Note**
>
> If you've enabled the on-hand change schedule and available-to-promise (ATP) features, your query can also include the `QueryATP` Boolean parameter, which controls whether the query results include ATP information. For more information and examples, see Inventory Visibility on-hand change schedules and available to promise.

The following example shows sample body content. It shows that you can query the on-hand inventory from multiple locations (warehouses).

JSON

```
{
    "dimensionDataSource": "pos",
    "filters": {
        "organizationId": ["usmf"],
        "productId": ["T-shirt"],
        "siteId": ["1"],
        "locationId": ["11","12","13"],
        "colorId": ["red"]
    },
    "groupByValues": ["colorId", "sizeId"],
    "returnNegative": true
}
```

The following example shows how to query all products in a specific site and location.

JSON

```
{
    "filters": {
        "organizationId": ["usmf"],
        "productId": [],
        "siteId": ["1"],
        "locationId": ["11"],
```

```
    },
    "groupByValues": ["colorId", "sizeId"],
    "returnNegative": true
}
```

Query by post API version 2.0

txt

```
Path:
    /api/environment/{environmentId}/onhand/indexquery?pageNumber=
{pageNumber}&pageSize={pageSize}
Method:
    Post
Headers:
    Api-Version="2.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    # Same as version 1.0
```

The request format for API version 2.0 is similar to that of version 1.0, but also supports two optional parameters: `pageNumber` and `pageSize`, which allow the system to split a single large result into several smaller documents. The results are sorted by warehouse (`locationId`), and the parameters are used as follows to split results into pages:

- `pageSize` establishes the number of warehouses (`locationId` values) that are returned in each page.
- `pageNumber` establishes the page number that's returned.

A request of this format returns on-hand inventory data starting from warehouse number *({pageNumber} − 1) × {pageSize}* and includes data for the next *{pageSize}* warehouses.

API version 2.0 responds with a document that uses the following structure:

txt

```
{
    Value: { # Response same as Api-Version=1.0 }
    nextLink: onhand/indexquery?pageNumber={pageNumber+1}&pageSize={pageSize}
}
```

When the request reaches the last warehouse (`locationId`), the `nextLink` value is an empty string.

API version 2.0 also lets you specify more than one organization ID in your request. To do so, include a comma-separated list of organization IDs in the `organizationId` filter of your request document. For example, `"organizationId": ["org1", "org2", "org3"]`.

Query by using the get method

txt

```
Path:
    /api/environment/{environmentId}/onhand
Method:
    Get
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Query(Url Parameters):
    groupBy
    returnNegative
    [Filters]
```

Here's a sample get URL. This get request is exactly the same as the post sample that was provided earlier.

txt

```
/api/environment/{environmentId}/onhand?
organizationId=SCM_IV&productId=iv_contoso_product&siteId=iv_contoso_site&locationI
d=iv_contoso_location&colorId=red&groupBy=colorId,sizeId&returnNegative=true
```

The system doesn't support querying inventory over multiple organization IDs with the GET method.

On-hand exact query

On-hand exact queries resemble regular on-hand queries, but they let you specify a mapping hierarchy between a site and a location. For example, you have the following two sites:

- Site 1, which is mapped to location A
- Site 2, which is mapped to location B

For a regular on-hand query, if you specify `"siteId": ["1","2"]` and `"locationId": ["A","B"]`, Inventory Visibility will automatically query the result for the following sites and locations:

- Site 1, location A
- Site 1, location B
- Site 2, location A
- Site 2, location B

As you see, the regular on-hand query doesn't recognize that location A exists only in site 1, and location B exists only in site 2. Therefore, it makes redundant queries. To accommodate this hierarchical mapping, you can use an on-hand exact query and specify the location mappings in the query body. In this case, you'll query and receive results for only site 1, location A and site 2, location B.

On-hand exact query query using the post method

The on-hand exact query by post API is available in two versions. The following table outlines the differences.

Expand table

API version 1.0	API version 2.0
Can only query one organization ID.	Can query multiple organization IDs.

On-hand exact query by post API version 1.0

txt

```
Path:
    /api/environment/{environmentId}/onhand/exactquery
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    {
        dimensionDataSource: string, # Optional
        filters: {
            organizationId: string[],
            productId: string[],
            dimensions: string[],
            values: string[][],
        },
        groupByValues: string[],
```

```
        returnNegative: boolean,
    }
```

In the body part of this request, `dimensionDataSource` is an optional parameter. If it isn't set, `dimensions` in `filters` will be treated as *base dimensions*. There are four required fields for `filters`: `organizationId`, `productId`, `dimensions`, and `values`.

- `organizationId` should contain only one value, but it's still an array.
- `productId` could contain one or more values. If it's an empty array, all products will be returned.
- In the `dimensions` array, `siteId` and `locationId` are required if and only if your data partition rule is set to *By location*. In this case, they could appear with other elements in any order.
- `values` could contain one or more distinct tuples of values corresponding to `dimensions`.

`dimensions` in `filters` will be automatically added to `groupByValues`.

The `returnNegative` parameter controls whether the results contain negative entries.

The following example shows sample body content.

JSON

```
{
    "dimensionDataSource": "pos",
    "filters": {
        "organizationId": ["SCM_IV"],
        "productId": ["iv_contoso_product"],
        "dimensions": ["siteId", "locationId", "colorId"],
        "values" : [
            ["iv_contoso_site", "iv_contoso_location", "red"],
            ["iv_contoso_site", "iv_contoso_location", "blue"],
        ]
    },
    "groupByValues": ["colorId", "sizeId"],
    "returnNegative": true
}
```

The following example shows how to query all products in multiple sites and locations.

JSON

```
{
    "filters": {
        "organizationId": ["SCM_IV"],
        "productId": [],
        "dimensions": ["siteId", "locationId"],
```

```
        "values" : [
            ["iv_contoso_site_1", "iv_contoso_location_1"],
            ["iv_contoso_site_2", "iv_contoso_location_2"],
        ]
    },
    "groupByValues": ["colorId", "sizeId"],
    "returnNegative": true
}
```

On-hand exact query by post API version 2.0

txt

```
Path:
    /api/environment/{environmentId}/onhand/exactquery
Method:
    Post
Headers:
    Api-Version="2.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    {
        dimensionDataSource: string, # Optional
        filters: {
            productId: string[],
            keys: string[],
            values: string[][],
        },
        groupByValues: string[],
        returnNegative: boolean,
    }
```

API version 2.0 differs from version 1.0 in the following ways:

- The `filters` section now has a `keys` field instead of a `dimensions` field. The `keys` field works like the `dimensions` field in version 1.0, but can now also include `organizationId`. You can specify the keys in any order.
- The `filters` section no longer supports the `organizationId` field. Instead, you can include `organizationId` among the dimensions in the `keys` field (for example, `keys: ["organizationId", "siteId", "locationId"]`) and define organization ID values at the matching position in the `values` field (for example, `values: ["SCM_IV", "iv_contoso_site_1", "iv_contoso_location_1"]`).

Other fields are identical to API version 1.0.

Query with product search

The following on-hand query APIs are enhanced to support product search:

- Query by using the post method
- Exact query by using the post method

> **Note**
>
> When you post an Inventory Visibility query that uses product search, use the `productSearch` request parameter (with a `ProductAttributeQuery` object inside) to find or filter by product ID. The newer APIs no longer support the older `productid` request parameter in the request body.

Prerequisites

Before you can start to use the product search APIs, your system must meet the following requirements:

- You must be running Dynamics 365 Supply Chain Management 10.0.36 or later.
- Inventory Visibility version 1.2.2.54 or later must be installed and set up as described in Install and set up Inventory Visibility.
- The Inventory Visibility search service must be installed and set up as described in Set up product search for Inventory Visibility.

Product search contract

The product search contract defines the rules for communicating with the product search APIs. It provides a standardized way to describe the capabilities and behavior of the product search capabilities. Therefore, users can more easily understand, interact with, and build applications that consume the Inventory Visibility APIs.

The following example shows a sample contract.

JSON

```
{
    "productFilter": {
        "logicalOperator": "And",
        "conditions": [
            {
                "conditionOperator": "Contains",
                "productName": [
```

```
                    "Deluxe"
                ],
            },
        ],
        "subFilters": [
            {
                "conditions": [
                    {
                        "conditionOperator": "IsExactly",
                        "productType": [
                            "Item"
                        ]
                    }
                ]
            }
        ]
    },
    "attributeFilter": {
        "logicalOperator": "Or",
        "conditions": [
            {
                "attributeName": "Weight Limit",
                "attributeTypeName":"PoundDomain",
                "attributeArea": " ProductAttribute",
                "attributeValues": [
                    "370"
                ],
                "conditionOperator": "GreaterEqual"
            }
        ],
        "subFilters": [
            {
                "conditions": [
                    {
                        "attributeName": "Weight Limit",
                        "attributeTypeName":"PoundDomain",
                        "attributeArea": " ProductAttribute",
                        "attributeValues": [
                            "330"
                        ],
                        "conditionOperator": "LessEqual"
                    }
                ]
            }
        ]
    },
}
```

The following table describes the fields that are used in the contract.

Expand table

Field ID	Description
`logicalOperator`	The possible values are `And` and `Or`. Use this field to connect multiple conditions or conditions and sub-filters. Note that `subFilters` is actually a `productFilter` or `attributeFilter` object. Therefore, you can have `subFilters` inside `subFilters`.
`conditionOperator`	The possible values are `IsExactly`, `IsNot`, `Contains`, `DoesNotContain`, `BeginsWith`, `IsOneOf`, `GreaterEqual`, `LessEqual`, and `Between`.
`ProductFilter`	Use this field to filter products by product-related information. For example, you can change `productName` in the contract to `Company`, `itemNumber`, `productSearchName`, `productType`, `productName`, `productDescription`, `inventoryUnitSymbol`, `salesUnitSymbol`, or `purchaseUnitSymbol` to fit your business needs.
`AttributeFilter`	Use this field to filter products by attribute-related information.
`attributeArea`	The possible values are `ProductAttribute`, `DimensionAttribute`, and `BatchAttribute`.

Query with product search

txt

```
Path:
    /api/environment/{environmentId}/onhand/productsearch/indexquery
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Body:
    {
        productSearch: {ProductAttributeQuery contract object inherited from
Product Search}
            dimensionDataSource: string, # Optional
            filters: {
                organizationId: string[],
                siteId: string[],
                locationId: string[],
                [dimensionKey:string]: string[],
            },
            groupByValues: string[],
            returnNegative: boolean,
    }
```

The following example shows sample body content.

JSON

```
{
    "productSearch": {
        "productFilter": {
            "conditions": [
                {
                    "conditionOperator": "contains",
                    "productName": [
                        "speaker cable"
                    ],
                },
            ],
        },
    },
    "returnNegative": true,
    "filters":
    {
        "organizationId": ["usmf"],
        "siteId": ["1"],
        "locationId": ["13"],
    },
    "groupByValues": ["colorid"],
}
```

The following example shows a successful response.

JSON

```
[
    {
        "productId": "M0030",

        }
    }
]
```

Available to promise

You can set up Inventory Visibility to let you schedule future on-hand changes and calculate ATP quantities. ATP is the quantity of an item that's available and can be promised to a customer in the next period. Use of the ATP calculation can greatly increase your order fulfillment capability. For information about how to enable this feature, and how to interact with Inventory Visibility through its API after the feature is enabled, see Inventory Visibility on-hand change schedules and available to promise.

Allocation

Allocation related APIs are located in Inventory Visibility allocation.

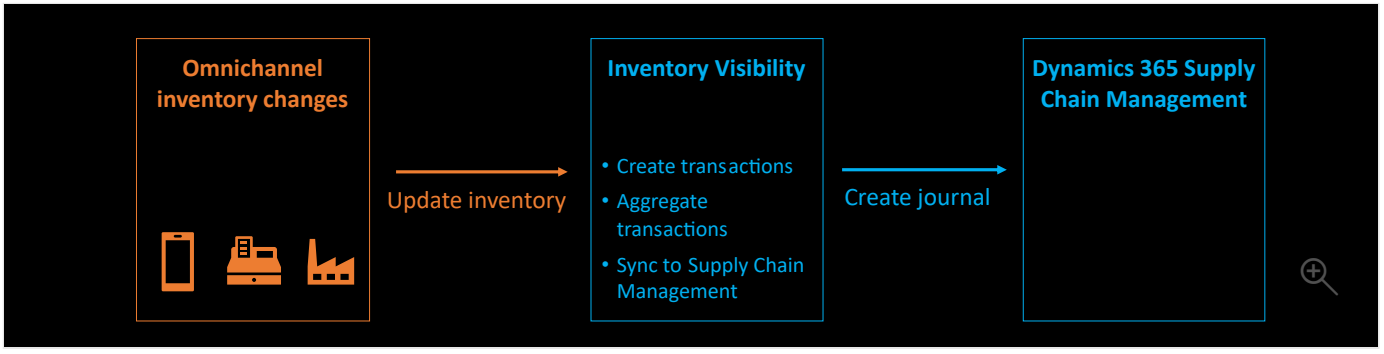
Last updated on 03/10/2026

Sync external inventory adjustments through Inventory Visibility

This article explains how to set up the system to sync inventory adjustment transactions registered in an external system to Microsoft Dynamics 365 Supply Chain Management and Inventory Visibility through the Inventory Visibility service business layer.

Some organizations have multiple sources or channels of inventory operations that work outside Supply Chain Management. By using this feature, those organizations can use Inventory Visibility to store their omnichannel inventory transactions. Based on these transactions, Inventory Visibility can create and post inventory adjustment journals to Supply Chain Management. These capabilities provide the following key business benefits:

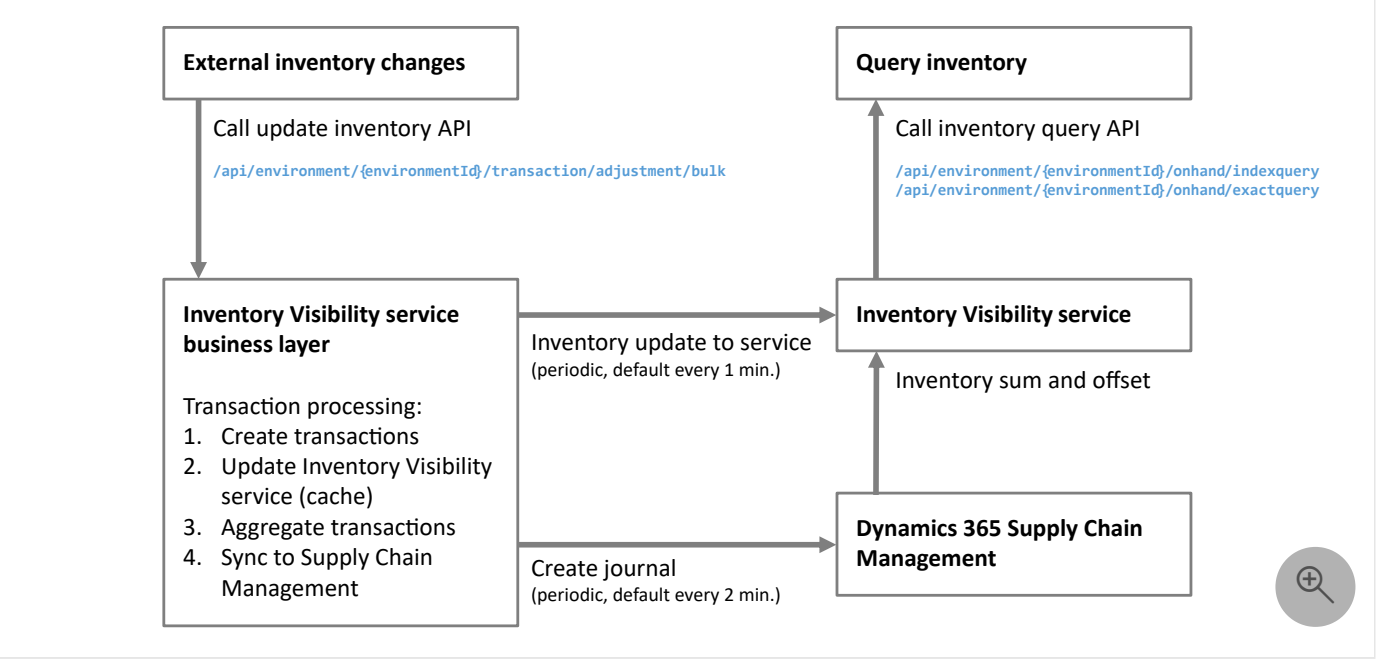
- **Manage all omnichannel inventory adjustments in one place.** You can post inventory adjustments across all channels and data sources to Inventory Visibility. Inventory Visibility then handles the aggregation and posting to Supply Chain Management.
- **Track inventory flow from end to end.** You can track inventory flows from source transactions and documents all the way to Supply Chain Management inventory and financial records. The system stores source document types and reference numbers when it posts inventory adjustments to Inventory Visibility. Inventory Visibility also links Supply Chain Management journal numbers to their original inventory transaction.



Architecture and data flow

Inventory Visibility introduces the concept of the *business layer*, which sits on top of the Inventory Visibility service. The Inventory Visibility service processes and updates data in the cache, but it doesn't directly write data back to Supply Chain Management. The business layer feature adds the following elements and capabilities:

- An inventory adjustment API (`/api/environment/{environmentId}/transaction/adjustment/bulk`) that is designed to create inventory adjustment transactions in the Inventory Visibility business layer. The business layer has columns that are used to integrate with Supply Chain Management journals and track source transactions and documents.
- An entity that stores omnichannel inventory transactions details that are posted to the Inventory Visibility business layer by using the new API.
- A configurable mechanism that automatically updates posted inventory adjustment transactions to the Inventory Visibility service (in-memory cache service) at a regular interval.
- A configurable mechanism that aggregates the detailed inventory adjustment transactions and syncs to Supply Chain Management at a regular interval and according to defined rules.
- A new user interface (UI) page for the Inventory Visibility app in Power Apps. This page lets you manually post inventory adjustment transactions to the Inventory Visibility business layer. It's an alternative to using the API. The UI also lets you view transactions in a detailed or aggregated format.



Prerequisites

Before you can use the features described in this article, ensure your system meets the following requirements:

- You're running Dynamics 365 Supply Chain Management version 10.0.41 or later.
- You're running Inventory Visibility service version 1.2.3.88 or later. For more information about how to install Inventory Visibility, check its version number, and update it as required,

see Install and set up Inventory Visibility.

- The following features are turned on in Feature management:
  - *Inventory Visibility integration with inventory adjustment offset* (This feature is a prerequisite. As of Supply Chain Management version 10.0.45, this feature is mandatory and can't be turned off.)
  - *Inventory Visibility integration* (This feature is a prerequisite. As of Supply Chain Management version 10.0.45, this feature is turned on by default.)
  - *Inventory Visibility transaction integration* (This feature adds the features that are described in this article. As of Supply Chain Management version 10.0.45, this feature is turned on by default. As of version 10.0.49, it's mandatory and can't be turned off.)

Configure inventory transaction synchronization

Set up the feature for the first time

To set up the feature for the first time, follow these steps:

1. Sign in to Supply Chain Management.
2. Go to **Inventory Management** > **Setup** > **Inventory Visibility** > **Inventory Visibility integration parameters**.
3. On the **Transaction** tab, set the **Enable adjustment journal sync** option to *Yes*.
4. Select **Generate configurations** to run an automatic deployment script that initializes the configuration in Supply Chain Management and the Inventory Visibility service.
5. Select **Enable posting job** to open the **Inventory Visibility posting job** dialog box.
6. Each time the *Inventory Visibility posting job* runs, it automatically posts the inventory adjustment journals submitted from the Inventory Visibility business layer. Schedule this job to run as often as is appropriate for your business. Depending on the volume of incoming data, this job can be resource intensive, so schedule it to run during off-peak hours. Select the **Recurrence** link to open the **Define recurrence** dialog, use it to set up your schedule, and then select **OK** to save your settings.
7. Select **OK** to close the dialog box.

Manage the feature configuration

To manage the feature configuration, follow these steps:

1. Sign in to Power Apps, and open the **Inventory Visibility** app.

2. On the navigation pane, select **Settings** > **Feature management**.

3. On the **Inventory transactions** tile, select **Manage**.

4. On the **Transaction** page, in the upper section, set the following fields:

    - **Enable feature** – Set this option to *True* to enable the feature. Set it to *False* to disable the feature. The feature is automatically turned on when you initialize the configuration as described in the previous section.
    - **Periodically synchronize transaction to IV** – Set this option to *True* if you want the system to automatically sync inventory updates from the Inventory Visibility business layer to the Inventory Visibility service at regular intervals. Set it to *False* to disable this functionality.
    - **Inventory Visibility synchronization frequency** – Enter an integer to specify how often (in minutes) the system syncs inventory updates from the Inventory Visibility business layer to Supply Chain Management (if you enabled this functionality). The default value is *5*.

5. In the **Fno Synchronization Settings** section, set the following fields:

    - **Enable Sync Job** – Set this option to *True* if you want the system to automatically aggregate and sync inventory updates from the Inventory Visibility business layer to Supply Chain Management at regular intervals. When this option is set to *False*, omnichannel transactions are still stored in the Inventory Visibility business layer. However, they aren't synced to Supply Chain Management.
    - **Job settings** – Select the setting value to open the detailed settings page, where you can specify the start and end time, recurrence interval, and unit for synchronizing inventory updates from the Inventory Visibility business layer to the Inventory Visibility service (if this functionality is enabled). The job is automatically scheduled with default settings when you install Inventory Visibility.
    - **Fno sync max line count in adjustment journal** – Enter an integer to specify the maximum number of inventory adjustment lines that are allowed per adjustment journal during synchronization back to Supply Chain Management. The default value is *10,000*.
    - **Fno sync max journal count in package** – Enter an integer to specify the maximum number of inventory adjustment journals that are allowed per data package during synchronization back to Supply Chain Management. The default value is *1*.

6. Use the **Fno integration mappings** section to control how data is mapped from the Inventory Visibility business layer to Supply Chain Management. Use the buttons on the

toolbar to add, edit, or delete mappings as required. For each mapping, set the following fields:

- **Physical measure name** – Select the physical measure that provides the quantity of the inventory.
- **Target FnO Transaction type** – Specify the type of inventory journal that is created in Supply Chain Management. The default value is *Inventory adjustment journal*.
- **Target FnO Transaction Status** – Select one of the following values to specify the status of the inventory journal that is created in Supply Chain Management:
  - *None* – The system doesn't create transactions in Supply Chain Management.
  - *Created* – The system creates transactions but doesn't automatically post them in Supply Chain Management.
  - *Posted* – The system creates transactions and financially posts the journal in Supply Chain Management.

7. If you set the **Periodically synchronize transaction to Fno** option to *True*, you must ensure that your system in configured to offset inventory adjustments to prevent inventory quantities from being updated twice. Learn more in Inventory Visibility adjustment offset.

Manually enter inventory adjustments in the Inventory Visibility app

Use the Inventory Visibility app in Power Apps to manually enter inventory adjustments directly in the Inventory Visibility business layer.

1. Sign in to Power Apps, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Inquiries and reports** > **Inventory transactions**.
3. On the toolbar, select **Create transaction** > **Inventory adjustment**.
4. On **Create inventory adjustment**, on the **Product and dimension information** FastTab, specify the product that you want to adjust inventory for. If some of the product dimensions that you need (such as color or style) aren't shown, select **Edit dimensions** to add them.
5. On the **Adjustment quantity** FastTab, select the data source, physical measure, and quantity of the inventory adjustment. To immediately update inventory adjustments to the Inventory Visibility service cache from the staging area, select the **Instant update to IV service** checkbox.

6. On the **Additional information** FastTab, set the following optional fields:

    - **External reference category** – Specify the source transaction type for the inventory adjustment, such as sales order, inventory counting delta, or POS transaction.
    - **External reference ID** – Enter the source document ID from the external system.
    - **Supply Chain Management journal name** – Specify the inventory adjustment journal to use in Supply Chain Management. If you leave this field blank, the default journal name that is set in Supply Chain Management is used.
    - **Item cost price** – Specify the item cost price to create in Supply Chain Management. If you leave this field blank, the journal that is created in Supply Chain Management uses the default cost calculation method that is set in Supply Chain Management to calculate the cost price.
    - **Trans date** – The transaction date to set on the journal line when it's created in Supply Chain Management.

7. To preview what your inventory adjustment looks like when it's posted to the Inventory Visibility business layer through the API, select **Developer reference**. This action shows the JavaScript Object Notation (JSON) body that's sent to the Inventory Visibility business layer when you post the transaction.

8. On the toolbar, select **Post**.

Submit inventory adjustments to the Inventory Visibility API

External systems typically submit inventory adjustments to the Inventory Visibility business layer through the Inventory adjustment API. The following example shows the API and body content details.

txt

```
Path:
    /api/environment/{environmentId}/transaction/adjustment/bulk
Method:
    Post
Headers:
    Api-Version="1.0"
    Authorization="Bearer $access_token"
ContentType:
    application/json
Query(Url Parameters):
    createWithIVSync # bool, optional
Body:
```

```
[
    {
        "id": string
        "organizationId": string,
        "productId": string,
        "quantityDataSource": string,
        "physicalMeasure": string,
        "dimensions": {
            "siteId": string,
            "locationId": string,
            [key:string]: string, # optional
        },
        "quantity": number,
        "externalReferenceCategory": string, # optional
        "externalReferenceId": string, # optional
        "fnoJournalNameId": string, # optional
        "costPrice": number, # optional
        "transDate": date, # optional
    },
]
```

Learn more about how to work with the Inventory Visibility API, including how to authenticate and get an access token, in Inventory Visibility public APIs.

View inventory transactions in the Inventory Visibility app

The Inventory Visibility app in Power Apps provides a UI where you can view detailed and aggregated inventory transactions.

- Detailed inventory transactions include all individual transactions together with all the original details.
- Aggregated inventory transactions combine lines that have matching dimension values (such as site, warehouse, and color). Some information might be omitted. Instead of showing every individual transaction, the UI shows totals or averages over the specified dimensions. Only the aggregated transactions sync with Supply Chain Management.

Detailed and aggregated transactions differ in the following ways:

- Granularity:
  - Detailed transactions show individual original inventory adjustment transactions and provide fine-grained data.
  - Aggregated transactions show summarized data and provide a higher-level overview.
- Data volume:

- Detailed transaction data sets are typically larger because they include every transaction.
- Aggregated transaction data sets are typically smaller because they condense multiple similar transactions into single records.

View detailed inventory transactions

To view detailed inventory transactions, follow these steps:

1. Sign in to Power Apps, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Inquiries and reports** > **Inventory transactions**.
3. In the row where the **Type** field is set to *Detail*, in the **Action** column, select **View**.

   On the **Transaction details** page, a grid lists details for each successful transaction. Most of the columns are self-explanatory, but here are some important columns to note:

   - **Line record ID** – The globally unique identifier (GUID) that is automatically generated for each original inventory adjustment transaction. Select the link to view more details about the transaction.
   - **Source line status** – The current status of the transaction. The following values are used:
     - *Created* – The adjustment was created in the Inventory Visibility business layer and is waiting to be posted. This status is the initial status for the inventory adjustment records.
     - *IVPosted* – The adjustment was successfully updated in the Inventory Visibility cache from the staging area. This status is the prerequisite status for aggregation.
     - *Aggregated* – Detailed lines were successfully aggregated based on matching dimension values. This status is the prerequisite status for synchronization to Supply Chain Management.
   - **Aggregated line ID** – Select the link to view details about the linked aggregated line. After the aggregated lines are successfully created and/or posted in Supply Chain Management, the journal ID and journal line ID that Supply Chain Management returns are added to the aggregated transaction details.

View aggregated inventory transactions

To view aggregated inventory transactions, follow these steps:

1. Sign in to Power Apps, and open the **Inventory Visibility** app.
2. On the navigation pane, select **Inquiries and reports** > **Inventory transactions**.
3. In the row where the **Type** field is set to *Aggregated*, in the **Action** column, select **View**.

   On the **Transaction aggregated** page, a grid lists details for each successful aggregated transaction. Most of the columns are self-explanatory, but here are some important columns to note:

   - **Line record ID** – The GUID that's automatically generated for each aggregated inventory adjustment transaction. Select the link to view more details about the aggregated transaction. After the aggregated lines are successfully created and/or posted in Supply Chain Management, the journal ID and journal line ID that Supply Chain Management returns are included in the aggregated transaction details.
   - **Aggregated line status** – The current status of the aggregated transaction. The following values are used:
     - *Created* – The aggregated transaction record was successfully created. This status is the initial status for the aggregated transaction record.
     - *DoNotSync* – The line isn't synced to Supply Chain Management. This status typically occurs because the inventory change quantity of the aggregated line is 0 (zero). (Because the inventory quantity wasn't changed, there's no need to sync it.)
     - *FnOSyncEnqueued* – Inventory Visibility sent a request to sync the line with Supply Chain Management. This status indicates that the record was synced in Supply Chain Management and is awaiting further processing.
     - *FnOTransCreated* – Supply Chain Management successfully processed the synchronization request and created the inventory journal.
     - *FnOTransCreateError* – An error occurred during the attempt to create the inventory journal in Supply Chain Management. Use the message ID to check the error. Go to **Supply Chain Management** > **System administration workspace** > **Data Management IT** > **Recurring data jobs**.
     - *FnOTransPosted* – The inventory journal was successfully posted.
     - *FnOTransPostError* – Inventory journal posting failed.

Export transaction details

To export transaction details, you must access them from the Dataverse entity and export them from there. The entity names are *Adjustment Line* and *Aggregated Adjustment Line*.

Check inventory journals posted to Supply Chain Management

To view the aggregated lines that are successfully posted or created in Supply Chain Management, follow these steps:

1. Sign in to Supply Chain Management.
2. Go to **Inventory Management** > **Journal entries** > **Items** > **Inventory adjustment**.
3. Change the filter for the **Posted** column as required to view posted journals, unposted journals, or all journals.

> **Note**
>
> Some of the optional fields that you can submit to the Inventory Visibility business layer don't exist as standard fields in Supply Chain Management. These fields include **External reference category**, **External reference ID**, and any other external dimensions. These fields aren't synced to Supply Chain Management. However, they are stored in the business layer and can be read by using the Inventory Visibility app, as described earlier in this article.

Log and view successful API posts

08/14/2025

This article describes how to set up and use the *inventory log history* feature for Inventory Visibility. This feature creates a log of successfully updated inventory API posts. The posts include a timestamp and specify the API type.

Set up inventory log history

To start to keep a log of successfully updated inventory API posts, you must enable the feature in Microsoft Power Apps.

1. Sign in to Power Apps, and go to **Inventory Visibility** > **Settings** > **Feature Management**.
2. Enable the *Inventory log history* feature.
3. Go to **Admin settings**, and select **Update configuration**.

View inventory log history

After the feature is enabled, you can view the log entries either by using the Inventory Visibility app in Power Apps or by calling the API.

View log entries by using the Inventory Visibility app in Power Apps

Follow these steps to view the log by using the Inventory Visibility app in Power Apps.

1. Sign in to Power Apps, and go to **Inventory Visibility** > **Operational visibility** > **Inventory log history**.
2. To retrieve and view the log details, enter a product ID, organization ID, site ID, warehouse ID, and date range.

Retrieve log entries by calling the API

Follow these steps to retrieve log entries by calling the Inventory Visibility API.

1. Run a tool that lets you call APIs. Use the tool to access the `{inventoryVisibilityEndpoint}/api/environment/{yourEnvironmentId}/logTransactionDetails` API by using the `Post` method.

2. Set up and submit a request body to retrieve the log data that you're interested in. The following example shows a request body that asks the system to prepare and retrieve the log. This step is necessary because the log is stored in Azure Data Lake and is transferred to Dataverse only on request. The API returns a log history job ID that you can use to check the job completion status.

```txt
Path:

    /api/environment/{environmentId}/logTransactionDetails

Method:

    Post

Headers:

    Api-Version="1.0"

    Authorization="Bearer $access_token"

ContentType:

    application/json

Body:

    {
    "id": "id-contoso-{{datetime}}",
    "organizationId": "usmf",
    "UtcFromDate": "2023/8/23",
    "UtcToDate": "2023/8/23",
    "productId": "D0001",
    "dimensions": {
        "SiteId": "1",
        "LocationId": "13"
    }
}
```

3. Use the `{inventoryVisibilityEndpoint}/api/environment/{yourEnvironmentId}/getJobProgress?jobId={jobIdFromPreviousStep}` API to track the status of the inventory log history job.

4. When the API reports that the job is successfully completed, you can review the logs in Dataverse by opening the transaction logging report table (`is_transactionloggingreport`).

Inventory Visibility diagnostic tool

08/13/2025

This article describes how to set up and use the Inventory Visibility diagnostic tool. This tool helps identify and fix discrepancies between on-hand inventory records in Microsoft Dynamics 365 Supply Chain Management and on-hand inventory records in the `fno` data source in Inventory Visibility.

Set up the Inventory Visibility diagnostic tool

The Inventory Visibility diagnostic tool is turned on by default, and no extra steps are required to make it available. However, the tool requires that Inventory Visibility is set up for your system and the data synchronization batch job is running. Learn more in Set up Inventory Visibility in Supply Chain Management.

Use the Inventory Visibility diagnostic tool

1. Sign in to your Supply Chain Management environment.
2. Go to **Inventory Management** > **Set up** > **Inventory Visibility diagnostic tool**.
3. On the **Inventory Visibility diagnostic tool** page, select **Run diagnostic**.
4. In the **Inventory Visibility on-hand diagnostic process** dialog box, set the following options:

    - **Fix inventory discrepancy** – Set this option to *Yes* to immediately force synchronization and address mismatches. Set it to *No* to check for and view discrepancies, but without immediately fixing or syncing them. (In this case, you can fix previously found discrepancies later by rerunning the tool and setting this option to *Yes*.) The synchronization process takes about a minute.
    - **Only check warehouse items** – Set this option to *Yes* if you want to review only items that are enabled for warehouse management processes (WMS). Set it to *No* to review all items.
    - **Only check previous mismatched data** – Set this option to *Yes* to verify the effectiveness of the forced synchronization, confirm the resolution of previous discrepancies, and also find any new discrepancies. If the **Fix inventory discrepancy** option is also set to *Yes*, the system syncs any remaining mismatches.
    - **Batch Processing** – You must leave this option set to *Yes*, because the tool can run only in batch mode.

5. Select the **Filter** link to open a dialog box where you can set up a filter to limit the set of items that's checked. By default, the **No open quantities** option for the filter is set to *No*. Therefore, the tool checks only for items that have open quantities. You can change the setting of this option as you require.

6. Select **OK** to apply your settings and return to the **Inventory Visibility diagnostic tool** page.

7. You receive the following message: "The Inventory Visibility on-hand diagnostic process job is added to the batch queue." To monitor the progress of the batch job, go to **System Administrator** > **Inquiries** > **Batch Jobs**.

8. When the job has finished running, the Inventory Visibility diagnostic tool shows the results of the test. If you chose not to fix discrepancies, you can fix them now. Rerun the diagnostic, and set the **Fix inventory discrepancy** option and/or the **Only check previous mismatched data** option to *Yes*.

Inventory Visibility tips

Summarize this article for me

> **Important**
>
> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

Here are a few tips that you should consider when you set up and use the Inventory Visibility Add-in:

- Unless you using the unified developer experience, you should check for linking mismatch warnings in Microsoft Dynamics Lifecycle Services before you install Inventory Visibility. To do so, open the details page for your environment in Lifecycle Services and look for a warning that resembles the following example: "Microsoft has detected that your environment is linked via dual-write to a different destination than specified in Power Platform Integration, which isn't recommended." If you see this warning, it's possible that your dual-write environment is linked to a Dataverse instance, but Lifecycle Services isn't set up for Power Platform integration. This linking mismatch can cause unexpected behavior. For information about how to fix this issue, see Linking mismatch. After the linking mismatch is fixed, you can install Inventory Visibility.
- If you have more than one Supply Chain Management environment, create a different Microsoft Entra application for each environment. If you use the same application ID and tenant ID to install the Inventory Visibility Add-in for different environments, a token issue will occur for older environments. Only the latest installation of the Inventory Visibility Add-in will be valid.
- Inventory Visibility isn't currently supported for cloud-hosted environments. It's supported only for Tier-2+ environments.

- The application programming interface (API) allows multiple `SiteID` and `LocationID` values to be specified in each query. The maximum limit is defined by the following equation: `NumOf(SiteID)` × `NumOf(LocationID)` ≤ 100.
- The `fno` data source is reserved for Supply Chain Management. If your Inventory Visibility Add-in is integrated with a Supply Chain Management environment, we recommend that you not delete configurations that are related to `fno` in the data source.
- Inventory Visibility can't change any data for the `fno` data source. The data flow is one-way, which means that all quantity changes for the `fno` data source must come from your Supply Chain Management environment. Therefore, you can't use the API to send on-hand change or reservation requests for the `fno` data source.
- If you add one or more new measures to your Supply Chain Management environment, you should also add them in Inventory Visibility. However, all quantity changes for new measures must come from your Supply Chain Management environment.
- A partition configuration controls how data is distributed. Operations that are performed inside the same partition provide better performance, at lower cost, than operations that cross partitions. By default, partition configuration is automatically set up and shouldn't be customized.
- Base dimensions that are reserved in a partition configuration (set number *0*) shouldn't be included in other on-hand index configurations.
- Your on-hand index configuration must include at least one on-hand index in addition to the partition configuration (set number *0*). If you aren't interested in querying specific dimension combinations, you can set up an index that has only one base dimension, `Empty`. Otherwise, queries will fail, and you'll receive the following error: "No index hierarchy has been set."
- Data source `@iv` is a predefined data source and the physical measures defined in `@iv` with prefix `@` are predefined measures. These measures are a predefined configuration for the allocation feature and the soft reservation feature. Therefore, don't change or delete them. Otherwise, you're likely to encounter unexpected errors when you use those two features.
- You can add new physical measures to the predefined calculated measure `@iv.@available_to_allocate`, but you must not change its name.
- If you restore a Supply Chain Management database or copy a Dataverse environment, additional steps are required to run Inventory Visibility in your target environment. For details, see Move data between Supply Chain Management Database and Dataverse.

> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Human Resources, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

Sensor Data Intelligence for Microsoft Dynamics 365 Supply Chain Management enables organizations to drive business processes in Supply Chain Management, based on Internet of Things (IoT) signals from machines and equipment on the production floor. It's an updated, renamed version of the *IoT Intelligence* feature that was previously available for Supply Chain Management.

Sensor Data Intelligence lets you perform the following tasks:

- Collect details from machines and equipment to update maintenance asset counter values in Supply Chain Management and drive predictive maintenance.
- Set up the solution by using a simple onboarding wizard instead of manually installing and configuring components in Microsoft Dynamics Lifecycle Services.
- Deploy components on your own subscription, so that you have more flexibility to manage Azure components.

- Configure, scale, and extend the solution as business logic that runs on Azure components. Those components are now managed on your own subscription. Therefore, you can customize them as required to meet your unique business needs.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Business scenarios

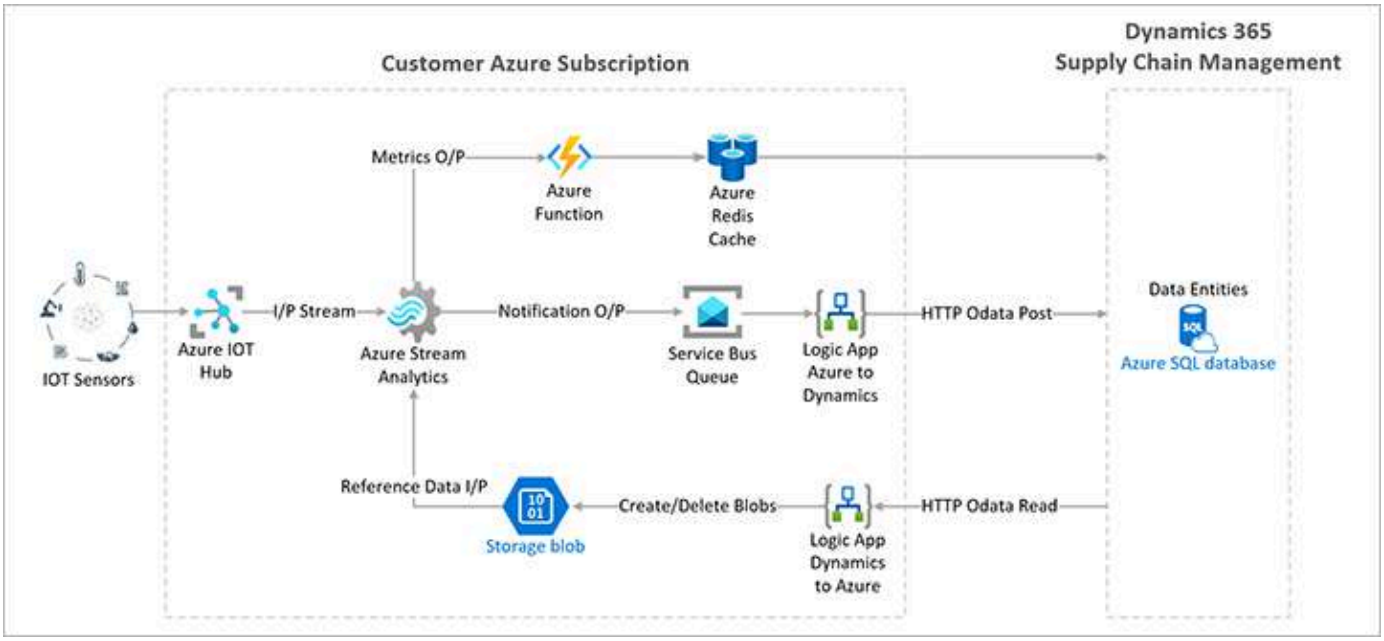
Sensor Data Intelligence enables several types of functionality, each represented by a specific *scenario* in the system. Each scenario provides a specialized set of configuration options, as detailed in the following table.

Expand table

Scenario	Description
Asset downtime	Accurately track the efficiency of machine assets by using sensor data to track machine downtime.
Asset maintenance	Minimize maintenance costs and extend asset life by improving maintenance plans based on sensor readings of critical control points for machine assets.
Machine status	Ensure operation efficiency by using sensor readings to notify planners about machine outages and provide options for mitigating potential delays.
Product quality	Ensure the quality of product batches by comparing sensor readings for actual properties of each product batch, such as moisture, temperature, or custom-defined quality metrics. The system notifies users when deviations occur.
Production auto report	Automatically report finished quantities when a machine generates enough sensor signals to reach a defined output threshold.
Production delays	Use sensor readings to compare actual cycle time to planned cycle time, and notify supervisors when production isn't on schedule. Supervisors can then intervene as required to ensure maximum operation efficiency.

Architecture

The following architectural diagram provides an overview of the solution and its components.



> **Note**
>
> For more information about how to connect sensors to the Azure IoT Hub, see Azure industrial IoT analytics guidance.

Turn on Sensor Data Intelligence for your system (preview)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

[This article is prerelease documentation and is subject to change.]

This article explains how to turn on Sensor Data Intelligence for your system.

Video instructions

The following video shows how to turn on the Sensor Data Intelligence feature and deploy the required Azure resources. The other section in this article provides the same instructions in a text-based format.

https://learn-video.azurefd.net/vod/player?id=90804485-5a57-475a-aa9e-753df28dd0d4&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Fsensor-data-intelligence%2Fsdi-enable-feature

Procedure

Before you can use Sensor Data Intelligence, it must be turned on for your system.

1. Go to **System administration** > **Workspaces** > **Feature management**. (Learn more in Feature management overview.)
2. On the **All** tab, use the **Filter** field to search for the feature named *Sensor Data Intelligence*.
3. If the *Sensor Data Intelligence* feature is enabled on your system, select it in the list, and then select **Disable** to disable it. You can't use this older version of the feature together with the new preview version that you will enable in the next step.
4. Use the **Filter** field to search for the feature named *(Preview) Sensor Data Intelligence*.
5. Select the feature in the list, and then select **Enable now** to enable it.
6. If you'd also like to use the production auto report scenario (optional), use the **Filter** field to search for the feature named *(Preview) Sensor Data Intelligence - Auto report progress*, and then select **Enable now** to enable it.

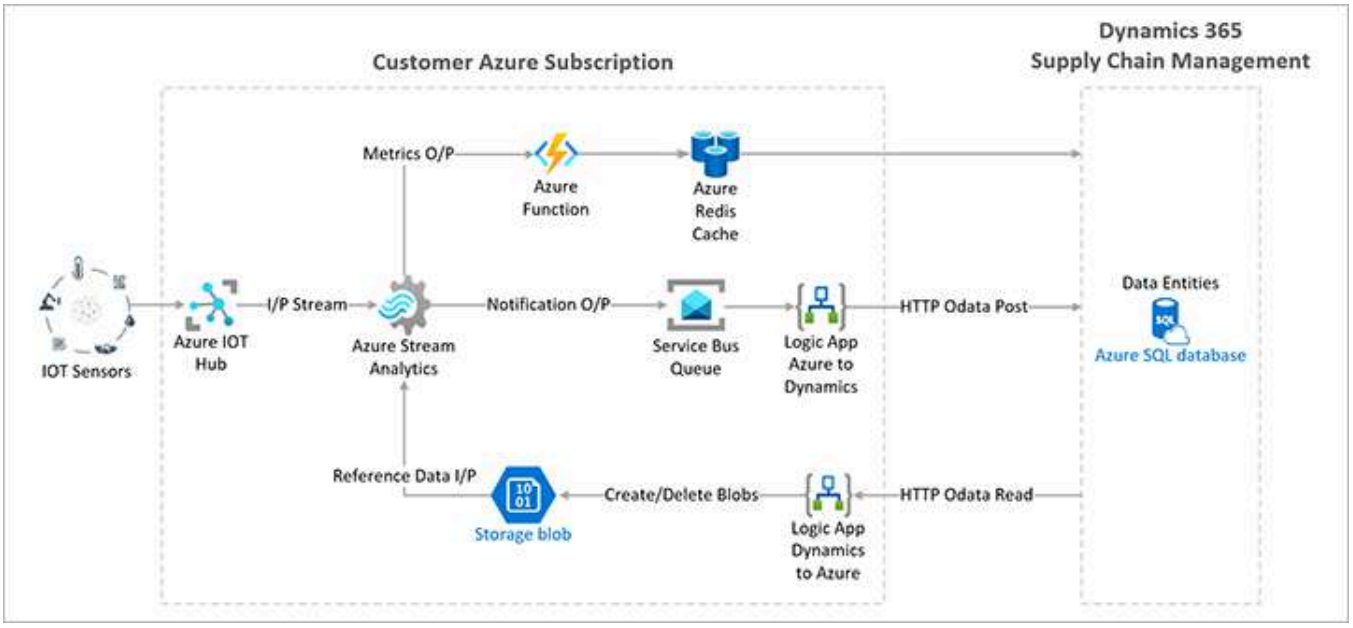
Deploy an IoT solution on Azure (preview)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

[This article is prerelease documentation and is subject to change.]

Sensor Data Intelligence uses data from sensors that are connected to Microsoft Azure. To enable Azure to retrieve data from your sensors and share it with Dynamics 365 Supply Chain Management, you must deploy an Internet of Things (IoT) solution on your Azure subscription. The following architectural diagram provides an overview of the solution and its components.



Prerequisites

To deploy and administer Azure components for Sensor Data Intelligence, your Azure environment and user account must meet the following requirements:

1. You must sign in using an Azure organizational account that is tied to your Supply Chain Management environment. You can't use a personal Azure account (such as one registered to an Outlook or Gmail address).
2. Your Azure account must have one of the following security roles:

    - Owner
    - Co-administrator

- Service administrator
- Account administrator

3. The Power Apps component framework must be enabled for your Azure environment. For instructions, see Enable the Power Apps component framework.

Video instructions

The following video shows how to turn on the Sensor Data Intelligence feature and deploy the required Azure resources. The other section in this article provides the same instructions in a text-based format.

https://learn-video.azurefd.net/vod/player?id=90804485-5a57-475a-aa9e-753df28dd0d4&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Fsensor-data-intelligence%2Fsdi-deploy-iot-solution-on-azure

Procedure

> **Important**
>
> Before you start this procedure, make sure your Azure environment and user account fulfil the prerequisites listed earlier in this article.

Follow these steps to deploy the required resources on Azure.

1. Sign in to Supply Chain Management as an admin.
2. Go to **System administration** > **Setup** > **Sensor Data Intelligence** > **Deploy and connect Azure resources** to open the deployment wizard.
3. On the **Welcome** page, read the information, and then select **Next**.
4. On the **Deploy the sample IoT solution to Azure** page, read the information, and then, in the **Instructions** section, select **Deploy**.
5. A new browser tab is opened, and you're taken to the Azure portal so that you can deploy the Azure resources. If you're prompted, sign in by using your credentials for your Azure subscription.
6. On the **Custom deployment** page, in the **Subscription** field, select your subscription.
7. Under the **Resource group** field, select **Create new** to create a resource group for the Azure components that you will deploy.

8. In the drop-down dialog box that appears, in the **Name** field, enter a name for the new resource group (for example, *IoT-demo*). Then select **OK**.

9. Set the following fields:

    - **Resource group** – Select the resource group that you just created.
    - **Region** – Select a region, ideally the region where your Supply Chain Management environment is deployed. Keep in mind that Azure regions have different pricing. You can view estimated costs for your region by using the Sensor Data Intelligence price calculator.
    - **Supply Chain Management environment URL** – Enter the URL for your Supply Chain Management environment.
    - **Reuse existing Azure IoT Hub** – Leave this checkbox cleared.

10. Select **Next: Review + Create**.

11. On the **Custom deployment** page, verify that the validation has passed, and then select **Create**.

12. The **Deployment is in progress** page tracks the progress of your deployment. The deployment process can take up to 30 minutes. When the **Deployment is in progress** page indicates that the deployment is completed, select the link for the resource group name to open a page that shows the list of resources that are deployed in the group.

13. In the resource list, find the record where the **Type** field is set to *Managed Identity*. In the **Name** column, select the name to open the details page for the resource.

14. Copy the value in the **Client ID** field (for example, by selecting the **Copy to clipboard** button).

15. Go back to the browser tab where Supply Chain Management is running, *but don't close the tab for the Azure portal*. The **Deploy the sample IoT solution to Azure** wizard page should still be open.

16. Select **Next**.

17. On the **Connect Azure resources** page, in the **Microsoft Entra Application client ID** field, paste the **Client ID** value that you copied.

18. Go back to the browser tab where the Azure portal is open, *but don't close the tab for Supply Chain Management*. The details page for the resource should still be open.

19. Select the browser's **Back** button to return to the list of resources in the new resource group.

20. In the resource list, find the record where the **Type** field is set to *Azure Cache for Redis*. In the **Name** column, select the name to open the details page for the resource.
21. In the left navigation pane, select **Access keys**.
22. On the **Access keys** page, copy the value that is shown for **Primary connection string (StackExchange.Redis)** (for example, by selecting the **Copy to clipboard** button).
23. Go back to the browser tab where Supply Chain Management is running. The **Connect Azure resources** page should still be open.
24. In the **Redis metric store connection string** field, paste the **Primary connection string (StackExchange.Redis)** value that you copied.
25. Select **Finish**.

Azure resources for Sensor Data Intelligence are now deployed on your Azure subscription.

> **Note**
>
> At any time, you can view or edit the connection information that is saved in Supply Chain Management by opening the **Sensor Data Intelligence parameters** page. Learn more in Sensor Data Intelligence parameters.

Last updated on 05/07/2025

Sensor Data Intelligence parameters (preview)

09/26/2025

[This article is prerelease documentation and is subject to change.]

The **Sensor Data Intelligence parameters** page provides a few settings that you can use to configure the feature. These settings include Azure connection parameters and a parameter for the lifetime of alert messages that are sent to users in response to sensor measurements.

Read and change connection details for your Azure IoT solution

Typically, you will set up your Azure IoT solution and connect it to Microsoft Dynamics 365 Supply Chain Management from the **Deploy and connect Azure resources** page, which will guide you through both procedures. (Learn more in Deploy an IoT solution on Azure.) You can also view and edit the connection details at any time in Supply Chain Management by following these steps.

1. Go to **System administration** > **Setup** > **Sensor Data Intelligence** > **Sensor Data Intelligence parameters**.
2. On the **Time series** tab, in the **Redis metric store connection string** field, enter the **Primary connection string (StackExchange.Redis)** value for the Azure IoT solution that you want to connect to. For more information about how to find this value, see Deploy an IoT solution on Azure.
3. On the **Integrations** tab, in the **Microsoft Entra application client ID** field, enter the **Client ID** value for the Azure IoT solution you want to connect to. For more information about how to find this value, see Deploy an IoT solution on Azure.

Set the lifetime of alert messages

Each time that Sensor Data Intelligence detects a situation that requires user attention, it sends a notification to the relevant user. To prevent these notifications from piling up in the system, you should set them to expire after a few days.

1. Go to **System administration** > **Setup** > **Sensor Data Intelligence** > **Sensor Data Intelligence parameters**.
2. On the **Notifications** tab, in the **Notification days to live** field, enter the number of days to keep a notification. After the specified amount of time passes, the notification will be

deleted.

Set up a simulated sensor for testing (preview)

Summarize this article for me

> **Note**
>

[This article is prerelease documentation and is subject to change.]

If you want to test Sensor Data Intelligence without installing any physical sensors, you can use the *Raspberry PI Azure IoT Online Simulator* service to emulate sensor signals and send them to your Internet of Things (IoT) solution on Microsoft Azure. For more information about the simulator, see Connect Raspberry Pi online simulator to Azure IoT Hub (Node.js).

Video instructions

The following video shows how to set up a simulated sensor for testing. The remaining sections in this article provide the same instructions in a text-based format.

https://learn-video.azurefd.net/vod/player?id=73e8b915-2b43-4285-9100-9bd2a4ed1be6&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Fsensor-data-intelligence%2Fsdi-set-up-simulated-sensor

Create a device in Azure IoT Hub

You must first set up a device to authenticate the sensor signals to the Azure IoT Hub.

1. In Azure, go to the list of resources for the resource group that you created for use with Sensor Data Intelligence. (Learn more in Deploy an IoT solution on Azure.)
2. In the resource list, find the record where the **Type** field is set to *IoT Hub*. In the **Name** column, select the name to open the details page for the resource.
3. In the left navigation pane, select **Devices**.
4. On the **Devices** page, select **Add device**.

5. On the **Create a device** page, set the following fields:

    - **Device ID** – Enter a name for the new device (for example, *My-IoT-Device*).
    - **Authentication type** – Select *Symmetric keys*.
    - **Auto-generate keys** – Select this checkbox.
    - **Connect this device to an IoT hub** – Select *Enable*.

6. Select **Save** to return to the **Devices** page.

7. Find the new device in the list. In the **Device ID** column, select the name to open the details page for the device. If you don't see the new device in the list, refresh the page.

8. Copy the **Primary connection string** value (for example, by selecting the **Copy to clipboard** button). You will need this value later when you set up the Raspberry Pi IoT simulator to emulate sensor signals. Therefore, consider pasting it into a text file for now.

Add the Azure connection string to the Raspberry Pi IoT simulator

Follow these steps to add the connection string from the device in Azure IoT Hub to the script in the Raspberry service.

1. Open the Raspberry Pi IoT simulator.

2. In the code editor pane, find the line that contains the following command.

    ```
    const connectionString = '[Your IoT hub device connection string]';
    ```

3. Replace the help text, including the brackets, with the **Primary connection string** value that you copied in the previous section. The result should resemble the following example.

    ```
    const connectionString = 'HostName=XXX;DeviceId=YYY;SharedAccessKey=ZZZ';
    ```

Add sensor IDs and values to the payload in the Raspberry Pi IoT simulator

You must now set up the Raspberry Pi IoT simulator with simulated sensors and the values that they will send as payloads.

- In the code editor of the Raspberry Pi IoT simulator, find the `getMessage` function, and edit it so that it matches the following code. (The sensors are set up in the `cb()` lines.)

C++

```
function getMessage(cb) {
    messageId++;
    sensor.readSensorData()
    .then(function (data) {
        cb(JSON.stringify({ value: 1, sensorId: 'MachineStatus' }), false);
        cb(JSON.stringify({ value: 70, sensorId: 'Quality' }), false);
        cb(JSON.stringify({ value: 1, sensorId: 'AssetMaintenance' }), false);
        cb(JSON.stringify({ value: 1, sensorId: 'ProductionDelay' }), false);
        cb(JSON.stringify({ value: 20, sensorId: 'AssetDowntime' }), false);
    })
    .catch(function (err) {
        console.error('Failed to read out sensor data: ' + err);
    });
}
```

> **ⓘ Important**
>
> The sensors IDs that are defined in the code editor for the Raspberry Pi IoT simulator must be identical to the sensor IDs that you will specify later for the scenarios in Supply Chain Management. The preceding example code uses human-readable sensor IDs. However, in an actual scenario, the sensor IDs will be globally unique identifier (GUID) values that are provided by the sensor manufacturer. The human-readable sensor IDs that are used in this example code are also used in the examples for the product quality scenario, asset maintenance scenario, production delays scenario, asset downtime scenario, and machine status scenario). Therefore, use this code if you will work through those scenarios.

Edit the interval for sending sensor signals

You must now set the interval at which the Raspberry Pi IoT simulator should send the emulated sensor signals.

1. In the code editor of the Raspberry Pi IoT simulator, find the following function invocation.

   ```
   setInterval(sendMessage, 2000);
   ```

2. By default, the Raspberry Pi IoT simulator sends a sensor signal every 2,000 milliseconds (two seconds). You can adjust the value as you require.

Run the Raspberry Pi IoT simulator

- Select **Run** to start the simulator and begin to send simulated sensor data.

Last updated on 02/25/2026

Asset downtime scenario (preview)

Article • 03/19/2024

[This article is prerelease documentation and is subject to change.]

The asset downtime scenario generates a maintenance downtime record if no signal is received from a machine within a defined time threshold since the last signal was received. The scenario requires that you fit your machine with a sensor that periodically sends a signal to your Azure IoT Hub while the machine is operating, but doesn't send a signal when the machine isn't operating.

Set up the asset downtime scenario

Follow these steps to set up the *asset downtime* scenario in Supply Chain Management.

1. Go to **Asset Management** > **Setup** > **Sensor Data Intelligence** > **Scenarios** to open the **Scenarios** page.

2. In the **Asset downtime** scenario box, select **Configure** to open the setup wizard for this scenario.

3. On the **Sensors** page, select **New** to add a sensor to the grid. Then set the following fields for it:

    - **Sensor ID** – Enter the ID of the sensor that you're using. (If you're using the Raspberry PI Azure IoT Online Simulator and have set it up as described in Set up a simulated sensor for testing, enter *AssetDownTime*.)
    - **Sensor description** – Enter a description of the sensor.

4. Repeat the previous step for each additional sensor that you want to add now. You can come back and add more sensors at any time.

5. Select **Next**.

6. On the **Business record mapping** page, in the **Sensors** section, select the record for one of the sensors that you just added.

7. In the **Business record mapping** section, select **New** to add a row to the grid.

8. On the new row, set the **Business record** field to the resource that you're using the selected sensor to monitor. (If you're using the demo data, select *AK-101, Air Knife for Line 1*.)

9. Select **Next**.

10. On the **asset downtime threshold** page, define how long after the last signal the system should wait before send a asset downtime notification. There are two ways to define the threshold:

    - **Default threshold (minutes)** – Set this field to define the default threshold. This value applies to all resources where the **Notification threshold (minutes)** field is set to two minutes or less. The minimum value is *2* (minutes).
    - **Threshold to determine machine not responding (minutes)** – For each resource in the grid where don't want to use the default threshold, enter an override value in this field. Resources that are set to use a threshold of two minutes or less will use the **Default threshold (minutes)** setting instead.

11. Select **Next**.

12. On the **Activate sensors** page, in the grid, select the sensor that you set up, and then select **Activate**. For each activated sensor in the grid, a check mark appears in the **Active** column.

13. Select **Finish**.

Work with the asset downtime scenario

If no sensor signal is received from an asset within the threshold defined in the scenario configuration, the system will create a maintenance downtime record for that asset. Managers should periodically review the downtime records (for example, once during each working shift) and apply appropriate reason codes and end times for each downtime registration. Follow these steps to view the maintenance downtime records for an asset:

1. Go to **Asset management** > **Assets** > **All assets**.
2. Find and select the asset you want to inspect. (If you're using the demo data, select *AK-101*.)
3. On the Action Pane, open the **Asset** tab and, from the **Work order** group, select **Maintenance downtime** to open the page for maintenance downtime records for the selected asset.

Asset maintenance scenario (preview)

Article • 03/19/2024

[This article is prerelease documentation and is subject to change.]

The *asset maintenance* scenario lets you use sensor data to create counter records. Counter records track the use of a machine asset and are used as input to generate the maintenance schedule for machine assets.

Video instructions

The following video shows how to set up and try out the asset maintenance scenario using standard demo data. The remaining sections in this article provide the same instructions in a text-based format.
https://learn-video.azurefd.net/vod/player?id=24d48e9f-b79f-4b78-832a-3ee9a6958cad&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Fsensor-data-intelligence%2Fsdi-scenario-asset-maintenance

Prepare demo data for the asset maintenance scenario

If you want to use a demo system to test the *asset maintenance* scenario, use a system where the demo data is installed, select the *USMF* legal entity (company), and prepare the additional demo data as described in this section. If you're using your own sensors and data, you can skip this section.

In this section, you will set up the *AK-101, Air knife* asset in demo data as an example. You will then see how upcoming maintenance work can be predicted based on sensor signals that measure the number of hours that the air knife has been running. You will also set up a maintenance plan where the air knife must be maintained every 10,000 hours.

Set up a sensor simulator

If you want to try this scenario without using a physical sensor, you can set up a simulator to generate the required signals. Learn more in Set up a simulated sensor for testing.

Create an asset counter to track production hours

Follow these steps to create an asset counter to track production hours.

1. Go to **Asset management** > **Setup** > **Asset types** > **Counters**.
2. On the Action Pane, select **New** to create a counter.
3. On the header, set the following values:
    - **Counter:** *ProductionHr*
    - **Name:** *Production hours*
4. On the **General** FastTab, set the following values:
    - **Unit:** *hr*
    - **Update:** *Manual*
    - **Total aggregate:** *Sum*
5. On the **Asset types** FastTab, select **Add line**.
6. On the new line, set the **Asset type** field to *Air knife*.

Create a maintenance plan for the asset

Follow these steps to create a maintenance plan for the asset.

1. Go to **Asset management** > **Setup** > **Preventive maintenance** > **Maintenance plan**.
2. On the Action Pane, select **New** to create a maintenance plan.
3. On the header, set the following values:
    - **Maintenance plan:** *AirKnife*
    - **Name:** *Plan for air knives*
4. On the **Details** FastTab, set the following values:
    - **Plan date:** Enter today's date.
    - **Active:** *Yes*
5. On the **Lines** FastTab, select **Add asset counter line** to add a line to the grid. Then set the following values for it:
    - **Work order description:** *Maintenance for air knife*
    - **Maintenance job type:** *Preventive*
    - **Interval type:** *Repeated from last work order*

- **Period frequency:** *10000*
- **Counter:** *ProductionHr*

Set up the asset maintenance scenario

Follow these steps to set up the *asset maintenance* scenario in Supply Chain Management.

1. Go to **Asset management** > **Setup** > **Sensor Data Intelligence** > **Scenarios**.
2. In the **Asset maintenance** scenario box, select **Configure** to open the setup wizard for this scenario.
3. On the **Sensors** page, select **New** to add a sensor to the grid. Then set the following fields for it:
    - **Sensor ID** – Enter the ID of the sensor that you're using. (If you're using the Raspberry PI Azure IoT Online Simulator and have set it up as described in Set up a simulated sensor for testing, enter *AssetMaintenance*.)
    - **Sensor description** – Enter a description of the sensor.
4. Repeat the previous step for each additional sensor that you want to add now. You can come back and add more sensors at any time.
5. Select **Next**.
6. On the **Business record mapping** page, in the **Sensors** section, select the record for one of the sensors that you just added.
7. In the **Business record mapping** section, select **New** to add a row to the grid.
8. On the new row, the **Business record type** field should automatically be set to *Assets(EntAssetObjectTable)*. Set the **Business record** field to the resource that you're using the selected sensor to monitor. (If you're using the demo data that you created earlier in this article, set it to *AK-101, AK-101 Air Knife for Line 1*.)
9. Immediately after you select a business record type for the row that you added in the previous step, a second row is automatically added to the grid. On this row, the **Business record type** field should be set to *Counters(EntAssetCounterType)*. Set the **Business record** field to the asset counter that you're updating based on signals from the selected sensor. (If you're using the demo data that you created earlier in this article, set it to *ProductionHr, Production hours*.)
10. Select **Next**.

11. On the **Activate sensors** page, in the grid, select the sensor that you added, and then select **Activate**. For each activated sensor in the grid, a check mark appears in the **Active** column.

12. Select **Finish**.

Work with the asset maintenance scenario

View counter values

After the data is prepared, and the *asset maintenance* scenario is configured and activated, you can see how records for an asset counter are inserted based on sensor data.

1. Go to **Asset management** > **Assets** > **All assets**.
2. Find and select the asset that you want to inspect. (If you're using the demo data that you created earlier in this article, select *AK-101*.)
3. On the Action Pane, on the **Asset** tab, in the **Preventive** group, select **Counters** to open the page for counter records for asset *AK-101*.

> **Note**
>
> The counter records are configured by default to be inserted every three hours, which means sensor data will be aggregated at that interval. You can change the interval by editing the query in the Azure Stream Analytics component.

Generate maintenance work orders

After you enable the *asset maintenance* scenario and set up the maintenance plan, you can run the maintenance schedule to generate maintenance work orders. For more information about how to work with preventive maintenance, see Preventive maintenance overview.

Machine status scenario (preview)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

[This article is prerelease documentation and is subject to change.]

The *machine status* scenario lets you use sensor data to monitor the availability of your equipment. If you set up a sensor that sends a signal when a production job on a machine resource produces output, but no sensor signal is received within a specified interval, a notification is shown on the supervisor's dashboard.

Scenario dependencies

The *machine status* scenario has the following dependencies:

- A notification can be triggered only if a production job is in progress on a mapped machine.
- A signal that represents a *part-out* signal must be sent to the IoT hub.

Prepare demo data for the machine status scenario

If you want to use a demo system to test the *machine status* scenario, use a system where the demo data is installed, select the *USMF* legal entity (company), and prepare the additional demo data as described in this section. If you're using your own sensors and data, you can skip this section.

Set up a sensor simulator

If you want to try this scenario without using a physical sensor, you can set up a simulator to generate the required signals. Learn more in Set up a simulated sensor for testing.

Verify that resource 3118 is used for product P0111

A production order will be scheduled and released. Therefore, a production job is released to resource *3118* (*Foam cutting machine*). Follow these steps to verify that resource *3118* is used

for product *P0111* in your demo data.

1. Go to **Product information management** > **Products** > **Released products**.
2. Find and select the product where the **Item number** field is set to *P0111*.
3. On the Action Pane, on the **Engineer** tab, in the **View** group, select **Route**.
4. On the **Route** page, on the **Overview** tab at the bottom of the page, select the line where the **Oper. No.** field is set to *30*.
5. On the **Resource requirements** tab at the bottom of the page, make sure that resource *3118* (*Foam cutting machine*) is associated with the operation.

Create and release a production order for product P0111

Follow these steps to create and release a production order for product *P0111*.

1. Go to **Production control** > **Production orders** > **All production orders**.
2. On the **All production orders** page, on the Action Pane, select **New batch order**.
3. In the **Create batch** dialog box, set the following values:
    - **Item number:** *P0111*
    - **Quantity:** *10*
4. Select **Create** to create the order and return to the **All production orders** page.
5. Use the **Filter** field to search for production orders where the **Item number** field is set to *P0111*. Then find and select the production order that you just created.
6. On the Action Pane, on the **Production order** tab, in the **Process** group, select **Estimate**.
7. In the **Estimate** dialog box, select **OK** to run the estimate.
8. On the Action Pane, on the **Production order** tab, in the **Process** group, select **Release**.
9. In the **Release** dialog box, make a note of the number of the batch order that you just created.
10. Select **OK** to release the order.

Configure the production floor execution interface

You will use the production floor execution interface to start the job that was scheduled and released for item number *P0111* in the previous section. Follow these steps to configure the production floor execution interface.

1. Go to **Production control** > **Manufacturing execution** > **Production floor execution**.
2. If you haven't previously set up the interface, a sign-in page appears. Enter your credentials.
3. On the welcome page, select **Configure** to open the **Configure device** wizard.
4. On the **Configure device - Step 1 - Select configuration** page, select the *Default* configuration.
5. Select **Next**.
6. On the **Configure device - Step 2 - Define the production floor area** page, set the **Resource** field to *3118*.
7. Select **OK**.

Enable the search option in the production floor execution interface

To make it easier to find the production job for the production order that was released earlier, follow these steps to enable the search option in the production floor execution interface.

1. Go to **Production control** > **Setup** > **Manufacturing execution** > **Configure production floor execution**.
2. Select the *Default* configuration.
3. On the Action Pane, select **Edit**.
4. On the **General** FastTab, set the **Enable search** option to *Yes*.
5. Close the page.

Start the first job in the batch order

Follow these steps to start the job scheduled on resource *3118*.

1. Go to **Production control** > **Manufacturing execution** > **Production floor execution**.
2. In the **Badge ID** field, enter *123*. Then select **Sign in**.
3. If you're prompted for an absence reason, select one of the cards for absence, and then select **OK**.
4. In the **Search** field, enter the batch order number that you previously made a note of. Then select the **Return** key.
5. Select the order, and then select **Start job**.
6. In the **Start job** dialog box, select **Start**.

Set up the machine status scenario

Follow these steps to set up the *machine status* scenario in Supply Chain Management.

1. Go to **Production control** > **Setup** > **Sensor Data Intelligence** > **Scenarios**.
2. In the **Machine status** scenario box, select **Configure** to open the setup wizard for this scenario.
3. On the **Sensors** page, select **New** to add a sensor to the grid. Then set the following fields for it:
    - **Sensor ID** – Enter the ID of the sensor that you're using. (If you're using the Raspberry PI Azure IoT Online Simulator and have set it up as described in Set up a simulated sensor for testing, enter *MachineStatus*.)
    - **Sensor description** – Enter a description of the sensor.
4. Repeat the previous step for each additional sensor that you want to add now. You can come back and add more sensors at any time.
5. Select **Next**.
6. On the **Business record mapping** page, in the **Sensors** section, select the record for one of the sensors that you just added.
7. In the **Business record mapping** section, select **New** to add a row to the grid.
8. On the new row, set the **Business record** field to the resource that you're using the selected sensor to monitor. (If you're using the demo data that you created earlier in this article, set the field to *3118, Foam cutting machine*.)
9. Select **Next**.
10. On the **Machine status threshold** page, define how long after the last *part-out* signal the system should send a machine status notification. There are two ways to define the threshold:
    - **Default threshold (minutes)** – Set this field to define the default threshold. The value will then apply to all resources where the **Threshold to determine machine not responding (minutes)** field is set to two minutes or less. The minimum value is *2* (minutes).
    - **Threshold to determine machine not responding (minutes)** – For each resource in the grid that you don't want to use the default threshold for, enter an override value in this field. Resources that are set to use a threshold of two minutes or less will use the **Default threshold (minutes)** setting instead.

    > ⓘ **Note**

> Typically, you will use a *part-out* signal to monitor machine status. Therefore, you should verify that the threshold for each machine resource is longer than the machine requires to produce each part.

11. Select **Next**.
12. On the **Activate sensors** page, in the grid, select the sensor that you added, and then select **Activate**. For each activated sensor in the grid, a check mark appears in the **Active** column.
13. Select **Finish**.

Work with the machine status scenario

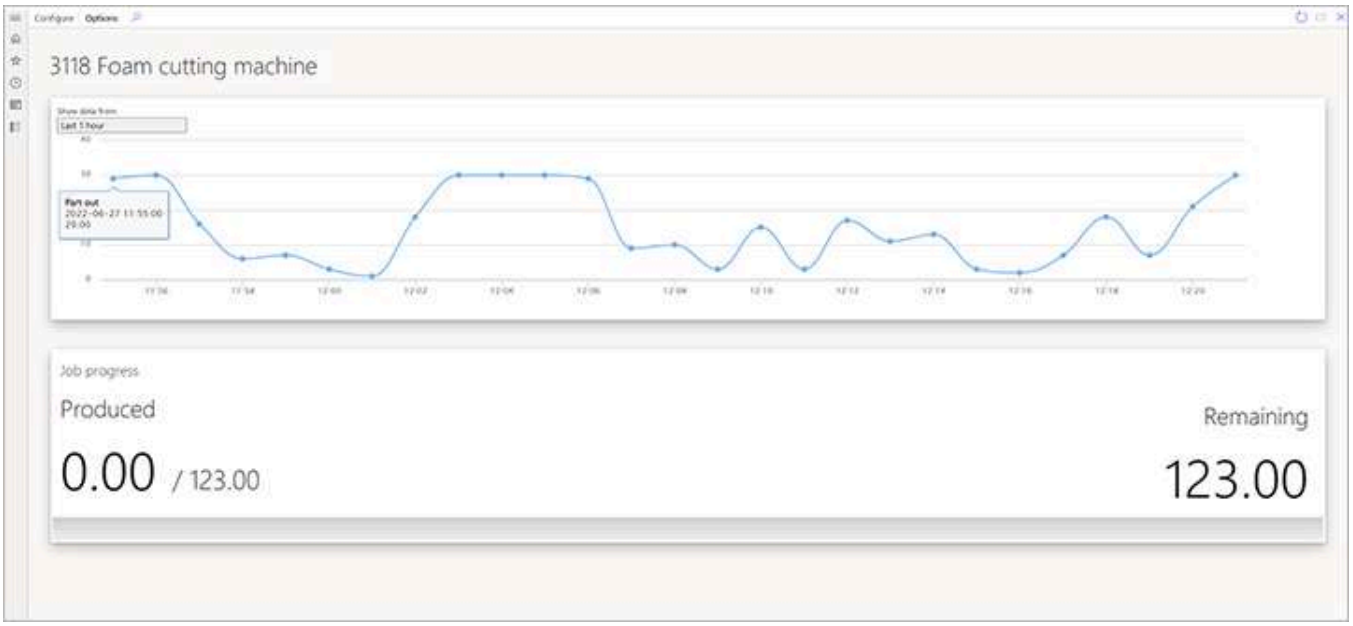
After you install your sensors and configure the scenario, you can view machine status events in Supply Chain Management. This section describes where and how to view this information.

View machine status data on the Resource status page

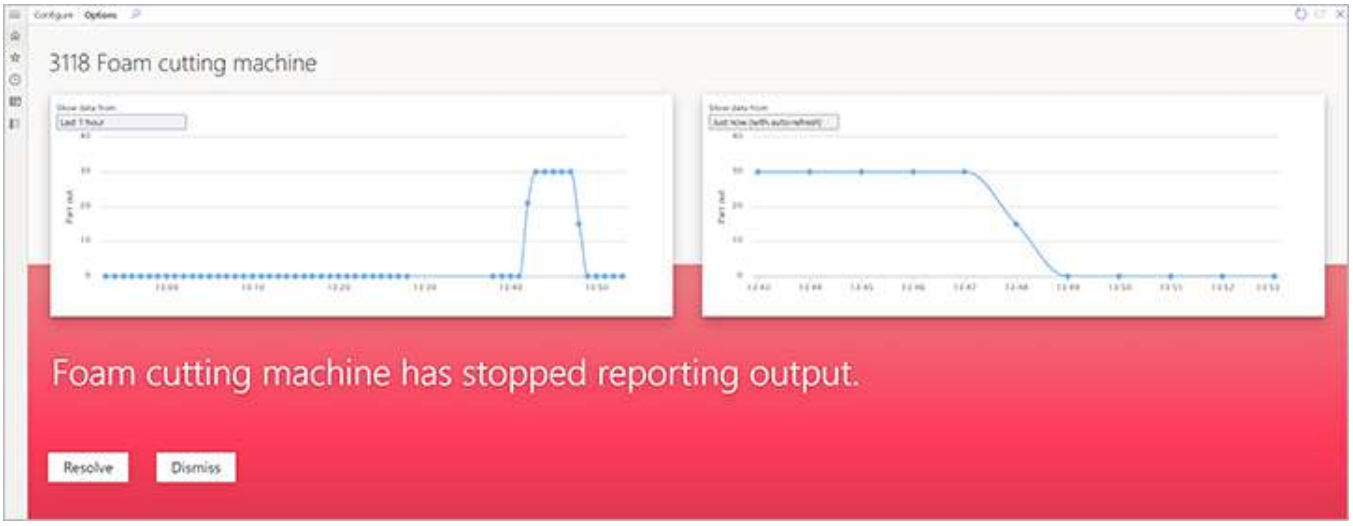
On the **Resource status** page, supervisors can monitor a timeline of the *part-out* signal that is received from the sensors that are mapped to each machine resource. Follow these steps to configure the timeline.

1. Go to **Production control** > **Manufacturing execution** > **Resource status**.
2. In the **Configure** dialog box, set the following fields:
    - **Resource** – Select the resources that you want to monitor. (If you're working with the demo data, select *3118*.)
    - **Time series 1** – Select the record (metric key) that has the following format for its name: *MachineReportingStatus:<Sensor>*
    - **Display name** – Enter *Parts out signal*.

The following illustration shows an example of machine status data on the **Resource status** page during standard operation.



The following illustration shows an example of machine status data when downtime is detected.

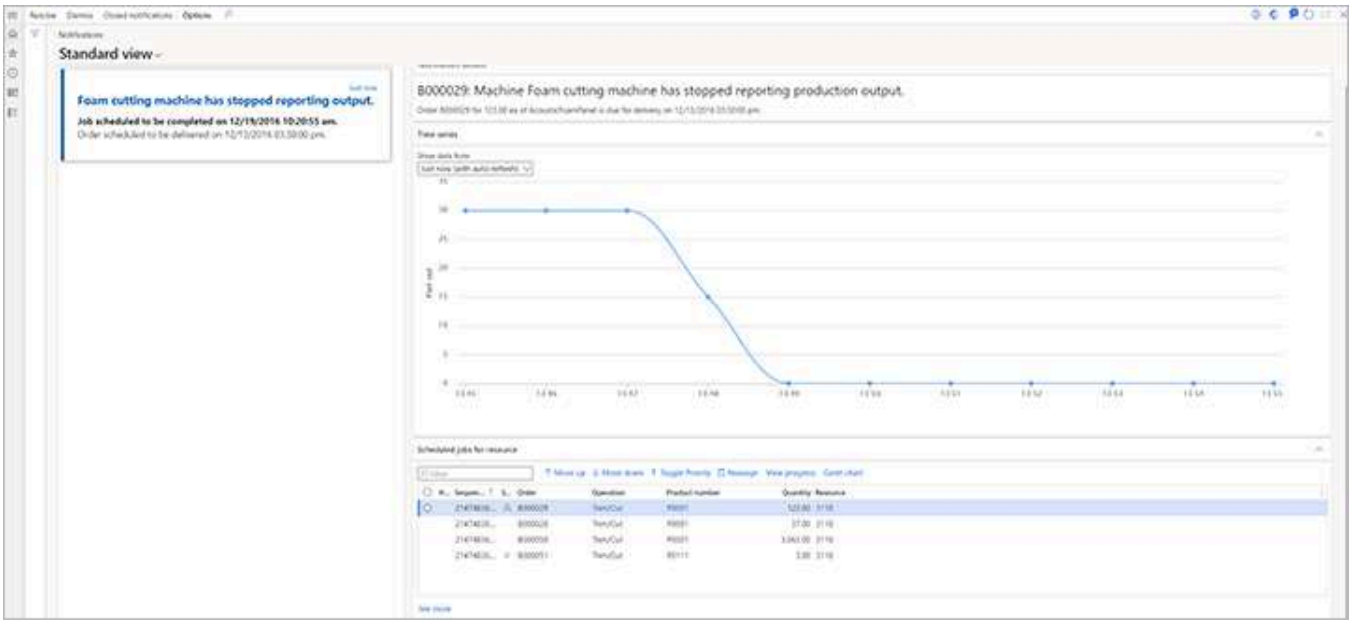


View machine status on the Notifications page

On the **Notifications** page, supervisors can view the notifications that are generated when too much time has passed since the sensor last delivered a *part-out* signal. Each notification provides an overview of the production job that is affected by the outage and gives the option to reassign the affected job to another resource.

To open the **Notification** page, go to **Production control** > **Inquiries and reports** > **Sensor Data Intelligence** > **Notifications**.

The following illustration shows an example of a machine status notification.



Last updated on 05/07/2025

Product quality scenario (preview)

Article • 10/18/2022

[This article is prerelease documentation and is subject to change.]

In the *product quality* scenario, a sensor is set up to measure the quality of a product batch on the shop floor. If a measurement falls outside a defined threshold for the product, a notification is shown on the supervisor's dashboard. For example, a sensor is measuring the moisture of a food product that comes out of the production line. If the measurement is outside the allowed minimum or maximum value for moisture for the product, a notification is generated.

Scenario dependencies

The *product quality* scenario has the following dependencies:

- An alert can be triggered only if a production order is running on a mapped machine, and if that machine is producing a product that has a mapped batch attribute.
- A signal that represents the batch attribute must be sent to the IoT hub, and a unique property name must be included.

Prepare demo data for the product quality scenario

If you want to use a demo system to test the *product quality* scenario, use a system where the demo data is installed, select the *USMF* legal entity (company), and prepare the additional demo data as described in this section. If you're using your own sensors and data, you can skip this section.

In this section, you will set up the demo data so that you can use released product *P0111* (*Composite Case*) with the *product quality* scenario. In this scenario, the system tracks whether a batch attribute value that is measured by a sensor is outside the defined threshold for a batch attribute that is associated with the product.

Set up a sensor simulator

If you want to try this scenario without using a physical sensor, you can set up a simulator to generate the required signals. Learn more in Set up a simulated sensor for

testing.

Associate a batch attribute and resource with product P0111

Follow these steps to associate a batch attribute with product *P0111* (*Composite Case*) and verify that resource *3118* (*Foam cutting machine*) is used for it.

1. Go to **Product information management** > **Products** > **Released products**.
2. Find and select the product where the **Item number** field is set to *P0111*.
3. On the Action Pane, on the **Manage inventory** tab, in the **Batch attributes** group, select **Product specific**.
4. On the **Product specific** page, select **New** to create a product-specific batch attribute.
5. On the header, set the following fields:
    - **Attribute code** – Select the scope of attributes that you will monitor (*Table*, *Group*, or *All*). For this scenario, select *Table*, because you will always monitor a single attribute.
    - **Attribute relation** – Select the attribute that you will use the *product quality* scenario to monitor the value of. For this example, select *Concentration*, which is an attribute that is included in the standard demo data.
6. On the **Values** FastTab, in the **Minimum** and **Maximum** fields, define the range of acceptable values that the attribute must report to pass the quality check. If the sensor reports a value outside this range, the system will identify it as a quality violation. The other fields on this FastTab aren't relevant to the *product quality* scenario. The default values that you currently see come from the demo data. Therefore, leave them as they are, and close the **Product specific** page to return to the **Released product details** page for item *P0111*.
7. On the Action Pane, on the **Engineer** tab, in the **View** group, select **Route**.
8. On the **Route** page, on the **Overview** tab at the bottom of the page, select the line where the **Oper. No.** field is set to *30*.
9. On the **Resource requirements** tab at the bottom of the page, make sure that resource *3118* (*Foam cutting machine*) is associated with the operation.

Create and release a production order for product P0111

Follow these steps to create and release a production order for product *P0111*.

1. Go to **Production control** > **Production orders** > **All production orders**.
2. On the **All production orders** page, on the Action Pane, select **New batch order**.
3. In the **Create batch** dialog box, set the following values:
    - **Item number:** *P0111*
    - **Quantity:** *10*
4. Select **Create** to create the order and return to the **All production orders** page.
5. Use the **Filter** field to search for production orders where the **Item number** field is set to *P0111*. Then find and select the production order that you just created.
6. On the Action Pane, on the **Production order** tab, in the **Process** group, select **Estimate**.
7. In the **Estimate** dialog box, select **OK** to run the estimate.
8. On the Action Pane, on the **Production order** tab, in the **Process** group, select **Release**.
9. In the **Release** dialog box, make a note of the number of the batch order that you just created.
10. Select **OK** to release the order.

Configure the production floor execution interface

If you haven't already done so, configure the production floor execution interface to show jobs that are assigned to resource *3118* (*Foam cutting machine*). For instructions, see the following sections:

- Configure the production floor execution interface
- Enable search option on the production floor execution interface

Start the first job in the batch order

Follow these steps to start the first job in the batch order.

1. Go to **Production control** > **Manufacturing execution** > **Production floor execution**.
2. In the **Badge ID** field, enter *123*. Then select **Sign in**.

3. If you're prompted for an absence reason, select one of the cards for absence, and then select **OK**.
4. In the **Search** field, enter the batch order number that you previously made a note of. Then select the **Return** key.
5. Select the order, and then select **Start job**.
6. In the **Start job** dialog box, select **Start**.

Set up the product quality scenario

Follow these steps to set up the *product quality* scenario in Supply Chain Management.

1. Go to **Production control** > **Setup** > **Sensor Data Intelligence** > **Scenarios**.

2. In the **Product quality** scenario box, select **Configure** to open the setup wizard for this scenario.

3. On the **Sensors** page, select **New** to add a sensor to the grid. Then set the following fields for it:

    - **Sensor ID** – Enter the ID of the sensor that you're using. (If you're using the Raspberry PI Azure IoT Online Simulator and have set it up as described in Set up a simulated sensor for testing, enter *Quality*.)
    - **Sensor description** – Enter a description of the sensor.

4. Repeat the previous step for each additional sensor that you want to add now. You can come back and add more sensors at any time.

5. Select **Next**.

6. On the **Business record mapping** page, in the **Sensors** section, select the record for one of the sensors that you just added.

7. In the **Business record mapping** section, select **New** to add a row to the grid.

8. On the new row, the **Business record type** field should automatically be set to *Resources(WrkCtrTable)*. Set the **Business record** field to the resource that you're using the selected sensor to monitor. (If you're using the demo data that you created earlier in this article, set it to *3118, Foam cutting machine*.)

9. Immediately after you select a business record type for the row that you added in the previous step, a second row is automatically added to the grid. On this row, the **Business record type** field should be set to *Batch attributes(PdsBatchAttrib)*. Set the **Business record** field to the batch attribute that you're using the selected sensor to

monitor. (If you're using the demo data that you created earlier in this article, set it to *Concentration, Concentration Percentage*.)

10. Select **Next**.

11. On the **Activate sensors** page, in the grid, select the sensor that you added, and then select **Activate**. For each activated sensor in the grid, a check mark appears in the **Active** column.

12. Select **Finish**.

Work with the product quality scenario

View product quality data on the Resource status page

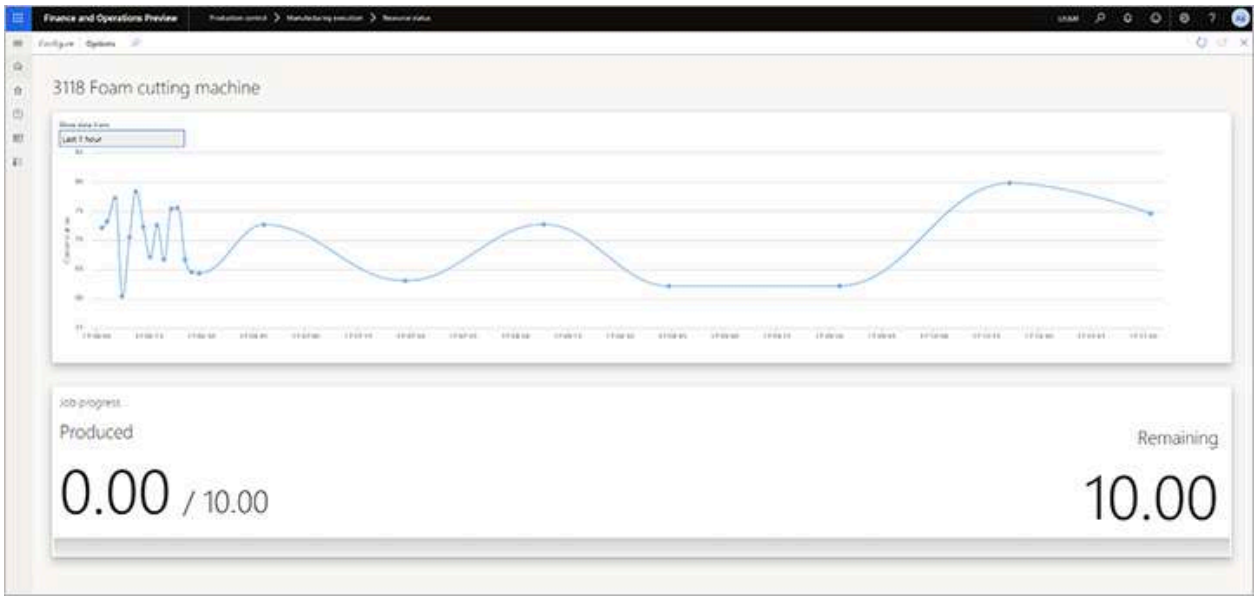
On the **Resource status** page, supervisors can monitor a timeline of the product quality signal that is received from the sensors that are mapped to each machine resource. Follow these steps to configure the timeline.

1. Go to **Production control** > **Manufacturing execution** > **Resource status**.

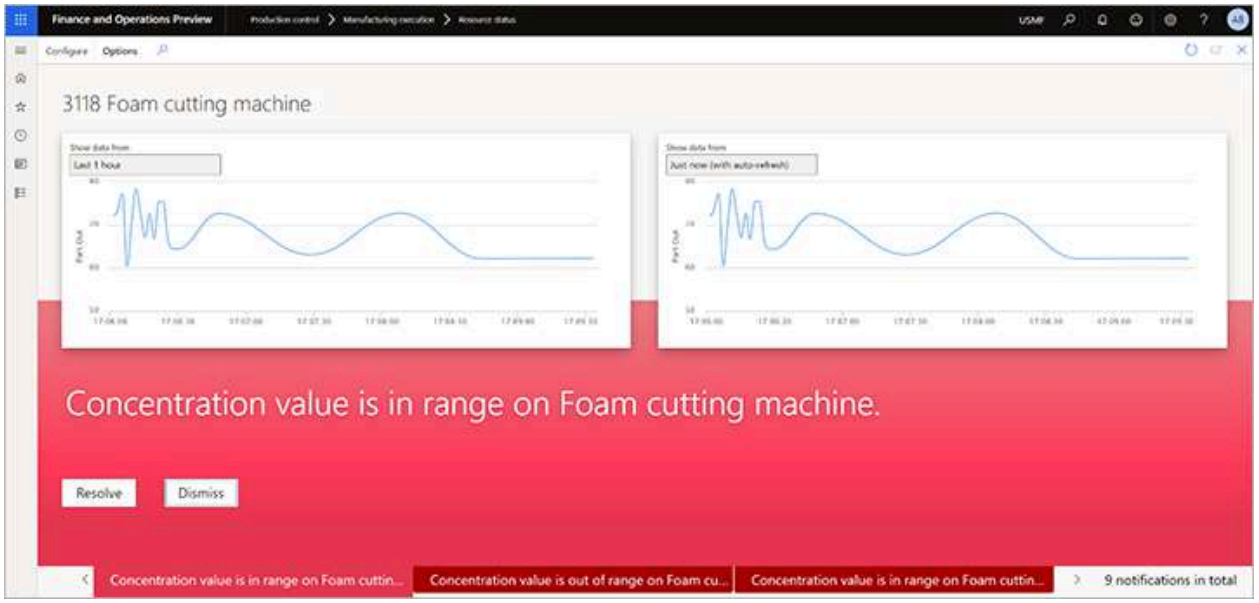
2. In the **Configure** dialog box, set the following fields:

    - **Resource** – Select the resources that you want to monitor. (If you're working with the demo data, select *3118*.)
    - **Time series 1** – Select the record (metric key) that has the following format for its name: *ProductQuality:<JobId>:<AttributeName>*
    - **Display name** – Enter *Batch attribute values*.

The following illustration shows an example of product quality data on the **Resource status** page when the value is in the range of acceptable values.



The following illustration shows an example of product quality data when an out-of-range value is detected.



View product quality data on the Notifications page

On the **Notifications** page, supervisors can view the notification that are generated when the sensor measures a batch attribute value that falls outside the defined threshold for the batch attribute. Each notification provides an overview of the production job that is affected by the outage and gives the option to reassign the affected job to another resource.

To open the **Notification** page, go to **Production control** > **Inquiries and reports** > **Sensor Data Intelligence** > **Notifications**.

The following illustration shows an example of a product quality notification.

Production auto report scenario (preview)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

[This article is prerelease documentation and is subject to change.]

The *production auto report* scenario automatically reports finished quantities when a machine generates enough sensor signals to reach a defined output threshold. The scenario requires fitting the machine with a sensor that emits a signal for each production cycle, and mapping that sensor to the corresponding resource and operation in Supply Chain Management. By defining how many signals correspond to one finished unit, the system can automatically determine when progress should be reported and update the production order and inventory accordingly.

Prerequisites

To use the features described in this article, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.47 or later.
- The following features must be turned on in feature management.
  - *(Preview) Sensor Data Intelligence*
  - *(Preview) Sensor Data Intelligence - Auto report progress*

Set up the production auto report scenario

To set up the production auto report scenario, you need to define the sensors that are installed on the machines, map those sensors to the corresponding resources and operations in Supply Chain Management, and define thresholds for how many sensor signals correspond to finished units for each operation. Follow these steps to set up the scenario:

1. Go to **Production control** > **Setup** > **Sensor Data Intelligence** > **Scenarios** to open the **Scenarios** page.

2. In the **Production auto report** box, select **Configure** to open the setup wizard for this scenario.

3. On the **Sensors** page, select **New** to add a sensor to the grid. Then set the following fields for it:

    - **Sensor ID** – Enter the ID of the sensor that you're using. (If you're using the Raspberry PI Azure IoT Online Simulator and have set it up as described in Set up a simulated sensor for testing, enter *AssetDownTime*.)
    - **Sensor description** – Enter a description of the sensor.

4. Repeat the previous step for each sensor that you want to add now. You can come back and add more sensors at any time.

5. Select **Next**.

6. On the **Business record mapping** page, in the **Sensors** section, select the record for one of the sensors that you just added.

7. In the **Business record mapping** section, select **New** to add a row to the grid.

8. On the new row, set the **Business record** field to the resource that you're using the selected sensor to monitor.

9. Repeat the previous step for each sensor that you want to set up now. You can come back and set up more sensors at any time.

10. Select **Next**.

11. On the **Set auto-reporting threshold** page, select the operation relation you want your configuration to apply to. You can find a specific operation relation by following these steps:

    - Select the **Item relation** column heading to open a drop-down dialog box that includes search filters for the column. Enter the product that the operation relation is created for.
    - Select the **Route relation** column heading to open a drop-down dialog box that includes search filters for the column. Enter the route number that the operation relation is created for.

    > **Tip**
    >
    > Each operation relation defines the detailed properties of an operation—such as setup time, run time, cost categories, and resource requirements—for a specific route or product. It lets each operation have several different properties depending on where it's used.

12. When you have found the applicable operation relation, enter values in the following columns for it:

    - **Pulses per cycle** – Number of pulses the sensor emits in a production cycle.
    - **Units per cycle** – Number of parts produced by the operation in a production cycle.

    > **Tip**
    >
    > A production cycle is the smallest repeatable unit of work performed by a machine that produces a measurable output.

13. Set up more operation relations with their corresponding thresholds as needed. You can come back and set up more operation relations at any time.

14. Select **Next**.

15. On the **Activate sensors** page, in the grid, select the sensor that you set up, and then select **Activate**. For each activated sensor in the grid, a check mark appears in the **Active** column.

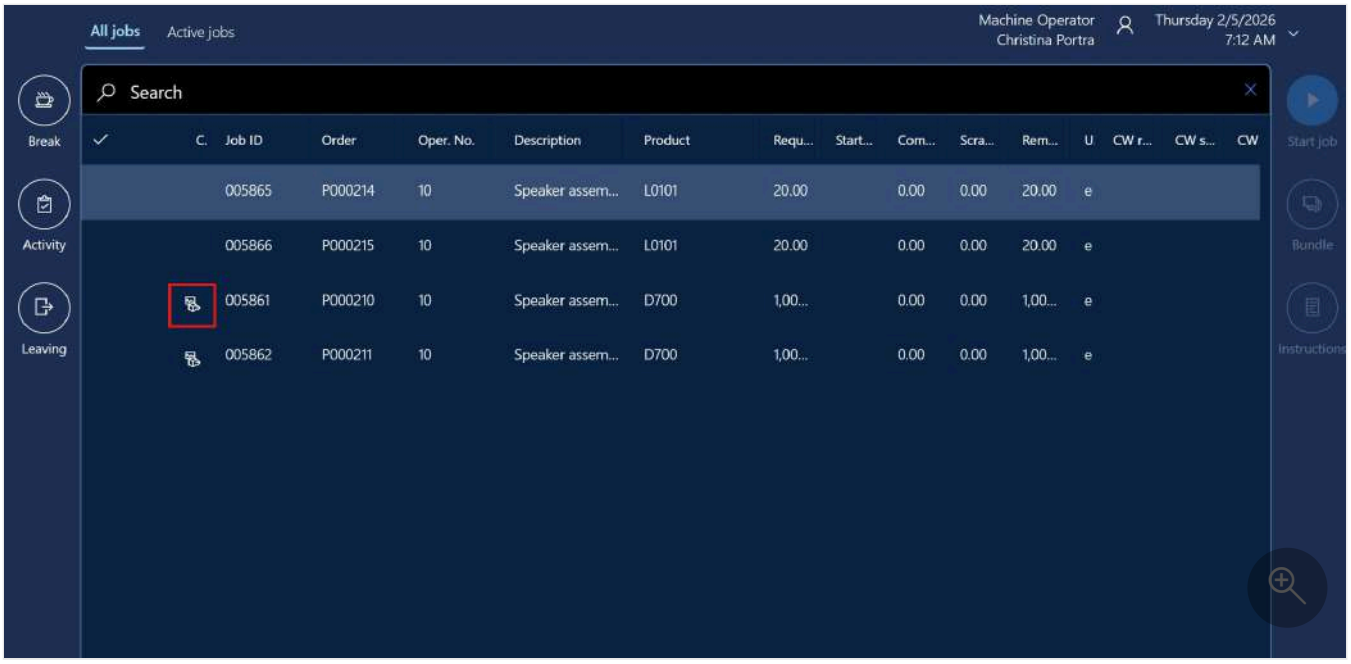
16. Select **Finish**.

Add counter displays to the production floor execution interface

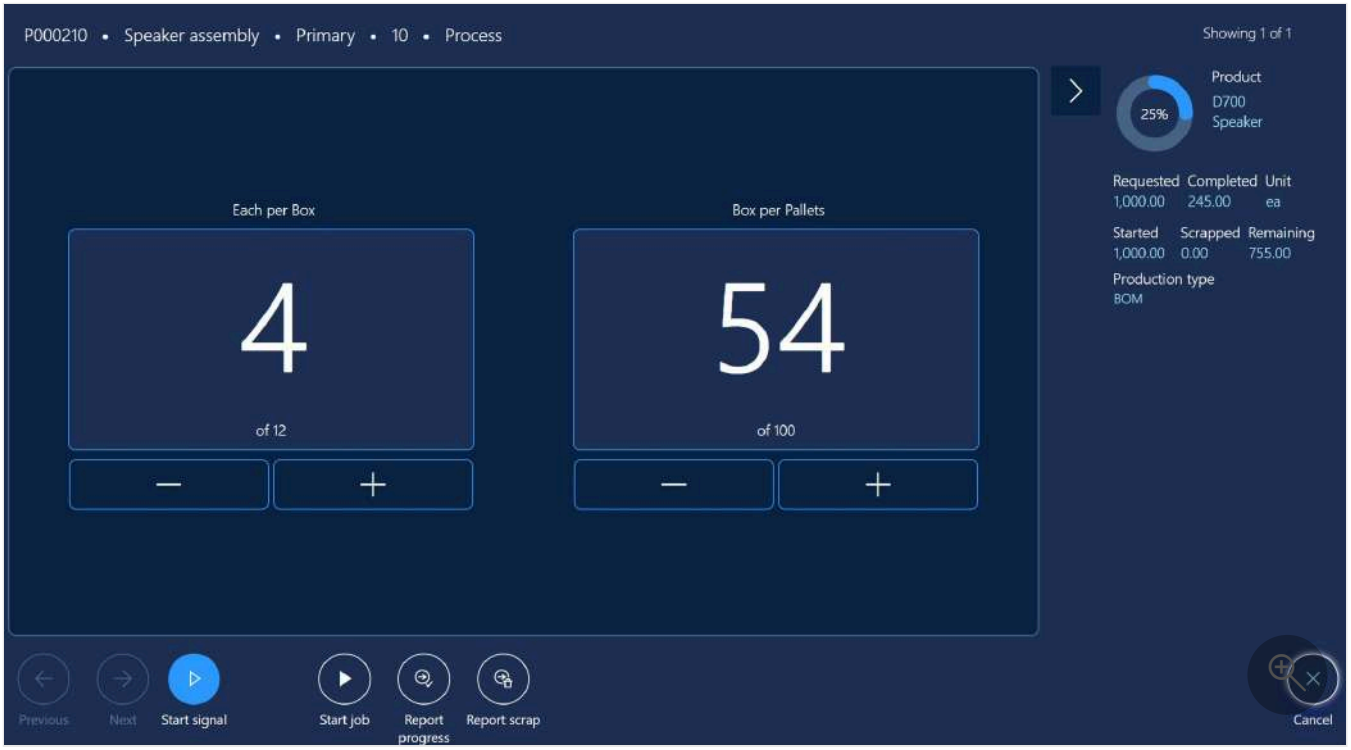
To make counter information available to workers, add a button to the relevant toolbars on the production floor execution interface. Follow the procedure provided in Design the production floor execution interface to insert the action called *View counter* at suitable locations of the production floor execution interface UI.

View sensor counters in the production floor execution interface

Jobs configured for auto reporting through a sensor signal show a dedicated icon in the job list on the production floor execution interface, as indicated in the following image.



After you start a sensor-controlled job, you can open the **View counter** dialog by selecting **View counter** from the toolbar in the job list. As shown in the following image, the **View counter** dialog displays the current progress counters for the job.



Counters are shown in one or two levels. The number of levels depends on the **Unit sequence group ID** defined on the finished product. Learn more about how to set up unit sequence groups in: Unit of measure and stocking policies.

Example of counters in a two level setup

In the example **View counter** dialog shown in the previous image, the first-level (left-hand) counter indicates how many pieces have been added to the box currently being filled. Each

time a sensor signal is received, the level-1 counter (*Pieces per box*) increases. When the threshold of 12 pieces per box is reached, the level-1 counter resets to zero and the level-2 counter (*Boxes per pallet*) increases by one. When the level-2 threshold of 100 boxes per pallet is reached, the level-2 counter also resets to zero, indicating that a new pallet is ready to be filled. At this point, the system automatically reports a pallet as finished. The report as finished posting is processed through the message queue as an asynchronous (deferred) operation. Learn more about deferred posting in Make finished goods physically available before posting to journals.

Pausing signals and adjusting counters

If something unexpected happens, such as a dropped counter signal or a counted item that needs to be scrapped, you can pause the sensor signal and adjust the counters and report quantities as needed. Follow these steps to pause the signal, adjust counters, or adjust reported quantities:

1. Open the counter dialog by selecting **View counter** from the toolbar in the job list.
2. In the counter dialog, select the **Pause signal** button to pause the sensor signal. This allows you to report scrap, report progress, and adjust the counters without new signals coming in.
    - If you need to adjust the counter values, use the + and – buttons below each counter as needed.
    - If you need to report some counted quantity as scrap, select the **Report scrap** button. This action opens the **Reporting as scrap** dialog, where you can enter the quantity to be scrapped and the reason for scrapping.
    - If you need to manually report progress (for example, because a sensor signal was missed), select the **Report progress** button. This action opens the **Reporting progress** dialog, where you can enter the quantity to report as finished.
3. Select the **Start signal** button to restart the sensor signal.

Navigating between multiple sensor enabled jobs

If multiple jobs in the job list are enabled for sensor controlled reporting, use the **Previous** and **Next** buttons of the **View counter** dialog to switch between jobs without closing the dialog.

Production delays scenario (preview)

Article • 10/18/2022

[This article is prerelease documentation and is subject to change.]

The *production delays* scenario generates a notification if production throughput falls below a specific threshold value. In this scenario, a *part-out* signal is sent to Microsoft Azure IoT Hub for each item that is produced. In Dynamics 365 Supply Chain Management, the order delay is calculated based on the amount of time that the production order is scheduled to run, the number of items that should be produced, the amount of time that the job has been running, and the number of *part-out* signals that have been received. A delay notification is generated if the number of *part-out* signals for the job falls below the threshold value.

Scenario dependencies

The *production delays* scenario has the following dependencies:

- An alert can be triggered only if a production order is running on a mapped machine.
- A signal that represents a mapped machine's *part-out* signal must be sent to IoT Hub, and a unique property name must be included.
- A UNIX timestamp property, where the value is expressed in milliseconds (ms), must be present in the Azure IoT Hub message.

Prepare demo data for the product delays scenario

If you want to use a demo system to test the *production delays* scenario, use a system where the demo data is installed, select the *USMF* legal entity (company), and prepare the additional demo data as described in this section. If you're using your own sensors and data, you can skip this section.

Set up sensor simulator

If you want to try this scenario without using a physical sensor, you can set up a simulator to generate the required signals. Learn more in Set up a simulated sensor for testing.

Verify that resource 3118 is used for product P0111

A production order will be scheduled and released. Therefore, a production job is released to resource *3118* (*Foam cutting machine*). Follow these steps to verify that resource *3118* is used for product *P0111* in your demo data.

1. Go to **Product information management** > **Products** > **Released products**.
2. Find and select the product where the **Item number** field is set to *P0111*.
3. On the Action Pane, on the **Engineer** tab, in the **View** group, select **Route**.
4. On the **Route** page, on the **Overview** tab at the bottom of the page, select the line where the **Oper. No.** field is set to *30*.
5. On the **Resource requirements** tab at the bottom of the page, make sure that resource *3118* (*Foam cutting machine*) is associated with the operation.

Create and release a production order for product P0111

Follow these steps to create and release a production order for product *P0111*.

1. Go to **Production control** > **Production orders** > **All production orders**.
2. On the **All production orders** page, on the Action Pane, select **New batch order**.
3. In the **Create batch** dialog box, set the following values:
    - **Item number:** *P0111*
    - **Quantity:** *10*
4. Select **Create** to create the order and return to the **All production orders** page.
5. Use the **Filter** field to search for production orders where the **Item number** field is set to *P0111*. Then find and select the production order that you just created.
6. On the Action Pane, on the **Production order** tab, in the **Process** group, select **Estimate**.
7. In the **Estimate** dialog box, select **OK** to run the estimate.
8. On the Action Pane, on the **Production order** tab, in the **Process** group, select **Release**.
9. In the **Release** dialog box, make a note of the number of the batch order that you just created.
10. Select **OK** to release the order.

Configure the production floor execution interface

If you haven't already done so, configure the production floor execution interface to show jobs that are assigned to resource *3118* (*Foam cutting machine*). For instructions, see the following sections:

- Configure the production floor execution interface
- Enable search option on the production floor execution interface

Start the first job in the batch order

Follow these steps to start the first job in the batch order.

1. Go to **Production control** > **Manufacturing execution** > **Production floor execution**.
2. In the **Badge ID** field, enter *123*. Then select **Sign in**.
3. If you're prompted for an absence reason, select one of the cards for absence, and then select **OK**.
4. In the **Search** field, enter the batch order number that you previously made a note of. Then select the **Return** key.
5. Select the order, and then select **Start job**.
6. In the **Start job** dialog box, select **Start**.

Set up the production delays scenario

Follow these steps to set up the *production delays* scenario in Supply Chain Management.

1. Go to **Production control** > **Setup** > **Sensor Data Intelligence** > **Scenarios**.

2. In the **Production delays** scenario box, select **Configure** to open the setup wizard for this scenario.

3. On the **Sensors** page, select **New** to add a sensor to the grid. Then set the following fields for it:

    - **Sensor ID** – Enter the ID of the sensor that you're using. (If you're using the Raspberry PI Azure IoT Online Simulator and have set it up as described in Set up a simulated sensor for testing, enter *ProductionDelay*.)
    - **Sensor description** – Enter a description of the sensor.

4. Repeat the previous step for each additional sensor that you want to add now. You can come back and add more sensors at any time.

5. Select **Next**.
6. On the **Business record mapping** page, in the **Sensors** section, select the record for one of the sensors that you just added.
7. In the **Business record mapping** section, select **New** to add a row to the grid.
8. On the new row, set **Business record** to the resource that you're using the selected sensor to monitor. (If you're using the demo data that you created earlier in this article, set it to *3118, Foam cutting machine*.)
9. Select **Next**.
10. On the **Production delay deviation threshold** page, if you're using the demo data that you created earlier in this article, follow these steps:
    a. Select the **Item relation** column heading to open a drop-down dialog box that includes search filters for the column. Enter *P0111* in the search box, and then select **Apply**.
    b. Select the line where the **Operation** field is set to *Trim/Cut*. Set the **Notification threshold for delay (%)** field to the threshold (as a percentage) that a notification should be sent at.
11. Select **Next**.
12. On the **Activate sensors** page, in the grid, select the sensor that you added, and then select **Activate**. For each activated sensor in the grid, a check mark appears in the **Active** column.
13. Select **Finish**.

Work with the production delays scenario

View production delay data on the Resource status page

On the **Resource status** page, supervisors can monitor a timeline of signals that are received from the sensors that are mapped to each machine resource. Follow these steps to configure the timeline.

1. Go to **Production control** > **Manufacturing execution** > **Resource status**.
2. In the **Configure** dialog box, set the following fields:

    - **Resource** – Select the resources that you want to monitor. (If you're working with the demo data, select *3118*.)

- **Time series 1** – Select the record (metric key) that has the following format for its name: *ProductionJobDelayed:ActualQuantity:<JobId>*
- **Display name** – Enter *Parts out signal*.

IoT Intelligence now replaced by Sensor Data Intelligence

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The IoT Intelligence feature has been updated to version 2.0 and, at the same time, renamed to *Sensor Data Intelligence*. The new version is currently available as a preview feature for Supply Chain Management version 10.0.30 or later.

Sensor Data Intelligence introduces a new deployment model where the required Azure components are deployed on your own Azure subscription rather than being managed by Microsoft. This new model enhances your ability to customize the feature and to integrate it with third-party systems. The new version also introduces support for two new internet of things (IoT) scenarios for Asset management.

Because of these upcoming changes, Microsoft recommends against starting any new projects based on the existing IoT Intelligence feature. If you are interested in adding IoT capabilities to your system, we recommend that you get started by working with the preview version of Sensor Data Intelligence instead. For more information about Sensor Data Intelligence and how to work with it, see the Sensor Data Intelligence home page.

At its core, master planning helps you determine and balance the future need for raw materials and capacity to meet your goals. Master planning assesses the following questions:

- What raw materials and capacities are currently available?
- What raw materials and capacities are required to complete production? For example, what must be manufactured, purchased, transferred, or set aside as safety stock before you can complete production.

Master planning uses this information to calculate the requirements and generate planned orders.

The three main planning processes are:

- **Master planning** - The master plan calculates net requirements. It's based on actual current orders and enables you to control inventory replenishment on a short-term, day-to-day basis. Another term to describe it is the *Net requirements plan*. Learn more in Master plans overview.
- **Forecast planning** - The forecast schedule calculates gross requirements. It's based on future projections (or forecasts), and enables you to conduct long-term planning of materials and capacity. Learn more in Demand forecasting overview.
- **Intercompany master planning** - The intercompany master plan calculates net requirements across legal entities. It connects demand and supply between companies not only for short term, but also for long-term, planned (not yet firmed) demand and supply. Learn more in Intercompany planning.

You can change the output of the plan.

Master scheduling plans typically involve the short term, which can be anywhere from one week to six months. The Master planning module determines the supply (materials) and capacity (resources) needs that will meet current demand (the net requirements). In most companies, this planning process extends to include the longest cumulative lead time among the products to be received.

> **Note**
>
> With Planning Optimization, all plans are regenerative, whereas the deprecated master planning engine had a concept of net change and regenerative planning run. Regenerative plans update all requirements, whereas net change plans only update the plan for items with new requirements that were added since the last scheduling run.

Get started with master planning

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Human Resources, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

Master planning in Supply Chain Management is provided by an external service called the Planning Optimization Add-in for Dynamics 365 Supply Chain Management. This article explains how to obtain and set up that service.

Availability

Planning Optimization is currently available in the following Azure geographies: United States, United States government cloud, Canada, Brazil, Europe, France, United Kingdom, Norway, Switzerland, Australia, Asia Pacific, Japan, United Arab Emirates, South Africa, and India. If you try to install the add-in from another geographic region, Microsoft Dynamics Lifecycle Services shows a message that this geographic isn't supported. For more information about Azure geographies and the related regions, see Azure geographies.

> **Note**
>
> Planning Optimization doesn't support on-premises deployments of Dynamics 365 Supply Chain Management.

Licensing

You can run master planning using your current Supply Chain Management licenses. Planning Optimization is the master planning engine for Supply Chain Management and is licensed as part of the standard licenses for the system. There are no extra costs associated with using Planning Optimization.

Install and enable Planning Optimization

To use Planning Optimization, make sure your system has all the prerequisites in place. Then, enable its configuration key and install the Planning Optimization Add-in for Dynamics 365 Supply Chain Management.

Prerequisites

Before you install the Planning Optimization Add-in, make sure the following prerequisites are in place:

- You must be running Supply Chain Management on a Lifecycle Services enabled high-availability environment, tier 2 or higher (not a OneBox environment), with Dynamics 365 Supply Chain Management version 10.0.23 or later. If you try to install the add-in on a OneBox environment, the installation won't complete and you'll need to cancel the installation.

  > **ⓘ Important**
  >
  > Planning Optimization can't be installed on a development (OneBox) environment. It requires a Lifecycle Services–enabled, high-availability environment, tier 2 or higher. If you need to troubleshoot installation issues, see **Troubleshoot Planning Optimization**.

- Your system must be set up for Power Platform integration. Learn more in Microsoft Power Platform integration with finance and operations apps.

- Your Microsoft Entra account must have a Supply Chain Management licensed assigned to it. As mentioned previously, you don't need an extra license for Planning Optimization, but you do need a Supply Chain Management license to install it. If you get an error message regarding licensing while installing the Planning Optimization Add-in, check your licenses as described in Assign licenses to users.

- You must sign in to your Power Platform environment using an account with administrator privileges and an access mode of *Read-Write*. If you get an error message regarding missing user permissions while installing the Planning Optimization Add-in, follow these steps:

    1. Go to the Power Platform admin center.
    2. Open the environment where you want to install the add-in.
    3. Go to **Settings** > **Users** and select your user account from the list to see its details.
    4. From your user details page, select the **Client Access License (CAL) information** link.
    5. On the **Client Access License (CAL) information** page, make sure that **Access Mode** is set to *Read-Write*.

    For more information about licenses and access modes for the Power Platform, see Create a Power Platform admin account.

Enable the Planning Optimization configuration key

To use Planning Optimization, you must enable its configuration key. follow these steps:

1. Put your system into maintenance mode, as described in Maintenance mode.
2. Go to **System administration** > **Setup** > **License configuration**.
3. On the **Configuration keys** tab, select the check box for **Planning Optimization**.
4. Turn off maintenance mode, as described in Maintenance mode.

Install the Planning Optimization Add-in

You must install the add-in from your Lifecycle Services project and then turn on the Planning Optimization functionality from the Supply Chain Management user interface.

To install the Planning Optimization Add-in:

1. Sign in to Lifecycle Services, and open the desired environment.
2. Go to **Full details**.
3. Scroll down to the **Environment add-ins** FastTab.
4. Select **Install a new add-in**.
5. Select **Planning Optimization**.
6. Follow the installation guide, and agree to the terms and conditions.
7. Select **Install**.
8. On the **Environment add-ins** FastTab, you should see that Planning Optimization is installing.

9. After a few minutes, **Installing** changes to **Installed** (you might need to refresh the page). When installed, you're ready to activate Planning Optimization in Dynamics 365 Supply Chain Management.

The main purpose of installing the Planning Optimization Add-in is to connect the service and the environment. Therefore, you must install the add-in separately on each environment where you use Planning Optimization, regardless of any code moved between the environments.

Turn on Planning Optimization for your environment

After you install the Planning Optimization Add-in for your environment, you must enable it in Supply Chain Management before you can start using it.

> **Note**
>
> You can continue to use the deprecated master planning engine for one or more previously created companies (until you're ready to migrate them) even while using Planning Optimization for the others. For instructions on how to set a company to use the deprecated master planning engine, see Continue to use deprecated master planning with existing companies.

To configure your system to use the Planning Optimization Add-in for master planning, follow these steps:

1. Sign in to Supply Chain Management.
2. Go to **Master planning** > **Setup** > **Planning Optimization parameters**.
3. Open the **General** tab.
4. Check the **Connection status**. It shows one of the values listed in the following table.

Expand table

Connection status	Description	Can Planning Optimization be used?
Connected	A connection is established between the Planning Optimization service and Supply Chain Management.	Yes

Connection status	Description	Can Planning Optimization be used?
Enabling connection	A request to turn on the connection to the Planning Optimization service is currently in progress.	No
Disconnected	There's no connection to the Planning Optimization service. You can turn on the connection from Lifecycle Services, as described earlier in this article.	No
Disabling connection	A request to turn off the connection to the Planning Optimization service is currently in progress.	No
Getting status	The system is waiting for status information from the Planning Optimization service.	No

5. If the **Connection status** is *Connected*, the **Use Planning Optimization** option is read-only and set to *Yes*. In most cases, Planning Optimization is now the only planning engine available for Supply Chain Management, so you can't turn it off. However, in some rare cases, Microsoft Support might make the deprecated planning available for one or more specific companies (learn more in Migration to Planning Optimization for master planning).

> **ⓘ Important**
>
> If existing planning batch jobs that were created for the deprecated master planning engine are triggered while the **Use Planning Optimization** option is set to *Yes*, those jobs will fail.

Master planning system architecture

> **Important**
>
> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

In Supply Chain Management, the Planning Optimization Add-in for Microsoft Dynamics 365 Supply Chain Management manages master planning. This add-in enables master planning calculation to occur outside Dynamics 365 Supply Chain Management and the related SQL database. The benefits of the Planning Optimization functionality include improved performance and minimal impact on the SQL database during master planning runs. You can run quick planning runs even during office hours, so that planners can immediately react to demand or parameter changes.

To use Planning Optimization, install the Planning Optimization Add-in from your project in Microsoft Dynamics Lifecycle Services and turn on the Planning Optimization functionality in Supply Chain Management. Learn more in Get started with master planning.

The following illustration shows the advantage of running Planning Optimization during office hours.

Performance

You can use Planning Optimization in scenarios that involve long-running master plans. It's specifically designed for very fast calculations that involve very large volumes of data. Because it's built as a hyper-scalable multitenant service, multiple instances can work together simultaneously to calculate the plan. Additionally, the planning service removes the load of master planning from your system and works with a data stream that minimizes the server load.

Planning Optimization can help you achieve the following goals:

- Improve planning performance through a shorter runtime.
- Reduce the impact on other processes during the master planning run.
- Do more frequent planning runs. (You're not limited to daily runs.)
- Be confident that future business growth won't overload the planning system.

Architecture and data flow

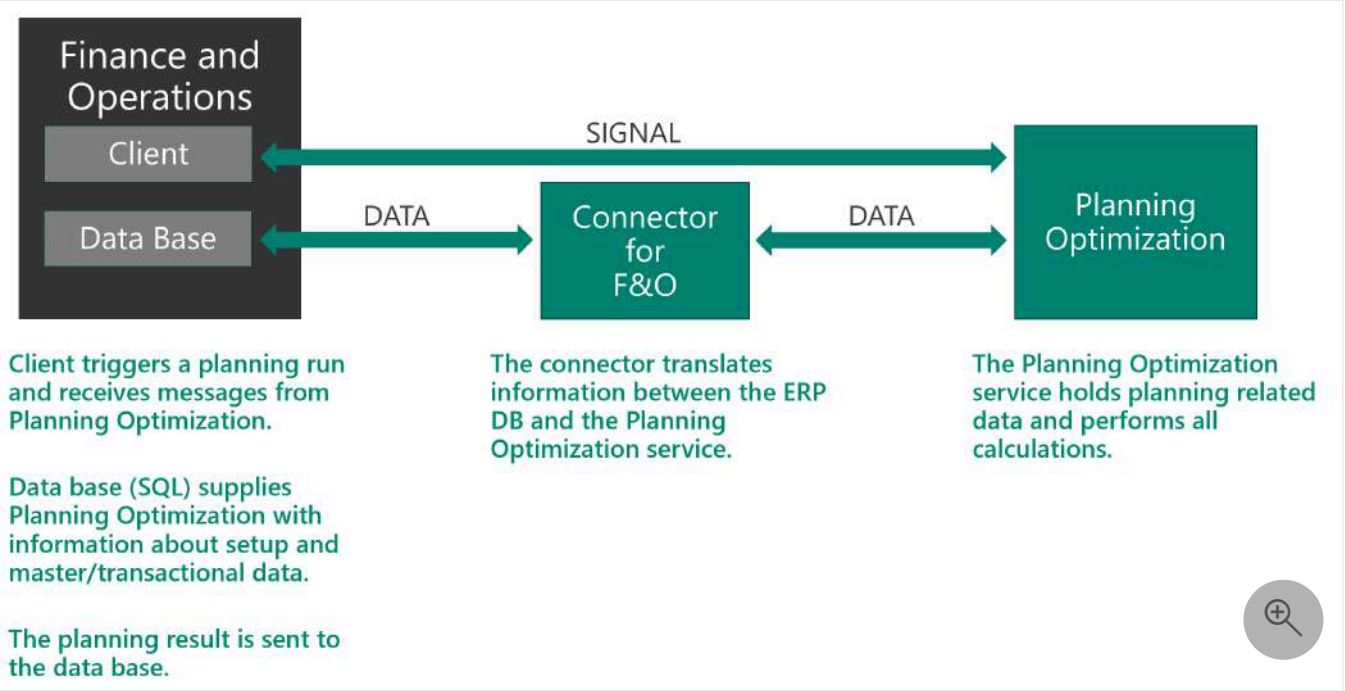
When you install the Planning Optimization Add-in from Lifecycle Services, you establish a secure connection to the Planning Optimization service. The service is located in the same data center country or region as the related Supply Chain Management instance. After you set up Planning Optimization, when you run master planning, Supply Chain Management sends master data and transactional data to the Planning Optimization service.

If you uninstall the Planning Optimization Add-in, the system removes all related data in the Planning Optimization service.

High-level data flow for regeneration runs

1. The Supply Chain Management client sends a signal to request a planning run from Planning Optimization.
2. Planning Optimization requests the required data through the integrated connector.
3. The SQL database sends the requested information about setup, master, and transactional data to Planning Optimization through the connector. The connector translates information between Supply Chain Management and the Planning Optimization service.
4. The Planning Optimization service holds planning-related data in memory and performs the required calculations.
5. The planning result is sent to the Supply Chain Management database through the connector. The results include information such as planned orders and pegging information. Planning Optimization sends a signal to Supply Chain Management to indicate that the planning run is complete. It also sends any relevant messages and warnings.

The following illustration shows the data flow.



Last updated on 03/25/2026

Planning Optimization release process and release history

Microsoft updates Planning Optimization monthly. However, based on business requirements, the product team occasionally releases other updates between the scheduled releases.

Each release is published to the individual regions where Planning Optimization is available. The process typically takes three days.

While Planning Optimization is updating, master planning might run a bit more slowly than usual.

All environments that use Planning Optimization automatically receive the latest release regardless of which version of Supply Chain Management you're using. Therefore, you don't need to backport updates. No user action is required: the service is automatically updated. However, the release process never automatically pushes breaking-change functionality to environments. By default, any changes that are considered breaking are turned off and must be explicitly turned on by using feature management. Therefore, those changes don't appear in environments until you choose to enable them.

Because notifications aren't shown when Planning Optimization is updated in your environment, you can review the release notes in the following table to determine when changes were released and what functionality they introduced. This table shows the changes that were released for Planning Optimization, whether those changes are associated with a feature from feature management, and the date of the release.

Expand table

Changes	Feature management details	Release dates
General performance, quality, and stability improvements. Customer reported bug fixes: • 1144004 – Planning Optimization is not correctly managing vendor calendars when calculating dates for planned purchase orders. • 1145533 – Planning optimization uses Sales Order Requested Ship Date instead of Requested Receipt Date to calculate Sellable Days.	No feature management required	August 18, 2026

Changes	Feature management details	Release dates
• 1146505 – A planned purchase order for service item is generated before a planned production order (FG) is approved, but no planned purchase order is regenerated after approval. • 1147129 – Planned batch order cannot be firmed after BOM explosion fails. • 1159839 – Planning Optimization fails to plan item during earliest replenishment rescan when dynamic positive days is enabled. • 1161762 – Scheduling incorrectly reports "Capacity could not be found" when overlapping slot fetches reload reservations.		
General performance, quality, and stability improvements. Customer reported bug fixes: • 1123148 – Planning results inconsistency in replenishment generation • 1126454 – The requirement date of the expired batch does not match the expiration date • 1133251 – Inconsistent standard formula consumption between BOM calculation and master planning due to midpoint rounding default difference • 1147342 – Transfer order lead time is calculated using source warehouse calendar	No feature management required	July 7, 2026
General performance, quality, and stability improvements. Customer reported bug fixes: • 1121678 – Planning Optimization incorrectly assigns expired supply to future demand despite best-before date limits • 1129635 – WRKCTRACTIVITYRESOURCEREQUIREMENT may cause errors during planning due to 'dat' as ResourceDataAreaId • 1134181 – FORCESEEK hint may select partner-extension index instead of Microsoft index, leading to SQL error 362 after partner index changes	No feature management required	June 1, 2026
General performance, quality, and stability improvements. Customer reported bug fixes:	No feature management required	April 28, 2026

Changes	Feature management details	Release dates
• 1097597 – Planning Optimization does not assign BOM/route to planned production orders when pegged requirement date equals BOM/route To date • 1107603 – The calendars considered by the planned transfer order are inconsistent when calculating the reorder margin • 1119156 – Cleanup process may accidentally remove current records, preventing post-planning actions from running • 1122974 – Data analyzer does not group finished goods and raw materials together when raw materials is set as a configuration group		
General performance, quality, and stability improvements. Customer reported bug fixes: • 1084691 – Planning Optimization incorrect derived requirements for predefined variant • 1084495 – Property value not transferred in Planning Optimization for planned batch orders • 1087477 – Production start dates perpetually push out when using vendor BOM lines, finite capacity, and active change management	No feature management required	January 19, 2026
General performance, quality, and stability improvements. Customer reported bug fixes: • 1027305 – Strict safety stock pegging and batch expiry are not supported by Planning Optimization • 1050426 – Infinite scheduling with primary operation having fractional resource load and 24h calendar resource availability • 987667 – Production start dates perpetually push out when using vendor BOM lines, finite capacity, and active change management • 1037977 – Incorrect requirement date for intercompany demand from demand forecast with transport days on net requirements form • 1068793 – Route Number Not Used in Planning Optimization for Quotations • 1030103 – Planning service is loading capacity reservation for resources that are not finite capacity leading to the performance issue	No feature management required	December 8, 2025

Changes	Feature management details	Release dates
• 1067693 – Optimization planning generates an unnecessary gap between operations for planned production order when one of the materials is linked with the end of the operation • 1028513 – Unnecessary delay given when material is consumed at operation end and next operation starts at non-working day • 1028853 – Issue with the order date in the planned purchase order related to the configuration of purchase transport days. Start date and end dates are disregarding working days and order day is pushed forward • 1063642 – Demand forecast is reduced with transfer issues • 1072379 – In PLOP, there's double reduction in the forecast due to the container reference • 1076273 – Duplicate replenishment order for purchase requisition over multiple planning runs with partial pegging		
General performance, quality and stability improvements. Internal infrastructure changes. Customer reported bug fixes: • 1003359 - Planning Optimization issue with minimum keys • 1019384 - Reference of quarantine order show as "inventory journal" in net requirement when using Planning Optimization • 1055013 - Unhandled error in min/max scenario with short positive days and demand in the future • 1050881 - Inconsistent BOM formula consumption between BOM calculation and master planning • 1020039 - We have identified an issue with how quantities are classified as "Qualified demand" in the net flow calculation for DDMRP-managed parts • 1033476 - Planned transport days are not properly considered when evaluating working calendars marked as "Closed for pickup" in Planning Optimization	No feature management required	October 6, 2025
General performance, quality, and stability improvements. Customer reported bug fixes: • 1015507 – Incorrect raw material estimation in planned batch orders (PLOP) when using yield and rounding	No feature management required	August 21, 2025

Changes	Feature management details	Release dates
• 1020065 – Forecast lines with different required BOM/route for the same date are grouped together • 976755 – Step consumption does not support negative BOM quantity		
General performance, quality, and stability improvements. Customer reported bug fixes: • 987667 – Production start dates perpetually push out when using vendor BOM lines, finite capacity, and active change management • 1029247 – Incorrect start date for planned production order • 987448 – Operation scheduling with overlap and calendar efficiency can lead to error "Internal error in scheduling engine" • 1028099 – Operation scheduling fails with an exception error	No feature management required	July 30, 2025
General performance, quality and stability improvements. Internal infrastructure changes. Customer reported bug fixes: • 1009010 – Planning Optimization is inconsistently considering on-hand that is due to expire • 986770 – Route scrap not considered when firming planned production orders • 977625 – Job scheduling is failing with error "Production order could not be scheduled. Not enough capacity could be found" when route contains two operations with hard links branching into the next operation • 987448 – Operation scheduling with overlap and calendar efficiency can lead to error "Internal error in scheduling engine" • 1034160 – When CX is running Planning Optimization, the system shows the error message "Planning Optimization client retry count exceeded" • 1028099 – Operation scheduling fails with an exception error	No feature management required	July 14, 2025
General performance, quality and stability improvements. Internal infrastructure changes.	No feature management required	May 15, 2025

Changes	Feature management details	Release dates
Customer reported bug fixes: • 987836 – Finished good scheduling to start at 12:00AM prior to an approved planned production order completion time that is being consumed • 976713 – Planning Optimization generates planned orders for inventory which has been blocked • 991562 – Formula line with negative quantity is disappearing from derived requirements form on planned orders upon running planning for different item which contains the same formula line item • 991826 – Lead time does not update to planned order by running Planning Optimization • 968759 – Ship calendar of vendor and lead time is not respected on purchase order		
General performance-, quality- and stability improvements. Customer reported bug fixes: • 1001064 – Planned supply order is considering demand beyond the coverage period • 1003359 – Planning Optimization issue with minimum keys • 1004623 – When disabling strict safety stock feature and then enabling it but not using it, the number of planned orders that have condition "Cancel" is different • 988317 – Forecast reduction not correct when order date is on the first of the reduction period and the forecast is later • 1012963 – Allow batch mixing if no `reqItemTable` record is specified is not considered • 978372 – Forecast is reduced with counting transactions when reduce forecast by Orders	No feature management required	April 11, 2025
General performance, quality, and stability improvements. New feature added: Planning by site/warehouse. This feature will be enabled in version 10.0.44 Customer reported bug fixes: • 974508 – The form "Item requirement statistics" shows wrong period when planned orders are created from Planning Optimization • 976713 – Planning Optimization generates planned orders for inventory which has been blocked	No feature management required	February 26, 2025

Changes	Feature management details	Release dates
• 972843 – Planning generates excess of demand by ignoring available on-hand in some cases of shelf life		
General performance, quality, and stability improvements. Customer reported bug fixes: • 946720 – Strict safety stock pegging feature ignores pegging priority (not chronologically) and negative days (planned purchase orders proposed before firmed purchase orders)	No feature management required	February 12, 2025
General performance, quality, and stability improvements. Support for step consumption Support for catch weight quantity calculations Customer reported bug fixes: • 942711 – Identical demands with required BOM are not grouped according to period coverage • 969100 – [Planning Optimization] Different between pegging quantity and requirement quantity in planned order • 943781 – Derived requirements are not coverage calculated if the planned batch order is inside the freezing time fence	Support for step consumption requires the *Support for material step consumption for Planning Optimization* feature to be enabled in feature management. Support for catch weight quantity calculations requires the *Calculate catch weight quantities for catch weight enabled products in Planning Optimization* feature to be enabled in feature management.	January 13, 2025
General performance, quality, and stability improvements. New features for Planning Optimization: • Support for dimension-based product configuration • Support for reducing demand and supply forecast in the current period by invoiced and delivered orders using "Transactions reduction key" Customer reported bug fixes: • 945437 – Planning Optimization doesn't update the confirmed delivery and receipt date for sales order lines with CTP for Planning Optimization status = Not ready and Delivery date control = CTP for Planning Optimization • 942038 – Excessive planned orders created for expired batch	No feature management required	November 6, 2024

Changes	Feature management details	Release dates
• 962570 – When firming a planned batch order with co-products, error about maximum decimals for stock keeping unit		
General performance, quality, and stability improvements. Customer reported bug fixes included: • 954429 – When running Planning Optimization, unit conversion is not working when conversion is set up at product variant level • 942716 – Job scheduling throws `NullReferenceException` when route group of secondary operation has job type not activated on primary operation • 867912 – Circularity detected for transfer with receipt pegged against shipment • 950963 – Expired batch inventory considered available and pegged despite shelf life setting • 934157 – Forecast plan time fence overrides coverage time fence • 936056 – Planning Optimization fails to meet demand in scenario with planning item, co-product, formula item, and forecast • 947035 – Planned production order route doesn't show link types	No feature management required	September 23, 2024
General performance, quality, and stability improvements. Customer reported bug fixes included: • 942649 – Scheduling engine returns `InternalError` for overlap and finite capacity cases • 947020 – Planned production order may not include BOM line with a validTo date • 942726 – Period coverage can give wrong results when different time zones are used • 942275 – Required BOM/route not passed through transfer orders when using period grouping for the transfer warehouse • 951751 – Coverage by inventory status leads to unpredictable scheduling/planning results • 854350 – Transfer requirement does not consider sellable days from demand sales order or forecast	No feature management required	August 22, 2024

Changes	Feature management details	Release dates
General performance, quality, and stability improvements. Customer bugs fixed: • 944132 – Inefficient finite capacity scheduling during conflict retry • 906505 – Wrong batch expiration date on on-hand inventory when legal entity time zone is changed • 896583 – Quarantine warehouse item is included in on-hand calculation in net requirements • 906576 – Supplier requested and confirmed shipment dates feature does not consider ship calendar set on vendor • Uptake of scheduling engine improvements made for production scheduling: • 883492 – Scheduling optimization timeout and many possible resources can cause misalignment of parallel jobs • 879271 – If delays occur in production orders in certain scenarios, scheduling is not done correctly	No feature management required	July 2, 2024
General performance, quality, and stability improvements. Customer bugs fixed: • 842762 – Planning Optimization does not consider default issue location from warehouse setup • 859663 – Duplicate planned orders created if the plan include purchase requisition but not inventory transactions • 922016 – Resolving location of parent transaction is not respecting active storage dimensions	No feature management required	June 11, 2024
General performance, quality, and stability improvements. Customer bugs fixed: • 842762 – Planning Optimization does not consider default issue location from warehouse setup • 859663 – Duplicate planned orders created if the plan include purchase requisition but not inventory transactions • 922016 – Resolving location of parent transaction is not respecting active storage dimensions	No feature management required	May 14, 2024
General performance, quality, and stability improvements.	No feature management required	March 15–20, 2024

Changes	Feature management details	Release dates
General performance, quality, and stability improvements.	No feature management required	February 10–15, 2024
General performance, quality, and stability improvements.	No feature management required	January 19–25, 2024
Planning items support. General performance, quality, and stability improvements.	No feature management required	December 10–15, 2023
General performance, quality, and stability improvements.	No feature management required	October 12–19, 2023
Positive days support. General performance, quality, and stability improvements.	No feature management required	October 2–6, 2023
General performance, quality, and stability improvements.	No feature management required	September 20–22, 2023
General performance, quality, and stability improvements.	No feature management required	August 15–20, 2023
Custom inventory dimensions. Transport days. General performance, quality, and stability improvements.	No feature management required	July 3–7, 2023
General performance, quality, and stability improvements.	No feature management required	June 15–20, 2023
BOM lines with rounding or multiple setups. BOM/formula lines with negative quantity. General performance, quality, and stability improvements.	No feature management required	May 22–31, 2023
General performance, quality, and stability improvements.	No feature management required	May 4–8, 2023
Process manufacturing support for Planning Optimization. This includes support for creating planned batch orders for formula products, co-products, and by-products, formula measurement, and formula versions with yield, but doesn't include support for planning items or item substitutions (plan groups). General performance, quality, and stability improvements.	No feature management required	April 17–21, 2023

Changes	Feature management details	Release dates
General performance, quality, and stability improvements.	No feature management required	March 27–30, 2023
General performance, quality, and stability improvements.	No feature management required	March 13–17, 2023
General performance, quality, and stability improvements.	No feature management required	February 15–24, 2023
Bills of material with constant scrap or variable scrap defined Demand with specific BOM or route requirements defined Calculated delays: Add the calculated delay to the requirement date settings on master plans	No feature management required	January 10–15, 2023
Batch disposition codes Include on-hand inventory and inventory transaction parameters on master plans Released production orders that aren't started, where scheduled start date is earlier than today General performance, quality, and stability improvements	No feature management required	October 10–14, 2022
Resource scheduling with finite capacity General performance, quality, and stability improvements	No feature management required	September 19–23, 2022
Master planning for products with limited shelf life General performance, quality, and stability improvements	No feature management required	August 29 to September 3, 2022
Centralized calendar maintenance Suggestions to optimize existing supply Support for subcontracting General performance, quality, and stability improvements	No feature management required	March 7–11, 2022
Planning priority support for production orders	Available with version 10.0.25 as part of the feature named *Priority driven MRP support for Planning Optimization*.	November 12–18, 2021

Changes	Feature management details	Release dates
General performance, quality, and stability improvements	No feature management required	November 12–18, 2021
Support for process time calculation formulas, production route with overlap, and production operation number on requirement transactions Enhanced error messages for production scheduling related to timeout, capacity couldn't be found, and cyclic route Improved consistency when calculating receipt dates and issue dates on both planned orders and firmed orders General performance, quality, and stability improvements	No feature management required as of Supply Chain Management version 10.0.43.	October 22–27, 2021
Support for considering scrap percentage in processing time calculation Support for operation number and materials usage during scheduling	No feature management required as of Supply Chain Management version 10.0.43.	October 5–7, 2021
Support for production route job types: **Queue before**, **Queue after**, and **Transport time** General performance, quality, and stability improvements	No feature management required as of Supply Chain Management version 10.0.43.	September 25–30, 2021
Support for master plans with **Scheduling method** set to *Operations scheduling* On the **Route groups** page, respect settings for the **Activation**, **Working time**, and **Capacity** check boxes for rows with a **Route/job type** of *Setup* or *Process* General performance, quality, and stability improvements	No feature management required as of Supply Chain Management version 10.0.43.	September 9–17, 2021
General performance, quality, and stability improvements	No feature management required	August 25–30, 2021
Added **Lead time** field to planned orders. General performance, quality, and stability improvements.	No feature management required	August 12–17, 2021
Added resource type requirements for infinite capacity scheduling Improved resource efficiency and calendar efficiency for infinite capacity scheduling Learn more in Scheduling with infinite capacity	No feature management required as of Supply Chain Management version 10.0.43.	July 6–12, 2021

Changes	Feature management details	Release dates
General quality improvements	No feature management required	July 6–12, 2021

The resource scheduling engine schedules routes for planned and released production orders.

The job shop scheduling problem is an extremely complex combinatorial problem where solution time grows exponentially with the number of decision variables. Customers often set up production routes and related data in ways that create scheduling problems that aren't solvable in reasonable time, even on modern hardware. This article explains the scheduling engine and how a specific setup influences performance.

Improve scheduling performance by reducing the complexity of the problem the engine solves. Some of the main factors that can affect performance include:

- Routes with many operations
- Routes with parallel operations
- Operations with more than one resource
- Operations with many applicable resources
- Use of hard links
- Use of finite capacity
- Number of different calendars used
- Number of working time slots per day in the calendar
- Total duration of the route
- Running multiple scheduling engines in parallel

Overview of basic scheduling flow

To understand how a given setup affects performance, you need to know how the process flows inside the engine and in the X++ code that surrounds it.

The basic process of scheduling an order consists of three main steps:

- **Loading data** – X++ data models transform into the engine's internal data model as jobs and constraints.
- **Scheduling** – The engine processes the given model and constraints to generate a result. It requests working time information and existing capacity reservations from X++ as needed.
- **Save data** – X++ code processes the engine result, in the form of job capacity reservation slots, to save capacity reservations and update the start and end times of the jobs, operation, or order.

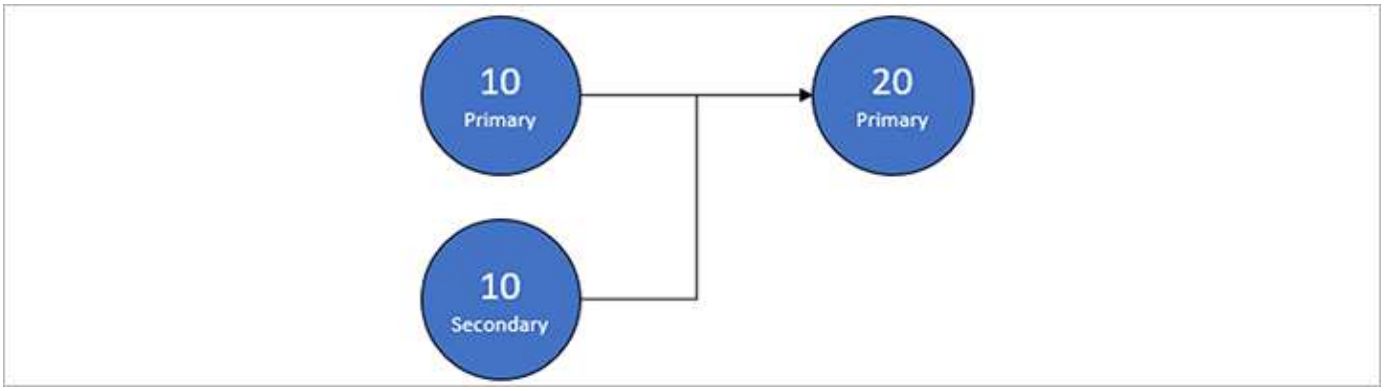
Load data into the engine

The scheduling engine uses a more abstract data model than the Supply Chain Management database because it's a generic engine that handles multiple data sources. The concepts of route, secondary operations, and run time are translated into the generic job and constraint model that the engine exposes. The logic for building the model includes significant business logic and varies depending on the source data. The responsible X++ class is `WrkCtrScheduler`, which includes derived classes for planned production orders, released production orders, and project forecasts.

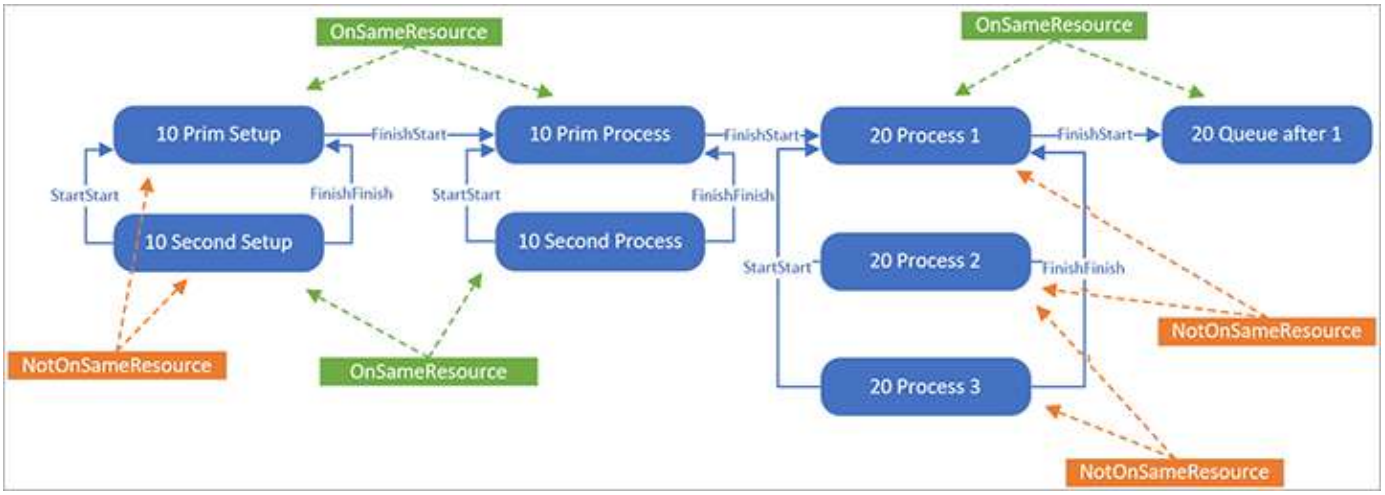
For example, consider a route shown in the following table and image, which is relatively simple.

Expand table

Oper. No.	Priority	Setup time	Run time	Queue time after	Quantity of resources	Next
10	Primary	1.00	2.00		1	20
10	Secondary 1				1	20
20	Primary		3.00	1.00	3	0



When you send this route to the engine, it splits the route into eight jobs, as shown in the following illustration (select the image to enlarge it).



The standard link between two jobs is `FinishStart`, which means the end time of one job must occur before the start time of another. The setup must be done by the same resource that later handles the process, so there are `OnSameResource` constraints between them. Between the jobs for the primary and secondary operation for 10, there are `StartStart` and `FinishFinish` links, which mean the jobs must both start and end at the same time. Additionally, there are `NotOnSameResource` constraints, which prevent the same resource from being used for both primary and secondary operations.

For operation 20, where the quantity of resources is set to 3, the process job is split into three distinct jobs where all the jobs must run at the exact same time. In this case, the route group is set up to not reserve capacity for queue after times, which is why there's only a single job for the queue after.

The scheduling engine understands only the concepts of jobs and doesn't recognize operations. This limitation means that during operation scheduling, the system splits operations into jobs, although these jobs aren't persisted in the database.

For each job, you define what the job capacity requirement is (the number of seconds required). Depending on how the resource requirements are defined, you might also send, for each job, a list of all the potential applicable resources that the job could run on and what the capacity requirement is for that specific resource. Although you send the list of applicable resources when building the model, the engine ensures the resource assignment stays valid for the entire job duration.

Scheduling engine internals

Scheduling engine interface

To understand how the engine works internally, review the functionality it exposes externally. In X++, the main interface is `WrkCtrSchedulerEngineInterface`. It has the methods described in the following subsections.

General engine

Expand table

Method	Purpose
`run`	Schedules all loaded jobs and returns the error code.
`getJobSchedulingSequenceResult`	Gets the scheduling result and the first error job for the sequence identified by a specific job.
`validateJobCapacityReservations`	Validates the capacity reservations for all the jobs stored by the engine.
`setReservationsTimeStamp`	Sends a timestamp to the engine set on all new capacity reservations for the scheduled jobs in the cache of the engine.
`addPropertyToGroupAggregation`	Adds a property prefix to the set of properties used when capacity is aggregated.
`addResource`	Adds a resource to the scheduling engine resource pool.
`addResourceGroup`	Adds a resource group to the scheduling engine resource group pool.
`addResourceGroupMembership`	Adds a resource as a member to a resource group.
`addOptimizationGoal`	Adds a scheduling optimization goal (duration or priority).

Individual jobs

Expand table

Method	Purpose
`addJobInfo`	Adds a job information record that informs the engine about a job that should be scheduled.
`addConstraintJobEndsAt`	Adds a constraint that a job should end at a specified date and time.
`addConstraintJobStartsAt`	Adds a constraint that a job should start at a specified date and time.
`addConstraintMaxJobDays`	Defines the constraint that a job can span over a specified maximal number of days.
`addConstraintResourceRequirement`	Adds the constraint that the job must be scheduled on a specific resource.

Method	Purpose
`addJobBindPriority`	Adds a job bind priority for a (job, constraint level) pair. A higher priority value means the job variables are bound earlier. The job is processed before jobs with lower priority value in the same sequence.
`addJobCapacity`	Adds capacity load information for a job (like the required job runtime) independent on which resource the job runs on.
`addJobResourceCapacity`	Adds a resource to the set of resources that can be used to perform a job, and states the capacity required when running on that resource.
`addJobGoal`	Adds job goal information for a specific constraint level (earliest end time or latest start time).
`addJobResourcePriority`	Adds the priority to use when a job is scheduled on a resource.
`addJobResourceRuntime`	Specifies a job time that is dependent of the resource the job is scheduled on.
`addJobRuntime`	Specifies a job time that is independent of the resource on which the job is scheduled.
`scheduleJobOnResourceGroup`	Marks a job for scheduling on the resource group level.
`setJobResourcePreemptionAllowed`	Sets whether preemption is allowed for a job on a resource (if engine is allowed to schedule the job in noncontiguous capacity slots).
`setRequiredNumberOfResources`	Sets the number of resources required to schedule a job (only for operations scheduling).

Constraints between jobs

Expand table

Method	Purpose
`addJobLink`	Adds a link (such as finish>start) between two jobs.
`addConstraintEndsDelayed`	Defines the constraint that a job can't end before another jobs end plus some delay time.
`addConstraintJobListWorkingTimeIntersect`	Adds a constraint that the capacity slots reserved for the jobs must be on the intersecting working times for the two resources used by the jobs.
`addConstraintJobOverlap`	Adds a constraint that defines how jobs are sequenced when a given quantity of an item can be moved between two resources while the first resource is still not finished processing, so that the second resource can start processing.

Method	Purpose
`addConstraintNotOnSameResource`	Adds a constraint that two jobs shouldn't be scheduled on the same resource.
`addConstraintOnSameResource`	Adds a constraint that two jobs must be using the same resource.
`addJobSameReservations`	Adds a constraint that a job must end up having capacity reservations for the same time slots as the primary job.
`setPrimaryParallelJob`	Adds information about what job is the primary job in a set of parallel jobs.

Solver

The engine is a specialized constraint solver with custom heuristics. The solver is based on two main elements: variables and constraints.

Variable

A variable represents a domain of possible values. The scheduling engine has two types of variables:

- **DateTime variable** - Has a domain of all dates and times. You can restrict the domain by moving the lower and upper bounds for the time of the variable closer to each other.
- **Resource variable** - Has a domain of applicable resources. You can restrict the domain by eliminating resources from the list.

Constraint

A constraint acts on variables by restricting their domains. It also depends on variables, so it gets activated when variables change. The process of "constraint propagation" is when a constraint performs its main function and reports back to the main logic if successful.

A variable is considered bound when it can't be restricted further. For a DateTime variable, this condition means that the upper and lower bounds are the same. For the Resource variable, it means that it has only a single applicable resource. When all variables are bound, a solution is found.

Constraint levels

When scheduling is part of the material requirements planning (MRP) coverage phase, the system schedules orders backward from the requirement date. However, if the system can't find a schedule that starts today or later and ends before the requirement date, it changes the scheduling direction to forward from today.

The system organizes the constraints in levels to handle this main business rule. If the system doesn't find a solution when using the constraints on the highest level, it drops all the constraints on that level and tries the lower level. In practice, this process means that for backward scheduling, the model contains a level 1 with job goals of latest start time given a maximum end time constraint (the requirement date), and a level 0 with job goals of earliest end time and given a minimum start time constraint of today.

Algorithm

The main steps of the engine algorithm are:

1. Find sequences (job chains) that can be solved separately.
2. Try to find an initial solution for the sequence at the highest constraint level.
    a. Sort the jobs in the sequence based on job goal and priorities, so the system can find a start job.
    b. Loop through the jobs in the following sequence:
        i. Find all constraints that need to be propagated and run propagation.
        ii. If all variables for the job are bound, then a solution for that job is found.
        iii. If one of the variables can't be bound without violating the constraints, roll back the variable binding, try a different value in the domain (for resource variable), and rerun the constraint propagation.
3. If no solution is found, remove all constraints on the current constraint level, lower the constraint level (if any lower levels are available), and retry solution search with the new set of constraint.
4. If a feasible solution is found, start the optimization phase, which tries to find a better solution until the optimization timeout is reached or all resource combinations are exhausted.

The constraint solver doesn't account for the specifics of the scheduling algorithm. The "magic" happens in the definition and combination of the various constraints.

Determining working times

A large part of the (internal) constraints in the engine controls the working time and capacity of a resource. Essentially, the task is to traverse the working time slots for a resource from a given point in a given direction, and find a long enough interval in which the job's required capacity (time) can fit.

To do this, the engine needs to know the working times of a resource. Unlike the main model data, the working times are *lazy loaded*, which means that they're loaded into the engine as needed. The reason for this approach is that there are often working times in Supply Chain Management for a calendar for a very long period and typically many calendars exist so the data would be quite large to preload.

The engine requests calendar information in chunks by invoking the X++ class method `WrkCtrSchedulingInteropDataProvider.getWorkingTimes`. The request is for a specific calendar ID in a specific time interval. Depending on the state of the server cache in Supply Chain Management, each of these requests could end up in several database calls, which takes a long time (relative to the pure computational time). Also, if the calendar contains very elaborate working time definitions with many working time intervals per day, this complexity adds to the time the loading takes.

When the scheduling engine loads the working-time data, it retains this data in its internal cache for the specific calendar. This retention means that if any other jobs or resources use the same calendar, the next lookups can be performed quickly from memory. One common cause of bad performance is if a separate calendar ID is used for each resource, because data is then requested for each calendar, even though the content of the calendars might be the same.

Finite capacity

When you use finite capacity, the system splits and reduces the working time slots from the calendar based on the existing capacity reservations. The same `WrkCtrSchedulingInteropDataProvider` class fetches these reservations along with the calendars, but it uses the `getCapacityReservations` method. When scheduling during master planning, the system considers the reservations for the specific master plan. If you enable the setting on the **Master planning parameters** page, the system also includes reservations from firmed production orders. Similarly, when scheduling a production order, you can choose to include reservations from existing planned orders, although this sequence isn't as common as the other way around.

Scheduling takes longer when you use finite capacity for several reasons:

- Fetching the capacity information from the database is a slow operation. The server-side caching of capacity information is typically not as good as for working times because they

aren't shared among resources like calendars typically are.
- The number of working time slots to traverse increases due to the splits. The system typically needs to investigate slots for a longer time period before it can find a solution.
- After scheduling is complete, the system must check for conflicting reservations (see the "Running scheduling engines in parallel" section for details).

Examining the resource combinations

If the job sequence only contains the standard `FinishStart` links, meaning it forms a simple chain without any branches, the system can achieve an optimal result (seen from the single order, not across orders) by finding the best solution for the first job and then moving on to find the best solution for the next job. The best solution for a job is to find the resource that can get the from and to date of the job closest to the job goal (in forward scheduling this means getting the end date of the job as early as possible) while still respecting the constraints.

When there are parallel jobs, finding a solution might involve examining different combinations of resources. The number of possible resource combinations is the product of the number of applicable resources for the connected parallel jobs. Especially when scheduling an order backwards from a requirement date, it can take quite a while for the logic to realize that there's no solution to the problem that will make the parallel jobs fit before today's date. The logic needs to check all the combinations because there could be some resources that have a higher efficiency or a different calendar that might give a result. This condition means that if you don't set a timeout limit, the process runs for a long time before changing the direction to forward.

This combinatorial logic also means that adding more applicable resources might make the engine run slower. If performance problems occur when you have parallel operations and scheduling with infinite capacity, you can partly fix the problem by having the route designer take a decision on which resource should be used and then assign the resource directly on the operation (because the engine in most cases always ends up picking the same resource, so the end result is the same).

Hard links

When you set the link type between two jobs to hard, you ensure that there's no time gap between the finish of one job and the start of the next one. This condition is useful in scenarios where metal is heated in one job and processed in the next, and cooling between jobs isn't desirable.

By using standard soft links and forward scheduling, if the route forms a simple chain without any branches, you can achieve a result by finding a solution for the first job that satisfies its own constraints and then moving on through the chain propagating the end time from the previous job to the next job. If the current job can't find any capacity, the system moves the start time out further, without any consequence for the previous jobs. This action potentially creates gaps between the jobs. However, by using hard links (especially in connection with finite capacity) for the same scenario, the fact that one job later in the chain can't find capacity, means that all previous scheduled jobs must be "dragged" along one by one and thereby rescheduled several times. Especially in scenarios with high load for multiple resources, the hard links can cause a chain reaction where the jobs affect each other and several iterations must be performed before the result stabilizes into a feasible schedule.

Running scheduling engines in parallel

When you perform scheduling as part of a master planning run where you use helpers, each of the master planning helper threads can also pick up production order scheduling tasks. This approach means that multiple scheduling engines can run at the same time. While multithreading provides a significant performance benefit, it also introduces some functional downsides for scheduling.

In MRP, the system schedules all production orders for a given bill of materials (BOM) level in requirement date sequence. This sequence means that the system schedules those orders with the earliest requirement date first, so they have the highest chance of getting the available resource capacity. However, when multiple engines pick from the list of unscheduled orders, the sequence isn't ensured because one engine might complete faster than the other.

When you schedule with finite capacity and multiple engine instances, a race condition can occur if you try to schedule orders that use the same resources at the same time. The **Scheduling conflicts** field on the master plans history page records the number of race conditions. The conflict resolution logic follows these steps:

1. Schedule an order (lock-free) and get capacity reservations.
2. Take the lock.
3. Check if newer capacity reservations exist for the scheduled resources in the time span.

    - If no, write the capacity and release the lock.
    - If yes, release the lock and reschedule the order from the beginning.

When scheduling with multiple engine instances, the result isn't fully deterministic because it depends on the exact timing of each thread.

Operation scheduling performance

Operation scheduling, also known as rough-cut capacity planning, can be harder to solve from an engine standpoint if finite capacity is used because more data is needed to determine feasibility.

The capacity of a resource group depends on which and how many resources are members of the resource group. A resource group itself doesn't have any capacity—only when resources are members of the group does it have capacity. Because the resource group membership can vary over time, capacity must be evaluated per day.

In operations scheduling, the resource group's calendar is used to determine the start and end times for each operation. This calendar places a limit on how much time you can schedule operations for one operation on one day in one resource group. Unlike the calendar for specific resources, the efficiency data of the resource group's calendar is ignored because it only denotes opening hours, not actual capacity.

For example, if the working time for a resource group on one specific date is from 8:00 to 16:00, one operation can't put more load on the resource group than what can fit into 8 hours, no matter how much capacity the resource group has available in total on that day. However, the available capacity can limit the load further.

Job scheduling load on all resources in the resource group for a given day is considered when calculating the available capacity for that day. For each date, the calculation is:

Available resource group capacity = Capacity for resources in the group based on their calendar − Job scheduled load on the resources in the group − Operations scheduled load on the resources in the group − Operations scheduled load on the resource group

On the **Resource requirements** tab on the route operation, you can specify the resource requirements using either a specific resource (in which case the operation is scheduled using that resource), a resource group, a resource type, or one or more capabilities, skill, course, or certificate. Using all these options provides flexibility in route design but complicates scheduling for the engine because capacity must be accounted for per 'property' (an abstract name used in the engine for capability, skills, and so on).

The resource group's capacity for a capability is the sum of the capacity for all resources in the resource group that have the capability in question. If a resource in the group has a capability,

the engine considers it no matter what level of the capacity is required.

In operations scheduling, the available capacity for a certain capability for a resource group is reduced when it's loaded with an operation that requires the capability in question. If the operation requires more than one capability, the capacity is reduced for all required capabilities.

For each date, the required calculation is:

Available capacity for a capability = Capacity for the capability − Job scheduled load on the resources with the specific capability, included in the resource group − Operations scheduled load on the resources with the specific capability, included in the resource group − Operations scheduled load on the resource group itself that require the specific capability

If a specific resource has a load, the engine considers it when calculating the resource group's available capacity per capability because the load reduces its contribution to the group's capacity, regardless of whether the load is for that specific capability. If there's load on the resource group level, the engine considers it in the calculation of the resource group's available capacity per capability only if the load is from an operation that requires the specific capability.

This logic applies to each type of property, so using operations scheduling with finite capacity requires loading a significant amount of data.

Improve MRP performance

The following tech conference video provides tips to improve master planning performance when you use MRP with the deprecated master planning engine: Help! MRP is slow!

Viewing scheduling engine input and output

To get specific details about the input and output of the scheduling process, enable logging by going to **Organization administration** > **Setup** > **Scheduling** > **Scheduling tracing cockpit**.

On this page, select **Enable logging** on the Action Pane, and then run the scheduling for the production order. When complete, return to the **Scheduling tracing cockpit** page and select **Disable logging** on the Action Pane. Refresh the page, and a new line appears in the grid. Select the new line, and then select **Download** on the Action Pane. This action gives you a .zip compressed folder containing the following files:

- **Log.txt** – This log file describes the steps the engine goes through. It's detailed and can be overwhelming, but when you experiment with the route setup to resolve performance

problems, look for the time difference between the first and last line. This difference shows the exact time the scheduler spent.

- **XmlModel.xml** – This file contains the model that is built in X++ and that the engine operates on. The `JobId` used in the file correlates to the `RecId` from the source table containing the jobs (`ReqRouteJob` or `ProdRouteJob`). In this file, check that the dates in `ConstraintJobStartsAt` and `ConstraintJobEndsAt` are as expected, the `JobGoal` property is set correctly, and the jobs are related through the `JobLink` constraints.
- **XmlSlots.xml** – This file contains all the working times and capacity reservations that the engine requests. The calendar working times and reservations are only requested by the engine for the time periods where it tries to place the jobs (and an extra buffer), so if the file contains times very far in the future, it might be an indication of a problem with the setup. The `ResourceProperty` nodes display the resource group and capabilities associated with each resource, along with the relevant time periods.
- **Result.xml** – This file contains the result of the scheduling run.

The tracing functionality adds significant performance overhead, so use it only to investigate scheduling specific orders in a controlled manner. If you turn it on during a master planning run, it quickly reaches its size limit and stops.

Troubleshooting performance

As you can see from the previous sections, some pitfalls in the setup and usage of the scheduling engine can lead to performance problems. The following checklist can help you troubleshoot these problems. Look at all the points because it's often a combination of multiple factors that leads to problems.

> **Tip**
>
> The following table summarizes the most common job scheduling performance problems and their recommended solutions. Use the links to jump to the detailed guidance for each area.
>
> Expand table

Problem	Recommendation	Details
Scheduling not needed during MRP	Set capacity time fence to zero or use a standard production lead time	Scheduling as part of MRP

Problem	Recommendation	Details
Too many applicable resources	Assign a specific resource to the operation at route design time	Many applicable resources
Parallel operations slow scheduling	Model pairs as "virtual" resources or exclude non-bottleneck operations	Parallel operations
Resource quantity greater than one	Review whether multiple resources are truly required for the operation	Resource quantity
Finite capacity overhead	Use the bottleneck option and separate capacity time fence for bottleneck resources	Finite capacity
Hard links complicate scheduling	Use hard links only when strictly necessary	Hard links
Separate calendar per resource	Reuse calendars among resources as much as possible	Calendars
Many time slots per calendar day	Minimize working time slots (for example, skip five-minute break modeling)	Time slots
Missing or large scheduling timeouts	Enable both timeout settings; set maximum scheduling time to about 30 seconds	Timeouts

Performing scheduling as part of MRP when it isn't needed

Although routes are used for production control purposes like costing and reporting, they might not need to be considered during MRP. In some cases, having a standard production lead time specified for the item will be sufficient for planning. Set the capacity time fence to zero to turn off route scheduling. If scheduling is needed, carefully set the capacity time fence because routes might not need to be considered for the full extent of the MRP's coverage time fence.

If the order isn't scheduled during MRP, then it will instead need to be scheduled when the planned order is firmed. This means that the firming process will take longer, so depending on how many of the suggested planned orders get firmed the performance gain during MRP might be lost at firming.

Route with unnecessary operations

When you design the route, avoid trying to model the real world exactly with all the steps the production process goes through. While this approach can be useful in some cases, it isn't good for performance because the engine's model grows larger (in terms of jobs and constraints), and more SQL statements are executed to insert and update jobs and capacity reservations. Also,

there's the downstream effect of having to eventually report progress on the jobs, which automatic postings can mitigate. If the data isn't used for anything, it creates unnecessary load.

Create only the operations strictly needed for scheduling (typically bottleneck resources) or costing purposes. Instead, group many smaller distinct operations into one larger operation that represents a greater part of the process.

Many applicable resources for an operation

Resource requirements set on the operation relation determine the number of applicable resources for an operation. The requirement can either be for a specific resource or it can be based on the resource's membership in a resource group or capability.

If you don't use finite capacity for scheduling and all the applicable resources have the same calendar and efficiency, the scheduling engine always picks the same resource for an operation, but only after it tries all the applicable resources to check if there's one that is better than the others. In this case, you can greatly reduce the load of the scheduling by always assigning a specific resource to the operation at the route design time.

Route with parallel operations

While parallel operations (primary/secondary) are a powerful tool to model scenarios like when a machine and an operator are both needed to perform a specific task, they're also the source of many performance problems. If you assign a requirement for a specific individual resource to both the primary and secondary operation, it's typically not a problem. But if there are many possible resources for each of the operations, then it adds significant computational complexity to the scheduling.

An alternative to using parallel operations is either to model the pairs as "virtual" resources (which then represent the team that always goes together for the operation) or to simply not model one of the operations if it doesn't represent a bottleneck.

Route with quantity of resources higher than one

If the quantity of resources needed for an operation is greater than one, the result is effectively the same as using primary/secondary operations because multiple parallel jobs are sent to the engine. However, for this case, you can't use specific resource assignments because a quantity higher than one requires more than one resource to be applicable for the operation.

A secondary operation that has a resource load quantity greater than one means that the specified quantity of secondary resources is needed for each resource of the primary operation. For example, if a primary operation has its quantity of resources set to two and its secondary operation has its resource quantity set to three, then a total of six resources is needed for the secondary operation.

Excessive use of finite capacity

Using finite capacity requires the engine to load capacity information from a database, which can add computational overhead, especially in environments where resources are booked close to maximum capacity. As a result, it's important to carefully evaluate if a resource really needs to use finite capacity or they can be overbooked. Because there might be a difference among finite capacity resources in how important they are to not overbook, use the bottleneck option on a resource in combination with a separate value on the plan in "Capacity time fence for bottleneck resources." Using the bottleneck concept can enable lowering the general finite capacity time fence.

Setting hard links

The standard link type of the route is *soft*, which allows a time gap between the finishing time of one operation and the start of the next. If you allow this gap, it can cause production to be idle if materials or capacity aren't available for one of the operations. This situation can lead to an increase in work in progress. This problem doesn't happen with hard links because the finish and start must align perfectly. However, setting hard links makes the scheduling problem more difficult because the system must calculate working time and capacity intersections for the two resources of the operations. If the schedule also involves parallel operations, this requirement adds significant computational time. If the resources of the two operations have different calendars that don't overlap at all, the problem is unsolvable.

Use hard links only when strictly necessary, and carefully consider if it's necessary for each operation of the route.

To reduce work in progress without applying hard links, schedule the order twice with changing to the opposite direction for the second pass. If the first schedule was done backward from delivery date, then the second schedule should be done forward from the scheduled start date. This approach compresses the jobs as much as possible so that the work in progress is minimized.

Separate calendar for each resource

One of the main sources of data for the scheduling engine is calendar information, which can be expensive to load from the database. Because calendars are generated based on templates, it might seem tempting to generate a calendar for each resource and then adjust the information in this calendar when the resource has downtime and other issues. However, this approach severely limits the engine's ability to cache the calendar data because it needs to request new data for each resource. This approach can cause performance problems. Reuse calendars as much as possible between resources, and control downtime changes by assigning a different calendar ID for a period.

High number of working time slots per calendar day

Because the engine works by examining time slots one-by-one for capacity, it's beneficial to minimize the number of time slots per calendar day. For example, consider whether it's important for the resulting schedule to reflect that workers take a five-minute break every hour.

Large (or none) scheduling timeouts

You can optimize scheduling engine performance by using parameters found on the **Scheduling parameters** page. Always set the **Scheduling timeout enabled** and **Scheduling optimization timeout enabled** settings to *Yes*. If you set them to *No*, scheduling can potentially run infinitely if an unfeasible route with many options is created.

The value for **Maximum scheduling time per sequence** controls how many seconds can, at most, be spent trying to find a solution for a single sequence (in most cases a sequence corresponds to a single order). The value to use here highly depends on the complexity of the route and settings like finite capacity, but a maximum of about 30 seconds is a good starting point.

The value for **Optimization attempts timeout** controls how many seconds can at most be used to find a better solution than the one originally found. This value only influences routes that use parallel operations as these operations make it necessary to test different combinations.

> **Note**
>
> The values you set for the timeouts apply both to scheduling of released production orders and to planned orders as part of MRP. As a result, setting very high values can significantly add to the run time of MRP when running for a plan with many planned production orders.

Common job scheduling errors

The following table lists known job scheduling errors with links to information that can help you resolve them.

Expand table

Error message	Resolution
Planned production order must be scheduled before it can be firmed	Planned production order must be scheduled before it can be firmed
Production scheduling doesn't consider the safety margins	Production scheduling doesn't consider the safety margins
Master planning is scheduling more than the available capacity	Master planning is scheduling more than the available capacity
Not enough capacity could be found	Not enough capacity could be found Fix the "Not enough capacity could be found" scheduling engine error
The delay value isn't updated when you reschedule a planned order	The delay value isn't updated when you reschedule a planned order

> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Human Resources, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

This article describes how to fix common issues that you might encounter while working with Planning Optimization.

Installation of the Planning Optimization Add-in isn't completed or fails with an error

If you're having trouble installing the Planning Optimization Add-in, consider the advice provided in the following subsections.

Make sure your environment meets the prerequisites

Planning Optimization requires a Microsoft Dynamics Lifecycle Services–enabled, high-availability environment, tier 2 or higher (not a OneBox environment), with Dynamics 365 Supply Chain Management version 10.0.23 or later. If you try to install the add-in on a OneBox environment, the installation won't complete.

Fix: Cancel the installation and use a high-availability environment, tier 2 or higher (not a OneBox environment).

Make sure your user account meets the prerequisites

The Planning Optimization Add-in requires a successfully linked Power Platform environment. To install the add-in, you must sign in to your Microsoft Power Platform environment using an account with administrator privileges and an access mode of *Read-Write*. If you try to install the add-in using an account with insufficient permissions, you might see one of the following error messages:

> Current user does not have enough permission on Power platform environment to complete installation for Planning optimization. Consider changing user Access Mode to Read-write on Power platform admin center.

> Current user is not exist in Power platform environment. Please contact with your administrator to assign the user via Power platform admin center.

> Current user does not have assigned license to complete installation for Planning optimization. Consider assigning license on Microsoft admin center.

Fix: Set up your user account as described under *Prerequisites* in Get started with master planning.

Review the error details

An error in your Power Platform environment might prevent the installation of the Planning Optimization Add-in.

Fix: Check the error details and modify your Power Platform organization settings accordingly. It might be a temporary error, so try to install the add-in again later. If the issue persists, contact Microsoft Support.

Planning Optimization job times out

Planning Optimization has a set timeout of 60 minutes. Therefore, if it runs for more than 60 minutes, the planning job stops because of a timeout.

> **Tip**
>
> The following table summarizes the most effective approaches for improving Planning Optimization performance. Try them in order of impact.

Expand table

Approach	When to use	Impact
Reduce time fences	Time fences are larger than your business requires	High—coverage time fence has the largest effect
Plan only needed products	Many items are included that don't need planning	High
Split large jobs	A single job plans too many items for the 60-minute window	High
Reduce scheduling time	Finite capacity scheduling is enabled and adds significant time	Medium
Reduce resource group size	Large resource groups slow down scheduling calculations	Medium
Review item coverage	Multiple coverage lines apply the same settings for all warehouses	Low to medium

If your Planning Optimization jobs frequently time out, consider implementing one or more of the options that are described in the following subsections.

Review your setup to remove time fences and options that you don't need

Follow these steps to review your setup and remove time fences and other options that you don't need:

1. Adjust the time fences to make them as small as possible while still fulfilling your business needs.

    a. Check the following settings for each of the coverage groups on the **Coverage groups** page:

    - **Coverage time fence (days)**
    - **BOM explosion time fence (days)**
    - **Capacity scheduling time fence (days)**
    - **Forecast plan time fence**
    - **Action time fence**
    - **Calculated delays time fence**

b. On the **Master plans** page, check whether the time fences have been overwritten and consider whether the values could be smaller while still fulfilling your business needs for the various time fences. Check the following settings for each plan:

- **Coverage**
- **Explosion**
- **Forecast plan**
- **Capacity**
- **Action message**
- **Calculated delays**
- **Approved requisitions time fence (days)**

> **Important**
>
> The coverage time fence has the largest impact on the time that planning takes to run. Adjust it to the lowest possible value that still fulfills your business needs.

2. On the **Master plans** page, review the following settings for each plan. Set each option to *No* unless it applies to your master plan. Don't leave any option set to *Yes* if it isn't needed for your business processes.

   - **Use shelf life dates**
   - **Finite capacity**
   - **Include on-hand inventory**
   - **Include inventory transactions**
   - **Include requests for quotations**
   - **Include sales quotations**
   - **Include supply forecast**
   - **Include demand forecast**
   - **Include requisitions**

3. Use finite capacity only when it's necessary. For plans that don't need it, set the **Finite capacity** option to *No* on the **Master plans** page.

Reduce scheduling time

Review your scheduling configuration to optimize run times. To check whether scheduling is the main reason that Planning Optimization is timing out, try disabling finite capacity in the plan settings and then rerun planning to see if the issue is solved.

For more information about how to reduce scheduling times, see Improve scheduling engine performance.

Plan only for the products you need

Review the following settings to make sure that you're planning only for the products that you need:

- Use the **Product lifecycle state** field to indicate products or variants that don't need to be fulfilled by master planning. For each such product, select a product lifecycle state where the **Is active for planning** option is set to *No*. Use the **Change lifecycle state for obsolete products** page to identify products that aren't used in any transactions for a while. These products might now be obsolete. Therefore, you can remove them from your planning.
- For plans that should only apply for a certain set of items, set up a plan filter to limit the run to just those items. Learn more in Run planning for a subset of items.
- Set item coverage to manual for each warehouse that doesn't need to be supplied by master planning. For each such warehouse listed on the **Warehouses** page, expand the **Master Planning** FastTab and, in the **Item Coverage** field group, set **Manual** to *Yes*.

Split large planning jobs into several smaller jobs

If you have a large planning job that frequently times out, you might be able to prevent the timeout by splitting the job into several smaller jobs.

Option 1: Run the same master plan but only for a subset of products

For example, you have a master plan named *PlanA*. It runs nightly as a batch job for 1,000 items that have item numbers ranging from *A0001* through *A1000*. If this job often times out after 60 minutes, you can split it into three jobs, each of which runs for a third of the items. You run *PlanA* for the first third (*A0001* through *A0333*), then for the second third (*A0334* through *A0666*), and then for the last third (*A0667* through *A1000*). In this way, each smaller job has the full 60-minute timeout window. You're not trying to use the same 60 minutes to plan all 1,000 items.

To split a large job into several jobs, follow these steps:

1. Go to **System administration** > **Inquiries** > **Batch jobs**.
2. In the grid, find the recurring planning job that's timing out. Then select the value in the **Job ID** column to open the job details.
3. On the Action Pane, select **Change status**.

4. In the **Select new status** dialog box, select *Withhold*, and then select **OK**.

5. On the **Batch tasks** FastTab, the grid should include a single row for Planning Optimization, where the **Class name** field is set to *MpsMasterPlanningRunnerRegen*. Select this task, and then select **Parameters** on the FastTab toolbar.

6. A dialog box appears, where you can set values for the task. On the **Records to include** FastTab, select **Filter** to open a standard query editor dialog box.

7. On the **Range** tab, add a row, and set the following fields for it:

    - **Table** – Select *Items*.
    - **Derived table** – Select *Items*.
    - **Field** – Select *Item number*.
    - **Criteria** – Specify the range of item numbers that you want to include in the first of the smaller jobs. Separate the first and last item numbers in the range with three periods. For example, enter *A0001...A0333*.

8. Select **OK** to close the query editor. Then select **OK** to close the task settings dialog.

9. On the **Batch tasks** FastTab, select **Add** on the toolbar to add a task.

10. Set the following fields for the new task:

    - **Task description** – Enter a description of the task (for example, *PlanA part 2*).
    - **Class name** – Select *MpsMasterPlanningRunnerRegen*.
    - **Company** – Select the same company that's selected for the original task.

11. Set the filter for the new task to find the second third of the items (for example, item numbers in the range *A0334...A0666*).

12. Repeat the previous three steps to add a third task and set the filter to find the last third of the items (for example, item numbers in the range *A0667...A1000*).

13. Select the **Task ID** value for the first task, and copy it to the clipboard (by selecting **Ctrl+C**).

14. Select the second task. Then, on the **Batch task details** FastTab, on the **Constraints** tab, select **New** on the toolbar to add a row to the grid.

15. Set the following fields for the new row. These settings cause the second task to run after the first task finishes running or encounters an error.

    - **Task ID** – Paste the value that you copied to the clipboard.

- **Expected status** – Select *Ended or error*.

16. Repeat the previous three steps to set the third task to run after the second task finishes running or encounters an error.
17. On the Action Pane, select **Change status**.
18. In the **Select new status** dialog box, select *Waiting*, and then select **OK**.
19. On the Action Pane, select **Save**.

> **Tip**
>
> This procedure shows just one way to split a large job into several smaller jobs and set them to run in series. You can split the job into even more jobs and filter on different criteria as needed.

Option 2: Different master plans, each for a subset of products

If your products have different characteristics that affect planning, consider running different master plans, each for a subset of products.

For example, you have a master plan for purchasing items that have a long lead time (such as a year) but that are used to produce manufactured products that have a short manufacturing lead time (such as a week). In this case, you can make one master plan for purchased products (*PlanPurch*) that has a coverage time fence of 365 days. Then make another plan for manufactured items (*PlanManuf*) that has a coverage time fence of 30 days. Because each set of products is in a different master plan, you can run both master plan jobs in parallel. When you run different plans in different batch tasks, each batch task can run in parallel. They don't have to run sequentially.

To implement this strategy, follow these steps:

1. Open your existing master plan, and modify it so that it covers only a subset of the original items (for example, purchased items). You can make this modification by adding a filter as described in Applying a plan filter.
2. Create another master plan to cover the remaining items. Again, set up a plan filter to include only the items that you want to include in this plan (for example, manufactured items). This plan can be a copy of the original plan that you modify to filter for a different set of items.

3. Go to **System administration** > **Inquiries** > **Batch jobs**.
4. In the grid, find the recurring planning job that's timing out. Then select the value in the **Job ID** column to open the job details.
5. On the Action Pane, select **Change status**.
6. In the **Select new status** dialog box, select *Withhold*, and then select **OK**.
7. On the **Batch tasks** FastTab, the grid should include a single row for Planning Optimization, where the **Class name** field is set to *MpsMasterPlanningRunnerRegen*. On the FastTab toolbar, select **Add** to add a task.
8. Set the following fields for the new task:
    - **Task description** – Enter a description of the new task.
    - **Class name** – Select *MpsMasterPlanningRunnerRegen*.
    - **Company** – Select the same company that's selected for the original task.
9. Select the new task, and then select **Parameters** on the FastTab toolbar.
10. A dialog box appears, where you can set values for the task. On the **Parameters** FastTab, set the **Master plan** field to the name of the new plan that you created.
11. On the Action Pane, select **Change status**.
12. In the **Select new status** dialog box, select *Waiting*, and then select **OK**.
13. On the Action Pane, select **Save**.

Because you set each batch task to run a different master plan, both batch tasks run in parallel.

Review your item coverage settings

- Review your item coverage settings. For items that use multiple item coverage lines to apply the same settings for all warehouses at the same site, replace those lines with a single line for the site (with the **Warehouse** column blank). That setting then applies to all warehouses at that site.

Consider reducing the size of your resource groups

Consider whether you can split large resource groups (with many resources) into several smaller groups (each with fewer resources). For example, you might be able to split a large resource

group called *AssemblyStations* (which contains 20 resources) into two smaller resource groups based on location (such as *AssemblyStationsNorth* and *AssemblyStationsSouth*), where each contains just 10 assembly stations. After splitting the group, reassign each new resource group to the right routes based on whether a product is produced in the northern or southern area of the plant.

Data export timeout

The following message appears if a data export times out for Planning Optimization:

> Master planning job timed out when exporting the data to perform the calculation. This condition can be temporary—try running the job again later. If you see this message often, review your setup to limit the amount of data used for planning, as indicated in (this page).

If you receive this message, try one or both of the approaches that are described in the following subsections.

Review your setup for time fences and options that you don't need

Follow these steps to review your setup for time fences and options that you don't need.

1. Go to **Master Planning** > **Setup** > **Coverage** > **Coverage groups**.
2. Review the following settings for each coverage group on the **Coverage groups** page. Consider whether some or all of the values can be smaller but still fulfill your business needs for the different time fences.
    - **Coverage time fence (days)**
    - **BOM explosion time fence (days)**
    - **Capacity scheduling time fence (days)**
    - **Forecast plan time fence**
    - **Action time fence**
    - **Calculated delays time fence**
3. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
4. On the **Master plans** page, check whether the time fences have been overwritten, and consider whether the values can be smaller but still fulfill your business needs for the different time fences. Review the following settings for each plan:

- **Coverage**
- **Explosion**
- **Forecast plan**
- **Capacity**
- **Action message**
- **Calculated delays**
- **Approved requisitions time fence (days)**

5. If your plan times out because it generates a large number of orders, consider changing your business strategy for replenishing items. Here are some examples:

    - If you use coverage groups where the **Coverage code** field is set to *Requirement*, the system creates a specific supply for it each time that there's a demand. Consider whether a **Coverage code** value of *Period* works for your business. In this case, the system groups all demand for a selected number of days into a single supply order that covers that period. This approach also makes planned orders easier to manage. Alternatively, consider using a **Coverage code** value of *Min/Max*. In this case, the system creates a planned order only when the on-hand inventory falls below the minimum value. The on-hand inventory is then replenished to its maximum value.
    - Consider whether you can purchase or produce items in larger amounts. If you can, increase the **Max. order quantity** value on **Default order settings** page for each item that you're ordering. The higher the value, the fewer orders you're likely to generate for that item.

Plan only for the products that you need

Your data export might complete more quickly if you reduce the number of products that the system considers for each planning run. Consider using one or both of the following strategies:

- Identify products and variants that don't need to be fulfilled by master planning, and set their **Product lifecycle state** value to a state where the **Is active for planning** option is set to *No*. (Learn more in Exclude products that have specific product lifecycle states). The **Change lifecycle state for obsolete products** page can help you identify products that haven't been used in any transactions for a while. These products might now be obsolete. Therefore, you can remove them from your planning.
- Use a plan filter to remove unneeded items from your plan.

No planned orders are created

If master planning runs but doesn't create any orders, check the following settings:

- Make sure the items you're expecting to generate supply for are set up with a lifecycle state where **Exclude from master planning** is set to *No*.
- If you're running a filtered plan, make sure that there aren't any typos in your filter values. (Learn more in Run planning for a subset of items.)
- Make sure that there's demand for the items you're expecting master planning to create supply for.

Planning of batch jobs fails when Planning Optimization is enabled

When you enable Planning Optimization, the deprecated master planning engine is automatically disabled. Master planning batch jobs that were created for the deprecated master planning engine fail if they're triggered while Planning Optimization is enabled. You might receive an error message such as *This operation triggered master planning that isn't supported when Planning Optimization is enabled*.

Fix: Cancel all master planning batch jobs that were created for the deprecated master planning engine.

Planning Optimization results are different from earlier results

Planning Optimization differs from the deprecated master planning engine design in some areas. This difference can also be caused by pending features.

Fix: Run Planning Optimization fit analysis and then analyze the results while referring to the related documentation to understand the impact. Learn more in Planning Optimization fit analysis.

Can't disable Planning Optimization

The **Use Planning Optimization** option is set to *Yes* and is grayed out, so you can't turn it off.

This behavior is by design. Planning Optimization is now the only planning engine available for Supply Chain Management, so you can't turn it off. However, in some rare cases, Microsoft Support might make the deprecated planning available for one or more specific companies. Learn more in Migration to Planning Optimization for master planning.

Error message is shown during CTP

If you try to run capable to promise (CTP) from a sales order when Planning Optimization is enabled, you receive the following error message: *This operation triggered master planning that isn't supported when the Planning Optimization is enabled*.

This error message is related to a pending feature that is planned as part of the support for production orders.

Fix: Avoid CTP calculations when Planning Optimization is enabled until CTP support is available.

Error message about active planning dimensions not matching

After running a master plan, you might receive the following error message:

> Supply setting with id: <SettingID> for MinMax on product <ProductID> doesn't match the active planning attributes for this product and was ignored.

If you see this error, check the tracking and coverage dimensions for the specified product. For example, if the product is tracked by serial number, you can't use the serial number dimension as a coverage dimension because the system doesn't know which serial numbers it should supply. Either deselect the serial number as a coverage dimension or change the item coverage group to a group that doesn't use serial number tracking (if serial tracking isn't needed for the specified product).

Planning Optimization client request retry count exceeded

After running master planning, you receive one of the following error messages:

> Planning Optimization client request retry count exceeded.

or

> Planning Optimization run failed.

This error can occur for different reasons. Check the following causes and fixes.

Cause 1: Transient service failure

Planning Optimization is a cloud-based service. Occasionally, transient service failures can occur that are specific to a particular region. These temporary outages can prevent Planning Optimization from completing a run.

Fix: Wait a short time and then retry the master planning run. If the issue persists for more than a few hours, contact Microsoft Support because the issue might require action from the service engineering team.

Cause 2: Connection lost after a database refresh

If you recently performed a database refresh on your environment, the Planning Optimization connection might be broken. The connection status on the **Planning Optimization parameters** page (**Master planning** > **Setup** > **Planning Optimization parameters**) might show *Not connected* even though the add-in appears as installed.

A database refresh is environment-specific, and it resets the Planning Optimization service binding. This is a known behavior.

Fix: Uninstall and reinstall the Planning Optimization Add-in for your environment from the admin center. After reinstallation, verify that the connection status shows *Connected* on the **Planning Optimization parameters** page. Learn more in Get started with master planning.

Cause 3: Temporary connectivity issue

Intermittent network or service connectivity problems between your environment and the Planning Optimization service can cause this error.

Fix: Retry the master planning run. If the error occurs repeatedly, check the **Planning Optimization parameters** page to verify the connection status. If the connection status shows *Not connected*, try reinstalling the add-in. If the status shows *Connected* and the error persists, contact Microsoft Support.

Company information tab is blank on the Planning Optimization parameters page

When you open the **Planning Optimization parameters** page and select the **Company information** tab, the tab appears blank. The **Exclude company from running Planning Optimization** toggle might also appear greyed out and disabled.

This behavior is by design. The **Company information** tab and toggle are only relevant for companies that have been granted an exception to continue using the deprecated master planning engine. Starting from Supply Chain Management version 10.0.41, Planning Optimization is the standard master planning engine for all new deployments and legal entities. If your company wasn't enabled to use the deprecated planning engine, the **Company information** tab is intentionally empty and the toggle is disabled because there's no need to configure an exclusion.

If your company received an exception to use the deprecated planning engine and you still see the tab as blank, create a support ticket stating the reason for the exception.

Learn more in Continue to use deprecated master planning with existing companies and Migration to Planning Optimization for master planning.

Fix the "Not enough capacity could be found" scheduling engine error

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you run scheduling, you might receive the following error message:

> Production order %1 could not be scheduled. Not enough capacity could be found.

There are several reasons why the scheduling engine might fail and issue this error message. This article provides guidelines that help you find the root cause of the error and then mitigate it.

Review the applicable resources

The error can occur if no applicable resources satisfy the operation requirements at the production order site.

To review the applicable resources, follow these steps:

1. Go to **Production control** > **Production orders** > **All production orders**, and open or select the production order that can't be scheduled.
2. On the Action Pane, on the **Production order** tab, in the **Production details** group, select **Route**.
3. On the **Production route** page, select the operation, and then, on the Action Pane, select **Applicable resources**.
4. In the **Applicable resources** dialog box, set the **Use requirements for** field to *Operations scheduling* or *Job scheduling*, depending on the type of scheduling that you're using.
5. Make sure that there are applicable resources at the production order site.

Review the calendars associated with resources

The error can occur if no calendar is associated with the resource or resource group, or if the associated calendar isn't correctly set up (for example, it has no working times, or its efficiency as a percentage is 0 [zero]).

To verify that a calendar is associated with the resource or resource group, follow these steps:

1. Go to **Production control** > **Production orders** > **All production orders**, and open or select the production order that can't be scheduled.
2. On the Action Pane, on the **Production order** tab, in the **Production details** group, select **Route**.
3. On the **Production route** page, select the operation, and then, on the Action Pane, select **Applicable resources**.
4. In the **Applicable resources** dialog box, select the resource, and then select **View resource**. Alternatively, select and hold (or right-click) in the **Resource group** field, and then select **View details**.
5. On the **Resources** page or the **Resource groups** page, on the **Calendars** FastTab, make sure that a calendar is associated with the resource or resource group.

> ⓘ **Note**
>
> If the error occurs during operation scheduling, you must make sure that a calendar is associated with all applicable resource groups.

To review the setup of the calendar, follow these steps:

1. Go to **Organization administration** > **Setup** > **Calendars** > **Calendars**, and select the calendar that is associated with the resource or resource group.
2. On the Action Pane, select **Working times**.
3. On the **Working times** page, make sure that the page isn't blank. Additionally, for the days that you're interested in, make sure that the **Control** field isn't set to *Closed*, working times exist, and the **Efficiency is percentage** field isn't set to *0* (zero).

If the calendar is associated with the base calendar, you must also review the setup of the base calendar.

> ⓘ **Note**
>
> In operation scheduling, the resource group's calendar is used to determine the start and end times and dates for each operation. It also limits the amount of time that the system can

schedule for one specific operation for one specific day in one specific resource group. For example, if the working times for a resource group on one specific day are from 8:00 AM to 4:00 PM, the load that one operation puts on the resource group can't exceed the load that can be fit into eight hours, regardless of the amount of available capacity that the resource group has on that day. However, the available capacity can further limit the load.

Review the scheduling parameters

To ensure good performance, the scheduling engine searches for a resource only for a specific amount of time and a specific number of scheduling conflicts.

To review the scheduling parameters, follow these steps:

1. Go to **Organization administration** > **Setup** > **Scheduling parameters**.
2. Follow one of these steps:
    - If the **Scheduling timeout enabled** option is set to *No*, move on to step 3.
    - If the **Scheduling timeout enabled** option is set to *Yes*, increase the value of the **Maximum scheduling time per sequence** field to give processing more time to finish.
3. Follow one of these steps:
    - If the **Scheduling optimization timeout enabled** option is set to *No*, move on to step 4.
    - If the **Scheduling optimization timeout enabled** option is set to *Yes*, increase the value of the **Optimization attempts timeout** field to give processing more time to finish.
4. If you changed any of the settings on the page, reschedule the order to try again.

Review capacity

The error can occur when you perform finite scheduling, but there's no free capacity.

To perform infinite capacity scheduling, follow these steps:

1. Go to **Production control** > **Production orders** > **All production orders**, and select or open the production order that can't be scheduled.
2. On the Action Pane, on the **Schedule** tab, in the **Production order** group, select **Schedule operations** or **Schedule jobs**.

3. In the **Operations scheduling** or **Jobs scheduling** dialog box, set the **Finite capacity** option to *No*.
4. Select **OK** to schedule the order.

To review the available capacity on the resource, follow these steps:

1. Go to **Organization administration** > **Resources** > **Resources**, and select a resource that is applicable to the order that can't be scheduled.
2. On the Action Pane, on the **Resource** tab, in the **View** group, select **Capacity load** or **Capacity load, graphically**, and make sure that there's available capacity.

To review the available capacity on the resource group, follow these steps:

1. Go to **Organization administration** > **Resources** > **Resource groups**, and select a resource group that is applicable to the order that can't be scheduled.
2. On the Action Pane, on the **Resource group** tab, in the **View** group, select **Capacity load** or **Capacity load, graphically**, and make sure there's available capacity.

Master planning books a resource when the resource calendar is closed

When using operations scheduling, master planning plans capacity according to the calendar of the primary resource group. It books the secondary operation at the same time as the primary operation and doesn't take into account the calendars or capacity of the secondary operation. This can result in the production order being scheduled on a closed calendar or at a time when the secondary operation isn't available (calendar closed, no capacity).

When using job scheduling, master planning takes into account the capacity and calendar of both the primary and secondary operation when scheduling the order. For the order to be scheduled, calendars for the resources of both operations must be open and have available capacity.

Maximum job lead time is too short

The scheduling engine can't schedule an order if the **Maximum job lead time** set for your site is less than the lead time specified for an item in its default order settings or coverage settings.

To view or edit the **Maximum job lead time** setting for your site, go to **Production control** > **Setup** > **Production control parameters** and open the **General** tab.

To view or edit the default order settings for an item, follow these steps:

1. Go to **Product information management** > **Products** > **Released products**.
2. Find and select the relevant product in the list.
3. On the Action Pane, open the **Manage inventory** tab and select **Default order settings**.
4. Expand the **Inventory** FastTab and view or edit the **Inventory lead time** setting as needed.

To view or edit the coverage settings for an item, follow these steps:

1. Go to **Product information management** > **Products** > **Released products**.
2. Find and select the relevant product in the list.
3. On the Action Pane, open the **Plan** tab and select **Item coverage**.
4. Open the **Lead time** tab and view or edit the **Production time** value as needed.

Excessive quantity of required resources

During scheduling, the engine tries to match the required resource quantity set for a route operation to the applicable resources according to the operation resource requirements. Setting the resource quantity too high can make a route unfeasible and produce a scheduling error.

Use the following procedure to check both the specified quantity and applicable resources for a selected product, route, and route operation:

1. Go to **Product information management** > **Products** > **Released products**.
2. Find and select the relevant product in the grid.
3. On the Action Pane, open the **Engineer** tab and select **Route**.
4. Find and select the relevant route in the grid.
5. Open to the **Overview** tab at the bottom of the page.
6. Select an operation from the list of the selected route operations.
7. Select **Applicable resources** to open a dialog where you can view the applicable resources for the selected route operation.
8. Open the **Resource load** tab. The **Quantity** field here shows the resource quantity required for the selected route operation. View and/or edit it as needed.

Cancel a planning job

In Microsoft Dynamics 365 Supply Chain Management, you can cancel an active planning job that uses the Planning optimization functionality. When you select **Cancel** in the dialog box when a Planning optimization job is triggered directly from the user interface (not in the background), this will not cancel the Planning optimization job. Even if you receive a warning such as "Operation canceled", you will still need to use the following steps to cancel a planning job with Planning optimization.

To cancel an active planning job, follow these steps:

> ⓘ **Note**
>
> Only active jobs can be canceled.

1. Go to **Master planning** > **Setup** > **Plans**.
2. Select an appropriate plan for the planning run.
3. Select **History**.
4. Select the planning job to cancel.
5. Select **Cancel**.

The job status will be **Canceling** until the Planning Optimization service confirms that the job has been canceled. The status will then be changed to **Canceled**.

> ⓘ **Note**
>
> To see status changes, you must refresh the page by selecting the **Refresh** button.

Lean manufacturing for Planning Optimization

Lean manufacturing is a production philosophy that maximizes value for customers while minimizing waste. It comes from the Toyota production system and focuses on continuous improvement and operational efficiency. The *Lean manufacturing for Planning Optimization* feature allows Planning Optimization to consider demand and supply that originates from lean-manufacturing models (such as kanbans) when generating plans in Supply Chain Management. Learn more in Lean manufacturing overview.

To use lean manufacturing processes with Planning Optimization, your system must meet the following requirements:

- To use the preview release of this feature, you must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.45.
- To use the general availability release of this feature, you must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.46 or later.
- The feature that is named *Lean manufacturing for Planning Optimization* must be turned on in feature management.

Unified developer experience for planning optimization (preview)

[This article is prerelease documentation and is subject to change.]

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Microsoft Power Platform provides a unified developer experience that includes tools and environments for writing and debugging extensions for the Planning Optimization Add-in for Microsoft Dynamics 365 Supply Chain Management. This topic provides an overview of the process for setting up a development environment and testing your extensions.

Learn more in Unified developer experience for finance and operations apps.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Extensibility scenarios

Developers can extend Planning Optimization to add support for scenarios that apply after master planning runs. Developers can test their extensions by connecting the Planning Optimization service to their development environment.

The most common extensibility scenario for Planning Optimization involves the application of custom processing after a plan is updated. Microsoft Power Platform supports low-code development that enables new solutions to be created quickly. At the same time, developers can make sure that their extensions work correctly by using the real-time results that Planning Optimization produces.

Set up an environment for testing your Planning Optimization extensions

Provision a new environment

To provision an environment that you can use for Planning Optimization, follow the instructions in Tutorial: Provision a new environment with an ERP-based template.

> **Important**
>
> When you provision the environment, you must set the template ID to *D365_FinOps_SCM*.

After you complete the steps in the Step-by-step provisioning guide, your new environment will be prepared in Power Platform admin center.

Confirm that the Planning Optimization Add-in is installed

To confirm that you successfully added the Planning Optimization Add-in to your environment, follow these steps:

1. Sign in to Power Platform admin center.
2. On the navigation pane, select **Environments**, and then open the environment where you installed the add-in.
3. In the **Resources** section, select **Dynamics 365 apps**.
4. In the list, find the row where the **Name** field is set to *Planning optimization add-in for D365 SCM*. Confirm that the **Status** field is set to *Installed*.

Turn on Planning Optimization for your Supply Chain Management environment

To turn on Planning Optimization for your Supply Chain Management environment, follow these steps:

1. Sign in to your new Supply Chain Management environment. (You can find your Supply Chain Management URL on the environment page in Power Platform admin center.)
2. Follow the instructions in Turn on Planning Optimization for your environment.

Planning Optimization extensibility

07/31/2025

This article describes the extensibility scenarios that are related to master planning and supported in Planning Optimization.

> **Tip**
>
> If you've finished developing an extension and want to set up an end-to-end testing environment, see Unified developer experience for planning optimization (preview).

Custom processing when master planning is completed

The most common extensibility scenario for Planning Optimization is to apply custom processing after the plan has been updated. For example, you might add a column to the planned orders table (`ReqPO`), or you might want to derive some statistical information from the generated plan. The main extensibility point that enables this scenario is the `jobCompletedSuccessfully` method in the `MpsMasterPlanningEvents` class. To apply processing after a job fails, use the `jobFailed` method in the same class.

> **Important**
>
> Post-processing actions that use the current extensibility point will only apply to items directly specified in the filters (if used) and not to their subcomponents. Therefore, additional items included as a result of enabling the **Include all BOM levels** and/or **BOM levels to include** options in the **Planning Optimization** run dialog won't be affected by these post-processing actions. For more information about how to use the filters, see Run planning for a subset of items

The job completed successfully method

This section shows how to use the `jobCompletedSuccessfully` method.

```
X++
```

```
public static void
jobCompletedSuccessfully(MpsMasterPlanningJobCompletedSuccessfullyEventArgs _args)
```

Here's an example of an extension that sets a custom `CstmOrderPriority` field on the planned order.

```
X++
```

```
[ExtensionOf(classStr(MpsMasterPlanningEvents))]
public static final class MpsMasterPlanningEvents_Cstm_Extension
{
    public static void
jobCompletedSuccessfully(MpsMasterPlanningJobCompletedSuccessfullyEventArgs _args)
    {
        ttsbegin;

        var affectedPlannedOrdersQuery =
_args.parmPostProcessingQueryBuilder().buildAffectedPlannedOrdersQuery();
        var affectedPlannedOrdersQueryRun = new
QueryRun(affectedPlannedOrdersQuery);

        while (affectedPlannedOrdersQueryRun.next())
        {
            ReqPO reqPO = affectedPlannedOrdersQueryRun.get(tableNum(ReqPO));
            reqPO.selectForUpdate(true);
            reqPO.CstmOrderPriority = reqPO.ReqDate - systemDateGet() < 7 ?
CstmPlannedOrderPriority::Urgent : CstmPlannedOrderPriority::Regular;
            reqPO.doUpdate();
        }

        ttscommit;

        next jobCompletedSuccessfully(_args);
    }

}
```

When you add custom logic, consider the following constraints and best practices:

- The `jobCompletedSuccessfully` method is called outside the transaction scope. Therefore, the plan is already visible to the user when the custom logic starts to run. If your customization sets other fields on planned orders, it's important that you let users know that the values of those fields will eventually be consistent (in other words, they might be out of date immediately after a planning job is completed).
- Another master planning job can start when the `jobCompletedSuccessfully` method is called. The new job might affect the full plan or part of the plan. The new job might update or delete the same planned orders or requirement transactions that were created or updated as part of the planning job that was handled in `jobCompletedSuccessfully`. Update conflict exceptions must be handled when this event is extended.
- Avoid using single transaction scope when you extend this method. A single master planning run can produce millions of requirement transactions and hundreds of

thousands of planned orders. If all these transactions and planned orders are processed in the scope of a single transaction, many SQL locks will occur and block other planning processes. Additionally, if the transaction is held for a long time, "ghost records" will be created in the SQL database. Ghost records will negatively affect every process in the system.

- The query included in `MpsMasterPlanningJobCompletedSuccessfullyEventArgs` includes all the items that were included in the original filters, including those that had errors.
- The query included for `jobCompletedSuccessfully` won't include items added as a result of enabling the **Include all BOM levels** and/or **BOM levels to include** options in the **Planning Optimization** run dialog.

The job failed method

When a Planning Optimization job fails, it might be necessary to start another process (such as a retry operation). For this, you can use the `jobFailed` method, which is supported in Supply Chain Management version 10.0.31 and higher.

When adding custom logic, keep in mind that the query included for the `jobFailed` method won't include items added as a result of enabling the **Include all BOM levels** and/or **BOM levels to include** options in the **Planning Optimization** run dialog.

View plan history and planning logs

Summarize this article for me

This article explains how to view the history of planning jobs in Microsoft Dynamics 365 Supply Chain Management.

Each time you run a new master planning calculation, the system adds a new history record.

To view the history for a plan, open the plan by going to **Master planning** > **Setup** > **Plans** > **Master plans** and selecting **History**. The history lists all the jobs for the selected plan. The list includes completed and active jobs.

In addition to seeing the start time and status of jobs, you can view the log for a specific job. The log includes additional information and warnings. Not all jobs have a log. To view the log for a job, select **Log**. Log entries are only stored for 60 days after the date the job finished, after that they are automatically deleted.

If the **Batch processing** option on the **Run in the background** FastTab was enabled when master planning processing was set up, the batch job log shows more information about any warnings and errors that were generated during the master planning run. For example, auto-firming errors are captured only in the batch job log. They aren't shown in logs on the **History** page.

To view auto-firming errors and other warnings or errors that occurred during a master planning run, follow these steps:

1. Go to **System administration** > **Inquiries** > **Batch jobs**.
2. Find and select the record that represents the master planning run that you're interested in. (For example, the value of the **Job description** field might start with *Master planning*.)
3. Follow one of these steps, depending on whether you're using the *enhanced form* or the *legacy (unenhanced) form* for the **Batch jobs** page:
    - If you're using the enhanced form: On the Action Pane, select **Batch job history**. Then, on the **Batch job history** page, on the Action Pane, select **Log**.

- If you're using the legacy form: On the Action Pane, on the **Batch job** tab, select **Log**.

4. Select **Message details** to open the **Message details** pane, where you can view all warnings and errors that were captured during processing.

Date and time parameters used by Planning Optimization

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides information about the date and time parameters that Planning Optimization uses during its operation.

Whereas the deprecated master planning engine uses transaction dates in all calculations, Planning Optimization works with date and time values that are converted to dates. This difference in behavior can lead to situations where, for example, forecast transactions that are created at midnight on the day when master planning is run aren't included because Planning Optimization considers that they were created before the current date.

Parameters for issue and demand transactions

The following table lists the parameters that Planning Optimization uses when it processes issue and demand transactions.

Expand table

Parameter	Parameter name in Planning Optimization	Description	Equivalent field in Microsoft Dynamics 365 Supply Chain Management (in the ReqTrans table)
Planned issue time	`PlannedIssueTime`	The date that the issue is currently planned for.	**To date** (`FuturesDate`) and **Delayed to time** (`FuturesTime`)
Requested issue time	`RequestedIssueTime`	The date of issue that the user requests and is set in Supply Chain Management. This parameter is applicable only for	**Requested date** (`ReqDateDlvOrig`)

Parameter	Parameter name in Planning Optimization	Description	Equivalent field in Microsoft Dynamics 365 Supply Chain Management (in the ReqTrans table)
		released or approved planned orders. For planned orders, it's blank by default.	
Required issue time	`RequiredIssueTime`	The required issue date that Planning Optimization adjusts. If this time falls in the past when Planning Optimization runs, it is moved to the first open day that is no earlier than today. If the time is marked as blocked in the calendar, it is instead adjusted to the first open day before that date.	**Requirement date** (`ReqDate`) and **Requirement time** (`ReqTime`)
Issue time delay	`IssueTimeDelay`	The time difference between the planned issue time and either the requested issue time for approved and released orders or the required issue time.	**Delay (in days)** (`FuturesDays`)

Parameters for receipt and supply transactions

The following table lists the parameters that Planning Optimization uses when it processes receipt and supply transactions.

Expand table

Parameter	Parameter name in Planning Optimization	Description	Equivalent field in Supply Chain Management (in the ReqTrans or ReqPO table)
Planned availability time	`PlannedAvailabilityTime`	The date when the receipt is planned to be available.	**Requirement date** (`ReqDate`) and **Requirement time** (`ReqTime`)
Planned receipt time	`PlannedReceiptTime`	The date when the receipt arrives at the location.	**To date** (`FuturesDate`), **Delayed to time** (`FuturesTime`), and **Delivery date** (`ReqDateDlv`) or **Requested date** (`ReqDateDlvOrig`) if the order isn't released yet.
Required availability	`RequiredAvailabilityTime`	The required availability date that Planning Optimization	**Requirement date** (`ReqDate`) and **Requirement time**

Parameter	Parameter name in Planning Optimization	Description	Equivalent field in Supply Chain Management (in the ReqTrans or ReqPO table)
time		adjusts.	(`ReqTime`)
Expected receipt time	`ExpectedReceiptTime`	The expected receipt date for a released receipt. The user sets the value in Supply Chain Management. THe value isn't adjusted in Planning Optimization. This parameter applies only to released receipts.	**Requested date** (`ReqDateDlvOrig`)
Required receipt time	`RequiredReceiptTime`	The required receipt date that Planning Optimization adjusts.	**Requirement date** (`ReqDate`) and **Requirement time** (`ReqTime`)
Planned ordering time	`PlannedOrderingTime`	The ordering date that Planning Optimization calculates.	**Order date** (`ReqDateOrder`) and **Order time** (`ReqTimeOrder`)
Planned activity start time	`PlannedActivityStartTime`	The date when the activity for this receipt should start.	**Start date** (`SchedFromDate`)
Receipt time delay	`ReceiptTimeDelay`	The time difference between the planned receipt time and the required receipt time.	**Delay (days)** (`FuturesDays`) and **Delayed to time** (`FuturesTime`)

Examples of date parameter use by Planning Optimization

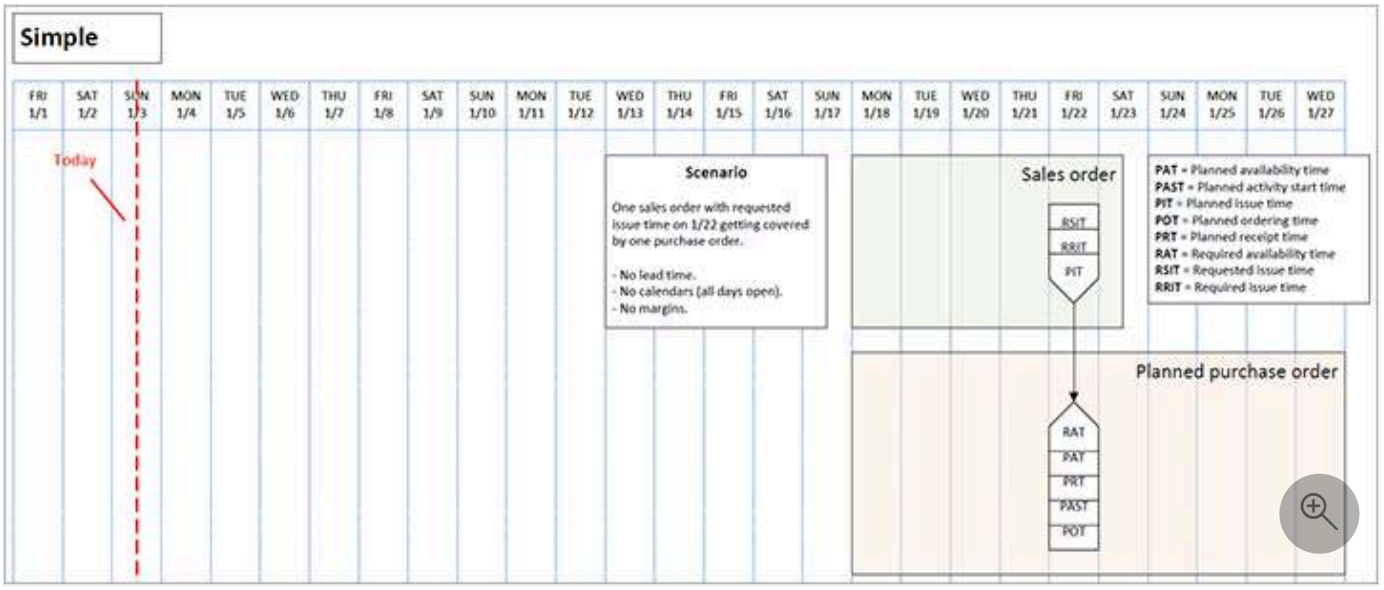
The plans in the following illustrations are at the day level, but Planning Optimization runs at a more detailed level. For example, because margins can be in hours, the planning ordering time can be January 22, 2021, at 11:35, and so on.

Example 1: Simple scenario

One sales order that has a requested issue time on January 22 is covered by one purchase order. The following settings are used:

- No lead time
- No calendars (All days are open.)
- No margins

The following illustration shows this scenario. (Select the illustration to open a larger version.)

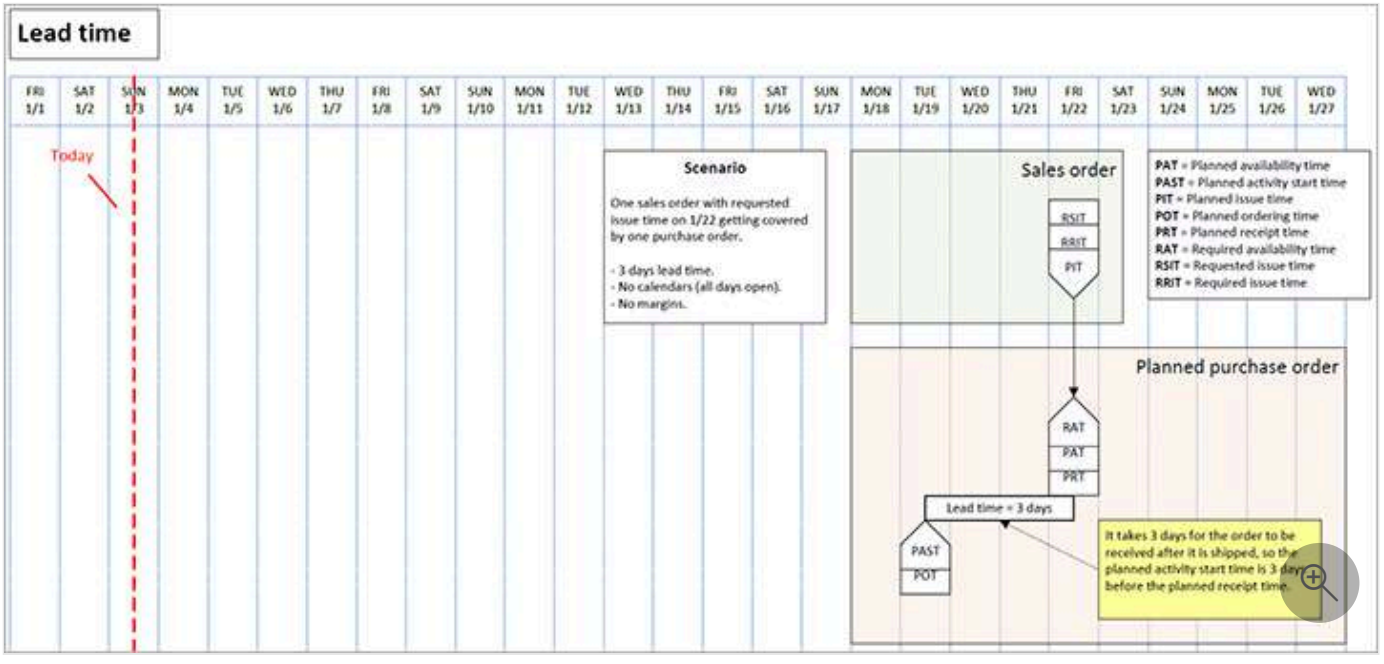


Example 2: Lead time scenario

One sales order that has a requested issue time on January 22 is covered by one purchase order. The following settings are used:

- Three days of lead time
- No calendars (All days are open.)
- No margins

The following illustration shows this scenario. (Select the illustration to open a larger version.)

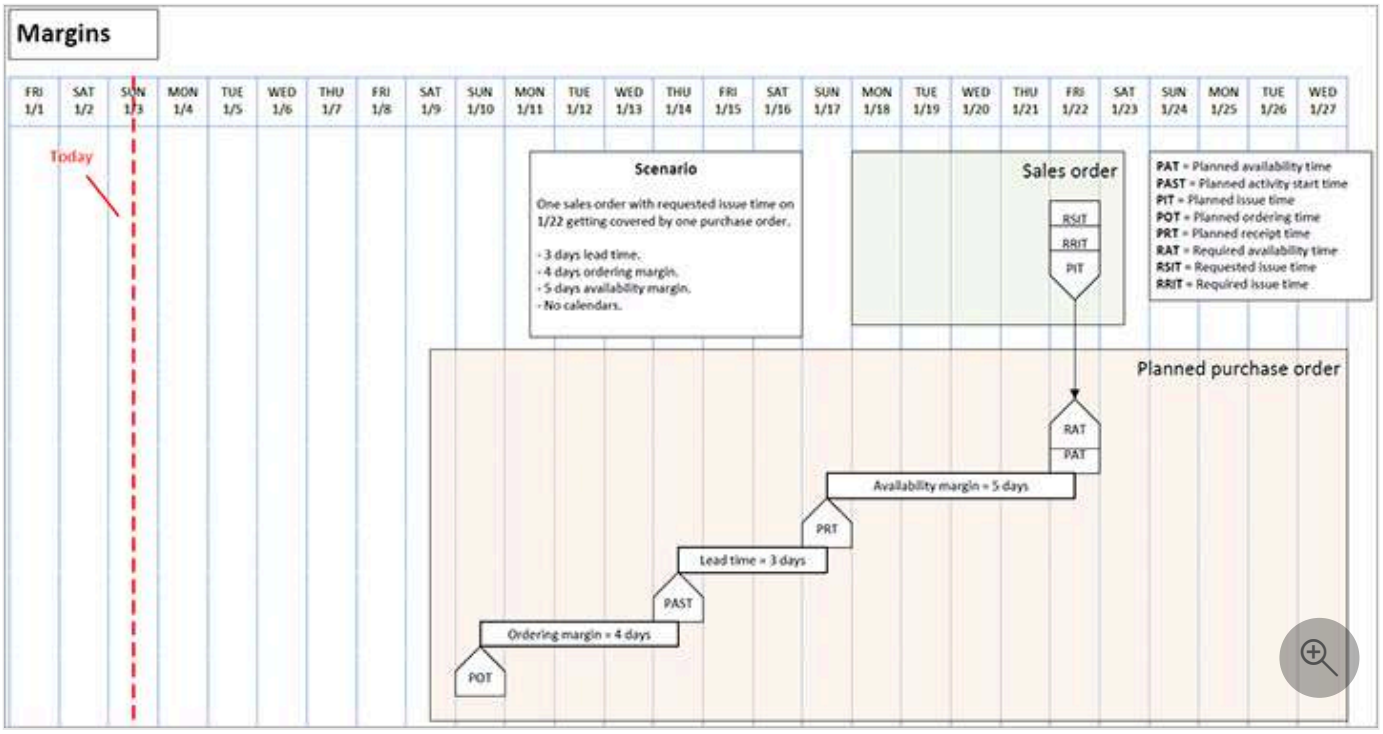


Example 3: Margin scenario

One sales order that has a requested issue time on January 22 is covered by one purchase order. The following settings are used:

- Three days of lead time
- Four-day ordering margin
- Five-day availability margin
- No calendars (All days are open.)

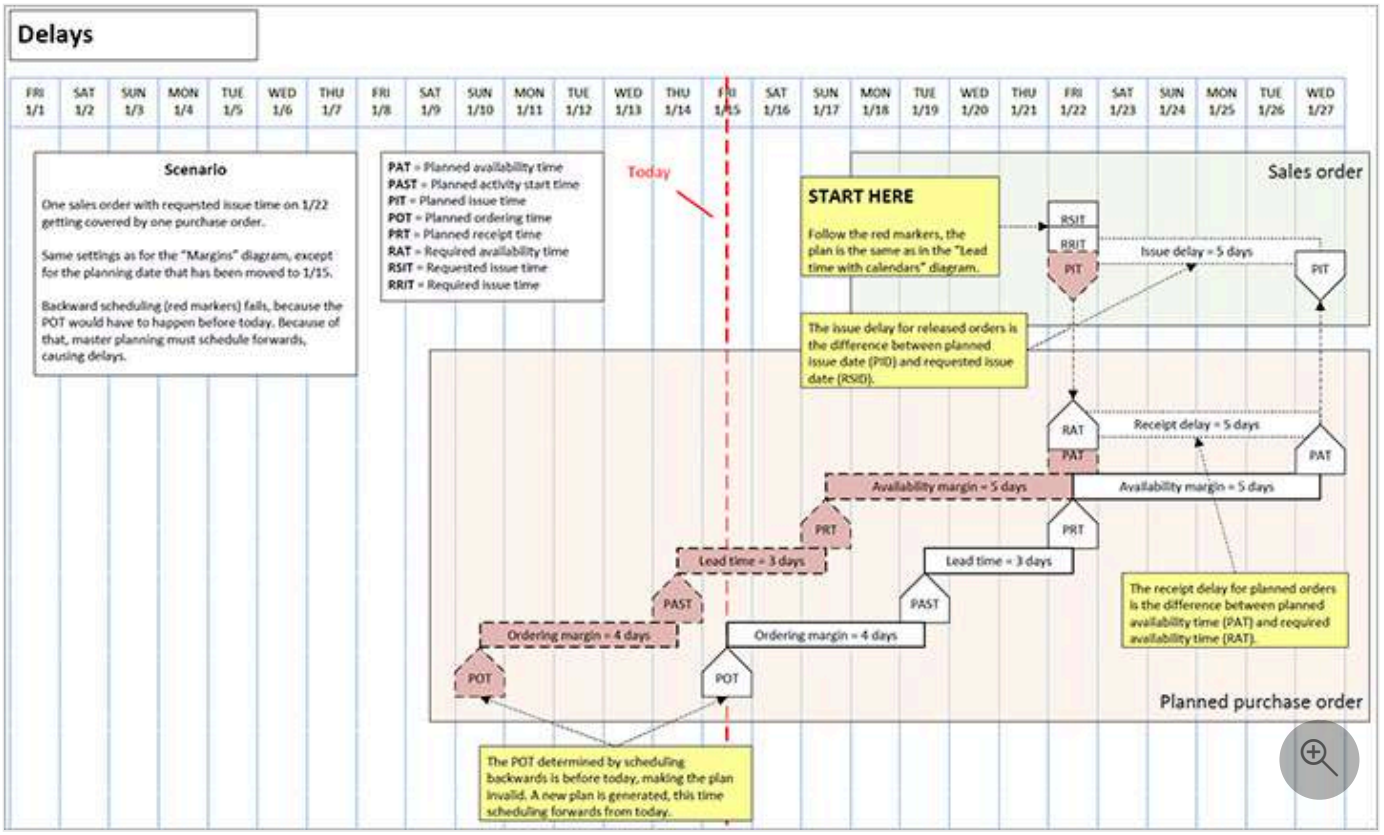
The following illustration shows this scenario. (Select the illustration to open a larger version.)



Example 4: Delay scenario

One sales order that has requested issue time on January 22 is covered by one purchase order. This example uses the same settings as example 3, but the planning date is moved to January 15. Backward scheduling (red markers) fails because the planned ordering time would have to be before today's date. Therefore, master planning must schedule forward, and delays occur.

The following illustration shows this scenario. (Select the illustration to open a larger version.)

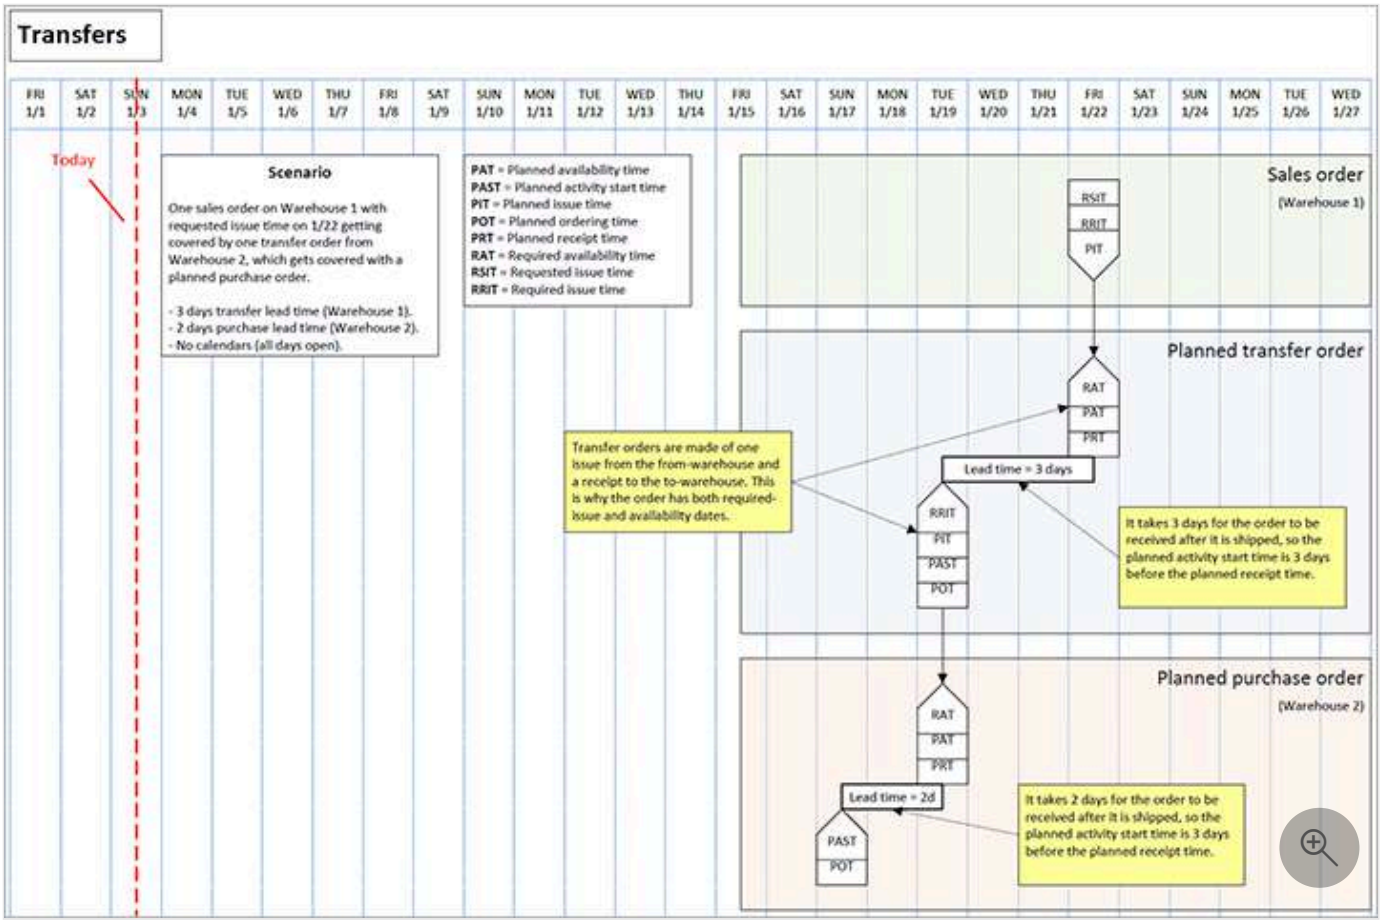


Example 5: Transfer scenario

One sales order from warehouse 1 that has a requested issue time on January 22 is covered by one transfer order from warehouse 2 that is covered by a planned purchase order. The following settings are used:

- Three days of transfer lead time (warehouse 1)
- Two days of purchase lead time (warehouse 2)
- No calendars (All days are open.)

The following illustration shows this scenario. (Select the illustration to open a larger version.)

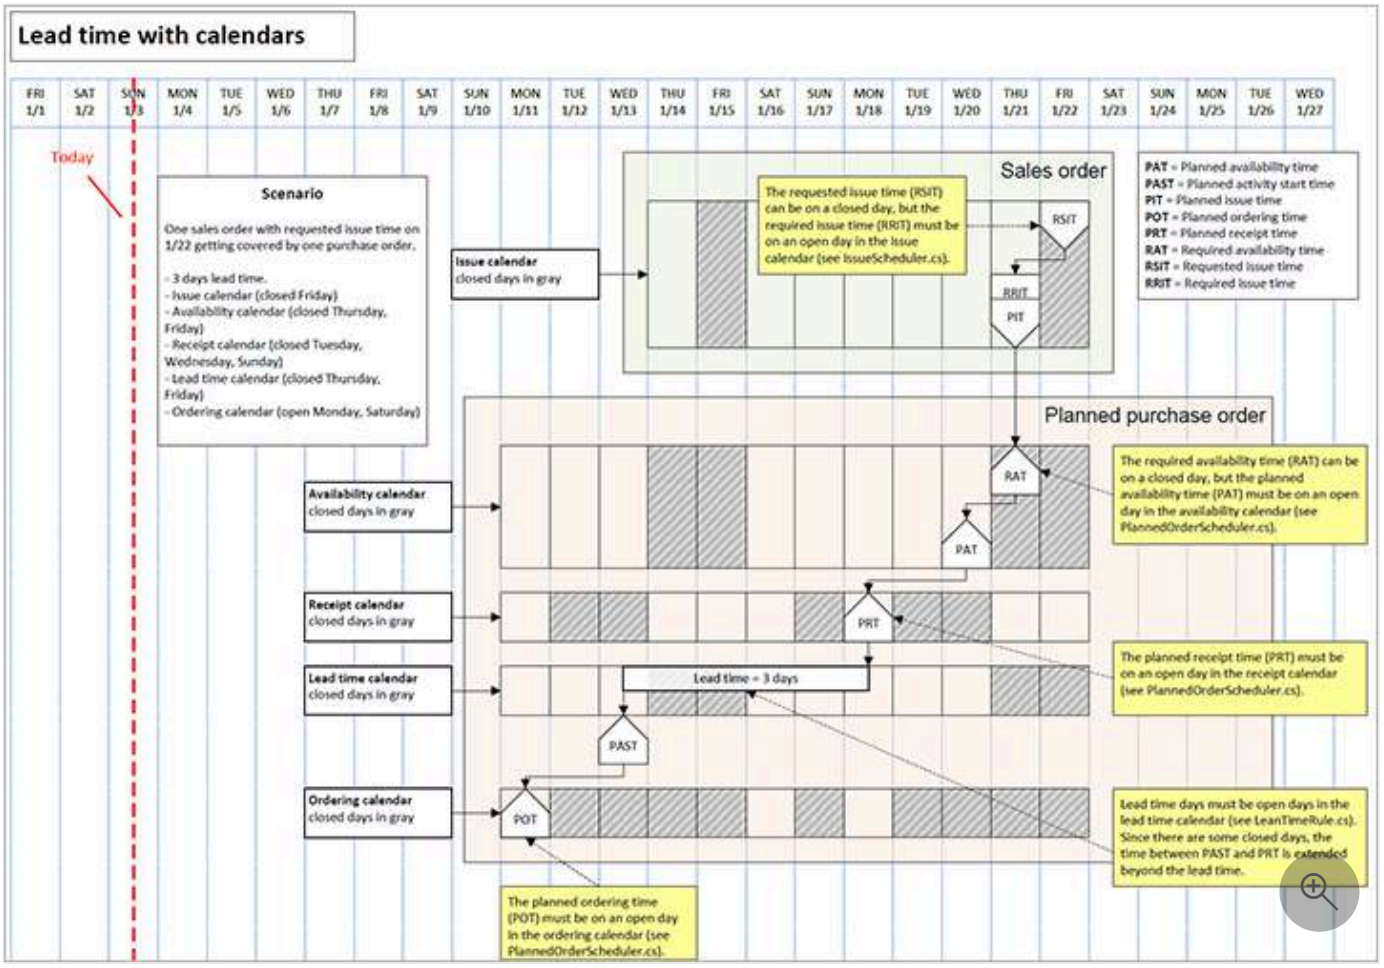


Example 6: Lead time with calendars scenario

One sales order that has a requested issue time on January 22 is covered by one purchase order. The following settings are used:

- Three days of lead time
- Issue calendar (closed on Friday)
- Availability calendar (closed on Thursday and Friday)
- Receipt calendar (closed on Tuesday, Wednesday, and Sunday)
- Lead time calendar (closed on Thursday and Friday)
- Ordering calendar (open on Monday and Saturday)

The following illustration shows this scenario. (Select the illustration to open a larger version.)



Example 7: Delay with calendars scenario

One sales order that has a requested issue time on January 22 is covered by one purchase order. This example uses the same settings as example 6, but the planning date is moved to January 13. Backward scheduling (red markers) fails because the planned ordering time would have to be before today's date. Therefore, master planning must schedule forward, and delays occur.

The following illustration shows this scenario. (Select the illustration to open a larger version.)

Delays

08/25/2025

This article provides information about delayed dates in master planning. A delayed date is a realistic due date that a transaction receives if the earliest fulfillment date that master planning calculates is later than the requested date.

Master planning can calculate the earliest fulfillment date for a transaction, based on lead times, material availability, capacity availability, and various planning parameters.

If master planning calculates an order date that precedes the current date, the order can't be fulfilled on time. Therefore, the order is delayed. In this case, master planning forward-plans the order from the current date and includes lead times. These lead times start with any lower-level component items. The order then receives a delayed date. A delayed date is a realistic due date, based on the current data. Master planning also calculates the number of delay days.

In some situations, you might choose not to calculate delays, such as when users know that they can expedite lead times by selecting alternative modes of delivery.

You can configure how delays are calculated for a coverage group. You can then attach the coverage group to an item later.

On the **Master planning parameters** page, you can set the start time for the calculation of delays. If an order is fulfilled after this time, a delay of one day is added to the delay date of the order.

> **Note**
>
> In earlier versions, calculated delays were known as *futures messages*, the delayed date was known as the *futures date*, and a delayed transaction was referred to as *a transaction that was future set*.

Limited delays in production setup with multiple BOM levels

When you work with delays in a production setup that has multiple bill of material (BOM) levels, it's important to note that only the items directly above the item (in the BOM structure) causing the delay, will be updated with a delay as part of the master planning run. Other items in the BOM structure won't get the delay applied until the first master planning run, when the planned order for the top level is approved or firmed.

To work around this known limitation, the production orders on the top of the BOM structure with delays can be approved (or firmed) before the next master planning run. This way the delay from the delayed approved planned production order will be kept and all underlying components will be updated accordingly.

Action messages can also be used to identify planned orders that can be moved to a later date, due to other delays in the BOM structure.

Desired date

On the **Planned order** page, under the **Delays** tab is the **Desired date** for the planned order. The desired date of a planned order is the base date for delays, which is a computed date that equals the **Requested date** calculated from the **Net Requirement**. If the planned order is a BOM line, production line, or kanban line, the desired date is based on the **Requirement date** and the desired date won't be shown on the **Planned order** page.

Use tracing for explosion

This article explains how you can use tracing to explore the causes behind the outcome of an order explosion.

By enabling tracing, you can view information about the factors that contributed to the outcome of the explosion of a particular order. The following examples show how you can use the tracing information:

- View relations between the actions on planned orders to optimize the supply chain and inventory reservations.
- View relations to orders that are already approved. You can focus on automatically firming derived requirements and then prioritize orders more accurately.
- Simulate planning results to determine whether the planning parameters are optimal.
- Identify how information such as production dates, quantities, and priorities for an order were determined.

You can view details about futures and actions for a selected order. On the **Explosion** page, tracing information is available on the **Explanation** tab in the upper pane. Tracing occurs when you explode an order. To start tracing for the order, click **Update**, and then select the **Enable trace** check box. You can use the **Find text** field to search the log for specific information. Search results are highlighted in the tree.

Make-to-order supply automation

08/22/2025

The *Make-to-order supply automation* feature adds several enhancements to Microsoft Dynamics 365 Supply Chain Management. These enhancements let you perform the following tasks:

- View the resource capacity load for a user-defined period, and therefore enable long-term evaluation of the capacity load.
- Improve flexibility by controlling the delay tolerance (negative days) for each master plan.
- Keep products available for last-minute orders and optimize the use of existing supply by pegging the latest possible supply to a demand instead of using the first possible supply.
- Keep component assignment flexible for production orders after firming, so that the system can optimize for last-minute demand changes. In other words, limit marking to one level.
- Control the fulfillment policy for each sales order. Default settings are taken from the customer setup.
- Enhance intercompany information flow. Purchase orders are updated so that they include fields for the mode of delivery, delivery terms, and external item number. This change ensures that detailed demand information can flow to the supplying company.

This article describes how to set up and use each enhancement.

Set the number of days to show on Capacity load page

The **Capacity load** page lets you review a resource's available capacity. The *Make-to-order supply automation* feature enhances the **Capacity load** page by adding a **Number of days** field. You can use this field to limit the number of days that the **Overview** grid shows. The value that you set is saved in memory. Therefore, if you leave the page and then return later, the **Overview** grid will still show the number of days that you last specified.

To open the **Capacity load** page so that you can review the available capacity for an individual resource, follow these steps.

1. Go to **Organization administration** > **Resources** > **Resources**.
2. Select a resource to inspect.
3. On the Action Pane, on the **Resource** tab, in the **View** group, select **Capacity load**.
4. Use the **Number of days** filter to limit the number of days that the **Overview** grid shows.

To open the **Capacity load** page so that you can review the available capacity for a resource group, follow these steps.

1. Go to **Organization administration** > **Resources** > **Resource groups**.
2. Select a resource group to inspect.
3. On the Action Pane, on the **Resource group** tab, in the **View** group, select **Capacity load**.
4. Use the **Number of days** filter to limit the number of days that the **Overview** grid shows.

Apply a single level of marking when you firm planned orders

Marking is used to link supply and demand. It resembles *pegging*, which indicates how master planning expects to cover demand. However, marking is more permanent than pegging. The *Make-to-order supply automation* feature adds the ability to limit inventory marking to a single level when planned orders are firmed. It adds the following new options to the **Update marking** field in the **Firming** dialog box when you're firming a planned order:

- *Single level standard* – Single-level marking is used. Single-level marking marks only the main item, not its bill of materials (BOM) components. Therefore, you can keep component assignment for production orders flexible after firming. Single-level marking enables the system to optimize for last-minute demand changes. In *standard* single-level marking, requirement orders are marked against their fulfillment orders, but fulfillment orders aren't marked if they have remaining quantity.
- *Single level extended* – Single-level marking is used. In *extended* single-level marking, requirement orders are marked against their fulfillment orders, and fulfillment orders are always marked, regardless of whether any quantity remains.

These options are also available in the **Update marking** field on the **Standard update** tab of the **Master planning parameters** page, where you define the default selection for the **Firming** dialog box.

Learn more in Inventory marking.

Set delay tolerance (negative days) at the master plan level

The *Make-to-order supply automation* feature adds the ability to configure delay tolerance (negative days) at the master plan level. The setting is also available at the item coverage and coverage group levels. If negative days are assigned at more than one level, the system applies the following hierarchy to decide which setting to use:

- If negative days are configured on the **Master plans** page, that setting overrides all other negative days settings when the plan runs.
- If negative days are configured on the **Item coverage** page, that setting overrides the coverage group setting.
- Negative days that are configured on the **Coverage groups** page apply only if negative days haven't been configured for a relevant item or master plan.

To set negative days for a master plan, follow these steps.

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Select a master plan in the list pane, or create a new one.
3. On the **Time fences in days** FastTab, set the **Negative days** option to *Yes*.
4. In the nearby field, enter the number of negative days to allow.

For more information about how to use negative days, see Delay tolerance (negative days).

Control the pegging sequence used during master planning

Master planning uses a *pegging sequence* to determine which supply will cover which demand. The *Make-to-order supply automation* feature adds a new **Use latest possible supply** option that gives you more control over the pegging sequence. The new option lets you keep products available for last-minute orders and optimize the use of existing supply by pegging the latest possible supply to a demand instead of using the first possible supply.

You can set the pegging sequence at the master plan, item coverage, or coverage group level. If a pegging sequence is set up at more than one level, the system applies the following hierarchy to decide which setting to use:

- If a pegging sequence is set up on the **Master plans** page, that setting overrides all other pegging sequence settings when the plan runs.
- If a pegging sequence is set up on the **Item coverage** page, that setting overrides the coverage group setting.
- The pegging sequence that is set up on the **Coverage groups** page applies only if pegging sequence settings haven't been configured for a relevant item or master plan.

To set up pegging at the coverage group level, follow these steps.

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.
2. Select a group in the list pane, or create a new one.
3. On the **General** FastTab, in the **Pegging sequence** section, use the **Consume on-hand inventory** and **Use latest supply** fields to configure your pegging sequence. The table

later in this section shows how these settings are combined to define your pegging sequence.

To set up pegging at the item coverage level, follow these steps.

1. Go to **Product information management** > **Products** > **Released products**.
2. Select a product in the grid, or create a new one.
3. On the Action Pane, on the **Plan** tab, select **Item coverage**.
4. The **Item coverage** page provides rows that let you define coverage rules that apply to the item at each warehouse. Select an existing row in the grid, or create a new one.
5. On the **General** tab, select the **Override pegging sequence** checkbox.
6. Use the **Consume on-hand inventory** and **Use latest supply** fields to configure your pegging sequence. The table later in this section shows how these settings are combined to define your pegging sequence.

To set up pegging at the master plan level, follow these steps.

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Select a master plan in the list pane, or create a new one.
3. On the **General** FastTab, set the **Override pegging sequence** option to *Yes*.
4. Use the **Consume on-hand inventory** and **Use latest supply** fields to configure your pegging sequence. The table later in this section shows how these settings are combined to define your pegging sequence.

The following table shows how the **Consume on-hand inventory** and **Use latest supply** settings are combined to establish your pegging sequence.

Expand table

	Use latest supply = Yes	**Use latest supply = No**
Consume on-hand inventory = *Before all supply*	1. On-hand 2. Existing supply that can meet the demand date 3. Existing supply that can't meet the demand date, but still within negative days 4. Create new supply (planned order)	1. On-hand 2. Existing supply that can meet the demand date 3. Existing supply that can't meet the demand date, but still within negative days 4. Create new supply (planned order)
Consume on-hand inventory = *After all supply*	1. Existing supply that can meet the demand date 2. On-hand	1. Existing supply that can meet the demand date 2. Existing supply that can't meet the demand date, but still within

	Use latest supply = Yes	Use latest supply = No
	3. Existing supply that can't meet the demand date, but still within negative days 4. Create new supply (planned order)	negative days 3. On-hand 4. Create new supply (planned order)

Review and set the fulfillment policy that applies to each sales order

Fulfillment policies control the percentage of the total order price or quantity that must be physically reserved before you can release a sales order to the warehouse. You can set a global default fulfillment policy and then override it for specific customers as you require. The *Make-to-order supply automation* feature adds the ability to view what default policy actually applies to any order and apply an order-specific override as required.

- To set the global fulfillment policy default for sales orders, go to **Accounts receivable** > **Setup** > **Accounts receivable parameters**. Then, on the **Warehouse management** tab, set the **Sales order fulfillment policy** field to the name of the policy that you want to use.
- To set a customer-specific fulfillment policy for sales orders, go to **Accounts receivable** > **Customers** > **All customers**. Then, on the **Warehouse** tab, set the **Fulfillment policy** field to the name of the policy that you want to use.

To view the default policy that applies to any order and apply an order-specific override, follow these steps.

1. Go to **Sales and marketing** > **Sales orders** > **All sales orders**.
2. Open the sales order that you want to inspect or edit.
3. Select the **Header** view.
4. On the **Warehouse** FastTab, review and edit the following fields as required:
    - **Order fulfillment policy** – Select the fulfillment policy to use for the selected order. The default policy will be overridden. To use the default fulfillment policy that is shown in the **Default fulfillment policy** field, leave this field blank.
    - **Default fulfillment policy** – This field shows the default fulfillment policy that applies if the **Order fulfillment policy** field is blank. This field is read-only. If it's blank, no customer-specific or global default fulfillment policy is defined.

If both the **Order fulfillment policy** field and the **Default fulfillment policy** field are blank, no fulfillment policy applies. However, other restrictions might be in place, and might require that reservations or other conditions be met before the sales order can be released.

Set the delivery mode and terms on individual purchase order lines

All purchase orders include **Delivery terms** and **Mode of delivery** settings on the order header. The *Make-to-order supply automation* feature adds these settings to each order line. Therefore, you can define overrides of the **Delivery terms** and/or **Mode of delivery** value for any or all order lines as required. For lines where no override is defined, the value from the header is used. You can specify whether a change to the value of one or both of these fields on the order header should also update all lines.

To specify what should happen to line settings if a user changes the **Delivery terms** and/or **Mode of delivery** value on an order header, follow these steps.

1. Go to **Procurement and sourcing** > **Setup** > **Procurement and sourcing parameters**.
2. On the **General** tab, on the **Default values and parameters** FastTab, select the **Update order lines** link.
3. In the **Update order lines** dialog box, in the **Updating Delivery terms** and **Update Mode of delivery** fields, select one of the following values:
    - *Never* – Never update the order lines after the settings are changed on the order header.
    - *Always* – Always update all order lines after the settings are changed on the order header.
    - *Prompt* – If a user changes one or both settings on the order header, open a dialog bot that asks whether the user wants to update all lines so that they match the change to one or both settings.

To set delivery information on a purchase order header, follow these steps.

1. Go to **Procurement and sourcing** > **Purchase orders** > **All purchase orders**.
2. Open the purchase order that you want to edit.
3. Select the **Header** view.
4. On the **Delivery** FastTab, set the **Mode of delivery** and **Delivery terms** fields as required.
5. Depending on the settings on the **Procurement and sourcing parameters** page, you might be asked whether you want to apply your changes to all order lines.

To set delivery information overrides for a purchase order line, follow these steps.

1. Go to **Procurement and sourcing** > **Purchase orders** > **All purchase orders**.
2. Open the purchase order that you want to edit.
3. Select the **Lines** view.
4. On the **Purchase order lines** FastTab, select the line to edit.
5. On the **Line details** FastTab, on the **Delivery** tab, set the **Mode of delivery** and **Delivery terms** fields as required. Clear one or both fields to use the matching settings on the header.

For intercompany orders, values for the **Mode of delivery** and **Delivery terms** fields on each purchase order line will be synced between the purchase order and its related sales order.

Sync external item IDs and descriptions for intercompany orders

For intercompany orders, the *Make-to-order supply automation* feature enables external item IDs and text descriptions on purchase order lines to be synced with the related intercompany sales order lines, regardless of whether the purchase order is for direct delivery. The feature also adds the ability to specify the final external customer account on an intercompany purchase order. The system will then automatically take external item IDs and text descriptions from the external customer record instead of the (internal) intercompany vendor record.

To set up an intercompany vendor to sync external item IDs and item names between intercompany purchase orders and their related intercompany sales orders, follow these steps.

1. Go to **Procurement and sourcing** > **Vendors** > **All vendors**.
2. Select the intercompany vendor that you want to set up.
3. On the Action Pane, on the **General** tab, in the **Set up** group, select **Intercompany**.
4. On the **Intercompany** page, on the **Purchase order polices** tab, in the **Intercompany purchase order -> Intercompany sales order** section, select the **External item ID and item name** checkbox.

To specify the final external customer account for an intercompany purchase order, follow these steps. The **Customer account** field applies only to intercompany purchase orders. Use it to specify the account number of the customer who will eventually receive the goods. When this field is set, purchase order lines will take external item descriptions and numbers from the specified customer account instead of the intercompany vendor that is specified on the purchase order. If you change the customer account later, external item descriptions and IDs will be updated so that they match the values for the new account. External item descriptions and IDs for each line will also be synced to the matching intercompany sales order.

1. Go to **Procurement and sourcing** > **Purchase orders** > **All purchase orders**.
2. Open the purchase order that you want to set up, or create a new one.
3. Select the **Header** view.
4. In the **Reference** section, set the **Customer account** field to the relevant external customer account.

To specify external item IDs and text descriptions for a purchase order line for an intercompany order, follow these steps. The values that you set will be synced with the related intercompany sales order lines, regardless of whether the purchase order is for direct delivery.

1. Go to **Procurement and sourcing** > **Purchase orders** > **All purchase orders**.
2. Open the purchase order that you want to set up, or create a new one.
3. Select the **Lines** view.
4. On the **Purchase order lines** FastTab, select the line to edit.
5. On the **Line details** FastTab, on the **General** tab, in the **Order line** section, in the **Text** field, provide an external description of the item that is specified on the selected order line. This value will be synced with the related intercompany sales order line.
6. In the **Reference** section, in the **External** field, provide an external item ID for the item that is specified on the selected order line. This value will be synced with the related intercompany sales order line.

Negative days and dynamic negative days

08/25/2025

This article provides information about negative days and dynamic negative days, and how you can use them to help your business. The *negative days time fence* represents the number of days that you're willing to wait before you order new replenishment when you have negative inventory.

In this article, you'll learn the following information:

- How planned orders are created
- The correlation between the negative days time fence and the item's lead time
- How the dynamic negative days time fence is calculated, and how the item's lead time is factored into the calculation
- How to interpret the suggestions for improving the running time for material requirements planning (MRP) (master planning) that are related to negative days

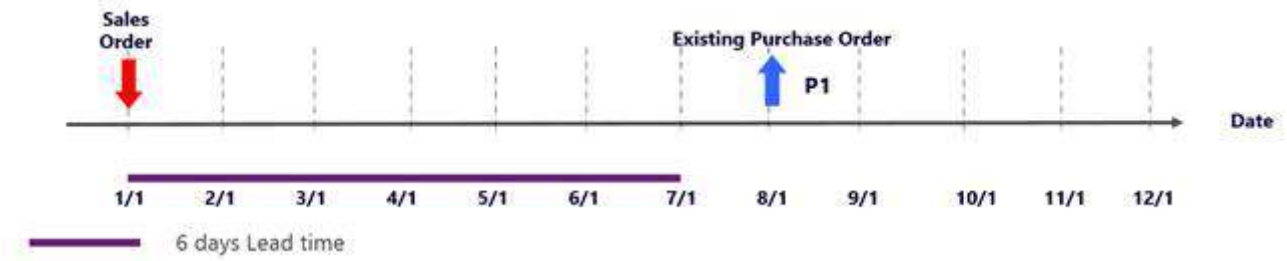
This article uses three hypothetical scenarios to help you understand this information. The difference between the scenarios is the point at which you get demand: before, during, or after the item's lead time period.

Scenario 1: You get demand before the item's lead time period

You might get demand either relatively early in your item's lead time or just before the lead time period begins. Here's an example of this scenario:

- The DemoProduct item has a six-day purchase lead time.
- On day zero (January 1), the inventory level for the DemoProduct item is 0 (zero).
- On day zero (January 1), you get a sales order for a quantity of 10 of the DemoProduct item.
- On day seven (January 8), there's an existing purchase order for a quantity of 10 of the DemoProduct item.

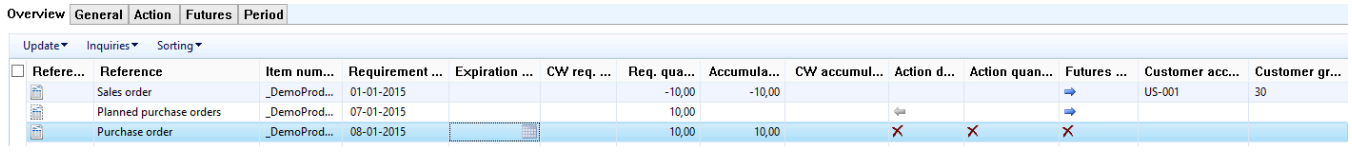
The following illustration shows a graphical view of this scenario.



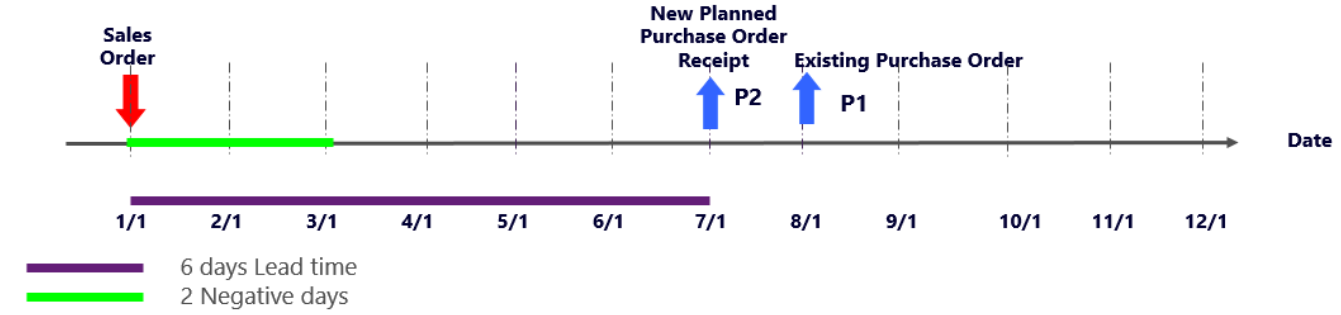
Case 1A: Negative days are less than the item's lead time

If you set the negative days to a number that is less than the item's lead time, MRP looks for receipts for the DemoProduct item inside the negative days time fence. Because it doesn't find any receipts, MRP creates a new planned purchase order. This planned order is immediately delayed by six days (the lead time). Therefore, it will arrive on January 7. The existing purchase order gets a **Cancel** action message, because the creation of the new planned purchase order has made it redundant.

The following illustration shows a screenshot of this case.



The following illustration shows a graphical view of what occurs in this case.



If you consider MRP performance and plan nervousness, this case doesn't perform well. MRP must create a new planned order, and must calculate delays and actions. These tasks are time-consuming. This case also adds two more transactions to your plan. On the other hand, the sales order is delayed by only six days, not seven days.

Case 1B: Negative days are more than the item's lead time

To help improve MRP performance, you can set the negative days to a number that is more than the item's lead time. Because you can't get the supply inside the lead time in this scenario,

you can search for receipts for as long as this search makes sense. Although the running time for MRP will be shorter, you should watch out for additional delays to the orders.

Case 1C: Automatically correlate the item's lead time to the negative days time fence

To automatically correlate the item's lead time to the negative days time fence, use dynamic negative days. To use dynamic negative days, go to **Master planning** > **Setup** > **Master planning parameters**, and then, on the **General** tab, in the **Coverage** section, set the **Use dynamic negative days** option to *Yes*. MRP then looks for receipts inside the dynamic negative days time fence. This time fence is calculated by using the following formula:

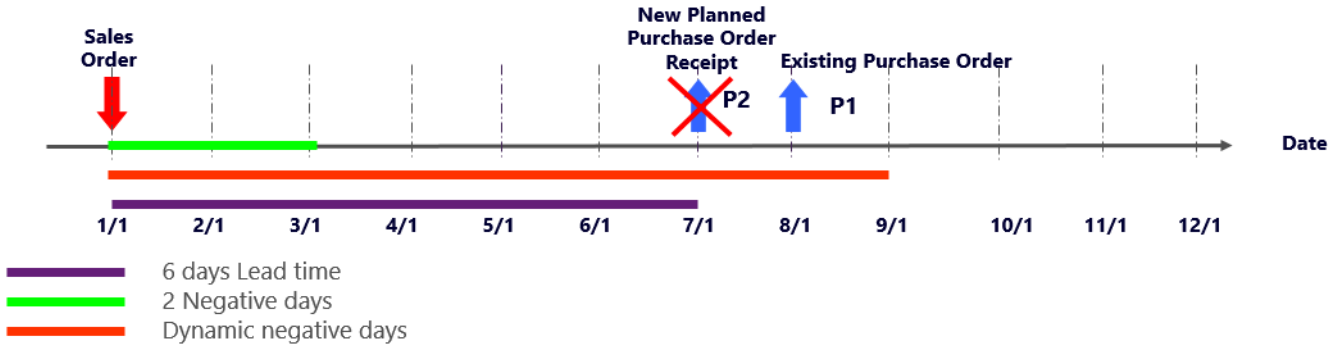
Dynamic negative days time fence = Purchase lead time + Negative days time fence + (Current date – Requirement date)

(If the default order type of the DemoProduct item is *Production* or *Transfer*, the lead time is the *inventory* lead time.)

When dynamic negative days are used, the time fence that MRP looks at for receipts is now 6 + 2 + 0 = 8 days. MRP finds the existing purchase order and pegs the sales order against it. No new planned orders are created. Therefore, the running time for MRP is shorter. The following illustration shows the net requirements for the DemoProduct item.

Reference	Reference	Number	Item number	Requireme...	Expiration date	CW req. qty	Req. quantity	Accumulated	CW accumulated	Action date	Action quantity	Futures date
	Sales order	000787	_DemoProd...	01-Jan-15			-10.00	-10.00				
	Purchase order	000044	_DemoProd...	08-Jan-15			10.00					

The following illustration shows a graphical view of what occurs in this case.

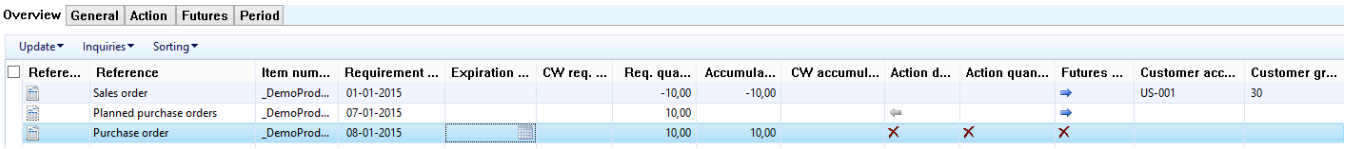


Case 1D: Use only dynamic negative days

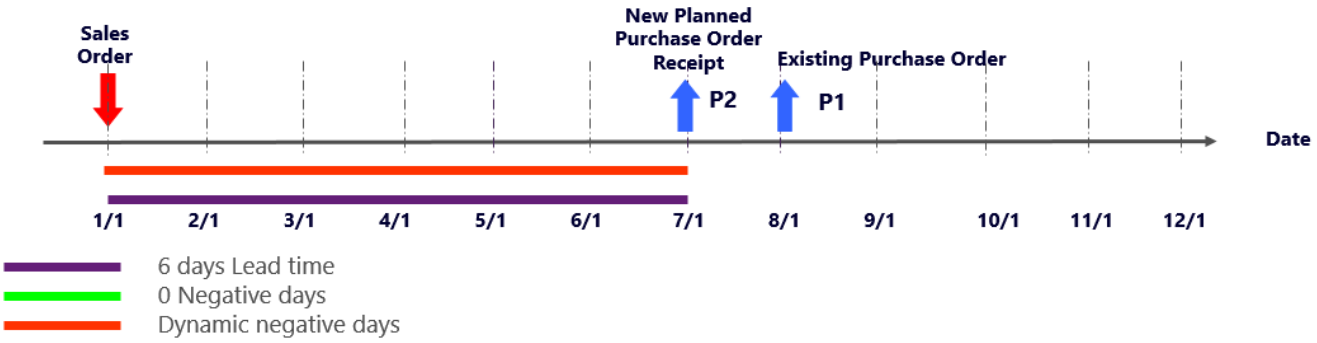
If you set the negative days to *0* (zero) and use only the dynamic negative days time fence, the dynamic negative days time fence is 6 + 0 + 0 = 6 days. In this case, the result is the same as the result in case A for this scenario. MRP must create a new planned order, and must calculate delays and actions. These tasks are time-consuming and can also be frustrating. You also have

two more transactions to process. Because the demand can't be fulfilled on time for the item to arrive, this case adds unnecessary complications to your plan.

The following illustration shows a screenshot for this case.



The following illustration shows a graphical view of what occurs in this case.



Case 1E: Use both negative days that are more than the item's lead time and the dynamic negative days time fence

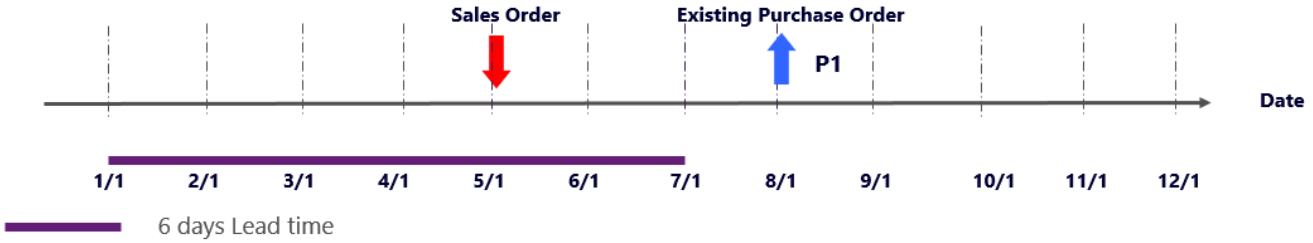
If you set the negative days to a number that is more than the item's lead time, and if you also use the dynamic negative days time fence, the dynamic negative days time fence is 6 + 6 + 0 = 12 days. This approach might produce a very long time fence that MRP must search for results in. For information about how case E is related to a situation where you set the negative days to a long time fence, see the Conclusion section of this article.

Scenario 2: You get demand during the item's lead time period

You might get demand sometime during your item's lead time. Here's an example of this scenario:

- The DemoProduct item has a six-day purchase lead time.
- On day zero (January 1), the inventory level for the DemoProduct item is 0 (zero).
- On day four (January 5), which is inside the item's lead time, you get a sales order for a quantity of 10 of the DemoProduct item.
- On day seven (January 8), there's a purchase order for a quantity of 10 of the DemoProduct item.

The following illustration shows a graphical view of this scenario.



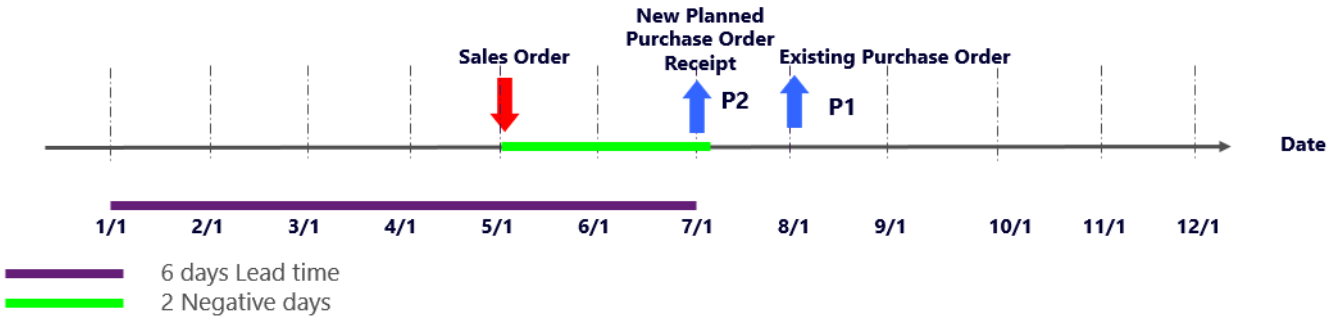
Case 2A: Negative days are less than the item's lead time

If you set the negative days to a number that is less than the item's lead time, MRP looks for receipts for the DemoProduct item inside the negative days time fence. Because it doesn't find any receipts, MRP creates a new planned purchase order that uses the current date as the order date. This planned order is immediately delayed by six days (the lead time). Therefore, it will arrive on January 7. The existing purchase order gets a **Cancel** action message, because the creation of the new planned purchase order has made it redundant.

The following illustration shows a screenshot for this case.

Refere...	Reference	Numb...	Item num...	Requirem...	Expiration ...	CW req. ...	Req. qua...	Accumula...	CW accumul...	Action d...	Action quan...	Futures ...
	Sales order	000787	_DemoProd...	05-Jan-15			-10.00	-10.00				
	Planned purchase orders	013283	_DemoProd...	07-Jan-15			10.00					
	Purchase order	000044	_DemoProd...	08-Jan-15			10.00	10.00				

The following illustration shows a graphical view of what occurs in this case.



Case 2B: Negative days are more than the item's lead time

This case resembles case B for scenario 1. If you set the negative days to a number that is more than the item's lead time, you don't get a new planned order. The sales order is attached to the existing purchase order.

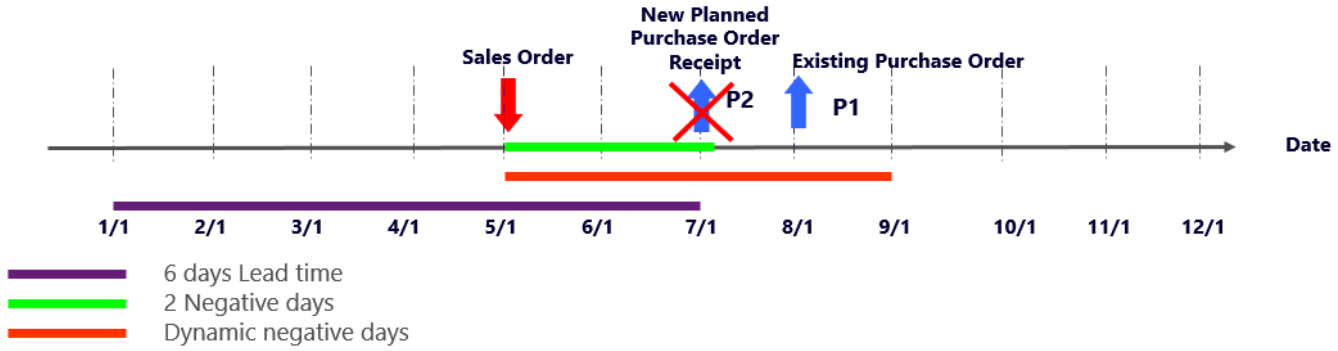
Case 2C: Automatically correlate the item's lead time to the negative days time fence

This case resembles case C for scenario 1, because dynamic negative days work just as well as they do in that case. The dynamic negative days time fence is now 6 + 2 – 4 = 4 days. If you use this approach, MRP finds the existing purchase order and attaches the sales order to it. Because no new planned orders are created, the running time for MRP is shorter.

The following illustration shows a screenshot of this case.

Reference	Reference	Number	Item number	Requirement ...	Expiration date	CW req. qty	Req. quantity	Accumulated	CW accumulated	Action date	Action quantity	Futures date
	Sales order	000787	_DemoProd...	05-Jan-15			-10.00	-10.00				
	Purchase order	000044	_DemoProd...	08-Jan-15			10.00					

The following illustration shows a graphical view of what occurs in this case.



Case 2D: Use only dynamic negative days

If you set the negative days to *0* (zero) and use only the dynamic negative days time fence, the dynamic negative days time fence is now 6 + 0 – 4 = 2 days. In this case, the result is the same as the result in case A for this scenario. For a graphical view of what occurs, see case A for this scenario.

Case 2E: Use both negative days that are more than the item's lead time and the dynamic negative days time fence

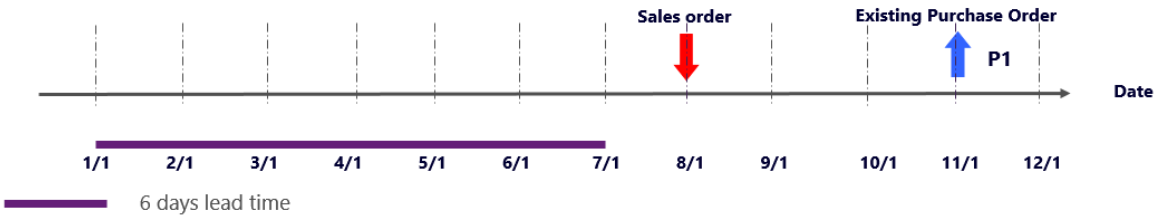
If you set the negative days to a number that is more than the item's lead time, and if you also use the dynamic negative days time fence, the dynamic negative days time fence is 6 + 6 – 4 = 8 days. This approach might produce a very long time fence that MRP must search for results in. For information about how case E is related to a situation where you set the negative days to a long time fence, see the Conclusion section of this article.

Scenario 3: You get demand after the item's lead time period

You might get demand after the item's lead time. Here's an example of this scenario:

- The DemoProduct item has a six-day purchase lead time.
- On day zero (January 1), the inventory for the DemoProduct item is 0 (zero).
- On day seven (January 8), which is outside the item's lead time, you get a sales order for a quantity of 10 of the DemoProduct item.
- On day ten (January 11), there's a purchase order for a quantity of 10 of the DemoProduct item.

The following illustration shows a graphical view of this scenario.



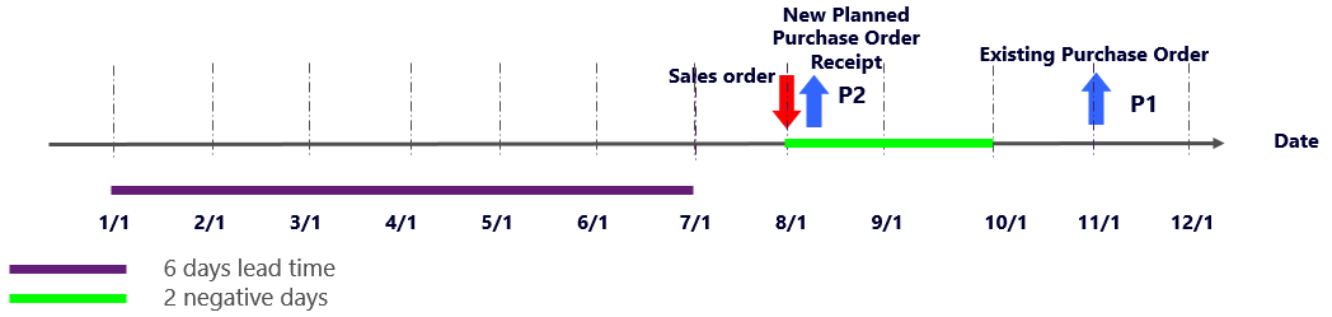
Case 3A: Negative days are less than the item's lead time

If you set the negative days to a number that is less than the item's lead time, MRP looks two days ahead of the sales order's requirement date. Because it doesn't find anything, MRP creates a planned purchase order on January 2. This planned purchase order will be shipped just in time to fulfill the sales order demand. The existing purchase order gets a **Cancel** action message, because it isn't required.

The following illustration shows a screenshot of this case.

Reference	Reference	Number	Item number	Requirement ...	Expiration date	CW req. qty	Req. quantity	Accumulated	CW accumulated	Action date	Action quantity	Futures date
	Planned purchase orders	013695	_DemoProd...	08-Jan-15			10.00	10.00				
	Sales order	000787	_DemoProd...	08-Jan-15			-10.00					
	Purchase order	000044	_DemoProd...	12-Jan-15			10.00	10.00		✕	✕	✕

The following illustration shows a graphical view of what occurs in this case.



> **Note**
>
> In the preceding screenshot, the purchase order requirement date is January 12. Because that screenshot was taken in 2015, when January 11 was a Sunday, MRP moved the

requirement date to the next working day, which was Monday, January 12. Nevertheless, the purchase order has a delivery date of January 11.

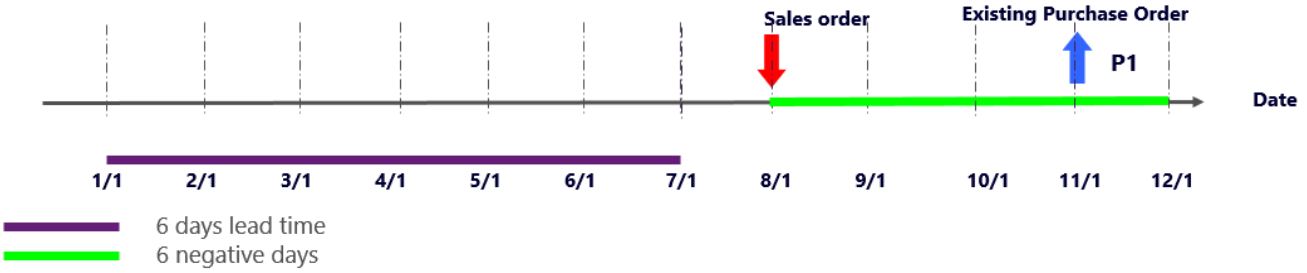
Case 3B: Negative days are more than the item's lead time

If you set the negative days to a number that is more than the item's lead time, you don't get a new planned order. The sales order is pegged against the existing purchase order. Therefore, the sales order is delayed. If you create a planned order, you can ship the sales order on time.

The following illustration shows a screenshot of this case.

Reference	Reference	Number	Item number	Requirement ...	Expiration date	CW req. qty	Req. quantity	Accumulated	CW accumulated	Action date	Action quantity	Futures date
	Sales order	000787	_DemoProd...	08-Jan-15			-10.00	-10.00				
	Purchase order	000044	_DemoProd...	12-Jan-15			10.00					

The following illustration shows a graphical view of what occurs in this case.

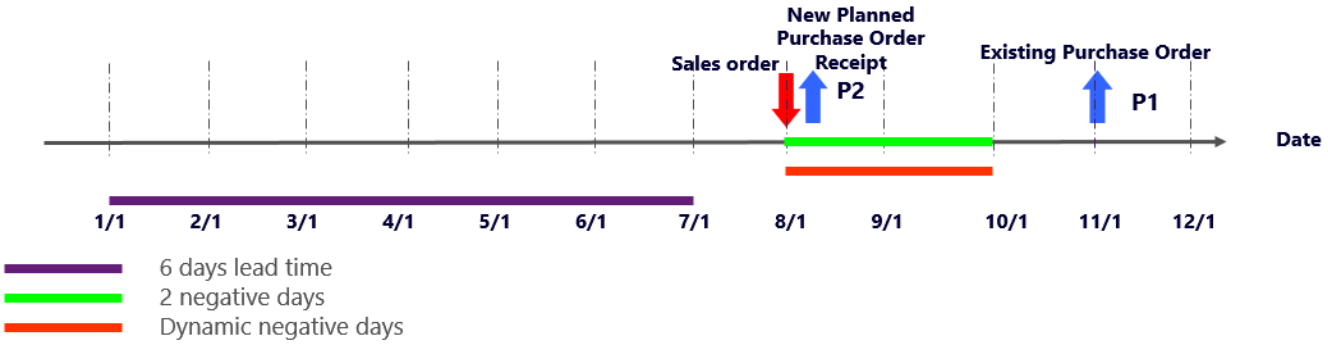


Case 3C: Automatically correlate the item's lead time to the negative days time fence

This case resembles case C for scenario 1, because dynamic negative days work just as well as, if not better than, they work in case B for this scenario.

The dynamic negative days time fence is 6 + 2 – 7 = 1 day. However, in this case, the system still considers the negative days lead time (2), because MRP considers the maximum value between the negative days lead time and the dynamic negative days lead time. Therefore, the result in this case is the same as the result in case A for this scenario.

The following illustration shows a graphical view of what occurs in this case.



Case 3D: Use only dynamic negative days

If you set the negative days to *0* (zero) and use only the dynamic negative days time fence, the dynamic negative days time fence is now 6 + 0 – 7 = -1 day. In this case, the system still considers the negative days lead time (2). Therefore, the result in this case is the same as the result in case A for this scenario and has all the same drawbacks. For a graphical view of what occurs, see case A for scenario 2.

Case 3E: Use both negative days that are more than the item's lead time and the dynamic negative days time fence

This case is the same as case E for scenarios 1 and 2. It has basically the same benefits and drawbacks.

Conclusion

As the three scenarios in this article show, it's a good idea to set the negative days to a number that is more than the lead time of the items in the coverage group. It's also a good idea to use only dynamic negative days, and to set the negative days to the number of days that you're willing to wait before you order new replenishment when you have negative inventory (in other words, the number of days that you're willing to further delay demand). Additionally, items in the same coverage group should have similar lead times.

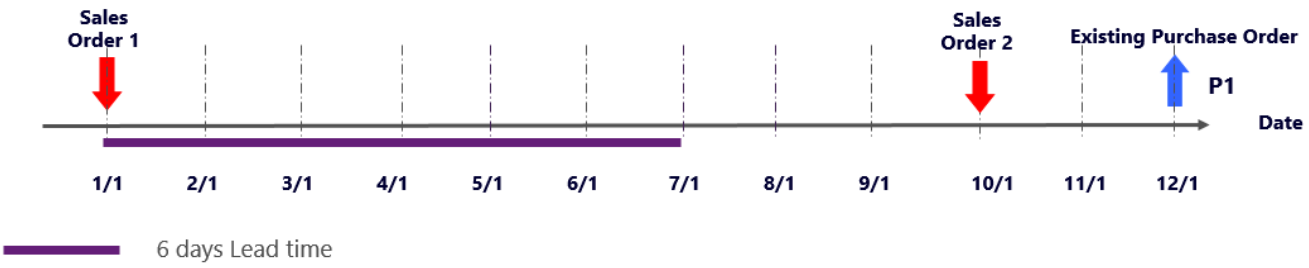
If you set the negative days to *0* (zero) and don't use dynamic negative days, MRP always creates a new planned order to fulfill demand. In this situation, it's important that you work with the action messages to make sure that you don't pile up inventory.

You might want to set the negative days to a long time fence and then work with the action messages. This approach produces good planning results, but it's also a bit slower. It might also be more difficult to analyze, because you must analyze and apply the action messages. Here's an example:

- The DemoProduct item has a six-day purchase lead time.

- On day zero (January 1), the inventory for the DemoProduct item is 0 (zero).
- On day zero (January 1), you get a sales order for a quantity of 10 of the DemoProduct item.
- On day nine (January 10), you get a sales order for a quantity of 10 of the DemoProduct item.
- On day eleven (January 12), there's a purchase order for a quantity of 10 of the DemoProduct item.
- Negative days are set to *20*, which is much more than the item's lead time.

The following illustration shows a graphical view of what occurs.



MRP produces the following results.

Reference	Reference	Number	Item number	Requirement ...	Expiration date	CW req. qty	Req. quantity	Accumulated	CW accumulated	Action date	Action quantity	Futures date
	Sales order	000787	_DemoProd...	01-Jan-15			-10.00	-10.00				
	Planned purchase orders	012459	_DemoProd...	09-Jan-15			10.00					
	Sales order	000788	_DemoProd...	09-Jan-15			-10.00	-10.00				
	Purchase order	000044	_DemoProd...	12-Jan-15			10.00					

In the preceding screenshot, the sales order requirement date is January 9 instead of January 10. Because that screenshot was taken in 2015, when January 10 was a Saturday, the requirement date of the order should be the previous working day, which was Friday, January 9.

MRP creates a planned purchase order to fulfill the demand that is requested by the first sales order, but then it also recommends that you cancel the planned order, because you can advance the existing purchase order and increase the quantity on it.

The results aren't wrong, but the running time for MRP might be longer, because MRP must create all the delays and suggestions. Additionally, the planner might require more time to understand the MRP results. Most importantly, in this case, it's essential that the planner understands and uses the action messages.

If you reduce the negative days to a number that's closer to the item's lead time, and you use dynamic negative days, MRP produces the following results.

Reference	Reference	Number	Item number	Requirement ...	Expiration date	CW req. qty	Req. quantity	Accumulated	CW accumulated	Action date	Action quantity	Futures date
	Sales order	000787	_DemoProd...	01-Jan-15			-10.00	-10.00				
	Planned purchase orders	013066	_DemoProd...	07-Jan-15			10.00					
	Sales order	000788	_DemoProd...	09-Jan-15			-10.00	-10.00				
	Purchase order	000044	_DemoProd...	12-Jan-15			10.00					

MRP creates a planned order that is attached to the first sales order. Then, as is expected, the second sales order is pegged against the existing purchase order, based on the negative days setting. This planning result is also correct, and the running time for MRP might be shorter. In this case, it isn't essential that you understand and know how to work with the action messages.

To help guarantee that the correct values are entered for your business, you must think in terms of both functionality and MRP running time. Therefore, it can take a little trial and error to determine the optimal values.

Dynamic positive days for last-minute orders

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Dynamic positive days help increase your sales order fulfillment rate by using on-hand inventory and planned receipts for last-minute orders. When you use dynamic positive days, master planning applies the following rules to determine whether to create a new planned order or use existing supply:

- If an item is needed outside its lead time, master planning suggests that a new planned order should be created.
- If an item is needed within its lead time, master planning suggests that existing supply should be used.

This strategy enables sales orders that are created later than, but requested earlier than, another sales order to use existing purchase orders. It lets you fulfill all demand and, at the same time, better manage your supply and delivery dates (including when you use capable-to-promise).

When the system determines which supply to peg, it doesn't just consider the lead time. It also considers the positive days. The number of positive days that apply to a given item are set on that item's item coverage group and can be overwritten at the master plan level. This strategy enables some master plans to have a higher number of positive days than others. Therefore, the plans that are used for capable-to-promise can differ from the plans that are used for day-to-day business.

Prerequisites

Before you can use dynamic positive days, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management 10.0.38 or later.
- The feature that's named *Dynamic positive days for Planning Optimization* must be turned on in Feature management. As of Supply Chain Management version 10.0.43, this feature is turned on by default.

Set up your system to use dynamic positive days

Follow these steps to set up your system to use dynamic positive days.

1. Go to **Master planning** > **Setup** > **Master planning parameters**.
2. On the **General** tab, set the **Use dynamic positive days** option to *Yes*.
3. On the Action Pane, select **Save**.

> **Note**
>
> The **Use dynamic positive days** setting applies to all legal entities (companies) and master plans in your Supply Chain Management environment.

Assign the number of positive days to an item coverage group

Follow these steps to assign the number of positive days to an item coverage group.

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.
2. Select an existing coverage group, or create a new one.
3. On the **General** FastTab, set the **Positive days** field to the number of positive days that you want to use for the coverage group.

Example scenarios

This section provides some example scenarios to help you understand how dynamic positive days work.

Example scenario 1: Demand within the lead time

The following scenario shows how the system handles demand that's requested for a date that's within the lead time.

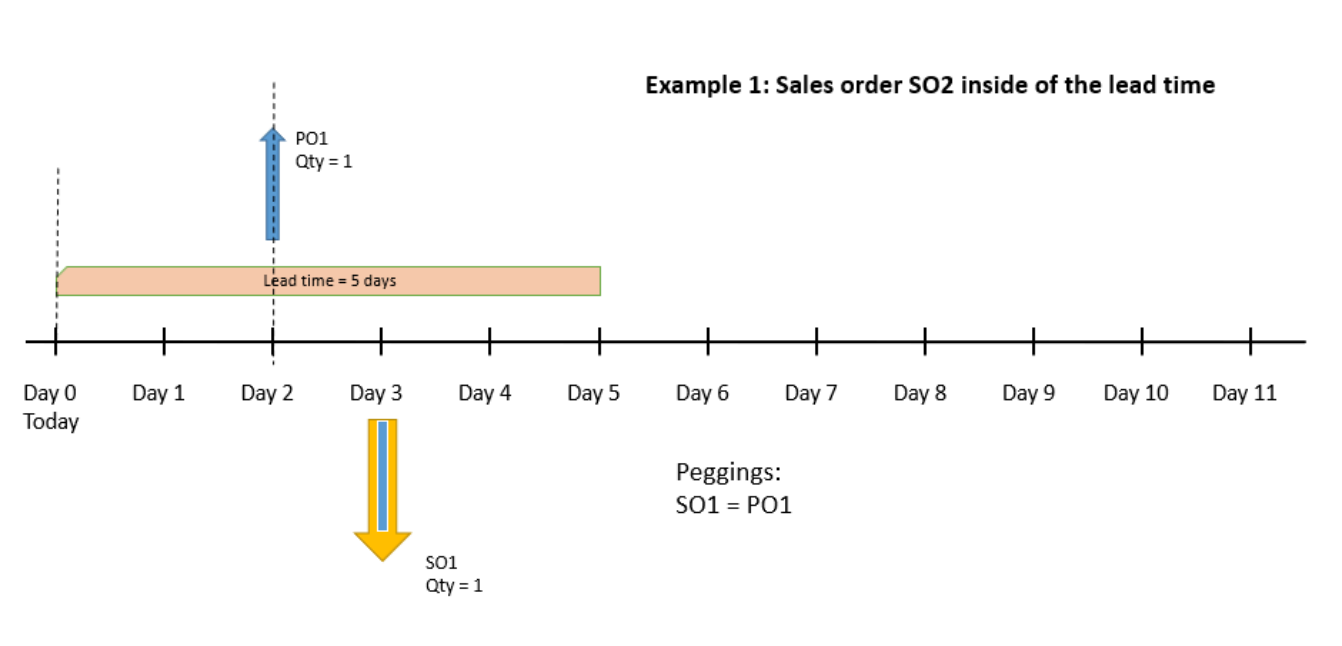
1. Your system is set up in the following way:

    - You have an item that belongs to a coverage group that's set up with three positive days and three negative days.
    - The lead time of the item is five days.
    - Dynamic positive days are enabled.
    - Your master plans don't include any positive day overrides.

- You have a purchase order for the item. It's scheduled to be delivered on day 2.

2. A new sales order is created for the item. The requested ship date is day 3.

3. Because the requested ship date is within the lead time, the system pegs the new sales order to the existing purchase order.



Example scenario 2: Demand outside the lead time

The following scenario shows how the system handles demand that's requested for a date that's outside the lead time.

1. Your system is set up in the following way:

   - You have an item that belongs to a coverage group that's set up with three positive days and three negative days.
   - The lead time of the item is five days.
   - Dynamic positive days are enabled.
   - Your master plans don't include any positive day overrides.
   - You have a purchase order (PO1) for the item. It's scheduled to be delivered on day 2.
   - You have another purchase order (PO2) for the item. It's scheduled to be delivered on day 6.

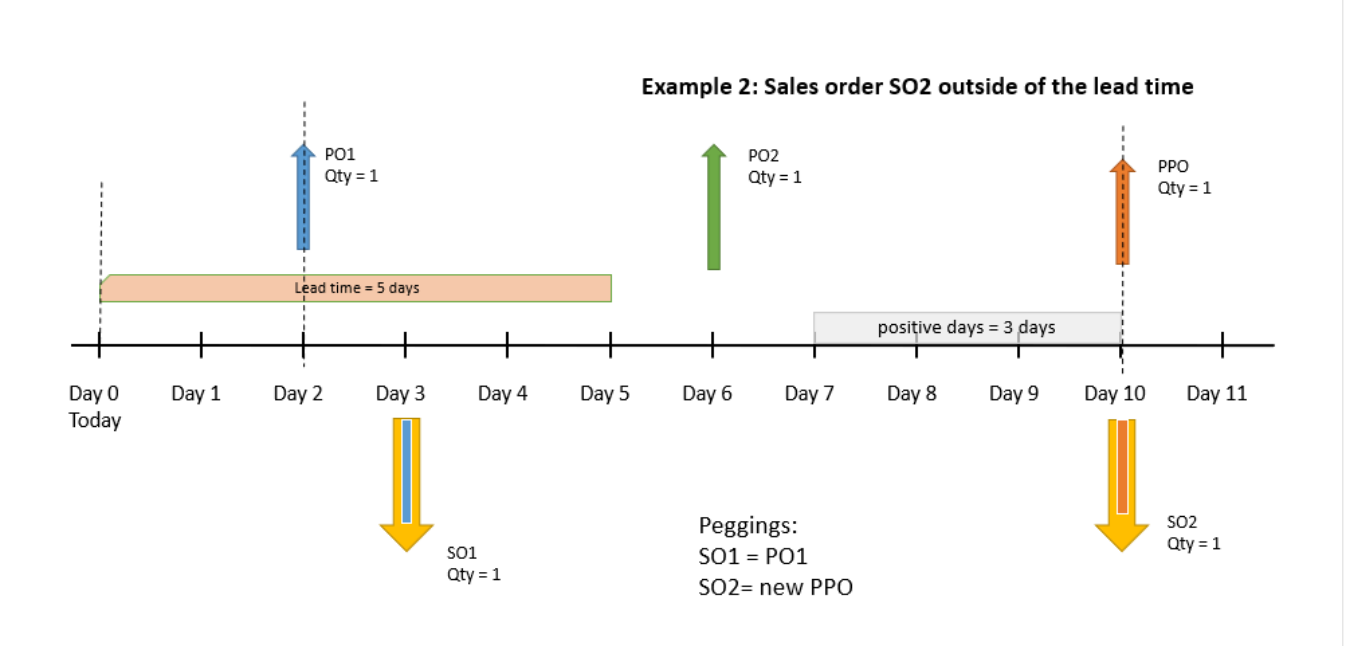
2. The following sales orders are created for the item:

   - Sales order 1 (SO1) has a requested ship date of day 3.
   - Sales order 2 (SO2) has a requested ship date of day 10.

3. The system takes the following actions:

    - Peg SO1 against existing PO1.
    - Create a new planned purchase order, and peg SO2 against it.

    Because SO2 is outside the lead time, the system creates a new planned order to supply it. (There's no supply within the positive days.)



Example scenario 3: Sales order within the positive days but outside the lead time

The following scenario shows how the system handles demand that's requested for a date that's within the positive days but outside the lead time.

1. Your system is set up in the following way:

    - You have an item that belongs to a coverage group that's set up with three positive days and three negative days.
    - The lead time of the item is five days.
    - Dynamic positive days are enabled.
    - Your master plans don't include any positive day overrides.
    - You have a purchase order (PO1) for the item. It's scheduled to be delivered on day 2.
    - You have another purchase order (PO2) for the item. It's scheduled to be delivered on day 8. (Therefore, this example differs from the previous example in that PO2 is scheduled for delivery within the range of positive days.)

2. The following sales orders are created for the item:

- Sales order 1 (SO1) has a requested ship date of day 3.
- Sales order 2 (SO2) has a requested ship date of day 10.

3. The system takes the following actions:

- Peg SO1 against existing PO1.
- Peg SO2 against existing PO2.

Calendars and master planning

This article provides an overview of supply chain calendars and how they affect master planning. It explains the different calendars that the master planning engine uses, including how they affect the shipping and receiving dates in the planned orders. It also provides recommendations for assigning, using, and updating calendars.

Definition of a calendar

To define a calendar for your organization, go to **Organization administration** > **Setup** > **Calendars** > **Calendars**. Use the buttons on the Action Pane to add, remove, or edit calendars as needed.

To manage the details of a selected calendar, select **Working times** on the Action Pane. Each date entry in a calendar can be open or closed, or it can inherit its open or closed status and working times from the base calendar. You specify the value in the **Control** column on the **Working times** page. For each date, set the **Column** field to one of the following values:

- *Open* – Work is performed on the selected day. The calendar is updated according to the working time template.
- *Closed* – Work isn't performed on the selected day.
- *Base calendar* – The specific date inherits its working times and open or closed status from the base calendar. Therefore, when you update the base calendar, you update the selected calendar.

For any closed dates, the **Closed for pickup** checkbox is automatically selected. For open dates, you can manually select the **Closed for pickup** checkbox. By selecting this option, you indicate that work is performed on the date, but shipping isn't performed.

Calendars that affect master planning

Calendar for a coverage group

A coverage group defines a common set of parameters that are used for replenishment of all items that belong to the group.

To add a calendar for a coverage group, go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**. Find the coverage group that you want to assign the calendar to, and then select it in the

Calendar field.

You can assign the coverage group on different pages:

- On the **Released product details** page of an item. To view the coverage group for an item, go to **Product information management** > **Products** > **Released products**, and select the item to open the **Released product details** page. The **Plan** FastTab shows the item coverage group.
- On the **Item coverage** page. On the **Released product details** page, select **Item coverage** to open the **Item coverage** page. The **Overview** tab shows different parameters for replenishment, depending on the site, warehouse, and product dimensions. The coverage group for each item is inherited from the coverage group on the **Released product details** page. However, you can override it by selecting **Use specific settings** or **Override group setting** on the **General** tab.
- On the **Master planning parameters** page. If no coverage group is assigned to an item on the previously mentioned pages, master planning uses the general coverage group that's set in the **General coverage group** field on the **Master planning parameters** page (**Master planning** > **Setup** > **Master planning parameters**).

> ⓘ **Note**
>
> If you don't define a calendar for the coverage group of an item, Planning Optimization uses the calendar of the default coverage group defined on the **Master Planning Parameters** page.

Define the lead time for a purchased item

Specify the purchase lead time for an item (and whether only working days should be considered) on the **Default order settings** page for the product. To open this page, go to **Product information management** > **Products** > **Released products**, and select **Default order settings**.

> ⓘ **Note**
>
> The **Working days** checkbox for purchase lead time indicates working days as counted on the coverage group calendar. For example, a coverage group calendar set to allow delivery only on Tuesdays, with a lead time of 10 days and the **Working days** checkbox selected, indicates that it would take 10 weeks (10 Tuesdays) for the item to be delivered. Therefore, in most cases, don't select **Working days** for purchase order lead times.

Calendars for a vendor

Vendor working days and shipping days

You can set up calendars that define each vendor's standard operating hours, such as the days when the vendor can receive purchase orders, and the days when the vendor can ship goods. The system uses these calendars when it calculates lead times, delivery times, and other dates. Follow these steps to set up vendor calendars.

1. Go to **Organization administration** > **Calendars** > **Calendars**, and either set up or identify the calendars that you want to use for each purpose.
2. Go to **Accounts payable** > **Vendors** > **All vendors**, and select the vendor that you want to assign the calendars to.
3. To set the standard operating hours for the vendor, on the **Purchase order defaults** FastTab, in the **Purchase calendar** field, select a calendar.
4. The days when the vendor can ship orders might differ from the standard operating hours. To set the shipping days, on the **Invoice and delivery** FastTab, in the **Ship calendar** field, select a calendar. For more information about this field and how it's used, see Calculate requested ship dates for purchase orders.

Define lead times from the trade agreements page

You can set up master planning to include all trade agreements for vendors. Trade agreements are fixed prices or discount agreements that you set up for one or more customers or vendors for the sale or purchase of individual or multiple products. To include the trade agreements during planning, go to **Master planning** > **Setup** > **Master planning parameters**, and then, on the **Planned orders** tab, select **Find trade agreements**. Master planning can select the vendor that has either the minimum lead time or the lowest unit price.

Calendar for a warehouse

Assign a calendar to a warehouse to indicate the open dates for receiving and shipping. If you don't assign a calendar to a warehouse, the system assumes that the warehouse is open every day.

> **Note**
>
> Assigning a calendar to a transit warehouse doesn't have any impact. Transit warehouses support transfer orders. The open days within the "from" warehouse and the "to" warehouse,

and the mode of delivery calendar, define the applicable shipping or receipt dates for the orders.

Closed for pickup policy

To indicate that a warehouse is open for receiving but pickup isn't possible, set the **Closed for pickup policy** field in the warehouse calendar. This setting also applies to customer pickups.

Transport calendar

To indicate the dates when transfer orders can be shipped, set up transport calendars for each mode of delivery or for each combination of mode of delivery and "from" warehouse.

To set up a transport calendar, go to **Sales and marketing** > **Setup** > **Distribution** > **Modes of delivery**, select a mode of delivery, and then select **Transport calendar**.

You can create a line for each warehouse and mode of delivery. The **Transport calendar** column specifies the transport calendar that's applied when goods are shipped from the warehouse that uses the mode of delivery.

To apply a transport calendar to all shipments that use a specific mode of delivery, regardless of the warehouse, create a line where you don't specify a warehouse.

If you don't assign a transport calendar, the system assumes that all days are open for transport.

Closed for pickup policy on the transport calendar

By default, Planning Optimization considers the **Closed for pickup** setting only on the warehouse calendar of the issuing warehouse when it schedules transfer order shipments. When the *Consider open for pickup on transport calendar for planned transfer orders with Planning Optimization* feature is enabled, Planning Optimization also considers the **Closed for pickup** setting on the transport calendar. The issue calendar becomes the intersection of both calendars. Therefore, the shipping date must be open for pickup on both the warehouse calendar and the transport calendar.

This feature also changes how Planning Optimization selects the receipt calendar for transfer orders. When the feature is enabled, the warehouse calendar of the receiving warehouse takes precedence over the coverage group calendar, if you specify a warehouse calendar. Without the feature, the coverage group calendar takes precedence. For more information, see Receipt date of a planned transfer order later in this article.

Prerequisites

To use this feature, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.49 or later.
- The feature named *Consider open for pickup on transport calendar for planned transfer orders with Planning Optimization* must be turned on in feature management.

Example

Consider the following setup:

- Warehouse *WH11* uses a calendar that's open every weekday. Wednesdays are marked as **Closed for pickup**.
- The transport calendar for the *Truck* mode of delivery is open every weekday. Fridays are marked as **Closed for pickup**.
- A planned transfer order ships items from *WH11* by using the *Truck* mode of delivery.

When the feature is disabled, Planning Optimization can schedule the shipment on any weekday except Wednesday, because only the **Closed for pickup** setting on the warehouse calendar is considered.

When the feature is enabled, Planning Optimization can schedule the shipment only on Monday, Tuesday, or Thursday. Both the warehouse calendar (Wednesday is closed for pickup) and the transport calendar (Friday is closed for pickup) must be open for pickup on the shipping date.

Calendar for a customer

Assign a receipt calendar to the customer to indicate the dates when a customer can accept deliveries. If you don't assign a calendar to a customer, the system assumes that the customer can receive orders every day.

This setup affects the receipt date on sales order lines. If the date that you select on the sales order lines isn't open in the customer calendar, the system indicates that the receipt date isn't valid.

You can assign only one calendar to each customer. If a customer has multiple addresses, and you must include a calendar for each address, create one customer per address and then assign the appropriate calendar to each customer.

The customer calendar and the delivery date control method affect the requested receipt date on the sales order lines. Learn more about how the earliest delivery date is calculated in Order Promising.

Shipping calendar for a legal entity

Set up a shipping calendar for a legal entity to indicate the dates when the legal entity can ship goods. Go to **Organization administration** > **Organizations** > **Legal entities**, select the legal entity, and then, on the **Foreign trade and logistics** tab, in the **Shipping calendar** field, add the calendar. The shipping calendar acts as a source of default values for all warehouse calendars in the legal entity.

How calendars affect dates in planning

Order date of a planned purchase order

The order date of a planned purchase order indicates the date when you place the order. It must be an open date in both the vendor calendar and the coverage group calendar. Sometimes, vendors need a margin of a few days between the date when they receive the purchase order and the date when they can ship the goods. The vendor's margin days indicate these dates. However, if the item that you purchase is assigned to a coverage group that has margin days, those margin days override the vendor's margin days.

Delivery date of a planned purchase order

The receipt date of a purchase indicates the date when you expect to receive the goods. It's an open date in the calendar. To determine which days you can receive the purchase orders, the system considers the following calendars, in order from highest to lowest priority:

1. Vendor's calendar
2. Coverage group calendar
3. Warehouse calendar for the receiving warehouse

You can set the coverage group calendar on different pages. The system prioritizes the various page settings in the following order:

1. Item coverage group on the **Item coverage** page
2. Item coverage group on the **Released products details** page
3. Default item coverage group on the **Master planning parameters** page

Shipping date of a planned transfer order

When you create a transfer order between two warehouses, you specify the shipping date and the receipt date in the transfer order header, along with the "from" warehouse and "to" warehouse. The difference between these two dates is the expected transportation time (in days) between the warehouses.

The shipping date of a planned transfer order indicates the date when the goods are shipped from the "from" warehouse. The calendars that are used to specify the available shipping date are listed here in order of priority:

1. Warehouse calendar of the "from" warehouse
2. Coverage group calendar (See the fallback order for this calendar earlier in this article.)

If you set a warehouse calendar, the system sets a shipping date that's open in that calendar. If you don't set a warehouse calendar, the system uses the coverage group calendar.

Receipt date of a planned transfer order

The receipt date for a transfer order indicates the date that the goods are received in the "to" warehouse.

The calendars that specify the receipt date are listed here in order of priority:

1. Coverage group calendar
2. Warehouse calendar of the "to" warehouse

If you set a coverage calendar, the system sets a receipt date that's open in that calendar. If you don't set a coverage group calendar, the system uses the warehouse calendar.

When the *Consider open for pickup on transport calendar for planned transfer orders with Planning Optimization* feature is enabled, this priority order is reversed. The warehouse calendar of the "to" warehouse takes precedence over the coverage group calendar, if you specify a warehouse calendar. If you don't set a warehouse calendar, the system uses the coverage group calendar. For more information, see Closed for pickup policy on the transport calendar earlier in this article.

To determine the shipping and receipt dates for the planned transfer, the system also considers the margins that you define for shipping and receiving.

Using calendars in master planning

Assign calendars

Set the calendars to identify the working days of the company. Best practice is to set a calendar for each element that has different working days. In other words, set all external calendars (customer and vendor) and all internal calendars (warehouse, coverage group, and mode of delivery) that are related to the company.

Recommendation for warehouse calendars

We recommend that you use one calendar for each warehouse, to include the specific changes that affect only that warehouse. For example, two or more warehouses have the same working days but a different pickup policy. In this case, the best practice is to use a separate calendar for each warehouse and its pickup policy. By using this approach, the system can include the best dates for planned purchase, transfer, and production orders.

If you don't set warehouse calendars, the legal entity calendar provides default values for the warehouse calendar.

Recommendation for coverage group calendars

A coverage group calendar overrides receipt dates in master planning. Use coverage group calendars cautiously. They're especially useful in cases where replenishment must happen on specific days of the week.

Update calendars

Although it's important that all relevant calendars are assigned in their appropriate place (vendor, customer, warehouse, mode of delivery, or coverage group), it's equally important to update them to reflect changes. The system defines the production, transfer, purchase, and sales order dates based on the combination of assigned calendars.

Clarify who is responsible for assigning and updating calendars in their appropriate place. In the event of a breakdown or any other unusual change in the working days, update the calendars according to that change. Rerun all tasks that depend on calendars, such as master planning and production scheduling, when you update calendars.

Calculate requested ship dates for purchase orders

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Purchase orders in Microsoft Dynamics 365 Supply Chain Management can include both a *requested receipt date*, which specifies when the order should be received at your company's location, and a *requested ship date*, which specifies when the vendor should ship from their location. The system calculates requested ship dates based on the requested receipt date, lead time, the transport days setup, the vendor ship calendar, and other settings. The transport days setup lets you define the number of days that are required to transport items between pairs of addresses. Vendor ship calendars define the days when each vendor can ship.

If any of your vendors don't have specific delivery terms (such as delivery duty paid, delivery at place, or delivery at place unloaded), you must tell them when they should ship.

When master planning suggests a date for placing a planned order, it also considers the transport days setup. This approach helps ensure that the goods arrive on time.

Prerequisites

To calculate requested shipment dates for purchase orders, your system must meet the following requirements:

- You must be running Dynamics 365 Supply Chain Management version 10.0.40 or later.
- You must be using Planning Optimization, not the deprecated master planning engine.

Enable supplier requested and confirmed shipment dates for a company

To enable supplier requested and confirmed shipment dates for a legal entity (company), follow these steps:

1. Use the company picker to select the legal entity where you want to calculate requested shipment dates for purchase orders.
2. Go to **Procurement and sourcing** > **Setup** > **Procurement and sourcing parameters**.
3. Open the **Delivery** tab.
4. Set **Supplier requested and confirmed shipment dates** to *Yes* to make the feature available to the current legal entity. Set to *No* to hide the feature for the current legal entity.
5. Repeat this procedure for each legal entity where you want to turn on (or turn off) the option.

> ⓘ **Note**
>
> If you use intercompany trade, then each of the legal entities involved must have this option turned on to allow requested shipment dates to be calculated for intercompany purchase orders.

Specify whether requested ship dates can be in the past

Sometimes, because of your requested receipt date, plus the lead time, transport days, vendor ship calendar, and other settings, the system might calculate a requested ship date that's in the past. To specify how the system handles this situation, follow these steps:

1. Go to **Procurement and sourcing** > **Setup** > **Procurement and sourcing parameters**.
2. On the **Delivery** tab, in the **Requested ship date in the past** field, select one of the following values:
    - *None* – Always allow requested ship dates to be in the past, without showing a warning.
    - *Allow with warning* – Allow requested ship dates to be in the past, but show a warning message to users when this situation occurs.
    - *Disallow with warning* – Always find the next earliest ship date that's after the current date, and show a warning message to users when this situation occurs.

Set up purchase transport days

To define the number of days that are required to transfer goods between addresses, follow these steps:

1. Go to **Procurement and sourcing** > **Setup** > **Distribution** > **Purchase transport days**.

2. Follow one of these steps:

    - To use an existing record, use the filters at the top of the grid to find it. To edit the record that you find, select the link in the **Shipping country/region** column. To delete the record, select it, and then select **Delete** on the Action Pane.
    - To create a new record, on the Action Pane, select **New**.

3. On the details page for the new or selected record, on the **General** tab, use the fields to define the shipping address, the receiving address, and the number of days that are required to transport goods between them. For more information about each field, hover over its label to open a tooltip.

    > **Tip**
    >
    > - When you must enter an address, first enter a value in the **Shipping ZIP/postal code** field. Often, the system can automatically fill in the rest of the address fields for you, based on the postal code.
    > - To calculate the ship date, the system uses the most specific purchase transport days record that it can find. For example, you have two purchase transport days records: one that specifies 30 days from Spain to the United States and another that specifies 20 days from Madrid to New York. In this case, a purchase order that's shipped from Madrid to New York uses 20 days, whereas an order from Valencia to New York uses 30 days.
    > - If the shipping address and receiving address have equal priority, the shipping address takes precedence.

4. On the **Transport days per mode of delivery** FastTab, you can set specific transport days for any number of delivery modes (such as road, rail, and air). Use the buttons on the toolbar to add and remove rows in the grid as you require.

    - For each row, select a mode of delivery, and then specify the number of transport days for that mode.
    - If you want one of the modes of delivery to define the default transport days that apply to any modes that aren't specified in the grid, select the **Default** checkbox for

that mode's row.
    - If the **Default** checkbox isn't selected for any row, the **Transport in days** value that's specified on the **General** FastTab is used as the default travel time.

5. On the Action Pane, select **Save**.

Vendor settings for calculating requested ship dates

To calculate requested ship dates, you must set up an address for each vendor. To help make the calculation more accurate, you can also set up vendor ship calendars that define specific days when each vendor can ship.

Set up vendor addresses

To set up addresses for a vendor, follow these steps:

1. Go to **Procurement and sourcing** > **Vendors** > **All vendors**.
2. Open the vendor record that you want to work with.
3. On the **Addresses** FastTab, add and remove addresses as you require. If more than one address is specified on the **Addresses** FastTab, when the system uses the purchase transport days setup to calculate the shipping date, it uses the address where the **Primary** option is set to *Yes* as the shipping point.

> **Tip**
>
> - The vendor address is applied to the purchase order and used as the shipping point for purchase transport days.
> - The receiving point for purchase transport days is the second factor that's used to calculate the shipping date. The delivery address depends on the setup, and a default value can be taken from the company, site, or warehouse. Any update to the site or warehouse for a purchase order header or line triggers a recalculation of the shipping date, because the new site or warehouse might have a different delivery address.

How calendars affect ship and receipt date calculations

The following calendars are relevant for ship and receipt date calculations:

- **Purchase calendar** – This calendar defines when a vendor is open. For example, a vendor might accept orders on workdays but not weekends.

- **Vendor ship calendar** – This calendar defines when purchase orders can be shipped from the vendor.
- **Warehouse calendar** – This calendar defines when purchase orders can be received at the site or warehouse.

The purchase and vendor ship calendars are considered when the ship date is calculated. The warehouse (item coverage group) calendar is used when the receipt date is calculated.

> **Note**
>
> If no coverage group is assigned to an item on the **Released product details**, **Item coverage**, or **Master planning parameters** page, then master planning uses the *general coverage group* (which is set in the **General coverage group** field on the **Master planning parameters** page) and calculates the working days based on the calendar assigned to that group.

Learn more in Calendars and master planning.

The following examples show how calendars affect the calculation of requested ship and receipt dates for purchase orders.

Calculation example 1

This example shows how requested ship and receipt dates are calculated for a product that has five days of lead time and two purchase transport days.

The following table shows the calendars that apply.

Expand table

Calendar	Mon	Tue	Wed	Thu	Fri	Sat	Sun	Mon	Tue
Purchase calendar	Open	Open	Open	Open	Open	Open	Open	Open	Open
Vendor ship calendar	Open	Closed	Closed	Closed	Open	Open	Open	Open	Open
Warehouse calendar	Open	Open	Open	Open	Closed	Closed	Closed	Closed	Open

The following table shows the calculated dates.

Expand table

Date type	Mon	Tue	Wed	Thu	Fri	Sat	Sun	Mon	Tue
Order date	X								
Ship date						X			
Receipt date									X

The calculation results are based on the following information:

- The ship date is Saturday, which is the first open day that's available in the vendor ship calendar after the five days of lead time.
- The receipt date is Tuesday, which is the first open day that's available in the warehouse calendar after the two transport days.

Calculation example 2

This example shows how requested ship and receipt dates are calculated for a product that has three days of lead time and two purchase transport days.

The following table shows the calendars that apply.

Expand table

Calendar	Mon	Tue	Wed	Thu	Fri	Sat	Sun	Mon	Tue
Purchase calendar	Open	Open	Open	Open	Open	Open	Open	Open	Open
Vendor ship calendar	Open	Closed	Closed	Closed	Open	Open	Open	Open	Open
Warehouse calendar	Open	Open	Open	Open	Closed	Closed	Closed	Closed	Open

The following table shows the calculated dates.

Expand table

Calendar	Mon	Tue	Wed	Thu	Fri	Sat	Sun	Mon	Tue
Order date	X								
Ship date					X				
Receipt date									X

Compared to the previous example, the results are calculated in the following way:

- The ship date is moved one day, because the vendor ship calendar shows that the vendor is closed on Thursday.
- The receipt date is moved two days, because the warehouse calendar shows that the warehouse is closed on Sunday and Monday.

Assign vendor ship calendars

For each vendor, you can specify a ship calendar that indicates the dates when the vendor can ship. For example, some vendors might be able to ship during all opening hours, whereas others can ship only on Mondays. You can define as many specific ship calendars as you require and then apply them to each vendor as appropriate.

If you have goods that must be expedited, and the relevant vendor makes an exception on their vendor ship calendar, you can change or remove the vendor ship calendar for the relevant purchase order lines.

For information about how to set up a ship calendar and define the available ship dates and times for it, see Calendars and master planning.

To assign a ship calendar to a vendor, follow these steps:

1. Go to **Procurement and sourcing** > **Vendors** > **All vendors**.
2. Open the vendor record that you want to assign a ship calendar to.
3. On the **Invoice and delivery** FastTab, in the **Ship calendar** field, select the ship calendar that applies to the vendor.

Date calculations and recalculations

This section describes how and when the system calculates and recalculates requested ship dates.

Requested ship date

The requested ship date calculation considers lead time (lead time per vendor if it's set up on trade agreements), the mode of delivery, and the vendor ship calendar. The lead time is the time that the vendor takes to produce the item. It doesn't include transport days (from vendor to company).

You can configure how the system handles requested ship dates that are in the past. Learn more in the Specify whether requested ship dates can be in the past section.

Order date of planned purchase orders

When a master planning run indicates that a planned order is needed, the order date is calculated backward from the requirement date. The calculation considers margins, lead time, and the purchase transport days setup. The requested ship date is calculated according to the same rules that are used for purchase orders. However, for planned orders, the requested ship date isn't saved as a field value or shown on the **Planned purchase order** details page.

The requested ship date is also calculated for manually created planned purchase orders.

Recalculations for updated orders

When you edit a purchase order where the requested and/or confirmed ship date has already been calculated, the system does the following recalculations:

- If the **Requested ship date** value is changed, the **Requested receipt date** value is recalculated.
- If the **Requested receipt date** value is changed, the **Requested ship date** value is recalculated.
- If the **Confirmed ship date** value is changed, the **Confirmed receipt date** value is recalculated.
- If the **Confirmed receipt date** value is changed, the **Confirmed ship date** value is recalculated.
- If any of the following information is changed, the relevant ship and receipt dates are recalculated:
  - Address on the header
  - Mode of delivery (on the header or on a line)
  - Warehouse on a line

If you change the **Requested ship date** or **Confirmed ship date** value on the header of a purchase order, the system asks you whether the relevant ship and receipt dates should also be updated for each line.

> ⓘ **Note**
>
> If any subsequent changes are made at the line level (such as modifying the unit, warehouse quantity, or site), the line **Requested ship date** and **Requested receipt date** are recalculated based on the current date rather than the header date. To ensure accurate date calculations,

we recommend that you complete all necessary updates at the line level before updating the header **Requested ship date** or **Confirmed ship date**.

Purchase order ship and receipt date calculation logic

This section explains how the **Requested ship date** and **Requested receipt date** are calculated for purchase orders. These dates are influenced by lead times, transport days, vendor calendars, and other settings.

Key terms and concepts

The following table describes key terms and concepts related to purchase order ship and receipt date calculations.

Expand table

Term	Description
Requested ship date	The date on which you want the vendor to ship the goods.
Requested receipt date	The date on which you want to receive the goods.
Confirmed ship date	The date on which the vendor ships the goods, as confirmed by the vendor.
Confirmed receipt date	The date on which you receive the goods, as confirmed by the vendor.
Lead time	The number of days the vendor requires to prepare an item.
Transport days	The number of days needed to ship goods from vendor to warehouse.
Purchase calendar	The calendar that defines when a vendor is open for business.
Vendor ship calendar	The calendar that defines when purchase orders can be shipped from the vendor.
Warehouse calendar	The calendar that defines when purchase orders can be received at the site or warehouse
Item coverage calendar	An optional calendar used to adjust receipt dates.

Calculation logic

The following table summarizes the logic used to calculate purchase order ship and receipt dates.

Expand table

Calculation	Description
Requested ship date	Calculated as today's date plus lead time. Adjusted to the next working day if the assigned calendar is *Active*.
Requested receipt date	Calculated as the requested ship date plus transport days. Adjusted to the next working day if the assigned calendar is *Active*.
Lead time (on the **Line details** tab)	Populated only if **Calculate PO delivery date** is set to *Yes* and the purchase order originates from a purchase requisition, purchase agreement, or request for quotation.
Transport days	Applied based either on the selected mode of delivery at the purchase order line level or the default mode of delivery configured for the warehouse master.
Confirmed dates	Manually entered by the vendor and not adjusted by any calendar.
Trade agreement working days	When enabled, lead time is calculated using only open working days.

For details about how to update the **Requested ship date** and **Requested receipt date** in the header, see Recalculations for updated orders.

Example date calculation scenarios

This section provides examples that show how requested ship and receipt dates for purchase orders are calculated in various scenarios.

Example scenario prerequisites

These scenarios have the following prerequisites:

- Your system must meet all the feature prerequisites that are listed in the Prerequisites section of this article.
- The **Purchase transport days** page must be configured with at least one receiving address, shipping address, and number of transport days. The addresses must match the vendors and receiving warehouses that you use for these scenarios.
- Unless otherwise specified, all calendars must have all days open.
- On the **Procurement and sourcing parameters** page, on the **Delivery** tab, the **Requested ship date in the past** field must be set to *None*.

Example scenario 1: Standard purchase order

In this scenario, there are two purchase transport days from the vendor shipping address to the site/warehouse receiving address. Dates are calculated forward, and the purchase transport days are added to the requested ship date to determine the requested receipt date.

1. Go to **Procurement and sourcing** > **Setup** > **Distribution** > **Purchase transport days**.
2. Make sure that you have a record for delivery from the vendor shipping address that you plan to order from to the warehouse receiving address where you plan to receive the order. Set the **Transport days** field to *2* for this record.
3. Go to **Procurement and sourcing** > **Purchase orders** > **All purchase orders**.
4. On the Action Pane, select **New** to create a purchase order.
5. On the **Vendor** FastTab, set the **Vendor account** field to the vendor whose shipping address you set up on the **Purchase transport days** page. Then select **OK** to create and open the purchase order.
6. On the **Purchase order lines** FastTab, in the **Item number** field, select an item. Then set the **Site** and **Warehouse** fields to the warehouse that you set up a receiving address for on the **Purchase transport days** page.
7. On the **Line details** FastTab, on the **Delivery** tab, you see the following values:

    - **Requested ship date** – The value is the current date (unless you specified another date for the order header).
    - **Requested receipt date** – The value is a date that's two days later than the **Requested ship date** value for the purchase order. The system calculates this date based on your setup on the **Purchase transport days** page. The following settings can also affect the calculation:
        - If the product that's ordered has lead time, the system adds that lead time to the transport time when it calculates the receipt date. (Therefore, the formula is *Requested ship date = Requested ship date + Product lead time*.)
        - The vendor ship calendar and warehouse calendar can also affect the date calculation by allowing for closing times at one or both locations. (Learn more in the How calendars affect ship and receipt date calculations section.)

    Any update to the **Requested ship date** or **Requested receipt date** value causes the system to recalculate the dates. An update to the **Requested ship date** value triggers a forward

calculation of the **Requested receipt date** value, and an update to the **Requested receipt date** value triggers a backward calculation of the **Requested ship date** value.

Example scenario 2: Purchase order with dates in the past

This scenario shows how the system handles requested ship dates that are in the past, based on the **Requested ship date in the past** setting. (Learn more in the Specify whether requested ship dates can be in the past section.)

The default value of the **Requested ship date in the past** field is *None*. In this case, requested ship dates in the past are always allowed, and no warning is shown. This scenario shows what happens if you change the value to *Disallow with warning*. In this case, a warning message is always shown if requested ship dates are in the past. The system then finds the next earliest ship date that's after the current date.

1. Go to **Procurement and sourcing** > **Setup** > **Procurement and sourcing parameters**.
2. On the **Delivery** tab, set the **Requested ship date in the past** field to *Disallow with warning*. Then select **Save**.
3. Go to **Procurement and sourcing** > **Setup** > **Distribution** > **Purchase transport days**.
4. Make sure that you have a record for delivery from the vendor shipping address that you plan to order from to the warehouse receiving address where you plan to receive the order. Set the **Transport days** field to *2* for this record.
5. Go to **Procurement and sourcing** > **Purchase orders** > **All purchase orders**.
6. On the Action Pane, select **New** to create a purchase order.
7. On the **Vendor** FastTab, set the **Vendor account** field to the vendor whose shipping address you set up on the **Purchase transport days** page. Then select **OK** to create and open the purchase order.
8. On the **Purchase order lines** FastTab, in the **Item number** field, select an item. Then set the **Site** and **Warehouse** fields to the warehouse that you set up a receiving address for on the **Purchase transport days** page.
9. On the **Line details** FastTab, on the **Delivery** tab, set the **Requested receipt date** field to a date that doesn't allow for enough time for transport. (For example, select today's date.)

The system shows a warning message such as "The requested ship date 1/18/2024 is not valid because it is before today. Earliest possible requested ship date is 1/22/2024 with requested receipt date 1/26/2024." The requested date fields are updated to match the warning message.

If you try to directly enter a requested ship or receipt date that's in the past, you receive a warning that doesn't include any suggested dates (for example, "The requested ship date 1/8/2024 is not valid because it is before today"). In this case, you can't save the order until you select a valid date.

Example scenario 3: Purchase order created from a sales order

In this scenario, you create a purchase order from a related sales order and observe how the requested ship and receipt dates are calculated for both orders.

1. Go to **Procurement and sourcing** > **Setup** > **Distribution** > **Purchase transport days**.
2. Make sure that you have a record for delivery from the vendor shipping address that you plan to order from to the warehouse receiving address where you plan to receive the order. Set the **Transport days** field to *2* for this record.
3. Go to **Sales and marketing** > **Sales orders** > **All sales orders**.
4. On the Action Pane, select **New** to create a sales order.
5. On the **Customer** FastTab, set the **Customer account** field to any customer account (it doesn't matter which one). Then select **OK** to create and open the sales order.
6. On the **Sales order lines** FastTab, in the **Item number** field, select an item. Then set the **Site** and **Warehouse** fields to the warehouse that you set up a receiving address for on the **Purchase transport days** page.
7. On the **Line details** FastTab, on the **Delivery** tab, set the **Delivery date control** field to *None*.
8. Set both the **Requested ship date** field and the **Requested receipt date** field to a date that's one week from now.
9. On the Action Pane, on the **Sales order** tab, in the **New** group, select **Purchase order**.
10. On the **Lines** FastTab, you see a line that matches the line from your sales order. For this line, set the **Vendor account** field to the vendor whose shipping address you set up on the **Purchase transport days** page.

11. Select the **Include** checkbox for the line.
12. Select **OK** to create the purchase order and return to your sales order.
13. On the Action Pane, on the **General** tab, in the **Related information** group, select **Purchase order**.
14. The related purchase order opens. On the **Line details** FastTab, on the **Delivery** tab, you see the following values:
    - **Requested receipt date** – The value matches the sales order's requested ship date.
    - **Requested ship date** – The value is calculated backward from the receipt date, based on the number of purchase transport days, to the first available open date.

Example scenario 4: Direct delivery created from a sales order

This scenario is similar to the previous one, but you create a direct delivery order from a sales order. Because you're using direct delivery for this scenario, the shipment never arrives at your warehouse. Therefore, transport time is calculated based only on the *vendor's shipping address* and the *customer's receiving address*.

1. Go to **Procurement and sourcing** > **Setup** > **Distribution** > **Purchase transport days**.
2. Make sure that you have a record for delivery from the vendor shipping address that you plan to order from to the receiving address of the *customer* that you plan to ship to. Set the **Transport days** field to *2* for this record.
3. Go to **Sales and marketing** > **Sales orders** > **All sales orders**.
4. On the Action Pane, select **New** to create a sales order.
5. On the **Customer** FastTab, set the **Customer account** field to the customer whose receiving address you set up on the **Purchase transport days** page. Then select **OK** to create and open the sales order.
6. On the **Sales order lines** FastTab, in the **Item number** field, select an item. Then set the **Site** and **Warehouse** fields if they're required. However, these fields don't affect the delivery time calculation, because you're using direct delivery.
7. On the **Line details** FastTab, on the **Delivery** tab, set the **Delivery date control** field to *None*.
8. Set both the **Requested ship date** field and the **Requested receipt date** field to a date that's one week from now.

9. On the Action Pane, on the **Sales order** tab, in the **New** group, select **Direct delivery**.
10. On the **Lines** FastTab, you see a line that matches the line from your sales order. For this line, set the **Vendor account** field to the vendor whose shipping address you set up on the **Purchase transport days** page.
11. Select the **Include** checkbox for the line.
12. Select **OK** to create the purchase order and return to your sales order.
13. On the **Line details** FastTab, on the **Delivery** tab, you see the following values:
    - **Requested receipt date** – The value is the requested ship date that you entered earlier.
    - **Requested ship date** – The value is calculated backward from the receipt date, based on the number of purchase transport days, to the first available open date.
14. On the Action Pane, on the **General** tab, in the **Related information** group, select **Purchase order**.
15. The related purchase order is opened. On the **Line details** FastTab, on the **Delivery** tab, notice that the **Requested receipt date** and **Requested ship date** values match the values of the sales order. These dates are synced because this order is a direct delivery order.

Example scenario 5: Intercompany order

For intercompany orders, the requested ship and receipt dates must be synced for both sales orders and purchase orders. The purchase transport days, lead time, delivery date control, and calendar availability must also be considered.

To complete this scenario, first set up an intercompany relationship between the customer and vendor that you use.

1. Use the company picker to select the company that's purchasing an item. This company is the one where you must set up the purchase transport days and create the purchase order.
2. Go to **Procurement and sourcing** > **Setup** > **Distribution** > **Purchase transport days**.
3. Make sure that you have a record for delivery from the vendor warehouse to the customer warehouse that you're using for this scenario. Set the **Transport days** field to *2* for this record.
4. Go to **Procurement and sourcing** > **Purchase orders** > **All purchase orders**.

5. On the Action Pane, select **New** to create a purchase order.

6. On the **Vendor** FastTab, set the **Vendor account** field to the intercompany vendor whose shipping address you set up on the **Purchase transport days** page. Then select **OK** to create and open the purchase order.

7. On the **Purchase order lines** FastTab, in the **Item number** field, select an item. Then set the **Site** and **Warehouse** fields to the warehouse that you set up a receiving address for on the **Purchase transport days** page.

8. On the **Line details** FastTab, on the **Delivery** tab, you see the following values:

    - **Requested ship date** – The value is the current date (unless you specified another date for the order header).
    - **Requested receipt date** – The value is a date that's five days later than the **Requested ship date** value of the purchase order. The system calculated this date based on your purchase transport days setup.

9. On the Action Pane, on the **Manage** tab, in the **Intercompany tracing** group, select **Intercompany sales order**. The requested dates on the sales order line should match the dates that you saw on the purchase order line.

> **Tip**
>
> The sourcing order determines whether and how the purchase order transport days are calculated.
>
> - If dates are updated on the sales order, lead time and customer transport days take precedence, and purchase order transport days are calculated. These dates are editable only when you source from the sales order.
> - If dates are updated on the purchase order, purchase transport days and lead time are calculated, and requested and confirmed dates are synced back to the sales order.

Example scenario 6: Purchase agreement

This scenario shows how requested ship and receipt dates are calculated when you create a purchase order from a purchase agreement.

1. Go to **Procurement and sourcing** > **Setup** > **Distribution** > **Purchase transport days**.

2. Make sure that you have a record for delivery from the vendor shipping address that you plan to create a purchase agreement for to the warehouse receiving address where you plan to receive the order. Set the **Transport days** field to *2* for this record.
3. Go to **Procurement and sourcing** > **Purchase agreements** > **Purchase agreements**.
4. On the Action Pane, select **New** to create a purchase agreement.
5. On the **Vendor** FastTab, set the **Vendor account** field to the vendor whose shipping address you set up on the **Purchase transport days** page. Then select **OK** to create and open the purchase agreement.
6. On the **Purchase agreement lines** FastTab, select **Add line**.
7. In the **Item number** field, select an item. Then set the **Site** and **Warehouse** fields to the warehouse that you set up a receiving address for on the **Purchase transport days** page.
8. On the Action Pane, on the **Purchase agreement** tab, in the **Generate** group, select **Confirmation**.
9. In the **Confirm purchase agreement** dialog box, select **OK**.
10. On the Action Pane, on the **Purchase agreement** tab, in the **New** group, select **Release order**.
11. In the **Create release order** dialog box, in the **Purchase quantity** field for the line, enter a value. Then set the **Requested receipt date** field to one week from today.
12. Select **Create** to create the purchase order.
13. Make a note of the purchase order number that's shown in the message at the top of the page.
14. Go to **Procurement and sourcing** > **Purchase orders** > **All purchase orders**.
15. Open the purchase order that you just created. Use the purchase order number that you made a note of to find it.
16. On the **Line details** FastTab, on the **Delivery** tab, you see the following values:
    - **Requested receipt date** – The value is the date that you entered when you released the purchase order.

- **Requested ship date** – The value is calculated backward from the receipt date, based on the number of purchase transport days, to the first available open date.

Example scenario 7: Purchase requisition

This scenario shows how requested ship and receipt dates are calculated when you create a purchase order from a purchase requisition.

1. Go to **Procurement and sourcing** > **Setup** > **Distribution** > **Purchase transport days**.
2. Make sure that you have a record for delivery from the vendor shipping address that you plan to create a purchase requisition for to the warehouse receiving address where you plan to receive the order. Set the **Transport days** field to *2* for this record.
3. Go to **Procurement and sourcing** > **Purchase requisitions** > **All purchase requisitions**.
4. On the Action Pane, select **New** to create a purchase requisition.
5. In the **Name** field, enter a name for the requisition. Then select **OK** to create and open the purchase requisition.
6. On the **Purchase requisition lines** FastTab, on the toolbar, select **Add line**.
7. In the **Item number** field, enter a value. Then, in the **Quantity** field, specify a quantity.
8. On the **Line details** FastTab, on the **Inventory dimensions** tab, set the **Site** and **Warehouse** fields to the warehouse that you set up a receiving address for on the **Purchase transport days** page.
9. On the Action Pane, select **Workflow** to open a dropdown dialog box. Select **Submit** to open a dialog box where you can enter a comment. Then select **Submit** in this dialog box to submit the requisition for approval.
10. Generate a purchase order for the purchase requisition through the **Submit requisition for approval** workflow. The resulting purchase order should have the following requested dates:

    - **Requested receipt date** – The value is the **Requested date** value from the purchase requisition.
    - **Requested ship date** – The value is calculated backward two purchase transport days from the requested receipt date of the purchase order.

Example scenario 8: Purchase request for quotation

This scenario shows how requested ship and receipt dates are calculated when you create a purchase order from a request for quotation (RFQ) reply.

1. Go to **Procurement and sourcing** > **Setup** > **Distribution** > **Purchase transport days**.
2. Make sure that you have a record for delivery from the vendor shipping address that you plan to create a purchase requisition for to the warehouse receiving address where you plan to receive the order. Set the **Transport days** field to *2* for this record.
3. Go to **Procurement and sourcing** > **Setup** > **Procurement and sourcing parameters**.
4. On the **Request for quotation** tab, set the **Purchaser can edit vendors bid** option to *Yes*.
5. Go to **Procurement and sourcing** > **Requests for quotations** > **All requests for quotations**.
6. On the Action Pane, select **New** to create an RFQ.
7. Set the **Requested receipt date** field to one week from today. Then enter values in any other required fields, and select **OK** to create the RFQ.
8. On the **Request for quotation lines** FastTab, in the **Item number** field, select an item. Then set the **Site** and **Warehouse** fields to the warehouse that you set up a receiving address for on the **Purchase transport days** page.
9. On the **Header** tab, on the **Vendor** FastTab, set the **Vendor account** field to the vendor whose shipping address you set up on the **Purchase transport days** page.
10. On the Action Pane, select **Save**.
11. On the Action Pane, on the **Quotation** tab, in the **Process** group, select **Send**.
12. In the **Sending request for quotation** dialog box, select **OK**.
13. On the Action Pane, on the **Quotation** tab, in the **Replies** group, select **Manage replies**.
14. On the Action Pane, select **Edit** > **Edit RFQ reply**.
15. On the Action Pane, select **Submit**.
16. In the **Submit** dialog box, select **OK**.
17. On the Action Pane, on the **Reply** tab, in the **Process** group, select **Accept**.

18. In the **Accepting request for quotation** dialog box, select **OK** to create the purchase order.
19. On the Action Pane, on the **General** tab, in the **Other information** group, select **Purchase order**.
20. Open the new purchase order.
21. On the **Line details** FastTab, on the **Delivery** tab, you see the following values:
    - **Requested receipt date** – The value matches the **Requested receipt date** value from the RFQ.
    - **Requested ship date** – The value is calculated backward from the requested receipt date, based on the purchase transport days setup.

Create a schedule for a site

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure shows how to schedule production orders that are not yet started for a site. The demo data company USMF is used to complete this procedure.

Identify production orders that are not started

1. Go to Production control > Production orders > All production orders.
2. Use the Quick Filter to find records. For example, filter on the Site field with a value of '1'.
    - 1 represents a site in USMF. If you are not using USMF, select a site from your own company.
3. Open the Status column filter.
4. Apply a filter on the "Status" field, with a value of "Scheduled", using the "is exactly" filter operator.

Create a schedule

1. In the list, mark or unmark all rows.
2. On the Action Pane, click Schedule.
3. Click Schedule jobs.
4. In the Scheduling direction field, select 'Backward from delivery date'.
5. Select No in the Finite capacity field.
6. Select No in the Finite material field.
7. Click OK.
    - This may take a while.

View the result of scheduled production orders

1. In the list, mark the selected row.

- You can mark any row.

2. On the Action Pane, click Production order.
3. Click All jobs.

    - On this page, you can see the list of jobs. On the Scheduling tab, you can see the Start date and End date for a job.

4. Click Materials.

    - On this page, you can see the estimated material consumption for the operations on the production order and the current available inventory.

Master planning with demand forecasts

Use a demand forecast to account for expected demand in your master planning. You can manually create a demand forecast, import it, or generate it by using the demand forecasting functionality in Microsoft Dynamics 365 Supply Chain Management. For more information about demand forecasting, see Demand forecasting overview.

> **Note**
>
> Planning Optimization doesn't support separate forecast planning. Therefore, the **Current forecast plan** setting on the **Master planning parameters** page has no effect when you use Planning Optimization.

Set up a master plan to include a demand forecast

To configure a master plan so that it includes a demand forecast, follow these steps:

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Select an existing plan, or create a new plan.
3. On the **General** FastTab, set the following fields:
    - **Forecast model** – Select the forecast model to apply. This model is considered when a supply suggestion is generated for the current master plan.
    - **Include demand forecast** – Set this option to *Yes* to include the demand forecast in the current master plan. If you set it to *No*, demand forecast transactions aren't included in the master plan.
    - **Method used to reduce forecast requirements** – Select the method that should be used to reduce forecast requirements. Learn more in the Forecast reduction keys section later in this article.
4. On the **Time fence in days** FastTab, set the following fields to specify the period that the demand forecast is included during:
    - **Forecast plan** – Set this option to *Yes* to override the forecast plan time fence that originates from the individual coverage groups. Set it to *No* to use the values from the individual coverage groups for the current master plan.

- **Forecast time period** – If you set the **Forecast plan** option to *Yes*, specify the number of days (from today's date) that the demand forecast should be applied.

> **Important**
>
> Planning Optimization doesn't support the **Forecast plan** setting.

Set up a coverage group to include a demand forecast

To configure a coverage group to include a demand forecast, follow these steps:

1. Go to **Master planning** > **Setup** > **Plans** > **Coverage groups**.
2. Select an existing coverage group, or create a new group.
3. On the **Other** FastTab, set the following fields:
   - **Forecast plan time fence** – Enter the number of days (from today's date) that the demand forecast should apply to. You can override this value by using the **Forecast plan** option on the master plan, as described in the previous section.
   - **Reduction key** – Select the reduction key to apply. Learn more in the Create and set up a forecast reduction key and Use a reduction key sections later in this article.
   - **Reduce forecast by** – For master plans where the **Method used to reduce forecast requirements** field is set to *Transactions - reduction key* or *Transactions - dynamic period*, specify which transactions should reduce the forecast. Select one of the following values:
     - **All transactions** – All transactions reduce the forecast.
     - **Orders** – Only sales orders reduce the forecast.

     > **Note**
     >
     > If you select *All transactions*, the system considers transactions that have both demand and supply in the same inventory dimensions neutral and it ignores them during the forecast reduction. For example, if the planning dimension is set to site only, not warehouse, the system ignores a transfer order between site 1, warehouse 11, and site 1, warehouse 13, and it doesn't reduce the remaining demand forecast.

- **Include intercompany orders** – Set this option to *Yes* if intercompany orders should be included when the forecast is reduced. Otherwise, set it to *No*.

- **Include customer forecast in the demand forecast** – Specify whether a customer forecast should be included in the overall forecast. This option determines how actual demand reduces the forecasted demand. Use it to ensure that master planning covers the supply of items that specific customers purchase.
  - Set this option to *Yes* to include a customer forecast in the overall forecast. In this case, actual customer demand reduces both the customer forecast and the overall forecast. Master planning generates planned orders to cover only the overall forecast quantity.
  - Set this option to *No* if you don't want to include a customer forecast in the overall forecast. In this case, actual customer demand reduces only the customer forecast. Master planning generates planned orders to cover both the overall forecast quantity and the forecast for each customer quantity.

Forecast reduction keys

This section provides information about the different methods that reduce forecast requirements. It includes examples of the results of each method. It also explains how to create, set up, and use a forecast reduction key. Some methods use a forecast reduction key to reduce forecast requirements.

Methods to reduce forecast requirements

When you include a forecast in a master plan, select how to reduce the forecast requirements when actual demand is included. Master planning excludes forecast requirements from the past, which means all forecast requirements before today's date.

To include a forecast in a master plan and select the method to reduce forecast requirements, go to **Master planning** > **Setup** > **Plans** > **Master plans**. In the **Forecast model** field, select a forecast model. In the **Method used to reduce forecast requirements** field, select a method. The following options are available:

- None
- Percent – reduction key
- Transactions – reduction key
- Transactions – dynamic period

The following sections provide more information about each option.

None

If you select *None*, the forecast requirements aren't reduced during master scheduling. In this case, master planning creates planned orders to supply the forecasted demand (forecast requirements). These planned orders maintain the suggested quantity, regardless of other types of demand. For example, if sales orders are placed, master planning creates additional planned orders to supply the sales orders. The quantity of the forecast requirements isn't reduced.

Percent – reduction key

If you select *Percent - reduction key*, the system reduces the forecast requirements according to the percentages and periods that the reduction key defines. In this case, master planning creates planned orders where the quantity is calculated as forecasted quantity × reduction key in each period. If other types of demand exist, master planning also creates planned orders to supply that demand.

Example: Percent – reduction key

This example shows how a reduction key reduces demand forecast requirements according to the percentages and periods that the reduction key defines.

For this example, you include the following demand forecast in a master plan.

Expand table

Month	Demand forecast
January	1,000
February	1,000
March	1,000
April	1,000

On the **Reduction keys** page, you set up the following lines.

Expand table

Change	Unit	Percent
1	Month	100

Change	Unit	Percent
2	Month	75
3	Month	50
4	Month	25

You assign the reduction key to the item's coverage group. Then, on the **Master plans** page, in the **Method used to reduce forecast requirements** field, you select *Percent - reduction key*.

In this case, if you run forecast scheduling on January 1, the system consumes the demand forecast requirements according to the percentages that you set up on the **Reduction keys** page. The following requirement quantities are transferred to the master plan.

Expand table

Month	Planned order quantity	Calculation
January	0	= 0% × 1,000
February	250	= 25% × 1,000
March	500	= 50% × 1,000
April	750	= 75% × 1,000
May through December	1,000	= 100% × 1,000

Transactions – reduction key

If you set the **Method used to reduce forecast requirements** field to *Transactions - reduction key*, the system reduces the forecast requirements by the qualified demand transactions that occur during the periods that the reduction key defines.

The **Reduce forecast by** field on the **Coverage groups** page defines the qualified demand. If you set the **Reduce forecast by** field to *Orders*, only sales order transactions are considered qualified demand. If you set it to *All transactions*, any non-intercompany issue inventory transactions are considered qualified demand. If intercompany sales orders should also be considered qualified demand, set the **Include intercompany orders** option to *Yes*.

Forecast reduction starts with the first (earliest) demand forecast record in the reduction key period. If the quantity of qualified inventory transactions is more than the quantity of demand forecast lines in the same reduction key period, the balance of inventory transactions quantity is

used to reduce the demand forecast quantity in the previous period (if there's unconsumed forecast).

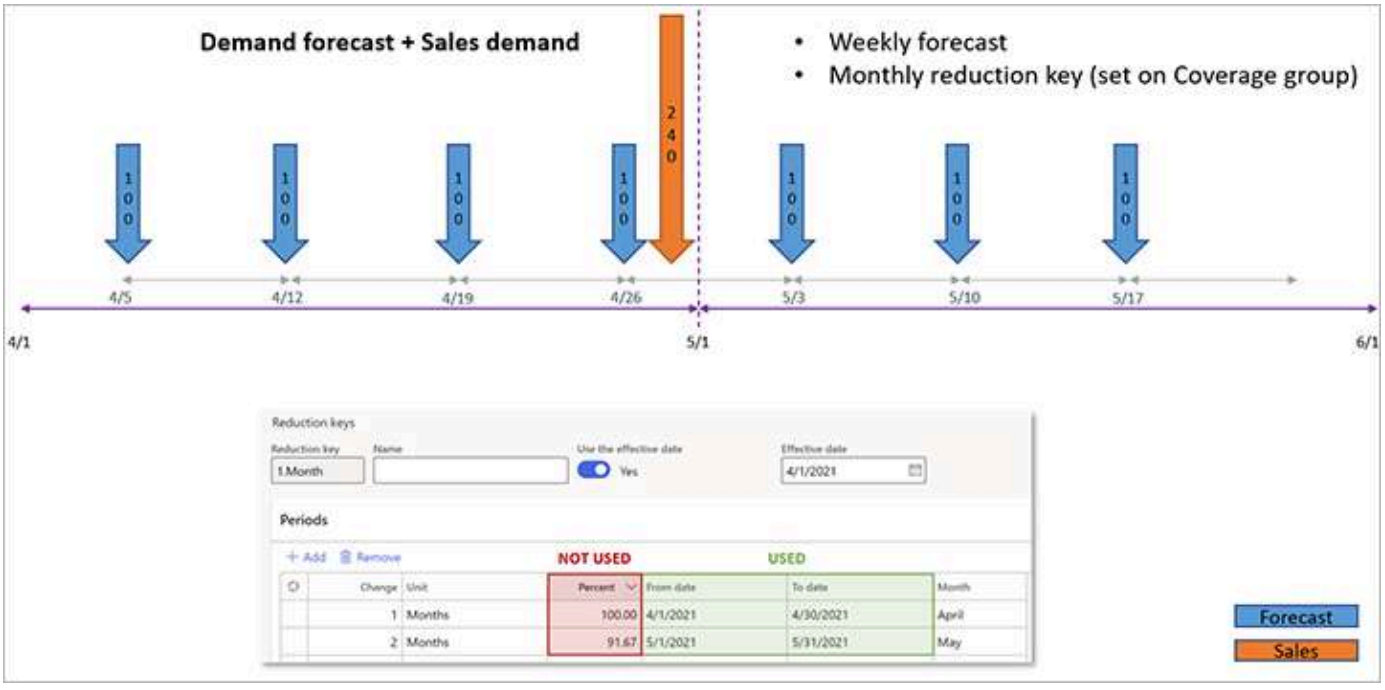
If no unconsumed forecast remains in the previous reduction key period, the balance of inventory transactions quantity reduces the forecast quantity in the next month (if there's unconsumed forecast).

The value of the **Percent** field on the reduction key lines isn't used when the **Method used to reduce forecast requirements** field is set to *Transactions - reduction key*. Only the dates define the reduction key period.

> **Note**
>
> The system ignores any forecast that you post on or before today's date and doesn't use it to create planned orders. For example, if you generate your demand forecast for the month on January 1, and you run master planning that includes demand forecasting on January 2, the calculation ignores the demand forecast line that is dated January 1.

Example: Transactions – reduction key

This example shows how actual orders that occur during the periods that the reduction key defines reduce demand forecast requirements.



For this example, you select *Transactions - reduction key* in the **Method used to reduce forecast requirements** field on the **Master plans** page.

The following demand forecast lines exist on April 1.

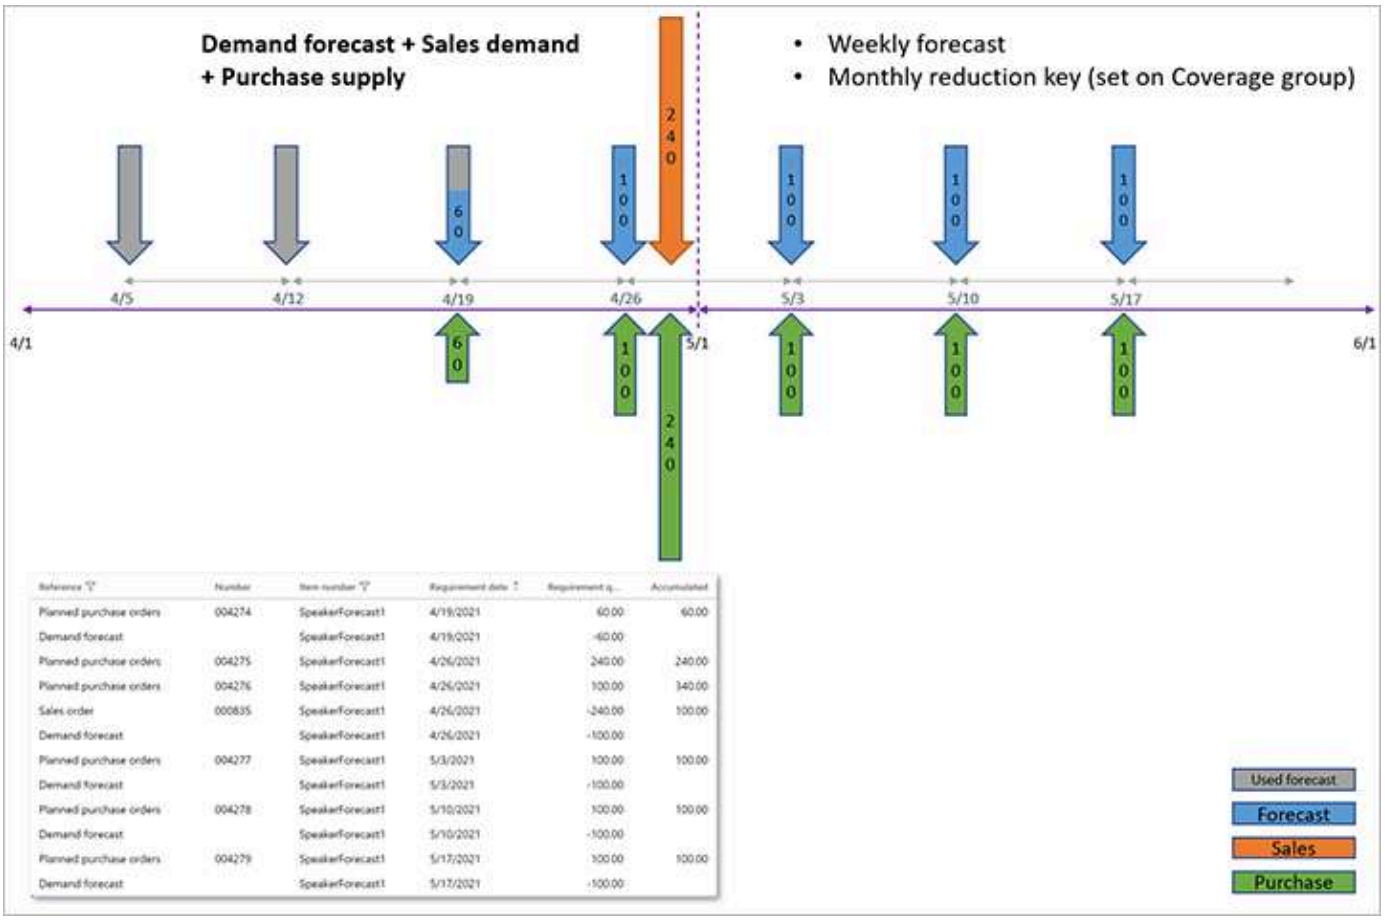
Expand table

Date	Number of pieces forecasted
April 5	100
April 12	100
April 19	100
April 26	100
May 3	100
May 10	100
May 17	100

The following sales order lines exist in April.

Expand table

Date	Number of pieces requested
April 27	240



The following requirement quantities are transferred to the master plan when master planning is run on April 1. As you see, the April forecast transactions were reduced by the demand quantity of 240 in a sequence, starting from the first of those transactions.

Expand table

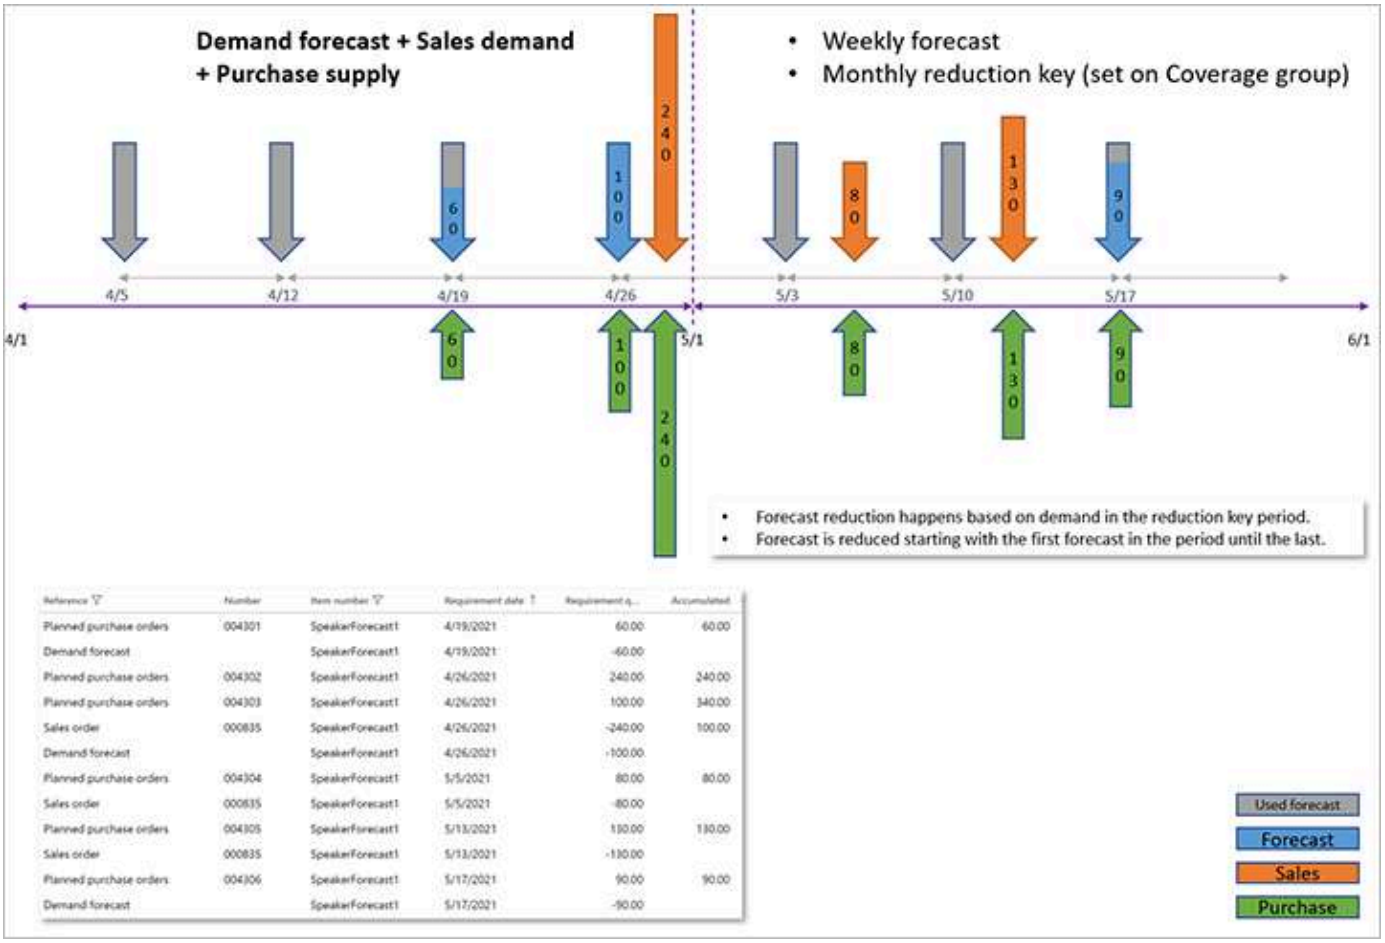
Date	Number of pieces required
April 5	0
April 12	0
April 19	60
April 26	100
April 27	240
May 3	100
May 10	100
May 17	100

Now, assume that you import new orders for the period of May.

The following sales order lines exist in May.

Expand table

Date	Number of pieces requested
May 4	80
May 11	130



When you run master planning on April 1, the system transfers the following requirement quantities to the master plan. As you see, the demand quantity of 240 reduces the April forecast transactions in a sequence, starting from the first of those transactions. However, the demand quantity of 210 reduces the May forecast transactions, starting from the first demand forecast transaction in May. The totals per period are preserved (400 in April and 300 in May).

Expand table

Date	Number of pieces required
April 5	0
April 12	0

Date	Number of pieces required
April 19	60
April 26	100
April 27	240
May 3	0
May 4	80
May 10	0
May 11	130
May 17	90

Transactions – dynamic period

If you select *Transactions - dynamic period*, actual order transactions that occur during the dynamic period reduce the forecast requirements. The dynamic period covers the current forecast dates and ends at the start of the next forecast. In this case, master planning creates planned orders to supply the forecasted demand (forecast requirements). However, when you place actual order transactions, they reduce the forecast requirements. The actual transactions consume part of the forecasted requirements.

When you use this option, the following behavior occurs:

- Reduction keys aren't required or used.
- If the forecast is completely reduced, the forecast requirements for the current forecast become 0 (zero).
- If there's no future forecast, the system reduces forecast requirements from the last forecast that you entered.
- Time fences are included in the forecast reduction calculation.
- Positive days are included in the forecast reduction calculation.
- If actual order transactions exceed the forecasted requirements, the remaining transactions aren't forwarded to the next forecast period.

Example 1: Transactions – dynamic period

Here's a simple example that shows how the *Transactions - dynamic period* method works.

For this example, you include the following demand forecast in a master plan.

Expand table

Date	Demand forecast
January 1	1,000
February 1	1,000

You also create the following sales orders.

Expand table

Date	Sales order quantity
January 15	200
February 15	400

In this case, the system creates the following planned orders.

Expand table

Demand forecast date	Quantity	Explanation
January 1	800	Forecast requirements (= 1,000 – 200)
January 15	200	Sales orders requirements
February 1	600	Forecast requirements (= 1,000 – 400)
February 15	400	Sales orders requirements

Example 2: Transactions – dynamic period

In most cases, systems are set up so that transactions reduce demand forecast in specific forecast periods: weeks, months, and so on. These periods are defined in the reduction key. However, the time between two demand forecast lines can also *imply* a period.

For this example, you create a demand forecast for the following dates and quantities.

Expand table

Date	Demand forecast
January 1	1,000
January 5	500

Date	Demand forecast
January 12	1,000

Notice that, in this forecast, there isn't a clear period between the forecast dates. Between the first and second dates, there's a four-day span, and between the second and third dates there's a seven-day span. These spans are the dynamic periods.

You also create the following sales order lines.

Expand table

Date	Sales order quantity
December 15 in the previous year	500
January 3	100
January 10	200

The sales orders reduce the forecast in the following ways:

- Because the first sales order isn't in any period, it doesn't reduce any forecast.
- Because the second sales order is between January 1 and January 5, it reduces the forecast for January 1 by 100.
- Because the third sales order is between January 5 and January 12, it reduces the forecast for January 5 by 200.

Therefore, the system creates the following planned orders.

Expand table

Demand forecast date	Quantity	Explanation
December 15 in the previous year	500	Sales order requirements
January 1	900	Forecast requirements period January 1 to January 5 (= 1,000 – 100)
January 3	100	Sales order requirements
January 5	300	Forecast requirements period January 5 to January 10 (= 500 – 200)
January 12	1,000	Forecast requirements period January 12 to end

Create and set up a forecast reduction key

A forecast reduction key is used in the *Transactions - reduction key* and *Percent- reduction key* methods for reducing forecast requirements. Follow these steps to create and set up a reduction key.

1. Go to **Master planning** > **Setup** > **Coverage** > **Reduction keys**.
2. Select **New** to create a reduction key.
3. In the **Reduction key** field, enter a unique identifier for the forecast reduction key. Then, in the **Name** field, enter a name.
4. Define the periods and the reduction key percentage in each period:
    - The **Effective date** field indicates the date when creation of the periods starts. When the **Use the effective date** option is set to *Yes*, the periods start on the effective date. When it's set to *No*, the periods start on the date when master planning is run.
    - Define the periods that the forecast reduction should occur during.
    - For a specific period, specify the percentages that the forecast requirements should be reduced by. Enter positive values to decrease requirements or negative values to increase requirements.

Use a reduction key

A forecast reduction key must be assigned to the coverage group of the item. Follow these steps to assign a reduction key to an item's coverage group.

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.
2. On the **Other** FastTab, in the **Reduction key** field, select the reduction key to assign to the coverage group. The reduction key then applies to all items that belong to the coverage group.
3. To use a reduction key to calculate forecast reduction during master scheduling, you must define this setting in the setup of the forecast plan or the master plan. Go to one of the following locations:
    - **Master planning** > **Setup** > **Plans** > **Forecast plans**
    - **Master planning** > **Setup** > **Plans** > **Master plans**

4. On the **Forecast plans** or **Master plans** page, on the **General** FastTab, in the **Method used to reduce forecast requirements** field, select either *Percent - reduction key* or *Transactions - reduction key*.

Reduce a forecast by transactions

When you select *Transactions - reduction key* or *Transactions - dynamic period* as the method for reducing forecast requirements, you can specify which transactions reduce the forecast. On the **Coverage groups** page, on the **Other** FastTab, in the **Reduce forecast by** field, select *All transactions* if all transactions should reduce the forecast or *Orders* if only sales orders should reduce the forecast.

Consider customer, customer group, required BOM, and required Route in demand forecast reduction

Each demand forecast line can specify a customer, a customer group, a *required BOM*, and a *required Route*. When you turn on the *Consider BOM and route in supply- and demand forecast reduction with Planning Optimization* feature in Feature management, Planning Optimization respects all four of these dimensions when it decides whether an existing demand transaction (such as a sales order line) reduces a forecast line.

Prerequisites

Before you can use the BOM and route forecast reduction behavior described in this section, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.49 or later.
- The feature named *Consider BOM and route in supply- and demand forecast reduction with Planning Optimization* must be turned on in Feature management.

Matching principle

The behavior follows a single principle:

> A transaction reduces a forecast line only when, for every dimension the forecast line specifies, the transaction either matches that value or doesn't specify a value for that dimension. A transaction that specifies a different value than the forecast line for any dimension can't reduce that forecast line.

In other words, a transaction can be at the same specificity as the forecast line or less specific, but it can't be specific in a *different* way.

Specificity rules for demand forecast lines

The principle leads to the following rules. In each rule, *transaction* refers to a sales order line (or, when the coverage group is set to **All transactions**, any qualifying issue inventory transaction) that would otherwise reduce the forecast.

- A forecast line that specifies both a required BOM and a required Route is reduced only by transactions that specify the same BOM and the same route, or that leave one or both of those values blank.
- A forecast line that specifies a required BOM but no required Route is reduced by transactions that specify the same BOM (regardless of route) and by transactions that specify no BOM.
- A forecast line that specifies a required Route but no required BOM is reduced by transactions that specify the same route (regardless of BOM) and by transactions that specify no route.
- A forecast line that specifies neither a required BOM nor a required Route is reduced by any otherwise-qualifying transaction.
- A transaction that specifies neither a BOM nor a route can reduce any forecast line, regardless of how specific that forecast line is.

The same principle applies to the customer and customer group dimensions on the forecast line: a sales order for a specific customer can reduce a forecast line that specifies the same customer, or that specifies only the customer group that the customer belongs to, or that specifies no customer or customer group. A sales order for a different customer can't reduce a customer-specific forecast line.

The following table summarizes the matching behavior for the BOM and route dimensions. A *Yes* indicates that the transaction reduces the forecast line. A *No* indicates that the transaction doesn't reduce the forecast line because it specifies a conflicting value.

Expand table

Forecast line specifies	**Tx (B1, R1)**	**Tx (B1, R2)**	**Tx (B2, R1)**	**Tx (B1, –)**	**Tx (–, R1)**	**Tx (–, –)**
required BOM = B1, required Route = R1	Yes	No	No	Yes	Yes	Yes

Forecast line specifies	Tx (B1, R1)	Tx (B1, R2)	Tx (B2, R1)	Tx (B1, –)	Tx (–, R1)	Tx (–, –)
required BOM = B1 only	Yes	Yes	No	Yes	Yes	Yes
required Route = R1 only	Yes	No	Yes	Yes	Yes	Yes
Neither specified	Yes	Yes	Yes	Yes	Yes	Yes

> **Note**
>
> This specificity logic is independent of the **Include customer forecast in the demand forecast** option on the coverage group. That option still controls whether a customer-specific forecast also reduces (and contributes to) the overall forecast. The rules in this section determine which transactions are *eligible* to reduce a given forecast line in the first place.

Example: Two demand forecast lines with different required BOMs

You have an item that has the following demand forecast lines.

Expand table

Model	Date	Quantity	Unit	Customer	Customer group	Required BOM	Required Route	Site	Warehouse
CurrentF	10/10/22	10	ea			B1		1	11
CurrentF	10/10/22	10	ea			B2		1	11

A sales order line exists for a quantity of *15 ea* with BOM *B2*, dated within the same forecast period.

The system behaves differently based on whether the *Consider BOM and route in supply- and demand forecast reduction with Planning Optimization* feature is turned on:

- **When the feature is turned *off*** – The sales order reduces the demand forecast in the order that the lines are encountered, without checking the BOM. The first line is reduced to *0*, the second line is reduced to *5*, and Planning Optimization creates a planned order to cover the residual *5 ea* of forecast on the second line.

- **When the feature is turned *on*** – Only the second line matches the sales order's BOM. The sales order reduces the second line to *0* and leaves the first line at *10*. Planning Optimization then creates a planned order to cover the *10 ea* of remaining demand with BOM *B1*, plus a planned order to cover the *15 ea* of sales-order demand with BOM *B2*.

Example: Combined customer, customer group, required BOM, and required Route

You have an item that has the following demand forecast lines. Customer *Cust-1* belongs to customer group *CG-1*. Customer *Cust-2* doesn't belong to customer group *CG-1*.

Expand table

Line	Quantity	Customer	Customer group	Required BOM	Required Route
L1	10	Cust-1	CG-1	B1	R1
L2	10		CG-1	B1	
L3	10				R1
L4	10				

The following sales order lines exist for the same item, site, and warehouse within the same forecast period.

Expand table

Sales order	Quantity	Customer	BOM	Route
SO-A	5	Cust-1	B1	R1
SO-B	5	Cust-1	B1	
SO-C	5	Cust-2	B1	R1
SO-D	5			

With the feature turned on, Planning Optimization evaluates each sales order against each forecast line. When a sales order can reduce more than one forecast line, Planning Optimization applies the reduction to the most specific matching line first, so that less-specific forecast lines remain available to cover other demand.

- *SO-A* (Cust-1, B1, R1) matches every dimension of *L1*. It also matches *L2* (the customer belongs to *CG-1*, the BOM matches, and *L2* doesn't constrain the route), but *L1* is more specific, so it reduces *L1* by *5*.
- *SO-B* (Cust-1, B1, no route) matches the customer and BOM of *L1* and is less specific on route, so it also reduces *L1* by *5*. *L1* is now fully consumed.
- *SO-C* (Cust-2, B1, R1) can't reduce *L1* or *L2*, because *Cust-2* doesn't match *L1*'s customer and doesn't belong to *L2*'s customer group. It does match *L3* on route (and is allowed to be more specific than the forecast line on the other dimensions), so it reduces *L3* by *5*.
- *SO-D* (no customer, no BOM, no route) is fully unspecified, so it can reduce any remaining forecast line. Planning Optimization applies it to the most specific line that still has open quantity, which is *L2*, reducing *L2* by *5*.

The residual demand forecast quantities are *L1* = 0, *L2* = 5, *L3* = 5, and *L4* = 10. Planning Optimization creates planned orders to cover this residual demand together with the sales-order demand.

> **Note**
>
> When the feature is turned on, the same BOM and route matching also applies to demand transactions that have already been processed within the forecast period–for example, invoiced sales orders. The BOM and route that were specified on the original sales order are honored when the order reduces a forecast line, just as they are for open sales orders.
>
> Reduction by already-processed transactions is itself controlled by a separate feature management feature: *Include invoiced and delivered orders during supply and demand forecast reduction for planning optimization*. That feature must also be turned on for processed orders to participate in forecast reduction at all. The *Consider BOM and route in supply- and demand forecast reduction with Planning Optimization* feature then governs how the BOM and route on those processed orders are matched.

The same rules apply to supply forecasts. Learn more in Consider sub-BOM and sub-Route in supply forecast reduction.

Forecast models and submodels

This section describes how to create forecast models and how to combine multiple forecast models by setting up submodels.

A *forecast model* names and identifies a specific forecast. After you create the forecast model, you can add forecast lines to it. To add forecast lines for multiple items, use the **Demand forecast lines** page. To add forecast lines for a specific selected item, use the **Released products** page.

A forecast model can include forecasts from other forecast models. To achieve this result, add other forecast models as *submodels* of a parent forecast model. You must create each relevant model before you can add it as a submodel of a parent forecast model.

The resulting structure gives you a powerful way to control forecasts, because it lets you combine (aggregate) the input from multiple individual forecasts. Therefore, from a planning point of view, it's easy to combine forecasts for simulations. For example, you might set up a simulation that is based on the combination of a regular forecast with the forecast for a spring promotion.

Submodel levels

You can add unlimited submodels to a parent forecast model. However, the structure can be only one level deep. In other words, a forecast model that is a submodel of another forecast model can't have its own submodels. When you add submodels to a forecast model, the system checks whether that forecast model is already a submodel of another forecast model.

If master planning encounters a submodel that has its own submodels, you receive an error message.

Submodel levels example

Forecast model A has forecast model B as a submodel. Therefore, forecast model B can't have its own submodels. If you try to add a submodel to forecast model B, you receive the following error message: "Forecast model B is a submodel for model A."

Aggregating forecasts across forecast models

The system aggregates forecast lines that occur on the same day across their forecast model and its submodels.

Aggregation example

Forecast model A has forecast models B and C as submodels.

- Forecast model A includes a demand forecast for 2 pieces (pcs) on June 15.
- Forecast model B includes a demand forecast for 3 pcs on June 15.
- Forecast model C includes a demand forecast for 4 pcs on June 15.

The resulting demand forecast is a single demand for 9 pcs (2 + 3 + 4) on June 15.

> ⓘ **Note**
>
> Each submodel uses its own parameters, not the parameters of the parent forecast model.

Create a forecast model

To create a forecast model, follow these steps:

1. Go to **Master planning** > **Setup** > **Demand forecasting** > **Forecast models**.
2. On the Action Pane, select **New**.
3. Set the following fields for the new forecast model:
    - **Model** – Enter a unique identifier for the model.
    - **Name** – Enter a descriptive name for the model.
    - **Stopped** – Usually, you should set this option to *No*. Set it to *Yes* only if you want to prevent editing of all forecast lines that are assigned to the model.

    > ⓘ **Note**
    >
    > The **Include in cash flow forecasts** field and the fields on the **Project** FastTab aren't related to master planning. Therefore, you can ignore them in this context. Consider them only when you work with forecasts for the **Project management and accounting** module.

Assign submodels to a forecast model

To assign submodels to a forecast model, follow these steps:

1. Go to **Inventory management** > **Setup** > **Forecast** > **Forecast models**.
2. In the list pane, select the forecast model to set up a submodel for.
3. On the **Submodel** FastTab, select **Add** to add a row to the grid.
4. In the new row, set the following fields:

- **Submodel** – Select the forecast model to add as a submodel. This forecast model must already exist, and it must not have any submodels of its own.
- **Name** – Enter a descriptive name for the submodel. For example, this name might indicate the submodel's relation to the parent forecast model.

Last updated on 07/23/2026

Master planning with supply forecasts

Supply forecasts let you specify the supply that you expect to need during a future period. Typically, you base the estimate on the previous year's sales history and then use the forecast for budgeting purposes. You can also set up your master plans to consider forecasts during planning.

Set up a master plan to consider supply forecasts

You can specify whether each master plan should consider forecasts when it runs. Use the following procedure to set forecasting options for each plan.

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Select an existing master plan in the list pane, or select **New** on the Action Pane to create a new one.
3. On the **General** FastTab, set the following fields:
    - **Forecast model** – Select the model that contains the supply and demand forecasts that the master plan should consider.
    - **Include supply forecast** – Set this option to *Yes* if the master plan should consider supply forecasts.
    - **Include demand forecast** – Set this option to *Yes* if the master plan should consider demand forecasts. Although this setting is independent of the **Include supply forecast** setting, some of the other settings on the page apply to both supply forecasts and demand forecasts. For more information about planning that considers demand forecasts, see Master planning with demand forecasts.
    - **Method used to reduce forecast requirements** – Select the method to use to reduce forecast requirements during master planning:
        - *None* – Forecast requirements aren't reduced during master planning.
        - *Percent - reduction key* – Forecast requirements are reduced according to the percentages and time periods that you define in the reduction key.
        - *Transactions – reduction key* – Forecast requirements are reduced by the transactions that occur during the time periods that you define in the reduction key.

- *Transactions – dynamic period* – Forecast requirements are reduced by the order transactions that occur during the dynamic period. The dynamic period covers the current forecast dates, and it ends when the next forecast begins. The *Transactions – dynamic period* method doesn't use or require a reduction key. When you use it, the following conditions apply:
  - If the forecast is completely reduced, the forecast requirements for the current forecast become 0 (zero).
  - If there's no future forecast, forecast requirements from the last forecast that you entered are reduced.
  - Time fences are included in the forecast reduction calculation.
  - Positive days are included in the forecast reduction calculation.
  - If actual order transactions exceed the forecasted requirements, the remaining transactions aren't forwarded to the next forecast period.

> ⓘ **Note**
>
> The **Method used to reduce forecast requirements** setting also applies to demand forecasts if you enable them for the master plan, and it affects them in a similar way. Learn more in Master planning with demand forecasts.

Set reduction options for coverage groups

To set options that control how a coverage group reduces its forecast requirements for master plans that use transaction-based reduction, follow these steps:

1. Go to **Master planning** > **Setup** > **Plans** > **Coverage groups**.
2. Select an existing coverage group in the list pane, or select **New** on the Action Pane to create a new one.
3. On the **Other** FastTab, in the **Reduce forecast by** field, specify how supply forecast requirements should be reduced for items in the coverage group, for master plans where the **Method used to reduce forecast requirements** field is set to *Transactions - reduction key* or *Transactions - dynamic period*. Select one of the following values:
   - *All transactions* – All transactions reduce the forecast.
   - *Orders* – Only orders of the same type reduce the forecast.

For example, the default order settings for an item indicate that it should be produced. There's a supply forecast line for a quantity of 50, and there's an existing purchase order for a quantity of 20. If you set the **Reduce forecast by** field to *Orders*, a planned production order is created for a quantity of 50. If you set it to *All transactions*, the planned production order is reduced to a quantity of 30.

This setting also applies to demand forecasting reduction. Learn more in Master planning with demand forecasts.

Enter a supply forecast for a product

To enter a supply forecast for a product, follow these steps:

1. Go to **Product information management** > **Products** > **Released products**.
2. Select the product that you want to enter a forecast for.
3. On the Action Pane, on the **Plan** tab, select **Supply forecast**.
4. On the **Supply forecast** page, on the Action Pane, select **New** to add a forecast to the grid.
5. Fill out the new line to specify your forecast.

Plan for an item with supply forecast lines

When you run a master plan that includes an item that has a supply forecast, the system creates a purchase order for the supply lines that you entered. The system respects the default order settings for the item. If those default order settings specify a **Default order type** value of *Purchase order*, and you don't specify a vendor account on the supply forecast line, the system uses the default vendor for the item.

Consider sub-BOM and sub-route in supply forecast reduction

Each supply forecast line can specify a *sub-BOM* and a *sub-route*. When you turn on the *Consider BOM and route in supply- and demand forecast reduction with Planning Optimization* feature in Feature management, Planning Optimization respects these values when it decides whether an existing transaction (such as a released purchase order, a released production order, or a released transfer order) reduces a forecast line.

Prerequisites

Before you can use the BOM and route forecast reduction behavior described in this section, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.49 or later.
- The feature named *Consider BOM and route in supply- and demand forecast reduction with Planning Optimization* must be turned on in Feature management.

Matching principle

The behavior follows a single principle:

> A transaction reduces a forecast line only when, for every dimension the forecast line specifies, the transaction either matches that value or doesn't specify a value for that dimension. A transaction that specifies a value that's different from the forecast line value for any dimension can't reduce that forecast line.

In other words, a transaction can be at the same specificity as the forecast line or less specific, but it can't be specific in a *different* way.

Specificity rules for sub-BOM and sub-route

The principle leads to the following rules. In each rule, *transaction* refers to a released purchase order, production order, or transfer order that would otherwise qualify to reduce the forecast.

- A forecast line that specifies both a sub-BOM and a sub-route is reduced only by transactions that specify the same BOM and the same route, or that leave one or both of those values blank.
- A forecast line that specifies a sub-BOM but no sub-route is reduced by transactions that specify the same BOM (regardless of route) and by transactions that specify no BOM.
- A forecast line that specifies a sub-route but no sub-BOM is reduced by transactions that specify the same route (regardless of BOM) and by transactions that specify no route.
- A forecast line that specifies neither a sub-BOM nor a sub-route is reduced by any otherwise-qualifying transaction.
- A transaction that specifies neither a BOM nor a route can reduce any forecast line, regardless of how specific that forecast line is.

The following table summarizes the matching behavior. A *Yes* indicates that the transaction reduces the forecast line. A *No* indicates that the transaction doesn't reduce the forecast line

because it specifies a conflicting value.

Expand table

Forecast line specifies	Tx (B1, R1)	Tx (B1, R2)	Tx (B2, R1)	Tx (B1, –)	Tx (–, R1)	Tx (–, –)
sub-BOM = B1, sub-route = R1	Yes	No	No	Yes	Yes	Yes
sub-BOM = B1 only	Yes	Yes	No	Yes	Yes	Yes
sub-route = R1 only	Yes	No	Yes	Yes	Yes	Yes
Neither specified	Yes	Yes	Yes	Yes	Yes	Yes

This specificity logic is layered on top of the dimension matching that already applies. For purchase orders, the vendor on the transaction must still match the vendor on the forecast line, as described in Reduction of forecasts by matching vendors only. For production orders and transfer orders, the vendor is ignored.

Example: Two supply forecast lines with different sub-BOMs

You have an item where the default order type is *Production*. It has the following supply forecast lines.

Expand table

Model	Date	Quantity	Unit	sub-BOM	sub-route	Site	Warehouse
CurrentF	10/10/22	10	ea	B1		1	11
CurrentF	10/10/22	10	ea	B2		1	11

A released production order exists for a quantity of *15 ea* with BOM *B2*.

The system behaves differently based on whether the *Consider BOM and route in supply- and demand forecast reduction with Planning Optimization* feature is turned on:

- **When the feature is turned *off*** – The production order reduces the supply forecast in the order that the lines are encountered, without checking the BOM. The first line is reduced to *0*, the second line is reduced to *5*, and Planning Optimization creates a planned production order for a quantity of *5* with BOM *B2*.

- **When the feature is turned *on*** – Only the second line matches the production order's BOM. The production order reduces the second line to *0* and leaves the first line at *10*. Planning Optimization then creates a planned production order for a quantity of *10* with BOM *B1*, which is the supply that is still needed to cover the unmatched forecast.

Example: Combined sub-BOM and sub-route on the forecast line

You have an item where the default order type is *Production*. It has the following supply forecast line.

Expand table

Model	Date	Quantity	Unit	sub-BOM	sub-route	Site	Warehouse
CurrentF	10/10/22	20	ea	B1	R1	1	11

The following released production orders also exist for the same item, site, and warehouse, all dated within the same forecast period.

Expand table

Production order	Quantity	BOM	Route
PO-A	5	B1	R1
PO-B	5	B1	R2
PO-C	5	B2	R1
PO-D	5		

With the feature turned on, Planning Optimization evaluates each production order against the forecast line.

- *PO-A* (B1, R1) matches both dimensions and reduces the forecast by *5*.
- *PO-B* (B1, R2) specifies a different route than the forecast line, so it doesn't reduce the forecast line. Planning Optimization treats it as separate supply.
- *PO-C* (B2, R1) specifies a different BOM than the forecast line, so it doesn't reduce the forecast line. Planning Optimization treats it as separate supply.
- *PO-D* (no BOM, no route) is less specific than the forecast line, so it reduces the forecast by *5*.

The forecast line is reduced from *20* to *10* (= 20 − 5 − 5), and Planning Optimization creates a planned production order for a quantity of *10 ea* with BOM *B1* and route *R1* to cover the remaining requirement.

> **Note**
>
> When the feature is turned on, the same BOM and route matching also applies to transactions that were already processed for the forecast period–for example, received purchase orders and ended production orders. The BOM and route that were specified on the original order are honored when the order reduces a forecast line, just as they are for open (released) orders.
>
> Reduction by already-processed transactions is itself controlled by a separate feature management feature: *Include invoiced and delivered orders during supply and demand forecast reduction for planning optimization*. You must also turn on that feature for processed orders to participate in forecast reduction at all. The *Consider BOM and route in supply- and demand forecast reduction with Planning Optimization* feature then governs how the BOM and route on those processed orders are matched.

The same rules apply to demand forecasts, with the additional dimensions of customer and customer group. Learn more in Consider customer, customer group, required BOM, and required Route in demand forecast reduction.

Check whether a planned order is a supply forecast order

Use the following procedure to check whether a planned order was created as a result of a supply forecast.

1. Go to **Master planning** > **Master planning** > **Planned orders**.
2. Open the planned order that you want to inspect.
3. On the **General** FastTab, check the value of the **Supply forecast** field. If the order was created to cover a supply forecast, this field is set to *Yes*.

Examples of master planning with supply forecasts

This section provides several examples that show how supply forecasting affects master planning.

Example 1: Supply forecast for an item

You have an item where the default order type is *Purchase order* and the default vendor is *US-002*. It has the following supply forecast line.

Expand table

Model	Date	Vendor account	Vendor group	Quantity	Unit	Site	Warehouse
CurrentF	10/10/22			35	ea	1	11

When you run master planning, a planned purchase order is created for *35 ea* from vendor *US-002*.

Example 2: Several supply forecast lines, with and without a vendor

You have an item where the default order type is *Purchase order* and the default vendor is *US-002*. It has the following supply forecast lines.

Expand table

Model	Date	Vendor account	Vendor group	Quantity	Unit	Site	Warehouse
CurrentF	10/10/22			35	ea	1	11
CurrentF	10/10/22	US-101		25	ea	1	11

In this case, the system treats the line that doesn't specify a vendor as a generic forecast, and it assumes that the line that does specify a vendor should be subtracted from the generic forecast. Therefore, master planning creates the following planned purchase orders for the item:

- A planned purchase order for a quantity of *25 ea* from vendor *US-101* (The vendor and quantity that are specified on the forecast line are used.)
- A planned purchase order for a quantity of *10 ea* from vendor *US-002* (Because no vendor was specified on the other forecast line, the default vendor is used, and the quantity of this forecast line is reduced by the quantity of the vendor-specific forecast line.)

Example 3: Plans that use the Transactions - dynamic period reduction method in a single forecast period

For master plans that use *Transactions - dynamic period* as the forecast reduction method, master planning reduces forecast quantities if existing transactions match those supply characteristics.

For example, you have an item where the default order type is *Purchase order*. It has the following supply forecast line.

Expand table

Model	Date	Vendor account	Vendor group	Quantity	Unit	Site	Warehouse
CurrentF	10/10/22	US-101		25	ea	1	11

Because there's only one supply forecast line, there's only one forecast period.

When you run a master plan that uses *Transactions – dynamic period* as the reduction method, one of the following results can occur:

- If a purchase order exists for vendor *US-101* and a quantity of *10 ea*, and the **Supply forecast** field is set to *Yes*, master planning creates a new planned purchase order for the remaining quantity of *15 ea*. The forecast line is reduced, because the vendor matches the existing purchase order.
- If a purchase order exists for vendor *US-102*, site *1*, warehouse *11*, and a quantity of *10 ea*, and the **Supply forecast** field is set to *Yes*, master planning creates a new planned purchase order for the full quantity of *25 ea*. The forecast line can't be reduced, because it has a different vendor than the existing purchase order.

> **Note**
>
> This situation can occur for planned purchase orders, because a vendor is associated with them. However, for transfer orders and production orders, the supply forecast amounts are always reduced by existing orders, because no vendor is specified for these types of orders.

Example 4: Plans that use the Transactions - dynamic period reduction method over several forecast periods

You have an item where the default order type is *Purchase order*. It has the following supply forecast lines.

Expand table

Model	Date	Vendor account	Vendor group	Quantity	Unit	Site	Warehouse
CurrentF	10/10/22	US-101		25	ea	1	11
CurrentF	10/15/22	US-101		25	ea	1	11

In this example, two forecast lines each have a different date. Therefore, the dates establish the boundaries of the forecast periods. The first period is from October 10 through October 14, 2022 (10/10/22–10/14/22). The second is from October 15, 2022 (10/15/22) onward.

A purchase order exists for vendor *US-101*, a quantity of *10 ea*, and the date *10/12/22* (October 12, 2022). When you run a master plan that is set up to use *Transactions – dynamic period* as the reduction method, it creates the following orders:

- A planned order for a quantity of *15 ea* and the date *10/10/22* (The quantity is reduced by the existing purchase order that is dated during the same forecast period.)
- A planned order for a quantity of *25 ea* and the date *10/15/22* (The quantity is the full quantity of the forecast.)

Example 5: Plans that use no reduction

When you run a plan where the forecast reduction method is *None*, master planning always creates planned supply for all supply forecast lines. After you approve that planned supply, it reduces future planned orders. However, purchase orders don't reduce the supply forecast lines.

For example, you have an item where the default order type is *Purchase order*. It has the following supply forecast line.

Expand table

Model	Date	Vendor account	Vendor group	Quantity	Unit	Site	Warehouse
CurrentF	10/10/22	US-101		25	ea	1	11

There's an existing purchase order for vendor *US-101*, site *1*, warehouse *11*, a quantity of *25 ea*, and the date *10/10/22*.

When you run a master plan that uses *None* as the reduction method, it creates a planned purchase order for vendor *US-101*, site *1*, warehouse *11*, a quantity of *25 ea*, and the date *10/10/22*. In other words, the existing purchase order isn't reduced, because the forecast reduction method is *None*.

You edit the planned purchase order that was created after the last planning run, and change the quantity to *15 ea*. You then approve the order. The next time that you run the master plan, it creates a planned purchase order for vendor *US-101*, site *1*, warehouse *11*, a quantity of *10 ea*, and the date *10/10/22*. This time, the quantity is reduced to reflect the quantity of the existing approved order from the previous planning run.

Differences between Planning Optimization and the deprecated master planning engine

Supply forecasts work slightly differently, depending on the planning engine that you're using (Planning Optimization or the deprecated master planning engine). This section describes the differences.

Vendor groups

When you add a forecasted line, you can specify a vendor and a vendor group. In the deprecated master planning engine, planned orders that you create are grouped by the combination of the vendor and vendor group values. In Planning Optimization, planned orders are grouped by vendor.

The following table provides some examples of supply forecast lines for an item.

Expand table

Model	Date	Vendor account	Vendor group	Quantity	Unit	Site	Warehouse
CurrentF	10/10/22		VendorGroupA	5	ea	1	11
CurrentF	10/10/22		VendorGroupA	6	ea	1	11
CurrentF	10/10/22			7	ea	1	11

Vendor *VendorA* is the default vendor for vendor group *VendorGroupA*. It's also the default vendor for the item.

The deprecated master planning engine creates the following orders:

- A planned purchase order for vendor *VendorA*, vendor group *VendorGroupA*, and a quantity of *11*
- A planned purchase order for vendor *VendorA* and a quantity of *7*

Planning Optimization creates just one order:

- A planned purchase order for vendor *VendorA*, vendor group *VendorGroupA*, and a quantity of *18*

Reduction of general forecasts by more specific forecasts

In the deprecated master planning engine, the result is unpredictable if some forecasts have a vendor but others don't.

In Planning Optimization, more specific forecasts always reduce general forecasts, as the following example shows.

The following table provides some examples of supply forecast lines for an item.

Expand table

Date	Quantity	Vendor	Vendor group
02/11/2022	5.00	Vendor-A	VendorGroup-A
02/11/2022	6.00	Vendor-A	VendorGroup-A
02/11/2022	15.00		

The more specific forecasts (for 5.00 + 6.00 = 11.00 pieces) reduce the general forecast (for 15.00 pieces). The remainder is assigned to the default vendor. The following table shows the planned orders.

Expand table

Date	Quantity	Vendor	Vendor group
02/11/2022	11.00	Vendor-A	VendorGroup-A
02/11/2022	4.00	Vendor-A	VendorGroup-A

Respect for default order settings when planned orders are generated

Each item can have default order settings, such as a minimum purchase order quantity. The deprecated master planning engine ignores these settings, and therefore translates forecasts into planned orders that have the same quantity. Planning Optimization respects these settings when planned orders are generated from supply forecasts.

Aggregation of planned orders as a result of reduction by approved orders

The deprecated master planning engine assumes that only one order reduces the existing supply forecast. Therefore, if several orders match a supply forecast line, only the first order reduces it. In Planning Optimization, all orders that match the supply forecast line reduce it.

Reduction of forecasts by matching vendors only

When the deprecated master planning engine reduces a forecast by existing released purchase orders, it doesn't ensure that the vendor on the purchase order matches the vendor from the forecast. Planning Optimization reduces forecasts only by purchase orders that have a matching value in the vendor field.

For transfer and production orders, the vendor field is always ignored, because it isn't relevant for those order types.

Reduction of forecasts by transfer orders

If the default order type for an item is *Transfer*, forecasts can be reduced only by existing planned transfer orders. However, for production orders and purchase orders, only released orders reduce the supply forecast.

The deprecated master planning engine reduces forecasts for all transfer order states, whereas Planning Optimization reduces forecasts only by transfer orders that are in the *Released* state.

Supply schedule

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The **Supply schedule** page shows a comprehensive overview of supply and demand for a product or product family. You can filter the information by location, master plan, and periods. Use the page to create new orders, modify existing planned orders, and run master planning.

Open the Supply schedule page

Open the **Supply schedule** page in any of the following ways:

- Go to **Master planning** > **Master planning** > **Supply schedule**. In the **Modify filter** dialog box, enter filter values in the fields to specify the plan and product that you're looking for. (In the rest of this article, the collection of filter values that you enter is referred to as "the filter" or "the current filter.") When you finish, select **OK**.
- Go to **Product information management** > **Products** > **Released products**. Select or open a product. Then, on the Action Pane, on the **Plan** tab, in the **View** group, select **Supply schedule**.
- Go to **Master planning** > **Setup** > **Demand forecasting** > **Item allocation keys**. Select an item allocation key that's used as a product family. Then, on the Action Pane, select **Supply schedule**.
- Go to **Master planning** > **Master planning** > **Planned orders**. Select or open a planned order. Then, on the Action Pane, on the **View** tab, in the **View** group, select **Supply schedule**.

> **Note**
>
> When you open the **Supply schedule** page from a product, product family, or planned order, you don't have to enter filter values. The system uses the default period template.

Use the Supply schedule page

The **Supply schedule** page consists of an upper section, the **Period end inventory** FastTab, an additional FastTab that becomes visible based on the line selected in the upper section, and the FactBox pane. To open the FactBox pane and view a FactBox, select **Related information** on the right edge of the page.

Upper section

The upper section of the **Supply schedule** page contains a grid that shows the following data for a product or product family. This data is broken down by periods defined by the **Period template** value from the filter.

- **Period start inventory** – This line shows the expected inventory balance at the start of the period if all orders in the system occur.
- **Period end inventory** – This line shows the expected inventory balance at the end of the period if all orders in the system occur.
- **Period end pegged inventory** – This line shows the amount of inventory at the end of the period that is pegged against future demand.
- **Period net supply** – This line shows the difference between supply and demand in the period.
- **Minimum inventory** – This node shows safety stock for a product or product family. To expand or collapse this node, select it, and then select **Expand** or **Collapse** on the toolbar. This node appears only when there's safety stock for the product or product family.
- **Demand** – This node shows demand for a product or product family. The demand is grouped by transaction type. To expand or collapse this node, select it, and then select **Expand** or **Collapse** on the toolbar. Demand transaction types include sales, transfers, and inventory journals. This node appears only when there's demand for the product or product family.
- **Supply** – This node shows supply for a product or product family. The supply is grouped by transaction type. To expand or collapse this node, select it, and then select **Expand** or **Collapse** on the toolbar. Supply transaction types include production, purchase, and transfers. This node appears only when there's supply for the product or product family.

Many of the available toolbar buttons, FactBox displays, and FastTab displays depend on your selections in the upper section. Typically, you choose a transaction type by selecting one of the rows under the **Supply** or **Demand** node. You then choose a period by selecting a specific column for the selected row.

The toolbar above the grid in the upper section of the **Supply schedule** page provides the following buttons:

- **Expand/Collapse** – Expand or collapse a selected node, such as the **Demand** node, the **Supply** node, and their subnodes. (Nodes show a **[+]** or **[-]** prefix to indicate whether they're currently collapsed or expanded.)
- **New** – Open a menu where each command, in turn, opens a dialog box or page that lets you add a specific type of item for the selection. Available commands include **Forecast supply**, **Planned order**, **Scheduled kanban**, **New production order**, **Purchase order**, and **Transfer order**.
- **Master planning** – Run master planning. A dialog box appears, where you can specify the plan to run. By default, the **Master plan** field is set to match the current filter.
- **Max. report as finished** – Open the **Max. report as finished** page for the product defined in the current filter.
- **Update planned orders** – Open the **Planned orders** page, which shows planned orders for the product or product family defined in the current filter.
- **Level** – Spread planned orders according to the settings from the dialog box that appears.
- **Material plan policy by location** – Open the **Item coverage** page for the product defined in the current filter.
- **Kanban rule** – Open the **Kanban rules** page for the product defined in the current filter.

FastTabs

The **Supply schedule** page can contain the following FastTabs:

- **Period end inventory** – This FastTab shows the period end inventory data in a graphical format.
- **Supply profile** – This FastTab shows the supply data in a graphical format. It becomes visible when you select a **Supply** node or a line below it in the upper section.
- **Summary** – This FastTab shows summary details that are related to the transaction type that you selected in the upper section. For example, if you select **Sales** under the **Demand** node, this FastTab shows fields that are related to sales orders, such as **Requested sales order lines** or **Total amount**. If you select **Production orders** under the **Production** subnode of the **Supply** node, this FastTab shows fields that are related to production orders, such as **Production orders scheduled** or **Total scheduled**. Field values depend on the period that you selected in the upper section.
- **[Transaction type] - [Period]** – This FastTab shows orders for the transaction type and period that you selected in the upper section. The name of the FastTab reflects those

selections. For example, it might be named **Sales orders - Backlog** or **Production orders - Week 37**.

Action Pane

The following buttons are available on the Action Pane:

- **Modify filter** – Open the **Modify filter** dialog box, where you can update filter values and then reopen the **Supply schedule** page, which reflects the updated filter settings.
- **Show delays** – Highlight the relevant lines in the upper section if there's a delayed order of that transaction type.

FactBox pane

To open the FactBox pane and view a FactBox, select **Related information** on the right edge of the page. The following FactBoxes are available on the **Supply schedule** page:

- **Item details** – This FactBox shows basic information about the product defined in the current filter. It's blank if you defined a product family in the filter.
- **Actions** – This FactBox shows actions for the orders of the transaction type that you selected in the upper section.
- **Delays** – This FactBox shows delays for the orders of the transaction type that you selected in the upper section.

Run planning for a subset of items

Article • 09/29/2023

Master planning lets you set up filters to limit the set of items that are included in a planning run, so that not all items are planned.

You can use two types of filters to limit the set of items that is planned:

- *Plan filters*, which are set up on the master plan itself
- *Runtime filters*, where you use options in the **Planning Optimization** run dialog box to select the items and bill of materials (BOM) levels to include in the run

Apply a plan filter

Plan filters are useful when you want to limit a plan to a specific group of items and ensure that no other items are included as part of the resulting master planning. When a plan filter is defined, it's always applied during a master planning run that uses the plan.

> ⓘ **Important**
>
> Plan filters are available only in systems where Planning Optimization is enabled.

Follow these steps to set up a plan filter.

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Select a plan in the list pane, or create a new one.
3. On the Action Pane, select **Plan filter**.
4. A standard query editor dialog box appears. There, you can enter settings to limit the set of products that are included when the current plan runs. These settings define the plan filter.
5. When you've finished setting up your filter, select **OK**.

> ⓘ **Note**
>
> If you set up a plan filter on the plan that is selected as the **Current dynamic master plan** on the **Master planning parameters** page, that filter will be applied each time that the dynamic plan runs. For example, if the net requirements are updated for an item that isn't part of the plan filter, no result will be generated.

Apply a runtime filter and set the BOM levels to include

You set up the runtime filter for a job from the **Planning Optimization** run dialog box. The runtime filter applies only to the job that you start or schedule from the dialog box. If you both a plan filter and a runtime filter are set up, intersection logic is used to combine them. (See the example later in this article.)

You also use the **Planning Optimization** run dialog box to control the number of levels of BOM components and subcomponents that are included for manufactured items that pass the combined filters.

For a recurring job, the runtime filter and BOM levels that you define when you set up the job are applied each time that it runs.

Follow these steps to set up the runtime filter and BOM levels for a master planning batch job.

1. Go to **Master planning** > **Master planning** > **Run**.
2. In the **Planning Optimization** dialog box, on the **Parameters** FastTab, set the following settings fields:
    - **Master plan** – Select the master plan to run.
    - **Comment** – Add a comment to describe the purpose of the job.
3. On the **Records to include** FastTab, set the following fields:
    - **Filter** – Select this link to open a standard query editor dialog box where you can enter settings to limit the set of products that are included in the current planning job. These settings define the runtime filter.
    - **Include all BOM levels** – For manufactured items that have a BOM, it's often convenient to plan all BOM components together with the main item, to ensure that all the required components are available when production begins. Set this option to *Yes* to include all BOM levels for items that pass both the runtime filter and the plan filter. Set it to *No* to limit the number of BOM levels that are included. Then use the **BOM levels to include** field to specify the maximum number of BOM levels to include.
    - **BOM levels to include** – If **Include all BOM levels** is set to *No*, use this field to specify the number of BOM levels to include. Here are some examples:
        - Set this field to *0* (zero) to ignore all BOM components.
        - Set this field to *1* to include supply for BOM components.

- Set this field to *2* to include supply for BOM components and their derived BOM components.

4. On the **Run in the background** FastTab, set recurrence and other batch options in the usual way. The fields work just as they do for other types of background jobs in Microsoft Dynamics 365 Supply Chain Management.

> **Note**
>
> The following limitations apply when you use a runtime filter with BOM levels:
>
> - If you run auto-firming or another post-processing job using **the current extensibility point**, then the system will only apply the auto-firming and other actions to the items specified directly on the filter (not to the subcomponents).
> - Delays from subcomponents are not propagated to their respective parent items.
> - The requirement date of a subcomponent may fall on a date closed by the calendar of the subcomponent. To update the date to an open date on the subcomponent calendar, you must make a full or filtered run that includes the subcomponent directly on the filter.
>
> If any of these issues are critical for you, then add the relevant subcomponents to the filter manually.

Combine plan filters and runtime filters

If you apply both a plan filter and a runtime filter during a master planning run, only the intersection of the two filters will be included in the run.

To see how the plan and runtime filters are combined, consider this example. You have a plan where a plan filter is set up to include items A, B, and C. You then run master planning run several times. Each run uses the same plan but a different runtime filter. The results are as follows:

- **Run 1: The runtime filter includes item D** – No items are planned, because there is no intersection between the plan filter and the runtime filter.
- **Run 2: The runtime filter includes items A and D** – Only item A is included, because item D isn't part of the plan filter.

- **Run 3: The runtime filter includes item B** – Only item B is included, and the previous planning output for item A is kept.
- **Run 4: The runtime filter includes all items (blank filter)** – Items A, B, and C are included, and the previous planning output for items A and B is overwritten.

The system will also include all the relevant BOM components and subcomponents for the manufactured products that are found by the combined filters, as specified by the BOM level settings that you entered in the **Planning Optimization** run dialog box when you set up the job.

Master planning with purchase trade agreements

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how master planning can find the vendor and/or lead time for a planned order, based on the best price or lead time found among all purchase trade agreements that are specified for a given product.

Prepare your system to evaluate purchase trade agreements during master planning

Follow these steps to configure your system to apply master planning that evaluates purchase trade agreements.

1. Go to **Master planning** > **Setup** > **Master planning parameters**. On the **Planned orders** tab, in the **Vendor** section, set the following values:
    - **Find trade agreement** – Set this option to **Yes** to include purchase trade agreements in master planning.
    - **Search criterion** – Select the factor that you want to prioritize for each purchase trade agreement: **Minimum lead time** or **Lowest unit price**.
2. Go to **Procurement and sourcing** > **Setup** > **Prices and discounts** > **Activate price/discount**, and make sure that the **Vendor** option is set to **Yes**.
3. Go to **Product information management** > **Setup** > **Dimension and variant groups** > **Storage dimension groups**, and select a storage dimension group that applies to products that master planning should evaluate purchase trade agreements for. Make sure that each relevant storage dimension in this group has a check mark in the **For purchase prices** column. Repeat this step for every other relevant storage dimension group.

Prepare a released product to evaluate purchase trade agreements during master planning

After your system is prepared as described in the previous section, follow these steps to make sure that each product you want to use with this feature is correctly set up.

1. Go to **Product information management** > **Products** > **Released products**, and open a target product.

2. On the **Purchase** FastTab, make sure that no vendor is assigned in the **Vendor** field.

3. On the Action Pane, on the **Plan** tab, in the **Coverage** group, select **Item coverage** to open the **Item coverage** page for the selected product. Verify the following settings:

    - On the **General** tab, set up vendor overrides. If you want master planning to use purchase trade agreements to select a vendor, prevent vendor overrides by clearing the **Use specific setting** check box.
    - On the **Lead time** tab, set up lead-time overrides. If you want master planning to use purchase trade agreements to select lead times, prevent lead-time overrides. Clear the check box for each type of lead time that you want to select by using purchase trade agreements (**Purchase**, **Production**, and/or **Transfer**).

4. Close the **Item coverage** page to return to the details page for the selected product.

5. On the Action Pane, on the **Plan** tab, in the **Forecast** group, select **Supply forecast** to open the **Supply forecast** page. Make sure that no row that is shown here has a value in the **Vendor account** column.

6. Close the **Supply forecast** page to return to the details page for the selected product.

7. On the Action Pane, on the **Purchase** tab, in the **Trade agreements** group, select **View trade agreements**. Make sure that all the relevant purchase trade agreements are listed. Also make sure that the **Disregard lead time** option is set to **No** for each agreement where you want master planning to use the lead time that is specified for that agreement.

8. On the Action Pane, on the **Plan** tab, in the **Order settings** group, select **Default order settings** to open the **Default order settings** page for the selected product. On the **Purchase order** FastTab, view the value of the **Purchase lead time** field. If no item coverage lead-time override is defined, master planning uses this value when it selects trade agreements where the **Disregard lead time** option is set to **Yes**. Therefore, adjust this value as you require.

9. Repeat this procedure for each relevant product.

> **Note**
>
> Master planning supports multi-currency purchase trade agreements. When searching for a trade agreement by using the **Lowest unit price** option, the system considers purchase trade agreement lines with different currencies, provided an exchange rate is defined between the trade agreement line currency and the accounting currency of the legal entity. Otherwise, the the trade agreement line is ignored, and you see an error during master planning. Therefore, master planning includes information from all relevant purchase trade agreement lines where prices can be converted to the accounting currency. It's important to note that rounding rules aren't taken into account during the trade agreement line price conversion.

Examples of how master planning finds vendor and lead times

The following table provides examples that show how various settings for a released product and its associated purchase trade agreements affect the values that are found for the resulting planned purchase order. The **bold** values in the two rightmost columns are the values selected by master planning. The ***bold and italic*** values in the other columns are the settings that produce those resulting values for each row.

Expand table

Released product: Vendor	Default order settings: Lead time	Item coverage: Override vendor	Item coverage: Override lead time	Trade agreement: Vendor	Trade agreement: Lead time	Trade agreement: Disregard lead time	Resulting vendor	Resulting lead time
US001	***1***	No	No	US003	3	No	**US001**	**1**
US001	1	***Yes: US002***	***Yes: 2***	US003	3	No	**US002**	**2**
(Blank)	1	No	No	***US003***	***3***	No	**US003**	**3**
(Blank)	***1***	No	No	***US003***	3	Yes	**US003**	**1**
(Blank)	***1***	***Yes: US002***	No	US003	3	No	**US002**	**1**
(Blank)	***1***	***Yes: US002***	No	US003	3	No	**US002**	**1**

Plan based on quotations and RFQs

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Quotations and requests for quotations (RFQs) represent possible or even likely future orders. Therefore, it makes sense to consider them during master planning, so that extra supply can be planned based on existing RFQs and the likelihood that each quotation will become an actual order. This article describes how to set up master planning to consider quotations and RFQs when it generates planned orders.

Set up master planning to consider sales quotations and/or RFQs

Use the following procedure to set up master planning to consider sales quotations and/or RFQs.

1. Go to **Master Planning** > **Setup** > **Plans** > **Master plans**.
2. Select an existing plan in the list pane, or select **New** on the Action Pane to create a new one.
3. On the **General** FastTab, set the following fields:
    - **Include sales quotations** – Set this option to *Yes* to consider sales quotations when the current plan is run. Set it to *No* to ignore them.
    - **Probability** % – Set the minimum level of confidence that is required for a quotation to be included in master planning. The master planning calculation will include all quotations that were created from opportunities that have this probability percentage or higher. To include all quotations, including quotations that have no probability assigned to them or no opportunity associated with them, set this field to *0* (zero). For more information about probabilities for quotations, see the next section.
    - **Include requests for quotations** – Set this option to *Yes* to consider RFQs when the current plan is run. Set it to *No* to ignore them. If you choose to consider RFQs, the system will create planned purchase orders for them, but it won't specify the vendor

until the RFQ is resolved. Planned purchase orders that are created for the RFQs might affect the quantities of other planned orders.

4. Continue to set up your master plan in the usual way.

Assign and view probabilities for quotations

As was mentioned in the previous section, a master plan will consider only quotations that meet or exceed the probability threshold that is defined for the plan (if a threshold is defined). However, the probability isn't set directly on each quotation. Instead, it's inherited from the opportunity that was used to generate the quotation. Therefore, quotations that are created directly on the **All quotations** page won't have a probability assigned to them or an opportunity associated with them, and they won't ever be considered by master planning (unless the **Probability %** field is set to *0* [zero]). To have a probability assigned to it, a quotation must be generated from an opportunity.

Create a quotation from an opportunity

Use the following procedure to assign a probability to an opportunity and then create a quotation from that opportunity.

1. Go to **Sales and marketing** > **Relationships** > **Opportunities** > **All opportunities**.
2. Select an existing opportunity, or select **New** on the Action Pane to create a new one.
3. Fill in the opportunity page to identify the opportunity as you want. Be sure to set the **Probability** field to an appropriate value. Only master plans that are set up to look for probabilities of this value or higher will consider quotations that are generated from this opportunity.
4. On the Action Pane, select **Save**.
5. On the Action Pane, on the **Opportunity** tab, in the **New** group, select **Sales quotation** or **Project quotation**, depending on the type of quotation that you want to create.
6. In the **Create quotation** dialog box, set the fields as you require, and then select **OK**.
7. A new quotation is created and opened. On the **Lines** FastTab, use the toolbar to add sales lines or project lines as required to define the content of the quotation.
8. On the Action Pane, select **Save**. Then close the quotation.

View the probability that is assigned to a quotation

The only way to view the probability that is assigned to a quotation is to open the opportunity that was used to create that quotation, as described in the following procedure.

1. Go to **Sales and marketing** > **Sales quotations** > **All quotations**.

2. If the **Opportunity ID** column isn't shown (it's hidden in a default installation), follow these steps to temporarily show it. (Alternatively, to keep the **Opportunity ID** column available, create a saved view that includes it.)
   a. Select and hold (or right-click) in the grid, and then select **Insert columns**.
   b. In the **Insert columns** dialog box, find the row where the **Field** field is set to *Opportunity*, and select the **Select** checkbox for that row.
   c. Select **Update** to add the selected column to the **All quotations** page.

3. In the grid, find the row for the relevant quotation. Then, in the **Opportunity ID** column, select the value for that row.

   > **Note**
   >
   > If you're looking for a project quotation, you might have to select the **Quotation type** column header and clear its filter. In a default installation, this filter is set so that only sales quotations are shown.

4. The related opportunity is opened. You can now view and edit the **Probability** value as you require.

Safety margins

This article describes how safety margins work during master planning.

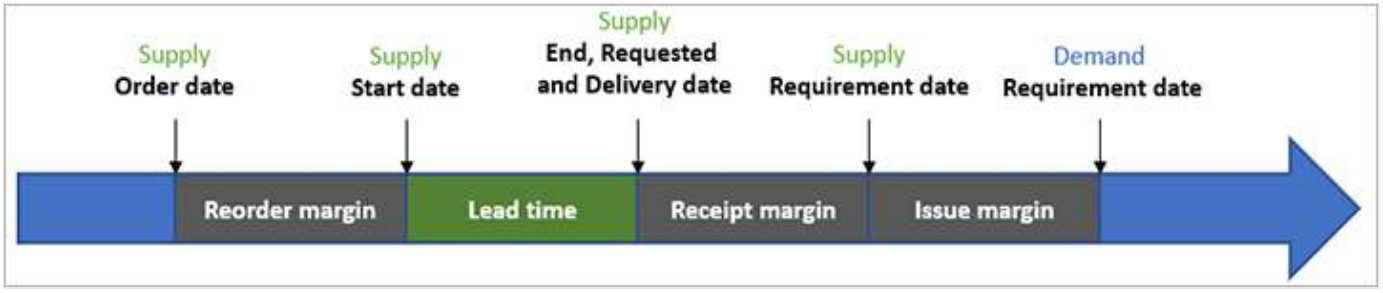
Safety margins overview

Safety margins provide buffer time beyond the normal lead time. For example, you might need to unpack or inspect material after it arrives from the vendor. You can't just add the extra time to the purchase lead time, because that approach gives extra buffer time to the supplier. Instead, use the receipt margin to ensure that the supplier delivers earlier. The receipt margin provides buffer time so that you can handle the goods internally.

Three types of safety margins exist:

- **Reorder margin** – The buffer time for placing the supply order
- **Receipt margin** – The buffer time for handling incoming supply
- **Issue margin** – The buffer time for handling shipments

The following illustration shows how these safety margins apply over time.

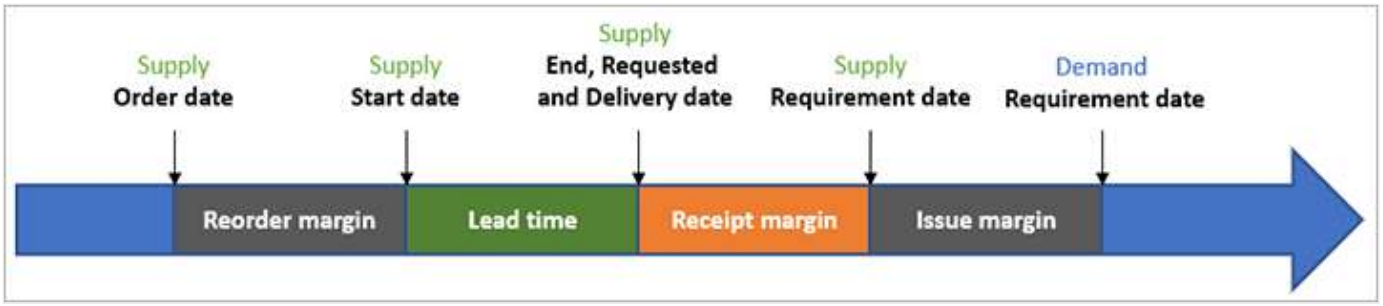


All margins are defined in days. The default value, *0* (zero), indicates that no margin is applied. If you set up multiple margins, they all add to the total time from the supply *order date* to the demand *requirement date*. For example, a setup has no lead time, and all three margin types are set to one day. In this case, three days exist between the supply order date and the demand requirement date, so if the order date is July 1, the requirement date is July 4.

Receipt margin

The receipt margin is probably the most commonly used of the three safety margins. The system applies it to the *delivery date* and calculates backward from the *requirement date*. In other words, you should receive the products the specified number of receipt margin days before you need them.

The following illustration highlights the receipt margin.



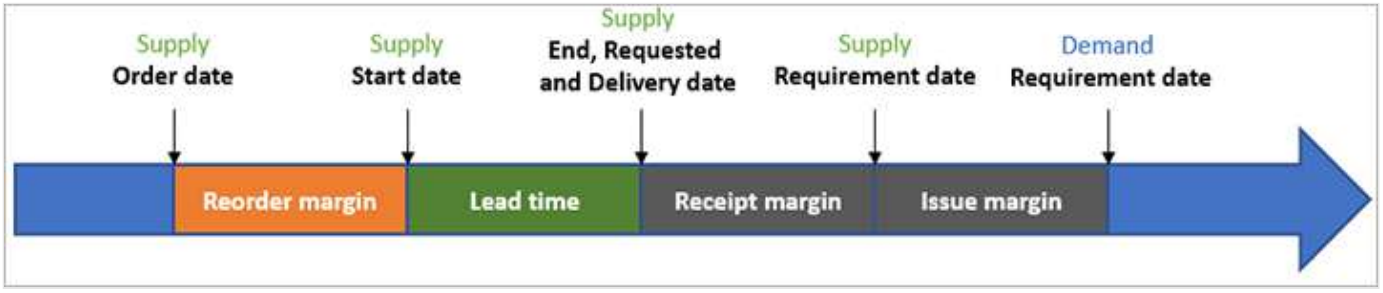
The receipt margin typically acts as a buffer to ensure time for warehouse registration or other time-consuming processes that the system doesn't capture as part of the general lead time. For purchases, one benefit is that the *delivery date* of the purchase order moves forward accordingly. If you increase the lead time instead of using a safety margin, the vendor still needs to deliver at the last minute.

The receipt margin doesn't change the *requirement date* of the supply. Therefore, you don't directly see the receipt margin when you compare requirement dates for demand and supply (for example, on the **Net requirements** page). For example, say the receipt margin is four days and a purchase order line is planned for receipt on the 15th of the month. Master planning calculates the adjusted receipt date as the 19th of the month.

A receipt margin isn't applied when on-hand inventory is used as the supply. All on-hand inventory is assumed to be available immediately, regardless of when you actually received it.

Reorder margin

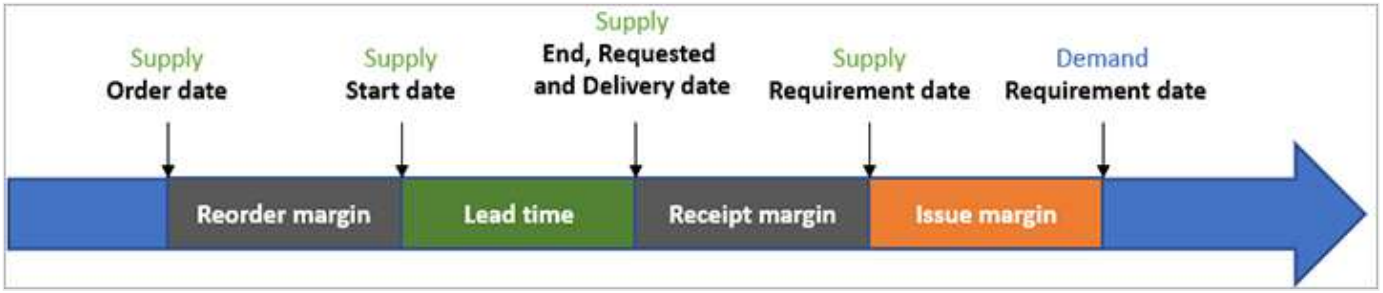
The following illustration highlights the reorder margin.



The reorder margin adds time before the item lead time for all planned orders during master planning. Therefore, it ensures extra time for placing a supply order. This margin typically acts as a buffer to ensure time for approval processes or other internal processes that are required during the creation of supply orders. The reorder margin goes between the supply *order date* and *start date*.

Issue margin

The following illustration highlights the issue margin.



During master planning, the system deducts the issue margin from the demand requirement date. This deduction helps ensure that you have time to react to and ship incoming demand orders. This margin acts as a buffer to ensure time for shipment and related outbound warehouse processes.

When you apply an issue margin, the related supply and demand requirement dates don't match. Instead, they differ by the issue margin, because the issue margin is added between the supply *requirement date* and the demand *requirement date*.

Set up safety margins

Define safety margins

Set safety margins on both the *coverage group* and the *master plan*. The system adds these margins together. For example, if you set a receipt margin of two days on the coverage group and three days on the master plan, the effective receipt margin is five days.

Set the margin on the master plan when you want to simulate longer lead times or uncertainty for a specific plan, but without affecting the daily planning.

Coverage group safety margins

To apply a safety margin to a coverage group, follow these steps:

1. Go to **Master planning** > **Setup** > **Coverage groups**.
2. In the list pane, select the coverage group.
3. On the **Other** FastTab, in the **Safety margins in days** section, use the following fields to set the required safety margins (in days):

- Receipt margin added to requirement date
- Issue margin deducted from requirement date
- Reorder margin added to item lead time

Master plan safety margins

To apply a safety margin to a master plan, follow these steps:

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. In the list pane, select the master plan.
3. On the **Safety margins in days** FastTab, use the following fields to set the required safety margins (in days):
    - Receipt margin added to requirement date
    - Issue margin deducted from requirement date
    - Reorder margin added to item lead time

Define whether calculations are based on calendar days or workdays

Set all safety margins to calculate based on either calendar days or workdays.

1. Go to **Master planning** > **Setup** > **Master planning parameters**.
2. On the **General** tab, in the **Safety margins in days** section, set the **Working days** option to *Yes* to calculate margins based on working days. Set the option to *No* to calculate margins based on calendar days.

For example, a calendar is open from Monday through Friday and closed from Saturday through Sunday. If there's a receipt margin of one day, a requirement date on a Monday produces a delivery date on the previous Friday, because Saturday and Sunday aren't working days.

The calendar that determines the working days depends on the setup and the supply type. The calendars of the coverage group, the warehouse, and the vendor control which days count as working days.

> ⓘ **Note**
>
> If *warehouse* isn't part of the coverage dimension (in other words, planning is based only on *site*), the warehouse calendar isn't used.

The system can handle a setup where one or more calendars are defined. The following subsections describe the possible combinations that you can use to control the result.

Calendar that is used for the duration

The defined calendars control the actual total lead time in calendar days, from the supply order date to the demand requirement date. The system uses the following calendar prioritization:

- **Purchase lead time** – Only the coverage group calendar is considered.
- **Receipt margin** – If a coverage group calendar is defined, the system uses it. Otherwise, the system uses the warehouse calendar.
- **Issue margin** – If a coverage group calendar is defined, the system uses it. Otherwise, the system uses the warehouse calendar.
- **Order margin** – Only the coverage group calendar is considered.

Calendar that is used for the final date

The following rules determine whether the planning engine can use a given date for a given date type:

- **Purchase receipt date** – If a vendor calendar is defined, the system uses it. Otherwise, if a coverage group calendar is defined, the system uses that calendar. If neither calendar is defined, the system uses the warehouse calendar.
- **Transfer receipt date** – If a coverage group calendar is defined, the system uses it. Otherwise, the system uses the warehouse calendar.
- **Production receipt date** – If a coverage group calendar is defined, the system uses it. Otherwise, the system uses the warehouse calendar.
- **Demand issue open day** – If a warehouse calendar is defined, the system uses it. Otherwise, the system uses the coverage group calendar.
- **Order open day** – The system uses a combination (intersection) of the coverage group calendar and the vendor calendar. Both calendars must be open to use the date. If only one calendar is defined, the system uses that calendar alone.

Calendar setup overview matrix

The following illustration presents a matrix that summarizes which calendars apply when safety margins are calculated. (Select the image to open a high-resolution version of it.) The following abbreviations and colors indicate where each type of calendar is specified:

- **Coverage group (CG):** Green

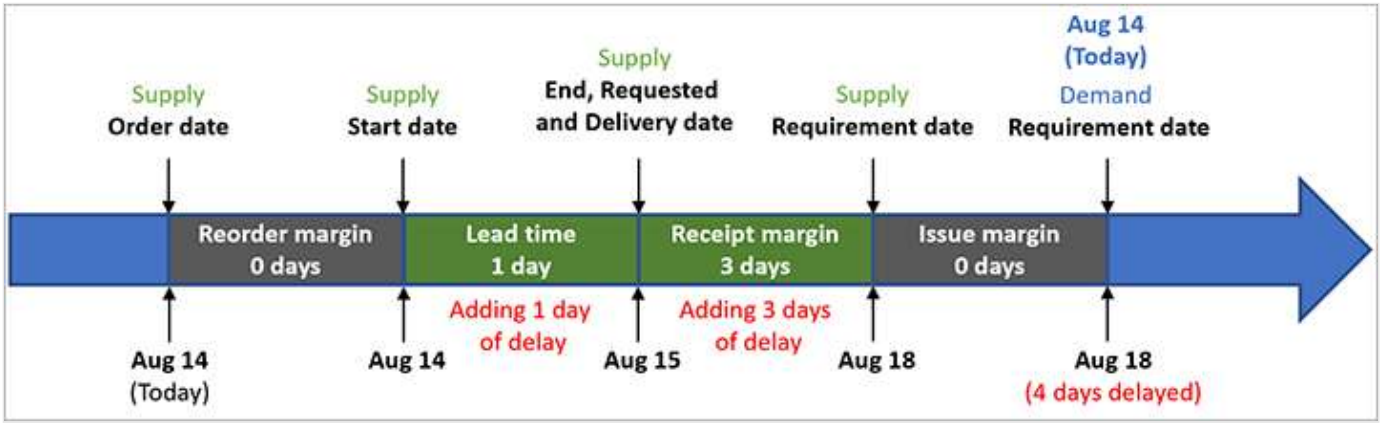
- **Warehouse (WH):** Yellow
- **Vendor (V):** Blue

Calendar is specified on			Calendar used for duration Only counting open days				Calendar used for final date Is the date open or closed				
Coverage group (CG)	Warehouse (WH)	Vendor (V)	Lead time	Receipt margin	Issue margin	Order margin	Purchase requirement date	Transfer requirement date	Production requirement date	Demand requirement date	Supply Order date
Yes	Yes	Yes	CG	CG	CG	CG	V	CG	CG	WH	CG+V
No	Yes	Yes	None	WH	WH	None	V	WH	WH	WH	V
Yes	No	Yes	CG	CG	CG	CG	V	CG	CG	CG	CG+V
Yes	Yes	No	CG	CG	CG	CG	CG	CG	CG	WH	CG
Yes	No	No	CG	CG	CG	CG	CG	CG	CG	CG	CG
No	Yes	No	None	WH	WH	None	WH	WH	WH	WH	None
No	No	Yes	None	None	None	None	V	None	None	None	V
No	No	No	None	None	None	None	None	None	None	None	None

Calculating delays

The system includes all three types of safety margins when it determines whether an order is delayed.

For example, an item has a lead time of one day and a receipt margin of three days. A sales order for this item is set as required today. In this case, the delay is calculated as *lead time* + *receipt margin* = four days. Therefore, if today is August 14, the four days of delay produces a delivery on August 18. The following illustration shows this example.



Issue margin and on-hand

Sometimes, the system doesn't apply the issue margin to an order when on-hand supply exists for an item. The reason for this behavior is that the on-hand supply doesn't have a date, so the system can't apply the issue margin.

This situation usually occurs when you sell an item that has an issue margin from a warehouse such as WH11. A transfer order from another warehouse such as WH13 replenishes the selling warehouse. In this case, one of the following situations could apply:

- **If on-hand supply exists in WH13** – On WH11, the system applies the margin between the sales order date and the transfer order receipt date. However, on WH13, the date of the transfer order shipment is the same as the receipt date because there's on-hand supply, so the system doesn't apply any issue margin.

- **If on-hand supply doesn't exist in WH13** – If there's no on-hand supply, and WH13 is to be replenished by other means (such as a purchase order), then the system applies the issue margin between the transfer order receipt date and the purchase order receipt date.

Soft issue margin

Soft issue margin causes the system to treat the issue margin as a preferred buffer rather than a hard requirement. Instead of always applying the full issue margin, a soft margin lets the system reduce it as needed to avoid pushing the requirement date into the future. Without soft issue margin, the system always applies the full margin, even when doing so delays a demand order.

The soft issue margin works as follows:

- *If the full issue margin can be applied without causing a delay* – The system applies the full issue margin, just as it does with the standard behavior. No change occurs.
- *If the full issue margin would cause a delay* – The system reduces the issue margin to the largest value that doesn't push the planned requirement date past the demand requirement date. The margin can be reduced to any value between zero days and its full configured value minus one day.
- *If the order is already delayed (the demand requirement date is in the past)* – The system ignores the issue margin entirely. The issue margin isn't included in the delay calculation. Instead, the difference between the demand requirement date and the planned order date is surfaced to indicate that the order can't be fulfilled on time.

This behavior applies independently at each level in the supply chain. If a bill of materials (BOM) structure includes both a finished good and a raw material, the system evaluates and adjusts the issue margin separately for each level.

Soft issue margin prerequisites

To use a soft issue margin, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.48 build 10.39.1837 or later.

- The feature named *Soft issue margins with Planning Optimization* must be turned on in feature management.

Enable soft issue margin for a coverage group

You enable soft issue margin at the coverage group level. To enable the soft issue margin for a coverage group, follow these steps:

1. Go to **Master planning** > **Setup** > **Coverage groups**.
2. Select the coverage group.
3. On the **Other** FastTab, set the **Soft issue margin** option to *Yes*.

Example 1: Issue margin is reduced to avoid delay

The following conditions apply in this example:

- The issue margin is 10 days on all items.
- Soft issue margin is enabled.
- Today's date is October 1.
- The **Add the calculated delay to the requirement date for production orders** option is disabled.

The demand requirement date is October 7. Without soft issue margin, the system applies the full 10-day issue margin at both the finished good level and the raw material level. Because only six days are available between today's date and the requirement date, the full margin causes a delay at both levels.

With the soft issue margin enabled, the system reduces the issue margin at both levels to the largest values that don't push the planned dates past the requirement date. The orders are planned without delay.

Example 2: Order already delayed, issue margin is ignored

The same conditions apply as in the previous example.

The demand requirement date is September 24. Without the soft issue margin, the system applies the full 10-day issue margin at both the finished good level and the raw material level, which further increases the delay.

With soft issue margin enabled, the system ignores the issue margin entirely at both levels because the demand requirement date is already in the past. The delay is surfaced as the

difference between the demand requirement date (September 24) and the earliest possible planned order date (October 1). The issue margin doesn't add to the delay.

Greedy application across multilevel supply chains

The soft issue margin is applied *greedily* along the supply chain, starting from the demand side. The first level in the chain (closest to the original demand) consumes as much of the available issue margin as possible. Subsequent levels (further from the demand, closer to the supply source) receive whatever margin remains.

For example, consider a supply chain where warehouse *WH12* fulfills a sales order at warehouse *WH11* through a transfer, and a purchase order replenishes *WH12*. If you configure the soft issue margin for the item at both warehouses, the system first allocates as much issue margin as possible to the issue from *WH11*, the warehouse closest to the customer demand. The issue from *WH12*, which is further upstream in the supply chain, then receives whatever margin is still available without causing a delay.

Greedy allocation means that downstream operations (closer to the customer) are prioritized for margin, while upstream operations absorb the reduction.

Known limitations of soft issue margin

The greedy application of soft issue margins can lead to situations where the requirement dates set by the engine are too optimistic. When the engine applies the soft issue margin date, it doesn't yet know about potential delays that could occur further up the supply chain. Once the system encounters upstream delays and factors them into the plan, requirement dates aren't updated to account for delays compressing the soft issue margin.

Greedy application of soft issue margins can lead to situations where the requirement date of a planned supply is set too early. After the system accounts for delays, it shows delay days even though only the soft issue margin was compressed instead of delaying the demand.

Example of known limitation

The following conditions apply in this example:

- Today's date is *May 18*.
- An item *P1* exists that is replenished by production orders.
- To produce item *P1*, a raw material *R1* is required, which is replenished by purchase orders with a purchase lead time of three days.

- The soft issue margin is set to two days on *P1* and *R1*.

A sales order for item *P1* has a requirement date of *May 22*. A soft issue margin of two days is configured on *P1*. The system greedily applies the full issue margin and schedules a production order with a requirement date of *May 20*. The production order requires raw material *R1*, which also has a two-day issue margin and is scheduled with a requirement date of *May 18*.

However, the purchase order for *R1* has a purchase lead time of three days. This lead time causes a three-day delay on the purchase order, which adjusts the planned date to *May 21*. The delay propagates up to the production order, which also adjusts to *May 21*. Because soft issue margin is enabled, the issue margin at the production level is compressed and doesn't add further delay. The delay also propagates to the sales order level. However, the system compresses the soft issue margin from two days to one day, so the sales order isn't delayed beyond *May 22*.

After delays are resolved, a discrepancy exists between the requirement dates and the planned dates. The requirement dates that were set before the delays were known are now too optimistic. The system doesn't retroactively adjust these requirement dates, which can result in delay days being shown even though the supply isn't delayed according to the soft issue margin. This behavior is by design and a known limitation of the soft issue margin feature.

Impact of known limitation

If delays occur and the system doesn't update the requirement dates, several other features that rely on requirement dates and delays might also be affected. For example:

1. Delay days
2. Actions
3. BOM/route selection
4. Trade agreements

Make sure to test this feature thoroughly to ensure that your intended use of soft issue margins is not affected by the known limitations.

Delay tolerance (negative days)

10/03/2025

The delay tolerance functionality enables Planning Optimization to consider the **Negative days** value that is set for coverage groups, item coverage, and/or master plans. It's used to extend the delay tolerance period that is applied during master planning. In this way, you can avoid creating new supply orders if existing supply will be able to cover the demand after a short delay. The purpose of the functionality is to determine whether it makes sense to create a new supply order for a given demand.

Delay tolerance in Planning Optimization

Delay tolerance represents the number of days beyond the lead time that you're willing to wait before you order new replenishment when existing supply is already planned. Delay tolerance is defined by using calendar days, not business days.

At the time of master planning, when the system calculates the delay tolerance, it considers the **Negative days** setting. You can set the **Negative days** value on the **Coverage groups** page, the **Item coverage** page, or the **Master plans** page. If negative days are assigned at more than one level, the system applies the following hierarchy to decide which setting to use:

- If negative days are enabled on the **Master plans** page, that setting overrides all other negative days settings when the plan runs.
- If negative days are configured on the **Item coverage** page, that setting overrides the coverage group setting.
- Negative days that are configured on the **Coverage groups** page apply only if negative days haven't been configured for a relevant item or plan.

The system links the delay tolerance calculation to the *earliest replenishment date*, which equals today's date plus the lead time. The delay tolerance is calculated by using the following formula, where *max()* finds the larger of two values:

max(Earliest replenishment date, Demand due date) – Demand due date + Negative days

This formula ensures that master planning doesn't create new supply orders when enough supply exists during the product lead time.

> ⓘ **Note**
>
> The delay tolerance calculation in Planning Optimization always uses the dynamic negative days calculation from the deprecated master planning engine. The **Use dynamic**

negative days setting on the **Master planning parameters** page has no effect on this behavior.

If the existing supply implies a demand delay that is less than or equal to the calculated delay tolerance, Planning Optimization pegs existing supply with the demand. In some cases, it's better to delay the demand than to end up with oversupply.

The following subsections provide examples that show how delay tolerance affects the creation of planned orders in Planning Optimization.

Example 1

A product has the following configuration:

- **Lead time:** *10*
- **Negative days:** *2*

The following supply and demand exist for the product:

- **Demand for today:** A sales order for a quantity of 10
- **Supply in 12 days:** A purchase order for a quantity of 10

Existing supply can cover the demand within 12 days, and that period equals the delay tolerance. Therefore, when master planning runs, no planned orders are created.

Example 2

A product has the following configuration:

- **Lead time:** *10*
- **Negative days:** *0*

The following supply and demand exist for the product:

- **Demand for today:** A sales order for a quantity of 10
- **Supply in 12 days:** A purchase order for a quantity of 10

Existing supply can cover the demand only after 12 days. However, the delay tolerance is 10 days. Therefore, when master planning runs, a planned order for a quantity of 10 is created.

Example 3

A product has the following configuration:

- **Lead time:** *10*
- **Negative days:** *2*

The following supply and demand exist for the product:

- **Demand in 11 days:** A sales order for a quantity of 10
- **Supply in 14 days:** A purchase order for a quantity of 10

Existing supply can cover the demand only after three days. However, the delay tolerance is two days. (In this case, the delay tolerance includes only the two negative days. The demand date isn't included because it's after the product lead time.) Therefore, when master planning runs, a planned order for a quantity of 10 is created.

Purchase requisitions

Master planning can replenish approved purchase requisitions. Therefore, to cover purchase requisitions, users don't have to use a workflow to create purchase orders. Instead, purchase requisitions can be covered by master planning. Because of this functionality, a purchase requisition can produce a purchase order, a transfer order, or a production order, depending on the **Planned order type** value that is set for the related product.

Enable master plans to include requisitions

To include requisitions during the coverage calculation for a master plan, follow these steps:

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Create or select a master plan.
3. On the **General** FastTab, set the **Include requisitions** option to *Yes*.
4. Repeat steps 2 and 3 for each additional master plan where you want to include requisitions.

Approved requisitions time fence

The *approved requisitions time fence* establishes how far back (in days) a master plan will include demand from approved replenishment requisitions. You can set an approved requisitions time fence at both the coverage group level and the master plan level.

Set the approved requisitions time fence for a coverage group

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.
2. Create or select a coverage group.
3. On the **Other** FastTab, set the **Approved requisitions time fence (days)** field to the number of days to include in the time fence.
4. Repeat steps 2 and 3 for each additional coverage group where you want to set an approved requisitions time fence.

Set the approved requisitions time fence for individual master plans

When you set an approved requisitions time fence for an individual master plan, the setting overrides the time fence setting for any applicable coverage group.

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Create or select a master plan.
3. On the **TIme fences in days** FastTab, set the **Approved requisitions time fence (days)** field to the number of days to include in the time fence.
4. Repeat steps 2 and 3 for each additional master plan where you want to set an approved requisitions time fence.

> ⓘ **Important**
>
> Approved requisitions time fences aren't supported for Planning Optimization. Until they are supported, all values that you enter in the **Approved requisitions time fence (days)** field will be ignored.

Independent supply, regardless of coverage code

Purchase requisitions are always covered by independent planned orders, regardless of the coverage code. This behavior ensures clear traceability and workflows between purchase requisitions and replenishment orders.

Example 1

A product is set up so that it has a **Coverage code** value of *Min/max*. It has the following inventory and requisition statuses:

- Inventory on-hand quantity = 10.
- Minimum inventory quantity = 15.
- Maximum inventory quantity = 20.
- A purchase requisition for one piece exists. It has a requested date of today.

When master planning runs, two planned orders are created: one for 10 pieces to replenish inventory to the maximum quantity, and one for one piece to replenish the purchase requisition.

Example 2

A product is set up so that it has a **Coverage code** value of *Min/max*. It has the following inventory and requisition statuses:

- Inventory on-hand quantity = 17.
- Minimum inventory quantity = 15.
- Maximum inventory quantity = 20.
- A purchase requisition for one piece exists. It has a requested date of today.

When master planning runs, one planned order for one piece is created to replenish the purchase requisition.

Example 3

A product is set up so that it has a **Coverage code** value of *Period* and a period length of seven days. It has the following inventory, sales order, and requisition statuses:

- Inventory on-hand quantity = 0.
- A sales order for five pieces exists. It has an expected ship date of today plus one day.
- A purchase requisition for three pieces exists. It has a requested date of today plus three days.

When master planning runs, two planned orders are created: one for three pieces to replenish the purchase requisition and one for five pieces to replenish sales order demand.

> **Note**
>
> After a planned order that is pegged to a purchase requisition is firmed, the planning engine keeps the pegging to the purchase requisition. If the firmed order is later found to be missing some quantity that is required to fulfill the purchase requisition, the system will create a new planned order for the difference.

For more information about purchase requisitions, see Purchase requisition overview.

Production planning

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The following video provides a short introduction to some of the concepts discussed in this article: Dynamics 365 Supply Chain Management: Planning Optimization enhancements.

Planned production orders

When master planning creates planned orders to fulfill requirements, the value of the **Planned order type** field determines the order type. If you set the **Planned order type** field to *Production*, the system creates planned production orders. These planned production orders include information about the active bill of materials (BOM) and the route ID from the related production setup.

Requirements from BOMs

Master planning uses BOM information. The plan output includes material supply to cover related material demand for production.

During master planning, the system uses the current, active BOM to determine the materials required for production. The system checks all levels of the BOM structure that relate to the required production order. The system fulfills material requirements by using available on-hand inventory, existing on-order supply, and approved planned orders. If the system finds that additional material is required, it creates a planned order to cover the demand.

When the system searches for an appropriate BOM version to use for an item in a coverage group that has the **Use the specified BOM or formula version** option turned off, it takes several parameters into account. These parameters include the validity period of the BOM version, whether the BOM version is active or approved, and the applicable quantity. The system doesn't reconsider the chosen BOM version after a receipt is scheduled in cases where a planned production order is delayed or scheduled to start earlier or later.

When you replenish a BOM component by using a production or batch order, the validity date that the system uses to search for the applicable BOM or formula version is determined after the system schedules its parent order. The validity date is based on the scheduled start or end date of an operation from the parent planned production order schedule (by default, the start date of the first operation). The system determines the scheduled start and end dates after it schedules the parent production order. If the system delays the parent planned production order later in the planning process and must push forward its scheduled start or end date times because a subcomponent order is delayed, the system doesn't reconsider the BOM version for the subcomponent. The BOM version is still based on the original scheduling attempt (backward in most cases) of the parent planned production order.

Individual BOM lines also have validity periods. The system evaluates these periods after it schedules a planned production order, so it uses the corresponding operation start or end dates to check for validity. Even though a BOM version and its lines might have the same validity periods, the system uses different dates to evaluate them. For a BOM version, the system uses the demand requirement date. For a BOM line, the system uses the scheduled start of the planned production order for the finished good.

The system takes the following actions:

1. Create a planned production order to replenish demand and select a BOM version to use.
2. Schedule the order without reevaluating the BOM version, even if the date shifts as a result of scheduling.
3. Assess the BOM lines for the selected BOM version to ensure they're valid for the scheduled dates.
4. Create BOM line requirements for the valid BOM lines only.
5. If required by the planning settings, cover BOM line requirements with supply down to the specific BOM level.
6. Evaluate whether supply of the lower BOM levels affects the delivery schedule for any parent production orders and adjust the schedules accordingly.

Scheduling during firming

Planned production orders include the route ID that is required for production scheduling. However, scheduling support during the planning run for planned orders is pending. The route ID is used to schedule planned production orders during firming. Therefore, the lead time on planned production orders can differ from the lead time on related scheduled, firmed production orders that are generated from them.

- **Planned production order** – The lead time is based on the static lead time from the released product.
- **Firmed production order** – The lead time is based on scheduling that uses route information and related resource constraints.

Delays

If the lead time for required material is longer than the period between today's date and the material requirement date, the planned order for the required material and the related production order are delayed. For planned orders, the system calculates the delay (in days) based on the lead time from the released product. The system then propagates the delay information through all levels of the BOM structure. Therefore, you can follow the impact of delayed raw material all the way to the customer sales order.

Modifying planned orders

When you change information on a planned order, you receive the following message: "Note that the impact of manual changes on planned orders won't be reflected in the rest of the plan until the next master planning run."

If you want to change information on a planned order and see the impact on the related material requirements, follow these steps:

1. Update the planned order.
2. Approve the planned order.
3. Run master planning.

> ⓘ **Note**
>
> If you change the delivery date of the planned order to a later date, the demand might peg against a new planned order. This behavior occurs when the new supply date causes a delay for the pegged demand but, according to the lead time settings, the delay can be avoided.

Explosion page

Use the **Explosion** page to analyze the demand that is required for a specific production order or planned production order, the related coverage, and pegging information. The system updates

information on the **Explosion** page during master planning. You can't update the information directly from the **Explosion** page.

Filters

Planning Optimization offers advanced filtering options that can apply at the plan level, runtime level, or both. To learn more about the various filter options, see Run planning for a subset of items.

Item substitution for formulas and bills of materials

07/21/2025

You can use substitute materials during planning for items that use formulas or bills of materials (BOMs). When you set up item substitution for a formula or BOM, you can specify a group of items that can serve as substitutes for a particular material. You can also specify the priority of each substitute material in the group. When master planning runs, it uses the preferred material if it's available. If the preferred material isn't available, master planning uses the substitute material that has the highest priority and is available. If no substitute materials are available, master planning creates a planned order for the preferred material.

Prerequisites

Before you can use substitution in planning for formulas, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.39 or later.
- The feature that's named *Item substitution (Plan group) support for Planning Optimization* must be turned on in Feature management. As of Supply Chain Management version 10.0.43, this feature is turned on by default.

Before you can use substitution in planning for BOMs, your system must meet the following requirements:

- You must be running Supply Chain Management version 10.0.40 or later.
- The feature that's named *Item substitution for bill of materials in Planning optimization* must be turned on in Feature management.

Set up plan groups

Before you can set up item substitution for formulas or BOMs, you must set up the plan groups that you need.

A plan group is a group of items that can be substituted for a particular material in a formula or BOM. Each plan group record establishes a name and a description, but it doesn't include any items. You assign items and their relative priorities to each plan group when you set up item substitution for a specific formula or BOM. You can reuse plan groups across multiple formulas and/or BOMs.

To set up plan groups, follow these steps.

1. Go to **Product information management** > **Setup** > **Bills of materials and formulas** > **Plan groups**.
2. Use the buttons on the Action Pane to add, remove, or edit plan groups as required. For each plan group, set the following fields:
    - **Plan group** – Specify a unique name for the plan group.
    - **Description** – Enter a short description of the plan group.
3. Continue to work until you finish setting up all the plan groups that you need.
4. On the Action Pane, select **Save**.

Item substitution for formulas

Example scenario: Substituting ingredients in a formula

A food manufacturing company is making an item from a formula that has 20 ingredients. One of the ingredients in the formula can be replaced by one of two other ingredients. However, because those two ingredients are more expensive than the preferred ingredient, substitution is used only when the preferred ingredient is out of stock.

For this scenario, the ingredient that can be replaced (the preferred ingredient) is named *ingredient A*. The two materials that can replace it are named *ingredient B* and *ingredient C*.

To set up the substitution, create a formula line for each of the three ingredients, and associate all three lines with the same plan group. Because ingredient A is the preferred ingredient, assign it the highest priority (lowest number). Assign each of the other ingredients (ingredient B and ingredient C) a priority that matches its relative level of preference. (The higher the number, the lower the preference.)

If you have a demand for the finished item, master planning determines whether the demand for ingredient A can be covered. If it can't, master planning looks at ingredients B and C in order of priority. If one of these ingredients is on hand, it's used (according to its priority) when a batch order is firmed for the formula. If none of the ingredients are on hand, master planning creates a planned order for the preferred ingredient (ingredient A).

Set up item substitution for formulas

Follow these steps to set up item substitution for a formula:

1. Go to **Product information management** > **Bills of materials and formulas** > **Formulas**.
2. Open the formula that you want to set up substitution for.
3. Find the formula line for the material that you want to be able to substitute. Set the following fields for it:
    - **Plan group** – Select the plan group name that you want to use to identify the group of items that can serve as substitutes for this material.
    - **Priority** – Enter a number that indicates the priority of this material in the plan group. The lower the number, the higher the priority. Therefore, the most preferred material should have the lowest number.
    - **Quantity** – Specify the quantity of the preferred material that's required in the formula. This quantity applies to whichever material from the plan group is used.
4. Find or add a formula line for the lower-priority substitute material. Set the following fields for it:
    - **Plan group** – Select the same plan group name that you selected for the preferred material.
    - **Priority** – Enter a number that indicates the priority of this material in the plan group. The lower the number, the higher the priority. Each material in the plan group must have a unique priority number.
    - **Quantity** – Enter *0*. This field isn't used for substitutes. The quantity of the preferred material (that is, the one that has the lowest priority) defines the quantity for all the materials in the plan group.
5. Repeat the previous step for each additional substitute material.
6. Repeat this procedure for each plan group that you want to set up for the current formula.

Shelf life and item substitution for formulas

When material substitution is used with products that have a limited shelf life, master planning always ensures that the shelf life of all materials is respected.

For example, a formula item is set up in the following way:

- **Material A:**
    - **Quantity:** 10
    - **Plan group:** Organic oils
    - **Priority:** 1
    - **Available on-hand:** 4, with an expiry date of today + five days

    - **Lead time:** One day

- **Material B (Substitute for material A):**
    - **Quantity:** 0
    - **Plan group:** Organic oils
    - **Priority:** 2
    - **Available on-hand:** 0
    - **Existing purchase order:** Qty 6, with an expected receipt date of today + six days, with 10 negative days

Master planning first selects material A, which has an available quantity of *4*. Because the required quantity is *10*, there isn't enough of material A. Therefore, master planning determines whether it can use the existing purchase order for the substitute (material B) for the remaining quantity. However, because the available receipt date of the substitute is later than the expiry date of the on-hand inventory of material A, the substitute isn't used. Instead, master planning creates a planned order for a quantity of *6* of material A to fulfill the remaining material that's required.

Item substitution for BOMs

Example scenario: Substituting components in a BOM

A manufacturing company is making an item from a BOM that has 20 components. One of the components in the BOM can be replaced by other components. It can even be replaced by the same item under a different item number.

For this scenario, the material that can be replaced (the preferred component) is named *material A*. The two materials that can replace it are named *material B* and *material C*.

To set up the substitution, create a BOM line for each of the three materials, and associate all three lines with the same plan group. Because material A is the preferred material, assign it the highest priority (lowest number). Assign each of the other materials (material B and material C) a priority that matches its relative level of preference. (The higher the number, the lower the preference.)

If you have a demand for the finished item, master planning determines whether the demand for material A can be covered. If it can't, master planning looks at materials B and C in order of priority. If one of these materials is on hand, it's used (according to its priority) when a batch order is firmed for the BOM. If none of the materials are on hand, master planning creates a planned order for the preferred material (material A).

Set up item substitution for BOMs

Follow these steps to set up item substitution for a BOM.

1. Go to **Product information management** > **Bills of materials and formulas** > **Bill of materials**.

2. Open the BOM that you want to set up substitution for.

3. Find the BOM line for the material that you want to be able to substitute. Set the following fields for it:

    - **Plan group** – Select the plan group name that you want to use to identify the group of items that can serve as substitutes for this material.
    - **Priority** – Enter a number that indicates the priority of this material in the plan group. The lower the number, the higher the priority. Therefore, the most preferred material should have the lowest number.
    - **Quantity** – Specify the quantity of the preferred material that's required in the BOM. This quantity applies to whichever material from the plan group is used.

4. Find or add a BOM line for the lower-priority substitute material. Set the following fields for it:

    - **Plan group** – Select the same plan group name that you selected for the preferred material.
    - **Priority** – Enter a number that indicates the priority of this material in the plan group. The lower the number, the higher the priority. Each material in the plan group must have a unique priority number.
    - **Quantity** – Enter *0*. This field isn't used for substitutes. The quantity of the preferred material (that is, the one that has the lowest priority) defines the quantity for all the materials in the plan group.

5. Repeat the previous step for each additional substitute material.

6. Repeat this procedure for each plan group that you want to set up for the current BOM.

Set up scrap to calculate raw material requirements

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to set up your bills of materials (BOMs), formulas, and route operations to record the quantity of raw material that's scrapped during manufacturing. The master planning engine can then use this information to calculate the quantity of raw materials that must be purchased to produce the desired quantity of the final product.

Scrap is the quantity of raw material that's left over and can't be used after an item is manufactured. You can set up scrap in the following places:

- Formula or BOM line
- Route operations

Scrap for route operations

Route scrap is the scrap that's produced during an operation in a route.

Set up scrap for route operations

To view or set the amount of scrap that an existing route operation produces, follow these steps:

1. Go to **Production control** > **All routes**.
2. In the list pane, select the route that you want to work with.
3. On the Action Pane, on the **Route** tab, select **Route details**.
4. The **Route details** page appears. The top grid lists each operation in the route. For each operation, you can view or set the following values that are related to the amount of raw material consumed as scrap for the operation:

- **Scrap percentage** – Specify the percentage of the input raw material consumed as scrap during the operation.

- **Accumulated** – The accumulated scrap percentage for the operation in the route. This value is read-only. The system calculates it in the following way:

  Accumulated = (*Accumulated percentage for the following operation* × 100) ÷ (100 – *Scrap percentage*)

Calculate scrap for route operations

This section describes an example where you're producing item *FG*, which uses 100 pieces of raw material *RM*. To produce FG, you use a route that has three operations: *Operation-1*, *Operation-2*, and *Operation-3*.

If the BOM line for RM doesn't specify which operation consumes the raw material, the system assumes that the first operation (Operation-1) does. Therefore, it calculates the quantity of RM that must be available at the beginning of Operation-1 to produce the required quantity of FG.

First, consider a scenario where the route operations require the following input:

- Operation-1 requires *X* liters of RM as input.
- Operation-2 requires the output of Operation-1 as input.
- Operation-3 requires the output of Operation-2 as input.

If each operation has a scrap percentage of 10 percent, the system does the following calculations to determine how many liters of RM are required as initial input to produce 100 liters of FG:

- **Operation-1:** *X* × (1 – 10%) = *Y*
- **Operation-2:** *Y* × (1 – 10%) = *Z*
- **Operation-3:** *Z* × (1 – 10%) = 100 liters of FG

When you solve for *X*, you get the following result:

X = 100 ÷ (0.9 × 0.9 × 0.9) = 137 liters of RM as input

Next, consider a scenario where the raw material starts to be consumed only later in the route, at Operation-2. In this case, the **Oper. Nr.** value on the BOM line must be set to the operation number of that operation. (For more information about how to set this value, see the next section.) If each operation has a scrap percentage of 10 percent, the system does the following

calculations to determine how many pieces of RM are required as initial input to produce 100 liters of FG:

- **Operation-1:** $X = Y$
- **Operation-2:** $Y \times (1 - 10\%) = Z$
- **Operation-3:** $Z \times (1 - 10\%) = 100$ liters of FG

When you solve for X, you get the following result:

$X = Y = 100 \div (0.9 \times 0.9) = 123$ liters of RM as input

Scrap for BOMs and formulas

BOM scrap and *formula scrap* are types of scrap that relate to a specific BOM line or formula line, depending on the type of product you're manufacturing. BOMs and formulas can include both constant and variable scrap.

Set up scrap for BOMs and formulas

To view or set the amount of scrap that a BOM or formula produces for a released product, follow these steps:

1. Go to **Product information management** > **Products** > **Released products**.
2. In the grid, find and select the product that you want to work with.
3. On the Action Pane, on the **Engineer** tab, select either **BOM versions** or **Formula versions**, depending on the type of product.
4. The **BOM versions** or **Formula versions** page appears. In the list pane, select the version that you want to work with.
5. On the **Bill of materials lines** or **Formula lines** FastTab, select the line that you want to set up scrap for.
6. On the toolbar of the FastTab, select **Edit**.
7. The **Edit BOM line** or **Edit Formula line** dialog appears. On the **General** tab, in the **Oper. No.** field, if the current line is consumed only during a specific route operation, enter the operation number of that route operation. The value must be an integer, and it must match the related operation number that's shown on the **Route details** page. If you leave this field blank, the system assumes that the line starts to be consumed during the first operation.

8. On the **Consumption calculation** tab, set the following fields as required:

    - **Constant scrap** – Enter the quantity of scrap that's always the same for a single production run, regardless of the quantity of finished goods that are manufactured. Specify the scrap in the same unit that's used on the BOM or formula line.
    - **Variable scrap** – Variable scrap grows in proportion to the quantity of finished goods that are produced. Specify the amount of scrap that's created as a percentage of the raw material that's required as input for the route. For example, if the variable scrap for a raw material is 20 percent, and the route requires 100 liters of that material as input for a given production run, the required purchase quantity is 120 liters (excluding any constant scrap).

9. Select **OK** to apply your settings and close the dialog box.

You can also configure the previously described settings directly on the BOM or formula instead of on the **Released products** page.

1. Follow one of these steps:

    - Go to **Product information management** > **Bills of materials and formulas** > **Bills of materials**.
    - Go to **Product information management** > **Bills of materials and formulas** > **Formulas**.

2. Open a BOM or formula, and then configure settings like those that are described in the previous procedure.

Calculate scrap for BOMs and formulas

Based on the configured constant and variable BOM or formula scrap values, the system does the following calculation to determine the quantity of raw material that must be purchased to meet your actual raw material requirement:

Purchased material = (*Required raw material* × [1 + *Variable BOM or formula scrap*]) + *Constant BOM or formula scrap*

For example, you have the following requirements and scrap values:

- Constant scrap = 10 liters
- Variable scrap = 20 percent
- Required raw material = 100 liters

In this case, to meet your material requirements, you must purchase the following quantity of raw material:

Purchased material = (100 liters × 1.20) + 10 liters = 130 liters

Calculate raw material requirements based on the total scrap

If both route scrap and BOM or formula scrap are set up, the system automatically performs the following calculation to determine how much raw material is required to produce a specific quantity of finished goods:

Purchased raw material = *Total start quantity according to the route calculation* × (1 + *Variable BOM or formula scrap*) × *Batch size* + *Constant BOM or formula scrap*

In this calculation, *Batch size* is the number of pieces of the final good that's produced.

Master planning for products with limited shelf life

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Shelf life is the amount of time that a product can be stored until it can no longer be used or sold. For products that have a limited shelf life, you'll probably use a first-expire, first-out (FEFO) warehouse strategy, which prioritizes the consumption and sale of items based on their remaining shelf life. This warehouse strategy is relevant for food, medicines, and other goods that are characterized by a short storage time. According to FEFO, items in the warehouse are stored like goods on a supermarket shelf: products that have a long shelf life are placed deep into the shelves, so that products that have a shorter remaining shelf life are shipped first.

Using shelf life in master planning

This section explains how master planning suggests supply for shelf-life items.

When you run a master plan, it generates suggested planned orders (supply) that fulfill your demand and also minimize delays. If your plan includes items with a limited shelf life, planning calculations become more complex. The plan must not only minimize delays but also use existing supply before it expires. The plan tries to use supply that's closest to its expiration date before supply that expires later. Therefore, master planning seeks to achieve the following goals, in this order:

1. Minimize the sum of delays.
2. Maximize the sum of FEFO supply.
3. Minimize the replenishment of inventory.

In some cases, there might be a conflict between the first two goals, and a choice must be made: do you want to delay a shipment, or do you want to use supply that expires later instead of supply that expires sooner? To resolve this conflict during master planning, the system prioritizes minimizing delays over using up soon-to-expire supply. In general, this type of conflict occurs when there might be delays and coverage by period. Therefore, use a coverage period that's shorter than the shelf life of an item. Other types of coverage (such as requirement) are unlikely to encounter this type of conflict.

Set up shelf life

Configure each master plan to consider shelf life

By default, master plans don't consider shelf life. Use the following procedure to enable shelf-life calculations for each master plan that requires them.

1. Go to **Master planning** > **setup** > **plans** > **Master plans**.
2. Either select an existing plan in the list pane or create a new one.
3. On the **General** FastTab, set the **Use shelf life dates** option to *Yes*.

Configure tracking dimension groups to track the batch dimension

You can track the shelf life of an item only if you track the item at the batch dimension. In other words, you must record the batch reference and the required dates when you receive or manufacture the item, and through every inventory transaction of the item. To manage this option, set up one or more tracking dimension groups to do the required tracking, and then assign the relevant items to these groups as required.

Use the following procedure to set up a tracking dimension group to track the batch dimension.

1. Go to **Product information management** > **Setup** > **Dimension and variant groups** > **Tracking dimension groups**.

2. Follow one of these steps:

    - On the Action Pane, select **New** to create a new tracking dimension group. Enter a name and description, then select **Save** on the Action Pane.
    - In the list pane, select the existing tracking dimension group that you want to set up to track the batch dimension.

3. On the **Tracking dimension** FastTab, in the **Batch number** row, select the checkboxes in the **Active** and **Physical inventory** columns.

Set up shelf life for a product

Use the following procedure to set up shelf life for a product.

1. Go to **Product information management** > **Products** > **Released products**.

2. Create or open the product that you want to set up.

3. To use the shelf-life settings, on the **General** FastTab, set the **Tracking dimension group** field to a tracking dimension group that tracks the batch dimension. You can set this field only when you're first creating a product. You can't change the value for existing products.

4. On the **Manage inventory** FastTab, set the following fields:

    - **Shelf advice period in days** – Specify the period (in days) by which to check a batch of this product to ensure that it's suitable for consumption or resale. The value of this field is added to a batch's *manufacturing date* to determine its *shelf advice date*. You can configure the system to generate quality orders when a batch approaches its shelf advice date.
    - **Shelf life period in days** – Specify the number of days before a batch of this product expires. This value is added to the *date of manufacture* to determine the *expiration date*. The batch is considered unusable after this date.
    - **Best before period in days** – Specify the period (in days) after which a batch of this product is deemed still sellable but can no longer retain some of its original properties. This value is added to the *date of manufacture* to determine the *best-before date*. You can run reports to identify inventory that's past its best-before date.

Set a sellable days rule for each customer

Sellable days functionality ensures that products from a batch that soon expires aren't sent to customers. Moreover, it ensures that when products are sent to a customer, an adequate number of sellable days still remain after delivery.

To use the sellable days functionality, you must define the number of sellable days that applies for each product (or group of products) for each customer. You must manually complete this process, because there's no data entity for it.

Use the following procedure to set up sellable days for each product for each customer.

1. Go to **Sales and marketing** > **Customers** > **All customers**.

2. Find and select the customer that you want to set up.

3. On the Action Pane, on the **Sell** tab, in the **Set up** group, select **Sell** > **Sellable days**.

4. On the **Sellable days for customer** page, the grid lists existing sellable days rules for each product or group of products. Use buttons on the Action Pane to add or edit rows in the grid as required. A **Filter** is provided to help you find existing rows.

5. For each row, set the following fields:

- **Item code** – Select one of the following values to specify the scope of items that are affected:
  - *Table* – The row applies to a specific item.
  - *Group* – The row applies to a specific item group.
  - *All* – The row applies to all items.

- **Item relation** – If you set the **Item code** field to *Table*, select a specific item. If you set the **Item code** field to *Group*, select an item group. If you set the **Item code** field to *All*, this field is unavailable.

- **Sellable days** – Enter the minimum number of days that the customer must have to sell matching products before the batch expires. The sellable days value is based on the requested receipt date (or the confirmed receipt date, if defined) for the matching products on the sales order.

- *(Other product dimensions)* – To further limit the scope of a row, specify other dimension values (such as **Size** and **Color**) as required. To control which dimensions are shown in the grid, select **Display dimensions** on the Action Pane.

Set up all relevant products so that they're FEFO date controlled

For sellable days to work, each relevant item must belong to an item model group where the **FEFO date-controlled** checkbox is selected.

Use the following procedure to set up an item model group so that it supports sellable days functionality.

1. Go to **Inventory management** > **Setup** > **Inventory** > **Item model groups**.
2. Select an existing group in the list pane or create a new one by selecting **New** on the Action Pane.
3. On the **Inventory policies** FastTab, select the **FEFO date-controlled** checkbox.
4. Set other fields for the group as required.

Use the following procedure to view or set the item model group that a product belongs to.

1. Go to **Product information management** > **Products** > **Released products**.
2. Open the product that you want to inspect or edit.
3. On the **General** FastTab, set the **Item model group** field to a group where the **FEFO date-controlled** checkbox is selected.

Example 1: Simple FEFO, 10-day period, zero days of lead time

This example shows a basic example of shelf life, where pegging between the supply orders and the demand satisfies the following goals of the system:

- Minimize the sum of delays.
- Maximize the sum of FEFO supply.
- Minimize the replenishment of inventory.

The system uses the following item and master plan settings:

- **Coverage code (replenishment strategy):** Period
- **Coverage period:** 10 days (equal to the shelf life)
- **Shelf life:** 10 days
- **Sellable days:** 0 days
- **Lead time:** 0 days
- **Negative days:** 0 days
- **Type of planned order (default order settings of the item):** Purchase order

The system has the following sales orders for the item:

- **SO1:** Quantity (qty) = 2, requested delivery date = today + 1 day
- **SO2:** Qty = 1, requested delivery date = today + 4 days
- **SO3:** Qty = 1, requested delivery date = today + 5 days

All these sales orders create demand for the item.

The system has the following supply for the item:

- **On-hand inventory:** Qty = 1, expiration date = today + 5 days
- **Purchase order 1 (PO1):** Receipt date = today + 2 days, qty = 1, expiration date = today + 4 days

The system creates a list of supply that can cover this demand, and it sorts the list by expiration date (by using FEFO).

Master planning creates the required pegging between supply and demand. It also creates any required demand based on the supply list (by using FEFO) and considers the availability date.

- SO1 can be fulfilled by the on-hand quantity, but it can't be fulfilled by PO1, because the availability date for PO1 is one day later than SO1 requires. Therefore, SO1 generates demand for one unit of goods.

- SO2 can be covered by PO1, because PO1 arrives by the requested time and the expiration date is still valid. Therefore, the SO2 requirement is fully covered by PO1.
- SO3 isn't covered, because resources aren't available. Therefore, SO3 generates demand for one unit of goods.

To cover all the remaining requirements, the system must create the following planned purchase order:

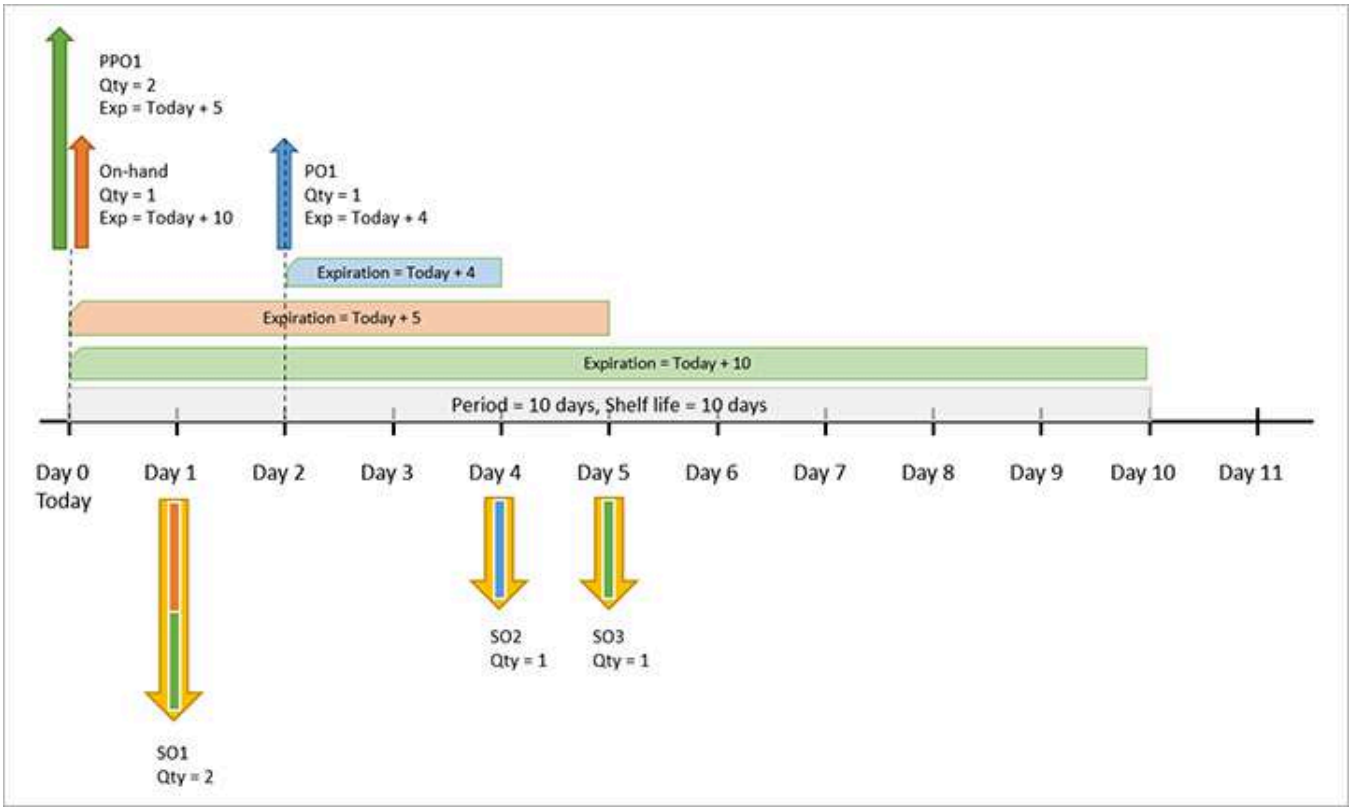
- **PPO1:** Receipt date = today, qty = 2, expiration date = today + 10 days

The following table summarizes the result.

Expand table

Demand	Pegging
SO1: Delivery date = today + 1 day, qty = 2	**On-hand:** Qty = 1, expiration date = today + 5 days **PPO1:** Receipt date = today, qty = 1, expiration date = today + 10 days
SO2: Delivery date = today + 4 days, qty = 1	**PO1:** Receipt date = today + 2 days, 1 qty, expiration date = today + 4 days
SO3: Delivery date = today + 5 days, qty = 1	**PPO1:** Receipt date = today, qty = 2, expiration date = today + 10 days

The following illustration shows the timeline for this example.



Example 2: Simple FEFO, requirement, three days of lead time

This example shows how the system's attempt to minimize delays can sometimes cause overordering.

The system uses the following item and master plan settings:

- **Coverage code (replenishment strategy):** Requirement
- **Shelf life:** 10 days
- **Sellable days:** 0 days
- **Lead time:** Established by the following vendor trade agreements:
  - **Trade agreement 1:** If qty = 1, lead time = 4
  - **Trade agreement 2:** If qty = 2, lead time = 3
- **Negative days:** 0 days
- **Type of planned order (default order settings of the item):** Purchase order

The system has the following sales order:

- **SO1:** Qty = 2, requested delivery date = today + 3 days

Existing supply and a confirmed purchase order cover this demand:

- **On-hand inventory:** Available = today, qty = 1, expiration date = today + 2 days
- **PO1:** Receipt date = today + 3 days, qty = 1, expiration date = today + 4 days

SO1 can't be fulfilled by on-hand inventory, because the inventory expiration date is before the shipment date. PO1 can cover the SO1 requirement with a quantity of only 1. Therefore, SO1 generates demand for one unit of goods. To cover this requirement, the system creates a planned purchase order (PPO1).

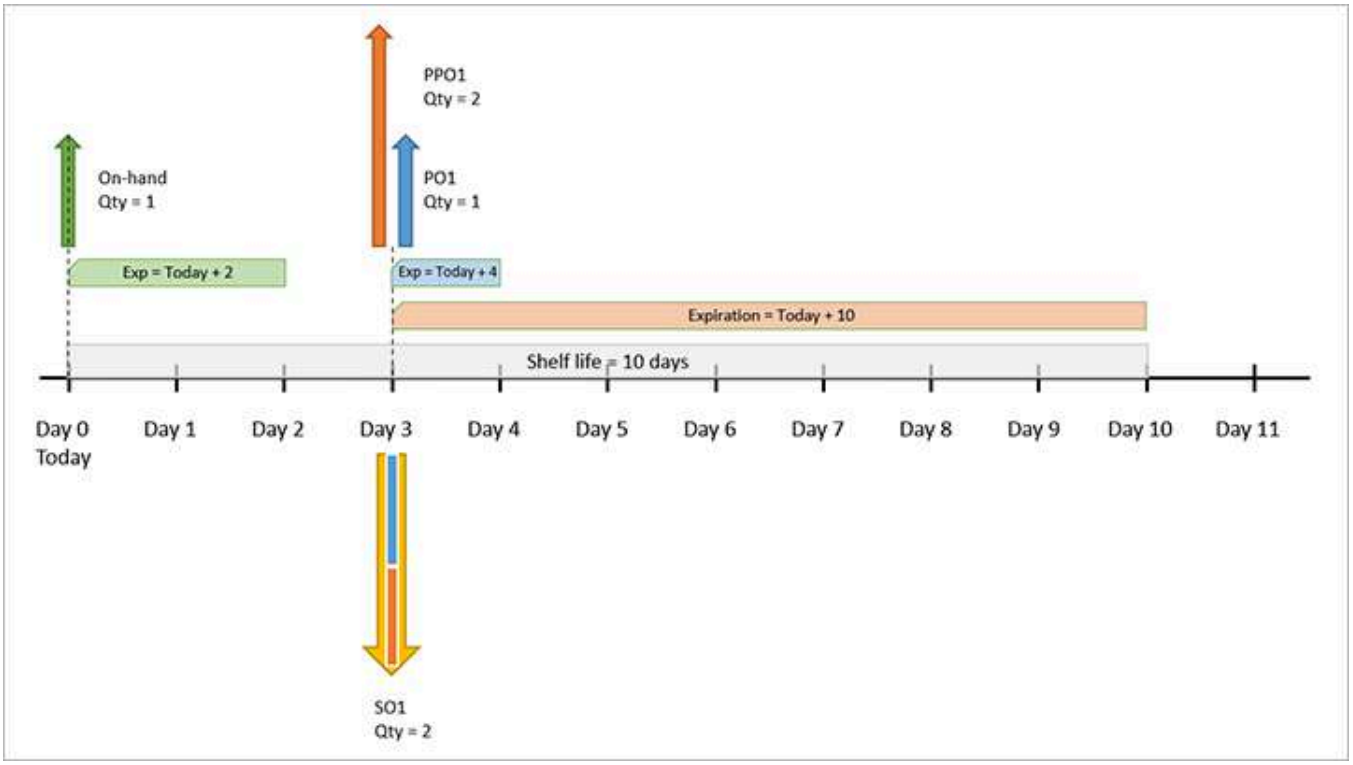
The system has two trade agreements (one for qty = 1, lead time = 4 days, and one for qty = 2, lead time = 3 days). Therefore, the system tries to minimize delays by creating a planned purchase order (PPO1) that meets the second trade agreement. The result is an overdelivery (qty = 2, expiration date = today + 10 days).

The following table summarizes the result.

Expand table

Demand	Pegging
SO1: Delivery date = today + 3 days, qty = 2	**PO1:** Receipt date = today + 3 days, qty = 1, expiration date = today + 4 days **PPO1:** Receipt date = today + 3 days, qty = 1, expiration date = today + 10 days

The following illustration shows the timeline for this example.



Example 3: Simple FEFO, requirement, three days of lead time, five sellable days

This example shows how shelf life works when you add sellable days for an item.

The system uses the following item and master plan settings:

- **Coverage code (replenishment strategy):** Requirement
- **Shelf life:** 10 days
- **Sellable days:** 5 days
- **Lead time:** 5 days
- **Negative days:** 0 days
- **Type of planned order (default order settings of the item):** Purchase order

The system has the following sales orders:

- **SO1:** Qty = 2, requested delivery date = today + 2 days

- **SO2:** Qty = 1, requested delivery date = today + 3 days
- **SO3:** Qty = 1, requested delivery date = today + 5 days

Existing supply and a confirmed purchase order cover this demand:

- **On-hand inventory:** Available = today, qty = 1, expiration date = Today + 6 days
- **PO1:** Receipt date = today + 2 days, qty = 3, expiration date = today + 10 days

The system creates a list of pegging candidates based on the supply (FEFO) list and availability dates. Therefore, the on-hand inventory can't fulfill SO1, because that inventory expires before the end of the sellable days that the customer requires (requested receipt date + 5 days). PO1 can cover the SO1 requirement with two units and the SO2 requirement with one unit. Therefore, only SO3 still has uncovered demand for one unit of goods. To cover this requirement, the system creates the following planned purchase order:

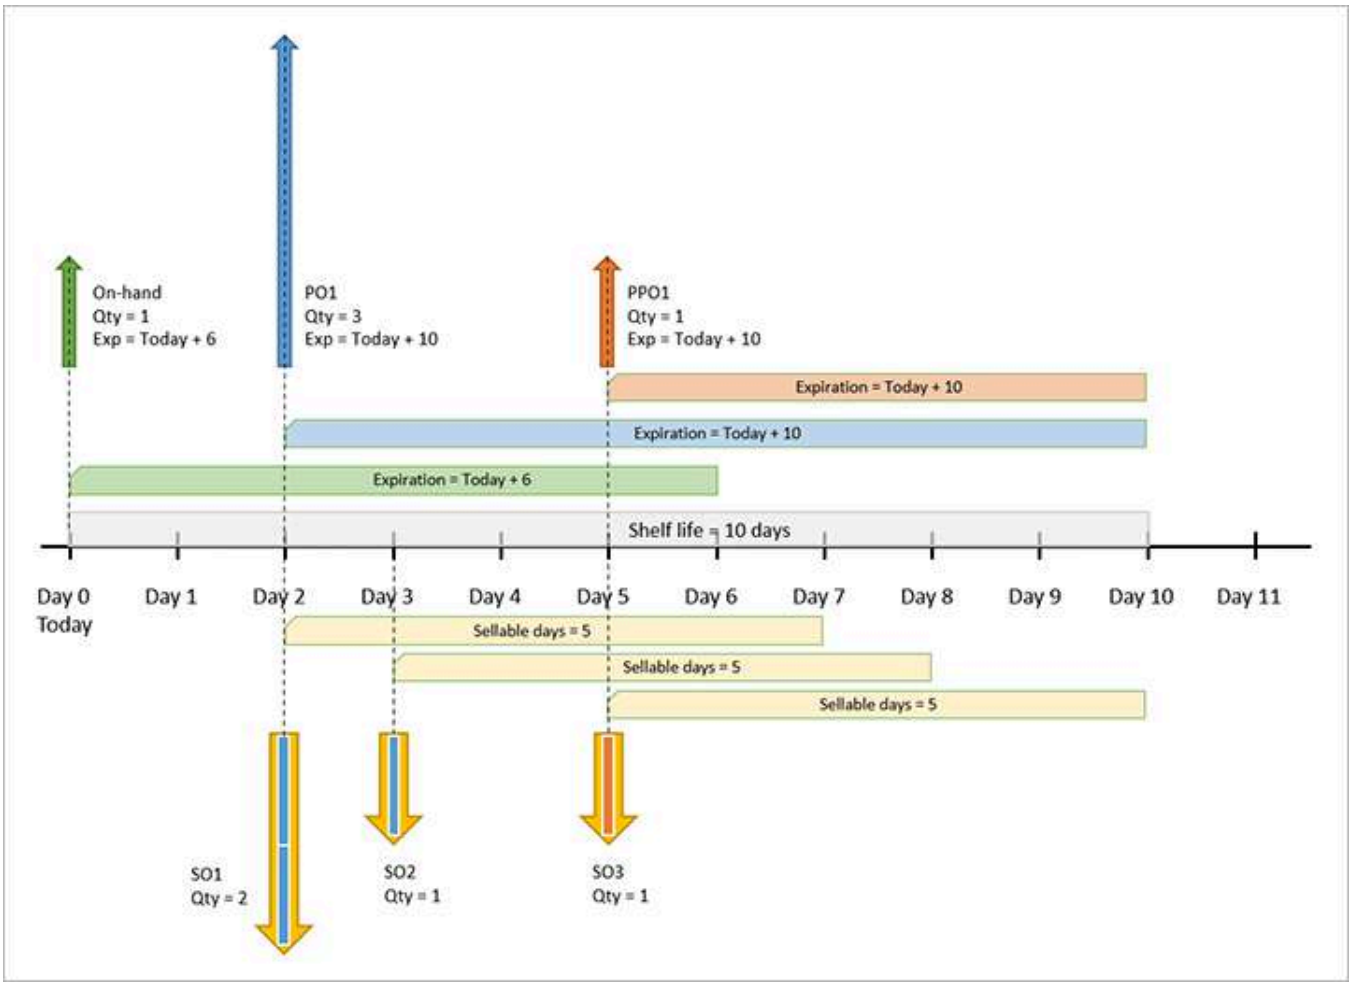
- **PP01:** Receipt date = today + 5 days, qty = 1, expiration date = today + 10 days

The following table summarizes the result.

Expand table

Demand	Pegging
SO1: Delivery date = today + 2 days, qty = 2	**PO1:** Receipt date = today + 2 days, qty = 2, expiration date = today + 10 days
SO2: Delivery date = today + 3 days, qty = 1	**PO1:** Receipt date = today + 2 days, qty = 1, expiration date = today + 10 days
SO3: Delivery date = today + 5 days, qty = 1	**PPO1:** Receipt date = today + 5 days, qty = 1, expiration date = today + 10 days

The following illustration shows the timeline for this example.



Example 4: Simple FEFO, period, lead time depends on the quantity

This example shows how the system's attempt to minimize delays can sometimes cause overordering.

The system uses the following item and master plan settings:

- **Coverage code (replenishment strategy):** Period
- **Coverage period:** 10 days (equal to the shelf life)
- **Shelf life:** 10 days
- **Sellable days:** 0 days
- **Lead time:** Established by the following vendor trade agreements:
  - **Trade agreement 1:** If qty = 1, lead time = 5
  - **Trade agreement 2:** If qty = 2, lead time = 0
- **Negative days:** 0 days

- **Type of planned order (default order settings of the item):** Purchase order

The system has the following sales orders:

- **SO1:** Qty = 1, requested delivery date = today
- **SO2:** Qty = 1, requested delivery date = today + 6 days

The system can partially cover this demand with existing supply from the following confirmed purchase orders:

- **PO1:** Receipt date = today + 1 days, qty = 1, expiration date = today + 2 days
- **PO2:** Receipt date = today + 3 days, qty = 1, expiration date = today + 7 days

The system has two trade agreements (one for qty = 1, lead time = 5 days, and one for qty = 2, lead time = 0 days). Therefore, the system tries to minimize delay by creating the following planned purchase order that meets the second trade agreement:

- **PP01:** Receipt date = today, qty = 2, expiration date = today + 10 days

SO1 is covered by one unit from PPO1. PO2 covers SO2, because PO2 expires sooner than PPO1.

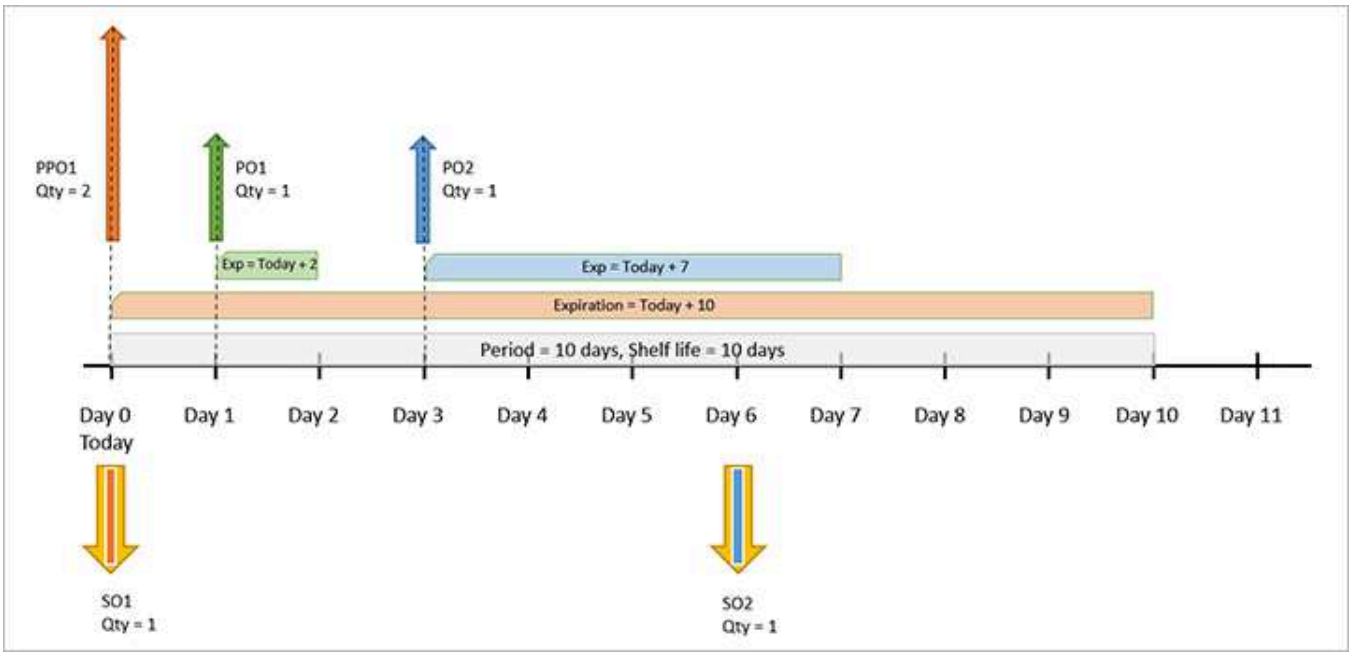
The following table summarizes the result.

Expand table

Demand	Pegging
SO1: Delivery date = today, qty = 1	**PPO1:** Receipt date = today, qty = 1, expiration date = today + 10 days
SO2: Delivery date = today + 6 days, qty = 1	**PO2:** Receipt date = today + 3 days, qty = 1, expiration date = today + 7 days

> **Note**
>
> The system doesn't use PO1, because it arrives too late for S01 and expires before S02 is delivered. PPO1 overorders by one unit to enable the lead time to be 0 (zero), per trade agreement 2.

The following illustration shows the timeline for this example.



Example 5: Simple FEFO, requirement, 10 negative days

This example shows how shelf life works when you add a large number of negative days for an item. Negative days are the number of days that you're willing to wait before you order replenishment of an item that has negative inventory. The system doesn't create supply unless the number of negative days is exceeded.

The system uses the following item and master plan settings:

- **Coverage code (replenishment strategy):** Requirement
- **Lead time:** 0 days
- **Negative days:** 10 days
- **Type of planned order (default order settings of the item):** Purchase order

The system has the following sales order:

- **SO1:** Qty = 1, requested delivery date = today

This demand can be covered by existing supply from the following confirmed purchase order:

- **PO1:** Receipt date = today + 3 days, qty = 1, expiration date = today + 5 days

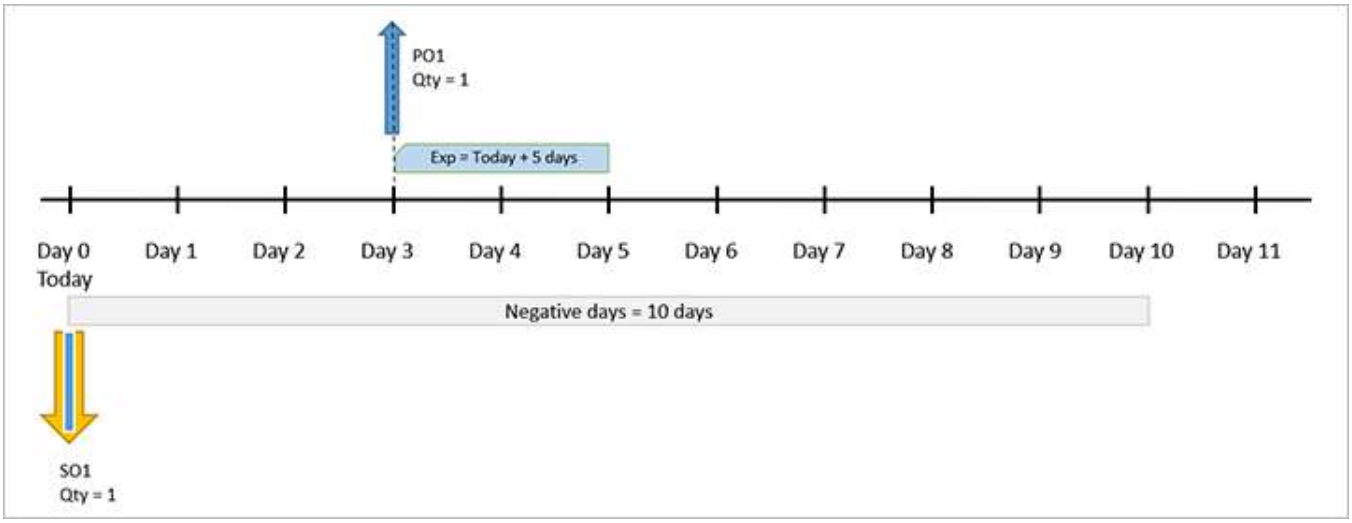
Because the system is configured to allow 10 negative days, it covers the demand of SO1 by using PO1, even though the result is a delay of three days because SO1 creates negative inventory until PO1 arrives. The system doesn't create a planned purchase order, even though the lead time is 0 (zero) and the creation of a planned purchase order would reduce delays.

The following table summarizes the result.

Expand table

Demand	Pegging
SO1: Delivery date = today, qty = 1	**PO1:** Receipt date = today + 3 days, qty = 1, expiration date = today + 5 days

The following illustration shows the timeline for this example.



Example 6: Simple FEFO, requirement, five negative days

This example shows how shelf life works when the number of negative days for an item is less than its shelf-life period.

The system uses the following item and master plan settings:

- **Coverage code (replenishment strategy):** Requirement
- **Sellable days:** 0 days
- **Lead time:** 0 days
- **Negative days:** 5 days
- **Type of planned order (default order settings of the item):** Purchase order

The system has the following sales order:

- **SO1:** Qty = 2, requested delivery date = today

The system can cover this demand with existing supply from the following confirmed purchase orders:

- **PO1:** Receipt date = today, qty = 1, expiration date = today + 1 day
- **PO2:** Receipt date = today + 2 days, qty = 1, expiration date = today + 3 days

However, the system must respect the restriction that shipped items can't be expired at the time of shipment. Therefore, the system can't use both PO2 and PO1 for SO1, because PO1 expires before PO2 arrives. The system creates the following planned purchase order to finish covering the demand for SO1:

- **PPO1:** Receipt date = today, qty = 1, expiration date = today + 10 days

The system can take advantage of the five negative days and use PO2 and PPO1 to cover SO1. However, this approach causes delivery to be delayed until PO2 arrives, and PO1 expires in the meantime. Therefore, the system covers SO1 by using PPO1 and PO1.

The following table summarizes the result.

Expand table

Demand	Pegging
SO1: Delivery date = today, qty = 2	**PO1:** Receipt date = today, qty = 1, expiration date = today + 1 day **PPO1:** Receipt date = today, qty = 1, expiration date = today + 10 days

The following illustration shows the timeline for this example.

Scheduling with infinite capacity

10/03/2025

The *Infinite capacity scheduling for Planning Optimization* feature introduces scheduling that is based on route information. It lets you schedule jobs based on a wide range of route setups. Scheduling covers frequently used route settings, including the route operation sequence or requirements for route operation resources.

Added functionality

The *Infinite capacity scheduling for Planning Optimization* feature enables job scheduling that is based on route information. Therefore, a route setup can be used to schedule production processes. Although this feature has some limitations that the deprecated master planning engine doesn't have, it supports the most common functionality that is required for manufacturing scenarios.

The feature considers both *simple routes* and *route networks*. By using the **Next** field on a route operation, you can set up complex routes that have multiple starting points and multiple operations that run in parallel. The system will consider complex route structures of this type during scheduling.

Additionally, the feature supports *parallel operations* in routes. By using the *Primary* and *Secondary* options in the **Priority** field on route operations, you can define a route structure where one route operation is the primary operation and another operation is secondary. In this case, the system will consider the route structure during scheduling.

During the scheduling process, the system also considers the *resource requirements* that are specified for an operation. The system uses resource requirements to determine which resources are required to perform the operation. Currently, the *Infinite capacity scheduling for Planning Optimization* feature supports following types of resource requirements:

- Resource type
- Resource
- Resource group
- Capability (Learn more in Scheduling with resource selection based on capability.)

> **Note**
>
> - If the resource and/or the resource group are set to infinite capacity, master planning will consider them as infinite capacity.

- Requirements that are related to human resources, such as skills or certificate requirements, aren't yet supported.

The feature also supports the **Setup time** and **Run time** operational properties. When you set these properties on a route operation, the scheduling process will create the appropriate setup and process jobs.

In summary, scheduling supports the most frequently used scenarios. You can create the route, add primary and secondary operations, define next operations, add resource requirements, and add setup time and run time. The system will then consider this information during scheduling.

Limitations

The following limitations apply when you use the *Infinite capacity scheduling for Planning Optimization* feature:

- The feature supports only infinite capacity.
- The feature doesn't support resource load functionality.
- The feature doesn't consider route scrap.
- The feature supports *Duration* only as the primary resource selection.

Finite capacity planning and scheduling

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Finite capacity is an approach that helps you understand how much work can be produced during a specific period when limitations on different resources are taken into consideration. The purpose of finite capacity scheduling is to ensure that work proceeds at an even and efficient pace throughout the plant.

Finite capacity planning and scheduling creates a more realistic schedule for the production processes than the infinite loading approach creates. If there isn't enough capacity on the resources, the delivery date is pushed out, and the job is scheduled when there's enough capacity.

> **Note**
>
> Finite capacity planning and scheduling works in nearly the same way, regardless of whether you use Planning Optimization or the deprecated master planning engine. However, Planning Optimization doesn't use the **Bottleneck time** fence parameter. When you use Planning Optimization, bottleneck resources are always scheduled by using the same time fence as non-bottleneck resources (as indicated by the finite capacity time fence).

Set up finite capacity functionality

To use finite capacity functionality, you must enable capacity planning globally, and you must enable finite capacity planning both for the master plan where you want to use it and for each resource where it applies. For plans and resources where finite capacity is enabled, scheduling of planned production orders considers capacity that is already reserved. Planned production orders are backward-scheduled from the requirement date. If capacity isn't available to meet the optimal schedule, the system tries to require component items on an earlier date. If your capacity can change as requirements change (for example, when you're working with shifts), you shouldn't use finite capacity functionality, because the calculated processing times won't be correct. Scheduling considers only capacity that is already reserved for resources where

finite capacity is enabled. By enabling finite capacity for a resource, you make it possible to modify the finite capacity time fence.

Activate Master planning parameters

To use finite capacity functionality, you must enable capacity planning on the **Master planning parameters** page.

1. Go to **Master planning** > **Setup** > **Master planning parameters**.
2. On the **Planned orders** tab, in the **Capacity planning** section, set the **Production** option to *Yes*.

Activate a master plan

You must enable finite capacity planning and scheduling for each master plan where you want to use it.

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. In the list pane, select a master plan that you want to set up to use finite capacity planning and scheduling.
3. On the **General** FastTab, in the **Planned production orders** section, set the **Finite capacity** option to *Yes*.
4. Repeat steps 2 and 3 for each additional master plan that you want to set up.

Activate resources

You must enable finite capacity planning and scheduling for each resource where you want to use it.

1. Go to **Production control** > **Setup** > **Resources** > **Resources**.
2. In the list pane, select a resource that you want to set up to use finite capacity planning and scheduling.
3. On the **Operation** FastTab, in the **Capacity button** section, set the **Finite capacity** option to *Yes*.
4. Repeat steps 2 and 3 for each additional resource that you want to set up.

Examples

This section provides the following examples that show how to work with both infinite and finite capacity planning and scheduling:

- Example 1 – Infinite capacity planning
- Example 2 – Finite capacity planning with a time fence of one day
- Example 3 – Finite capacity planning with a time fence of two days

Preconditions

All three examples assume the preconditions that are described in this section.

Product *Product1* has a route that contains the following operations.

Expand table

Operation no.	Operation name	Resource	Run time	Process qty.	Next
10	Welding	Welding line	1	2	20
20	Assembling	Assembling line	1	4	

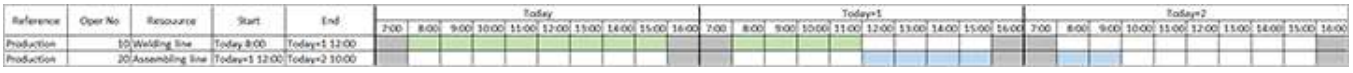
Workers at your company work in one shift for eight hours (8:00–16:00).

There's a scheduled production order for *24 pcs* of *Product1*. It has a delivery date of *Today + 3 days*.

As a result of planning, the system loads the resources in the following way:

- **Welding line:** This resource is loaded from *Today at 8:00* until *Today + 1 at 12:00*.
- **Assembling line:** This resource is loaded from *Today + 1 at 12:00* until *Today + 2 at 10:00*.

The following illustration shows the resulting Gantt chart (select it for a larger view).



Example 1 – Infinite capacity planning

This example shows the planning results when you use infinite capacity planning instead of finite capacity planning.

The master plan has the following relevant setting, which disables finite capacity planning for the plan:

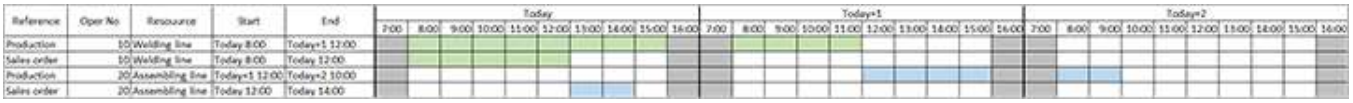
- **Finite capacity:** *No*

The **Finite capacity** option is also set to *No* for both the relevant resources to disable finite capacity planning for them:

- Welding line
- Assembling line

You now add a new sales order for *8 pcs* of *Product1* and run the plan. As a result, the system loads the welding line from *Today at 8:00* until *Today at 12:00*. After operations on the welding line are completed, the system will load the assembling line from *Today at 12:00* until *Today at 14:00*.

The following illustration shows the resulting Gantt chart (select it for a larger view).



Example 2 – Finite capacity planning with a time fence of one day

This example shows planning results when you use finite capacity planning and a time fence of one day.

The master plan has the following relevant settings, which enable finite capacity planning and set a time fence for the plan:

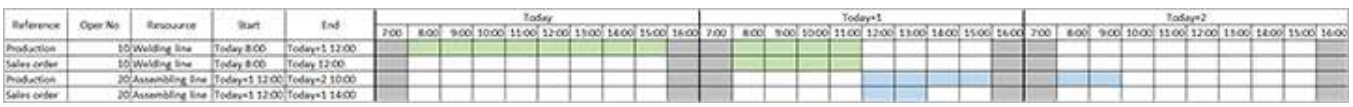
- **Finite capacity:** *Yes*
- **Finite capacity time fence:** *1*

The **Finite capacity** option is also set to *Yes* for both the relevant resources to enable finite capacity planning for them:

- Welding line
- Assembling line

You now add a new sales order for *8 pcs* of *Product1* and run the plan. As a result, the system loads the welding line from *Today + 1 at 8:00* until *Today + 1 at 12:00*. After operations on the welding line are completed, the system will load the assembling line from *Today + 1 at 12:00* until *Today + 1 at 14:00*. The system considers the finite capacity for only one day.

The following illustration shows the resulting Gantt chart (select it for a larger view).



Example 3 – Finite capacity planning with a time fence of two days

This example shows planning results when you use finite capacity planning and a time fence of two days.

The master plan has the following relevant settings, which enable finite capacity planning and set a time fence for the plan:

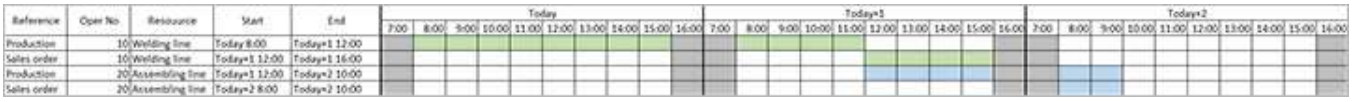
- **Finite capacity:** *Yes*
- **Finite capacity time fence:** *2*

The **Finite capacity** option is also set to *Yes* for both the relevant resources to enable finite capacity planning for them:

- Welding line
- Assembling line

You now add a new sales order for *8 pcs* of *Product1* and run the plan. As a result, the system loads the welding line from *Today + 1 at 12:00* until *Today + 1 at 16:00*. After operations on the welding line are completed, the system will load the assembling line from *Today + 2 at 8:00* until *Today + 2 at 10:00*. The system considers the finite capacity for only two days.

The following illustration shows the resulting Gantt chart (select it for a larger view).



> **ⓘ Important**
>
> You should always set the finite capacity time fence as required to fit your business needs. The examples that are provided in this article merely illustrate the functionality. In reality, a single-day time fence is probably too low for most manufacturers that use finite capacity planning.

Scheduling with resource selection based on capability

10/03/2025

By specifying resource requirements for an operation of a production route, you define what is required to perform that operation. For example, an operation might require a specific resource or a resource group, or a combination of skills or capabilities. This article describes resource selection during infinite capacity scheduling when you specify capabilities as resource requirements for an operation.

Capability-based scheduling

A capability is the ability of an operation resource to perform a specific activity. More than one capability can be assigned to a single operation resource, and a single capability can be assigned to more than one resource. Capabilities can be assigned to all types of resources, such as tools, vendors, machines, locations, facilities, and human resources.

When you specify capabilities as resource requirements, you can defer resource allocation until orders are scheduled. Instead of assigning specific resources or resource groups to a route operation, you can define the capabilities that are required for each route operation. Then, during scheduling, the system matches required capabilities with the capabilities that are defined for the resources. The system selects only resources that satisfy the requirements.

To assign capabilities to an operation resource, use the **Capabilities** FastTab of the **Resources** page. To assign resources to a capability, use the **Resources** FastTab of the **Resource capabilities** page. Both pages are accessible under **Production control** > **Setup** > **Resources** on the navigation pane. Both FastTabs include a grid that lists the resources that are associated with a selected resource or capability. Both FastTabs also include a toolbar that you can use to add, remove, and edit rows in the grid. The grid includes the following columns:

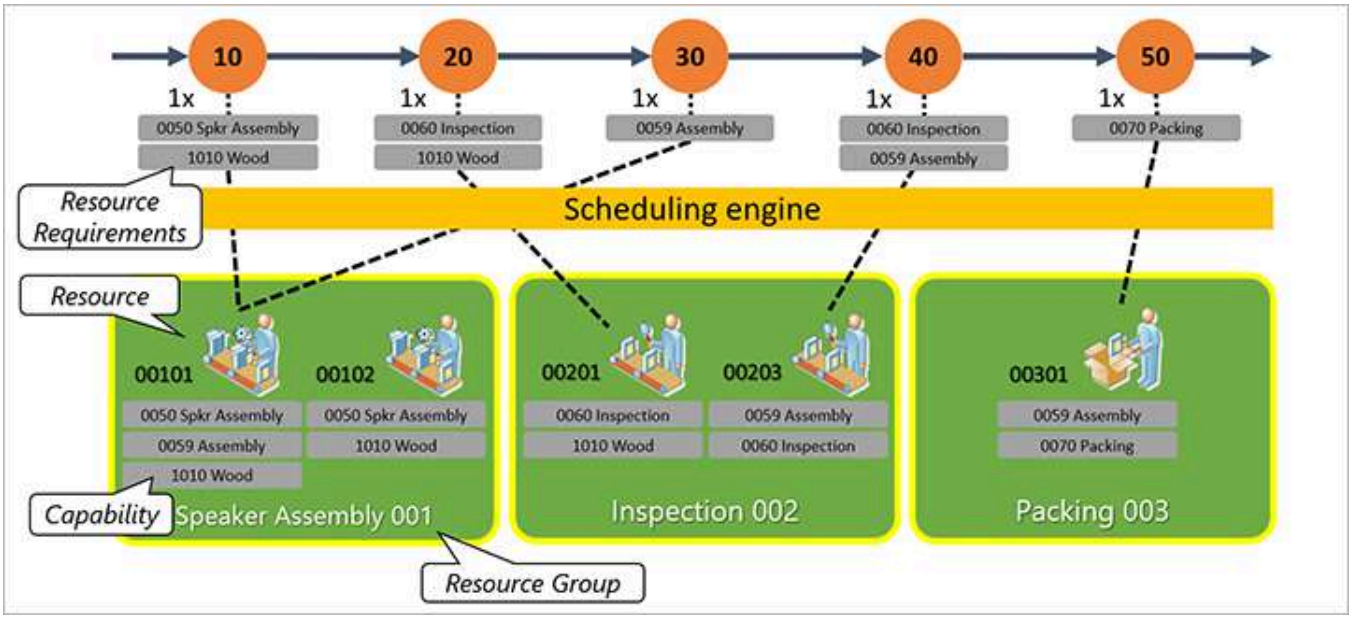
- **Resource** or **Capability** – Select the resource or capability that is being assigned by the row.
- **Description** – Enter a short description of the resource or capability.
- **Effective** – Specify the first date when the resource or capability assignment applies. During scheduling, the system won't use a resource or capability that has an expired capability assignment, even if that resource otherwise satisfies the requirements.
- **Expiration** – Specify the last date when the resource or capability assignment applies. During scheduling, the system won't use a resource or capability that has an expired capability assignment, even if that resource otherwise satisfies the requirements.

- **Level** – Specify the level of proficiency that the resource must have for the capability. Then, if you specify a **Minimum level needed** value for the resource or capability requirement, the scheduling engine considers the level of proficiency during resource selection. The system selects only resources that have the required capability at a level that equals or exceeds the minimum level that is specified in the resource requirement.
- **Priority** – Set a priority for the resource or capability. Then, if *Priority* is selected in the **Primary resource selection** field on the **Scheduling parameters** page, the system selects the available resource with the highest priority (that is, the lowest numeric value in the **Priority** field) during scheduling. The engine only evaluates priority among those resources that are both applicable and available, which means that during backward scheduling, if a resource with a high priority isn't available (for example because its calendar is closed) then another resource would be chosen.

Example

This example shows how the scheduling engine selects resources, based on capability.

A production route has five operations: *10*, *20*, *30*, *40*, and *50*. Each route operation requires a resource that has different capabilities. For example, route operation *10* requires a resource that has the capability to assemble a speaker (*0050 Spkr Assembly*) and the capability do woodworking (*1010 Wood capabilities*). Route operation *50* requires a resource that has the capability to pack a product (*0070 Packing capability*).



During scheduling, the engine looks for resources that satisfy the operation requirements. For example, the scheduling engine selects resource *00101* to perform operation *10*, because this resource is the first resource that is found that has both the required capabilities. The scheduling engine selects resource *00301* to perform operation *50*, because this resource is the only resource that has the packing capability.

Next, consider how this example is affected when proficiency levels are used:

- Operation *10* requires a minimum proficiency level of *7* for the *0059 Assembly* capability.
- Resource *00101* has a proficiency level of *5* for the *0059 Assembly* capability.
- Resource *00102* has a proficiency level of *10* for the *0059 Assembly* capability.

In this case, during infinite capacity scheduling, the scheduling engine selects resource *00102* to perform operation *10*, because this resource, unlike the resource *00101*, has the required proficiency level for the capability.

Inventory marking

10/03/2025

This article provides information about the options that are available for marking inventory in firmed orders.

Marking is used to link supply and demand. It resembles *pegging*, which indicates how master planning expects to cover demand. From a planning point of view, the main difference is that marking is more permanent than pegging.

Marking was introduced to support special costing scenarios for first in, first out (FIFO) and last in, first out (LIFO). However, it's now also used for some non-costing scenarios. Marking between supply and demand is optional and almost permanent. Marking can be removed manually by a user, or it can be removed by running a sales order line explosion where the **Remove marking** option is selected.

Pegging is controlled by master planning during coverage to link demand with the required supply. Pegging can be updated for each planning run to optimize the supply that is required to cover demand. When master planning updates pegging information, it respects any existing marking.

Pegging starts by including relevant marking, on-hand reservations, and on-order reservations, in the following sequence:

1. Marking between demand and supply
2. On-hand reservations
3. On-order reservations

When you firm a planned order, the **Firming** dialog box provides an **Update marking** field that you use to set marking options for the orders that are created during firming. Select one of the following values:

- *No* – No inventory marking is applied.
- *Standard* – Inventory marking is updated according to the pegging. A requirement order (demand) is marked against a fulfillment order (supply). If some quantity remains on the fulfillment order, it isn't marked, and the reference information is left blank. For example, if a sales order for 100 ea is pegged against a purchase order for 150 ea, reference information will be assigned only to the sales order.
- *Extended* – Both the requirement order (demand) and the fulfillment order (supply) are marked, regardless of any quantity that remains on the fulfillment order. For example, if a sales order for 100 ea is pegged against a purchase order for 150 ea, reference information will be assigned to both the sales order and the purchase order.

- *Single level standard* – Single-level marking is used. Single-level marking marks only the main item, not its bill of materials (BOM) components. Therefore, you can keep component assignment for production orders flexible after firming. Single-level marking enables the system to optimize for last-minute demand changes. In *standard* single-level marking, requirement orders are marked against their fulfillment orders, but fulfillment orders aren't marked if they have remaining quantity.
- *Single level extended* – Single-level marking is used. In *extended* single-level marking, requirement orders are marked against their fulfillment orders, and fulfillment orders are always marked, regardless of whether any quantity remains.

To set the default marking option for your system, go to **Master planning** > **Setup** > **Master planning parameters**. Then, on the **Standard update** tab, set the **Update marking** field to your preferred option.

Intercompany planning

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

For some organizations, logistics operations depend on other legal entities (companies) in the organization. Handle these operations by using intercompany sales and purchases because each legal entity has a separate chart of accounts.

This article describes intercompany planning and explains how to configure intercompany planning in Microsoft Dynamics 365 Supply Chain Management.

This article uses the following important intercompany terms:

- **Upstream** – A relative reference in a firm or supply chain. It indicates movement in the direction of the raw material supplier.
- **Downstream** – A relative reference in a firm or supply chain. It indicates movement in the direction of the customer.
- **Planned intercompany demand** – Planned demand for a product in a company, based on planned demand for the product from a downstream company.

In master planning, a plan in one company can include planned intercompany demand that relates to planned orders from a plan in another company. This capability is useful, because it provides full visibility into planned orders across companies. It also ensures that all required planned supply orders are created, but without requiring that planned orders be firmed for the intercompany demand.

If you run master planning from a master plan that includes planned downstream demand, planned purchase orders from the related intercompany vendors are included in the plan as demand.

Required setup

To use intercompany planning, prepare your system in the following way:

1. Release the relevant products in all the relevant companies. Learn more in Configure and use intercompany trade in Dynamics 365 Supply Chain Management.

2. Cover downstream demand by purchasing from a vendor that has an intercompany relation to the upstream company and relevant default inventory dimensions (site and warehouse) on the customer. Learn more in Configure and use intercompany trade in Dynamics 365 Supply Chain Management.
3. Include planned downstream demand in the master plan in the upstream company, and specify the relevant company and master plan in the downstream plans.

Include planned downstream demand

Follow these steps to configure your master plan so that it includes planned downstream demand.

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Select or create a master plan.
3. On the **Intercompany planning** FastTab, set the following fields:
    - **Include planned downstream demand** – Set this option to *Yes* to enable intercompany planning for the master plan.
    - **Downstream plans** – If you set the **Include planned downstream demand** option to *Yes*, use the toolbar and grid to add the desired master plans from other companies.

Peg across companies by using multilevel pegging

In multilevel pegging, you can view pegging across companies to see the initial source of demand that's covered by a supply.

To view multilevel pegging information, follow these steps.

1. Go to **Master planning** > **Master planning** > **Planned orders**.
2. Select or open a planned order.
3. On the Action Pane, on the **View** tab, in the **Requirements** group, select **Multilevel pegging**.

Intercompany example that involves two companies

For this example, a planned production order is created in the USMF company to cover a sales order in the DEMF company. In USMF, the direct demand is planned intercompany demand. To make this demand appear in USMF, run master planning first in DEMF and then in USMF.

The following illustration shows how this example might appear on the **Multilevel pegging** page for the planned production order.

Intercompany example that involves three companies

In this example, you create a planned purchase order in the USMF company to cover a sales order in the FRRT company. In the DEMF and USMF companies, the direct demand is planned intercompany demand. To make this demand appear in USMF, run master planning first in FRRT, then in DEMF, and finally in USMF.

The following illustration shows how this example might appear on the **Multilevel pegging** page for the planned production order.

Last updated on 11/19/2025

Exclude products that have specific product lifecycle states

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Released products and released product versions include a **Product lifecycle state** field. This field lets you control, among other things, which products are included during master planning. You can add, remove, and edit lifecycle states as required by going to **Product information management** > **Setup** > **Product lifecycle state**. For each product lifecycle state, set the **Is active for planning** option to *Yes* if products that have that state should be included during master planning. When the option is set to *No*, the associated products and variants will be excluded from all master planning and all calculations at the bill of materials (BOM) level.

Released products and variants where the **Product lifecycle state** field is left blank are treated as though they have a product lifecycle state where the **Is active for planning** option is set to *Yes*. In other words, they will be included during master planning.

> **Note**
>
> To help avoid unnecessary supply suggestions, we strongly recommend that you associate all obsolete released products and variants with a product lifecycle state where the **Is active for planning** option is set to *No*. This approach is especially important when you work with product configuration variants that aren't reusable, because it will help prevent waste.

Related information

To learn more about product lifecycle states, including how to exclude products from master planning and BOM-level calculations, go to Product lifecycle states.

Last updated on 01/09/2026

Coverage time fences

This article describes how to set up *coverage time fences*. Planners can define the planning horizon (the coverage time fence in days), and exclude supply and demand that falls beyond that horizon. Therefore, coverage time fences help prevent "noise" caused by supply suggestions that don't require attention for months. Examples include next year's forecast and customer orders that are placed far beyond the normal lead time.

A coverage time fence is the number of days after today's date (or, more precisely, the date when you do the planning run) that supply and demand are excluded. To help avoid delays, you must ensure that the coverage time fence is longer than the total lead time. The default system value is 100 days.

You can specify a coverage time fence at each of the following levels:

- **Coverage group** – You can set a default coverage time fence for each coverage group.
- **Item coverage** – You can override the coverage time fence that is inherited from the coverage group that is assigned to an item.
- **Master plan** – You can override the coverage time fences that are inherited from the coverage group and item coverage settings.

The following sections explain how to specify a coverage group at each level.

Set a coverage time fence for a coverage group

When you specify a coverage time fence for a coverage group, the setting applies to all items (products) that belong to that group. However, you can override the setting for specific items or specific master plans.

To specify a coverage time fence for a coverage group, follow these steps:

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.
2. Select an existing coverage group in the list, or create a new coverage group.
3. On the **General** FastTab, set the **Coverage time fence (days)** field to the number of days that you want to use as the coverage time fence for the coverage group.

Set a coverage time fence for a specific item

Every item (product) belongs to a coverage group. If you don't explicitly assign a coverage group to an item, a default coverage group applies. Every item inherits a coverage time fence from its coverage group. However, you can override this time fence for specific items.

To specify a coverage time fence for a specific item, follow these steps:

1. Go to **Product information management** > **Products** > **Released products**.
2. Select a product in the grid.
3. On the Action Pane, on the **Plan** tab, in the **Coverage** group, select **Item coverage**.
4. On the **Item coverage** page, on the **Overview** tab, select or create a row for the site where you want to set a coverage time fence.
5. Select the **General** tab to open the settings for the selected site.
6. Select the **Override coverage group settings** check box.
7. Set the **Coverage time fence (days)** field to the number of days that you want to use as the coverage time fence for the item.

Set a coverage time fence for a specific master plan

You can specify a coverage time fence at the master plan level. By using this setting, you define the number of days that the master planning calculation covers for a master plan. This setting overrides any coverage time settings that you define for each relevant item and coverage group.

To specify a coverage time fence for a specific master plan, follow these steps:

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Select an existing master plan in the list, or create a new master plan.
3. On the **Time fences in days** FastTab, set the **Coverage** option to *Yes*. Then, in the field under the option, enter the number of days that you want to use as the coverage time fence for the master plan.

Considerations for coverage time fences

As you set up coverage time fences, consider the following points:

- Coverage time fences affect only input data for master planning. If delays occur, the resulting planned orders might have a date that is after today's date plus the coverage time fence.
- Coverage time fences are specified in calendar days. Calendars that use working days don't affect the time fence calculation. For example, a week is always considered seven days, even if weekends are set up as closed days in the working time calendar.

- The system doesn't generate requirement transactions for any supply and demand that falls outside the coverage time fence.
- If any approved supply and demand fall outside the coverage time fence, the system doesn't load them into the engine. Therefore, they don't trigger any replenishment, and the system doesn't calculate delays. Nevertheless, don't remove this supply and demand from the system.
- The system ignores variations in safety stock quantities (from minimum keys) if they fall outside the coverage time fence.
- The system ignores intercompany demand if the requested ship date that is calculated isn't inside the coverage time fence. For the deprecated master planning engine, the coverage time fence doesn't limit intercompany demand.
- The system ignores demand forecasts if the budget date isn't inside the coverage time fence. For the deprecated master planning engine, the coverage time fence doesn't limit demand forecasts.
- Planning Optimization is time zone–aware. It considers the time zone at the supply and demand sites, and the time of the planning run. For example, master planning is triggered at 11 AM on October 15 from a site in Denmark (GMT+1 time zone), and a coverage time fence of ten days is used. In this case, supply and demand from a site in Seattle (GMT-8 time zone) is included until 2 AM on October 25 (which is ten 24-hour days after master planning was triggered, minus the time zone difference of nine hours). The deprecated master planning engine considers only the date of the time fence. Therefore, the result can differ.

Filter derived requirements by coverage time fence with Planning Optimization

In Supply Chain Management version 10.0.49 and later, the *Filter derived requirements by coverage time fence with Planning Optimization* feature is available in the Feature management workspace. In Supply Chain Management version 10.0.48 and earlier, this feature isn't available, and Planning Optimization doesn't filter derived requirements by coverage time fence.

When you turn on the *Filter derived requirements by coverage time fence with Planning Optimization* feature, Planning Optimization doesn't replenish derived requirements that fall outside the coverage time fence that applies to them. Examples include:

- Planned transfer issues, where the replenishing warehouse has different coverage time fence settings.

- Planned BOM component issues, where the raw material has different coverage time fence settings.

When the feature is on, derived demand follows the same coverage time fence boundaries that apply to a sales order. The *coverage time fence boundary* refers to the coverage time fence that applies to the inventory dimensions of the demand. Planning Optimization first checks the item coverage line, then the coverage group, and finally the global coverage time fence.

Examples of derived and internally created requirements include:

- Planned transfer issue
- Planned BOM/formula component issue
- Planned BOM line type service issue
- Safety stock issue
- Expired supply issue
- Kanban component issue

This behavior applies to all coverage codes: *Period*, *Requirement*, *Min/Max*, *Priority*, and *Decoupling point*.

Last updated on 07/23/2026

Net requirements and pegging information

07/21/2025

When you run master planning, it's important that you understand its output, how existing supply covers the demand, and why specific supply was generated. You can use the **Net requirements** page to better understand the calculated requirements that master planning produces.

The **Net requirements** page shows the net requirements that master planning calculated for the product. It also shows the coverage settings that were applied during the master planning run, a breakdown of the requirements totals by transaction type, and pegging information.

Open the Net requirements page

You can open the **Net requirements** page in any of the following ways:

- Go to **Product information management** > **Products** > **Released products**. Select or open a product. Then, on the Action Pane, on the **Plan** tab, in the **Requirement** group, select **Net requirements**.
- Go to **Sales and marketing** > **Sales orders** > **All sales orders**. Open a sales order. Then, on the **Sales order lines** FastTab, on the toolbar, select **Product and supply** > **Net requirements**.
- Go to **Master planning** > **Master planning** > **Planned orders**. Select or open a planned order. Then, on the Action Pane, on the **View** tab, in the **Requirements** group, select **Requirement profile**.

Use the Net requirements page

The **Net requirements** page consists of upper and lower sections. The Action Pane on this page includes an **Update** button.

Update the Net requirements page to reflect new supply and demand

Before new supply or demand will appear among the net requirements of an item, you must do one of the following:

- Run a master plan that includes the item.
- Open the **Net requirements** page for the item and then, from the Action Pane, select **Update** > **Master planning**. This action runs master planning for the selected item.

For example, if you manually create a planned order (supply), change an existing planned order (supply), or create sales order (demand), the changes won't appear on an item's **Net requirements** page until after master planning runs for that item.

Select a master plan to view

Before you review the net requirements of the product, be sure to select the relevant master plan in the **Plan** field at the top of the page.

Upper section

The upper section of the page provides the following tabs:

- **Overview** – View the item requirements of the product dimensions.
- **Item coverage** – View the coverage settings that were used during the calculation of requirements.
- **Summary** – View a breakdown of the requirements totals by transaction type.
- **Period** – View the receipts, issues, and projected available inventory for each period that is defined by the period template. You can also get a graphical view of the projected available inventory.

Lower section

The lower section of the page provides the following tabs:

- **Overview** – View the list of product requirements that were calculated during the master planning run, together with issue and receipt transactions that correspond to the requirements. By default, the list is sorted by requirement date. When you select a requirement, the **Pegging** FastTab in the lower section shows either the source of the requirement or the transactions that fulfill the requirement.
- **General** – View detailed information about the selected requirement.
- **Action** – View action messages for the requirements.

The Action Pane

The following commands are available on the Action Pane:

- **Update** > **Master planning** – Run master planning directly from the **Net requirements** page.
- **Update** > **Forecast planning** – Run forecast planning directly from the **Net requirements** page. Planning Optimization doesn't support this operation.

- **Update** > **Continuity scheduling** – Run continuity scheduling directly from the **Net requirements** page. Planning Optimization doesn't support this operation.

Example scenario

This example shows how pegging information is presented on the **Net requirements** page.

Prerequisites

Before you work through the scenario, prepare the following prerequisites:

1. You must work on a system where the standard sample data is available, and you must set the legal entity to *USMF*.
2. This example uses product *1000*, which is part of the USMF sample data. Make sure that this product is available, and that it's set up in the following way:
    - **Default order type:** *Purchase order*
    - **Inventory on-hand:** *10.00*
3. Create a sales order for a quantity of *25.00* of product *1000*. Use the storage dimensions where on-hand inventory is located.
4. Run master planning for the *DynPlan* master plan.

Review the calculated requirements

Next, you'll open the **Net requirements** page for product *1000* to review how calculated requirements correspond to each other.

1. Go to **Product information management** > **Products** > **Released products**.
2. Select the product that has an **Item number** value of *1000*.
3. On the Action Pane, on the **Plan** tab, in the **Requirement** group, select **Net requirements**.
4. On the **Net requirements** page, set the **Plan** field to *DynPlan*.
5. On the **Overview** tab in the lower part of the page, verify that the following requirements are listed as rows in the grid.

Expand table

Reference	Requirement quantity	Accumulated
On-hand	10.00	10.00
Planned purchase orders	15.00	25.00
Sales order	-25.00	(Blank)

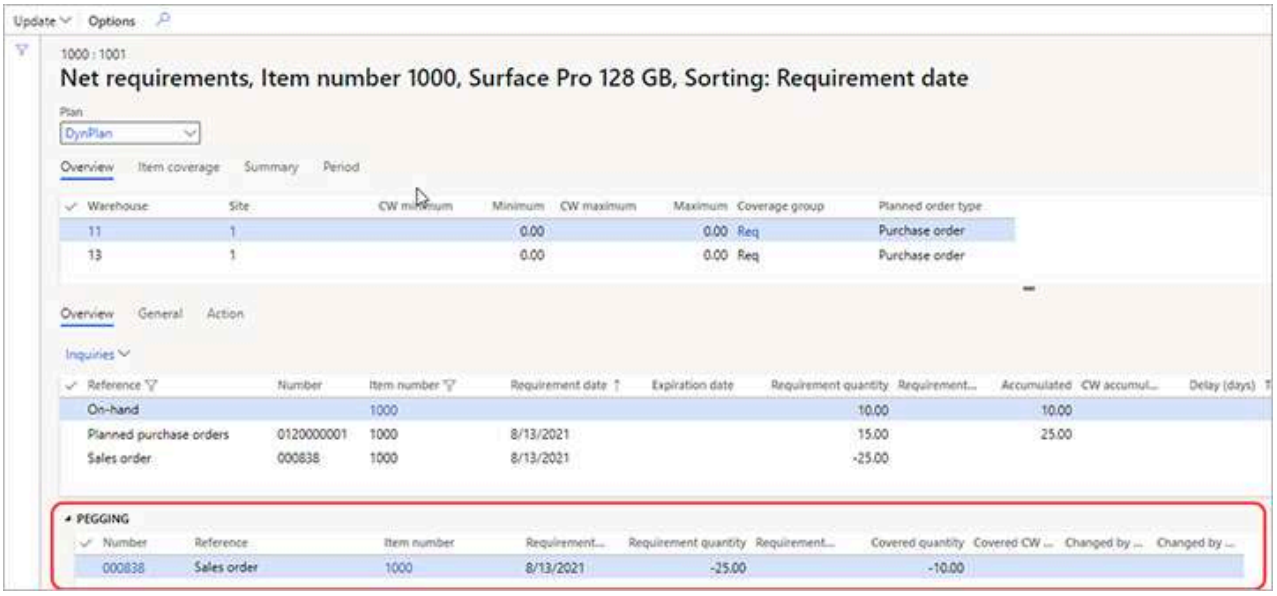
> **Note**
>
> The **Requirement quantity** field represents the total quantity that the requirement either requires (if the value is negative) or supplies (if the value is positive). The **Accumulated** field represents the total receipt and issue quantities that accumulated up through the selected period.

6. Select the *On-hand* requirement line, and then, on the **Pegging** FastTab, review the requirements that are covered by this supply. The following row should appear there.

Expand table

Reference	Requirement quantity	Covered quantity
Sales order	-25.00	-10.00

The existing on-hand inventory partially covers the demand that comes from the sales order.

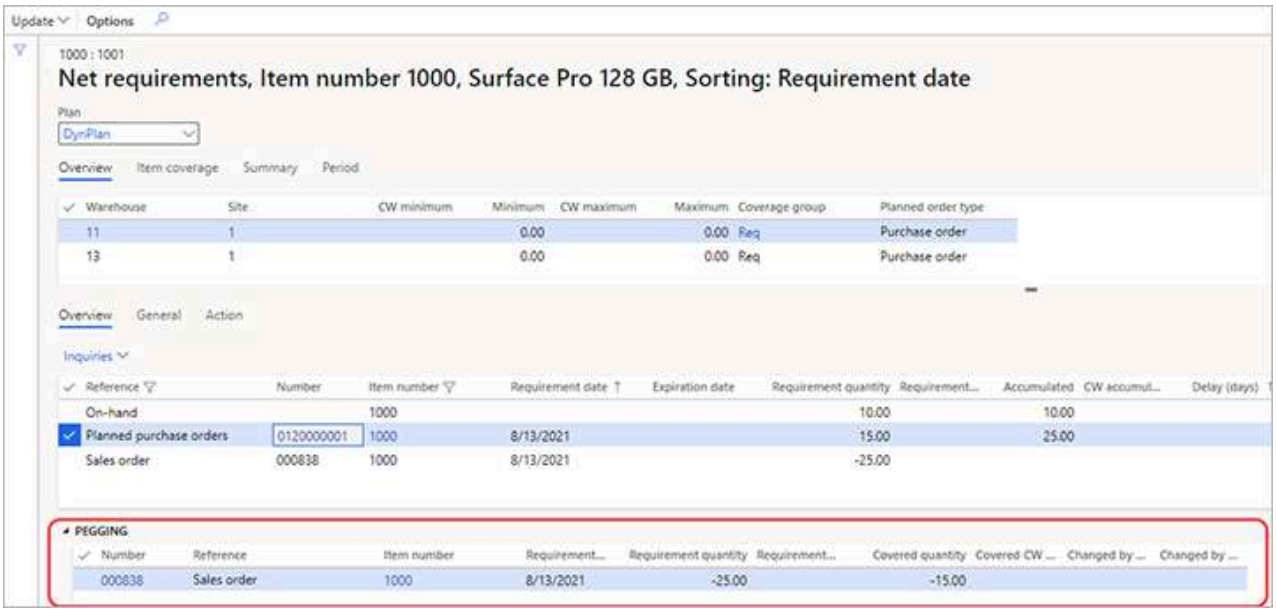


7. Select the *Planned purchase orders* requirement line, and then, on the **Pegging** FastTab, review the requirements that are covered by this supply. The following row should appear there.

Expand table

Reference	Requirement quantity	Covered quantity
Sales order	-25.00	-15.00

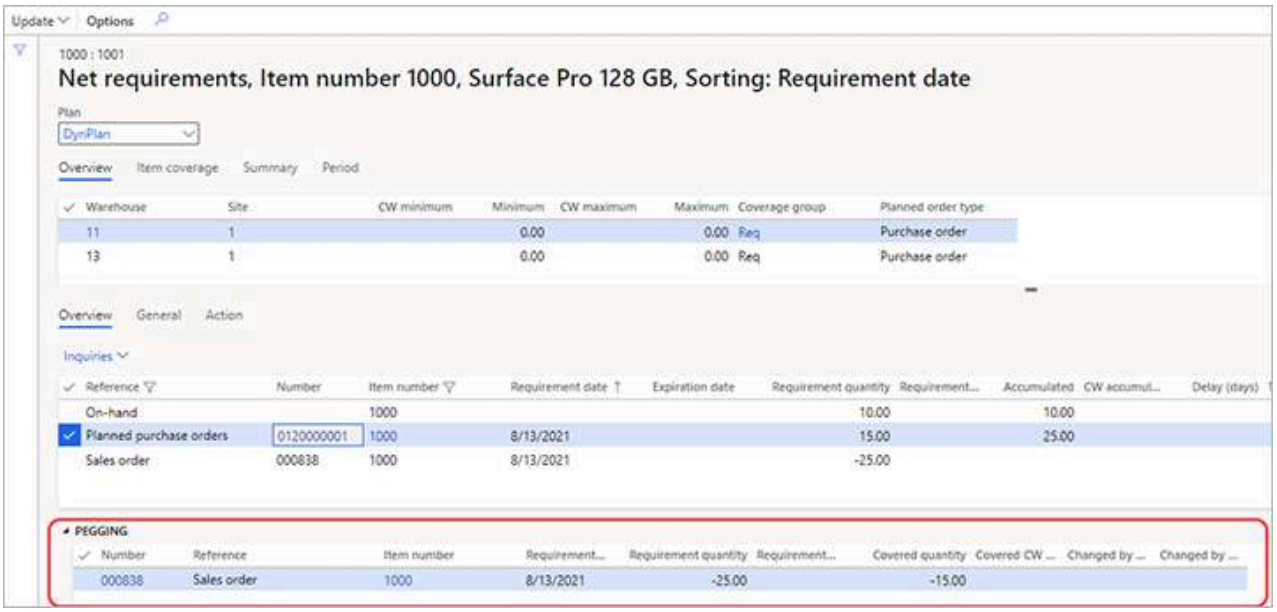
Because the sales order is already partially covered, the system creates a planned purchase order for the remaining uncovered quantity.



8. Select the *Sales order* requirement line, and then, on the **Pegging** FastTab, review the requirements that cover this demand. The following rows should appear there.

Expand table

Reference	Requirement quantity	Covered quantity
On-hand	10.00	10.00
Planned purchase orders	15.00	15.00



> **Note**
>
> The *Safety stock* requirement isn't included on the **Net requirements** page.

Planning with negative on-hand quantities

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

If the system shows a negative aggregate on-hand quantity, the planning engine treats the quantity as 0 to help avoid over-supply. Here's how this functionality works:

1. Master planning aggregates on-hand quantities at the lowest level of coverage dimensions. For example, if *location* isn't a coverage dimension, master planning aggregates on-hand quantities at the *warehouse* level.
2. If the aggregate on-hand quantity at the lowest level of coverage dimensions is negative, the system assumes that the on-hand quantity is really 0.

> **Important**
>
> The planning system is only as precise as the input data. If the input data is inaccurate, negative on-hand records indicate that the inventory information in Microsoft Dynamics 365 Supply Chain Management is out of sync with the real world. Therefore, the planning result is flawed. To get a precise planning result, minimize the number of records that show a negative on-hand quantity.

Example 1

Warehouse 13 is configured in the following manner:

- **Coverage code:** Min./Max.
- **Minimum:** 15 pieces (pcs.)
- **Maximum:** 25 pcs.

The lowest level of coverage dimensions is *warehouse*, and the following on-hand quantities are recorded at the *location* level:

- **Site 1, warehouse 13, location 1:** 20 pcs.
- **Site 1 warehouse 13, location 2:** −8 pcs.

Therefore, the aggregate on-hand quantity for warehouse 13 is 12 pcs. (= 20 pcs. − 8 pcs.).

In this case, the planning engine uses an aggregate on-hand quantity of 12 pcs. for warehouse 13.

The result is a planned order of 13 pcs. (= 25 pcs. − 12 pcs.) to refill warehouse 13 from 12 pcs. to 25 pcs.

Example 2

Warehouse 13 is configured in the following manner:

- **Coverage code:** Min./Max.
- **Minimum:** 15 pcs.
- **Maximum:** 25 pcs.

The lowest level of coverage dimensions is *warehouse*, and the following on-hand quantities are recorded at the *location* level:

- **Site 1, warehouse 13, location 1:** 4 pcs.
- **Site 1 warehouse 13, location 2:** −8 pcs.

Therefore, the aggregate on-hand quantity for warehouse 13 is −4 pcs. (= 4 pcs. − 8 pcs.). In other words, it's less than 0 (zero).

In this case, the planning engine assumes that the on-hand quantity for warehouse 13 is 0 pcs. instead of −4 pcs.

The result is a planned order of 25 pcs. (= 25 pcs. − 0 pcs.) to refill warehouse 13 from 0 pcs. to 25 pcs.

Planning when there is a reservation against negative on-hand inventory

If you adjust inventory while physical reservations exist, you can cause a situation where an order is physically reserved against negative inventory. In this case, because a physical reservation exists, you need to have supply to cover the reserved quantity. Therefore, replenishment is

required, so the system will either create a planned order to replenish the quantity that couldn't be covered by the existing on-hand inventory, or cover it with an existing order for the item.

The following example illustrates this scenario.

Example

The system is configured in the following way:

- Product *FG* exists and has *10* pcs. of on-hand inventory.
- The product configuration allows for physical negative inventory.
- A sales order exists for a quantity of *10* pcs. of product *FG*.
- The sales order quantity is physically reserved against existing on-hand inventory.

You then adjust the quantity of product *FG* so that the on-hand inventory becomes 5. Because the on-hand product inventory is 5, the sales order quantity is now reserved against quantity that isn't available on-hand (it would be similar if on-hand were 0, in which case the sales order would be reserved against negative inventory). If you run master planning now, a planned order of quantity 5 for *FG* is created to supply the sales order, because master planning always uses existing supply or creates a new planned order to supply the physical reservation.

Handle negative on-hand with coverage groups

Because Planning Optimization treats negative aggregate on-hand as 0, you might need to configure your coverage groups to ensure that inventory is replenished to the levels your business requires. To control how the system responds to negative on-hand scenarios, define minimum and maximum quantities in item coverage groups.

To configure coverage groups for handling negative on-hand, follow these steps:

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.
2. Select or create a coverage group, and then set the **Coverage code** field to *Min/Max*.
3. Go to **Master planning** > **Master planning** > **Setup** > **Coverage** > **Item coverage** for the relevant items.
4. Set the **Minimum** field to the lowest inventory level that you want to maintain.
5. Set the **Maximum** field to the target inventory level for replenishment.

When you run master planning, the system creates planned orders to bring inventory back up to the maximum level whenever the projected on-hand falls below the minimum level. This

approach helps maintain appropriate inventory levels even when the system encounters negative on-hand quantities.

Learn more about coverage codes and how each replenishment method works in Coverage settings.

Calculate sales order delivery dates using CTP

Capable-to-promise (CTP) functionality lets you give customers realistic dates for when you can promise specific goods. For each sales line, you can provide a date that takes account of existing on-hand inventory, production capacity, and transportation times.

CTP extends available-to-promise (ATP) functionality by considering capacity information. Whereas ATP considers material availability and assumes infinite capacity resources, CTP considers availability of both materials and capacity.

CTP works slightly differently, depending on the master planning engine that you're using (Planning Optimization or the deprecated master planning engine). This article describes how to set it up for each engine.

How CTP compares to ATP

Use ATP when you sell from stock and capacity isn't a constraint. Use CTP when you assemble or make-to-order and capacity constraints must be taken into account. In such cases, CTP can often provide a more accurate result, as the following example shows.

Item A is an item that is composed of items B and C, and the on-hand quantity of item A is 0 (zero). If you do an ATP check, the ATP quantity is also 0 (zero). However, if you do a CTP check, the system checks the availability of items B and C, checks the resources that are required to make them into item A, and calculates how many of item A can be made. In addition, the CTP calculation can check the resources and materials that are required to make more of items B and C, and to use them to make more of item A.

A CTP calculation that considers both materials and resources might show a larger quantity than a calculation that checks only materials, particularly when the item that's being checked is an assemble or make-to-order item. In other words, CTP functionality is based on the explosion function and can be run for a selected sales order line to calculate the expected delivery date.

Near real-time CTP

Near real-time CTP enables the system to calculate CTP confirmed dates in the background, without blocking user interface (UI) interactions and without requiring that you run planning to

update the dates. *Near real-time CTP* also lets you use standard CTP delivery date control with Planning Optimization. This approach removes some of the limitations that apply when you use CTP with either planning engine. Without *Near real-time CTP*, you must use *Batch CTP* instead of *CTP* delivery date control if you're using Planning Optimization.

> **Note**
>
> - Because both Planning Optimization and the deprecated master planning engine can now use standard *CTP* delivery date control, CTP for Planning Optimization delivery date control is renamed in Supply Chain Management version 10.0.41. It's now named *Batch CTP* instead of *CTP for Planning Optimization* to better describe the difference.
> - Because CTP considers material and capacity availability and lead times for the bill of material and route for the item sold, the CTP calculation isn't as fast as the ATP calculation. When deciding which order promising policy to apply for an item, base the policy on whether the item is produced to and sold from stock (ATP, ATP + Issue Margin, or Sales Lead Time) or if it's an assemble or make-to-order item (CTP).

Enable Near real-time CTP

Before you can use *Near real-time CTP*, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.41 or later.
- The following features must be turned on in Feature management (in this order):
    1. *Improve Planning Optimization performance by merging and queueing plan regeneration jobs*
    2. *Near real-time CTP*

Queueing and merging plan regeneration jobs

The prerequisite feature, *Improve Planning Optimization performance by merging and queueing plan regeneration jobs*, enables the system to queue and merge plan regeneration requests. This capability eliminates the "Another job for the same plan is currently in progress" error and minimizes the average time that is required to complete a planning run when multiple users are working at the same time.

Here's how queueing and merging works:

- By default, the system can merge up to 10 planning requests into a single job. When the system reaches that limit, it adds new planning requests to the queue as standalone jobs. The system can also merge those jobs into another new job. If you need to change the maximum number of planning requests, contact Microsoft Support for assistance.

- You can merge planning requests into a single job only if they meet the following requirements:
  - All merged requests must belong to the same organization and master plan.
  - All merged requests must use the same filter attribute (such as `ItemId`).
  - All merged requests must have the same UI language.

- Before the system adds a planning request to the queue as a standalone job, it checks for other existing jobs that aren't yet started and can be merged with it.

- By default, the queue can hold up to 20 jobs. When the queue reaches that limit, all users who submit planning runs receive an error until more space becomes available in the queue. Each job in the queue can include several merged planning jobs. If you need to change the maximum number of jobs that are allowed in the queue, contact Microsoft Support for assistance.

Near real-time CTP functionality

Near real-time CTP provides the following functionality:

- Multiple sellers can create sales lines at the same time and immediately get confirmed delivery dates.
- When you mass-import sales lines, the system automatically calculates confirmed delivery dates.
- You can use the **Calculate confirmed delivery dates** dialog box to make the system recalculate all confirmed dates for a sales order. If you set the **Allow multiple deliveries** option to *No*, the system automatically sets all sales order lines so that they use the same delivery date.

How CTP differs, depending on the master planning engine and delivery date control that you use

The following table summarizes how CTP differs, depending on the master planning engine and delivery date control that you use.

Expand table

Element	Batch CTP	CTP
Planning engine support	Planning Optimization only	Planning Optimization and the deprecated master planning engine
Delivery date control setting for orders, order lines, and products	*Batch CTP*	*CTP*
Calculation time	The calculation is triggered when a dynamic plan is run as a scheduled task.	The calculation is immediately triggered each time that you enter or update a sales order line.
Batch CTP status field value	A value of *Not ready* is shown for orders and order lines where the dynamic plan hasn't been run since the orders and lines were created or last updated. A value of *Ready* is shown for orders and lines where CTP was used to calculate confirmed delivery dates by running the dynamic plan.	A value of *Ready* is always shown.
CTP status field value	The field isn't shown.	A value is shown only if you're using Planning Optimization. The value represents the status of the delivery date calculation.

Set default delivery date control methods

The system can use any of several methods to calculate delivery date estimates for each order and order line. Set the delivery date control method that you want to use most often as the global default method. You can also set individual overrides for each product. Later, you can override the default methods for each order and/or order line as you require.

Set the global default delivery date control

The default delivery date control method applies to all new order lines where an override doesn't apply. To select a method, follow these steps:

1. Go to **Accounts receivable** > **Setup** > **Accounts receivable parameters**.

2. On the **Shipments** tab, on the **Delivery control** FastTab, in the **Delivery date control** field, select the method that you want to use as the default method for your company:

    - *None* – Don't calculate delivery dates.
    - *Sales lead time* – Sales lead time is the time between creation of the sales order and shipment of the items. The delivery date calculation is based on a default number of days, and doesn't consider stock availability, known demand, or planned supply.
    - *ATP* – ATP is the quantity of an item that's available and can be promised to a customer on a specific date. The ATP calculation includes uncommitted inventory, lead times, planned receipts, and issues.
    - *ATP + Issue margin* – The shipping date equals the ATP date plus the issue margin for the item. The issue margin is the time that is required to prepare the items for shipment.
    - *CTP* – Use the standard CTP calculation, which provides near-real-time calculations. To use this option with Planning Optimization, you must enable *Near real-time CTP* for your system.
    - *Batch CTP* – Use the non-real-time CTP calculation that's available for Planning Optimization. This setting has no effect if you're using the deprecated master planning engine.

Set delivery date control overrides for individual products

Assign overrides for specific products when you want to use a delivery date control method other than the one that you set as your global default method.

1. Go to **Product information management** > **Products** > **Released products**.
2. Select the product that you want to set up.
3. On the Action Pane, on the **Manage inventory** tab, in the **Order settings** group, select **Default order settings**.
4. On the **Default order settings** page, on the **Sales order** FastTab, set the **Override delivery control** option to *Yes*.
5. In the **Delivery date control** field, select the method to use for the selected product. The same options that are described in the Set the global default delivery date control section are available.

Schedule Batch CTP calculations

When you use Batch CTP, you must run a dynamic plan to trigger the system to do the CTP calculations and then set the confirmed ship and receipt dates for all relevant orders. The plan

must include all items that confirmed ship and receipt dates are required for. (When you use standard CTP delivery date control, the CTP calculations are immediately done locally. Therefore, you don't have to run a dynamic plan to see the CTP results.)

To ensure that the dates are available in good time for all users, set up batch jobs to run the relevant plans on a recurring basis. For example, a batch job that is set up to run a dynamic plan every 30 minutes sets the confirmed ship and receive dates every 30 minutes. Therefore, users who enter and import orders wait a maximum of 30 minutes to get the confirmed ship and receive dates.

To set up a batch job to run a dynamic plan on a regular schedule, follow these steps:

1. Go to **Master planning** > **Master planning** > **Run** > **Master planning**.
2. In the **Master planning** dialog box, on the **Parameters** FastTab, set the **Master plan** field to the dynamic plan that you want to run.
3. On the **Run in the background** FastTab, set the **Batch processing** option to *Yes*.
4. Select **Recurrence**, and set up the schedule as required.
5. Select **OK** to save the schedule.
6. Select **OK** to create the batch job and close the dialog box.

Use standard CTP delivery date control

To use standard CTP delivery date control, you must either use the deprecated master planning engine or use Planning Optimization with *Near real-time CTP* enabled.

Create a new order that uses standard CTP delivery date control

Each time that you add a new sales order or order line, the system assigns a default delivery date control method to it. The order header always starts with the global default method. If you assign an override to an ordered item, the new order line uses that override. Otherwise, the new order line also uses the global default method. Therefore, set your default methods so that they match the delivery date control method that you most often use. After you create an order, you can override the default method at the order header and/or order line level as you require. Learn more in Set default delivery date control methods and Change existing sales orders to use CTP.

View confirmed delivery dates when you use standard CTP delivery date control

CTP calculations apply to orders and order lines where the **Delivery date control** field is set to *CTP*.

For sales lines that use standard CTP delivery date control, the system automatically sets the **Confirmed ship date** and **Confirmed receipt date** fields each time that you save a sales line. If you make a relevant change to a sales line later (for example, by changing its quantity or site), the system immediately recalculates the dates.

- To view the confirmed delivery dates for a sales order line, open the sales order, and select the sales line. Then, on the **Line details** FastTab, on the **Delivery** tab, review the **Confirmed ship date** and **Confirmed receipt date** values.
- To view the confirmed delivery dates for an entire order, open the sales order, and select the **Header** view. Then, on the **Delivery** FastTab, review the **Confirmed ship date** and **Confirmed receipt date** values.

Use Batch CTP

Create a new order that uses Batch CTP

Each time that you add a new sales order or order line, the system assigns a default delivery date control method to it. The order header always starts with the global default method. If you assign an override to an ordered item, the new order line uses that override. Otherwise, the new order line also uses the global default method. Therefore, set your default methods so that they match the delivery date control method that you most often use. After you create an order, you can override the default method at the order header and/or order line level as you require. Learn more in Set default delivery date control methods and Change existing sales orders to use CTP.

View confirmed delivery dates when you use Batch CTP

Batch CTP calculations apply to orders and order lines where the **Delivery date control** field is set to *Batch CTP*.

For sales lines that use Batch CTP, the **Confirmed ship date** and **Confirmed receipt date** fields stay blank until you run the appropriate dynamic plan (typically by using a periodic batch job). The system then sets these fields automatically. Learn more in Schedule Batch CTP calculations.

The **Batch CTP status** field shows whether confirmed dates are calculated for each line that uses Batch CTP. The field is set to *Not ready* for lines and orders where the confirmed delivery dates aren't calculated yet or are no longer valid because of other changes. The field is set to *Ready* for lines and orders that are calculated. You can view the status for each line and for the entire order.

- To view the status for a sales order line, open the sales order, and select the sales line. Then, on the **Line details** FastTab, on the **Delivery** tab, review the **Batch CTP status** value. The **Delivery** FastTab also shows the **Confirmed ship date** and **Confirmed receipt date** values for the line after they're calculated.
- To view the status for an entire order, open the sales order, and select the **Header** view. Then, on the **Delivery** FastTab, review the **Batch CTP status** value. The **Delivery** FastTab also shows the **Confirmed ship date** and **Confirmed receipt date** values for the order after they're calculated.

> ⓘ **Note**
>
> - If you update a sales order line after Batch CTP calculates confirmed dates for it, the system clears those dates until the next time that the appropriate dynamic plan runs.
> - If you edit a related setting that might affect existing confirmed dates (for example, by changing lead times, reservations, or markings), clear the confirmed dates for the relevant existing orders. This action changes the status of each relevant line to *Not ready*. This change causes the system to recalculate the confirmed dates the next time that it runs the dynamic plan.
> - Batch CTP only calculates confirmed dates for sales lines with status *Not Ready*, so subsequent Planning Optimization runs that affect planned supply for sales lines with status *Ready* might cause the confirmed dates to become out of sync with the latest plan result. To prevent this, consider firming planned orders early to make sure that generated supply remains unaffected by future Planning Optimization runs.

Change existing sales orders so that they use CTP

You can change the **Delivery date control** value for any open order at any time. You can change the value at the header level and/or for each line as you require.

Change to CTP at the order header level

To change an order so that it uses CTP at the order header level, follow these steps:

1. Go to **Accounts receivable** > **Orders** > **All sales orders**.
2. Open the sales order that you want to set up, or create a new one.
3. Select **Header** to open the header information on the **Sales order details** page.

4. On the **Delivery** FastTab, set the **Delivery date control** field to one of the following values, depending on the planning engine that you're using:

    - *CTP* – Use the standard CTP calculation, which provides near-real-time calculations. To use this option with Planning Optimization, you must enable *Near real-time CTP* for your system.
    - *Batch CTP* – Use the non-real-time CTP calculation that's available for Planning Optimization. This setting has no effect if you're using the deprecated master planning engine.

5. Select **OK** to apply your changes.

Change to CTP at the order line level

If you create an order line by using a different delivery date control method, you can change to CTP at any time. Changes that you make at the line level don't affect any other lines. However, they might cause the overall order delivery dates to move forward or backward, depending on how each updated line calculation changes.

To change an order so that it uses CTP at the line level, follow these steps:

1. Go to **Accounts receivable** > **Orders** > **All sales orders**.

2. Open the sales order that you want to set up, or create a new one.

3. On the **Sales order details** page, on the **Sales order line** FastTab, select the sales order line that you want to set up.

4. On the **Line details** FastTab, on the **Delivery** tab, set the **Delivery date control** field to one of the following values, depending on the planning engine that you're using:

    - *CTP* – Use the standard CTP calculation, which provides near-real-time calculations. To use this option with Planning Optimization, you must enable *Near real-time CTP* for your system.
    - *Batch CTP* – Use the non-real-time CTP calculation that's available for Planning Optimization. This setting has no effect if you're using the deprecated master planning engine.

    The **Available ship and receipt dates** dialog box appears, and shows the available ship and receipt dates. This dialog box works the same way for order lines as it does for the order header, as described in the previous section.

5. On the Action Pane, select **Save**.

- Keep supply for confirmed demand in Planning Optimization
- Optimize confirmed dates for CTP line changes

Last updated on 07/27/2026

Keep supply for confirmed demand in Planning Optimization

The *keep supply for confirmed demand* feature ensures that customer commitments provided by capable-to-promise (CTP) functionality are strictly preserved between planning runs. This functionality is applied across all BOM levels, meaning that all derived requirements originating from a confirmed sales line are preserved. Such requirements are referred to as *confirmed requirements*.

What qualifies as confirmed demand

A sales order line is considered confirmed demand when it meets the following criteria:

- The sales order line has a **Line status** equal to *Open order*.
- The **Confirmed ship date** field is populated. The CTP calculation typically sets this date.

What data is preserved

When the system identifies confirmed demand, it preserves the following data across planning runs:

- Planned orders
- Pegging information for planned orders, released orders, and on-hand inventory
- Routes
- Route jobs
- Capacity reservations

> **Important**
>
> The following behavior applies to this feature:
>
> - Action dates and futures are updated for all requirements, including confirmed requirements.
> - This feature doesn't respect the *Period* coverage code for confirmed supplies created between planning runs.
> - This feature doesn't reevaluate product substitution after requirements are confirmed. For example, planning doesn't substitute a confirmed requirement with an alternate

item, even if the alternate item becomes available later.
- Sales order demands for co-products and by-products aren't treated as confirmed demand, even if they have a confirmed ship date.

Prerequisites

Before you can use the *keep supply for confirmed demand* feature, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.48 build 10.0.2645.33 or later.
- You must use Planning Optimization.
- The *Keep supply for confirmed demand in Planning Optimization* feature must be turned on in Feature management.

> **Note**
>
> This feature works together with CTP delivery date control. You can use either *Near real-time CTP* or *Batch CTP* delivery date control. The supply chain is retained if you later change the delivery date control to other values, as long as the confirmed ship date remains populated.

Set a master plan to keep supply for confirmed demand

You can choose to keep supply for confirmed demand at the master plan level. This setting controls whether the system preserves confirmed requirements for the selected master plan. The value applies to both non-interactive scenarios (such as CTP calculation, BOM explosion, and scheduling with finite capacity) and interactive scenarios (such as the master planning run dialog, where it serves as the default value).

To set a master plan to keep supply for confirmed demand:

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Select or create a master plan.
3. On the **General** FastTab, set the **Keep supply for confirmed demand** option to one of the following values:

    - *Yes* – The system identifies confirmed sales lines and preserves the full supply chain linked to them during planning runs. Planned orders that are part of a confirmed

supply chain aren't replanned.

- *No* – The system doesn't consider confirmed requirements. All planned orders that aren't approved and fall outside the freezing time fence are replanned during each planning run. This is the default behavior.

Keep supply for confirmed demand when running a master plan interactively

You can choose to keep supply for confirmed demand when you run master planning interactively. The planning run dialog provides the **Keep supply for confirmed demand** option, and the selected master plan automatically sets the default value.

To keep supply for confirmed demand when running a master plan interactively:

1. Go to **Master planning** > **Master planning** > **Run** > **Master planning**.
2. In the **Master planning** dialog box, on the **Parameters** FastTab, set the **Keep supply for confirmed demand** option to *Yes* or *No*. The behavior is identical to that described in the previous section.

Check master planning history to see whether supply was kept for confirmed demand

After a planning run completes, you can verify whether the **Keep supply for confirmed demand** parameter was active for that run by reviewing the master planning history.

To view the history of a master planning run and check whether supply was kept for confirmed demand:

1. Go to **Master planning** > **Master planning (Workspace)** > **History**.
2. Select the planning run you want to inspect.
3. On the **Request** FastTab, locate the **Keep supply for confirmed demand** field. The value shows whether confirmed requirements were preserved during that specific run.

> **Tip**
>
> Reviewing the master planning history is useful when troubleshooting scenarios where confirmed delivery dates appear to have changed unexpectedly. If the parameter shows *No*

for a given run, that run may have replanned supply that was previously backing a confirmed sales order line.

Control how on-hand inventory is pegged to confirmed demand

By default, the *keep supply for confirmed demand* feature preserves planned orders, pegging, routes, route jobs, and capacity reservations that are part of a confirmed supply chain. However, the pegging from confirmed demand to *received supply* (on-hand inventory) is still subject to the *Positive days* coverage group setting. This condition applies when a confirmed sales line is initially pegged to a purchase order (or other supply) that you later receive and add to on-hand inventory. As a result, if the confirmed sales line falls outside positive days, the system can reallocate the on-hand inventory to an earlier demand during the next planning run, even if the original sales line still has a confirmed ship date.

To override this behavior, use the **Keep received supply outside positive days** parameter on the coverage group.

> ⓘ **Note**
>
> This parameter is visible only when both Planning Optimization and the *Keep supply for confirmed demand in Planning Optimization* feature are enabled. The parameter is used by Planning Optimization and takes effect only for confirmed demand (sales orders with a confirmed ship date) when you run master planning with the **Keep supply for confirmed demand** parameter enabled.

To set the **Keep received supply outside positive days** parameter on a coverage group:

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.
2. Select or create a coverage group.
3. On the **General** FastTab, set the **Keep received supply outside positive days** option to one of the following values:

    - *No* – Confirmed demand is pegged to on-hand inventory only when the demand falls within the positive days. This setting allows on-hand inventory that was previously backing a confirmed sales line to be reallocated to earlier orders if the supply arrives earlier than required. This is the default setting.

- *Yes* – Confirmed demand is always pegged to on-hand inventory, regardless of the positive days setting. The pegging from a confirmed sales line to on-hand inventory is preserved across planning runs even when the demand date is outside positive days.

Interaction with approved planned orders and the freezing time fence

The *keep supply for confirmed demand* feature works alongside approved planned orders and the existing freezing time fence functionality. These features preserve planned orders from being replanned during planning runs, but they use different criteria:

Expand table

Feature	Criteria for preservation
Approved planned orders	Retains approved planned orders with the status of *Approved*.
Freezing time fence	Retains planned orders with a requirement date within the freezing time fence.
Keep supply for confirmed demand	Retains planned orders, pegging information, and other elements that are part of a confirmed supply chain, regardless of their requirement date and status.

Example scenario 1: Period grouping

This example shows how the *keep supply for confirmed demand* feature identifies and preserves confirmed requirements across a multilevel BOM, including scenarios where components are shared (grouped) between multiple sales orders.

Example scenario 1 setup

A manufacturer produces a finished good, *ItemFG1*, with the following BOM structure:

txt

```
ItemFG1 (finished good, produced)
└── ItemSFG1 (semi-finished, produced, coverage by period)
    └── ItemSFG2 (semi-finished, produced)
        └── ItemRM1 (raw material, purchased)
        └── ItemRM2 (raw material, purchased)
        └── ItemRM3 (raw material, purchased)
```

In this example, *ItemSFG1* is a component that uses period grouping, meaning its planned production order is grouped and shared across multiple sales orders.

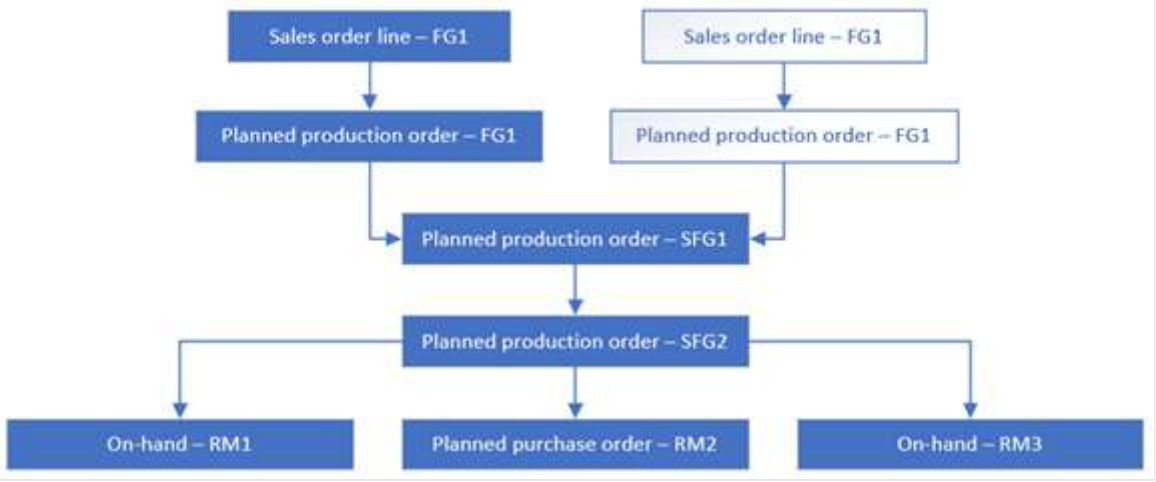
Identify confirmed requirements for example scenario 1

The following orders are entered:

- *Customer 1* places a sales order for *5 pcs* of *ItemFG1* and uses CTP delivery date control.
- *Customer 2* places a sales order for *5 pcs* of *ItemFG1* but doesn't use CTP delivery date control. No confirmed shipping date is set.

When planning runs, it groups the demand for *ItemSFG1* from both orders into a single planned production order. Because the sales line for *Customer 1* has a confirmed shipping date, the system traces the entire supply chain from that sales line and identifies all related requirements as confirmed, including the shared *ItemSFG1* branch and all its derived requirements.

The following illustration shows how the system identifies confirmed requirements for both customers. The shared (grouped) *ItemSFG1* planned production order and its entire subtree are marked as confirmed (highlighted in blue).



Remove a confirmed sales line

If the sales order for *Customer 2* is later canceled, the system removes only the confirmed requirements that are explicitly linked to that sales order line. As the following illustration shows, only the planned production order for *ItemFG1* that was created for *Customer 2* is removed.

The grouped *ItemSFG1* branch and all its subcomponents remain intact. Their quantities aren't reduced either, because they remain linked to demand from *Customer 1* and are therefore considered confirmed.

Example scenario 2: Coverage by requirement

This example shows how the *keep supply for confirmed demand* feature identifies and preserves confirmed requirements when components are planned with the *Requirement* coverage code, including scenarios where part of the supply is already firmed into a purchase order.

Example scenario 2 setup

A manufacturer produces a finished good, *ItemFG1*, with the following BOM structure:

```txt
ItemFG1 (finished good, produced)
└── ItemRM1 (raw material, purchased, coverage by requirement)
```

Because *ItemRM1* uses the *Requirement* coverage code, each demand for *ItemFG1* generates its own dedicated supply for *ItemRM1*.

Identify confirmed requirements for example scenario 2

The following orders are entered:

- *Customer 1* places a sales order for *5 pcs* of *ItemFG1* and uses CTP delivery date control.
- *Customer 2* places a sales order for *5 pcs* of *ItemFG1* and uses CTP delivery date control.

When planning runs, the *Requirement* coverage code creates a separate supply branch for each sales line. Both sales lines have a confirmed ship date, so the system identifies both branches as confirmed. The supply for *ItemRM1* differs between them: the demand for *Customer 1* is covered by a planned purchase order, while the demand for *Customer 2* is covered by a released purchase order that you firmed previously.

The following illustration shows the two confirmed branches. Both branches and their pegging are marked as confirmed (highlighted in blue).

Remove a confirmed sales line backed by a firmed purchase order

If you later cancel the sales order for *Customer 2*, the system removes only the confirmed planned requirements that are explicitly linked to that sales line—in this case, the planned production order for *ItemFG1* that you created for *Customer 2*. The released purchase order for *ItemRM1* that was pegged to that planned production order isn't removed.

The pegging from the planned purchase order is also preserved as-is. Planning doesn't re-peg the released purchase order to other confirmed demand, even though the sales line for *Customer 2* is no longer present. The released purchase order remains in the system and can be used by any other demand that isn't yet confirmed. If the released purchase order remains unpegged, planning assigns it a *Cancel* action, provided that actions are enabled.

Performance considerations

The *keep supply for confirmed demand* feature adds processing time to each planning run, because the system must identify confirmed sales lines, trace the full supply chain across all BOM levels, and preserve the related requirements. The impact depends on the number of open sales lines that have confirmed ship dates and the depth of the BOM structures involved.

To minimize performance impact, consider the following recommendations:

- **Use this feature with dynamic plans used by CTP** – Dynamic plans with a shorter coverage period are the best fit for this feature.
- **Avoid using this feature with static plans or long coverage periods** – For static plans or plans with long coverage time fences, the number of confirmed requirements can grow significantly, which increases processing time and might result in a timeout.

Additional resources

- Calculate sales order delivery dates using CTP
- Optimize confirmed dates for CTP line changes

Last updated on 07/23/2026

Optimize confirmed dates for CTP line changes

The *optimize confirmed dates for CTP line changes* feature ensures that confirmed ship and receipt dates on sales order lines stay accurate when you modify fields that affect transport days. When you use capable-to-promise (CTP) with Planning Optimization, this feature automatically adjusts the confirmed dates to optimize delivery without requiring user action.

When the feature applies

This feature applies when you modify a sales order line in a way that changes the calculated transport days. Changes to any of the following fields can affect transport days:

- **Mode of delivery**
- **Warehouse**
- **Delivery address**

Transport days can either increase (for example, when the delivery mode adds more days, or when the destination or warehouse changes to a more distant location) or decrease (for example, when the delivery mode is faster).

How the feature works

When you modify a field on a sales order line that impacts transport days, the system automatically recalculates the requested and confirmed dates to reflect the new transport days.

The system optimizes the confirmed dates as follows:

- If the confirmed receipt date equals the requested receipt date and no past shipment is needed, the ship date moves closer to the receipt date.
- If the confirmed receipt date is later than the requested receipt date, the system optimizes toward the requested date within shipping constraints.
- If the change would cause the ship date to fall in the past, the confirmed receipt date is scheduled forward from the first feasible ship date.

Prerequisites

Before you can use the *optimize confirmed dates for CTP line changes* feature, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.48 build 10.0.2645.33 or later.
- You must use Planning Optimization.
- You must use capable-to-promise (CTP) delivery date control on the sales order line. You can use either *Near real-time CTP* or *Batch CTP*.
- The *Optimize confirmed dates for CTP line changes* feature must be turned on in Feature management.

Example scenario 1: Changing to a faster mode of delivery

This example shows how the feature adjusts confirmed dates when you change the mode of delivery to one with fewer transport days.

Example scenario 1 setup

The following modes of delivery are configured:

- *Air* – 1 transport day
- *Truck* – 10 transport days

Initial sales order line with truck

The user creates a sales order line with **Mode of delivery** set to *Truck*. CTP returns the following dates:

- **Requested ship date** – *November 11, 2025*
- **Confirmed ship date** – *November 11, 2025*
- **Requested receipt date** – *November 10, 2025*
- **Confirmed receipt date** – *November 10, 2025*

Change the mode of delivery to air

The user changes **Mode of delivery** to *Air*. The *optimize confirmed dates for CTP line changes* feature automatically adjusts the dates to reflect the shorter transport time. The result is:

- **Requested ship date** – *November 9, 2025*

- **Confirmed ship date** – *November 9, 2025*
- **Requested receipt date** – *November 10, 2025*
- **Confirmed receipt date** – *November 10, 2025*

Without this feature, the requested and confirmed ship dates stay *November 1, 2025* even though only one transport day is required.

Example scenario 2: Changing to a slower mode of delivery

This example shows how the *optimize confirmed dates for CTP line changes* feature adjusts confirmed dates when you change the mode of delivery to one with more transport days.

Example scenario 2 setup

The following modes of delivery are configured:

- *Air* – 1 transport day
- *Truck* – 10 transport days

Initial sales order line with air

You create a sales order line with **Mode of delivery** set to *Air*. CTP returns the following dates:

- **Requested ship date** – *November 9, 2025*
- **Confirmed ship date** – *November 9, 2025*
- **Requested receipt date** – *November 10, 2025*
- **Confirmed receipt date** – *November 10, 2025*

Change the mode of delivery to truck

You change **Mode of delivery** to *Truck*. The *optimize confirmed dates for CTP line changes* feature automatically adjusts the dates to reflect the longer transport time. Assuming there's no delay and the item can be shipped on *November 1, 2025*, the result is:

- **Requested ship date** – *November 1, 2025*
- **Confirmed ship date** – *November 1, 2025*
- **Requested receipt date** – *November 10, 2025*
- **Confirmed receipt date** – *November 10, 2025*

Without this feature, the requested and confirmed receipt dates would shift to *November 19, 2025* because the original ship date of *November 9, 2025* plus 10 transport days would be used, even though the item is available earlier.

Master plans overview

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use various master plans to support your company's daily working operations, simulate different planning strategies that you want to monitor, and implement a company policy, such as a policy about internal performance or customer satisfaction.

This article describes various important strategies and parameters that you use to set up master planning. It also describes the main parameters that affect a plan and explains how those parameters influence the planned orders that are suggested.

You can configure master plans on the **Master plans** page.

Using master plans

Because of the speed at which the system processes master planning, you can set up as many plans as you like and run them as often as needed to fit your business requirements. For example, you can run a plan twice a day to always keep up with the latest demand and supply and to have other plans for different forecasts or simulations.

If you use capable to promise (CTP) for Planning Optimization, it runs the plan specified as the **Current dynamic master plan** fields on the **Master planning parameters** page (**Master planning** > **Setup** > **Master planning parameters**).

Types of scheduling methods

For each plan, on the **General** FastTab of the **Master plans** page (**Master planning** > **Setup** > **Plans** > **Master plans**), select the scheduling method that is used for production orders. You can schedule production at the operation level and the job level.

Operations scheduling

Use operations scheduling to provide a general estimate of the production process over time. Operations scheduling doesn't explode the operations for the production route into jobs. For

more information about operations scheduling, see Operations scheduling.

Job scheduling

Job scheduling is a more detailed scheduling method, where each operation is divided into its individual tasks or jobs. Job scheduling includes information about capacity. Use it to schedule individual jobs on the shop floor for an immediate or short-term time frame. For more information about job scheduling, see Job scheduling.

Time fences in days

For each plan, you can select how far in the future master planning calculates various requirements and other considerations. This period is known as a *time fence*. For the best performance in master planning, adjust the time fences to meet your business requirements. For each plan, find the time fences on the **Time fences in days** FastTab of the **Master plans** page (**Master planning** > **Setup** > **Plans** > **Master plans**).

> **Note**
>
> The time fences you select indicate how far in the future master planning calculates various requirements and other considerations. The time fences you select on this page override the time fences defined in the coverage group. This means setting a time fence option to *Yes* and defining the days overrides the time fence defined in the coverage group. When you set the option to *No*, the time fence is defined in the coverage group. Finally, if you don't want or need to use an option (for example, you don't want to use action messages), set it to *Yes*, and then set the time fence to **0** (zero) days.

Coverage

The coverage time fence represents the scheduling period, or how far out the demand should be included. In other words, it indicates your planning horizon.

By setting the **Coverage** option to *Yes*, you can override the coverage time fence that is defined for the item during master scheduling. Enter the number of days that the master scheduling calculation should cover requirements. The coverage time fence is calculated forward from the current date. Master planning always processes requirements that occur before the current date.

> **Note**

For the best performance in master planning, adjust the coverage time fence to your planning horizon.

Freeze

The freeze time fence represents the period when existing planned orders aren't changed when a new master schedule runs. The planned orders are frozen, and no new planned orders are suggested.

By setting the **Freeze** option to *Yes*, you can override the freeze time fence that is defined for the item during master scheduling. Enter the number of days that planning activity should be frozen. Remember that, during this period, no new planned orders are generated, and existing planned orders can't be changed.

Firming

The firming time fence indicates the time horizon in which planned orders are automatically converted to production and purchase orders. This process is also known as *automatic firming of planned orders*.

By setting the **Firming** option to *Yes*, you can override the firming time fence that is defined for the item during master scheduling. Enter the number of days that planned purchase orders and planned production orders should be automatically firmed. The firming time fence is calculated forward from the master scheduling date. Automatic firming of a planned purchase order can occur only if the item is associated with a vendor.

Forecast plan

The forecast plan time fence indicates how far in the future master planning creates planned orders for items where forecasted demand exists.

Set the **Forecast plan** option to *Yes* to override the forecast plan time fence that is defined for the item during master scheduling. Enter the number of days that the sales forecast from the forecast plan should be included in master planning.

Capacity

The capacity time fence indicates how far in the future the system considers the maximum capacity of your resources when it schedules orders. In other words, the plan schedules the production orders by using the production route for the items, and it considers the production route's resources and the maximum capacity of each resource.

Set the **Capacity** option to *Yes* to override the capacity time fence that is defined for the item during master scheduling. Enter the number of days that capacity should be planned for planned production orders. Master scheduling uses the active production route for the item and schedules backward from the requirement date. If the requirement date for a planned production order is outside the capacity time fence, the lead time is determined by the delivery time of the item. The capacity time fence is calculated forward from the current date.

Action message

Action messages suggest changes that you can make to the existing supply order to help optimize the supply plan. For example, they might recommend that you advance or postpone orders, or that you increase or decrease the order quantities.

Set the **Action message** option to *Yes* to override the action message time fence that is defined for the item during master scheduling. Enter the number of days that master scheduling should generate action messages for requirements. The action message time fence is calculated forward from the current date.

For more information about action messages, see Action messages.

> **Note**
>
> The calculation of action messages causes a longer running time for master planning. If you don't regularly analyze and apply action messages (daily, weekly, and so on), consider turning off the calculation during the master planning run. To turn off the calculation, on the **Master plans** page, set the **Action message** time fence to *0* (zero) for the master plan that you're running. Also make sure that the **Action message** setting is turned off for all the coverage groups.

Calculated delays

You can specify how far in the future possible delays in planned orders are detected and reported. In this way, you can schedule possible (delayed) delivery dates.

If a planned order can't be fulfilled for the requested date, the system plans the order for the earliest fulfillment date for a transaction, based on lead times, and material and capacity availability.

Approved requisitions time fence

You can set up master planning to create planned orders for requisition demand. Set the **Include requisitions** option to *Yes* on the **General** FastTab of the **Master plans** page. Then, when the purpose of an approved requisition is replenishment, master planning automatically creates a corresponding planned order to fulfill it. The replenishment method is determined by the supply policies that you set up for the items in your organization. After you create and approve the replenishment requisition, no additional user action is required.

By setting the **Approved requisitions time fence** option to *Yes* on the **Time fences in days** FastTab, you can override the approved requisitions time fence that is defined for the item during master scheduling. In this case, enter the number of days in the past that demand from approved requisitions with the replenishment purpose should be included in master scheduling. For example, you can specify that only unfulfilled, past-due demand from approved requisitions that were created in the last 10 days should be considered and planned for.

Sequencing

Sequencing enables you to arrange planned orders based on sequencing attributes that are associated with the finished product. It's often used to prepare production orders for packaging. For example, you can use it to pack boxes in a specific sequence, based on color and size.

By setting the **Sequencing** option to *Yes*, you can specify how far in the future the operations or jobs should be sequenced. Keep in mind that the longer the time fence is, the longer it takes for master planning to run.

Calculated delays FastTab

Delay options help guarantee that the orders have feasible planned dates. The following options are available on the **Calculated delays** FastTab of the **Master plans** page:

- **Ensure that the planned orders are not created prior to master planning run date** – Set this option to *Yes* to help guarantee that orders can't be scheduled for dates in the past.
- **Add the calculated delay to the requirement date** (under **Planned purchase orders**) – Set this option to *Yes* to add the calculated delay to the requirements.
- **Add the calculated delay to the requirement date** (under **Planned production orders**) – Set this option to *Yes* to add the calculated delay to the requirements.
- **Add the calculated delay to the requirement date** (under **Planned transfer**) – Set this option to *Yes* to add the calculated delay to the requirements.
- **Add the calculated delay to the requirement date** (under **Planned kanban**) – Set this option to *Yes* to add the calculated delay to the requirements.

When you set the **Add the calculated delay to the requirement date** options to *Yes* to add the delays to the requirements, the system considers the capacity of the resources and creates feasible planned orders. Recalculation of the planned order dates increases the running time for master planning. Therefore, if you don't need to use the delays, set the options to *No*.

Positive and negative days

Positive and negative days affect how master planning suggests planned orders and actions. Set positive and negative days on the item coverage group of the item. You can define the various coverage groups and set their parameters on the **Coverage groups** page (**Master planning** > **Setup** > **Coverage** > **Coverage groups**).

Positive days

Positive days indicate how far in the future master planning considers the current inventory or receipts to fulfill a future demand. For example, if you set the positive days to *100*, the current inventory can fulfill demand for the next 100 days. If there's an order 150 days from the current date, master planning creates a planned order to satisfy that demand, even though the on-hand inventory for the item can satisfy the order. For fast-moving items that have a short lead time, you might not want to use the on-hand inventory for an order that's far in the future. In this fast-moving case, the current on-hand inventory goes quickly, and more orders can be placed in the future to fulfill a future demand on time, which is possible due to the short lead time of the item.

The positive days also affect the action messages. For example, the system might recommend that you increase a planned purchase order so that it includes a demand that is within the number of positive days in the future. If you set the positive days to *100*, and if there's demand for an item in 30 days from the current date, the system creates a planned order to satisfy that demand. If there's demand for the same item in 90 days from the current date, the system recommends that you increase the quantity of the order in 30 days from the current date, so that the order also covers the demand in 90 days. However, if there's demand for the item in 150 days from the current date, the system doesn't recommend that you increase the quantity of the order that you already planned. Instead, a new planned order is created.

As a rule, set the positive days to a number that's between the longest lead time of the items and the coverage time fence. Assign items that you regularly procure or produce to a coverage group where the positive days equal the item's lead time.

Setting zero positive days in Planning optimization means that you always generate new supply for demand because the demand isn't allowed to be pegged against any existing supply.

Dynamic positive days

Dynamic positive days work like positive days, but they also consider the lead time. Learn more in Dynamic positive days for last-minute orders.

Negative days

Negative days indicate how late item receipts are allowed. They represent the number of days that you're willing to wait before you order new replenishment when you have negative inventory or don't have enough inventory. Negative days answer the question, Should we create a new purchase order for the item, or should we use an existing purchase, even though we know that the item will be late?

For example, you have a sales order for an item 15 days from the current date. You also have a purchase order for the same item. This purchase order is scheduled to be received in 20 days from the current date. Do you want the system to create a purchase order for that sales order, or do you want to use the existing order, even though you can't fulfill the sales order on time? If you set the negative days to less than *5* to indicate the item can be delayed a maximum of five days, the system creates a new planned purchase order to satisfy the sales order. If you set the negative days to greater than *5*, the system uses the existing order for the item.

The negative days also affect the performance of master planning. If you set the negative days to a high number, the system generates lots of action messages.

Set the negative days to a number that's less than the lead time of the item.

Dynamic negative days

Dynamic negative days consider the item's lead time and the negative days that you specify. The system creates a new planned purchase order based on the negative days time fence, which it calculates by using the following formula:

Lead time + Negative days + Current date – Requirement date

The system uses only the planned supply orders that are within this time fence, and it creates a new planned order outside it. The advantage of using dynamic negative days is that the system includes individual product lead times and reuses existing orders. It therefore avoids creating new planned orders that the system would push to a later day because of delays caused by lead time.

Learn more in Negative days and dynamic negative days.

Master planning setup wizard

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides a guide for the **Master planning setup wizard**. It explains how parameter suggestions are calculated and also provides examples that show how different companies set up master planning, based on their business needs.

https://learn-video.azurefd.net/vod/player?id=e574dd27-fecc-4163-a4e8-e3eaa5687574&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Fmaster-planning%2Fmaster-planning-setup-wizard

The Master planning setup wizard in Dynamics 365 Supply Chain Management video (shown above) is included in the finance and operations playlist available on YouTube.

Specific requirements of your company

The first page of the wizard asks about the specific requirements of your company. Your answers to these questions don't have to be exact, but you should be able to provide a rough approximation of the number of items and planned orders that there exist for the legal entity. Your answers are used to configure parameters that apply to your legal entity, not just to the master plan that you selected. The following sections describe the parameters that are calculated and the formulas that are used.

Number of threads

- **If you manufacture any of the items:** Number of threads = Number of planned orders ÷ 1,000
- **If you don't manufacture any of the items:** Number of threads = Number of items ÷ 1,000

If the calculated number of threads exceeds 75 percent of the available number of threads, it's capped at 75 percent of the number of threads available for each customer. (The number of

available threads is determined for each customer.)

Learn more in Number of threads.

Bundle size

The bundle size is set to **1**. This value is often the best value, because it helps improve the performance of master planning.

Learn more in Number of tasks in helper task bundle.

Firming bundle size

- **If you manufacture any of the items:** The firming bundle size is the larger of these two values: **10** and the bundle calculation.
- **If you don't manufacture any of the items:** The firming bundle size is the larger of these two values: **50** and the bundle calculation.

Bundle calculation = (Number of planned orders × (Firming time fence ÷ Coverage time fence) ÷ Number of threads) ÷ 10

Cache size

The cache size is set to **Maximum**. This value is often the best value because it helps improve the performance of master planning.

Learn more in Allocate time to jobs in a job bundle.

Manufacturing setup

If you manufacture items, a **Manufacturing setup** page appears later in the wizard.

Scope of the current plan

On the **Scope of the current plan** page of the wizard, answer questions related to how far in the future various requirements are considered and calculated in master planning. Each question asks whether you want to use a feature and how you want to configure it.

For example, for the forecast plan feature, the wizard asks, "Do you want to use a forecast plan in master planning so that planned orders are suggested to fulfill the forecasted demand?"

The following options are available:

- **No** – Master planning doesn't suggest planned orders to fulfill a forecast. On the **Time fences** tab of the **Master plans** page (**Master planning** > **Setup** > **Plans** > **Master plans**), the wizard sets the **Forecast plan (time fence)** option to **Yes** and sets the number of days to **0**. This setup overrides the time fence that is specified in the coverage group. Because the number of days is set to **0**, the feature isn't used.
- **Yes, as defined in this master plan** – A field becomes available, where you can enter the number of days that master planning suggests planned orders to fulfill the forecasted demand. The wizard sets the **Forecast plan (time fence)** option to **Yes** and sets the number of days to the number of days entered in the **Forecast plan** field on the **Time fences** tab of the **Master plans** page. This setup overrides the values that are set in the coverage groups.
- **Yes, as defined in the coverage** – The wizard sets the **Forecast plan (time fence)** option to **No**. The time fences that are specified in the coverage group are used to specify how long you plan for the forecast.

The remaining questions on this page and their answers follow the same schema:

- **No** – The **Forecast plan (time fence)** option is set to **Yes**, and the number of days is set to **0**.
- **Yes, as defined in this master plan** – The **Forecast plan (time fence)** option is set to **Yes**. The number of days that you enter is used and overrides the values that are set in the coverage groups.
- **Yes, as defined in the coverage group** – The **Forecast plan (time fence)** option is set to **No**.

Learn more in Job scheduling.

Scheduling options

The **Scheduling options** page appears only if you answer **Yes** to the "Do you manufacture any of the items planned?" question on the first page of the wizard.

Your answer to the first question on this page ("Do you need to schedule operations divided into individual jobs?") determines the scheduling method on the **General** tab of the **Master plans** page.

- **Yes** – Job scheduling will be used.
- **No** – Operations scheduling is used.

For more information, see Operations scheduling and Job scheduling.

Updates of demand and supply

The questions on the **Updates of demand and supply** page relate to firming, action messages, and delays.

The master planning setup is updated based on your answers, according to the same schema described in the previous section:

- **No** – The **Time fence** option on the **Master plans** page is set to **Yes**, and the number of days is set to **0**.
- **Yes, as defined in this master plan** – The **Time fence** option is set to **Yes**. The number of days that you enter overrides the values that are set in the coverage groups.
- **Yes, as defined in the coverage group** – The **Time fence** option is set to **No**.

For calculated delays, your answers to the questions in the wizard update the corresponding parameters on the **Calculated delays** tab of the **Master plans** page.

Summary of your changes

The last page of the wizard shows the changes that are recommended based on your responses. It shows both the value in your setup (**Current setup**) and the value that the wizard recommends (**New configuration**).

You can also modify the parameters in the new configuration. The parameters are separated into parameters that apply to your legal entity and parameters that apply only to the master plan that you selected. To view all the setup parameters that you can change by using the wizard, select **Show all parameters** at the bottom of the page. You can then change the parameters.

When you select **Finish**, the new configuration is applied. If you select **Cancel**, none of the changes are applied.

Examples

This section describes the setup of two fictional companies to show how the setup can change according to the needs of each business.

Example 1: Contoso Manufacturer

Contoso Manufacturer is a manufacturing company that produces speakers. It purchases the various raw materials and components that are used for the final speakers from various suppliers. Here are some of the characteristics of its supply and manufacturing:

- The final items that the company manufactures have a bill of materials (BOM) structure.

- All final items and components are planned by master planning. Manual planning isn't done.
- A route of operations is defined for the production of each final item.
- The manufacturing plant produces the final items. It has a defined number of milling and drilling machines that are used to process the components. The various components must be processed by these machines.
- There are many suppliers. The average lead time for items is one week. A group of items from the same supplier has a lead time of seven weeks.

In the wizard, the following values are entered for Contoso Manufacturer:

- **Coverage:**
  - **Question:** "Do you want to specify the number of days of your planning horizon?"
  - **Answer:** "Yes, as defined in the coverage groups."

  Because the lead time for items is very different, Contoso doesn't have to plan all the items for the same period in the future. Coverage groups for the items are created. Items that have a similar lead time are assigned to the same coverage group. The planning horizon for each coverage group (that is, the coverage time fence) is approximately the lead time plus a margin of one week. Master planning then makes sure that the items are planned in advance, based on their lead time.

  Therefore, two coverage groups are created for this example. One coverage group has a coverage time fence of two weeks, and the other has a coverage time fence of eight weeks.

  If **Yes, as defined in this master plan**, is selected as the answer, the number of days entered should exceed the longest lead time of all the items. However, because many items don't have to be planned so far in advance, many planned orders are calculated but never used. Therefore, the master planning runtime increases.

- **Scheduling:**
  - **Question:** "Do you need to schedule operations divided into individual jobs?"
  - **Answer:** "Yes."

  Contoso Manufacturing must plan and schedule the individual jobs that it performs on the shop floor. Therefore, it uses job scheduling.

- **Capacity:**
  - **Question:** "Do you want to schedule using the capacity of resources?"
  - **Answer:** "Yes, as defined in this master plan." **10 days** is entered.

The number of milling and drilling machines is limited. Production planning must take this limitation into account and arrange the jobs in time according to the capacity of the resources. In other words, the scheduled jobs are replanned based on the limitations of the resources. Planning uses the lead time in addition to the period that is defined. (Planned production orders can overlap.) Because the production lead time for the items is seven days, the capacity of the resources for master planning is considered during 10 days.

- **Sequencing:**
  - **Question:** "Do you want to sequence planned orders using the product's sequence values?"
  - **Answer:** "Yes, as defined in the coverage groups."

  A route is defined for the production of each final item. Therefore, master planning schedules the orders in time according to the defined routes.

- **Explosion:**
  - **Question:** "Do you want to plan orders for all the elements in a Bill of Materials (plan for the parent and all children items)?"
  - **Answer:** "Yes, as defined in the coverage groups."

  All the items that are used for the production must be planned. Because the items have very different lead times, master planning has better performance when it uses the coverage groups. Again, a margin of one week can be entered, and explosion can be done for the same time as the coverage.

Example 2: Contoso Retailer

Contoso Retailer is a distribution company in the fashion industry. It uses master planning to calculate when to place purchase orders, based on its forecasted sales. Here are some of its characteristics:

- Contoso Retailer uses a demand forecast to predict sales. Purchase orders are planned according to the forecast.
- Stores use requisitions for replenishment.
- The lead time from the main warehouse to each store is approximately two weeks for all items.

In the wizard, the following values are entered for Contoso Retailer:

- **Forecast demand:**

- **Question:** "Do you want to use a forecast plan in master planning so that planned orders are suggested to fulfill the forecasted demand?"
- **Answer:** "Yes, as defined in this master plan."

Contoso includes a demand forecast to predict its sales. Therefore, master planning must recommend planned orders to fulfill the forecast.

- **Firming:**
  - **Question:** "Do you want master planning to automatically firm planned orders into order documents, for example production or purchase orders?"
  - **Answer:** "Yes, as defined in this master plan." **1 day** is entered.

  Because Contoso Retailer creates purchase orders directly from the planned purchase orders, it's useful if the planned purchase orders are automatically firmed. Because the company runs master planning every day, a firming time fence of one day automatically firms all the orders that are required for the next day.

- **Approved requisitions:**
  - **Question:** "Do you want to include demand from approved requisitions to replenish retail stores?"
  - **Answer:** "Yes, as defined in this master plan." **1 day** is entered.

  Contoso uses the approved requisitions from its stores to create planned purchase orders to replenish those stores. Because master planning runs every day, the requisitions from the last day are included in the planning.

Exclude specific transactions or transaction types from master planning

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to exclude specific transactions or transaction types from master planning calculations.

Prerequisites

Before you can use the features that are described in this article, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.36 or later.
- Depending on the functionality that you require, one or both of the following features must be turned on in Feature management:
  - *Ignore specific transaction types using Planning Optimization* – This feature lets you select which transaction types should be excluded from master planning calculations.
  - *Exclude specific sales orders or sales order lines in Planning Optimization* – This feature lets you choose not to create supply for a specific sales order or sales order line when you use Planning Optimization. In this way, you can keep an order unplanned. This capability can be useful for orders that require a review or approval process. As of Supply Chain Management version 10.0.43, this feature is turned on by default.

Set a master plan to ignore specific transaction types

When the *Ignore specific transaction types using Planning Optimization* feature is enabled, you can set up each master plan to exclude specific transaction types.

1. Go to **Master planning** > **Setup** > **Plans**.

2. Select an existing master plan, or create a new one.

3. Set the following fields for the new or selected master plan:

    - **Include sales orders** – Set this option to *No* to ignore all existing sales orders. Set it to *Yes* to plan supply for sales orders.
    - **Include transfer orders** – Set this option to *No* to ignore all existing transfer orders. In this case, master planning replans transfer orders for requirements that must be transferred. (This behavior might be useful for simulation scenarios.) Set this option to *Yes* to include transfer orders as supply.
    - **Include purchase returns** – When a purchase order is scheduled to be returned at a future date, it can be picked up for another customer order. This capability is useful for high-value items such as jewelry or watches. In these cases, the return of an order must be considered to avoid over-purchasing the high-value item.
    - **Include retail sales orders** – Set this option to *No* to ignore orders that originate from the **Commerce** module. Set it to *Yes* to include orders that originate from the **Commerce** module as supply.

Exclude specific sales orders or sales order lines from master planning

When the *Exclude specific sales orders or sales order lines in Planning Optimization* feature is enabled, you can set each sales order and/or sales order line so that it's included in master planning calculations. This capability might be useful when you use some approval processes (such as the approval process for high-value items or high customer prices). It might also be useful in other confirmation workflows where supply shouldn't be planned until an order is cleared.

1. Go to **Master planning** > **Setup** > **Plans**.

2. Select an existing master plan, or create a new one.

3. Set the **Exclude specific transactions** option to *Yes*. If you set this option to *No*, the settings in the next steps have no effect.

4. Go to **Sales and marketing** > **Sales orders** > **All sales orders**.

5. Select an existing sales order, or create a new one.

6. To exclude the whole order from master planning, on the **Header** tab, on the **Master planning** FastTab, set the **Exclude from master planning** option to *Yes*. This setting defines the default value for new lines, but it doesn't override the value on existing lines

unless the **Updating Exclude from master planning** option is set to *Always* or *Prompt* on the **Accounts receivable parameters** page (as described in the next section).

7. To exclude one or more order lines from master planning, follow these steps:
   a. On the **Lines** tab, on the **Sales order lines** FastTab, select the order line that you want to exclude.
   b. On the **Line details** FastTab, on the **Sourcing** tab, set the **Exclude from master planning** option to *Yes*.

Configure whether sales lines are updated after changing exclude settings on the sales order header

To configure whether and how sales lines are updated after changing the **Exclude from master planning** option on the sales order header, follow these steps:

1. Go to **Accounts receivable** > **Setup** > **Parameters** > **Accounts receivable parameters**.
2. Open the **Updates** tab.
3. On the **Order lines** FastTab toolbar, select **Update order lines** to open the **Update order lines** dialog box.
4. Set the **Updating Exclude from master planning** option to one of the following values:

   - *Prompt* – When you change the **Exclude from master planning** option on the sales order header, a dialog box appears that asks whether you want to apply the same setting to all lines. If you select **Yes**, the system applies the same setting to all lines. If you select **No**, the system doesn't change the setting for any of the lines.
   - *Always* – When you change the **Exclude from master planning** option on the sales order header, the system automatically applies that setting to all lines without prompting.
   - *Never* – When you change the **Exclude from master planning** option on the sales order header, the system doesn't change the setting for any of the lines and doesn't prompt you.

Generate a constrained plan

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to create a plan that takes into account both material and capacity constraints. The plan ensures that manufacturing doesn't start before materials are available and resources are not overbooked.

The demo data company used to create this procedure is USMF. This procedure is intended for the production planner.

Set up a constrained plan

1. In the home page, select the **Master planning** workspace.
2. Select **Master plans** in the list of links on the far right side of the workspace.
3. In the list, find and select the desired record. Example: **StaticPlan**
4. Select **Yes** in the **Finite capacity** field.
5. In the **Finite capacity time fence** field, enter `30`.
6. Expand the **Time fences in days** section.
7. Select **Yes** in the **Capacity** field.
8. In the **Capacity scheduling time fence (days)** field, enter a number. Example: `60`
9. Select **Yes** in the **Calculated delays** field.
10. In the **Calculate delays time fence (days)** field, enter a number. Example: `60`
11. Expand the **Calculated delays** section.
12. Select **Yes** in all **Add the calculated delay to the requirement date** fields.
13. Close the page.

Create a constrained plan

1. Select **Run**.
2. In the **Master plan** field, enter or select the plan for which you have set up constraints.
3. Select **OK**.
4. Select **Planned orders**.

Coverage settings

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Master scheduling uses coverage settings to calculate item requirements.

You can specify coverage settings in several ways:

- Specify coverage settings for a coverage group.

  Create a coverage group that contains settings for all products linked to the coverage group. To create a coverage group, go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**. You can link a coverage group to a product. If the link is specific to a site, warehouse, or product dimension, use the **Coverage group** field on the **Item coverage** page. If the link is generic, regardless of the product dimensions, use the **Coverage group** field on the **Plan** FastTab of the **Product details** page. By default, if you don't link a coverage group to a product, master planning uses the general coverage group that you specify on the **Master planning parameters** page.

- Specify coverage settings for a product.

  Create coverage settings for a specific product. Go to **Product information management** > **Products** > **Released products**. Select the product, and then, on the Action Pane, on the **Plan** tab, in the **Coverage** group, select **Item coverage** to open the **Item coverage** page. If the product is already linked to a coverage group, you can override the coverage group settings by using the **Override** field. The coverage settings on the **Item coverage** page take precedence over the settings on the **Coverage group** page.

- Specify coverage settings for a product by using a wizard.

  The wizard guides you step by step through the process of setting up the primary item coverage parameters. On the **Item coverage** page, on the Action Pane, select **Wizard** to open the **Item Coverage Wizard**.

- Specify coverage settings for a dimension group.

  Go to **Product information management** > **Products** > **Released products**. On the **Released product details** page, on the **General** FastTab, in the **Administration** section,

select the link in the **Storage dimension group** field. On the **Storage dimension groups** page, select the **Coverage plan by dimension** check box to create the coverage settings for a dimension in the storage dimension group. You must select the **Coverage plan by dimension** field for all product dimensions, such as configuration, color, size, and style.

Coverage codes

You can configure master planning to use different replenishment methods. The system uses these replenishment methods, or lot-sizing methods, to determine the batch size for purchased or produced items.

Assign each replenishment method one of the following coverage codes:

- **Manual** – The lot-sizing method where the system doesn't suggest purchase, transfer, or production orders for the item. The planner for the item is responsible for creating the required orders to replenish the item.
- **Per requirement** – The lot-sizing method where the system creates a planned purchase, transfer, or production order for each requirement of the item. Use this method for expensive items with intermittent demand.
- **Per period** – The lot-sizing method that combines all the demand for a period into one order for the item. The order is planned for the first day of the period, and its quantity fulfills the net requirements during the established period. The period starts with the first demand of the item and covers the defined length in time. The next period starts with the next requirements of the item.
- **Min/Max** – The lot-sizing method that replenishes inventory up to a certain level when the predicted on-hand quantity is below a threshold. The replenishment quantity is the difference between the maximum level and the predicted on-hand level.
- **Priority** – A strategy that replenishes buffers for a product according to its minimum, reorder point, and maximum stock quantities. Whenever the projected on-hand inventory falls below the reorder point quantity, the system replenishes it to its maximum quantity. For replenishing, priority (not date) is considered, which ensures that the most urgent orders are replenished first. Learn more in Priority-based planning.
- **Decoupling point** – The coverage code that identifies a product as a decoupling point (buffer) according to the Demand Driven Material Requirements Planning (DDMRP) methodology. DDMRP is a specific planning and execution methodology. To specify that a product is a decoupling point, open its **Item coverage** page and, under **Use specific settings**, set **Coverage code** to a coverage group that has coverage code of *Decoupling point*. For more information about the DDMRP methodology, see Demand Driven Material Requirements Planning (DDMRP) overview.

Demand-specified BOM or formula versions and routes

For make-to-order businesses, it can be useful to configure coverage groups to consider BOM or formula versions and routes specified in demand lines (such as sales order lines) when creating supply (such as planned production orders). For demand where no BOM or formula version or route is specified, the system chooses the currently active ones.

Prerequisites

To use the **Prioritize existing supply over required BOM or formula version or route version** setting described in the next section, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management 10.0.38 or later.
- The feature named *Prioritize existing supply over required BOM/route in Planning Optimization* must be turned on in feature management. As of Supply Chain Management version 10.0.43, this feature is turned on by default.

The **Use the specified BOM or formula version** and **Use the specified route version** settings described in the next section don't require these prerequisites. However, without the *Prioritize existing supply over required BOM/route in Planning Optimization* feature, the system always works as though **Prioritize existing supply over required BOM or formula version or route version** is set to *No*.

Configure a coverage group to use demand-specified BOM or formula versions and routes

To configure a coverage group to use the BOM or formula versions and routes specified in demand lines, follow these steps:

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.
2. From the list pane, select the group you want to set up.
3. Make the following settings on the **General** FastTab for your selected group:

    - **Use the specified BOM or formula version** – Set to *Yes* to allow demand lines to identify a specific BOM or formula version when creating planned production orders for items that belong to the current coverage group. Set to *No* to always use the currently active BOM or formula version.
    - **Use the specified route version** – Set to *Yes* to allow demand lines to identify a specific route version when creating planned production orders for items that

belong to the current coverage group. Set to *No* to always use the currently active route version.

- **Prioritize existing supply over required BOM or formula version or route version** – This setting only applies when **Use the specified BOM or formula version** and/or **Use the specified route version** are set to *Yes*. Set this setting to *Yes* to prioritize existing supply (such as on-hand inventory, if available) over demand-specified BOM or formula versions and routes. Set to *No* if demand-specified BOM or formula versions or routes should always result in creating new supply (such as planned production orders), even if existing supply is available.

Define coverage rules for items

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure shows how to create coverage rules and override coverage settings for a specific item. It also shows how to specify default inventory settings. This procedure shows sample values that you can use with the USMF demo data company, but you can use your own values if you prefer.

Create a coverage group

Create a coverage group by following these steps:

1. Go to **Master planning** > **Setup** > **Coverage groups**.
2. Select **New**.
3. In the **Coverage group** field, enter a value.
4. In the **Name** field, enter a value.
5. In the **Calendar** field, enter a value. Choose the calendar that master planning uses to create replenishment suggestions for items in this group.
6. In the **Coverage code** field, select an option. Select *Requirement* for this procedure.
7. In the **Coverage time fence (days) field**, enter *90*. For items in this group, master planning will create replenishment suggestions for up to 90 days in the future.
8. In the **Negative days** field, enter *1*.
9. In the **Positive days** field, enter *1*.
10. Expand or collapse the **Other** section.
11. Under the **Safety margins in days** section, in the **Receipt margin added to requirement date** field, enter *1*. For example, if the receipt margin is set to one day, and a purchase order line is scheduled for receipt on May 15, master planning calculates the adjusted receipt date as May 16.
12. In the **Issue margin deducted from requirement date** field, enter *1*. For example, if the safety margin is set to one day, and a sales order line is scheduled for delivery on May 15, master scheduling calculates the adjusted delivery date as May 14.
13. In the **Reorder margin added to item lead time** field, enter *1*.
14. Select **Save**.

Create a new product

Create a new product by following these steps:

1. Go to **Product information management** > **Products** > **Released products**.
2. Select **New**.
3. In the **Product number** field, enter a value.
4. In the **Product name** field, enter a value.
5. In the **Item model group** field, select the drop-down button to open the lookup.
6. In the list, find and select the desired record.
7. In the list, select the link in the selected row.
8. In the **Item group** field, select the drop-down button to open the lookup.
9. In the list, find and select the desired record.
10. In the list, select the link in the selected row.
11. In the **Storage dimension group** field, select the drop-down button to open the lookup.
12. In the list, find and select the desired record.
13. In the list, select the link in the selected row.
14. In the **Tracking dimension group** field, select the drop-down button to open the lookup.
15. In the list, find and select the desired record.
16. In the list, select the link in the selected row.
17. Select **OK**.

Set up default order settings

Set up default order settings by following these steps:

1. On the Action Pane, select **Plan**.
2. Under **Order settings**, select **Default order settings**.
3. Under **Purchase order**, in the **Default site** field, enter the site used as default when purchase orders are created.
4. In the **Default warehouse** field, enter the site where the item is stored.
5. Expand or collapse the **Inventory** section.
6. In the **Multiple** field, enter *10*.
7. In the **Min. order quantity** field, enter *10*.
8. In the **Max. order quantity** field, enter *100*.
9. In the **Standard order quantity**, enter *10*.
10. In the **Purchase lead time** field, enter a number.
11. Select or clear the **Working days** check box.
12. Select **Save**.
13. In the **Default order type** field, select *Purchase order*.
14. Select **Save**.

15. Close the page. Close the Default order settings page.

Add an item to a coverage group

Add an item to a coverage group by following these steps:

1. Expand or collapse the **Plan** section.
2. In the **Coverage group** field, select the drop-down button to open the lookup.
3. In the list, find the **Coverage group** you have created.
4. In the list, select the link in the selected row.

Create item coverage rules

Create item coverage rules by following these steps:

1. On the Action Pane, select **Plan**.
2. Under **Coverage**, select **Item coverage**.
3. Select **New**.
4. Select the **General** tab.
5. Check the box on the header of **Override coverage group** settings.
6. In the **Coverage time fence (days)** field, enter *60*. Although items in coverage group *Requirement* are planned 90 days ahead, this item is planned 60 days ahead.
7. In the **Negative days** field, enter *2*.
8. In the **Positive days** field, enter *2*.
9. Select the **Lead time** tab.
10. Check the box on the header of **Purchase**.
11. In the **Purchase time** field, enter *5*.
12. Select **Save**.

> ⓘ **Note**
>
> For manufactured items, the **Production lead time** is used if there's no route for the item. If an active route is associated to the item, then master planning schedules the order and calculates its dates according to the route times and capacity of the resources (if applicable).

Source products and materials from multiple vendors

08/22/2025

Diversification of the supply network helps businesses be agile and respond to changes. One of the most common ways to diversify is to divide the supply of a specific product among different vendors by assigning a supply percentage to each of them. For example, if one of your products has both a main vendor and a secondary vendor, the usual split might be 80/20 or 70/30. Alternatively, you might divide equally among three different vendors in a 33/33/34 split.

This feature enables the system to automatically suggest a vendor for each planned purchase order so that, over time, the specified percentages for each vendor are respected. However, the system won't split an existing planned order into several smaller orders.

The following table shows a simple example where each planned order quantity is assigned to a single vendor, without splitting the order quantity and in such a way that the overall percentages are respected over time.

Expand table

Demand	Vendor A quantity (target: 50%)	Vendor B quantity (target: 50%)
100	100	0
100	0	100
200	200	0
100	0	100
100	0	100

Automatic vendor selection that's based on predefined splits helps improve supplier resilience. Because the system tracks actual purchases, not just planned purchases, it will also consider purchases that are made outside the planning system when it calculates the percentage of orders to assign to each supplier.

Prerequisites

Before you can use this feature, your system must meet the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management 10.0.31 or later.
- The feature that's named *Source products and materials from multiple vendors using Planning Optimization* must be turned on in feature management. As of Supply Chain Management version 10.0.36, this feature is turned on by default.

Define multisource policies

Multisource policies let you establish the sourcing percentages for each vendor. You can create as many policies as you require to set up different percentage splits among different combinations of vendors. Later, you'll assign a policy to each product as needed.

Follow these steps to create a multisource policy.

1. Go to **Procurement and sourcing** > **Setup** > **Policies** > **Multisource policies**.
2. Follow one of these steps:
    - To edit an existing policy, select it in the list pane, and then select **Edit** on the Action Pane. If the **Active** option is set to *Yes* for the policy, you must set it to *No* and save your change before you can edit or delete the policy. You can deactivate and edit only policies that aren't assigned to any products.
    - To create a new policy, select **New** on the Action Pane.
3. On the header of the new or selected policy, set the following fields:
    - **Name** – Enter a name for the policy. (You can't edit this field after the policy has been saved.)
    - **Description** – Enter a short description of the policy.
4. On the **General** FastTab, set the following fields:
    - **Active** – Specify whether the policy should be active. Only active policies can be assigned to products. You can edit or delete only policies that were last saved while this option was set to *No*. You can't deactivate policies that are currently used (that is, assigned to one or more products for the current period or a future period).
    - **Balance period (days)** – Specify the number of days that master planning should look into the past when it allocates orders to vendors. In other words, when master planning is trying to find a vendor for a planned purchase order, it will look this number of days into the past. It then selects the vendor that will result in an actual allocation that's closest to the preferred allocation that is established by the multisource policy. We recommend that you specify a balance period that will include purchases from the relevant vendors but without going too far back. The default period is 180 days.
5. On the **Policy rules** FastTab, add a line for each vendor that's part of the policy, and assign a target allocation to each vendor. The sum of all allocations that are specified in this grid must be 100 percent. Use the buttons on the toolbar to add lines to the grid or remove them. For each line, set the following fields:
    - **Vendor account** – Select the vendor that the line applies to.
    - **Target allocation (%)** – Specify the percentage of planned orders that should be assigned to this vendor (relative to the others) over time.
6. Follow one of these steps:
    - If you're ready to activate the policy, set the **Active** option to *Yes*, and then select **Save** on the Action Pane. The system will validate your settings (for example, to make sure that all percentages add up to 100 percent) and will proceed with the save only if the validation is passed. If the validation isn't passed, you'll receive an error that you must address before you can save.
    - If you want to prevent the policy from being used, or if you want to save it before you've finished setting up all the allocations, set the **Active** option to *No*, and then select **Save** on the Action Pane. This configuration will allow you to save an invalid policy, but you won't be able to assign the policy to any products.

Define minimum order quantities per vendor

If vendor agreements that you have in place establish a minimum quantity per order for some items, you can add rules for those conditions to the system. These minimum order settings apply to all multisource policies and only to multisource policies. (In other words, rules for minimum orders per vendor apply only to planned purchase orders that are created by master planning. They don't apply to quantities from manually created purchase orders.)

To set up minimum order per vendor rules, follow these steps.

1. Go to **Procurement and sourcing** > **Setup** > **Policies** > **Multisource policies**.
2. On the Action Pane, select **Order quantity per vendor**.
3. Follow one of these steps:
    - To edit an existing rule, find and select it in the grid, and then select **Edit** on the Action Pane.
    - To create a new rule, select **New** on the Action Pane.
4. Set the following fields for the new or selected rule:
    - **Vendor account** – Select the vendor that the rule applies to.
    - **Item number** – Select the item that the rule applies to.
    - **Minimum** – Enter the minimum purchase per order for the specified combination of a vendor and an item.
    - **Unit** – Shows the purchase unit of measure for the selected item (read only). It applies to the **Minimum** value.
5. On the Action Pane, select **Save**.

Assign multisource policies to products

To set up a product so that it can be purchased from multiple vendors, you must specify which multisource policy applies to it.

To specify the multisource policy that applies to a product, follow these steps.

1. Follow one of these steps:
    - Go to **Procurement and sourcing** > **Setup** > **Policies** > **Multisource policy assignments**.
    - If you're already on the **Multisource policies** page, select **Policy assignments** on the Action Pane.
2. Follow one of these steps:
    - To edit an existing assignment, find and select it in the grid, and then select **Edit** on the Action Pane.
    - To create a new assignment, select **New** on the Action Pane.
3. Set the following fields for the new or selected assignment:
    - **Item number** – Select the item to assign a policy to.
    - **Site** – Select the site where the policy should apply. If the assignment should apply to all sites, leave this field blank.
    - **Warehouse** – Select the warehouse where the policy should apply. If the assignment should apply to all warehouses, leave this field blank.
    - **From date** – Select the first date that the assignment should apply.

- **To date** – Select the last date that the assignment should apply.
- **Policy** – Select the policy that should apply to the assignment's combination of an item, site, warehouse, and date range.

4. On the Action Pane, select **Save**.

Review target vs. actual vendor allocations

For each multisource policy assignment, you can view your actual purchases and vendor allocations for the current period, and compare them against your target allocations.

To view and compare target and actual vendor allocations, follow these steps.

1. Go to **Procurement and sourcing** > **Setup** > **Policies** > **Multisource policy assignments**.
2. Select the assignment to inspect.
3. On the Action Pane, select **Current allocation**.
4. The **Current allocation** page appears and shows information about the selected assignment. For each vendor, you can view the total quantity that was purchased, the current allocation, the target allocation, and the amount by which each actual allocation deviates from the target. Each quantity and allocation value counts all purchases that were made during the *current period*. The current period extends backwards the number of days that is defined by the **Balance period (days)** setting for the assigned policy. However, it can't extend earlier than the first date that the assignment is valid (the **From date** value). It extends into the future until the last date that the assignment is valid (the **To date** value).

This feature is useful if, for example, you want to determine whether your Purchasing department is firming orders as master planning suggests or making changes. (If purchasers are following master planning's suggestions, the actual allocation will be close to the current allocation. However, if they're making changes, actual allocations might be quite different than the current allocation.)

Example of target vs. actual vendor allocations

The following table shows an example of how a product that has a multisource policy associated with it could be set up on the **Multisource policy assignments** page.

Expand table

Vendor account	Total quantity	Current allocation (%)	Target allocation (%)	Allocation deviation (%)
1001	350	63.64	70	-9.09
1002	200	36.36	30	21.21

Where:

- **Total quantity** – Represents the vendor's total sourced quantity.
- **Current allocation (%)** – Is equal to (Vendor's total sourced quantity ÷ Total accumulated quantity) × 100%. This value indicates how much of all the sourced quantity has been purchased from this vendor as a percentage of the total.
- **Target allocation (%)** – Is the target allocation as defined by the multisource policy for the vendor.
- **Allocation deviation (%)** – Is equal to ((Current allocation − Target allocation) ÷ Target allocation) × 100%.

How master planning suggests a vendor for each planned order

Each time that master planning suggests a vendor for a planned purchase order, it selects the vendor that will bring the total vendor allocations for the current period closest to the target allocation, as defined by the relevant multisource policy assignment and minimum vendor quantities.

How the system selects which vendor to assign for a new planned order

The system uses the following rules to select the vendor for a new planned order:

- The system will apply a multisource policy according to the following rules:
  - The planned order must match the product and all the dimensions that are specified for a multisource policy assignment.
  - The planned order date must occur during the *current period* for a matching multisource policy assignment. The current period extends backwards the number of days that is defined by the **Balance period (days)** setting for the assigned policy. However, it can't extend earlier than the first date that the assignment is valid (the **From date** value). It extends into the future until the last date that the assignment is valid (the **To date** value).
  - If more than one policy assignment matches the planned order, the most specific assignment is used. For example, if there's demand for item A0001, site 1, and warehouse 11, and the policies that are shown in the following table exist, policy Y will be used, because it's the more specific one.

Expand table

Item	Site	Warehouse	From date	To date	Policy
A0001	1		October 24, 2022		X
A0001	1	11	October 24, 2022		Y

- Classic vendor selection that is based on cost/price isn't used with trade agreements. If a multisource policy is established, the system will try to meet its vendor allocation targets.
- If a vendor lead time is specified in a trade agreement, it will be respected.
- The approved vendor list will be respected if it's available. If the system is set up to disallow vendors besides the approved vendors (that is, if the **Approved vendor check method** field is set to *Not allowed*), that setting will be respected. A vendor that is specified in the multisource policy will be selected only if it's approved. The default **Approved vendor check method** setting is defined at the item model group level but can be overridden at the released product level.
- Default order settings will be respected as follows:
  - The minimum, multiple, and maximum values that are defined in the default order settings will be respected if they're specified.

- If the multisource policy includes a relevant minimum order quantity for the vendor, that minimum quantity will also be applied. Therefore, the higher of the two minimum order values (the default order settings and the minimum vendor quantity) will take effect.

> **Important**
>
> Vendor calendars aren't taken into account when you use multi-vendor sourcing. In some cases, this can result in an order arriving later than it could if you chose a vendor manually.
>
> For example, suppose it's Monday and you have demand for Wednesday for an item provided by two vendors. One vendor is open all days while the second vendor is only open on Fridays. If the sourcing algorithm determines that the second vendor should supply (based on the target percentages), then this vendor will be chosen even though the demand won't arrive until Friday. Therefore, you might want to assign a vendor manually when fulfilling short-term demand.

Example: How vendors are selected based on a multisource policy

The table that follows shows how the system will assign orders to each of two different vendors, based on the target allocations that are defined for the relevant multisource policy. For each new order, the system will select the vendor that results in the least deviation from the target allocation, based on the quantities that are accumulated during the current period, as defined by the relevant policy and policy assignment.

Here's an explanation of the table:

- The "Demand" column shows the planned purchase order quantity.
- The "Vendor A quantity" and "Vendor B quantity" columns show the target allocations, and indicate the actual resulting quantities that are ordered from each vendor for each planned order.
- The "If vendor A is selected" and "If vendor B is selected" columns show the calculations that the system does to determine which vendor it should use. The system selects the vendor that results in the least deviation. The calculation uses the following values:
  - **Qty A** = Accumulated quantity for vendor A
  - **Qty B** = Accumulated quantity for vendor B
  - **A%** = (*Qty A* ÷ *Total accumulated quantity*) × 100%
  - **B%** = (*Qty B* ÷ *Total accumulated quantity*) × 100%
  - **Deviation** = (| *A%* − *Vendor A target* | + | *B%* – *Vendor B target* |) ÷ 2
- The "Total accumulate quantity" column shows the total quantity that is ordered after each new purchase order.
- All planned orders in the table occur during the same period, as defined by the relevant policy and policy assignment.

For vendor A, the target allocation is 80 percent. For vendor B, it's 20 percent.

Expand table

Demand	Vendor A quantity	Vendor B quantity	If vendor A is selected					If vendor B is selected					Total accumulated quantity
			Qty A	Qty B	A%	B%	Deviation	Qty A	Qty B	A%	B%	Deviation	
100	100	0	100	0	100%	0%	20%	0	100	0%	100%	80%	100
100	100	0	200*	0	100%	0%	20%**	100	100	50%	50%	30%	200
100	0	100	300	0	100%	0%	20%	200	100	66%	33%	13%	300

* 100 accumulated + 100 current demand

** (| 100% − 80% | + | 20% − 0% |) ÷ 2 = 20%

Priority-based planning

06/17/2025

This article describes the priority-based planning feature of Microsoft Dynamics 365 Supply Chain Management. The feature adds support for demand-driven planning, which is one step of Demand Driven Material Requirements Planning (DDMRP). Priority-based planning enables the system to generate planned orders that are driven by planning priorities instead of requirement dates.

Priority-based planning lets you prioritize replenishment orders to ensure that urgent demand is prioritized over less important demand. For example, a stockout replenishment order will be prioritized over a standard refill replenishment order. The system can automatically split larger orders into separate smaller orders where order lines are grouped by priority. It can then process all high-priority orders first.

To get a quick overview of this feature, see the following video: Planning optimization support for priority-based planning in Dynamics 365 Supply Chain Management.

Where and how planning priorities are assigned

Planning priority information about supply and demand is the backbone of priority-based planning. Planning priority defines the importance of a demand or supply line. Master planning uses it when the **Coverage code** field is set to *Priority*.

The planning priority is usually a number between 0 (zero) and 100, where 0 represents the highest importance. It's shown and set in the **Planning priority** field. You can find this field on the following pages: **Demand forecast lines**, **Sales order details**, **Purchase order details**, **Transfer order details**, and **Planned order details**.

When the **Coverage code** field for the relevant item or coverage group is set to *Priority*, master planning balances supply with demand by using a demand-driven approach as it calculates the planning priority and, for each released product, considers the values that are set for the **Minimum**, **Reorder point**, and **Maximum** fields on the **Item coverage** page.

> **Note**
>
> The *Priority* value is available for the **Coverage code** field only when Planning Optimization is enabled.

The related *planning priority models* control the planning priority and split planned orders by priority range. They also let you set default planning priority values for each supply or demand

type and define the priority calculation method.

Types of priority calculation methods

Each planning priority model has a **Priority calculation method** setting that controls how master planning applies priority to planned orders. The available values are *Percent of maximum inventory quantity* and *Priority ranges*. *Priority ranges* represents a more advanced version of the *Percent of maximum inventory quantity* method.

Percent of maximum inventory quantity

In the *Percent of maximum inventory quantity* calculation method, the supply priority calculation finds the current *total available inventory* (net flow) as a percentage of the **Maximum inventory quantity** value that is set for an item. A single planned order is then created per item and vendor (unless the maximum order quantity is used to force a split). The planning priority of the order is calculated as a percentage of the maximum.

The following formula is used:

Percentage of maximum = (*Net flow position* × 100) ÷ *Maximum inventory quantity value from the item coverage*

In this formula, *Net flow position* is calculated in the following way:

Net flow position = On-hand + On-order – Qualified demand

- *On-order* is the expected supply.
- *Qualified demand* represents the net requirements that have the requirement date within the planning time fence.

During the master planning run, new planned orders are created when the net flow position is less than the reorder point quantity for an item. The planned order quantity is the difference between the **Maximum inventory quantity** value that is set at the item level and the net flow position. The planned order priority is calculated as a *net flow position* percentage of the **Maximum inventory quantity** value.

> **Note**
>
> The calculated priority can't be negative, even if demand exceeds total supply. If demand exceeds total supply, the calculated priority is set to 0 (zero).

Priority ranges

The *Priority ranges* calculation method is more advanced than the *Percent of maximum inventory quantity* method and is configured at the level of the planning priority model. Several new planned supply orders can be created to fulfill the demand per item. The priorities of the planned supply follow the values that are defined in the **Planning priority ranges** grid on the **Planning priority models** page.

The following additional rules become effective when the **Priority calculation method** field is set to *Priority ranges*:

- If the **Consider demand priority** option for the planned priority model is set to *Yes*, priority that is set on each demand line will limit the priority range bucket. The priority of any new planned order for supply will be no lower than the demand's priority. The range's upper value is considered a threshold that the demand's priority value is compared against. If the demand's priority is exactly in the middle between the upper threshold values of two ranges, the range that has the highest priority (that is, the lowest priority value) will be selected.
- If the **Planned order creation** field for the planned priority model is set to *Single supply with most important priority*, only one supply will be created to fulfill all the way up to the maximum. The priority will be set to the priority of the first range that will trigger a supply.
- If there's no on-hand inventory, no supply, and no demand, the line in the **Planning priority ranges** grid where the **From quantity** field is set to *Zero* will be used.
- If there is demand, but no on-hand inventory or expected supply, the line in the **Planning priority ranges** grid where the **From quantity** field is set to *Zero or less* will be used.
- When the range that the demand is part of is evaluated, the setting of the **Consider demand priority** option will still have an effect.

Differences between traditional timeline calculations and priority-based planning

Priority-based planning differs from traditional timeline calculations in the following ways:

- All the regular preplanning processors are still in effect. These preprocessors include pegging of approved planned orders against sales demand, purchase requisition mapping, and reservation logic. Only demand that isn't fulfilled by these preprocessors is processed.
- During pegging, all supply is considered, regardless of its priority. This supply includes on-hand inventory, released supply, and the non-pegged portion of approved planned orders.

- No "negative days" demand can be pegged against supply during the whole coverage time.
- When supply is pegged against demand, the supply that has the highest priority (that is, the lowest priority value) is used up first. On-hand supply is considered to have a priority value of 0 (zero). Therefore, it will be consumed as the very first source.
- New planned supply lines will be created according to the regular rules for minimum order size, maximum order size, quantity multiple, and so on.

Planning priority models

Planning priority models are assigned to coverage groups and control the planning priority for planned orders. They define the logic that determines how the planning priority value is calculated for each planned order, and how priority is assigned to planned orders, supply lines, and demand lines.

To work with the planning priority models, go to **Master planning** > **Setup** > **Planning priority models**. As was previously discussed, one of a model's most important settings is the **Priority calculation method** value. This setting controls the calculation method that is used when master planning assigns a priority value to planned orders.

> ⓘ **Note**
>
> Planning priority models apply organization-wide, across all legal entities.

Coverage group

Set up a new coverage group that you plan to use for priority-based planning, as described in Define coverage rules for items. After you've created the coverage group, set the following additional fields:

- **Coverage code** – Select *Priority* if the coverage group will use priority-based planning.
- **Planning priority model** – Select any organization-wide planning priority model.

Item coverage

Set up item coverage settings as described in Coverage settings. By default, the **Coverage code** value that is selected for the coverage group is copied to the item coverage settings. However, you can override the default value as you require. In some cases, the **Coverage code** field for an item coverage record is set to *Planning*, but no planning priority model is defined for the related coverage group. In these cases, any model where the **Priority calculation method** field

is set to *Percent of maximum inventory quantity* and the **Planned order creation** field is set to *Single supply with most important priority* will be applied by default.

Set the **Coverage code** field to *Priority* to make the **Reorder point** field in the item coverage settings available. In this field, enter the reorder point quantity that the system should use while it's determining when to place planned orders that have a **Coverage code** value of *Priority*.

The reorder point quantity is often calculated as the demand during the lead time plus a minimum value (safety stock). It must be a value between the **Minimum** and **Maximum** values.

For example, you might set the fields in the following way:

- **Minimum:** *10*
- **Reorder point:** *45*
- **Maximum:** *60*

For this example, the reorder point quantity is based on a lead time of seven days and an average daily usage of 5. Therefore, the demand during the lead time is 35. The minimum value of 10 (safety stock) is then added to get a reorder point of 45. When this setup is used, supply will be suggested when the projected on-hand level is below 45. The order priority will be based on the planning priority setup.

Manage planning priority models

To work with your planning priority models. follow these steps.

1. Go to **Master planning** > **Setup** > **Planning priority models**.
2. Either select an existing model in the list pane, or select **New** on the Action Pane to create a new model.
3. On the header of the record, set the following fields:
    - **Name** – Enter a name for the model. The name must be unique across all legal entities in your organization.
    - **Description** – Enter a description of the model.
    - **Priority calculation method** – Select one of the following values:
        - *Priority ranges* – When you select this value, the **Planning priority ranges** grid becomes available. There, you must establish several priority ranges to define the planning priority value.
        - *Percent of Maximum inventory quantity* – Calculate the planning priority value as a percentage, based on the projected inventory level over the maximum

inventory quantity.

- **Planned order creation** – This field is available when the **Priority calculation method** field is set to *Priority ranges*. Select one of the following values:
  - *Single supply with most important priority* – Don't split planned orders based on the priority range. The planning priority for a planned order is based on the most important priority range (that is, the lowest planning priority value).
  - *Split according to priority ranges* – Split the demand into multiple planned orders, based on the planning priority ranges. The planning priority for individual planned orders is defined by the planning priority of the related planning priority range.

- **Consider demand priority** – Set this option to *Yes* to limit the priority of a new planned order that is created for supply. (The priority will be no lower than the related demand's priority.) If you set this option to *No*, the demand order's priority won't be considered when the supply order's priority is calculated.

4. If you set the **Priority calculation method** field to *Priority ranges*, use the **Add** and **Remove** buttons on the toolbar of the **Planning priority ranges** FastTab to add or remove priority range rows as you require. If multiple rows exist, and you insert a new row, the planning priority will automatically be set to the average of the selected row and the row above it. For each row, set the following fields:

   - **Planning priority** – Enter any value between 0.00 and 100.00. This value represents the planning priority that is used for the row. The lowest priority value represents the highest priority. A default value is assigned, but you can change it as you require. The same **Planning priority** value can't be used for more than one planning priority range in the same planning priority model.

   - **Description** – Enter a description of the planning priority range (such as *Reorder point to Maximum*).

   - **From quantity** – The lower limit of the planning priority range. This value is read-only, and is based on the **To quantity** and **Percentage of to quantity** values for the previous planning priority range.

   - **To quantity** – Select the field from the item coverage that should be used to define the range's upper limit. The following values are supported and will influence the **From quantity** value of the next range:
     - *Zero* – This value represents a negative to zero range (*Zero or less* to *Zero*). For rows where this value is selected, the **Percent of to quantity** field is read-only and is always set to *100* percent.

- *Minimum inventory quantity* – This value represents the **Minimum** value for an item on the **Item coverage** page. For rows where this value is selected, the **Percent of to quantity** field is editable and is used to set the **From quantity** value of the next range (for example, to *80% of Minimum inventory quantity*).
- *Reorder point* – This value represents the **Reorder point** value for an item on the **Item coverage** page. For rows where this value is selected, the **Percent of to quantity** field is editable and is used to set the **From quantity** value for the next range (for example, to *80% of Reorder point*).
- *Maximum inventory quantity* – This value represents the **Maximum** value for an item on the **Item coverage** page. For rows where this value is selected, the **Percent of to quantity** field is editable and is used to set the **From quantity** of the next range (for example, to *80% of Minimum inventory quantity*).
- *Infinite* – This value represents an infinite upper level of the range (*Infinite or less* to *Infinite*). For rows where this value is selected, the **Percent of to quantity** field is read-only and is always set to *100* percent.

- **Percent of to quantity** – Enter a percentage value that is used to calculate the upper limit of the planning priority range, based on the value that is selected in the **To quantity** field. For example, if the **To quantity** field is set to *Minimum inventory quantity*, and the **Percent of to quantity** field is set to *50*, the upper limit will be 50 percent of the minimum inventory quantity from the related item coverage.

5. On the **Planning priority defaults** FastTab, set the fields as you require to define default planning priorities for each type of supply or demand line (sales order, purchase order, transfer order, or demand forecast). Only positive values can be entered.

View and maintain planning priority

The planning priority is shown and set in the **Planning priority** field. You can find this field on the pages that are listed in the following table. The priority is set as a number between 0 (zero) and 100, where 0 represents the highest importance.

Expand table

Page	Field location	Value source
Demand forecast lines	**Item** tab (Select a line in the upper section, and then select the **Item** tab.)	Default value or value that is manually set
Sales order details	**Delivery** tab on the **Line details** FastTab	Default value, value from intercompany, or value that is manually set

Page	Field location	Value source
	(Select a line on the **Sales order lines** FastTab, and then, on the **Line details** FastTab, select the **Delivery** tab.)	
Purchase order details	**Delivery** tab on the **Line details** FastTab (Select a line on the **Purchase order lines** FastTab, and then, on the **Line details** FastTab, select the **Delivery** tab.)	Value that is set during firming from planned orders, value from intercompany, or value that is manually set
Transfer order details	**Delivery** tab on the **Line details** FastTab (Select a line on the **Transfer order lines** FastTab, and then, on the **Line details** FastTab, select the **Delivery** tab.)	Value that is set during firming from planned orders or value that is manually set
Planned order details	**General** FastTab	Value that is calculated during master planning or value that is manually set

Intercompany trade

The **Planning priority** value on intercompany supply and demand lines is shared between the linked entities. Modification on either side will be reflected on the linked order line.

Here are some examples:

- A user changes the planning priority for an intercompany sales order line from 20 to 30. This change is reflected on the linked intercompany purchase order line.
- A user changes the planning priority for an intercompany purchase order line from 40 to 50. This change is reflected on the linked intercompany sales order line.

Action messages

The system doesn't generate action messages for coverage codes with priority-based planning.

Replenishment methods and quantity modification

This article provides information about replenishment methods. It also explains how the multiple order quantity for a product affects the result.

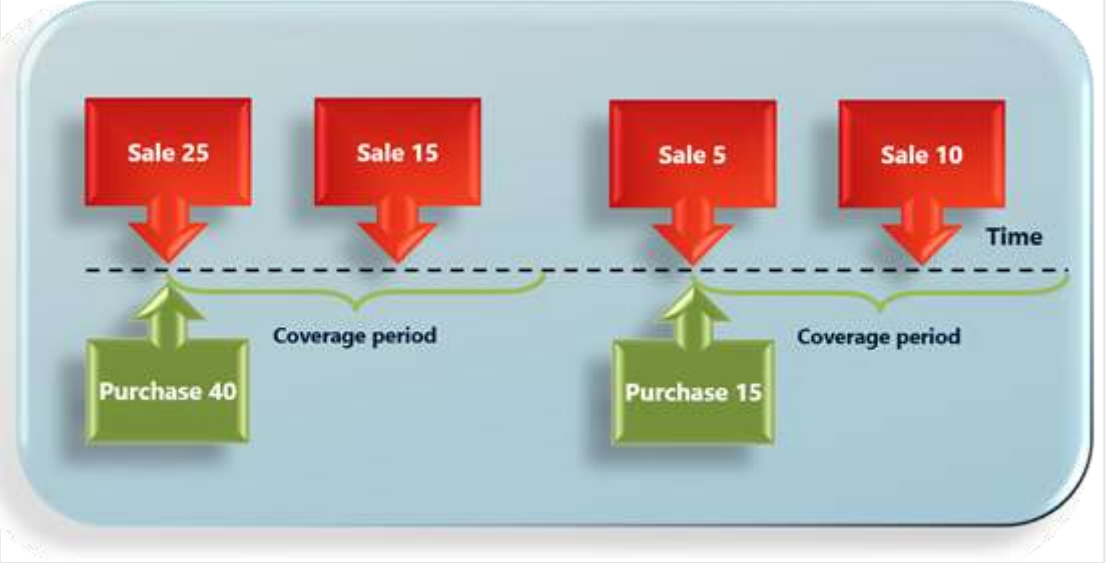
Replenishment methods are also known as coverage methods and lot-sizing methods.

Coverage codes

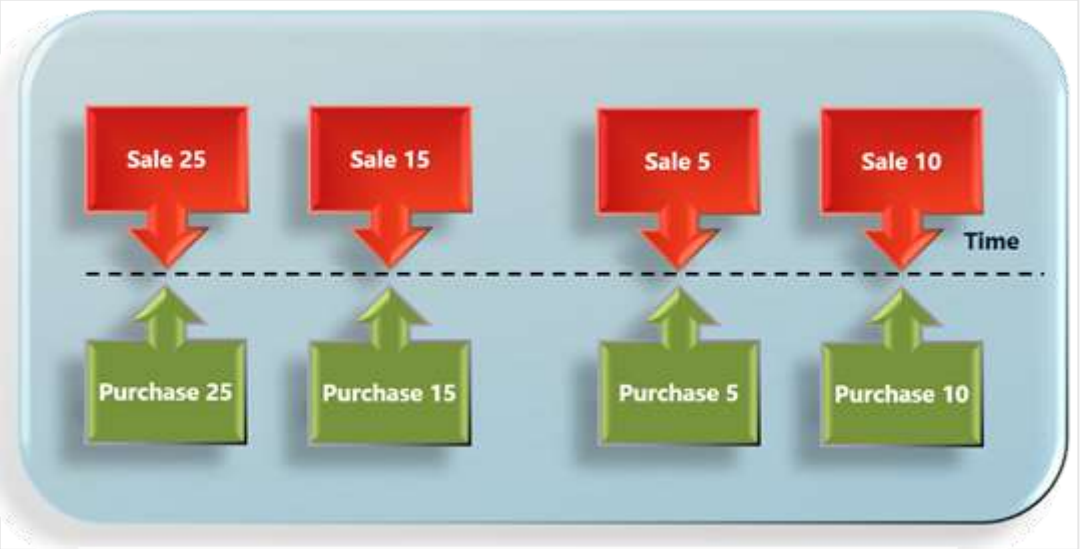
You can configure master planning to use different replenishment methods. Replenishment methods are the techniques that the system uses to calculate requirements for a product. Replenishment methods are defined by coverage codes that you can set up on either the coverage group or the product.

Use the following coverage codes:

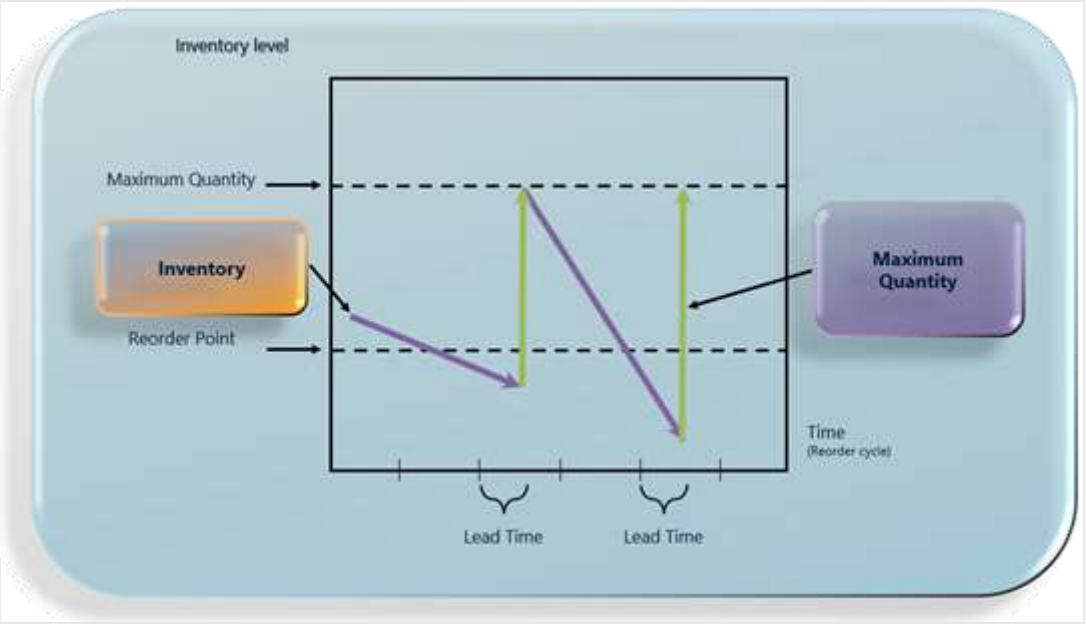
- **Period** – The replenishment method combines all the demand for a period into one order for the product. The order is planned for the first day of the period, and its quantity fulfills the net requirements during the established period. The period starts with the first demand of the product and covers the defined length of time. The next period starts with the next requirements of the product. Use the *Period* coverage code for non-predictable inventory draw, season-influenced products, or high-cost products. The following illustration shows an example.



- **Requirement** – In the replenishment method, the system creates a planned purchase, transfer, or production order per requirement for the product. Use this method for expensive products that have intermittent demand. The *Requirement* coverage code is often used for configurable products or make-to-order scenarios. The following illustration shows an example.



- **Min./Max.** – The replenishment method is based on the inventory level. It defines the replenishment of inventory up to a specific level when the predicted on-hand level is below a specific threshold. The replenishment quantity is the difference between the maximum level and the predicted on-hand level. Use the *Min./Max.* coverage code for predictable inventory draw, high runners, or less expensive products. The following illustration shows an example.



- **Manual** – In the replenishment method, the system doesn't suggest purchase, transfer, or production orders for the product. Instead, the planner for the product is responsible for

creating the required orders for the replenishment of the product. Use the *Manual* coverage code for products for which you don't want the system to generate planned orders.

Impact of the order quantity from default order settings

On the **Default order setting** page for a released product, you can specify each of the following quantity settings on the **Purchase order**, **Inventory**, and **Sales order** FastTabs. (The **Inventory** FastTab is used for both transfer orders and production orders.)

- **Multiple** – Planned orders are a multiple of this quantity.

  For example, if the **Multiple** field is set to *5*, an order can be for a quantity of 5, 10, 15, 20, and so on.

- **Min. order quantity** – Planned orders aren't less than the specified value.

  For example, if the **Min. order quantity** field is set to *10*, a planned order for a quantity of 10 is created, even if only four are required to fulfill the demand.

- **Max. order quantity** – Planned orders don't exceed the specified value. If the demand is more than the **Max. order quantity** value, multiple planned orders are created to cover it.

  For example, if the **Max. order quantity** field is set to *100*, and the demand is 450, four planned orders for a quantity of 100 and one planned order for a quantity of 50 are created.

Examples of replenishment that use the Min./Max. coverage code

If you don't specify a value in the **Multiple** field for a product on the **Default order setting** page, and if you're using the *Min./Max.* replenishment method, master planning replenishes the inventory up to a specific level when the predicted on-hand level is below a specific threshold.

If you define a multiple quantity for a product, the *Min./Max.* replenishment method changes its behavior and considers the **Multiple** value.

In other words, master planning still replenishes the inventory up to the defined maximum level when the predicted on-hand level is less than the defined minimum level. However, the replenishment quantity must be a multiple of the **Multiple** value.

If the replenishment quantity (the difference between the maximum level and the predicted on-hand level) isn't a multiple of the defined multiple quantity, master planning uses the first possible value that, together with predicted on-hand level, is below the maximum level. If the sum is less than the minimum level, master planning uses the first value that, together with predicted on-hand, is above the maximum level.

The following subsections provide some examples that show how the multiple order quantity for a product affects the result of the *Min./Max.* replenishment method.

Example 1

A product has the following configuration:

- **Coverage code:** *Min./Max.*
- **Minimum:** *15*
- **Maximum:** *22*
- **Multiple:** *0*

The product has 10 pieces of on-hand inventory, and there's no other demand or supply.

When master planning runs, it creates a planned order for 12 pieces to replenish inventory to the maximum quantity.

Example 2

A product has the following configuration:

- **Coverage code:** *Min./Max.*
- **Minimum:** *15*
- **Maximum:** *22*
- **Multiple:** *5*

The product has 10 pieces of on-hand inventory, and there's no other demand or supply.

When master planning runs, it creates a planned order for 10 pieces (because 15 pieces of replenishment plus 10 pieces of on-hand inventory exceed the maximum quantity).

Example 3

A product has the following configuration:

- **Coverage code:** *Min./Max.*

- **Minimum:** *21*
- **Maximum:** *24*
- **Multiple:** *5*

The product has 10 pieces of on-hand inventory, and there's no other demand or supply.

When master planning runs, it creates the planned order for 15 pieces (because 10 pieces of replenishment plus 10 pieces of on-hand inventory are less than the minimum quantity).

Master planning and multisite functionality overview

Master planning takes the settings of the site and warehouse inventory dimensions into account.

The site dimension is mandatory, and you can set the warehouse dimension to be mandatory.

When a dimension is mandatory, a dimension value must be entered on all inventory transactions. Therefore, during master planning, the site and the warehouse for the initial demand are known. The site dimension is also consistent so that during the explosion of lower-level demand, the site value does not change.

When the warehouse is not set to mandatory, it may not be known from the initial demand. The planning engine must determine which warehouse to use based on the settings that are defined for the item, individual warehouses, and the details of the order line.

The following articles describe how the planning engine works, when different settings are defined, to determine the warehouse to use.

Master planning for site and warehouse coverage, warehouse mandatory

Master planning for site coverage, mandatory warehouse

Master planning for site and warehouse coverage, warehouse not mandatory

Master planning for site coverage, warehouse not mandatory

Determine the BOM version

Last updated on 07/01/2026

Master planning for site coverage, mandatory warehouse

This article describes how an item that has the site as coverage dimension is planned. Warehouse is a mandatory dimension.

This master planning scenario involves the following conditions:

- The site dimension is set to mandatory and must be entered on the demand transaction. This setting can't be modified.
- The warehouse dimension is set to mandatory and must be entered on the demand transaction.
- The site dimension is set for coverage planning. Other dimensions may be set for coverage planning also. However, they are not affected by the multisite functionality.
- The warehouse dimension is not set for coverage planning. Therefore, supply and demand are aggregated by site and, perhaps, other coverage-planned dimensions also.

The following graphic illustrates how master planning proceeds. The parameters that are referred to in the graphic, and their locations, are as follows:

- Item coverage is defined for the item. Click **Product information management** > **Products**> **Released products**. Select the item, and then click **Plan** > **Item coverage**.
- Refill relations are defined for the warehouse. Click **Inventory management** > **Setup** > **Inventory breakdown** > **Warehouses**. On the **Master planning** tab, see the **Main warehouse** field group.
- The default order type is set to Production, Purchase order, or Kanban. Click **Product information management** > **Products**> **Released products**. Select the item, and then click **Plan** > **Default order settings**. In the **Default order settings** form, see the **Default order type**.

Master planning for site coverage, warehouse not mandatory

This article describes how an item that has the site dimension set for coverage is planned.

This master planning scenario involves the following conditions:

- The site dimension is set to mandatory and must be entered on the demand transaction.
- The warehouse dimension is not set to mandatory. The warehouse may be known, but it is not used in the master planning calculation.
- The site dimension is set for coverage planning.
- The warehouse dimension is not set for coverage planning. Therefore, supply and demand are aggregated by site and, perhaps, other coverage-planned dimensions also.

The following graphic illustrates how master planning proceeds. The parameters that are referred to in the graphic, and their locations, are as follows:

- Item coverage is defined for the item. Click **Product information management** > **Products**> **Released products**. Select the item, and then click **Plan** > **Item coverage**.
- Refill relations are defined for the warehouse. Click **Inventory management** > **Setup** > **Inventory breakdown** > **Warehouses**. On the **Master planning** tab, see the **Main warehouse** field group.
- The default order type is set to Production, Purchase order or Kanban. Click **Product information management** > **Products**> **Released products**. Select the item, and then click **Plan** > **Default order settings**. In the **Default order settings** form, see the **Default order type** field.

Master planning for site and warehouse coverage, warehouse mandatory

This article describes how an item that has site and warehouse as coverage dimensions is planned. The warehouse dimension is mandatory.

This master planning scenario involves the following conditions:

- The site dimension is set to mandatory and must be entered on the demand transaction.
- The warehouse dimension is set to mandatory and must be entered on the demand transaction.
- The site and warehouse dimensions are set for coverage planning. Other dimensions may be set for coverage planning also. However, they are not affected by the multisite functionality.

The following graphic illustrates how master planning proceeds. The parameters that are referred to in the graphic, and their locations, are as follows:

- The warehouse is set to **Manual**. Click **Inventory management** > **Setup** > **Inventory breakdown** > **Warehouses**. On the **Master planning** FastTab, see the **Manual** field.
- Item coverage is defined for the item. Click **Product information management** > **Products**> **Released products**. Select the item, and then, on the Action Pane, on the **Plan** tab, click **Item coverage**.
- Refill relations are defined for the warehouse. Click **Inventory management** > **Setup** > **Inventory breakdown** > **Warehouses**. On the **Master planning** FastTab, see the **Main warehouse** field group.
- The default order type is set to Production, Purchase order, or Kanban. Click **Product information management** > **Products**> **Released products**. Select the item, and then, on the Action Pane, on the **Plan** tab, click **Default order settings**. In the **Default order settings** form, see the **Default order type**.

Master planning for site and warehouse coverage, warehouse not mandatory

This article describes how an item that has site and warehouse as coverage dimensions is planned. The warehouse dimension is not mandatory.

This master planning scenario involves the following conditions:

- The site dimension is set to mandatory and must be entered on the demand transaction. This setting can't be modified.
- The warehouse dimension is not set to mandatory. The warehouse may be known, but it is not used in the master planning calculation.
- The site and warehouse dimensions are set for coverage planning. Other dimensions may be set for coverage planning also. However, they are not affected by the multisite functionality.

The following graphic illustrates how master planning proceeds. The parameters that are referred to in the graphic, and their locations, are as follows:

- The warehouse is set to Manual. Click **Inventory management** > **Setup** > **Inventory breakdown** > **Warehouses**. On the **Master planning** FastTab, see the **Manual** field.
- Item coverage is defined for the item. Click **Product information management** > **Products**> **Released products**. Select the item, and then, on the Action Pane, on the **Plan** tab, click **Item coverage**.
- Refill relations are defined for the warehouse. Click **Inventory management** > **Setup** > **Inventory breakdown** > **Warehouses**. On the **Master planning** FastTab, see the **Main warehouse** field group.
- The default order type is set to Production, Purchase order, or Kanban. Click **Product information management** > **Products**> **Released products**. Select the item, and then, on the Action Pane, on the **Plan** tab, click **Default order settings**. In the **Default order settings** form, see the **Default order type**.

Determine the BOM version

During a demand explosion, if an item has a default order type of Production, the planning engine finds a valid BOM version based on the site.

The site dimension is always known and is stated on the demand transaction. The following process is used to determine the BOM version to use:

- If there is a BOM version defined for the item at the demand site, the site-specific BOM is used.
- If there is no site-specific BOM version defined for an item at the demand site, a general BOM is used. A general BOM does not state a site, and it is valid for multiple sites. If there is a general BOM, it is used.
- If there is no general BOM version to use, the demand explosion stops at this point.

A valid BOM version, whether site-specific or general, must meet the required criteria for date and quantity.

Last updated on 07/01/2026

Explosion of a BOM version

This article explains a master planning scenario that involves explosion of a bill of materials (BOM) version.

A demand explosion of a bill of materials (BOM) version creates a demand for each BOM line item at a specific site and, possibly, at a specific warehouse. In a site-specific BOM, a specific warehouse can be defined for each BOM line. Additionally, for each BOM line, the item's dimension settings determine whether the warehouse is required. The resulting demand for each BOM line item then becomes the starting point for additional demand explosion. This master planning scenario involves the following conditions:

- The site dimension is mandatory and must be entered on the demand transaction.
- The site dimension is consistent. Therefore, the site for lower-level demand is the same as the site on the initial demand transaction.

The following illustration shows how the process for master planning demand explosion.

Safety stock fulfillment for items

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Safety stock is an item quantity that you hold in inventory to reduce the risk that the item runs out of stock. Use safety stock when the demand from sales orders is more than planned for final goods, and when a supplier can't deliver additional units in the expected time.

The system always tries to prevent the accumulated quantity of an item from falling below its safety stock limit. Whenever the master planning engine detects that the accumulated on-hand inventory for an item will fall below its minimum, it creates a planned order to replenish the item and schedules the order to arrive before the minimum threshold is crossed. Therefore, the system fulfills safety stock on *Today's date* + *Procurement time*.

During planning, if there's actual demand, the system pegs it against a planned order generated for safety stock provided it enables the demand to be fulfilled on time and strict safety stock pegging isn't enforced. Because the system always tries to keep the accumulated on-hand inventory level above the safety stock level, it creates a new planned order to cover the safety stock that the actual demand claimed. When strict safety stock pegging is enforced, actual demand isn't pegged against a planned order generated for safety stock.

> **Note**
>
> Because safety stock isn't really demand, any demand is prioritized over the safety stock when strict safety stock pegging is off. Therefore, the system can create a planned order to fulfill safety stock, but if actual demand arrives later, that demand can claim the safety stock quantity. (The new demand is pegged against the original planned order.)

Set the safety stock level for an item

To define safety stock for an item at a specific location, follow these steps:

1. Go to **Product information management** > **Products** > **Released products**.
2. Select the relevant product in the grid.
3. On the Action Pane, on the **Plan** tab, select **Item coverage**.

4. While you're on the **Overview** tab, select **New** on the Action Pane to add a line to the grid.
5. For the new line, specify the relevant product dimensions (**Site**, **Warehouse**, and other dimensions as required, such as **Color** or **Style**).
6. In the **Minimum** field, enter the safety stock value. The master planning engine always generates planned orders to prevent the accumulated inventory level from falling below this limit. The value is expressed in inventory units. If you leave the field blank, a default value of **0** (zero) is used.

> **Note**
>
> The **General** tab of the **Item coverage** page includes a **Fulfill minimum** field. When you use Planning Optimization, the setting of this field is ignored. (Instead, the system always behaves as though **Fulfill minimum** is set to *Today's date + procurement time*.) For information about how the **Fulfill minimum** setting works when you use the deprecated master planning engine, see Safety stock fulfillment with the deprecated planning engine.

Example: Safety stock

Set up your system as follows:

- The warehouse has 30 units of total on-hand inventory of item Z0001.
- A demand forecast shows that 2 units of item Z0001 are consumed every day.
- The safety stock for item Z0001 is set to 20 units.
- The lead time for item Z0001 is five days.

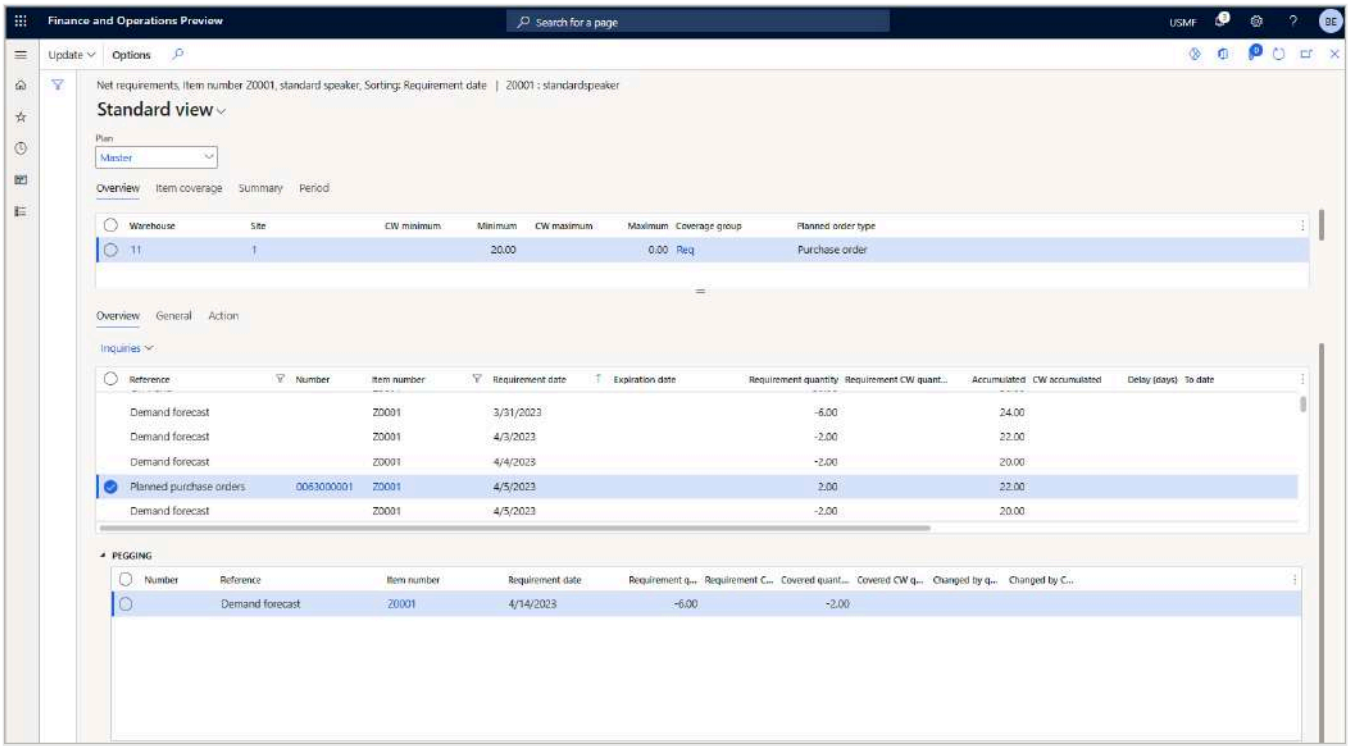
When you run master planning, it creates several orders to ensure that the accumulated on-hand inventory stays above the safety stock threshold. The following table provides an example.

Expand table

Reference	Item number	Requirement date	Requirement quantity	Accumulated
Demand forecast	Z0001	3/31/2023	-6.00	24
Demand forecast	Z0001	4/3/2023	-2.00	22
Demand forecast	Z0001	4/4/2023	-2.00	20
Planned purchase orders	Z0001	4/5/2023	2.00	22

Reference	Item number	Requirement date	Requirement quantity	Accumulated
Demand forecast	Z0001	4/5/2023	-2.00	20

Therefore, the **Net requirements** page for item Z0001 might resemble the following example.



Example: Minimum key

Use minimum keys to handle seasonal fluctuations in demand. For example, you can decrease the minimum inventory level for an item during the off-season and then gradually increase it during the other months.

To create a minimum key, go to **Master planning** > **Setup** > **Coverage** > **Minimum/maximum keys**. You can then specify the minimum key to adjust the safety stock level by seasonality by setting the **Minimum key** field on the **General** tab of the **Item coverage** page.

If you're using minimum keys, set the **Minimum periods** option to *Yes* to fulfill the minimum inventory level for all the periods that are set up in the minimum key. If you set the option to *No*, the minimum inventory is fulfilled for the current period only.

The following procedure shows an example of how to set up a minimum key that accounts for increased seasonal demand during the spring and summer months.

1. Go to **Master planning** > **Setup** > **Coverage** > **Minimum/maximum keys**.
2. Select **New** to create a minimum/maximum key.

3. In the **Minimum or maximum key** field, enter an identifier for the key. In the **Name** field, enter a name for the key.

4. Set the **Use the effective date** option to *Yes* and leave the **Effective date** field blank to make the key valid from the first day of the current year.

   > **Note**
   >
   > The combination of the **Use the effective date** and **Effective date** settings defines the date that the key is valid from.
   >
   > - When the **Use the effective date** option is set to *No*, the key is valid from the current date or system date.
   > - When the **Use the effective date** option is set to *Yes*, the key is valid from the date defined in the **Effective date** field.

5. In the **Periods** section, create 12 lines, and set the following values for them:

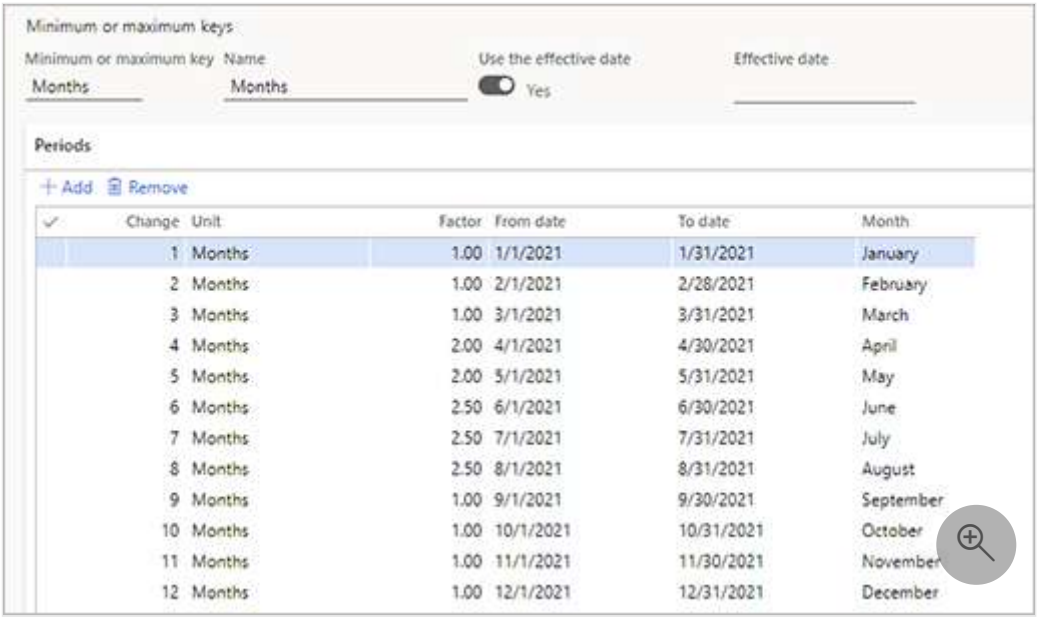
   - **Change** – Assign each line a unique number from 1 through 12. This field indicates the incremental change in the unit of time that is defined by the **Unit** field.
   - **Unit** – Select *Months* for every line.
   - **From date**, **To date**, and **Month** – These fields are automatically set, based on the **Change** and **Unit** settings. Monthly periods start from the first day of the current year.
   - **Factor** – Enter the values that are described in the following table. This field defines the factor that you want to multiply the minimum inventory by.

   Expand table

Line (Change)	Factor	Result
1–3	1	Minimum inventory is based on the setting for January through March on the **Item coverage** page.
4–5	2	Minimum inventory is multiplied by a factor of 2 for April through May.
6–8	2.5	Minimum inventory is multiplied by a factor of 2.5 for June through August.

Line (Change)	Factor	Result
9–12	1	Minimum inventory reverts to the setting for September through December on the **Item coverage** page.

Your settings now resemble the settings in the following illustration.



> **Note**
>
> You can also use a wizard to create a minimum/maximum key. On the **Minimum or maximum keys** page, on the Action Pane, select **Wizard** to open the **Minimum/Maximum Keys** wizard. The wizard guides you step by step through the process of creating and setting up the minimum/maximum key.

If the coverage code is *Min/Max*, you can also specify the maximum inventory quantity that you want to maintain for an item. The value is also expressed in inventory units. If the projected available inventory falls below the minimum quantity, master planning generates a planned order to fulfill all open requirements and brings the available inventory up to the specified maximum quantity. Just as when you set up the minimum inventory quantity, you must define all other planned coverage dimensions before you can set the **Maximum** field.

Example: Min/max coverage code

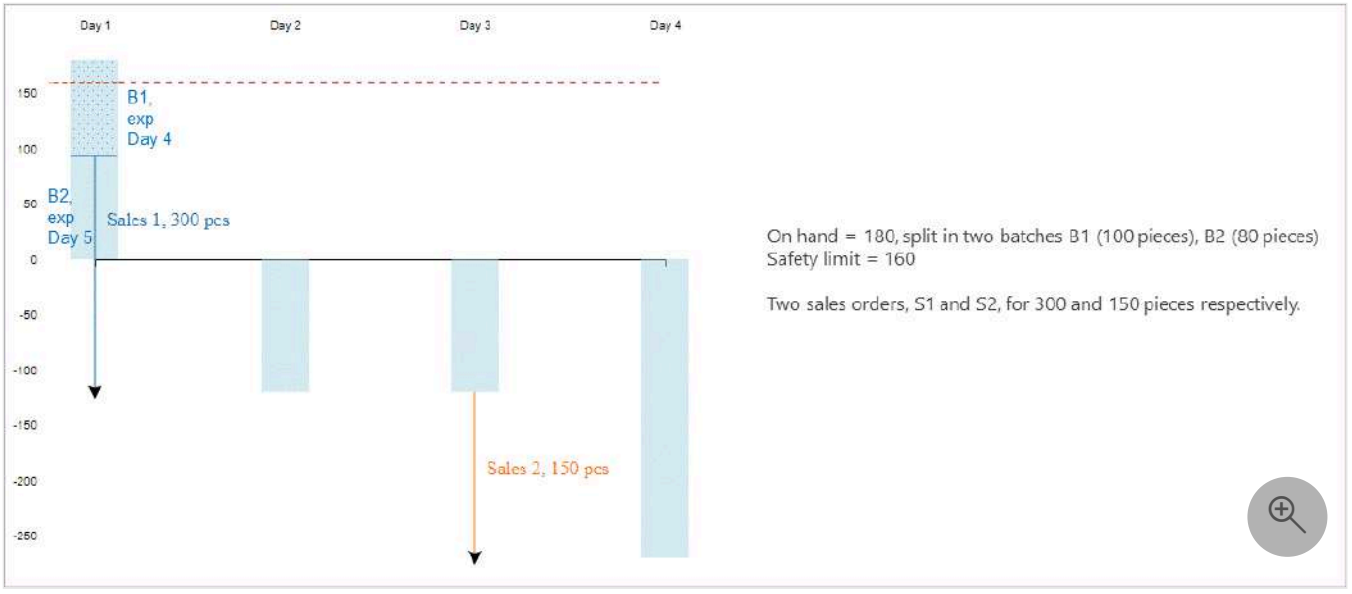
The minimum quantity is 10, and the maximum quantity is 15. Current on-hand inventory is 4. This situation gives a minimum quantity requirement of 6. However, because the maximum quantity is 15, master planning generates a planned order for 11 items.

For items that follow seasonal demands, you might need to maintain different maximum levels. To set up these levels, define **Maximum keys** by going to **Master planning** > **Setup** > **Coverage** > **Minimum/maximum keys**. Fill in the **Maximum key** field on the **Item coverage** page. You can view the information about the safety stock levels, defined through minimum keys on the **Min/Max** tab, on the **Item coverage** page. Make sure that, for a certain period, the minimum and the maximum values stay in sync.

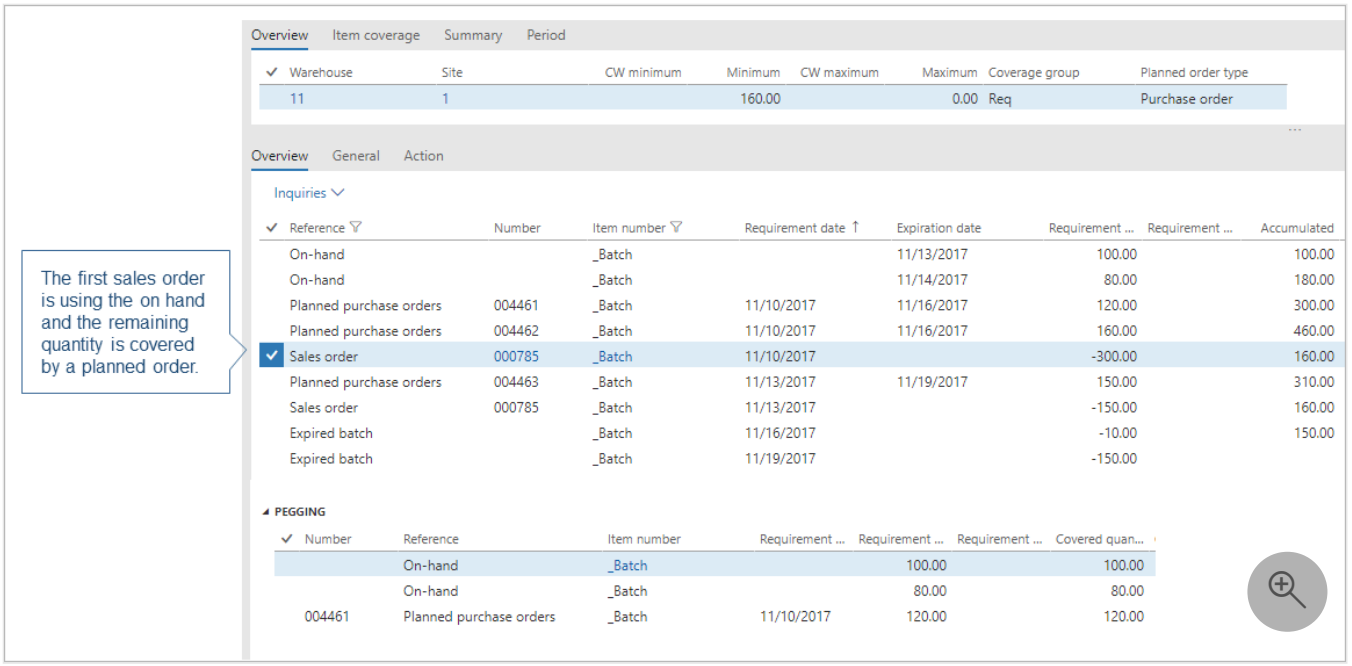
Plan safety stock replenishment for FEFO items

At any point in time, the inventory receipt with the latest expiry date is used for safety stock. This approach ensures that real demand, such as sales lines or BOM lines, is fulfilled in the first expired, first out (FEFO) order.

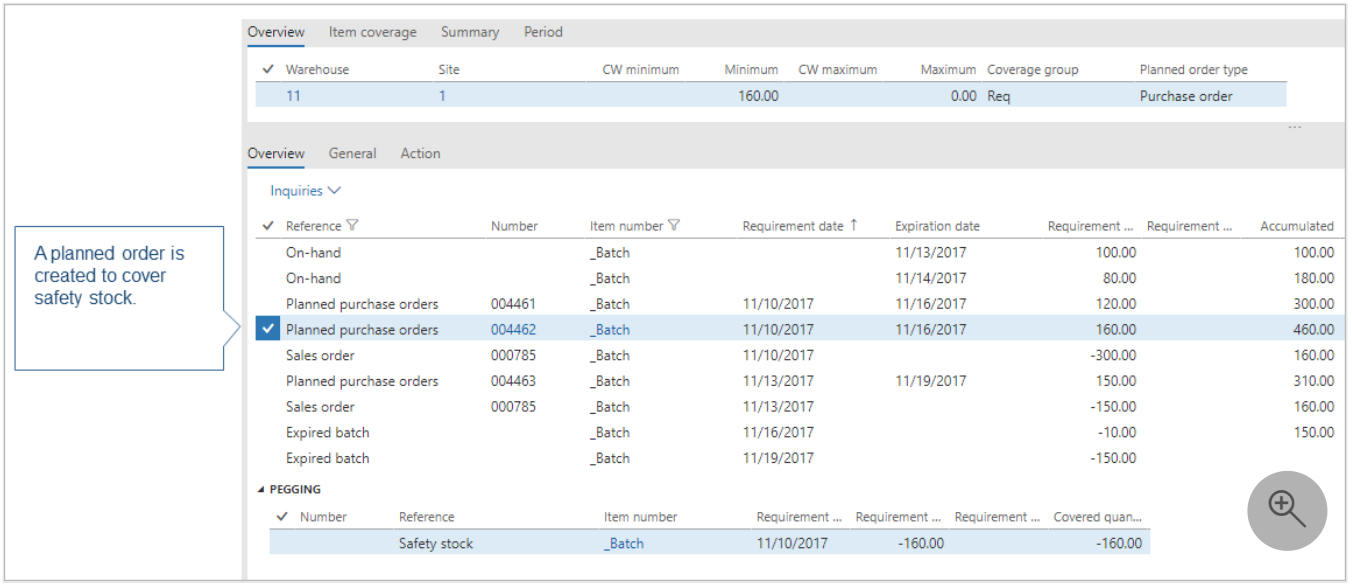
To see how this process works, consider the following scenario:



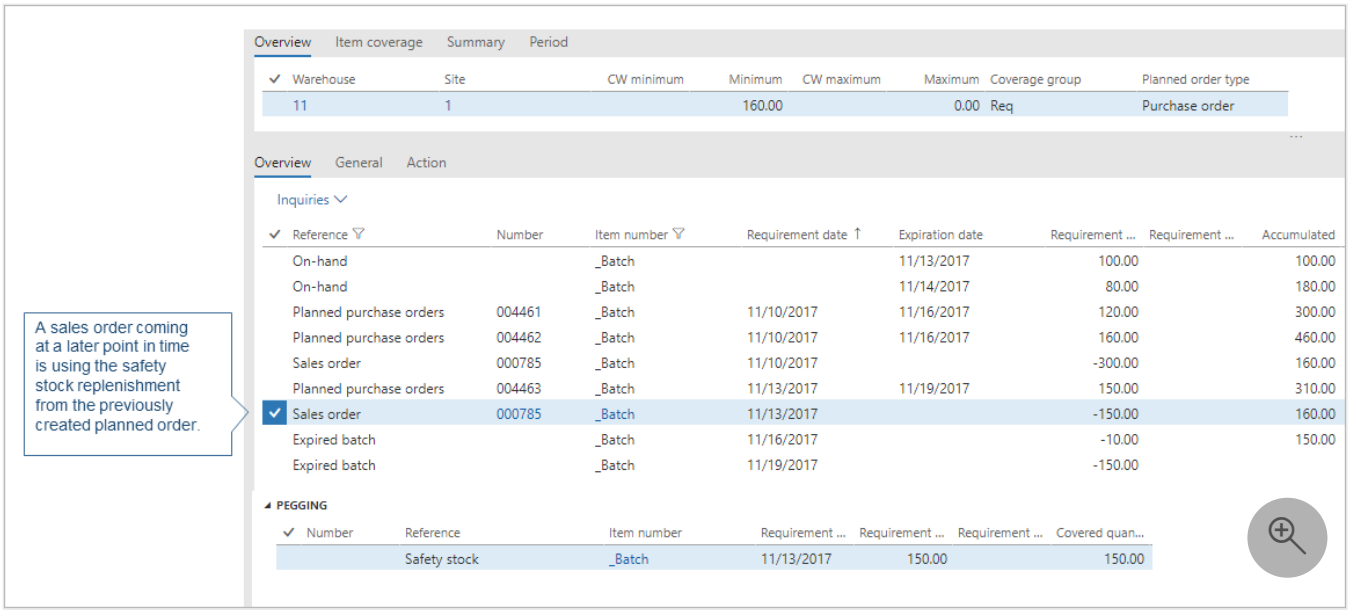
When you run planning, it covers the first sales order from the existing on-hand inventory and an additional purchase order for the remaining quantity.



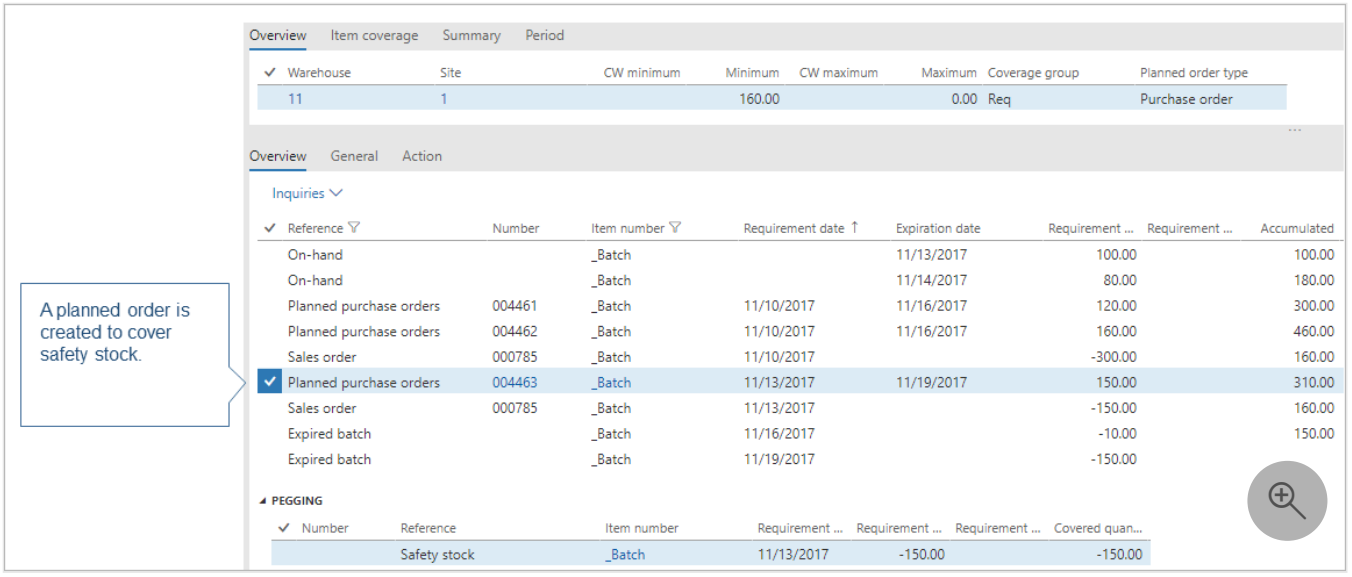
A planned order is created to bring the available inventory back to the safety limit.



When you plan the second sales order, the previously created planned order that covers the safety stock is used to cover this quantity. Hence, the safety stock is constantly rolling.



Finally, another planned order is created to cover the safety stock.



All the batches expire accordingly, and planned orders are created to refill the safety stock after it expires.

How master planning handles the safety stock constraint

The system tracks safety stock as a requirement type, just like sales lines or BOM requirements. You can see the safety stock requirement line on the **Net requirements** page if you remove the default filter on the **Requirement type** column.

If fulfilling the safety stock requirement causes delays in the fulfillment of real demand, such as sales lines, BOM lines, transfer requirements, or demand forecast lines, the system deprioritizes it. Otherwise, making sure that the available inventory is above the safety stock quantity has

the same priority as any other demand types. This approach ensures no delays for real transactions and helps prevent over-replenishment and early replenishment of safety stock.

During the coverage phase of master planning, the system no longer deprioritizes safety stock replenishment. The system can use on-hand inventory before any other demand types. During the delay calculation, new logic goes over the delayed sales lines, BOM line requirements, and all the other demand types to determine whether they can be delivered on time, provided that the safety stock is used. If the system identifies that it can minimize delays by using safety stock, the sales lines or BOM lines replace their initial coverage with the safety stock, and the system triggers the replenishment for the safety stock instead.

If you don't set up the plan or the item for delayed calculation, the safety stock constraint has the same priority as any other demand types. This priority means there's a reserve of on-hand and other available inventory before other demand types.

Safety stock pegging options

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Most industries prioritize customer demand over safety stock. Therefore, when you must both replenish safety stock and fulfill a customer order, the system uses existing planned orders to cover the customer demand instead of leaving those planned orders pegged against safety stock.

However, some businesses prefer to allow the system to keep existing planned orders pegged against safety stock, even if customer demand can't be fulfilled as a result. This approach is known as *strict safety stock pegging*.

For each coverage group, you can specify how strictly the system should peg safety stock as demand against the planned order that's created for it.

Prerequisites

Before you can use the features described in this article, ensure your system meets the following requirements:

- You must be running Microsoft Dynamics 365 Supply Chain Management version 10.0.36 or later.
- The feature that's named *Strict safety stock pegging for Planning Optimization* must be turned on in Feature management. As of Supply Chain Management version 10.0.43, this feature is turned on by default.

Set safety stock pegging options

Safety stock pegging options are set at the coverage group level. Follow these steps to set safety stock pegging options for a selected coverage group.

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.

2. Follow one of these steps:

    - To edit an existing group, select it in the list pane, and then select **Edit** on the Action Pane.
    - To create a new group, select **New** on the Action Pane.

3. On the **General** FastTab, in the **Strict safety stock pegging** field, select one of the following options:

    - *No* – The system doesn't consider safety stock as actual demand, and it prioritizes any actual demand over safety stock. Although you can create a planned order to fulfill safety stock, any actual demand that arrives later can claim the planned safety stock quantity. (The actual demand is pegged against the planned order.) This option lets you provide a higher level of service for your customers.
    - *Yes* – The system applies strict safety stock pegging. Any planned order that you create to fulfill safety stock remains pegged against safety stock. If you select this option, whenever the system calculates that a planned order is needed to fulfill safety stock, the system prioritizes that safety stock over real demand. This option can provide better visibility in some scenarios, such as when you're using a large number of negative days.

> ⓘ **Important**
>
> When you enable strict safety stock pegging, the system ignores pegging priority for safety stock planned orders. This behavior can lead to unreliable net requirements pegging and the creation of unwanted planned orders, because the safety stock demand is always prioritized regardless of any pegging priority rules you configured. Before you enable this option, carefully evaluate whether the trade-off between safety stock visibility and potential over-ordering is acceptable for your planning scenario. Learn more about how safety stock behavior differs between the deprecated master planning engine and Planning Optimization in Safety stock fulfillment with the deprecated master planning engine.

Use the safety stock journal to update minimum coverage for items

08/22/2025

Safety stock is an additional quantity of an item held in inventory to reduce the risk of it going out of stock. It acts as a buffer if sales orders arrive and the supplier can't meet the customer's requested ship date.

This article explains how to use the safety stock journal to calculate minimum coverage proposals from historical transactions and update item coverage with those proposals.

Overview of minimum coverage usage

Safety stock is set up on the **Item coverage** page for each item. Different types of replenishment are represented by different coverage codes. Learn more in Safety stock fulfillment for items. All coverage codes use the value set in the **Minimum** field on the **Item coverage** page for each item. There are two major approaches for using the **Minimum** field:

- **Minimum quantity for min/max purposes** – This approach uses the minimum quantity together with min/max logic. It applies when the **Coverage code** field is set to *Min/Max* for the relevant item or coverage group. The **Minimum** quantity represents the average daily usage multiplied by the item's lead time.
- **Minimum quantity for inventory plan purposes** – This approach uses the minimum quantity to represent an inventory plan in combination with demand forecasts. It applies when the **Coverage code** field is set to *Period* or *Requirement* for the relevant item or coverage group. The **Minimum** quantity represents an inventory plan that reflects the desired customer service level to help reduce stock-outs, partial shipments, and delivery lead times. The minimum quantity reflects a percentage of forecast accuracy for a given item. It doesn't represent a desired inventory position.

You can set the **Minimum** value in three ways:

- Manually on the **Item coverage** page.
- By the Data Management framework (*Item coverage* data entities).
- By the safety stock calculation done by safety stock journals.

Calculate minimum coverage based on historical usage

Safety stock journals calculate a proposed minimum quantity based on an item's historical usage, either for min/max or inventory planning purposes. Historical usage represents all issue transactions during a specified period. These issue transactions include sales order transactions and inventory adjustments. The calculations show the impact of the proposed minimum quantity on inventory value and its change compared to current minimum quantities.

Each safety stock journal line represents an item and its coverage dimensions. These journal lines are created and shown on the **Safety stock journal lines** page (**Master planning** > **Master planning** > **Run** > **Safety stock calculation**). The business process for using the safety stock journals to calculate the proposed minimum quantities is described later in this article.

The planner uses a safety stock journal to calculate proposed minimum quantities for selected items based on historical usage during specific periods. The proposed minimums can be manually overridden as required, and you can review the potential impact of the proposed minimums on inventory value. When the journal is posted, the associated minimum quantities in the item coverage are automatically updated.

Create a new safety stock journal name

Create at least one safety stock journal name before generating this type of journal. You might typically use several journal names to help separate your safety stock calculations.

1. Go to **Master planning** > **Setup** > **Safety stock journal names**.
2. On the Action Pane, select **New**.
3. On the new line, set the following fields:
    - **Name** – Enter a short name for the journal.
    - **Description** – Enter a description of the journal.
    - **Private for user group** – To limit the audience for the current journal name, select a user group.
    - **Delete lines after posting** – Select this checkbox to clean up journal lines by default as you post them. Clear it to keep all posted lines.

    The **Journal type** field is read-only and is preset to *Safety stock*.
4. Close the page.

Create a safety stock journal and lines

This step creates a journal and automatically adds lines to it. Each line identifies an item, its coverage dimensions, and several calculated quantities from the usage history. The calculated

quantities include average issues per item lead time, average issues per month, and the monthly standard deviation.

Automatically generate journal lines

You can automatically generate journal lines only if no lines exist for the current journal.

Use these steps to automatically generate journal lines.

1. Go to **Master planning** > **Master planning** > **Run** > **Safety stock calculation**.
2. On the Action Pane, select **New** to create a new safety stock journal.
3. On the **Journal header details** FastTab, set the following fields:

    - **Name** – Select the safety stock journal name to add the line to.
    - **Description** – The default value is the description of the journal name that you selected. However, you can edit the value as you require.
    - **Delete lines after posting** – Select this checkbox to clean up journal lines as you post them. Clear it to keep all posted lines. The setting is inherited from the selected journal name.

    The **Journal** field is read-only and shows the ID number of the journal that you're creating and adding lines to.
4. On the **Journal lines** FastTab toolbar, select **Create lines**.
5. In the **Create journal lines for proposed minimum inventory levels** dialog box, set the following fields:

    - **From date** – Select the start date of the period that issues should be included in the calculation for.
    - **To date** – Select the end date of the period that issues should be included in this calculation for. There must be at least two months between the start and end dates.
    - **Calculate standard deviation** – Set this option to *Yes* to calculate the standard deviation. You must set this option to *Yes* to use the **Use service level** option when you calculate the proposal (as described later in this article).
6. On the **Records to include** FastTab, you can set up filters and constraints to define which items are included. (For example, you can filter by **Coverage group** value.) Select **Filter** to open a standard query editor dialog box, where you can define selection criteria, sorting criteria, and joins. The fields work just as they do for other types of queries in Microsoft Dynamics 365 Supply Chain Management.

7. On the **Run in the background** FastTab, select whether to run the job in batch mode, and/or set up a recurrent schedule. The fields work just as they do for other types of background jobs in Supply Chain Management.

8. Select **OK**. Lines are created for the dimensions that have inventory transactions.

Manually add or remove journal lines

You can manually add and/or remove journal lines at any time (either after or instead of automatically generating lines). Use the following buttons on the toolbar of the **Journal lines** FastTab:

- **New** – Add a new line. Then enter a value in each column to define the product to calculate and apply new minimums for. Because proposed minimum calculations aren't available for manually added lines, no new **Calculated minimum quantity** values are shown for them. Therefore, you must manually enter the **New minimum quantity** values. However, you can still view the potential impact of the **New minimum quantity** value on inventory value and the potential change in inventory compared to the currently specified minimum.
- **Delete** – Delete the selected line.
- **Delete journal lines** – Delete all lines in the journal.

Calculate a proposal

This step calculates a proposed minimum for each journal line and the line's potential impact on inventory value. (The proposed minimum is shown as the **Calculated minimum quantity** value.) You can do the calculation multiple times, as you require. The calculation updates the **Calculated minimum quantity** value that is shown for all journal lines.

The calculations shown don't affect the actual minimum quantity values for each product until you select **Post** on the Action Pane. At that time, the **New minimum quantity** values will be applied to each product.

1. Go to **Master planning** > **Master planning** > **Run** > **Safety stock calculation**.

2. Open the journal to calculate a proposal for. Alternatively, create a new journal as described earlier in this article.

3. On the **Journal lines** FastTab, select **Calculate proposal** on the toolbar. (You don't have to select any lines.)

4. In the **Calculate proposal for minimum inventory level** dialog box, set the following fields:

- **Use average issue during lead time** – Select this option to generate **Calculated minimum quantity** values based on the average issue during the specified period. Then, in the **Multiplication factor** field, enter a value to adjust the result by as required. For example, enter *1.0* to use the exact calculated average or *1.1* to add an extra buffer of 10 percent.
- **Use service level** – Select this option to calculate a proposed minimum based on the desired service level. Then, in the **Service level** field, select your preferred service level.
- **Lead time margin** – Enter a value to extend the normal lead time by (for example, to allow for administration).
- **Use the calculated minimum quantity as the new minimum quantity** – Set this option to *Yes* to automatically copy values from the **Calculated minimum quantity** column to the **New minimum quantity** column for all lines after the calculation is completed. If you set this option to *No*, the **Current minimum quantity** value will be copied to the **New minimum quantity** column for all lines. You'll then have to manually edit the **New minimum quantity** values as required.

5. On the **Run in the background** FastTab, select whether to run the job in batch mode, and/or set up a recurrent schedule. The fields work just as they do for other types of background jobs in Supply Chain Management.

6. Select **OK**. The results of the calculation are shown in the **Calculated minimum quantity** column on the **Journal lines** FastTab. For now, the values are only proposed values that haven't yet been applied to your products.

Update minimum quantity

Select any line in a safety stock journal to manually override the value of its **New minimum quantity** field.

1. Go to **Master planning** > **Master planning** > **Run** > **Safety stock calculation**.
2. Open the journal to edit. Alternatively, create a new journal as described earlier.
3. On the **Journal lines** FastTab, find the line to adjust, and then edit the value in the **New minimum quantity** column. For example, you might set the **New minimum quantity** value so that it matches the **Calculated minimum quantity** value. If the **Calculated minimum quantity** value is *0* (zero), you can enter the desired future value.

Post the new minimum quantity and validate the result

Follow these steps to post the new minimum quantity and validate the result.

1. Go to **Master planning** > **Master planning** > **Run** > **Safety stock calculation**.

2. Open the journal to post new minimum quantities for. Alternatively, create a new journal as described earlier.

3. On the Action Pane, select **Post**.

4. In the **Post journal** dialog box, set the **Transfer all posting errors to a new journal** field as required. Then select **OK** to post the journal.

5. If you changed the **New minimum quantity** value for a line on the **Journal lines** FastTab, you can confirm the change by following these steps:
   a. For the line that you edited, select the link in the **Item number** column.
   b. In the **Product information** dialog box, select the link in the **Item number** field to open the related released product record.
   c. On the Action Pane, on the **Plan** tab, in the **Coverage** group, select **Item coverage**.
   d. Notice that the **Minimum** value for the site and warehouse that you adjusted by using the posted safety stock journal has now been updated to match your edit.

>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article provides information about how to manage planned orders. It describes how you can update the status of planned orders, firm them, and filter for planned orders that have the same status as a selected planned order.

You can manage planned orders from the **Master planning** workspace, the **Planned order** list, or the **Planned production orders**, **Planned purchase orders**, and **Planned transfer** lists.

Planned order status

You can use the **Status** field to help track your progress. The following values are used:

- When master planning generates planned orders, the planned orders have a status of *Unprocessed*.
- If you decide not to firm a planned order, you can give it a status of *Completed*.
- If you want to firm a planned order, you can change the status to *Approved*. Planned orders with *Approved* status are respected by master planning, so they aren't modified or deleted during a later master planning run. To achieve this, the planning logic copies the *Approved* planned orders from the old plan version to the new plan version during master planning.

Firming planned orders

When planned orders are firmed, real orders are created. These are also known as *released* or *open orders*. When a planned order is firmed, it's moved to the orders section of the relevant module.

You can select two firming options from the **Planned orders** page:

- **Firm** – Firms one or multiple selected planned orders.
- **Firm all** – Firms all planned orders in the filter. Using **Firm all** you don’t have to select the planned order, all planned orders within the filter ar firmed. This option can be useful if you're firming a high number of planned orders.

> **Note**
>
> You can track a planned order that was firmed from **Firming history** under **Planned orders form** > **View** > **Firming history**.

Parallelize firming

If you're planning to firm many orders at the same time, parallelizing the run can improve the run time or performance. This option is available when firming multiple planned orders with either **Firm** or **Firm all**. The following parameters are available:

- **Parallelize firming** – If *Yes*, the firming process is parallelized with the number of threads defined in **Number of threads**.
- **Number of threads** – Controls the number of threads used to parallelize the firming process. The parameter is only shown when **Parallelize firming** is set to *Yes*.

> **Note**
>
> The option for **Parallelize firming** is only shown when you have more than one planned order selected for firming.

View, manage, and approve planned orders

This article explains how to view, manage, and approve planned orders.

View and manage planned orders

You can view and manage planned orders on any planned orders list page. Go to one of the following places, depending on the type of planned orders that you want to work with:

- **Master planning** > **Workspaces** > **Master planning**
- **Master planning** > **Master planning** > **Planned orders**
- **Production control** > **Production orders** > **Planned production orders**
- **Procurement and sourcing** > **Purchase orders** > **Planned purchase orders**
- **Inventory management** > **Inbound orders** > **Planned transfers**
- **Inventory management** > **Outbound orders** > **Planned transfers**

View and edit the status of planned orders

Use the **Status** field of each planned order to track your progress or change how a planned order is processed. The following **Status** values are available:

- *Unprocessed* – When master planning generates planned orders, it assigns this status. Planned orders with this status are deleted during the next planning run.
- *Completed* – This status indicates that the planned order is completed. If you decide not to firm a planned order, you can manually change its status to *Completed*. The system treats the *Unprocessed* and *Completed* statuses in the same way.
- *Approved* – This status indicates that the planned order is approved for firming. If you want to firm a planned order, change its status to *Approved*. If you want to keep the edits that you made to a planned order, or if you're planning to firm a planned order, change its status to *Approved*. Planned orders with a status of *Approved* are considered fixed and expected supply by master planning. Therefore, they're not modified or deleted during later master planning runs. To achieve this behavior, the planning logic copies planned orders with a status of *Approved* from the old plan version to the new plan version during master planning. Planned orders with a status of *Approved* are considered supply only within the specific master plan.

To change the status of a single planned order, open any planned orders list page, open the order, and then follow one of these steps:

- On the **General** FastTab, change the value of the **Status** field.
- On the Action Pane, on the **Planned order** tab, in the **Process** group, select **Change status**.
- On the Action Pane, select **Approve** to mark the order as approved.

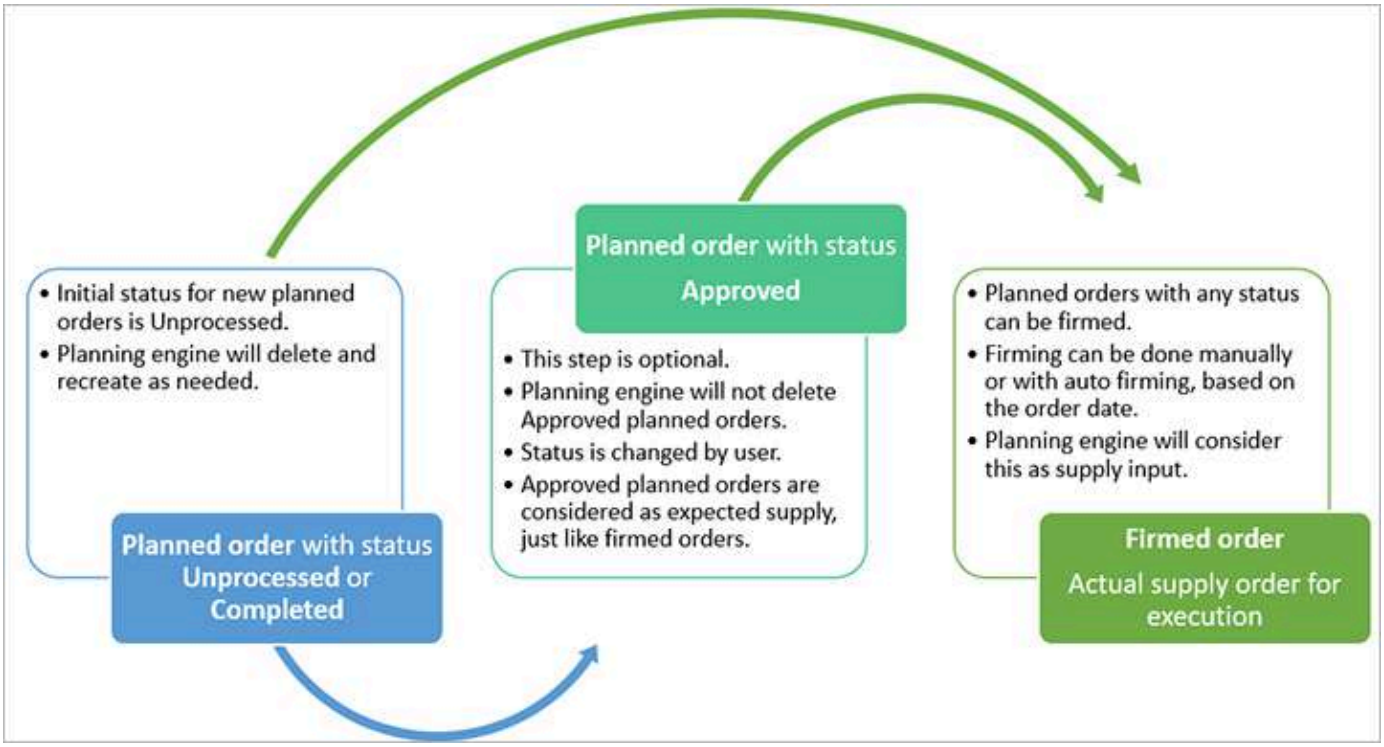
To change the status of several planned orders at the same time, open any planned orders list page, select the check box for each order that you want to change, and then follow one of these steps:

- On the Action Pane, on the **Planned order** tab, in the **Process** group, select **Change status**.
- On the Action Pane, select **Approve** to mark the orders as approved.

Approve planned orders

Approving planned orders is an optional step in the process of creating a firmed order from a planned order.

The following illustration shows how you can use the **Status** value that is assigned to each planned order to implement an approval workflow. To implement an approval process, manually adjust the **Status** value for each planned order as described in the previous section.



> **Tip**

We recommend that you approve all modified planned orders because the next planning run will ignore and overwrite all unapproved edits.

Avoid approving or editing planned orders during a planning run

The preceding text and illustration explain how approving planned orders prevents the system from ignoring and overwriting edits to those orders. However, an exception to this behavior might occur if you make changes to planned orders while the system is executing a full regenerative planning run.

This exception applies to all types of planned orders (production, purchase, and transfer) and can result in the system not preserving your changes, including split orders and field values (quantities, prices, dates, and so on). Even if you approve a planned order and therefore expect to find it after the next regenerative planning run, the order might not be available if you approved it in the middle of a planning run.

This exception occurs because, early in the planning run, the system creates a snapshot in the database during the data export stage. Then, at the end of the planning run, the system creates a new plan version, re-inserts the exported approved planned orders, and clears the previous plan version. As a result, if you approve planned orders or make changes to already approved planned orders during the exact period between the data export and re-insertion, the system overwrites those approved orders and ignores any changes to already approved planned orders. However, the demand still exists, and the planning run still considers it.

Tip

To completely avoid the risk of badly timed edits being ignored and overwritten, run master planning outside normal business hours.

Firm planned orders

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

As part of the master planning process, you must *firm* (release) planned orders. When you firm planned orders, they become actual purchase orders, transfer orders, or production orders. These orders are also known as *released orders* or *open orders*.

Use one of three methods to firm planned orders:

- **Manual firming** – Select specific planned orders in a list, and then manually start the process.
- **Auto-firming** – Define a default firming time fence for coverage groups, individual items, and combinations of items and master plans. Then, during master planning runs, the system automatically firms planned orders if the order date is within the specified time fence for firming.
- **Query-based firming** – Define a query to select planned orders based on their properties. You can set up a batch job to run the query and firm matching orders on a regular schedule.

This article describes each method in detail.

Manually firm planned orders

To manually firm planned orders, find and select the planned orders that you want to firm, and then manually start the firming process.

1. Open any planned orders list page.
2. Use the **Filter** field, **Plan** field, and column headings to filter and sort the list so that you can find the planned orders that you're looking for.
3. Select the check box for each planned order that you want to firm. If you want to firm all the planned orders that are currently listed on the page (based on the filters that you applied), skip this step.
4. On the Action Pane, select one of the following buttons:

- **Firm** – Firm only the selected planned orders.
- **Firm all** – Firm all the planned orders that are currently listed on the page (based on the filters that you applied), regardless of any check boxes that are selected. This option can be useful if you're firming many planned orders.

5. In the **Firming** dialog box, on the **Parameters** FastTab, set the following fields. (Many of these fields take their default values from the **Standard update** tab on the **Master planning parameters** page.)

   - **Update marking** – Select the inventory marking policy to use when planned orders are firmed.

   - **Stop firming if an error occurs** – Set this option to *Yes* to stop firming all selected planned orders if an error occurs in one of them. Set this option to *No* if the **Parallelize firming** option is set to *Yes*.

   - **Parallelize firming** – This option is available only if you select two or more planned orders for firming. Set it to *Yes* to run the firming processes in parallel. Parallel firming can help improve performance.

   - **Number of threads** – This option is available only if you set the **Parallelize firming** option to *Yes*. Enter the number of threads to use to parallelize the firming process. For advice about how to use this option in master planning, see Improve master planning performance.

     > ⓘ **Note**
     >
     > A value of *0* (zero) for the **Number of threads** field increases the running time of master planning. Therefore, always set this field to a value that's more than 0.

   - **Group by vendor** – Set this option to *Yes* to group planned purchase orders and create one purchase order per vendor during firming. Alternatively, you can create one purchase order that has one line for each planned order.

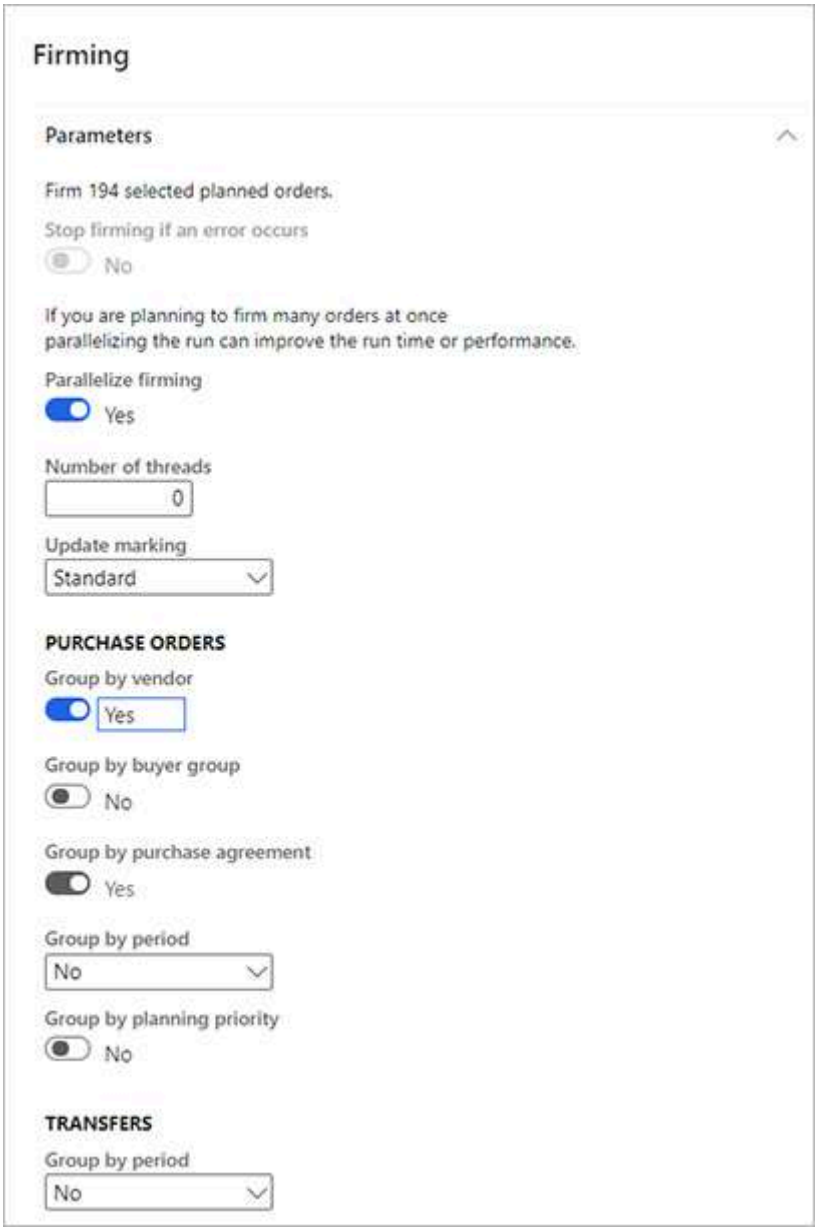
   - **Group by buyer group** – Set this option to *Yes* to group planned purchase orders and create one purchase order that combines the vendor and buyer group. To use this option, you must also set the **Group by vendor** option to *Yes*.

   - **Group by purchase agreement** – Set this option to *Yes* to group planned purchase orders that have the same vendor as existing purchase agreements and create one purchase order per purchase agreement. This option is automatically enabled when

Group by vendor is enabled. To use **Group by purchase agreement**, **Find purchase agreement** must be set to *Yes* on the **Master planning parameters** page.

- **Group by period** (in the **Purchase orders** section) – Select the period to group planned purchase orders by. To use this option, you must also select the **Group by vendor** option.
- **Group by period** (in the **Transfers** section) – Select the period to group planned transfer orders by. The orders are grouped based on **From warehouse** and **To warehouse** values.

> **Note**
>
> Each of the "Group by" options causes the system to convert each planned order to a line in the single purchase order that results from the grouping.



6. On the **Run in the background** FastTab, set up the job so that it runs in batch mode. However, it doesn't make sense to set up a recurrent schedule when you're doing manual firming. The fields work just as they work for other types of background jobs in Supply Chain Management. However, for manual firming, the batch job processes only the currently selected planned orders. It doesn't process any orders that fit the filters that are currently applied on the page.

7. Select **OK** to apply your settings and generate the firmed orders.

Auto-firm planned orders

Automatic firming lets you firm planned orders as part of the master planning process. You can define a firming time fence for coverage groups, individual items, and combinations of items and master plans. Then, during master planning runs, the system automatically firms planned orders if the order date is within the specified time fence for firming. The system handles the order date (start date) differently based on whether the planned order was generated by Planning Optimization or by the deprecated planning engine.

> **Note**
>
> You can auto-firm planned purchase orders only for items that are associated with a vendor.
>
> If you turn on change tracking, derived orders (that is, subcontract purchase orders) that the system firms have a status of *In-review*.

Auto-firming with Planning Optimization vs. the deprecated master planning engine

You can use both Planning Optimization and the deprecated master planning engine to auto-firm planned orders. However, some important differences exist. For example, Planning Optimization uses the order date (that is, the start date) to determine which planned orders to firm, whereas the deprecated master planning engine uses the requirement date (that is, the end date). The following table summarizes the differences.

Expand table

Feature	Planning Optimization	Deprecated master planning engine
Date basis	Auto-firming is based on the order date (start date).	Auto-firming is based on the requirement date (end date).

Feature	Planning Optimization	Deprecated master planning engine
Lead time	Because the order date (start date) triggers the firming, you don't have to consider the lead time as part of the firming time fence.	To help guarantee that the system firms orders quickly, the firming time fence must be longer than the lead time.
Orders for the current week	To firm all orders that must start during the current week, the firming time fence must be one week.	To firm all orders that must start during the current week, the firming time fence must be the lead time plus one week.

Set up auto-firming and the firming time fence

Turn on auto-firming by assigning an automated firming time fence to the relevant coverage setup, as described later in this section. If you don't turn on auto-firming for any coverage setup, or if you start planning from a specific page, such as the **Net requirements** page for a released product, the auto-firming process is skipped.

Grouping and marking options for auto-firming take their values from the **Standard update** tab on the **Master planning parameters** page.

You define the auto-firming time fence by the number of days that you enter for the relevant coverage setup. You can turn on auto-firming and control the firming time fence in the following ways:

- To define the default firming time fence for a coverage group, go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**, and select a coverage group. Then, on the **Other** FastTab, in the **Automatic firming time fence (days)** field, enter the number of days.
- To overwrite the firming time fence that you defined for the coverage group for a specific item, go to **Product information management** > **Released products**. On the Action Pane, select **Plan**, and then select **Item coverage**. On the **General** tab, select **Override time fence**, and then, in the **Automatic firming time fence (days)** field, enter the number of days.
- To overwrite the firming time fence that you defined for the coverage group and item coverage for a specific master plan, go to **Master planning** > **Setup** > **Master plans**, and select a master plan. Then, on the **Time fence in days** FastTab, set the **Firming** option to *Yes*, and enter the number of days.

If you set all the previously mentioned time fences to *0* (zero), you effectively disable auto-firming for the relevant covered items.

Firm planned orders by using a query

Query-based firming lets you plan to firm based on criteria that you define in advance. Unlike auto-firming, query-based firming lets you automate firming for different subsets of orders at different points in time. Additionally, you can use either manual or automated operations to firm different types of planned orders. You can also preview which firmed orders are selected based on your settings. Therefore, you can confirm that the selection fits your expectations.

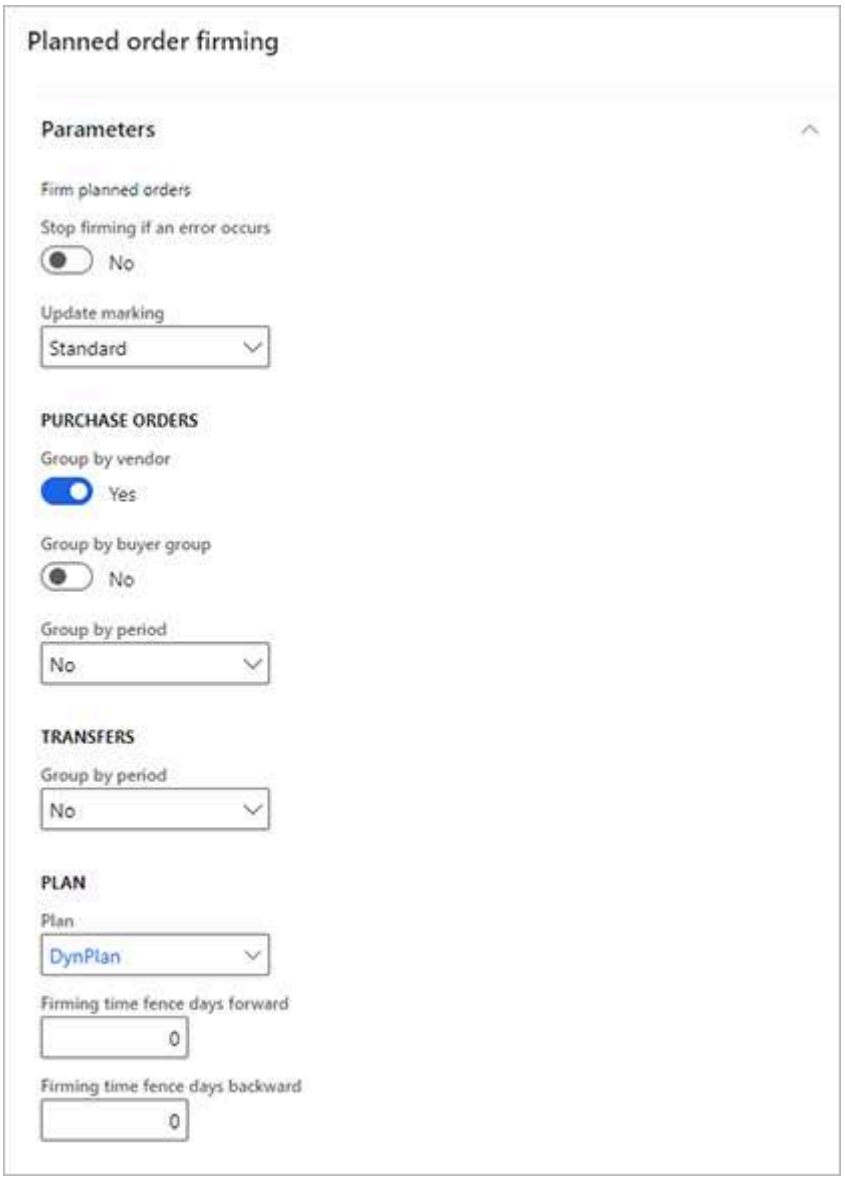
You can combine auto-firming with query-based firming. For example, a query-based firming job has a forward time fence that is longer than the time fence for a matching auto-firming coverage configuration. Therefore, the query-based firming job processes its planned orders before the auto-firming is triggered. You can take advantage of this behavior to schedule orders for specific vendors differently than orders for similar products from other vendors.

To firm a planned order by using the query-based firming process, follow these steps:

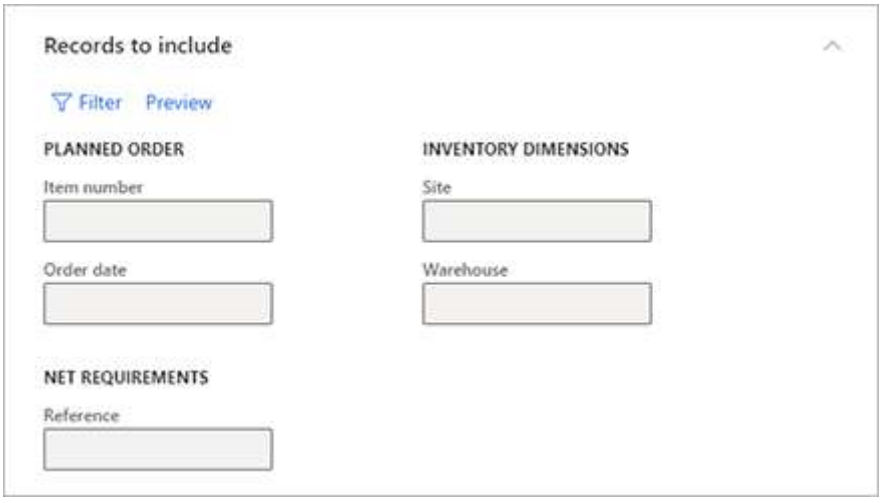
1. Go to **Master-planning** > **Master planning** > **Run** > **Planned order firming**.

2. In the **Planned order firming** dialog box, on the **Parameters** FastTab, set the basic processing, marking, and grouping options. These options work just as they do in the **Firming** dialog box. (See the previous section for descriptions.) Then, in the **Plan** section, set the following fields that are unique to the **Planned order firming** dialog box:

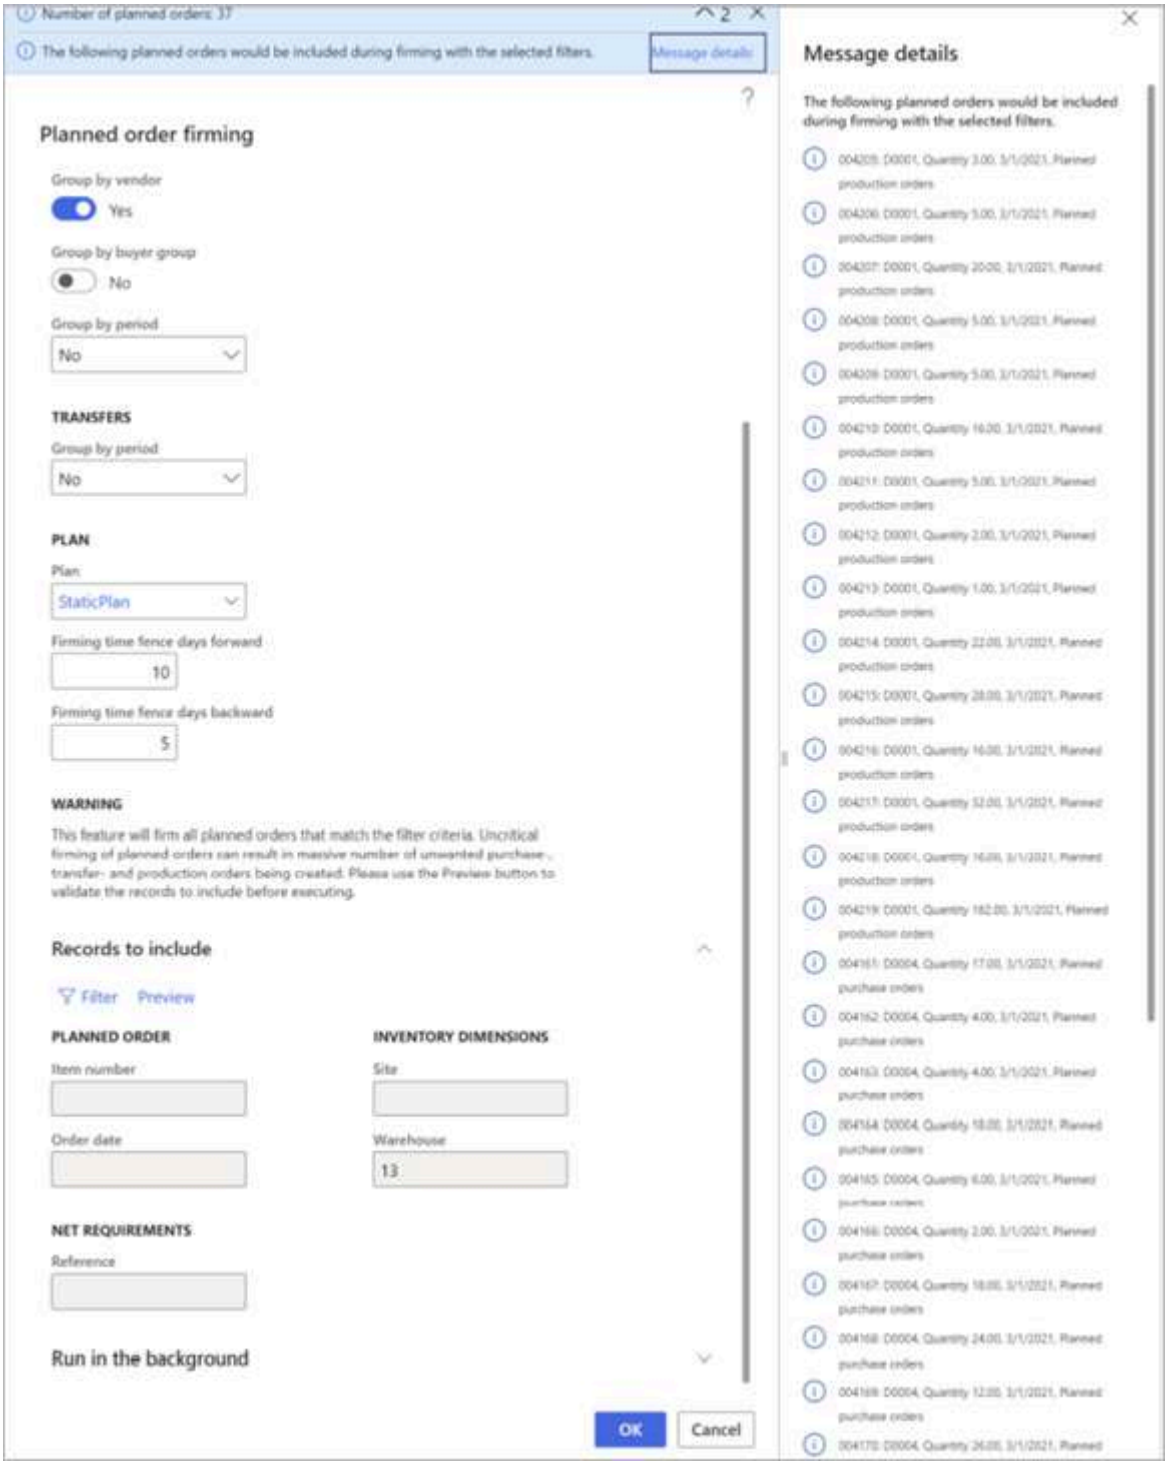
    - **Plan** – Select the master plan that should be applied during firming of the planned orders that this query finds.
    - **Firming time fence days forward** – Select how far in the future the various requirements and other considerations must be calculated by master planning.
    - **Firming time fence days backward** – Select how far in the past the various requirements and other considerations must be calculated by master planning.



3. To specify which records to include in the order, select the **Filter** button on the **Records to include** FastTab. A standard query dialog appears, where you can define selection criteria, sorting criteria, and joins. The fields work just as they do for other types of queries in Supply Chain Management. The fields are read-only and show values that are related to your query.



4. Select **Preview** to preview the content of your firmed order, based on your settings so far. The list of planned orders that the process firms is shown as a message. You can then adjust your settings as required until the preview shows the firmed order as you intend it.



> **⚠ Warning**
>
> This feature firms all planned orders that match the filter criteria. Uncritical firming of planned orders can cause massive numbers of unwanted purchase, transfer, and production orders to be created. Before you continue, always use the **Preview** button to validate the records that the process includes.

5. On the **Run in the background** FastTab, set up the job so that it runs in batch mode, and/or set up a recurrent schedule. The fields work just as they do for other types of background jobs in Supply Chain Management.

6. Select **OK** to apply your settings and generate the firmed orders.

Track firmed orders

To track planned orders that you firmed, go to **Master-planning** > **Inquiries and reports** > **Master planning** > **Firming history**.

> **Note**
>
> You can also access firming history from any of the planned order pages such as **Master-planning** > **Master planning** > **Planned orders**. The system creates firming history data for planned orders that you firm. Therefore, the firming history you see is unrelated to any planned order you select. The firming history you see is similar to the firming history you see when you access **Master-planning** > **Inquiries and reports** > **Master planning** > **Firming history**.

Planned orders simplified

10/03/2025

This article describes how you can view, manage, and firm planned orders by using the **Planned orders simplified** page.

The **Planned orders simplified** page is a simplified version of the **Planned orders** page. It provides fewer options but is faster to work with when all you have to do is review, approve, and firm your planned orders.

View, manage, and firm planned orders

The **Planned orders simplified** page is designed primarily for firming functionality. It shows all planned orders that have been generated for the selected plan, just as the standard **Planned orders** page does. Therefore, it can be used as an optimized alternative for viewing the results of a master planning run.

To open the **Planned orders simplified** page, go to **Master planning** > **Master planning** > **Planned orders simplified**. You can use this page to complete the following tasks:

- View all planned orders for a specific plan.
- Create new planned orders.
- Delete single or multiple planned orders.
- Firm single or multiple planned orders.
- Change the planned order status for single or multiple planned orders.
- Seamlessly open planned order details for an individual planned order to view full details of the order.
- Create custom views by using saved views.

Additional scenarios, such as split, are supported by the standard **Planned orders** page.

Action messages

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

An action message is a system-generated suggestion to change an existing planned, approved, or firmed order.

The master planning calculation generates action messages in response to changed requirements. For example, when you change the ship date or quantity on a sales order after you already create a purchase order to fulfill the demand for that sales order. In this case, the master planning calculation generates one or more action messages that suggest that you update the purchase order. You decide whether to make the suggested changes.

You can set up how action messages are calculated for a coverage group that you attach to an item.

> **Note**
>
> The system only creates action messages for unapproved planned orders while they're within the freeze time fence. Outside of the freeze time fence, the system only creates action messages for approved planned orders and firmed orders.

Select action messages

On the **Coverage groups** page, select the action messages that you want the system to generate, and the coverage groups or items that the messages apply to. The following table lists the action messages that you can select.

Expand table

Message	Description
Advance	The system generates action messages, as needed, to move orders to an earlier date. In the **Advance margin** field, specify the maximum number of days that can pass between a receipt and an issue without an advance action.

Message	Description
Postpone	The system generates action messages, as needed, to move orders to a later date. In the **Postpone margin** field, specify the maximum number of days that can pass between a receipt and an issue without a postpone action.
Decrease	The system generates action messages when production orders, purchase orders, and other receipt transactions should be decreased to prevent excess inventory levels.
Increase	The system generates action messages when production orders, purchase orders, and other receipt transactions should be increased to prevent shortages in inventory.
Derived actions	The system propagates action messages that it creates for receipt transactions to any derived requirements, and it generates the necessary action messages for the receipt transactions that satisfy those requirements.

The following sections provide a few detailed scenarios.

Increase and decrease actions with product default order quantities

On the **Default order settings** page for an item, you can set up a minimum order quantity, maximum order quantity, and multiple values. The system takes these settings into account when it suggests actions, to ensure that the suggestions never cause undersupply.

For example, you have an item that has the following settings on its **Default order settings** page:

- **Minimum order quantity:** *0*
- **Maximum order quantity:** *90*
- **Multiple:** *20*

If there's demand for a quantity of 60 of this item, master planning creates a planned purchase order for a quantity of 60. If you increase the demand by 30, master planning suggests an increase of 40, because it respects the multiple of 20 and never causes undersupply.

Action messages for orders related to safety stock

Action messages for orders that supply safety stock never suggest decreasing the quantity below the quantity that's needed for the safety stock. In other words, if there's an order that supplies safety stock and customer demand, and you decrease or cancel the demand, master planning suggests decreasing the planned order by the decreased demand. However, it never suggests a value that is lower than the safety stock that is needed.

The system doesn't suggest postponing actions for supplying safety stock, because it's assumed that the safety stock must be supplied at the required time and on the required date.

Advance and postpone actions related to BOMs

You must apply actions related to components of bills of material (BOMs) before the actions of their parent items. If you don't, further orders that are related to higher-level BOMs might be affected. Then, run master planning again to recalculate and suggest appropriate actions.

For example, consider the following situation:

- Final good *FG* of type *production* has a BOM that includes raw material *RM*.
- Today's date is January 21.
- An existing, released production order for *FG* is scheduled for January 25.
- To support the existing production order, master planning creates a planned purchase order for the required raw material *RM*. This order has a requirement date of January 25.
- A new sales order for *FG* is created today. It has a requirement date of today (January 21).
- January 21 is closed for delivery on the *RM* calendar, but January 22 is open.

When you run master planning, it generates advance action messages that suggest moving up the previously scheduled production so that you can fulfill today's order.

- To meet the new demand, it suggests moving the production order for *FG* up to January 21. (It makes this suggestion without considering the closed date for *RM*.)
- Because *RM* is still required for the production order, it suggests moving up the planned purchase order too. However, this time, it checks the *RM* calendar. Therefore, it suggests moving the planned purchase order for *RM* to January 22 (because January 21 is closed).

As you can see, the required raw material *RM* arrives too late for the scheduled production of *FG*. Therefore, you must first apply the advance action to the planned purchase order for *RM* and then run master planning again. At that point, master planning generates a new action message that suggests moving the production order for *FG* to January 22.

Inventory forecasts

08/22/2025

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the **Demand planning home page**.

This article describes how to view and create inventory forecasts. You can create and view supply and demand forecast lines for items, item groups, item allocation keys, customer accounts, customer groups, vendor accounts, and vendor groups.

For each forecast line, you can select the forecast model that is used. You can then specify the item or item group, plus the quantity or the transaction amount. You can also set up a time schedule for allocating the forecast quantity.

The supply and demand forecast lines produce an inventory forecast for the same combination of an item and a model. This inventory forecast represents a balance between the supply and demand that were entered for the same item. It can't be edited. The inventory forecast helps the inventory management team review expected changes to the on-hand inventory of an item during the upcoming period that has been forecasted.

After you enter your demand and/or supply, you can run forecast planning to calculate gross requirements for materials and capacity, and to generate planned orders.

View and manually enter forecast lines

Use this procedure to manually create forecast lines for products.

There are also other ways to create forecast lines:

- Generate a statistical baseline forecast.
- Import historical data for demand forecasts.
- Generate the forecast by using a Microsoft Azure Machine Learning web service.
- Import demand or supply forecast lines by using the data management framework (ForecastDemandForecastEntryStaging and ForecastSupplyForecastEntryStaging data entities).

As the table in step 1 shows, there are different ways to access the pages that are used.

1. Depending on the type of entity that you want to create a forecast for, and the type of forecast that you want to create, open a supply, demand, or inventory forecast page as described in the following table.

Expand table

Entity	Instructions
Released products	a. Go to **Product information management** > **Products** > **Released products**. b. Select the product to create a forecast for. c. On the Action Pane, on the **Plan** tab, in the **Forecast** group, select **Demand forecast**, **Supply forecast**, or **Inventory forecast**, depending on the type of forecast that you want to work with.
Released product variants	a. Go to **Product information management** > **Products** > **Released product variants**. b. Select the variant to create a forecast for. c. On the Action Pane, on the **Plan** tab, in the **Forecast** group, select **Demand forecast**, **Supply forecast**, or **Inventory forecast**, depending on the type of forecast that you want to work with.
Item groups	a. Go to **Inventory management** > **Setup** > **Inventory** > **Item groups**. b. Select the item group to create a forecast for. c. On the Action Pane, select **Forecasting** > **Demand**, **Forecasting** > **Supply**, or **Forecasting** > **Inventory forecast**, depending on the type of forecast that you want to work with.
Item allocation keys	a. Go to **Inventory management** > **Setup** > **Forecast**. b. Select the item allocation key to create a forecast for. c. On the Action Pane, select **Demand forecast**.
Customers	a. Go to **Master planning** > **Forecasting** > **Manual forecast entry** > **Customers**. b. Select the customer to create a forecast for. c. On the Action Pane, select **Define demand forecast**.
Customer groups	a. Go to **Master planning** > **Forecasting** > **Manual forecast entry** > **Customer groups**. b. Select the customer group to create a forecast for. c. On the Action Pane, select **Define demand forecast**.
Vendors	a. Go to **Master planning** > **Forecasting** > **Manual forecast entry** > **Vendors**. b. Select the vendor to create a forecast for. c. On the Action Pane, select **Entry** to open the **Supply forecast** page.
Vendor groups	a. Go to **Master planning** > **Forecasting** > **Manual forecast entry** > **Vendor groups**. b. Select the vendor group to create a forecast for. c. On the Action Pane, select **Entry** to open the **Supply forecast** page.

Entity	Instructions
All lines	• Go to **Master planning** > **Forecasting** > **Demand forecast lines** or **Master planning** > **Forecasting** > **Supply forecast lines**, depending on the type of forecast that you want to work with.

Depending on your selection, the **Supply forecast** or **Demand forecast** page appears. It shows any existing forecast lines for the record that you selected before you opened the page.

2. On the Action Pane, select **New** to add a forecast line to the grid in the upper part of the page.

3. On the new line, in the **Model** field, select the forecast model to use. Then enter other details as required, such as the item, item group, customer, or vendor account or group, item quantity, or total transaction amount. For complete details about the fields that are available on the **Supply forecast** and **Demand forecast** pages, see the later sections in this article.

4. To distribute the forecast over the period, on the **Overview** tab, select **Allocate forecast** on the toolbar.

5. In the **Allocation** grid, review the time horizon and the time intervals that are used to distribute the forecast quantities.

Supply forecast lines

The supply forecast lets you create a plan for items that must be purchased. It tells procurement and sourcing clerks what they're expected to order.

You can enter a supply forecast by item, item group, item allocation key, vendor, and vendor group. For information about all the ways to open the **Supply forecast** page for various entities and records, see the View and manually enter forecast lines section earlier in this article.

The upper part of the **Supply forecast** page provides a grid of supply forecast lines and a set of tabs that you can use to view and set more information about a selected forecast line. The lower part of the page provides an **Allocation** grid.

The following subsections describe all the fields that are available on each tab, and all the commands that are available on the page's Action Pane and on the toolbar on the **Overview** tab.

Action Pane commands on the Supply forecast page

The following table describes the commands that are available on the Action Pane of the **Supply forecast** page.

Expand table

Command	Description
Save	Save your current settings.
Edit	Enable settings on the page to be edited.
New	Add a forecast line to the upper grid.
Delete	Remove the selected forecast line from the upper grid.
Forecast balances	View forecast balances that have been calculated for the selected line's model ID for the current fiscal year. The balances are split by period (month).
Cash flow forecasts	View forecast transactions that have been allocated to the general ledger. Learn more in Cash flow forecasting.
Inventory > Display dimensions	Select the inventory dimensions that should be shown in the grid on the **Overview** tab.

Toolbar commands on the Overview tab of the Supply forecast page

The following table describes the commands that are available on the toolbar on the **Overview** tab of the **Supply forecast** page.

Expand table

Command	Description
Allocate forecast	If you're using an allocation method, generate the individual schedule lines for the forecast transaction. The line's quantity is then distributed by date (according to the selected time intervals), quantity, and amount for the whole time horizon. (See the Allocate forecast section later in this article.)
Bulk update	Open the **Edit forecast transactions** page. (See the Bulk update forecast transactions section later in this article.)
Inventory forecast	Open a view of the **Inventory forecast** page that is filtered for the selected item/model combination. (See the Inventory forecast section later in this article.)
Create item requirement	Open a dialog box where you can create item requirements, and sales order or item journal lines for project-related forecast transactions. Although this command is

Command	Description
	available for both supply forecast lines and demand forecast lines, it can't be used on the **Supply forecast** page.

The Overview tab on the Supply forecast page

The following table describes the fields on the **Overview** tab of the **Supply forecast** page.

Expand table

Field	Description
Model	The forecast model that the transaction is associated with.
Date	The start date of the transaction.
Vendor account	The vendor account that the transaction is associated with.
Vendor group	The vendor group that the transaction is associated with.
Item number	The identifier of the item.
Item group	The item group that the transaction is associated with.
Item allocation key	The item allocation key that is associated with the forecast.
CW quantity	The forecast quantity in the specified catch-weight unit.
CW unit	The catch-weight unit that the item is purchased in. The value is automatically retrieved from the item setup.
Quantity	The forecast quantity in the specified purchase unit.
Unit	The unit that the item is purchased in. The value is automatically retrieved from the item setup. However, you can modify it if unit conversions are set up.
Amount	The gross amount, minus discounts, that the forecast transaction contributes to the forecast.
Currency	The currency that is used for the forecast transaction. The default currency is automatically entered, but you can select a different currency.
(Other dimensions)	Additional dimensions can be shown as columns in the grid. To select the additional dimensions that are shown, select **Display dimensions** on the Action Pane.

The General tab on the Supply forecast page

The **General** tab shows more information about the line that is currently selected on the **Overview** tab. Some of this information is repeated from the **Overview** tab. The following table describes the fields that are unique to the **General** tab.

Expand table

Field	Description
Report	Set this option to *Yes* to include the transaction in reporting.
Comments	Enter any comments that you have about the forecast transaction.
Active	Select this checkbox to include the transaction in budget reporting.
Include in cash flow forecasts	Select this checkbox to allocate the forecast transaction to the general ledger. The setting of this checkbox can't be modified for reporting transactions.
Sales tax group	The tax group that is used to specify tax for the forecast transaction.
Item sales tax group	The item tax group that is used to specify tax for the forecast transaction.
Method	Select the method that is used to allocate the forecast transaction: • **None** – No allocation occurs. • **Period** – Forecast the same quantity for each period. If you select this value, specify a quantity in the **Per** field and a unit of time in the **Unit** field. • **Key** – Allocate the forecast according to the period allocation key that you specify in the **Period key** field. You can use this method when you want seasonal variation to be considered.
Per	Enter the number of time intervals into the future that the forecast extends. This field is available only if you select *Period* in the **Method** field. For example, you select *Period* in the **Method** field, enter *1* in the **Per** field, and select *Months* in the **Unit** field. In the **End** field, you specify an end date that extends one year into the future. In this case, one forecast line will be created for each month of the upcoming year, based on the item and quantity that are specified on the header line.
Unit	Select the unit of the time interval: *Days*, *Months*, or *Years*. Allocation then corresponds to the number of days, months, or years that you specify in the **Per** field.
Period key	Specify the period allocation key.
End	Specify the end date when you use the **Per** and **Unit** fields.

The Item tab on the Supply forecast page

The **Item** tab shows more item information about the line that is currently selected on the **Overview** tab.

The grid at the top of the **Item** tab repeats item information that is also shown on the **Overview** tab. In addition, it includes the **Unit price** field, which shows the purchase price for the number of units that is specified in the **Unit** field. The unit price is automatically retrieved from the item setup, but you can modify it.

The fields below the grid provide more item details. Some of this information is repeated from the **Overview** tab. The following table describes the fields that are unique to the **Item** tab.

Expand table

Field	Description
Price unit	The number of units that the purchase price applies to. The value is automatically retrieved from the Items table, but you can modify it.
Charges on purchases	Fixed charges on the purchase price. The charges are independent of the quantity.
Discount percentage	The discount as a percentage.
Discount amount	The discount as an amount per sales unit.
Gross amount	The amount when no discounts are applied.
Quantity	The transaction quantity in the item's inventory unit.
Sub-BOM	The bill of materials (BOM) number of a specific sub-BOM.
Subroute	The route number of a specific sub-route.

The Financial dimensions tab on the Supply forecast page

The **Financial dimensions** tab shows all the financial dimension values for the line that is currently selected on the **Overview** tab.

The Inventory dimensions tab on the Supply forecast page

The **Inventory dimensions** tab shows all the inventory dimension values for the line that is currently selected on the **Overview** tab.

The Allocation grid on the Supply forecast page

If you're using an item allocation key, or if you've entered an item forecast for one or more future periods, you can allocate the forecast by selecting **Allocate forecast** on the toolbar on the **Overview** tab. The quantity is then distributed in the manner that is indicated by the lines in the **Allocation** grid.

Demand forecast lines

The demand forecast lets you enter or generate demand for a customer. It helps sales and marketing clerks inform master planning clerks about the expected demand during the upcoming forecast period.

You can enter a demand forecast by item, item group, item allocation key, customer, and customer group. For information about all the ways to open the **Demand forecast** page for various entities and records, see the View and manually enter forecast lines section earlier in this article.

The upper part of the **Demand forecast** page provides a grid of demand forecast lines and a set of tabs that you can use to view and set more information about a selected forecast line. The lower part of the page provides an **Allocation** grid.

The following subsections describe all the fields that are available on each tab, and all the commands that are available on the page's Action Pane and on the toolbar on the **Overview** tab.

Action Pane commands on the Demand forecast page

The following table describes the commands that are available on the Action Pane of the **Demand forecast** page.

Expand table

Command	Description
Save	Save your current settings.
Edit	Enable settings on the page to be edited.
New	Add a forecast line to the upper grid.
Delete	Remove the selected forecast line from the upper grid.
Forecast balances	View forecast balances that have been calculated for the selected line's model ID for the current fiscal year. The balances are split by period (month).

Command	Description
Cash flow forecast	View forecast transactions that must be allocated to the general ledger. Learn more in Cash flow forecasting.
Display dimensions	Select the product, storage, and tracking dimensions that should be shown in the grid on the **Overview** tab.
General ledger preview	View the general ledger entries for the selected transaction.
Transfer quotation lines	Transfer quotation lines to the selected project.

Toolbar commands on the Overview tab of the Demand forecast page

The following table describes the commands that are available on the toolbar on the **Overview** tab of the **Demand forecast** page.

Expand table

Command	Description
Allocate forecast	If you're using an allocation method, generate the individual schedule lines for the forecast transaction. The line's quantity is then distributed by date (according to the selected time intervals), quantity, and amount for the whole time horizon. (See the Allocate forecast section later in this article.)
Bulk update	Open the **Edit forecast transactions** page. (See the Bulk update forecast transactions section later in this article.)
Inventory forecast	Open a view of the **Inventory forecast** page that is filtered for the selected item/model combination. (See the Inventory forecast section later in this article.)
Create item requirement	Open a dialog box where you can create item requirements, and sales order or item journal lines for project-related forecast transactions.

The Overview tab on the Demand forecast page

The following table describes the fields on the **Overview** tab of the **Demand forecast** page.

Expand table

Field	Description
Task name	The name of the batch task that was used to create the forecast line.
Model	The forecast model that the transaction is associated with.
Date	The start date of the transaction.
Customer account	The customer account that the transaction is associated with.
Customer group	The customer group that the transaction is associated with.
Item number	The identifier of the item.
Product name	The description of the item.
Item allocation key	The item allocation key that is used during inventory forecast allocation.
Sales quantity	The transaction quantity in the specified sales unit.
Unit	The unit that the item is sold in.
Amount	The gross amount, excluding discounts, that the forecast transaction contributes to the forecast.
Sales price	The sales price for the number of units that is specified in the **Price unit** field. The value is retrieved from the item setup, but you can modify it.
Sales currency	The currency that is used for the forecast transaction. The default currency is automatically entered, but you can select a different currency.
CW quantity	The forecast quantity in the specified catch-weight unit.
CW unit	The catch-weight unit that the item is sold in. The value is automatically retrieved from the item setup.
(Other dimensions)	Additional product, storage, and tracking dimensions can be shown as columns in the grid. To select the additional dimensions that are shown, select **Display dimensions** on the Action Pane.

The General tab on the Demand forecast page

The **General** tab shows more information about the line that is currently selected on the **Overview** tab. Some of this information is repeated from the **Overview** tab. The following table describes the fields that are unique to the **General** tab.

Expand table

Field	Description
Demand forecast sequence number	The unique number of the demand forecast line. This number is generated by using the number sequence that is selected for demand forecasts on the **Master planning parameters** page.
Item group	The item group that the transaction is associated with.
Report	Set this option to *Yes* to include the transaction in reporting.
Comments	Enter any comments that you have about the forecast transaction.
Active	Select this checkbox to include the transaction in budget reporting. The setting of this checkbox can't be modified for reporting transactions.
Include in cash flow forecasts	Select this checkbox to allocate the forecast transaction to the general ledger. The setting of this checkbox can't be modified for reporting transactions. Learn more in Cash flow forecasting.
Sales tax group	The tax group that is used to specify tax for the forecast transaction.
Item sales tax group	The item tax group that is used to specify tax for the forecast transaction.
Method	Select the method that is used to allocate the forecast transaction: • **None** – No allocation occurs. • **Period** – Forecast the same quantity for each period. If you select this value, specify a quantity in the **Per** field and a unit of time in the **Unit** field. • **Key** – Allocate the forecast according to the period allocation key that you specify in the **Period key** field. You can use this method when you want seasonal variation to be considered.
Per	Enter the number of time intervals into the future that the forecast extends. This field is available only if you select *Period* in the **Method** field. For example, you select *Period* in the **Method** field, enter *1* in the **Per** field, and select *Months* in the **Unit** field. In the **End** field, you specify an end date that extends one year into the future. In this case, one forecast line will be created for each month of the upcoming year, based on the item and quantity that are specified on the header line.
Unit	Select the unit of the time interval: *Days*, *Months*, or *Years*. Allocation then corresponds to the number of days, months, or years that you specify in the **Per** field.
Period key	Specify the period allocation key that is used to allocate the forecast. Learn more in Budget planning data allocation.
End	Specify the end date when you use the **Per** and **Unit** fields.

The Item tab on the Demand forecast page

The **Item** tab shows more item information about the line that is currently selected on the **Overview** tab. Some of this information is repeated from the **Overview** tab. The following table describes the fields that are unique to the **Item** tab.

Expand table

Field	Description
Price unit	The number of sales units that the sales price applies to. The value is automatically retrieved from the Items table, but you can modify it.
Sales charges	Fixed charges on the sales price. The charges are independent of the quantity.
Cost price	The cost for the current forecast transaction per inventory unit. The value is retrieved from the Items table, but you can modify it.
Discount percentage	The discount as a percentage.
Discount amount	The discount as an amount per sales unit.
Gross amount	The amount when no discounts are applied.
Inventory quantity	The transaction quantity in the item's inventory unit.
Use specific BOM	The BOM number of a specific BOM.
Use specific route	The route number of a specific sub-route.

The Project tab on the Demand forecast page

The **Project** tab shows more project information about the line that is currently selected on the **Overview** tab. Some of this information is repeated from the **Overview**, **General**, or **Item** tab. The following table describes the fields that are unique to the **Project** tab.

Expand table

Field	Description
Project date	The date of the demand forecast transaction.

Field	Description
Project ID	The identifier of the project that is referenced by the current transaction.
Funding source	The funding source that the demand forecast is associated with.
Activity number	The activity that is associated with the demand forecast transaction.
Category	The cost category of the current transaction.
Line property	The status that the transaction is attached to.
Transaction ID	The system identifier for the demand forecast transaction.
Cost amount	The amount of the demand forecast transaction.
Unit price	The price per unit.
Modified By	The identifier of the worker who last modified the selected transaction.
Invoice date	Enter the expected invoice date.
Elimination date	View or modify the elimination date. When the forecast is created, the elimination date is set to the end date of the project. If the project has no end date, the project date is applied. This field applies to fixed-price projects and investment projects.
Cost payment date	Enter the expected date of the purchase payment.
Sales payment date	Enter the expected date of the sales payment.

The Financial dimensions tab on the Demand forecast page

The **Financial dimensions** tab shows all the financial dimension values for the line that is currently selected on the **Overview** tab.

The Inventory dimensions tab on the Demand forecast page

The **Inventory dimensions** tab shows all the inventory dimension values for the line that is currently selected on the **Overview** tab.

The Allocation grid on the Demand forecast page

If you're using an item allocation key, or if you've entered an item forecast for one or more future periods, you can allocate the forecast by selecting **Allocate forecast** on the toolbar on the **Overview** tab. The quantity is then distributed in the manner that is indicated by the lines in the **Allocation** grid. (See the Allocate forecast section later in this article.)

Inventory forecast

The supply and demand forecast lines pages have an **Inventory forecast** button that opens a view of the **Inventory forecast** page that is filtered for the same item/model combination. The inventory forecast represents a balance between the supply and the demand that were entered for the same item. It can't be edited. The inventory forecast helps the inventory management team review expected changes to the on-hand inventory of an item during the upcoming period that has been forecasted.

The Action Pane on the Inventory forecast page

The following table describes the commands that are available on the Action Pane of the **Inventory forecast** page.

Expand table

Action	Description
Supply forecast	Open a view of the **Supply forecast** page that is filtered for the same item/model/date combination.
Demand forecast	Open a view of the **Demand forecast** page that is filtered for the same item/model/date combination.
Inventory > Display dimensions	Select the product, storage, and tracking dimensions that should be shown in the **Overview** grid.

The grid on the Inventory forecast page

The following table describes the fields in the grid on the **Inventory forecast** page.

Expand table

Field	Description
Model	The forecast model that the transaction is associated with.
Item number	The identifier of the item.

Field	Description
Budget date	The date of the forecast transaction.
Forecast type	The source of the transaction (*Demand forecast* or *Supply forecast*).
CW quantity	The forecast quantity in the catch-weight unit.
Quantity	The forecast quantity in the inventory unit.
CW Accumulated	The accumulated forecast quantity in the catch-weight unit when multiple forecast lines have been accumulated for the same item.
Sub-BOM	The BOM number of a specific sub-BOM.
Subroute	The route number of a specific sub-route.
(Other dimensions)	Additional dimensions can be shown as columns in the grid. To select the additional dimensions that are shown, select **Inventory** > **Display dimensions** on the Action Pane.

Allocate forecast

Use the following procedure to process selected forecast transaction lines. When you allocate a forecast, the quantity is then distributed as indicated by the lines in the **Allocation** grid.

1. Depending on the type of entity that you're creating a forecast for, and the type of forecast that you want to create, open a supply or demand forecast page as described in View and manually enter forecast lines.

2. On the supply or demand forecast lines page, select a forecast line, and then, on the **Overview** tab, select **Allocate forecast** on the toolbar.

3. In the **Allocate forecast** dialog box, set the fields that are described in the following table. (The value that you select in the **Method** field determines that other fields that are available.)

Expand table

Field	Description
Method	Select the method that is used to allocate the forecast transaction: • **None** – No allocation occurs. • **Period** – Forecast the same quantity for each period. If you select this value, specify a quantity in the **Per** field and a unit of time in the **Unit** field. • **Key** – Allocate the forecast according to the period allocation key that you specify in the **Period key** field. You can use this method when you want seasonal variations to be considered.
Per	Enter the number of time intervals into the future that the forecast extends. This field is available only if you select *Period* in the **Method** field. For example, you select *Period* in the **Method** field, enter *1* in the **Per** field, and select *Months* in the **Unit** field. Then, in the **End** field, you specify an end date one year into the future. In this case, one forecast line will be created for each month of the upcoming year, based on the item and quantity that are specified on the header line.
Unit	Select the unit of the time interval: *Days*, *Months*, or *Years*. Allocation then corresponds to the number of days, months, or years that you specify in the **Per** field.
Period key	Specify the period allocation key that is used to allocate the forecast. Learn more in Budget planning data allocation.
End	Specify the end date that applies to your settings in the **Per** and **Unit** fields.

4. Select **OK** to confirm your settings.
5. You can review the results on the **Allocation** tab for the same line.

Bulk update forecast transactions

Use this procedure to process existing forecast transaction lines. You can copy, edit, and delete forecast transaction lines.

1. On the supply or demand forecast lines page, select **Bulk update**.
2. In the dialog box, select **Filter**.
3. On the **Range** tab, select the criteria that identify the source forecast data that you want to copy, edit, or delete. This data might include the forecast model, item number, and customer account.
4. Select **OK** to confirm your selection.

After the data is selected, you can use the **Edit forecast transactions** dialog box to define how you want to copy, edit, or delete it.

> ⓘ **Note**
>
> The filtering step is a prerequisite for using the **Bulk edit** functionality. If you skip it, the program selects and updates **all** forecast lines. Therefore, you might unintentionally cause duplication or removal of transactions.

5. In the **Management** section, select whether you want to copy, update, or delete the selected forecast transactions.

6. Use the **Modifications in field** section to change the parameters of the forecast. Select the checkbox for a parameter, and then select among the available options. For example, select the **Model** checkbox, and then select a forecast model number. Existing forecast lines are copied to the selected forecast model.

7. Use the **Change of period** section to move the start and end dates of the forecast forward or backward. Select the checkbox, and then use the quantity and period fields to define how the forecast dates should be moved. You can enter a negative quantity to move the start date forward (that is, make it earlier).

   For example, to delay the forecast transaction start date by six months, select the checkbox, enter *6* as the quantity, and select *Months* as the period.

8. Use the **Correct field** section to update the actual forecast data. In the **Field** field, select the criterion that you want to change. In the **Factor** field, enter a multiplication factor to apply to the selected criterion, or enter a constant to add or subtract. For example, select *Quantity* as the criterion, and enter a factor of *1.5* to multiply the item quantity by 1.5. Alternatively, enter a constant of *-25* to decrease the item quantity by 25 units.

9. Use the **Financial dimensions** section to update the financial dimensions of forecast lines. Select the financial dimensions that you want to change, and then enter a value to apply to the selected dimensions.

10. Select **OK** to apply your changes.

Use forecasts with master planning

After you enter your demand forecast and/or supply forecast, you can include the forecasts during master planning to account for expected demand and/or supply in your master

planning run. When forecasts are included in master planning, gross requirements for materials and capacity are calculated, and planned orders are generated.

Set up a master plan to include an inventory forecast

To set up a master plan so that it includes an inventory forecast, follow these steps.

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**.
2. Select an existing plan, or create a new plan.
3. On the **General** FastTab, set the following fields:
    - **Forecast model** – Select the forecast model to apply. This model will be considered when a supply suggestion is generated for the current master plan.
    - **Include supply forecast** – Set this option to *Yes* to include the supply forecast in the current master plan. If you set it to *No*, supply forecast transactions won't be included in the master plan.
    - **Include demand forecast** – Set this option to *Yes* to include the demand forecast in the current master plan. If you set it to *No*, demand forecast transactions won't be included in the master plan.
    - **Method used to reduce forecast requirements** – Select the method that should be used to reduce forecast requirements. Learn more in Forecast reduction keys.
4. On the **Time fences in days** FastTab, you can set the following fields to specify the period that the forecast is included during:
    - **Forecast plan** – Set this option to *Yes* to override the forecast plan time fence that originates from the individual coverage groups. Set it to *No* to use the values from the individual coverage groups for the current master plan.
    - **Forecast time period** – If you set the **Forecast plan** option to *Yes*, specify the number of days (from today's date) that the demand forecast should be applied.

    > **Important**
    >
    > The **Forecast plan** option isn't supported with Planning Optimization.

Run a master plan that includes an inventory forecast

To run a master plan that includes an inventory forecast, follow these steps.

1. Go to **Master planning** > **Workspaces** > **Master planning**.

2. In the **Master plan** field, enter or select the master plan that you set up in the previous procedure.
3. On the **Master planning** tile, select **Run**.
4. In the **Master planning** dialog box, set the **Track processing time** option to *Yes*.
5. In the **Number of threads** field, enter a number.
6. On the **Records to include** FastTab, select **Filter**.
7. A standard query editor dialog box appears. On the **Range** tab, select the row where the **Field** field is set to *Item number*.
8. In the **Criteria** field, select the item number to include in the plan.
9. Select **OK**.

To view the requirements that are calculated, open the **Gross requirement** page. For example, on the **Released products** page, on the Action Pane, on the **Plan** tab, in the **Requirements** group, select **Gross requirement**.

To view the planned orders that are generated, go to **Master planning** > **Common** > **Planned orders**, and select the appropriate forecast plan.

Guide: Modify a demand forecast manually

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the Demand planning home page.

This procedure shows how to modify the forecast for an item. This procedure is intended for the production planner.

Modify the forecast for a selected item

To modify the forecast for a selected item:

1. Go to **Product information management** > **Products** > **Released products**.
2. In the list, find and select the desired record. Select the item for which you want to modify the forecast.
3. On the Action Pane, open the **Plan** tab and select **Demand forecast**.
4. In the list, select a row. If there are no forecast lines, create a new line by selecting **New** on the Action Pane.
5. In the **Sales quantity** field, enter a positive number. This number represents the forecasted quantity for the item. An error will be shown if you enter a negative number.
6. Fill out the other fields as needed.
7. Select **Save** on the Action Pane.

Modify the forecast for one or more items with Microsoft Excel

To modify the forecast for one or more items with Microsoft Excel:

1. Do one of the following:

    - Open the **Demand forecast** page for any item (it doesn't matter which one) as described in the previous section.
    - Go to **Master planning** > **Forecasting** > **Manual forecast entry** > **Demand forecast lines**.

2. On the Action Pane, select **Open in Microsoft Office** > **Demand forecast entries**.
3. Select a download location, save, and then open the downloaded file in Excel.
4. If you see a warning, choose to **Enable editing**.
5. In Excel, sign in to Supply Chain Management using the Microsoft Dynamics task pane. You must sign in with the **Keep me signed in** option enabled and you must trust the data connection app.
6. The Excel spreadsheet now shows all the current demand forecast lines for your company. Add, delete, and edit demand forecast lines as needed.
7. Select **Publish** on the Microsoft Dynamics task pane to upload your changes back to Supply Chain Management.

> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the Demand planning home page.

Use demand forecasting to predict independent demand from sales orders and dependent demand at any decoupling point for customer orders. The enhanced demand forecast reduction rules provide an ideal solution for mass customization.

To generate the baseline forecast, a summary of historical transactions is passed to Microsoft Azure Machine Learning hosted on Azure. Because this service isn't shared among users, you can easily customize it to meet industry-specific requirements. Use Supply Chain Management to visualize the forecast, adjust the forecast, and view key performance indicators (KPIs) about forecast accuracy.

> **Note**
>
> Microsoft Azure Machine Learning Studio (classic) is required for forecast generation with machine learning. As of December 1, 2021, you can't create new Machine Learning Studio (classic) resources. However, you can continue to use your existing Machine Learning Studio (classic) resources until August 31, 2024. For updated information, see Azure Machine Learning Studio.

Dynamics 365 Supply Chain Management version 10.0.23 and later support the new Azure Machine Learning Studio.

Key features of demand forecasting

Here are some of the main features of demand forecasting:

- Generate a statistical baseline forecast that's based on historical data.
- Use a dynamic set of forecast dimensions.
- Visualize demand trends, confidence intervals, and adjustments of the forecast.
- Authorize the adjusted forecast for use in planning processes.
- Remove outliers.
- Create measurements of forecast accuracy.

Major themes in demand forecasting

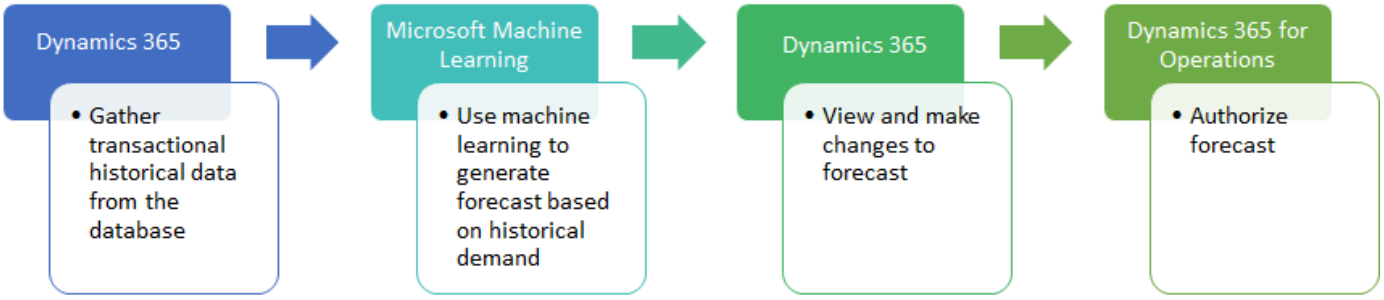
Demand forecasting implements three major themes:

- **Modularity** – Demand forecasting is modular and easy to configure. You can turn the functionality on and off by changing the configuration key at **Trade** > **Inventory forecast** > **Demand forecasting**.
- **Reuse of the Microsoft stack** – Machine Learning lets you quickly and easily create predictive analysis experiments, such as demand estimation experiments, by using algorithms R or Python programming languages and a simple drag-and-drop interface.
  - You can download the Demand forecasting experiments, change them to meet your business requirements, publish them as a web service on Azure, and use them to generate demand forecasts. You can download the experiments if you purchase a Supply Chain Management subscription for a production planner as enterprise-level user.
  - You can create your own experiments in Microsoft Azure Machine Learning studio (classic), publish them as services on Azure, and use them to generate demand forecasts.
  - If you don't require high performance, or if you don't require that a large amount of data be processed, you can use the Machine Learning free tier. Always start from this tier, especially during implementation and testing phases. If you require higher performance and additional storage, you can use the Machine Learning standard tier. This tier requires an Azure subscription and involves additional costs. For details about Machine Learning pricing, see Machine Learning Studio pricing .
- **Forecast reduction at any decoupling point** – Demand forecasting builds on this functionality, which lets you forecast both dependent and independent demand at any

decoupling point.

Basic flow in demand forecasting

The following diagram shows the basic flow in demand forecasting.



Demand forecast generation starts in Supply Chain Management. Historical transactional data from the Supply Chain Management transactional database is gathered and populates a staging table. This staging table is later fed to a Machine Learning service. By performing minimal customization, you can plug various data sources into the staging table. The data sources can include Microsoft Excel files, comma-separated value (CSV) files, and data from Microsoft Dynamics AX 2009 and Microsoft Dynamics AX 2012. Therefore, you can generate demand forecasts that consider historical data that is spread among multiple systems. However, the master data, such as item names and units of measure, must be the same across the various data sources.

If you use the Demand forecasting Machine Learning experiments, they look for a best fit among five time series forecasting methods to calculate a baseline forecast. The parameters for these forecasting methods are managed in Supply Chain Management.

The forecasts, historical data, and any changes that were made to the demand forecasts in previous iterations are then available in Supply Chain Management.

You can use Supply Chain Management to visualize and modify the baseline forecasts. Manual adjustments must be authorized before the forecasts can be used for planning.

Limitations

Demand forecasting is a tool that helps customers in the manufacturing industry create forecasting processes. It offers the core functionality of a demand forecasting solution and is designed so that it can easily be extended. Demand forecasting might not be the best fit for

customers in industries such as commerce, wholesale, warehousing, transportation, or other professional services.

Demand forecast variant conversion limitation

Unit of measure (UOM) per variant conversion isn't fully supported when generating demand forecast if inventory UOM is different from the demand forecast UOM.

Generating forecast (**Inventory UOM** > **Demand forecast UOM**) uses product UOM conversion. When loading historical data for the demand forecast generation, the product level UOM conversion is always used when converting from inventory UOM to the demand forecast UOM, even if there are conversions defined on the variant level.

The first part of authorizing forecast (**Demand forecast UOM** > **Inventory UOM**) uses product UOM conversion. The second part of authorizing forecast (**Inventory UOM** > **Sales UOM**) uses the variant UOM conversion. When the generated demand forecast is authorized, the conversion to inventory UOM from demand forecast UOM uses product level UOM conversion. At the same time, conversion between the inventory unit and the sales UOM respects the variant level defined conversions.

> **Note**
>
> The demand forecast UOM doesn't have to have any specific meaning. It can be defined as *Demand forecast unit*. For each of the products, you can define the conversion to be 1:1 with the inventory UOM.

Troubleshoot demand forecasting

If you experience issues with demand forecasting, review the following table for guidance on common tasks and scenarios before you contact support.

Demand forecasting setup

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the Demand planning home page.

This article describes how to set up demand forecasting.

Item allocation keys

Item allocation keys establish groups of items. The system calculates a demand forecast for an item and its dimensions only if the item is part of an item allocation key. This rule groups large numbers of items so that the system can create demand forecasts more quickly. The system creates forecasts based on historical data only.

An item and its dimensions must be part of only one item allocation key if you use the item allocation key during forecast creation.

To create item allocation keys and add a stock-keeping unit (SKU) to them, follow these steps:

1. Go to **Master planning** > **Setup** > **Demand forecasting** > **Item allocation keys**.
2. Either select an item allocation key in the list pane, or select **New** on the Action Pane to create a new one. On the header for the new or selected key, set the following fields:
    - **Item allocation key** – Enter a unique name for the key.

- **Name** – Enter a descriptive name for the key.

3. Follow one of these steps to add items to the selected item allocation key or remove items:

    - On the **Item allocation** FastTab, use the **New** and **Delete** buttons on the toolbar to add or remove items as needed. For each row, select the item number, and then assign dimension values in the other columns as you require. Select **Display dimensions** on the toolbar to change the set of dimension columns that is shown in the grid. (The value in the **Percent** column is ignored when demand forecasts are generated.)
    - If you want to add a large number of items to the key, select **Assign items** on the Action Pane to open a page where you can find and assign multiple items to the selected key.

> ⓘ **Important**
>
> Be careful to include only relevant items in each item allocation key. Unnecessary items might cause increased costs when you use Microsoft Azure Machine Learning.

Intercompany planning groups

Demand forecasting can generate cross-company forecasts. In Dynamics 365 Supply Chain Management, group companies that you plan together into the same intercompany planning group. To specify, per company, which item allocation keys to consider for demand forecasting, associate an item allocation key with the intercompany planning group member.

> ⓘ **Important**
>
> Planning Optimization doesn't currently support intercompany planning groups. To do intercompany planning that uses Planning Optimization, set up master planning batch jobs that include master plans for all the relevant companies.

To set up your intercompany planning groups, follow these steps:

1. Go to **Master planning** > **Setup** > **Intercompany planning groups**.

2. Either select a planning group in the list pane, or select **New** on the Action Pane to create a new one. On the header for the new or selected group, set the following fields:

    - **Name** – Enter a unique name for the planning group.

- **Description** – Enter a short description of the planning group.

3. On the **Intercompany planning group members** FastTab, use the buttons on the toolbar to add a row for each company (legal entity) that should be part of the group. For each row, set the following fields:

    - **Legal entity** – Select the name of a company (legal entity) that is a member of the selected group.
    - **Scheduling sequence** – Assign the order that the company should be processed in relative to other companies. Low values are processed first. This order can be important when demand for one company affects other companies. In these cases, the company that supplies the demand is processed last.
    - **Master plan** – Select the master plan to trigger for the current company.
    - **Automatic copy to static plan** – Select this checkbox to copy the result of the plan to the static plan.
    - **Automatic copy to dynamic plan** – Select this checkbox to copy the result of the plan to the dynamic plan.

4. By default, if you don't assign item allocation keys to intercompany planning group members, the system calculates a demand forecast for all items that are assigned to all item allocation keys from all companies. You can find additional filtering options for companies and item allocation keys in the **Generate statistical baseline forecast** dialog box (**Master planning** > **Forecasting** > **Demand forecasting** > **Generate statistical baseline forecast**). To assign item allocation keys to a company in the selected intercompany planning group, select the company, and then, on the **Intercompany planning group members** FastTab, select **Item allocation keys** on the toolbar.

Learn more in Intercompany planning groups for demand forecasting.

> **Important**
>
> Include only relevant item allocation keys in each intercompany planning group. Unnecessary items might cause increased costs when you use Azure Machine Learning.

Set up demand forecasting parameters

Use the **Demand forecasting parameters** page to set up options that control how demand forecasting works in your system.

Open the Demand forecasting parameters page

To set up demand forecasting parameters, go to **Master planning** > **Setup** > **Demand forecasting** > **Demand forecasting parameters**. Because demand forecasting runs cross-company, the setup is global. It applies to all legal entities (companies).

General settings

Use the **General** tab of the **Demand forecasting parameters** page to define general settings for demand forecasting.

Demand forecast unit

Demand forecasting generates the forecast in quantities. Therefore, you must specify the unit of measure for the quantity in the **Demand forecast unit** field. This field defines the unit that the system uses for all demand forecasts, regardless of the usual inventory units for each product. By using a consistent forecast unit, you help ensure that the aggregation and percentage distribution make sense. For more information about aggregation and percentage distribution, see Make manual adjustments to the baseline forecast.

For every unit of measure that you use for SKUs included in demand forecasting, make sure that there's a conversion rule for the unit of measure and the general forecasting unit of measure that you select here. When you generate a forecast, the system logs the list of items that don't have a unit of measure conversion. Therefore, you can easily correct the setup. For more information about units of measure and how to convert among them, see Manage units of measure.

Transaction types

Use the fields on the **Transaction types** FastTab to select the transaction types that the system uses when it generates the statistical baseline forecast.

You can use demand forecasting to forecast both dependent demand and independent demand. For example, if you set only the **Sales order** option to *Yes*, and all the items that you consider for demand forecasting are items that are sold, the system calculates independent demand. However, you can add critical subcomponents to item allocation keys and include them in demand forecasting. In this case, if you set the **Production line** option to *Yes*, the system calculates a dependent forecast.

You can override transaction types for one or more specific item allocation keys by using the **Item allocation keys** tab. That tab provides similar fields.

Choose how to create the baseline forecast

Use the **Forecast generation strategy** field to select the method that the system uses to create a baseline forecast. Three methods are available:

- *Copy over historical demand* – Create forecasts by just copying historical data.
- *Azure Machine Learning Service* – Use a forecast model that uses the Azure Machine Learning Service. The Azure Machine Learning Service is the current machine learning solution for Azure. Therefore, use it if you want to use a forecast model.
- *Azure Machine Learning* – Use a forecast model that uses Azure Machine Learning Studio (classic). Azure Machine Learning Studio (classic) is deprecated and will soon be removed from Azure. Therefore, select *Azure Machine Learning Service* if you're setting up demand forecasting for the first time. If you're currently using Azure Machine Learning Studio (classic), you should plan to switch to the Azure Machine Learning Service as soon as possible.

You can override the forecast generation method for one or more specific item allocation keys by using the **Item allocation keys** tab. That tab provides similar fields.

Override default forecast algorithm parameters globally

Default forecast algorithm parameters and values are assigned on the **Demand forecasting parameters** page (**Master Planning** > **Setup** > **Demand forecasting** > **Demand forecasting parameters**). However, you can override them globally by using the **Forecast algorithm parameters** FastTab on the **General** tab of the **Demand forecasting parameters** page. (You can also override them for specific allocation keys by using the **Item allocation keys** tab on the **Demand forecasting parameters** page.)

Use the **Add** and **Remove** buttons on the toolbar to establish the required collection of parameter overrides. For each parameter in the list, select a value in the **Name** field, and then enter an appropriate value in the **Value** field. All parameters that aren't listed here take their values from the settings on the **Demand forecasting parameters** page. For more information about how to use the standard set of parameters and select values for them, see the Default parameters and values for demand forecasting models section.

Set forecast dimensions

A forecast dimension shows the level of detail for the forecast. Company, site, and item allocation key are required forecast dimensions. You can also generate forecasts at the warehouse, inventory status, customer group, customer account, country/region, state, and item level, and at

all item dimension levels. Use the **Forecast dimensions** tab on the **Demand forecasting parameters** page to select the set of forecast dimensions that is used when the demand forecast is generated.

At any time, you can add forecast dimensions to the list of dimensions that are used for demand forecasting. You can also remove forecast dimensions from the list. However, manual adjustments are lost if you add or remove a forecast dimension.

Set up overrides for specific item allocation keys

Not all items work in the same way from a demand forecasting perspective. Therefore, you can establish allocation key–specific overrides for most of the settings available on the **General** tab. The exception is the demand forecast unit. To set up overrides for a specific item allocation key, follow these steps:

1. On the **Demand forecasting parameters** page, on the **Item allocation keys** tab, use the toolbar buttons to add item allocation keys to the grid on the left, or remove them, as you require. Then select the allocation key that you want to set up overrides for.
2. On the **Transaction types** FastTab, enable the types of transactions that you want to use to generate the statistical baseline forecast for products that belong to the selected allocation key. The settings work just as they work on the **General** tab, but they apply only to the selected item allocation key. All the settings here (both the *Yes* values and the *No* values) override all the **Transaction types** settings on the **General** tab.
3. On the **Forecast algorithm parameters** FastTab, select the forecast generation strategy and forecast algorithm parameter overrides for products that belong to the selected allocation key. These settings work just as they work on the **General** tab, but they apply only to the selected item allocation key. Use the **Add** and **Remove** buttons on the toolbar to define the required collection of parameter overrides. For each parameter in the list, select a value in the **Name** field, and then enter an appropriate value in the **Value** field. For more information about how to use the standard set of parameters and select values for them, see the Default parameters and values for demand forecasting models section.

Set up the connection to the Azure Machine Learning Service

Use the **Azure Machine Learning Service** tab to set up the connection to the Azure Machine Learning Service. This solution is one of the options for creating the baseline forecast. These settings on this tab take effect only when the **Forecast generation strategy** field is set to *Azure Machine Learning Service*.

For more information about how to set up the Azure Machine Learning Service and then use the settings here to connect to it, see the Set up the Azure Machine Learning Service section.

Set up the connection to Azure Machine Learning Studio (classic)

> **Important**
>
> Azure Machine Learning Studio (classic) is deprecated. Therefore, you can't create new workspaces for it in Azure. Azure Machine Learning Studio (classic) is replaced by the Azure Machine Learning service, which provides similar functionality and more. If you're not already using Azure Machine Learning, start using the Azure Machine Learning service. If you already have a workspace that you created for Azure Machine Learning Studio (classic), you can continue to use it until the feature is removed from Azure. However, update to the Azure Machine Learning service as soon as possible. Although the application continues to warn you that Azure Machine Learning Studio (classic) is deprecated, the forecasting result isn't affected. For more information about the new Azure Machine Learning service and how to set it up, go to the Set up the Azure Machine Learning Service section.
>
> You can freely switch between using the new and old machine learning solutions with Supply Chain Management for as long as your old Azure Machine Learning Studio (classic) workspace remains available.

If you already have an available Azure Machine Learning Studio (classic) workspace, you can use it to generate forecasts by connecting it to Supply Chain Management. You can establish this connection by using the **Azure Machine Learning** tab on the **Demand forecasting parameters** page. (The settings on this tab take effect only when the **Forecast generation strategy** field is set to *Azure Machine Learning*.) Enter the following details for your Azure Machine Learning Studio (classic) workspace:

- Web service application programming interface (API) key
- Web service endpoint URL
- Azure storage account name
- Azure storage account key

> **Note**

You need the Azure storage account name and key only if you use a custom storage account. If you deploy the on-premises version, you must have a custom storage account in Azure, so that Machine Learning can access the historical data.

Default parameters and values for demand forecasting models

When you use machine learning to generate your forecast planning models, you control machine learning options by setting values for *forecasting algorithm parameters*. Supply Chain Management sends these values to Azure Machine Learning. Use the **Forecasting algorithm parameters** page to control which types of values to provide and which values each should have.

To set up the default parameters and values for demand forecasting models, go to **Master Planning** > **Setup** > **Demand forecasting** > **Forecasting algorithm parameters**. A standard set of parameters is provided. Each parameter has the following fields:

- **Name** – The name of the parameter, as used by Azure. Usually, you shouldn't change this name unless you've customized the experiment in Azure Machine Learning.
- **Description** – A common name for the parameter. Use this name to identify the parameter in other places in the system (for example, on the **Demand forecasting parameters** page).
- **Value** – The default value for the parameter. The value that you enter depends on the parameter that you're editing.
- **Explanation** – A short description of the parameter and how to use it. This description typically includes advice about valid values for the **Value** field.

The following parameters are provided by default. (To revert to this standard list, select **Restore** on the Action Pane.)

- **Confidence level percentage** – A confidence interval consists of a range of values that act as good estimates for the demand forecast. A 95% confidence level percentage indicates there's a 5% risk that the future demand falls outside the confidence interval range.

- **Force seasonality** – Specifies whether to force the model to use a specific type of seasonality. This parameter applies to ARIMA and ETS only. Options: *AUTO (default)*, *NONE*, *ADDITIVE*, *MULTIPLICATIVE*.

- **Forecasting model** – Specifies which forecasting model to use. Options: *ARIMA*, *ETS*, *STL*, *ETS+ARIMA*, *ETS+STL*, *ALL*. To select the best-fit model, use *ALL*.

- **Maximum forecasted value** – Specifies the maximum value to use for predictions. Format: +1E[n] or numeric constant.
- **Minimum forecasted value** – Specifies the minimum value to use for predictions. Format: -1E[n] or numeric constant.
- **Missing value substitution** – Specifies how to fill gaps in historical data. Options: *(numeric value)*, *MEAN*, *PREVIOUS*, *INTERPOLATE LINEAR*, *INTERPOLATE POLYNOMIAL*.
- **Missing value substitution scope** – Specifies whether the value substitution applies only to the date range of each individual granularity attribute or to the entire dataset. The following options are available for establishing the date range that the system uses when filling in gaps in historical data:
  - *GLOBAL* – The system uses the full range of dates of all granularity attributes.
  - *HISTORY_DATE_RANGE* – The system uses a specific date range defined by **From date** and **To date** fields in the **Historical horizon** section in the **Generate statistical baseline forecast** dialog.
  - *GRANULARITY_ATTRIBUTE* – The system uses the date range of the currently processed granularity attribute.

  > ⓘ **Note**
  >
  > A granularity attribute is a combination of forecast dimensions against which the forecast is done. You can define forecast dimensions on the **Demand forecasting parameters** page.

- **Seasonality hint** – For seasonal data, provide a hint to the forecasting model to improve forecast accuracy. Format: integer number that represents the number of buckets that a demand pattern repeats itself for. For example, enter *6* for data that repeats itself every six months.
- **Test set size percentage** – Percentage of historical data to use as a test set for forecast accuracy calculation.

Override the values for these parameters by going to **Master Planning** > **Setup** > **Demand forecasting** > **Demand forecasting parameters**. On the **Demand forecasting parameters** page, you can override the parameters in the following ways:

- Use the **General** tab to override the parameters globally.

- Use the **Item allocation keys** tab to override the parameters for specific item allocation keys. Parameters that you override for a specific item allocation key affect only the forecast of items that are associated with that item allocation key.

> ⓘ Note
>
> On the **Forecasting algorithm parameters** page, use the buttons on the Action Pane to add parameters to the list or remove parameters from the list. However, don't use this approach unless you customize the experiment in Azure Machine Learning.

Set up the Azure Machine Learning Service

Supply Chain Management calculates demand forecasts by using the Azure Machine Learning Service. You must set up and run this service on your own Azure subscription. This section describes how to set up the Azure Machine Learning Service in Azure and then connect it to your Supply Chain Management environment.

Enable the Azure Machine Learning Service in Feature management

To use this feature, it must be turned on for your system. As of Supply Chain Management version 10.0.32, it's turned on by default. As of Supply Chain Management version 10.0.36, the feature is mandatory and can't be turned off. If you're running a version older than 10.0.36, then admins can turn this functionality on or off by searching for the *Azure Machine Learning Service for demand forecasting* feature in the Feature management workspace.

Set up machine learning in Azure

> ⓘ Important
>
> Azure Machine Learning SDK v1 (`azureml-core`) is retired, so the demand forecasting template is updated to use Azure Machine Learning SDK v2 (`azure-ai-ml`). Because the Supply Chain Management connector calls the Azure Machine Learning v1 published-pipeline REST contract, which SDK v2 doesn't expose, the updated template adds a small *relay* (an Azure Function) that receives those calls and submits the SDK v2 pipeline job. The `quick_setup.ps1` script provisions and deploys the relay for you. Setups that still use the v1

template continue to work, but switch to the updated template as soon as it's convenient. Learn more in **About the relay**.

To enable Azure to use machine learning to process your forecasts, you must set up an Azure Machine Learning workspace for this purpose. You have two options:

- To set up the workspace by running a script that Microsoft provides, follow the instructions in the Option 1: Run a script to automatically set up your machine learning workspace section, and then skip ahead to the Set up Azure Machine Learning Service connection parameters in Supply Chain Management section.
- To manually set up your workspace, follow the instructions in the Option 2: Manually set up your machine learning workspace section, and then skip ahead to the Set up Azure Machine Learning Service connection parameters in Supply Chain Management section. This option takes more time, but it gives you more control.

About the relay

The Supply Chain Management demand forecasting connector communicates with Azure Machine Learning through the v1 published-pipeline REST contract: it submits a run, polls the run status, cancels a run, and queries active runs. Azure Machine Learning SDK v2 doesn't expose that contract, so the updated template includes a *relay*—a lightweight Azure Function—that accepts those four calls and submits the equivalent SDK v2 pipeline job. Input and output data continue to flow through the *demplan-azureml* blob container, exactly as in the v1 template.

The relay authenticates each caller by validating the service principal's Microsoft Entra token, so that only your Supply Chain Management environment can trigger forecasts. The `quick_setup.ps1` script creates the Function app, assigns it a managed identity that has access to the workspace and storage account, configures it, and deploys the relay code. The **Pipeline endpoint address** that you enter in Supply Chain Management is the relay's URL, which the script prints when it finishes.

Option 1: Run a script to automatically set up your machine learning workspace

This section describes how to set up your machine learning workspace by using an automated script that Microsoft provides. The script provisions the Azure Machine Learning resources, creates the service principal, and provisions and deploys the relay. If you prefer, you can manually set up all the resources by following the instructions in the Option 2: Manually set up your machine learning workspace section. You don't have to complete both options.

The script requires the Azure CLI and the Azure CLI ml extension (v2).

1. On GitHub, open the Templates for Dynamics 365 Supply Chain Management demand forecasting with Azure Machine Learning repository (repo). Either clone the repo or download it as a .zip file, so that you have the complete folder structure, including these items:

   - `quick_setup.ps1`
   - `sampleInput.csv`
   - `src/parameters.py`
   - `src/api_trigger.py`
   - `src/run.py`
   - `src/REntryScript/entry.py`
   - `src/REntryScript/forecast_entry.r`
   - `src/REntryScript/forecast.r`
   - The `relay` folder

2. Open a PowerShell window in the root of the repo, and run the `quick_setup.ps1` script. Provide the parameters that are described in the following table. Follow the on-screen instructions, including the Azure sign-in prompt.

Expand table

Parameter	Description
`-subscriptionId`	The Azure subscription to create the resources in.
`-resourceGroupName`	The resource group to create or reuse.
`-location`	The Azure region. Select the region that matches your Supply Chain Management deployment.
`-storageAccountName`	The storage account that is dedicated to demand forecasting.
`-workspaceName`	The Azure Machine Learning workspace to create or reuse.
`-AADApplicationName`	The name of the Microsoft Entra application (service principal) to create or reuse.
`-functionAppName`	The name of the Azure Function app that hosts the relay.
`-functionStorageAccountName`	The storage account that the Function app uses for its runtime.
`-d365TenantId` (optional)	The tenant that the connector authenticates from. If you omit this

Parameter	Description
	parameter, the script uses the current tenant.
`-d365AppId` (optional)	The connector's service principal application ID. If you omit this parameter, the script uses the application that it created.

The script is idempotent. If you run it again, it reuses existing resources. It does the following work:

- Creates (or reuses) the workspace, the storage account, the *demplan-azureml* blob container, the *workspaceblobdemplan* datastore, a compute instance, and the *e2ecpucluster* compute cluster.
- Creates (or reuses) the Microsoft Entra application and service principal, and assigns it the Contributor role on the workspace and storage account, and the Storage Blob Data Contributor role on the storage account.
- Provisions the Function app for the relay, assigns it a managed identity that has the required roles, configures it, and deploys the relay code.

3. In the **Certificates & secrets** section of the Microsoft Entra application that the script created, create a client secret. For instructions, see Add a client secret. Make a note of the secret value. You'll enter it in Supply Chain Management later.

4. When the script finishes, it prints the demand forecasting parameters that you enter in Supply Chain Management, including the **Pipeline endpoint address** (the relay URL). Make a note of these values.

5. Your workspace and relay are now set up. Skip ahead to the Set up Azure Machine Learning Service connection parameters in Supply Chain Management section.

Option 2: Manually set up your machine learning workspace

This section describes how to manually set up your machine learning workspace. Complete the procedures in this section only if you decided not to run the automated setup script, as described in the Option 1: Run a script to set up your machine learning workspace section.

Step 1: Create a new workspace

Use the following procedure to create a new machine learning workspace.

1. Sign in to your Azure portal.

2. Open the **Machine learning** service.

3. Select **Create** on the toolbar to open the **Create** wizard.

4. Complete the wizard by following the on-screen instructions. Keep the following points in mind as you work:

    - Use default settings unless other points in this list recommend different settings.
    - Be sure to select the geographic region that matches the region where your instance of Supply Chain Management is deployed. Otherwise, some of your data might pass through region boundaries. Learn more in the privacy notice later in this article.
    - Use dedicated resources, such as resource groups, storage accounts, container registries, Azure Key Vaults, and networking resources.
    - On the **Set up Azure Machine Learning Service connection parameters** page of the wizard, you must provide a storage account name. Use an account that's dedicated to demand forecasting. Demand forecasting input and output data are stored in this storage account.

Learn more in Create the workspace.

Step 2: Configure storage

Use the following procedure to set up your storage.

1. On GitHub, open the Templates for Dynamics 365 Supply Chain Management demand forecasting with Azure Machine Learning repo, and download the `sampleInput.csv` file.
2. Open the storage account that you created in the Step 1: Create a new workspace section.
3. Follow the instructions in Create a container to create a container that's named *demplan-azureml*.
4. Upload the `sampleInput.csv` file that you downloaded in step 1 to the container that you just created. You need this file to publish the pipeline and generate a test forecast. For instructions, see Upload a block blob.

Step 3: Configure a default datastore

To set up your default datastore, follow these steps:

1. In Azure Machine Learning studio, select **Datastores** in the navigator.
2. Create a new datastore of the *Azure Blob Storage* type that points to the *demplan-azureml* Blob storage container that you created in the Step 2: Configure storage section. If the authentication type of the new datastore is *Account key*, provide an account key for the created storage account. For instructions, see Manage storage account access keys.

3. Make your new datastore the default datastore by opening its details and selecting **Set as default datastore**.

Step 4: Configure compute resources

To set up a compute resource in Azure Machine Learning studio to run your forecasting generation scripts, follow these steps:

1. Open the details page for the machine learning workspace that you created in the Step 1: Create a new workspace section. Find the **Studio web URL** value, and select the link to open it.

2. Select **Compute** on the navigation pane.

3. On the **Compute instances** tab, select **New** to open a wizard that helps you create a new compute instance. Follow the on-screen instructions. Use the default settings. The compute instance is used to create the demand forecasting pipeline. You can delete it after the pipeline is published.

4. On the **Compute clusters** tab, select **New** to open a wizard that helps you create a new compute cluster. Follow the on-screen instructions. The compute cluster generates demand forecasts. Its settings affect performance and the maximum level of parallelization of the run. Set the following fields, but use the default settings for all other fields:

    - **Name** – Enter *e2ecpucluster*.
    - **Virtual machine size** – Adjust this setting according to the volume of data that you expect to use as input for demand forecasting. The node count shouldn't exceed 11, because one node is required to trigger demand forecast generation and the maximum number of nodes that can then be used to generate a forecast is 10. You'll also set the node count in the `parameters.py` file in the Step 5: Deploy the relay section. On each node, several worker processes run forecasting scripts in parallel. The total number of worker processes in your job is *Number of cores that a node has* × *Node count*. For example, if your compute cluster has a type of *Standard_D4* (eight cores) and a maximum of 11 nodes, and if the `nodes_count` value is set to *10* in the `parameters.py` file, the effective level of parallelism is 80.

Step 5: Deploy the relay

In SDK v2, the connector reaches Azure Machine Learning through the relay instead of through a v1 published pipeline. Follow these steps to deploy the relay manually. These steps use the Azure CLI and the Azure CLI ml extension (v2).

> **Tip**
>
> The `quick_setup.ps1` script in **Option 1** does all of these steps for you. You can run it with the `-RelayOnly` switch to deploy only the relay against a workspace that you set up manually.

1. On GitHub, open the Templates for Dynamics 365 Supply Chain Management demand forecasting with Azure Machine Learning repo, and clone it or download it as a .zip file, so that you have the `src` and `relay` folders.

2. Open the `src/parameters.py` file. Make sure that the `nodes_count` value isn't greater than the number of nodes that you configured for the compute cluster in the Step 4: Configure compute resources section. If the `nodes_count` value is greater than the number of nodes that are available in the cluster, the run might be queued until more resources become available.

3. Create a storage account for the Function app's runtime. This account is separate from the demand forecasting storage account.

   Azure CLI

   ```
   az storage account create --name <functionStorageAccountName> --resource-group
   <resourceGroupName> --location <location> --sku Standard_LRS
   ```

4. Create a Linux Function app that runs Python 3.11 on a Consumption plan, and enable the remote build.

   Azure CLI

   ```
   az functionapp create --name <functionAppName> --resource-group
   <resourceGroupName> --storage-account <functionStorageAccountName> --consumption-
   plan-location <location> --os-type Linux --runtime python --runtime-version 3.11
   --functions-version 4
   az functionapp config appsettings set --name <functionAppName> --resource-group
   <resourceGroupName> --settings SCM_DO_BUILD_DURING_DEPLOYMENT=1
   ENABLE_ORYX_BUILD=true
   ```

5. Assign the Function app a system-assigned managed identity.

   Azure CLI

   ```
   az functionapp identity assign --name <functionAppName> --resource-group
   ```

```
<resourceGroupName>
```

Assign the returned principal ID the *Contributor* role on the Azure Machine Learning workspace, and the *Storage Blob Data Contributor* role on the demand forecasting storage account. For instructions, see Assign Azure roles using the Azure portal.

6. Configure the relay's app settings. Set `RELAY_EXPECTED_TENANT_ID` and `RELAY_EXPECTED_APP_ID` to the tenant ID and the service principal application ID from the Set up a new Microsoft Entra application section. The relay rejects any caller that doesn't present a token from this tenant and application.

Azure CLI

```
az functionapp config appsettings set --name <functionAppName> --resource-group
<resourceGroupName> --settings AML_SUBSCRIPTION_ID=<subscriptionId>
AML_RESOURCE_GROUP=<resourceGroupName> AML_WORKSPACE_NAME=<workspaceName>
RELAY_DATASTORE=workspaceblobdemplan RELAY_EXPECTED_TENANT_ID=<tenantId>
RELAY_EXPECTED_APP_ID=<servicePrincipalApplicationId>
```

7. Copy the `src` folder into the `relay` folder (the relay imports the pipeline builders from it), package the relay, and deploy it with a remote build.

PowerShell

```
Copy-Item .\src .\relay\src -Recurse -Force
Compress-Archive -Path .\relay\* -DestinationPath .\relay.zip -Force
az functionapp deployment source config-zip --name <functionAppName> --resource-
group <resourceGroupName> --src .\relay.zip --build-remote true
```

> **ⓘ Important**
>
> The `--build-remote true` option is required. Without it, the packages in `relay/requirements.txt` aren't installed, and the relay fails at runtime.

8. The relay is now deployed. Its pipeline endpoint address has the following form. You enter this URL as the **Pipeline endpoint address** in Supply Chain Management. Only the host is used by the connector; the path segments supply the subscription, resource group, and workspace.

text

```
https://<functionAppName>.azurewebsites.net/pipelines/v1.0/subscriptions/<subscri
ptionId>/resourceGroups/<resourceGroupName>/providers/Microsoft.MachineLearningSe
```

```
rvices/workspaces/<workspaceName>/PipelineRuns/PipelineEndpointSubmit/Id/relay
```

Set up a new Microsoft Entra application

> **Note**
>
> If you set up your workspace by running the script (Option 1), the script already created this Microsoft Entra application and assigned the required roles. In that case, you only need to create a client secret (step 5 in this section). Complete the other steps in this section only if you set up your workspace manually (Option 2).

To authenticate by using a service principal with the resources dedicated to demand forecasting, you need a Microsoft Entra application. Therefore, the application should have the lowest level of privilege that is required to generate the forecast.

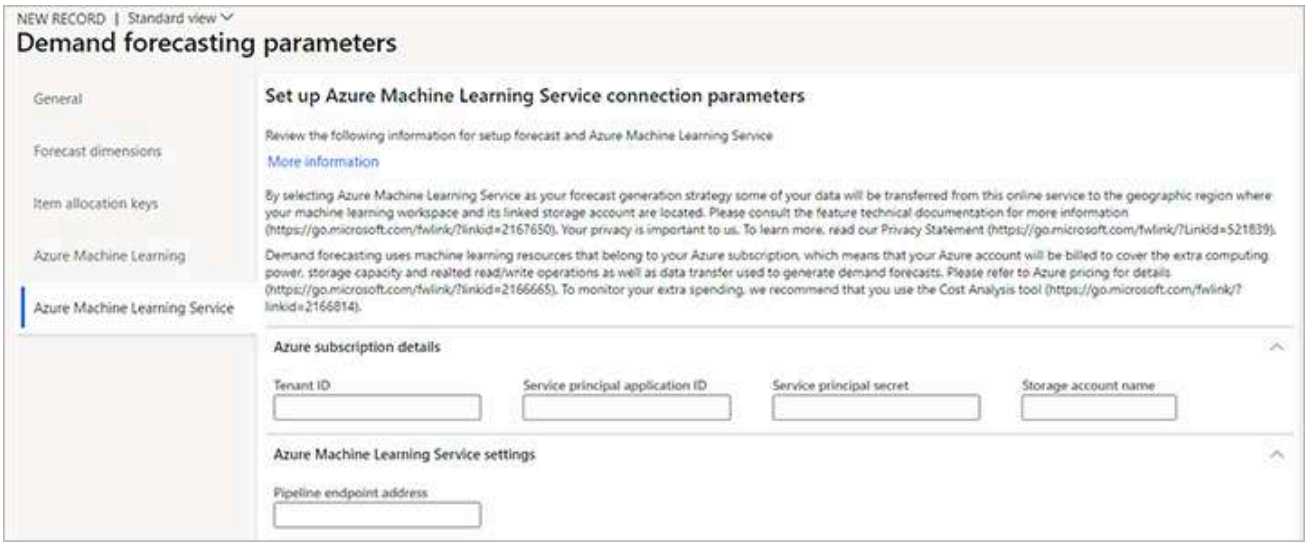
1. Sign in to your Azure portal.
2. Register a new application in the tenant's Microsoft Entra ID. For instructions, see Use the portal to create a Microsoft Entra application and service principal that can access resources.
3. Follow the on-screen instructions as you complete the wizard. Use the default settings.
4. Give your new Microsoft Entra application access to the following resources that you created in the Set up machine learning in Azure section. For instructions, see Assign Azure roles using the Azure portal. This step enables the system to import and export forecasting data, and to trigger machine learning pipeline runs from Supply Chain Management.
    - Contributor role to the machine learning workspace
    - Contributor role to the dedicated storage account
    - Storage Blob Data Contributor role to the dedicated storage account
5. In the **Certificates & secrets** section of the application that you created, create a secret for the application. For instructions, see Add a client secret.
6. Make a note of the application ID and its secret. You'll need the details of this application later, when you set up the **Demand forecasting parameters** page in Supply Chain Management.

Set up Azure Machine Learning Service connection parameters in Supply Chain Management

Use the following procedure to connect your Supply Chain Management environment to the machine learning service that you set up in Azure.

1. Sign in to Supply Chain Management.
2. Go to **Master planning** > **Setup** > **Demand forecasting** > **Demand forecasting parameters**.
3. On the **General** tab, make sure that the **Forecast generation strategy** field is set to *Azure Machine Learning Service*.
4. On the **Item allocation keys** tab, make sure that the **Forecast generation strategy** field is set to *Azure Machine Learning Service* for each allocation key that should use the Azure Machine Learning Service for demand forecasting.
5. On the **Azure Machine Learning Service** tab, set the following fields:

    - **Tenant ID** – Enter the ID for your Azure tenant. Supply Chain Management uses this ID to authenticate with the Azure Machine Learning Service. You can find your tenant ID on the **Overview** page for Microsoft Entra ID in the Azure portal.
    - **Service principal application ID** – Enter the application ID for the application that you created in the Active Directory Application section. Supply Chain Management uses this value to authorize API requests to Azure Machine Learning Service.
    - **Service principal secret** – Enter the service principal application secret for the application that you created in the Active Directory Application section. Supply Chain Management uses this value to acquire the access token for the security principal that you created to perform authorized operations against Azure Storage and the Azure Machine Language workspace.
    - **Storage account name** – Enter the Azure storage account name that you specified when you ran the setup wizard in your Azure workspace. (Learn more in the Set up machine learning in Azure section.)
    - **Pipeline endpoint address** – Enter the URL of the relay that you deployed when you set up machine learning in Azure. If you used the script (Option 1), this URL is the **Pipeline endpoint address** that the `quick_setup.ps1` script prints when it finishes. If you set up the relay manually (Option 2), construct the URL as described in the Step 5: Deploy the relay section.



Privacy notice

When you select *Azure Machine Learning Service* as your forecast generation strategy, Supply Chain Management automatically sends your customer data for historical demand, such as aggregated quantities, product names and their product dimensions, shipping and receiving locations, customer identifiers, and also forecast parameters, to the geographic region where your machine learning workspace and its linked storage account are located, for the purpose of forecasting future demands. The Azure Machine Learning Service might be in a different geographic region than the geographic region where Supply Chain Management is deployed. Some users can control whether this functionality is enabled by selecting the forecast generation strategy on the **Demand forecasting parameters** page.

Intercompany planning groups for demand forecasting

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the **Demand planning home page**.

This article describes how you can use intercompany planning groups during the demand forecasting process.

Collaboration is a vital aspect for many large-scale projects. When working with other legal entities (companies) during the development of a product or service, you can create intercompany planning groups to assist you during the demand forecasting process.

This gives all companies involved a greater understanding of the anticipated revenue that the product or service will generate. It also gives them the information necessary to devise and conduct business plans accordingly.

Many organizations utilize other companies within their organization to oversee various facets within collaborations and projects. Logistics operations that depend on other companies are handled by using intercompany sales and purchases since each legal entity has a separate chart of accounts.

Intercompany planning groups are created during the demand forecasting process after creating forecast models and removing outliers. For demand forecasts, set up downstream companies first, then set up upstream companies afterwards.

To further understand intercompany planning groups for demand forecasting, understand the following terms:

- **Demand forecast** – Allows your company to create "what if" scenarios and efficiently and cost-effectively plan for and meet demand. Accurate forecasts can make a critical difference in customer satisfaction levels about order promising dates and on-time delivery. Allows

businesses to predict future sales demand and use that data to drive certain business decisions.

- **Upstream** – A relative reference in a firm or supply chain. It indicates movement in the direction of the raw material supplier.
- **Downstream** – A relative reference in a firm or supply chain. It indicates movement in the direction of the customer.
- **Planned intercompany demand** – Planned demand for a product in a company, based on planned demand for the product from a downstream company.

A plan in one company can include planned intercompany demand that is related to orders from another company's plan. This capability is useful, because it provides full visibility into planned orders across companies. It also ensures that all required planned supply orders are created, but without requiring that planned orders be firmed for the intercompany demand.

To propagate the demand throughout the intercompany chain, you must set parameters to ensure that planned purchase orders are automatically firmed; that is, orders can't be changed in terms of time or quantity. Set up the **Firming time fence** on the coverage group, or the **Firming time fence** in the master plan.

If no **Firming time fence** is set up, no intercompany purchase orders are created automatically. Only the first execution of the master scheduling results in planned orders; however, because the intercompany purchase order is not actually created, no intercompany sales order is created, and, therefore, no additional intercompany purchase orders are created, and so on.

Generate a statistical baseline forecast

08/22/2025

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the **Demand planning home page**.

This article provides information about the parameters and filters that are used in the calculation of demand forecasting.

When you create a baseline forecast, you must first specify the parameters and filters that are used in the calculation. For example, you can create a baseline forecast that estimates demand based on transaction data from the past year for a specific company, for the coming month, and for a selected group of items.

To generate a demand forecast, go to **Master planning** > **Forecasting** > **Demand forecasting** > **Generate statistical baseline forecast**.

The forecast bucket can be selected at forecast generation time. The available values are Day, Week, and Month.

The number of buckets to generate a forecast for is set in the **Forecast horizon** field.

When the forecast strategy is set to **Copy over historical demand**, the end of the historical horizon is ignored. The system copies the number of buckets specified in the **Forecast horizon** field to the forecast demand, starting from the date set in the **From date** field under **Historical horizon**. By copying historical demand from a certain date forward, production planners can make the plan for the next quarter in two ways:

- By copying the demand from the same quarter last year.
- By copying the demand from the previous quarter.

To prevent confusion in the production plans, a certain number of forecast buckets can be frozen. This number is set in the **Freeze time fence** field. On the **Adjusted demand forecast** page, the cells for the frozen buckets are disabled, to give a visual indication that those values shouldn't be changed.

The start date for the baseline demand forecast doesn't have to be the current date or a date in the future. To set a different start date, use the **Baseline forecast start date - From date** field. For example, in June, users can generate a forecast for the next year. Because the forecast buckets between the end of historical demand and the start of the baseline are missing, the predictions might not be accurate. If you're using the Demand forecasting service, there are four ways in which you can fill in the missing gaps. You can choose the method that you want by setting the MISSING_VALUE_SUBSTITUTION parameter on the **Demand forecasting parameters** page.

> **Note**
>
> Missing value substitution only works for the gaps in data in between the start and end dates for historical data. It will not fill in data before or after the last physical data point, it only acts as extrapolation between actual existing data points.

The **Baseline forecast start date** - **From date** field has to be set to the beginning of a forecast bucket, for example, in the United States, a Sunday if the forecasting bucket is the week. The system automatically adjusts the **Baseline forecast start date** - **From date** field to match the beginning of a forecast bucket.

The **Baseline forecast start date** - **From date** field can be set to a date in the past. In other words, it's possible to generate a demand forecast in the past. This is useful, because it lets users adjust the forecast service parameters so that the statistical forecast generated in the past matches the actual historical demand. Users can then continue using these parameter settings to generate a statistical baseline forecast for the future.

Manual adjustments made in previous demand forecasting iterations can be automatically applied to the new baseline forecast if the **Transfer manual adjustments to the demand forecast** checkbox is selected. If the checkbox is cleared, the manual adjustments aren't added to the baseline forecast – but they aren't deleted. Manual adjustments made to a forecast can be deleted only at forecast import time, by clearing the **Save the manual adjustments made to the baseline demand forecast** checkbox. Manual adjustments are saved at authorization time. Therefore, if a user makes manual adjustments to the forecast, but doesn't authorize the forecast back to Supply Chain Management, the changes are lost. For more information about manual adjustments and how they work, see Authorize an adjusted forecast.

A demand forecast generation can have a name and comments to help users identify the forecast that was generated. These values are visible in forecast generation history on the **Statistical baseline forecast generation history** page.

The intercompany planning group, item allocation keys, and other filters can be applied at forecast generation time. These can be used to improve performance or to split the data into

manageable chunks. However, a demand forecast isn't generated for the members of any item allocation key that isn't associated with an intercompany planning group, even if the item allocation key is selected in the query.

> **Tip**
>
> Sometimes users might receive errors while generating a demand forecast, or forecast generation is completed with no session log. This can happen because of leftover data in the query that was previously used for forecast generation. To resolve this issue, select **Select** to open the **Query** page, select **Reset**, and then regenerate the baseline forecast.

If the forecast isn't generated for a large set of items, but, for example, for one item or one item allocation key at a time, then in order to get better performance, you can select the **Use request response mode** checkbox on the **Master planning - Setup - Demand forecasting - Demand forecasting parameters - Azure Machine Learning** tab.

> **Note**
>
> A potentially flat looking forecast can be due to the historical data that has to be of a longer historical timeframe (a minimum of three time periods in order to pick out patterns, such as three years with monthly forecast). To get a better result, you can try changing the granularity of the time range or increase the time range.

Make manual adjustments to the baseline forecast

10/03/2025

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the **Demand planning home page**.

This article explains how you can make manual adjustments to a baseline forecast and view details of the forecast.

Before you make manual adjustments, it's important that you understand a few concepts on various pages.

Grid on the Adjusted demand forecast page

The **Adjusted demand forecast** page includes a grid that has the following structure:

- The first column shows the items, item allocation keys, companies, and so on, that the forecast has been generated for. The subtitle of the page provides a description of the current forecast dimensions that are shown in the grid. For example, if the subtitle of the page is **Company / Site / Item allocation key**, and one of the row headers in the grid is **USMF / 1 / D_Alloc**, that row shows the forecast for the USMF company, site 1, and the **D_Alloc** item allocation key.
- Subsequent columns represent the forecast buckets that the forecast has been generated for. Each column header is the first date of the forecast bucket that the column shows.
- The values in the cells represent the forecast for one item, item allocation key, and so on, for that specific forecast bucket.

Forecast aggregation and de-aggregation

The subtitle of the page shows the level of forecast aggregation.

For example, if the subtitle of the page is **Company / Site / Allocation key / Item number / Color / Size / Configuration / Style**, there is no forecast aggregation, and the forecast is shown

at the level of the item and its dimensions. To change the aggregation, use the **Change forecast dimensions** page, which you can open from the application menu.

To modify the forecast, click in any of the cells that are available, and type the adjusted forecast value. The edited cell immediately becomes bold to indicate that the forecast that it shows isn't the forecast that the demand forecasting service created, but has been manually adjusted.

If you change the aggregation to make the page show more aggregated data, you can use the **Demand forecast lines** page to see the individual forecast lines that make up the aggregated forecast.

For example, you've generated the forecast at the item level, but you know that the demand for this item will increase across all sites because of a promotion or another similar event. In this case, you can set the aggregation to **Company / Item allocation key / Item** on the **Change forecast dimensions** page. You can adjust the global forecast for the item across all sites in the **Adjusted demand forecast** grid. To see the effect of your change across all sites, open the **Demand forecast lines** page. On this page, you will see one line for the item for each site, the adjusted forecast quantity, and the original forecast quantity.

When the adjustment of the forecasted quantity is made at an aggregated level, the system uses weighted allocation to distribute the change among the lines that create the aggregation.

You can also make manual adjustments on the **Demand forecast lines** page, by modifying either the **Total quantity** value or the **Quantity** cells in the de-aggregation grid.

Viewing details of the forecast

You can open the **Demand forecast details** page to view more information about the forecast.

The **Demand forecast details** page shows the following information in graphical and tabular formats:

- The historical demand that the forecast predictions are based on.
- The current forecast that is used by Master planning.
- The new demand forecast values and the amounts they have been manually adjusted by.
- The confidence interval for the forecasted values.
- The forecast model that was used to generate the forecast. If you're viewing aggregated data, you will see the list of all the methods that were used for all the aggregated time series.
- The internal model accuracy (MAPE). For more information about forecast accuracy, see Monitor forecast accuracy.

> **Note**

- The confidence interval that appears in the **Forecast** section of the page represents the difference between the confidence interval upper limit and the confidence interval lower limit. To see the values for the upper and lower limits, hover over the chart in the **Historical demand and forecast graphically** section.
- If you use the Demand forecasting Microsoft Azure Machine Learning, you can specify the confidence level percentage that the forecast that is generated should have. A confidence interval consists of a range of values that act as good estimates for the demand forecast. A 95-percent confidence level percentage indicates that there is a 5-percent risk that the demand forecast falls outside the confidence interval range.

You can also make manual adjustments to the forecast on the **Demand forecast details** page, by modifying the values in the **Forecast** row in the **Forecast** section.

Authorize an adjusted forecast

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the Demand planning home page.

Not all forecast data must be authorized immediately. This article explains how you can specify the period that a forecast is authorized for. It also explains how you can authorize the forecast for specific companies and forecast models.

Not all forecast data must be authorized immediately. You can specify the start and end dates of the period that the forecast is authorized for. This functionality lets you freeze specific buckets.

The start and end dates that you specify must correspond to the start and end dates of the bucket that the forecast is generated in. The system enforces this restriction and automatically adjusts the dates, if adjustment is required.

On the **Details** tab of the **Authorization** page, you can view details about the forecast that was most recently generated.

You can select the companies and the forecast models to authorize the forecast for use. By default, the grid includes all the companies that forecast demand has been created for. For each company, the forecast model that corresponds to the current forecast plan that is set up in the master planning parameters is prefilled. However, you can change this forecast model to any forecast model that belongs to that company. If no forecast demand data has been generated for a selected company, you receive a warning message at import time.

It's very important that you understand how the **Save the manual adjustments made to the baseline demand forecast** checkbox works. If you've made manual adjustments to the

statistical baseline forecast, the adjusted values are authorized for use, even if this checkbox is cleared. However, the changes are discarded after the authorization. Therefore, the next time that a forecast is generated, that forecast is only a statistical forecast and doesn't have any manual overrides, even if **Transfer manual adjustments to the demand forecast** is selected. Therefore, you can consider the **Save the manual adjustments made to the baseline demand forecast** checkbox a mechanism that lets you keep or discard all manual changes.

Import historical data for demand forecasts

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the Demand planning home page.

To help guarantee the accuracy of demand forecasts, you must have as much historical demand data as you can get per item or item allocation key. If the historical demand data isn't already imported, use the **Historical external demand** (ReqDemPlanHistoricalExternalDemandEntity) data entity in Dynamics 365 Supply Chain Management to import it.

In the **Data management** workspace, you can see an overview of all the fields in the entity.

1. Open the **Data management** workspace.
2. Select the **Data entities** tile.
3. Search the entity list for **Historical external demand**.
4. Select **Target fields**. The following entity fields are mandatory: site (**DeliveringSiteId**), date (**DemandDate**), quantity (**DemandQuantity**), and either item number (**ItemNumber**) or item allocation key (**ProductAllocationKeyId**).

To use the data entity, you must have a Microsoft Excel file or comma-separated values (CSV) file that contains the historical demand data. The following example shows how to import the data from a CSV file.

For more information about how to import data, including how to clean up data after an import, see Data import and export jobs overview and its related articles.

Learn more in Generate a statistical baseline forecast.

Remove outliers from historical transaction data when calculating a demand forecast

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the Demand planning home page.

This article describes how to exclude outliers from the historical data that is used to calculate a demand forecast. By excluding outliers, you can improve forecast accuracy.

You can exclude outliers to improve forecast accuracy. This is an optional task. Here is an overview of the process:

1. Go to **Master planning** > **Setup** > **Demand forecasting** > **Outlier removal** to open the **Outlier removal** page, where you can use a query to select the transactions to exclude.
2. Select the company that the query applies to, and then enter a name and description. The **Query date** field is automatically set to the current date.
3. Select the **Active** checkbox to exclude the transactions that the query finds from the historical data. This setting will take effect when you create a baseline forecast.
4. On the **Outlier removal query** page, you can add, remove, and select the criteria that define which transactions will be excluded when the baseline forecast is calculated. For example, select a specific item or order transaction to exclude.
5. Select **Display transactions**. The **Outlier transactions** page lists the transactions that meet the criteria that you defined in the query, and that will be excluded from the historical data when the demand forecast is calculated.

> **Note**

You can also create a query that is based on an existing query. Select the query to copy, and then select **Duplicate**. The **Query date** field identifies the version. You can use the query as it is, or you can select **Edit query** to modify the criteria. You can optionally modify the name and description of the new query.

Monitor forecast accuracy

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the Demand planning home page.

This article describes the types of forecast accuracy that Microsoft Dynamics 365 Supply Chain Management calculates, and explains how you can view the accuracy values.

Supply Chain Management calculates the following types of forecast accuracy:

- Historical forecast accuracy, by comparing the historical forecast that Master Planning uses with the historical demand. To view the values (both absolute values and percentage values) for historical forecast accuracy, select **Show accuracy** on the **Demand forecast details** page.
- The estimated accuracy of the forecasting model that is used to generate the predictions. You can view the accuracy percentage under **Model details - MAPE** on the **Demand forecast details** page.

> **Note**
>
> If you use the Demand forecasting Microsoft Azure Machine Learning, the calculation of internal model accuracy is based on the test data set. To specify the size of the test data set, set the **TEST_SET_SIZE_PERCENT** parameter on the **Demand forecasting parameters** page. For example, if you set the value to **20**, the last 20 percent of the historical data will be used to calculate the internal model accuracy.

Guide: Create a baseline forecast

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the Demand planning home page.

A production planner can create a baseline forecast either by using time series forecast models or by copying the historical demand. This procedure shows how to copy the historical demand to create a baseline forecast for all products using one item allocation key.

Set up an item allocation key

1. Go to **Master planning** > **Setup** > **Intercompany planning groups**.
2. Use the Quick Filter to find records. For example, filter on the *Name* field with a value of *10*.
    - Demand forecasting runs across legal entities. That's why you need to set up all the companies for which you want to generate forecasts in one intercompany planning group.
3. In the list, find and select the desired record.
4. Select **Item allocation keys**.
    - Select all the item allocation keys for which you want to create forecasts.
5. In the list, mark the selected row.
    - Select D_Aloc item allocation key.
6. Select >.

7. Close the page.
8. Close the page.

Set up the demand forecasting parameters

1. Go to **Master planning** > **Setup** > **Demand forecasting** > **Demand forecasting parameters**.
2. Expand the **Forecast algorithm parameters** section.
3. In the **Forecast generation strategy** field, select **Copy over historical demand**.
4. Select **Save**.

Create a baseline forecast

1. Go to **Master planning** > **Forecasting** > **Demand forecasting** > **Generate statistical baseline forecast**.
2. In the **From date** field, enter a date.

    - If you have sales orders starting from January 1, 2015, enter this date. If you don't, enter the earliest date of your sales orders.

3. In the **To date** field, enter a date.

    - Enter the last date of your sales orders, for example *2015-03-31*.

4. In the **From date** field, enter a date.

    - Enter *2015-04-01*. This date will be automatically calculated as the start date of the next forecasting bucket.

5. Expand the **Records to include** section.
6. Select **Filter**.
7. In the list, mark the selected row.

    - Mark the row where **Field** = *Intercompany planning group*.

8. In the **Criteria** field, type a value.

    - Type the intercompany planning group (for example, *10*) that you used in the first task.

9. In the list, find and select the desired record.

    - Select the row where **Field** = *Item allocation key*.

10. In the **Criteria** field, type a value.
11. Select **OK**.
12. Expand the **Advanced parameters** section.
13. In the **Forecast bucket** field, select *Month*.
14. In the **Forecast horizon** field, enter *3*.
15. In the **Freeze time fence** field, enter *1*.
16. Select **OK**.

Visualize the demand forecast

1. Go to **Master planning** > **Forecasting** > **Demand forecasting** > **Adjusted demand forecast**.
2. In the aggregated view table, select the cell in row 1, column 2. This is the second month for which you have created a forecast.
3. Set **QtyCell** to *400*.

    - In the cell, enter a different number than the one that was forecasted, for example, 400.

4. You have made a manual adjustment to the forecast. Notice the graphical indication in the next step.
5. Select **Forecast line details**.

    - In this page, you can see the accuracy values, historical demand, and forecast. You can make changes to the forecast as well.

> **Tip**
>
> This article describes demand forecasting functionality that's built into Microsoft Dynamics 365 Supply Chain Management. For an even better planning and forecasting experience, we recommend that you try *Demand planning in Microsoft Dynamics 365 Supply Chain Management*, which is Microsoft's next-generation collaborative demand planning solution. For details, see the Demand planning home page.

This article provides information about the different methods that you can use to reduce forecast requirements. It includes examples of the results of each method. It also explains how to create, set up, and use a forecast reduction key. Some methods use a forecast reduction key to reduce forecast requirements.

Methods to reduce forecast requirements

When you include a forecast in a master plan, you can select how the forecast requirements are reduced when actual demand is included. Master planning excludes forecast requirements from the past, which means all forecast requirements before today's date.

To include a forecast in a master plan and select the method to reduce forecast requirements, go to **Master planning** > **Setup** > **Plans** > **Master plans**. In the **Forecast model** field, select a forecast model. In the **Method used to reduce forecast requirements** field, select a method. The following options are available:

- *None*
- *Percent - reduction key*
- *Transactions - reduction key*
- *Transactions - dynamic period*

The following sections provide more information about each option.

None

If you select *None*, the forecast requirements aren't reduced during master scheduling. In this case, master planning creates planned orders to supply the forecasted demand (forecast requirements). These planned orders maintain the suggested quantity, regardless of other types of demand. For example, if sales orders are placed, master planning creates additional planned orders to supply the sales orders. The quantity of the forecast requirements isn't reduced.

Percent - reduction key

If you select *Percent - reduction key*, the system reduces the forecast requirements according to the percentages and periods that the reduction key defines. In this case, master planning creates planned orders where the quantity is calculated as forecasted quantity × reduction key in each period. If other types of demand exist, master planning also creates planned orders to supply that demand.

Example: Percent - reduction key

This example shows how a reduction key reduces demand forecast requirements according to the percentages and periods that the reduction key defines.

For this example, you include the following demand forecast in a master plan.

Expand table

Month	Demand forecast
January	1,000
February	1,000
March	1,000
April	1,000

On the **Reduction keys** page, you set up the following lines.

Expand table

Change	Unit	Percent
1	Month	100

Change	Unit	Percent
2	Month	75
3	Month	50
4	Month	25

You assign the reduction key to the item's coverage group. Then, on the **Master plans** page, in the **Method used to reduce forecast requirements** field, you select *Percent - reduction key*.

In this case, if you run forecast scheduling on January 1, the system consumes the demand forecast requirements according to the percentages that you set up on the **Reduction keys** page. The following requirement quantities are transferred to the master plan.

Expand table

Month	Planned order quantity	Calculation
January	0	= 0% × 1,000
February	250	= 25% × 1,000
March	500	= 50% × 1,000
April	750	= 75% × 1,000
May through December	1,000	= 100% × 1,000

Transactions - reduction key

If you set the **Method used to reduce forecast requirements** field to *Transactions - reduction key*, the system reduces the forecast requirements by the qualified demand transactions that occur during the periods defined by the reduction key.

The **Reduce forecast by** field on the **Coverage groups** page defines the qualified demand. If you set the **Reduce forecast by** field to *Orders*, only sales order transactions are considered qualified demand. If you set it to *All transactions*, any non-intercompany issue inventory transactions are considered qualified demand. If intercompany sales orders should also be considered qualified demand, set the **Include intercompany orders** option to *Yes*.

Forecast reduction starts with the first (earliest) demand forecast record in the reduction key period. If the quantity of qualified inventory transactions is more than the quantity of demand forecast lines in the same reduction key period, the balance of inventory transactions quantity doesn't reduce previous or future periods.

The value of the **Percent** field on the reduction key lines isn't used when the **Method used to reduce forecast requirements** field is set to *Transactions - reduction key*. Only the dates are used to define the reduction key period.

> **Note**
>
> The system ignores any forecast that you post on or before today's date and doesn't use it to create planned orders. For example, if you generate a demand forecast for the month on January 1, and you run master planning that includes demand forecasting on January 2, the calculation ignores the demand forecast line dated January 1.

Example: Transactions - reduction key

This example shows how actual orders that occur during the periods defined by the reduction key reduce demand forecast requirements.

For this example, you select *Transactions - reduction key* in the **Method used to reduce forecast requirements** field on the **Master plans** page.

The following sales orders exist on January 1.

Expand table

Month	Number of pieces ordered
January	956
February	1,176
March	451
April	119

If you use the same demand forecast of 1,000 pieces per month that was used in the previous example, the following requirement quantities are transferred to the master plan.

Expand table

Month	Number of pieces required
January	44
February	0
March	549

Month	Number of pieces required
April	881
May through December	1,000

Transactions - dynamic period

If you select *Transactions - dynamic period*, the system reduces the forecast requirements by the actual order transactions that occur during the dynamic period. The dynamic period covers the current forecast dates and ends at the start of the next forecast. In this case, master planning creates planned orders to supply the forecasted demand (forecast requirements). However, when actual order transactions are placed, the forecast requirements are reduced. The actual transactions consume part of the forecasted requirements.

When you use this option, the following behavior occurs:

- The system doesn't require or use reduction keys.
- If the forecast is completely reduced, the forecast requirements for the current forecast become 0 (zero).
- If there's no future forecast, the system reduces forecast requirements from the last forecast that you entered.
- The demand forecast reduction time fence isn't included in the forecast reduction calculation. Instead, the coverage group time fence is used for forecast reduction.
- Positive days are included in the forecast reduction calculation.
- If actual order transactions exceed the forecasted requirements, the system doesn't forward the remaining transactions to the next forecast period.

Example 1: Transactions - dynamic period

Here's a simple example that shows how the *Transactions - dynamic period* method works.

For this example, you include the following demand forecast in a master plan.

Expand table

Date	Demand forecast
January 1	1,000
February 1	1,000

You also create the following sales orders.

Expand table

Date	Sales order quantity
January 15	200
February 15	400

In this case, the system creates the following planned orders.

Expand table

Demand forecast date	Quantity	Explanation
January 1	800	Forecast requirements (= 1,000 – 200)
January 15	200	Sales orders requirements
February 1	600	Forecast requirements (= 1,000 – 400)
February 15	400	Sales orders requirements

Example 2: Transactions - dynamic period

In most cases, systems are set up so that transactions reduce demand forecasts in specific forecast periods: weeks, months, and so on. These periods are defined in the reduction key. However, the time between two demand forecast lines can also *imply* a period.

For this example, you create a demand forecast for the following dates and quantities.

Expand table

Date	Demand forecast
January 1	1,000
January 5	500
January 12	1,000

Notice that, in this forecast, there isn't a clear period between the forecast dates. Between the first and second dates there's a four-day span, and between the second and third dates there's a seven-day span. These spans are the dynamic periods.

You also create the following sales order lines.

Expand table

Date	Sales order quantity
December 15 in the previous year	500
January 3	100
January 10	200

In this case, the forecast is reduced in the following manner:

- The first sales order isn't in any period, so it doesn't reduce any forecast.
- The second sales order is between January 1 and January 5, so it reduces the forecast for January 1 by 100.
- The third sales order is between January 5 and January 12, so it reduces the forecast for January 5 by 200.

Therefore, the following planned orders are created.

Expand table

Demand forecast date	Quantity	Explanation
December 15 in the previous year	500	Sales order requirements
January 1	900	Forecast requirements period January 1 to January 5 (= 1,000 – 100)
January 3	100	Sales order requirements
January 5	300	Forecast requirements period January 5 to January 10 (= 500 – 200)
January 12	1,000	Forecast requirements period January 12 to end

Create and set up a forecast reduction key

Use a forecast reduction key with the *Transactions - reduction key* and *Percent - reduction key* methods to reduce forecast requirements. Follow these steps to create and set up a reduction key.

1. Go to **Master planning** > **Setup** > **Coverage** > **Reduction keys**.
2. Select **New** to create a reduction key.

3. In the **Reduction key** field, enter a unique identifier for the forecast reduction key. Then, in the **Name** field, enter a name.

4. Define the periods and the reduction key percentage in each period:

    - The **Effective date** field indicates the date when creation of the periods starts. When the **Use the effective date** option is set to *Yes*, the periods start on the effective date. When it's set to *No*, the periods start on the date when master planning is run.
    - Define the periods that the forecast reduction should occur during.
    - For a specific period, specify the percentages that the forecast requirements should be reduced by. Enter positive values to decrease requirements or negative values to increase requirements.

Use a reduction key

You must assign a forecast reduction key to the coverage group of the item. Follow these steps to assign a reduction key to an item's coverage group.

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.

2. On the **Other** FastTab, in the **Reduction key** field, select the reduction key to assign to the coverage group. The reduction key then applies to all items that belong to the coverage group.

3. To use a reduction key to calculate forecast reduction during master scheduling, you must define this setting in the setup of the forecast plan or the master plan. Go to one of the following locations:

    - **Master planning** > **Setup** > **Plans** > **Forecast plans**
    - **Master planning** > **Setup** > **Plans** > **Master plans**

4. On the **Forecast plans** or **Master plans** page, on the **General** FastTab, in the **Method used to reduce forecast requirements** field, select either *Percent - reduction key* or *Transactions - reduction key*.

Reduce a forecast by transactions

When you select *Transactions - reduction key* or *Transactions - dynamic period* as the method for reducing forecast requirements, you can specify which transactions reduce the forecast. On the **Coverage groups** page, on the **Other** FastTab, in the **Reduce forecast by** field, select **All transactions** if all transactions should reduce the forecast or **Orders** if only sales orders should reduce the forecast.

Demand Driven Material Requirements Planning (DDMRP) overview

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

For years, companies have used material requirements planning (MRP) as a system for calculating the materials and components that are required to manufacture a product. However, supply chains have changed. Parts have longer lead times because companies increasingly source them from overseas. Therefore, many companies experience stockouts or overstocks because they don't know how much inventory to stock. There's also more market fluctuation (sometimes inaccurately forecast), and customers are demanding products at a short lead time. Therefore, there are supply chain shortages all over the world. In addition, MRP tools often give planners thousands of actions to do. Therefore, it's hard to know what to focus on. Often, the solution to many of these issues is to switch to Demand Driven Material Requirements Planning (DDMRP).

DDMRP is a planning methodology that's based on the decoupling of supply and demand. You achieve this decoupling by setting up decoupling point items. For those items, you maintain buffers to ensure that you keep the correct amount of stock. The decoupling of supply and demand helps prevent the "bullwhip effect" because variability isn't passed through the chain. (The *bullwhip effect* refers to how small fluctuations in demand at the retail level can cause progressively larger fluctuations in demand at the wholesale, distributor, manufacturer, and raw material supplier levels.) Each buffer is intended to cover the average use of a part and can also be adjusted to cover demand spikes.

DDMRP is a valuable planning methodology for variable environments where customer tolerance times are shorter than cumulative lead times.

The five components of DDMRP

DDMRP has five sequential components (steps). The first three components essentially define the initial and evolving configuration of a demand-driven material requirements planning model. The last two components define the day-to-day operation of the methodology.

1. **Strategic inventory positioning** – Identify decoupling points in the supply chain network. Decoupling points are specific points of your supply chain where you put an inventory buffer that you monitor and replenish.
2. **Buffer profiles and levels** – For each decoupling point, identify the buffer sizes (minimum quantity, maximum quantity, and reorder point) and the reorder quantity.
3. **Dynamic buffer adjustments** – Adjust buffer levels, based on varying operating parameters or planned future events.
4. **Demand-driven planning** – Generate supply orders as they're required. These supply orders include manufacturing orders, purchase orders, and stock transfer orders.
5. **Highly collaborative and visible execution** – Run the supply orders with the help of visualization.

Manufacturers typically use DDMRP with a multilevel bill of materials (BOM). However, you can also apply it to distribution and retail networks.

DDMRP in Dynamics 365 Supply Chain Management

Microsoft Dynamics 365 Supply Chain Management includes DDMRP with no additional license fees. In Supply Chain Management, developers added DDMRP functionality to the existing **Master planning** module. However, it requires that you use the Planning Optimization Add-in.

DDMRP integrates with the existing planning setups in Supply Chain Management. Use it together with those setups to arrive at the correct planning configuration for your business. A new coverage code controls it. This code is completely different from period, min/max, requirement, and so on. DDMRP isn't a new module, and it doesn't replace existing planning functionality. However, it does give you more functionality to use.

Turn on the DDMRP feature for your system

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the **Request access to Finance and Operations Viva Engage Community** form and choose the community you want to join.

To use Demand Driven Material Requirements Planning (DDMRP) functionality, it must be enabled for your system. As of version 10.0.36, this feature is turned on by default. As of Supply Chain Management version 10.0.43, it's mandatory and can't be turned off. If you're running a version older than 10.0.43, then admins can turn this functionality on or off by searching for the *DDMRP for Planning Optimization* feature in the Feature management workspace.

Inventory positioning

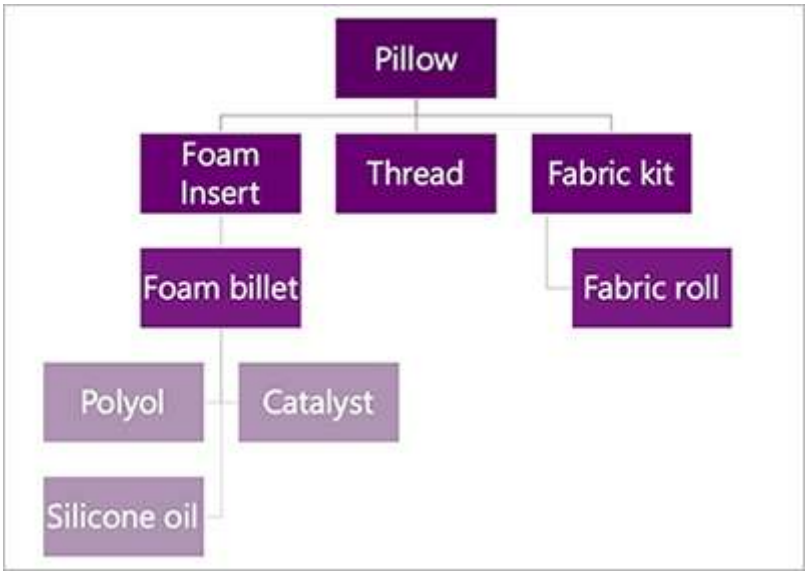
> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Strategic inventory positioning involves identifying decoupling points in your supply chain where you can build up on-hand inventory. Use this approach to help compress lead times and absorb shocks to your supply chain. It helps you mitigate the "bullwhip effect," because demand variability doesn't pass all the way down the supply chain. (The *bullwhip effect* refers to how small fluctuations in demand at the retail level can cause progressively larger fluctuations in demand at the wholesale, distributor, manufacturer, and raw material supplier levels.)

Inventory positioning is the first step of Demand Driven Materials Resource Planning (DDMRP).

Inventory positioning for manufacturing

This section provides an example that shows how to make inventory positioning decisions if you manufacture a typical pillow product. The pillow has a multilevel bill of materials (BOM), as shown in the following illustration.



Choose your decoupling points

When you choose where to put your decoupling points, consider all the following aspects of each item in the BOM as criteria:

- External variability
- Inventory leverage and flexibility
- Critical operation protection
- Customer tolerance time
- Sales order visibility horizon
- Market potential lead time

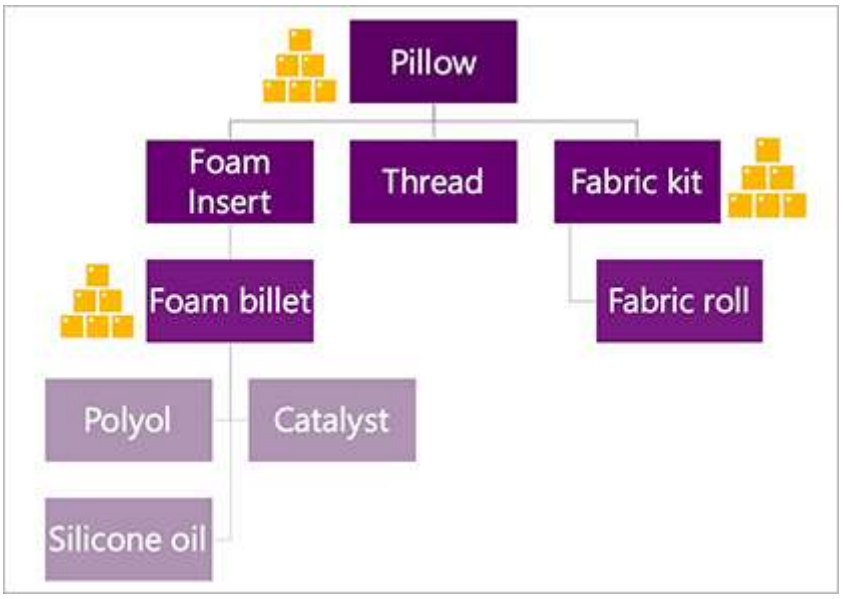
In the pillow example, you might put your first decoupling point at the *foam billets* for the following reasons:

- It's difficult to source the materials that are used to make the foam billets, and availability is volatile. Therefore, the *external variability* criterion is met.
- The foam billets can be cut into many different shapes and sizes to create foam inserts for other products that you manufacture, in addition to the pillow. Therefore, the *inventory leverage and flexibility* criterion is met.

You might then put your next decoupling point at the *fabric kit*, which is precut pillow fabric. You might choose this point because you have only one fabric cutting machine. Therefore, the *critical operation protection* criterion is met.

Finally, you might put your last decoupling point at the finished good pillow item. You might choose this point because you have a very low *customer tolerance time* on sales, and because your *sales order visibility horizon* is fairly short. Therefore, you want to ensure that you have the on-hand inventory to meet incoming orders. You can also set a higher price by keeping the lead time this short, which is what the *market potential lead time* criterion refers to.

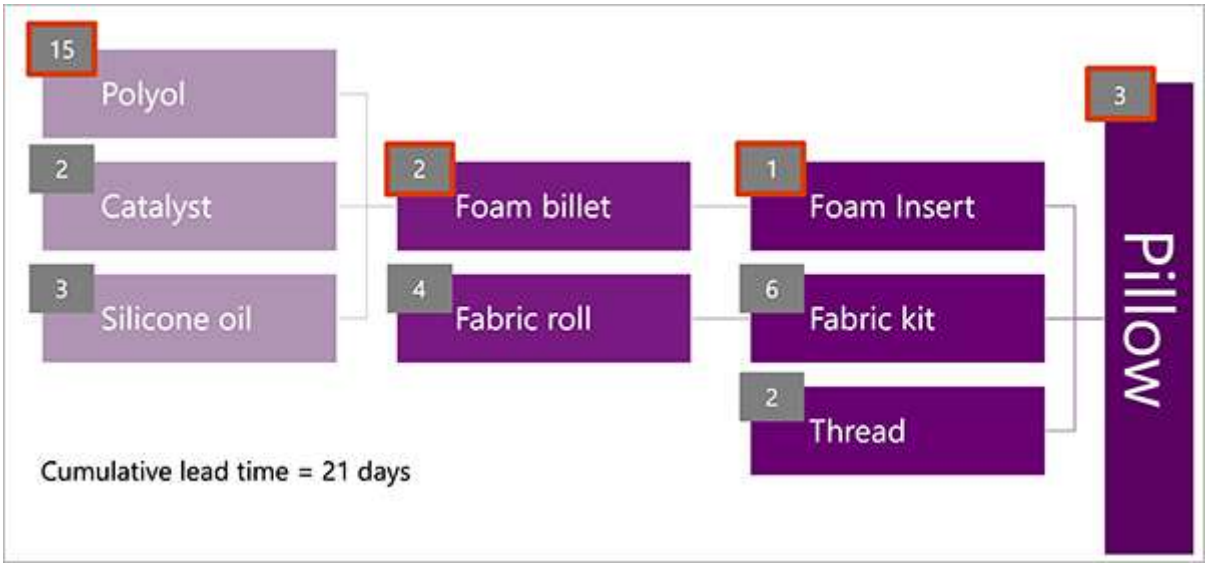
Based on this analysis, the following illustration shows what the pillow BOM looks like. Yellow inventory symbols highlight the decoupling points.



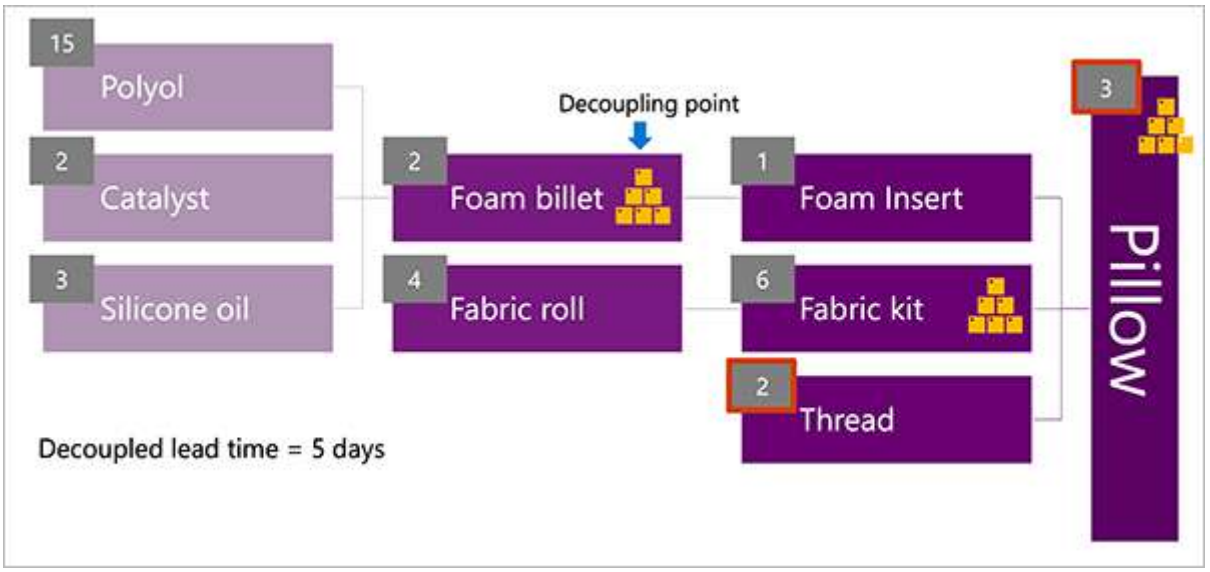
Calculate your decoupled lead time

This section shows how to calculate your new lead times after you introduce decoupling points.

In the following illustration for the pillow example that was started in the previous section, lead times appear in gray boxes at the upper left of each BOM component. Boxes that have a red outline indicate items that drive the cumulative lead time (the sum of the longest lead times at each level of the BOM). This lead time is 21 days when you start from scratch.



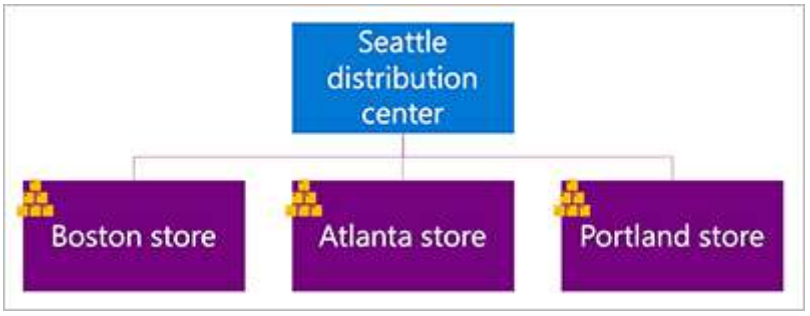
However, if you apply the decoupling points that you previously chose, the decoupled items are always in stock. Therefore, they have a lead time of 0 (zero). The new lead time for the pillow is now just five days: two days to purchase the thread and three days to produce the pillow. This lead time is known as the *decoupled lead time*.



Strategic inventory positioning in a retail model

Because retailers stock only finished products, BOMs aren't an issue. However, retailers can still use DDMRP by setting strategic inventory positioning and buffer levels based on storage locations in the distribution network.

The following illustration shows an example of a company that has a distribution center in Seattle, and stores in Boston, Atlanta, and Portland.



You might decide that the transfer time to move a blanket product between the distribution center and the stores violates your *customer tolerance time*, because your customers expect the blanket to be in stock when they visit. In this case, you set up a decoupling point for the blanket item at each of the three stores. Each store has different buffer levels, based on its lead times, demand patterns, and so on.

Implement inventory positioning in Dynamics 365 Supply Chain Management

This section describes how to implement your inventory positioning strategy in Microsoft Dynamics 365 Supply Chain Management.

Set up item coverage groups that create decoupling points

Items become decoupling points when they belong to a coverage group that you configure with a **Coverage code** value of *Decoupling point*. Therefore, the first step in the process of setting up DDMRP is to decide which coverage groups you must implement for your DDMRP strategy, and then create them by following these steps.

1. Go to **Master planning** > **Setup** > **Coverage** > **Coverage groups**.
2. On the Action Pane, select **New** to create a coverage group.
3. Enter information that identifies the coverage group, and then select the calendar to use.
4. On the **General** tab, set the **Coverage code** field to *Decoupling point*. This setting causes all items that belong to this coverage group to be treated as decoupling points for DDMRP. It also enables all DDMRP settings for this group, as described later in this procedure.
5. On the **Other** tab, in the **DDMRP parameters** section, set the following fields:
    - **Lead time factor** – Specify a factor (as a decimal value between 0 and 1) to control the impact that lead time should have when the minimum and maximum stock levels are calculated for items in this coverage group. In general, the longer the lead time an item has, the lower its lead time factor should be. A lower lead time factor produces lower minimum and maximum stock levels, and therefore causes smaller and more frequent orders. DDMRP methodology recommends a value between 0.20 and 0.40 for items that have long lead times, between 0.41 and 0.60 for items that have medium lead times, and between 0.61 and 1.00 for items that have short lead times. Learn more in Buffer profile and levels.
    - **Variability factor** – Specify a factor (as a decimal value between 0 and 1) to control the impact that varying demand should have when the minimum stock level is calculated for items in this coverage group. In general, the more variable an item's demand is, the higher its variability factor should be. A higher variability factor produces a higher minimum stock level. DDMRP methodology recommends a value between 0.00 and 0.40 for items that have low variability, between 0.41 and 0.60 for items that have medium variability, and between 0.61 and 1.00 for items that have high variability. Learn more in Buffer profile and levels.
    - **Min, max, and re-order point period** – Specify how often to calculate buffer values (*Daily* or *Weekly*).
6. On the **Other** tab, in the **Average daily usage** section, set the following fields:
    - **Average daily usage based on** – Select which time periods the calculation of the average daily usage (ADU) should be based on. Select one of the following values:

- *Past* – Look only at past usage for the number of days that you specify in the **Past period (days)** field. The ADU is calculated as the total demand for an item during the calculation period (in inventory units) divided by the number of days in the calculation period.
- *Forward* – Look only at projected future usage (including forecasts) for the number of days that you specify in the **Forward period (days)** field. The ADU is calculated as the total demand for an item during the calculation period (in inventory units) divided by the number of days in the calculation period.
- *Blended* – Look at both the past and future usage. Settings for the **Past period (days)** field, the **Forward period (days)** field, and blending options all apply.

  Blended ADU = ([*Past weighting* × *Past ADU*] + [*Forward weighting* × *Forward ADU*]) ÷ (*Past weighting* + *Forward weighting*)

- **Past period (days)** – Enter the number of past days (up to and including today) that the system should consider when it calculates the ADU of items in this coverage group. This setting applies only when the **Average daily usage based on** field is set to *Past* or *Blended*.
- **Forward period (days)** – Enter the number of future days (from today and up to the specified day) that the system should consider when it calculates the ADU of items in this coverage group. This setting applies only when the **Average daily usage based on** field is set to *Forward* or *Blended*.
- **Relative weight of past period for blended average daily usage** – Enter the weight (as a percentage) to apply to the past period when the blended ADU is calculated. This setting applies only when the **Average daily usage based on** field is set to *Blended*.
- **Relative weight of forward period for blended average daily usage** – Enter the weight (as a percentage) to apply to the forward period when the blended ADU is calculated. This setting applies only when the **Average daily usage based on** field is set to *Blended*.

7. For all other tabs and fields, enter the detailed settings that are used to calculate requirements for the items that are linked to this coverage group.

Set an item as a decoupling point

To set an item as a decoupling point, follow these steps.

1. Go to **Product information management** > **Products** > **Released products**.

2. Find and select a released item that you want to set up for DDMRP.
3. On the Action Pane, on the **Plan** tab, select **Item coverage**.
4. On the **Item coverage** page, you might see several item coverage records, each of which applies to a different combination of storage and product dimensions. You can select an existing item coverage record that applies to the dimensions where you want to create a decoupling point. Alternatively, you can select **New** on the Action Pane to create a new item coverage record.
5. Set up the item coverage record as usual. At a minimum, you must specify the site and warehouse where the decoupling point applies.
6. While the appropriate record is still selected, select the **General** tab.
7. Select the **Use specific settings** checkbox.
8. Set the **Coverage group** field to a coverage group that is set up to create decoupling points (as described in the previous section).
9. The item is now configured as a decoupling point. Usually, when you use DDMRP, you also configure settings here that affect buffer sizes and the reorder quantity. However, you can complete that configuration later. For more information about the settings, see Set up buffers for a decoupling point item.

> **Note**
>
> To plan items that aren't decoupling points, follow the same steps that you follow when standard material requirements planning (MRP) is used.

Last updated on 11/19/2025

Buffer profile and levels

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

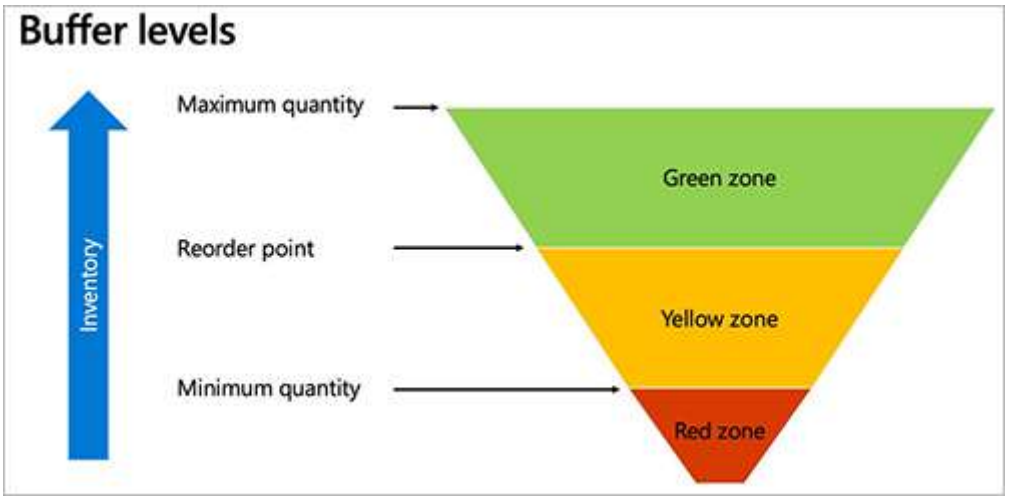
After you identify your decoupling points (key items that you strategically keep in stock), decide how much stock (buffer) to keep at each one. This task is the second step of Demand Driven Materials Resource Planning (DDMRP).

Buffer levels and zones

In DDMRP, each stock buffer is defined by using three values: the minimum quantity, the maximum quantity, and the reorder point. These values establish three difference zones, which are identified by the following color codes:

- **Red zone** – The area below the minimum quantity. The minimum quantity is also referred to as "top of red," and your planning strategy should be designed to ensure that stock levels are always above this point.
- **Yellow zone** – The area between the minimum quantity and the reorder point. The reorder point is also referred to as "top of yellow." When this point is reached, the system should reorder.
- **Green zone** – The area between the reorder point and the maximum quantity. The maximum quantity is also referred to as "top of green." This point is the maximum level that the stock is replenished to.

The following illustration shows the three colored zones and how they relate to the minimum quantity, maximum quantity, and reorder point.



Calculating the buffer zones

This section explains how the height of each buffer zone is calculated.

The yellow zone is typically calculated first. This zone represents the quantity that you consume from the moment when you order until the order arrives. In other words, it's the expected consumption during the replenishment lead time. It's calculated by using the following equation:

- **Yellow zone** = *Average daily usage (ADU)* × *Decoupled lead time*

The *decoupled lead time* represents the time that is required to produce or receive an item if the decoupling points are always in stock. It's usually much shorter than the *cumulative lead time* that is traditionally used in master planning. Correct buffer settings are key to ensuring that decoupling points are always actually in stock but not overstocked.

The red zone is calculated by using the following equations:

- **Red base** = *ADU* × *Decoupled lead time* × *Lead time factor*
- **Red safety** = *Red base* × *Variability factor*
- **Red zone** = *Red base* + *Red safety*

The green zone is calculated as the maximum result of the following three equations:

- *Minimum order quantity*
- *ADU* × *Order cycle*
- *ADU* × *Decoupled lead time* × *Lead time factor*

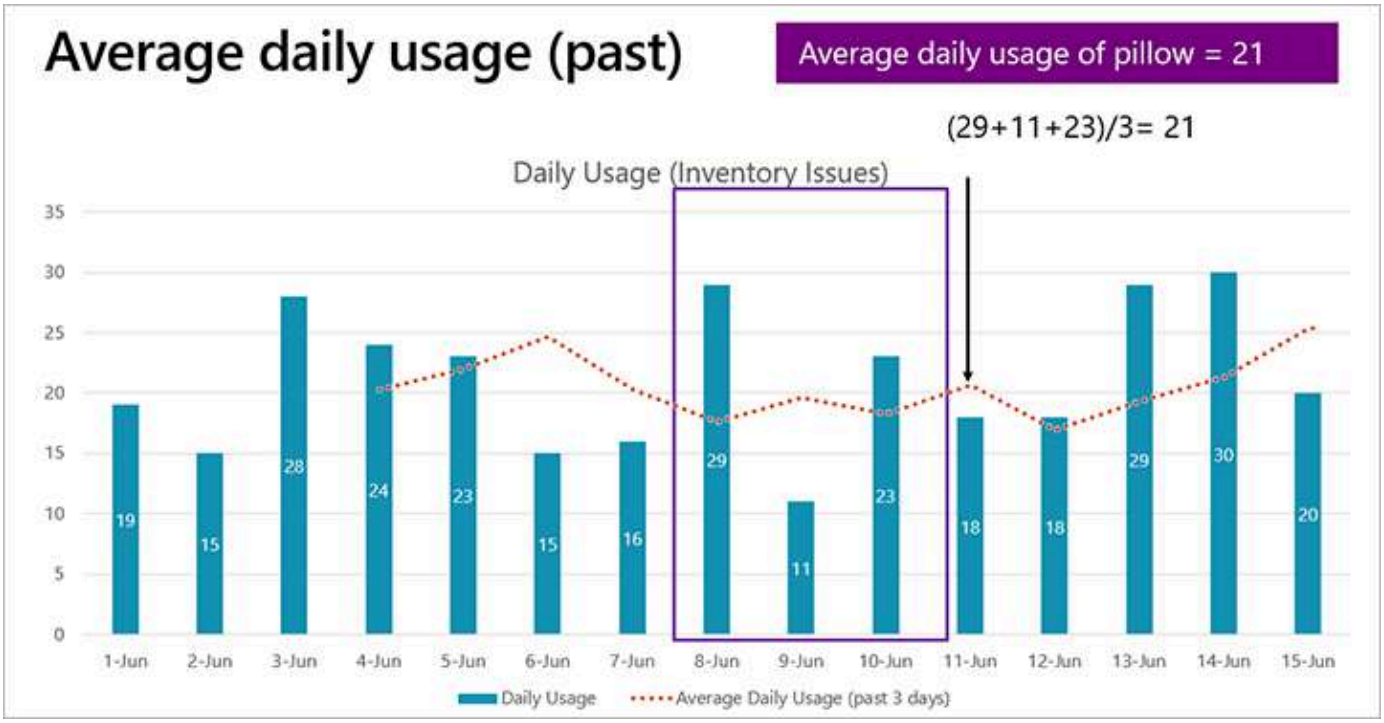
Calculating average daily usage

The system uses one of three approaches to calculate the amount that you consume per day:

- **Average daily usage (past)** – This approach is based on actual past consumption.
- **Average daily usage (forward)** – This approach is based on the forecasted future consumption.
- **Average daily usage (blended)** – This approach is based on a weighted mix of past and forecasted consumption.

Average daily usage (past)

Past ADU is calculated as an average by adding the quantities that are used each day for a specified number of past days and then dividing the total by the number of days. The following illustration shows how this approach works when the calculation looks three days into the past.



In the previous illustration, if today is the morning of June 11, the ADU for the previous three days (June 8, 9, and 10) is 21.

- **ADU (past)** = (29 + 11 + 23) ÷ 3 = 21

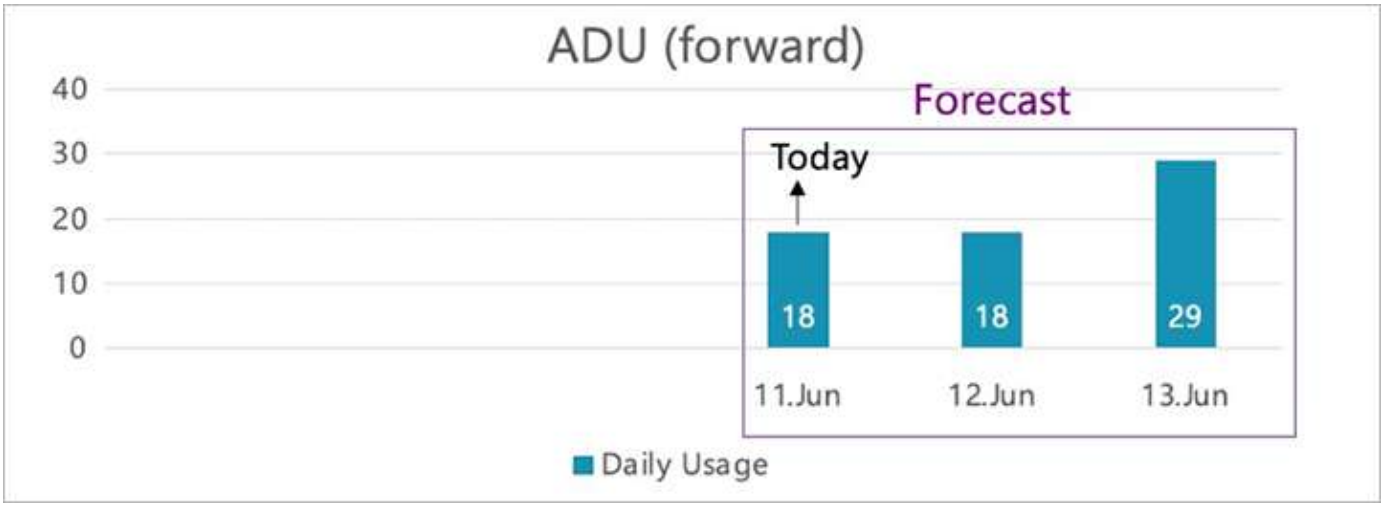
The following transactions are taken into account for the average daily usage (past) calculation:

- Transactions that diminish the quantity of the item (in the `inventtrans` table where quantity is less than zero)
- Transactions with a status of *On order*, *Reserved ordered*, *Reserved physical*, *Picked*, *Deducted*, or *Sold*
- Transactions dated within the chosen backwards period (the average daily usage past period)

- Transactions other than warehouse work, quarantine, sales quotations, or statements (`WHSWork`, `WHSQuarantine`, `SalesQuotation`, or `Statement`)
- Transactions other than transfer journals that are within the same coverage dimension

Average daily usage (forward)

For a new product, you might not have any past usage data. Therefore, you might instead use the projected ADU going forward (for example, based on forecasted demand). The following illustration shows how this approach works when the calculation looks three days into the future (including today).



In the previous illustration, if today is the morning of June 11, the ADU for the next three days (June 11, 12, and 13) is 21.66.

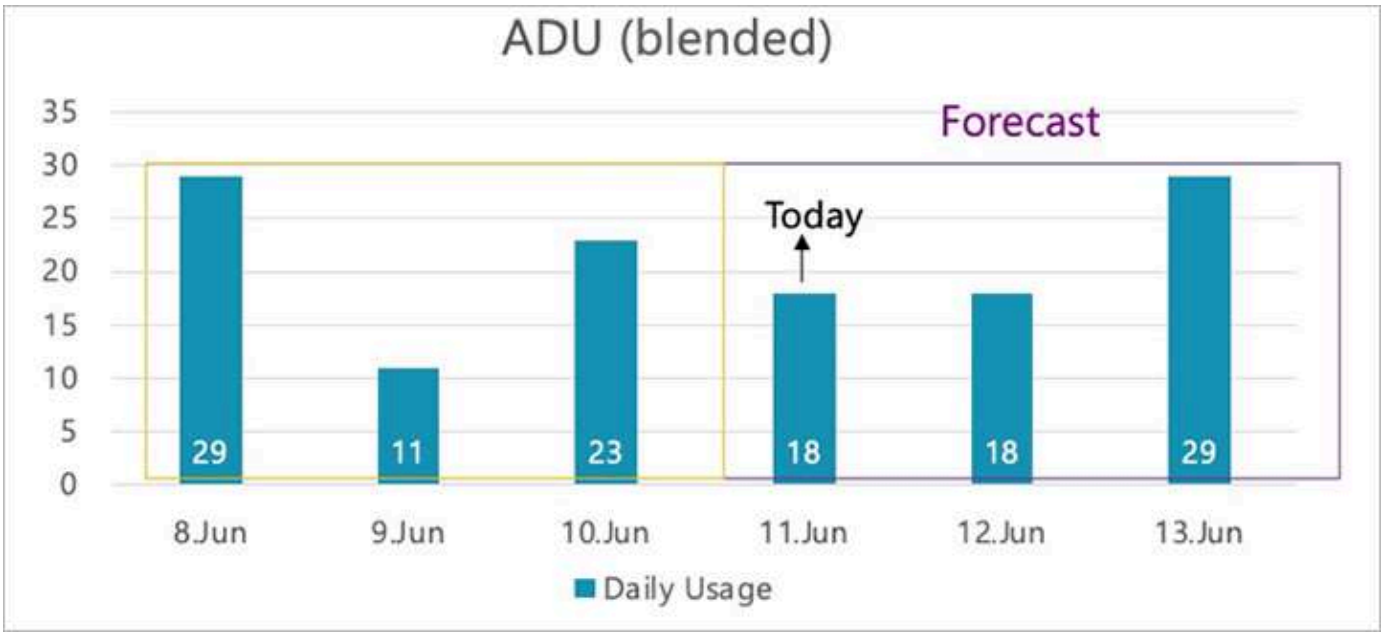
- **ADU (forward)** = (18 + 18 + 29) ÷ 3 = 21.66

The following transactions are taken into account for the average daily usage (forward) calculation:

- Forecast transactions for the item where the forecast is selected on the master plan
- Transactions dated within the chosen forward period (the average daily usage forward period)

Average daily usage (blended)

The blended ADU combines the average past usage and average forward usage, as shown in the following illustration.

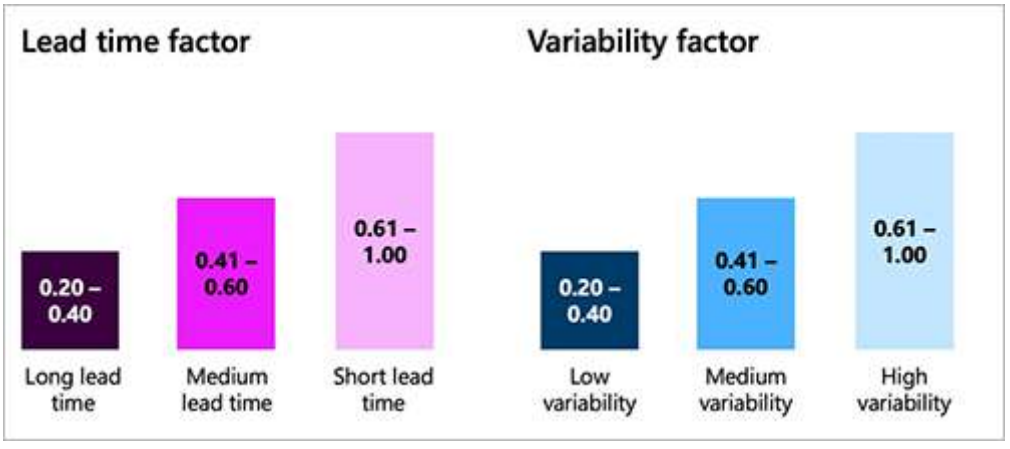


In the previous illustration, if today is the morning of June 11, the blended ADU for the previous and next three days (June 8 to 13) is 21.33.

- **ADU blended** = (*ADU past* + *ADU forward*) ÷ 2
  = (21 + 21.66) ÷ 2
  = 21.33

Buffer calculation factors

For each item, you can define two factors to adjust how large the red and green zones should be. In this way, you can compensate for the expected lead time and demand variability.



The first factor is the *lead time factor*. The value is a decimal value from 0 to 1. The longer the lead time is, the lower the value should be. The Demand Driven Institute recommends the following ranges:

- **Long lead time:** 0.20–0.40
- **Medium lead time:** 0.41–0.60

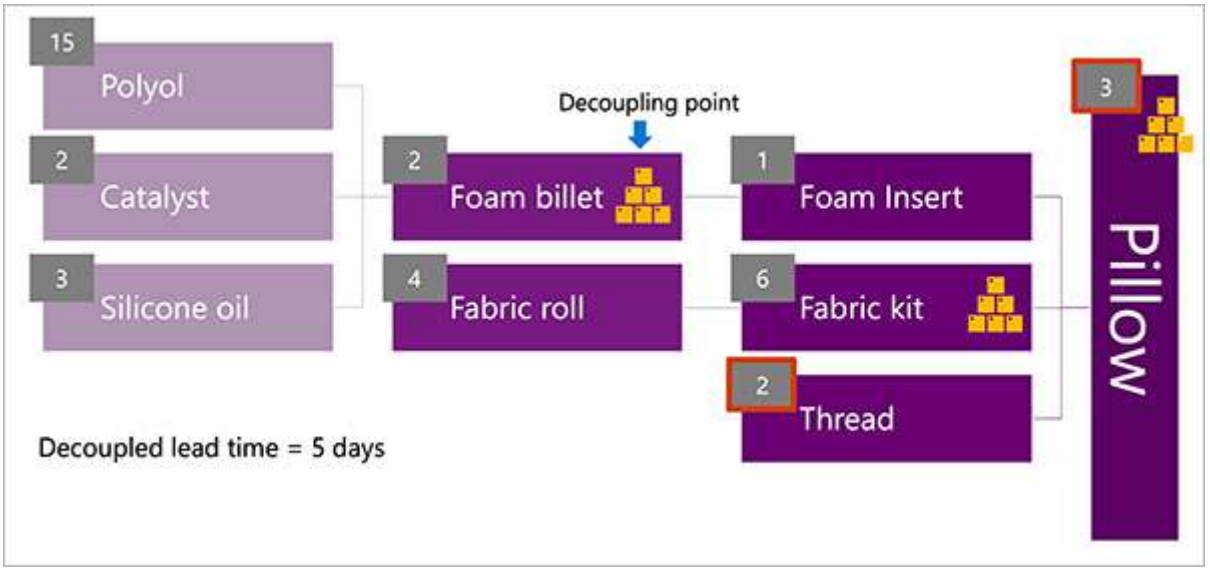
- **Short lead time:** 0.61–1.00

The second factor is the *variability factor*. The value is a decimal value from 0 to 1. The higher the demand variability is, the higher the value should be. The Demand Driven Institute recommends the following ranges:

- **Low variability:** 0.20–0.40
- **Medium variability:** 0.41–0.60
- **High variability:** 0.61–1.00

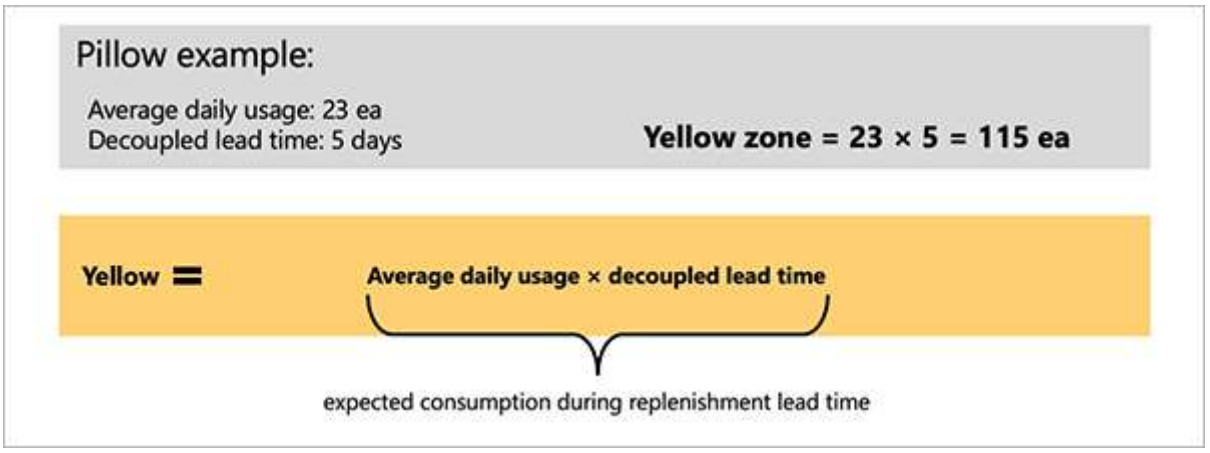
Buffer calculation examples

This example continues the pillow production example that is provided in Inventory positioning. In that example, you selected decoupling points that reduced the lead time from 21 days to five days, as shown in the following illustration.



For this example, assume that the ADU has been calculated as 23 pieces and, as shown in the previous illustration, the decoupled lead time is five days. By using these values, you can calculate the yellow zone by using the following equation:

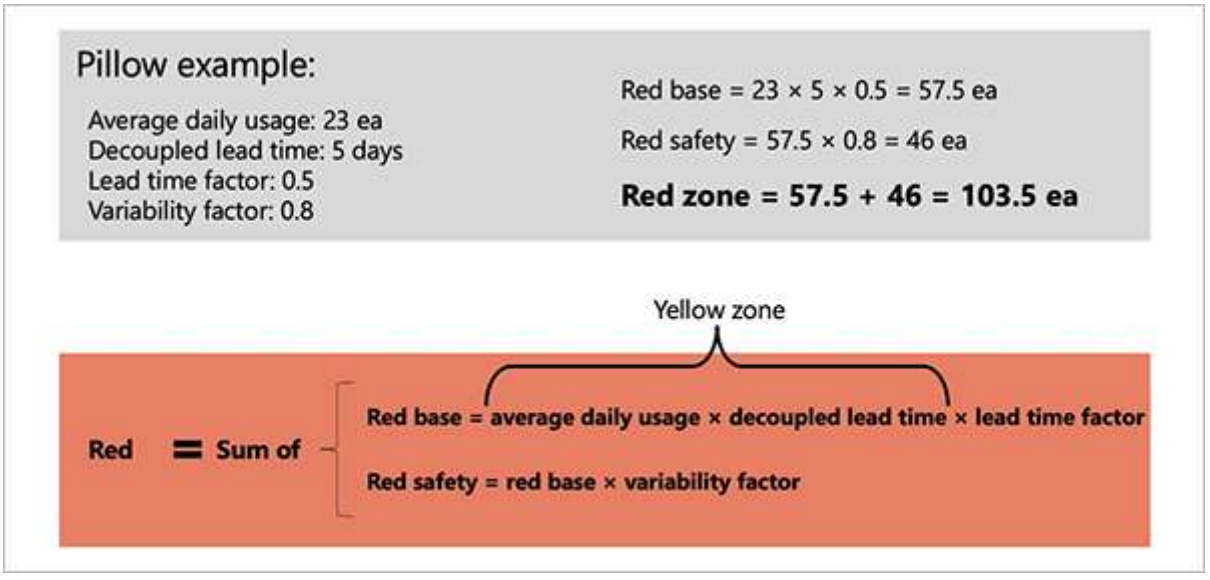
- **Yellow zone** = *ADU* × *Decoupled lead time* = 115



The red zone calculation resembles the yellow zone calculation, but it's padded for variability and lead time. For this example, assume that you've observed a medium lead time (factor = 0.50) and high demand variability (factor = 0.8). By using these values together with the components from the yellow zone equation, you can calculate the red zone by using the following equations:

- **Red base** = *ADU* × *Decoupled lead time* × *Lead time factor* = 57.5
- **Red safety** = *Red base* × *Variability factor* = 46
- **Red zone** = *Red base* + *Red safety* = 103.5

The system will round the red zone to 104 pieces (ea), because pieces are counted in whole numbers.



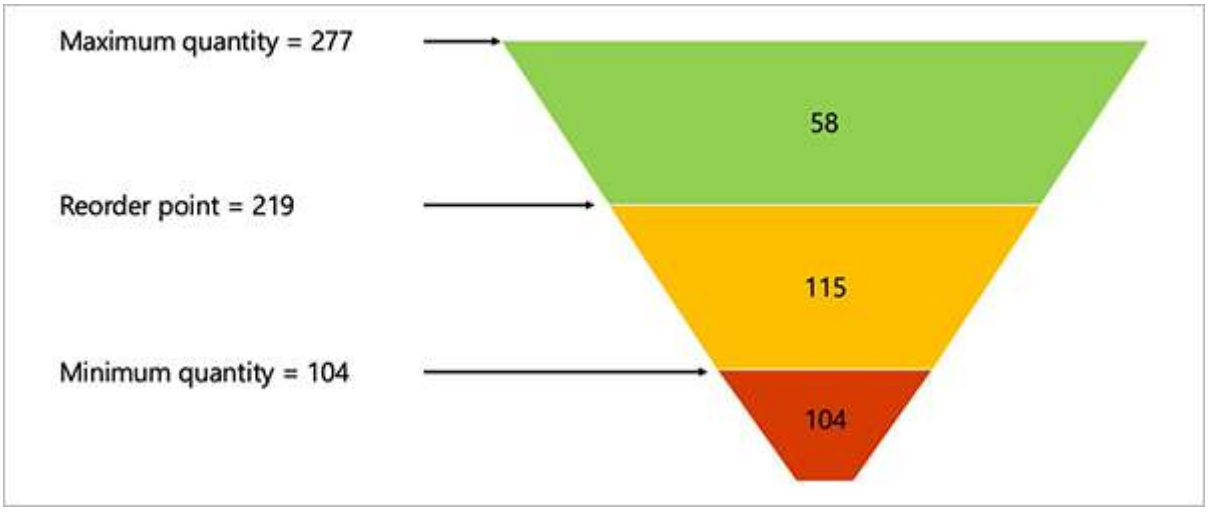
The green zone calculation also includes the components from the yellow zone equation, but it allows for a minimum order size, order cycle, and lead time factor. For this example, assume that there's no order cycle (therefore, you don't have any time constraints about how frequently you order), and the minimum order quantity is 10 pieces. The green zone is then calculated as the maximum result of the following three equations:

- *Minimum order quantity* = 10

- *ADU* × *Order cycle* = 0
- *ADU* × *Decoupled lead time* × *Lead time factor* = 57.5

The system will round the green zone to 58 pieces (ea), because pieces are counted in whole numbers.

The following illustration summarizes these zone calculation results by using the funnel graphic that is often used in DDMRP.



Dynamic adjustments

Dynamic adjustments let you apply a *demand adjustment factor* during periods of high or low demand. This factor multiplies the ADU in all calculations for the selected period. The buffer zones are then modified in turn. You usually apply this factor after you generate your initial buffer values so that you can fine-tune them over time and in response to changing conditions. This task is the third step of DDMRP.

For example, there might be more demand for a pillow product in August as people head out on vacation. Therefore, sales are expected to be higher. In this case, you can change the **Demand adjustment factor** value for the product to *1.5* for all the weeks in August.

In this way, you can calculate buffer values over time and then adjust them based on more than just the information that the system has. In a full DDMRP implementation, you calculate new buffer values every day through a batch job and automatically accept them. You then run planning as a batch job and review the planned orders every day to refill the buffers.

Implement buffers in Supply Chain Management

This section describes how to implement your buffer zone strategy in Microsoft Dynamics 365 Supply Chain Management. It assumes that you've already done the analyses and calculations that are outlined in the first half of this article.

Set up buffers for a decoupling point item

Follow these steps to set up buffer values for a decoupling point.

1. Go to **Product information management** > **Products** > **Released products**.
2. Select a released item that is set up as a decoupling point. (Learn more in Inventory positioning.)
3. On the Action Pane, on the **Plan** tab, select **Item coverage**.
4. On the **Item coverage** page, select an item coverage record that creates a decoupling point. (This record shows the name of a coverage group that is set up to create decoupling points.)
5. Select the **General** tab.
6. If you want the system to recalculate buffer values every day or every week, based on your sales history, forecasts, and coverage group settings, follow these steps:
   a. Set **Buffer values over time** option to *Yes*.
   b. A message box notifies you that your manual buffer settings (**Minimum**, **Reorder point**, and **Maximum**) will be reset if you continue. Select **Yes** to keep the new setting.

   Alternatively, if you prefer to calculate or enter your buffer settings just once, follow these steps:
   a. Set **Buffer values over time** option to *No*.

b. Set the **Minimum**, **Reorder point**, and **Maximum** fields to the buffer values that you've calculated for the item, as described earlier in this article.

7. Set the following fields to finish setting up the DDMRP calculations for the item:

   - **Order cycle** – Specify the number of days that must pass between purchase orders for the item. Set the value to *0* (zero) if no order restrictions exist. This field affects the maximum quantity buffer, as previously discussed in this article.
   - **Average daily usage** – You can optionally enter an estimated ADU for the item. This field is for informational purposes only. Usually, the value is automatically calculated as part of the buffer calculations.
   - **Order spike threshold** – Specify the minimum number of daily sales of the item that qualify as a sales spike (unusually high demand). The system uses this field to increase the reorder quantity of planned orders in periods of high demand. Learn more in Demand-driven planning.

Calculate or enter decoupled lead times

For items where you choose to allow the system to calculate your buffer zones automatically, follow these steps to calculate or enter decoupled lead times for a decoupling point item.

1. Open the **Item coverage** page for your decoupling point item. (Learn more in Set up buffers for a decoupling point item.)

2. Select an item coverage record that creates a decoupling point.

3. Select the **Buffer values** tab.

4. If no time periods are shown in the grid, on the Action Pane, on the **Buffer values** tab, select **Add time periods**. The system fills the grid with rows for each daily or weekly time period, depending on whether the **Min, max, and re-order point period** field for the coverage group is set to *Daily* or *Weekly*. The system adds enough rows to reach the time fence that is specified for the coverage group that is assigned to the item.

5. Select the time period where you want to calculate the decoupled lead time. (Usually, this time period is the period that includes today's date.)

6. On the Action Pane, on the **Buffer values** tab, select **Calculate decoupled lead time**.

7. In the **Calculate decoupled lead time** dialog box, set the following fields:

   - **BOM** – Select the bill of materials (BOM) that you want to run the calculation on.

- **Date** – Select the date that you want to run the calculation on. The set of available BOMs is filtered so that only BOMs that are active for the selected date are shown.
- **Quantity** – Enter the quantity that you want to run the calculation for. The set of available BOMs is filtered so that only BOMs that apply to the specified quantity are shown.

8. Select **OK** to run the calculation and close the **Calculate decoupled lead time** dialog box. The **Decoupled lead time** column for your selected time period now shows the calculated value.

Calculate or enter average daily usage

For items where you choose to allow the system to calculate your buffer zones automatically, follow these steps to calculate or enter the ADU for a decoupling point item.

1. Open the **Item coverage** page for your decoupling point item. (Learn more in Set up buffers for a decoupling point item.)

2. Select an item coverage record that creates a decoupling point.

3. Select the **Buffer values** tab.

4. If no time periods are shown in the grid, on the Action Pane, on the **Buffer values** tab, select **Add time periods**. The system fills the grid with rows for each daily or weekly time period, depending on whether the **Min, max, and re-order point period** field for the coverage group is set to *Daily* or *Weekly*. In addition, default values for the **Lead time factor** and **Variability factor** fields are taken from the coverage group. You can edit these values for each row as required.

5. Select a time period where you want to calculate ADU.

6. On the Action Pane, on the **Buffer values** tab, select **Calculate average daily usage**. The system tries to collect data that is required for the ADU calculation, as defined for the coverage group.

7. Follow one of these steps:

    - If the required data is available, calculation results are added to the **Average daily usage** column. In this case, no action is required.
    - If the required data isn't available, no values are automatically added. In this case, manually enter estimated values for each row where you're planning to calculate

buffer values.

Calculate and apply buffer values

For items where you choose to allow the system to calculate your buffer zones automatically, follow these steps to manually trigger the calculation of buffer values.

1. For the relevant decoupling point item, configure the buffer calculation, calculate or enter decoupled lead times, and calculate or enter average daily usage for all relevant time periods, as previously described in this article.

2. Open the **Item coverage** page for your decoupling point item.

3. Select the **Buffer values** tab, which should already show a list of time periods.

4. Select the time period where you want to calculate buffer values. (Usually, this time period is the period that includes today.) The row that you select must already have non-zero values in the **Average daily usage** and **Decoupled lead time** columns.

5. Edit the **Demand adjustment factor** field for one or more rows as required. The system applies this factor to the **Average daily usage** value in all buffer calculations where that value is used. This factor lets you adjust for the way that demand fluctuates by date (for example, for holidays or seasonal items).

6. On the Action Pane, on the **Buffer values** tab, select **Calculate min, max and reorder point quantities**. The system calculates and fills in the **Calculated min**, **Calculated reorder point**, and **Calculated max** columns in the grid on the **Item coverage** page.

7. When you finish reviewing the calculated values, you must apply them. Otherwise, they have no effect. When you apply a calculation for one or more rows, values from the **Calculated min**, **Calculated reorder**, and **Calculated max** fields are copied to the **Min**, **Reorder point**, and **Max** columns, respectively. On the Action Pane, on the **Buffer values** tab, in the **Take action** group, select one of the following buttons:

    - **Accept all calculations** – Apply all calculated values in the grid.
    - **Accept calculations for selected rows** – Apply calculated values for the selected rows only.
    - **Discard all calculations** – Discard all calculated values for minimum quantities, maximum quantities, and reorder points in the grid.
    - **Discard calculations for selected rows** – Discard all calculated values for minimum quantities, maximum quantities, and reorder points for the selected rows.

Schedule automatic buffer value calculations

After you fully set up your DDMRP settings and confirm that they work as expected, set up a batch job to periodically recalculate ADU and related buffer values as required, based on actual consumption data and/or updated forecasts. This procedure applies only to items where you choose to allow the system to automatically calculate your buffer zones.

Follow these steps to schedule automatic buffer value calculations.

1. Go to **Master planning** > **Master planning** > **DDMRP** > **Calculate buffer values**.

2. In the **Calculate buffer values** dialog box, set the following fields:

    - **Calculate average daily usage** – Set this option to *Yes* to recalculate the ADU of decoupling point items each time that the job runs. Set it to *No* to skip this calculation. Usually, set this option to *Yes*.
    - **Calculate decoupled lead time** – Set this option to *Yes* to recalculate the decoupled lead times each time that the job runs. Set it to *No* to skip this calculation. Usually, set this option to *Yes*.
    - **Calculate buffer values** – Set this option to *Yes* to recalculate buffer values each time that the job runs. Set it to *No* to skip this calculation. Usually, set this option to *Yes*.
    - **Accept calculation for min, max and reorder point** – Set this option to *Yes* to automatically approve and apply the recalculated buffer values each time that the job runs. Set it to *No* to leave the recalculated values unapplied. In this case, the recalculated values don't take effect unless somebody manually applies them later from each product's **Item coverage** page. Usually, set this option to *Yes*.
    - **Master plan** – Select a master plan that includes the items that are affected by the calculation. The calculation applies to all the items in the plan filter, which is further limited by the **Filter** settings in this dialog box.

3. To limit the set of records that this batch job should run on, on the **Records to include** FastTab, select **Filter** to open the **Inquiry** dialog box. This dialog box works just as it does for other types of background jobs in Supply Chain Management.

4. On the **Run in the background** FastTab, specify how, when, and how often the selected calculations should be done for the selected items. The fields work just as they do for other types of background jobs in Supply Chain Management.

5. Select **OK** to add the new job to a batch queue for execution.

Review and recalculate decoupled lead times for all items

Follow these steps to review and recalculate all decoupled lead times that are available in your legal entity (company).

1. Go to **Master planning** > **Master planning** > **DDMRP** > **Decoupled lead time**.
2. On the **Decoupled lead time** page, browse and filter the list as required to find the information that you're looking for. To view even more information for an item, select its link in the **Item number** column.
3. If you want to recalculate the decoupled lead time for any item, select the item, and then select **Calculate decoupled lead time** on the Action Pane. The **Calculate decoupled lead time** dialog box appears. This dialog box works just as it does when you calculate decoupled lead times for the same item on the **Item coverage** page.

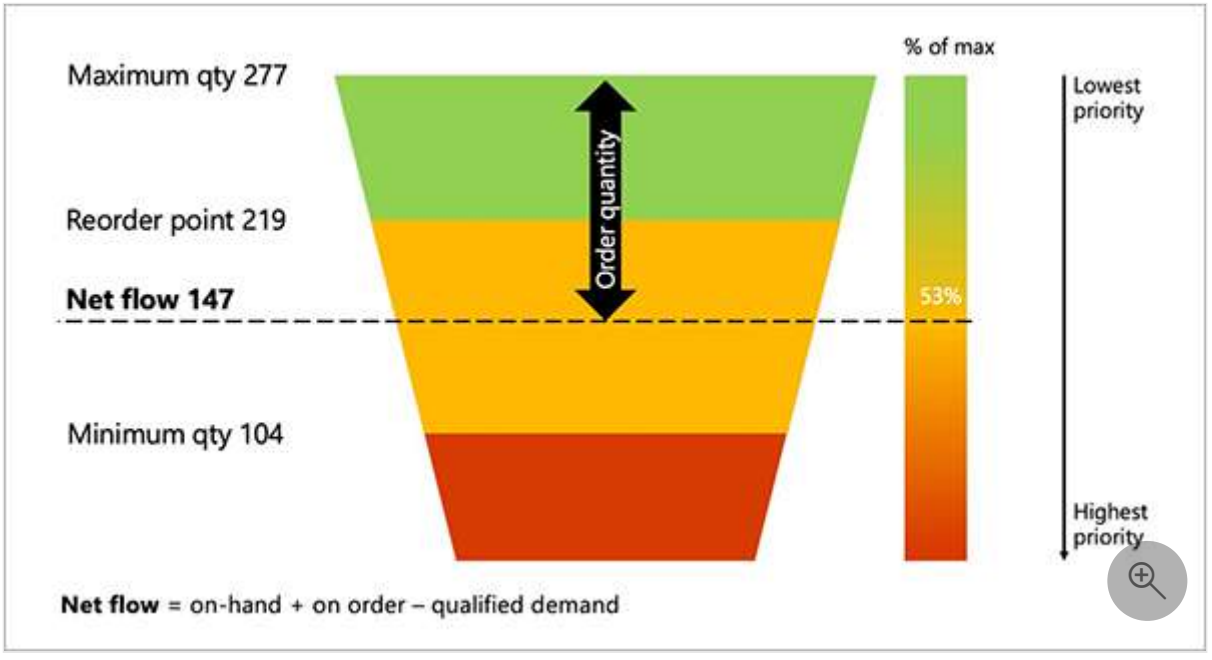
Demand-driven planning

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to generate planned orders for items that are set up as decoupling points.

Net flow and qualified demand

During master planning, the system uses the concept of *net flow* to calculate the effective on-hand quantity. The calculation starts with the actual on-hand inventory, adds inventory that is on order (existing supply orders that aren't yet received), and subtracts what is referred to as *qualified demand* (qualified upcoming sales), as shown in the following illustration. When the system determines which buffer zone an item belongs in and what the ordered quantity should be, it evaluates the net flow, not the actual on-hand inventory.



When a planned order is triggered during a planning run, the ordered quantity is the maximum level minus the net flow. To assign an order priority, the system uses priority-based planning functionality instead of requirement dates. Demand Driven Material Requirements Planning (DDMRP) assigns the priority of a planned order based on the net flow quantity as a percentage of maximum inventory. In the previous illustration, the net flow quantity is 53

percent of the maximum quantity. Therefore, the order priority for replenishment is 53. (For context, 0 is the highest priority, and 100 is the lowest priority.)

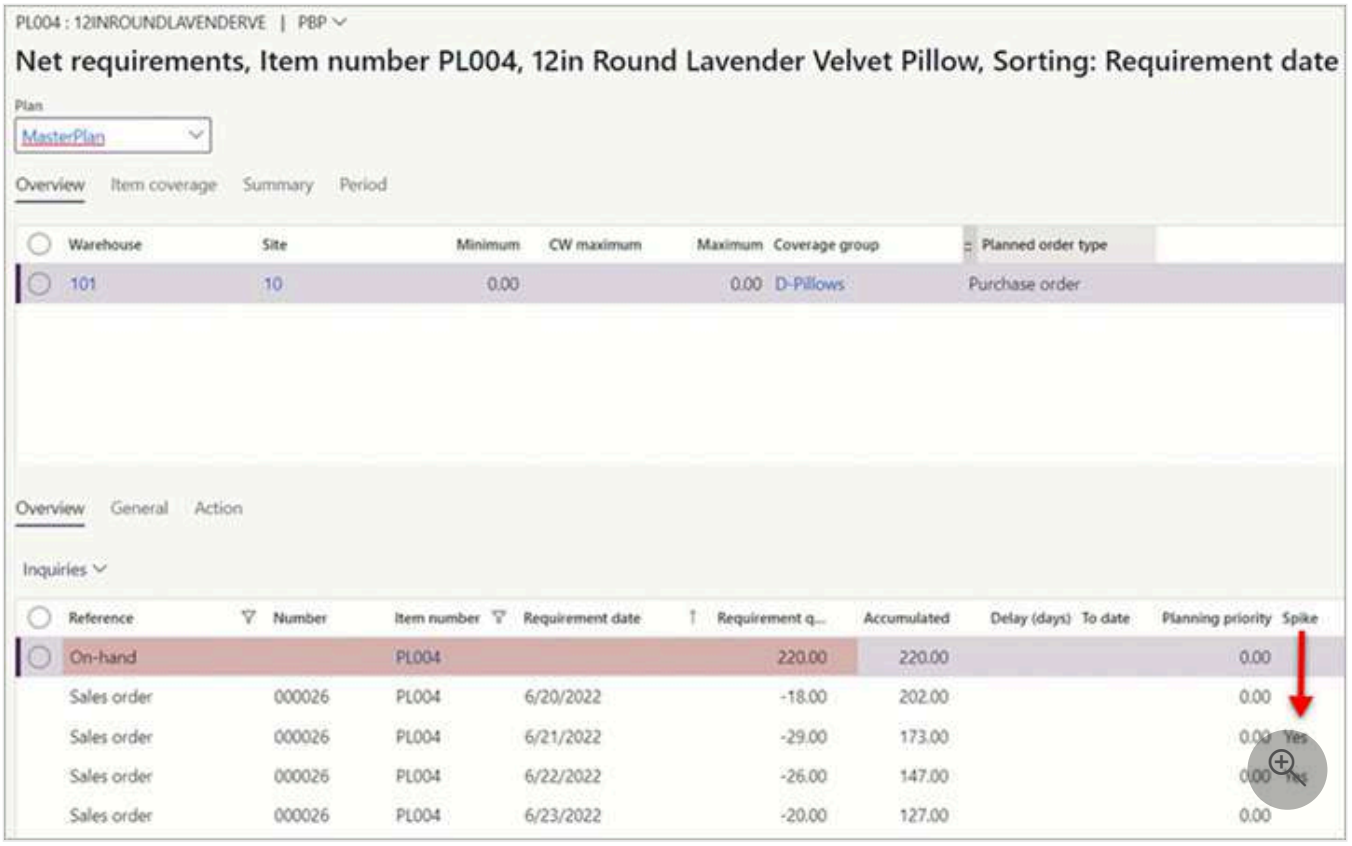
Qualified demand is the past-due demand, plus today's demand, plus qualified order spikes in the future. The following illustration shows an example of demand levels for today (June 12) and the next three days. DDMRP lets you set an order spike threshold to identify demand that exceeds normal expectations. If the threshold is set at 25 pieces, two of the future dates that are shown in the illustration qualify as order spikes. You must assign an order spike threshold for each product individually by using its **Item coverage** page, as described in Set up buffers for a decoupling point item.

If there's no past-due demand, you can add today's demand (18) to the quantities of the two order spikes (29 and 26) to get a qualified demand of 73. Even though there's demand for June 23, notice that it isn't included in the net flow calculation, because DDMRP triggers planned order differently than traditional planning coverage groups.

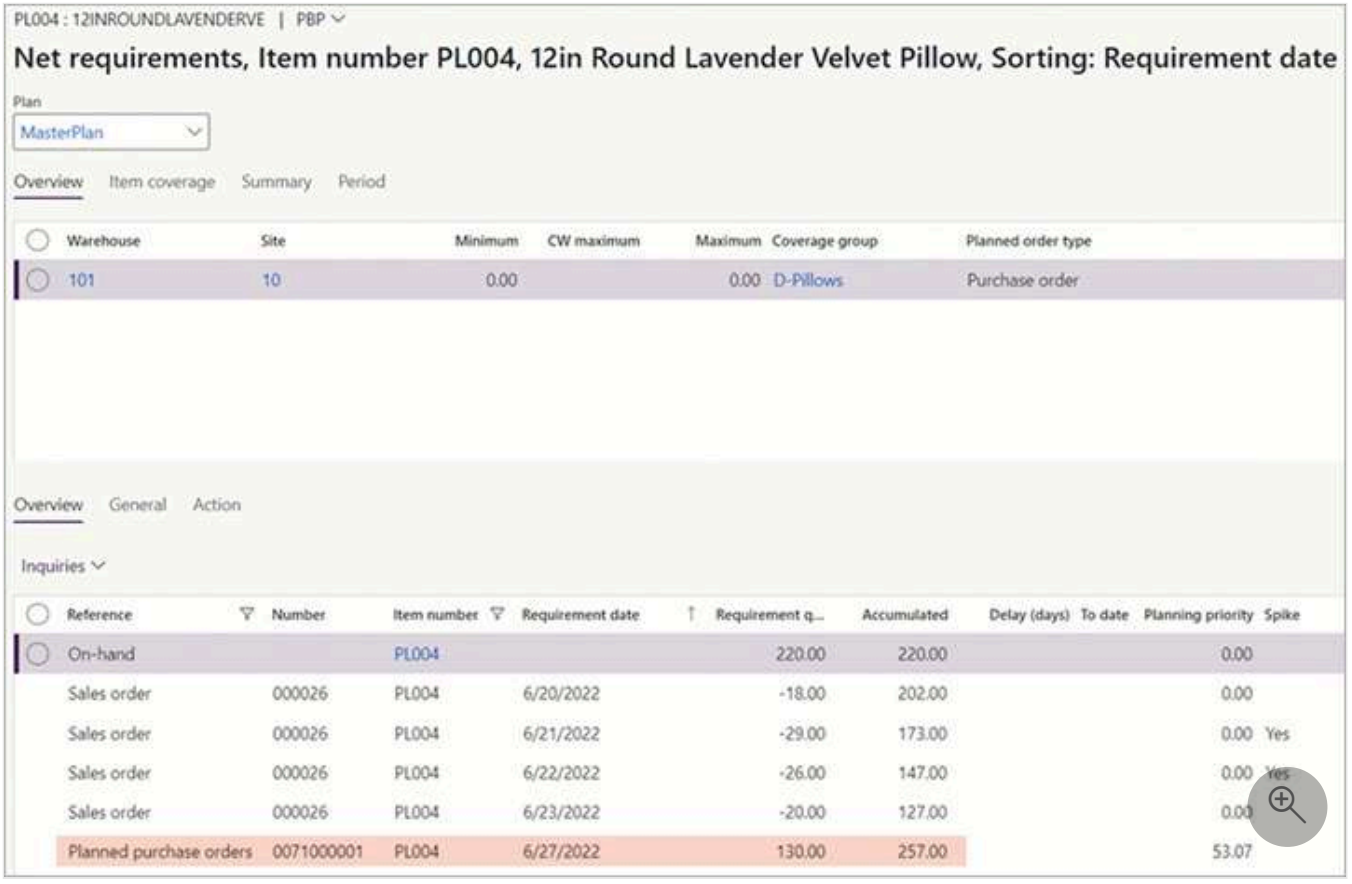
Generating planned orders with DDMRP

During a planning run, the system creates a new planned order if the net flow for an item drops below the reorder point. When you use DDMRP, you usually run a planning run every day. Therefore, you check your inventory levels once a day to determine which items you must replenish.

The following illustration shows an example of a situation where you have an order for 18 pieces on June 20, 29 pieces on June 21, 26 pieces on June 22, and 20 pieces on June 23. Because the spike threshold is set at 25 pieces, two of these orders are flagged as spikes. You have 220 pieces of this item on hand.



If you run master planning now, it generates a planned order if the net flow drops below the reorder point (219 pieces in this example).



This example produces a planned purchase order for a quantity of 130, which equals the maximum level minus the net flow. The planned order gets a priority of 53.07, based on its percentage of the maximum quantity. Because these values were found on June 20, the system

creates a planned order that is dated June 20 plus the decoupled lead time for the item (five business days in this example). Therefore, because five business days are one week from today, the planned order is dated June 27.

> **Note**
>
> Master planning calculates only decoupled items by using DDMRP. All other items are calculated by using standard material requirements planning (MRP).

Visual and collaborative execution

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how to monitor your Demand Driven Material Requirements Planning (DDMRP) decoupling points, buffer zones, planned orders, and history.

Visually track buffers and quantities for a selected item

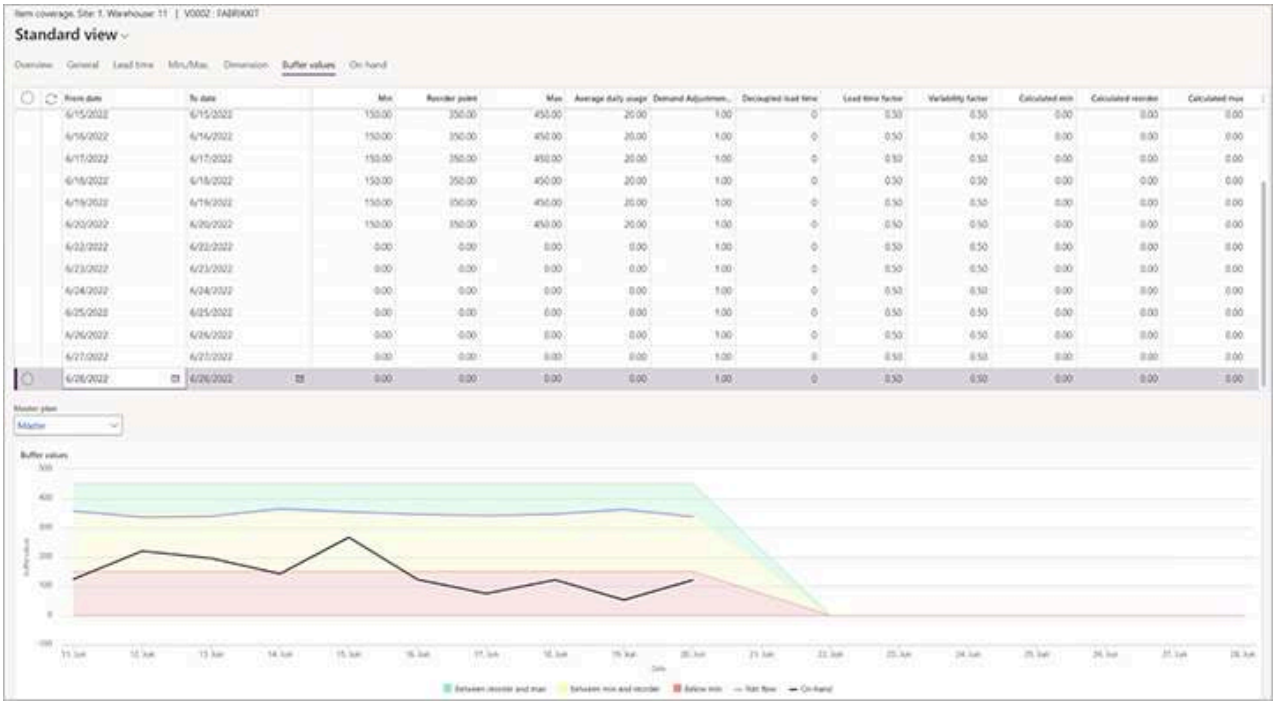
In Microsoft Dynamics 365 Supply Chain Management, you can visually track how buffers, on-hand quantities, and net-flow levels change over time for any selected released product. Follow these steps to open and review the charts.

1. Go to **Product information management** > **Products** > **Released products**.
2. Select a released item that is set up as a decoupling point. (Learn more in Inventory positioning.)
3. On the Action Pane, on the **Plan** tab, select **Item coverage**.
4. On the **Item coverage** page, select an item coverage record that creates a decoupling point. (This record will show the name of a coverage group that is set up to create decoupling points.)
5. Select the **On-hand** tab. This tab includes a chart that shows how on-hand quantities changed over time, together with the value of the on-hand level that was recorded for a specific period every time that master planning is run. The tab also includes a table that shows which of the following categories each recorded on-hand level falls into:

    - **Critically low** – Less than half the minimum for the period.
    - **Low** – Between half the minimum and the minimum.
    - **Average on-hand** – Between the minimum and the minimum plus the green zone.
    - **Higher than average** – Higher than average.

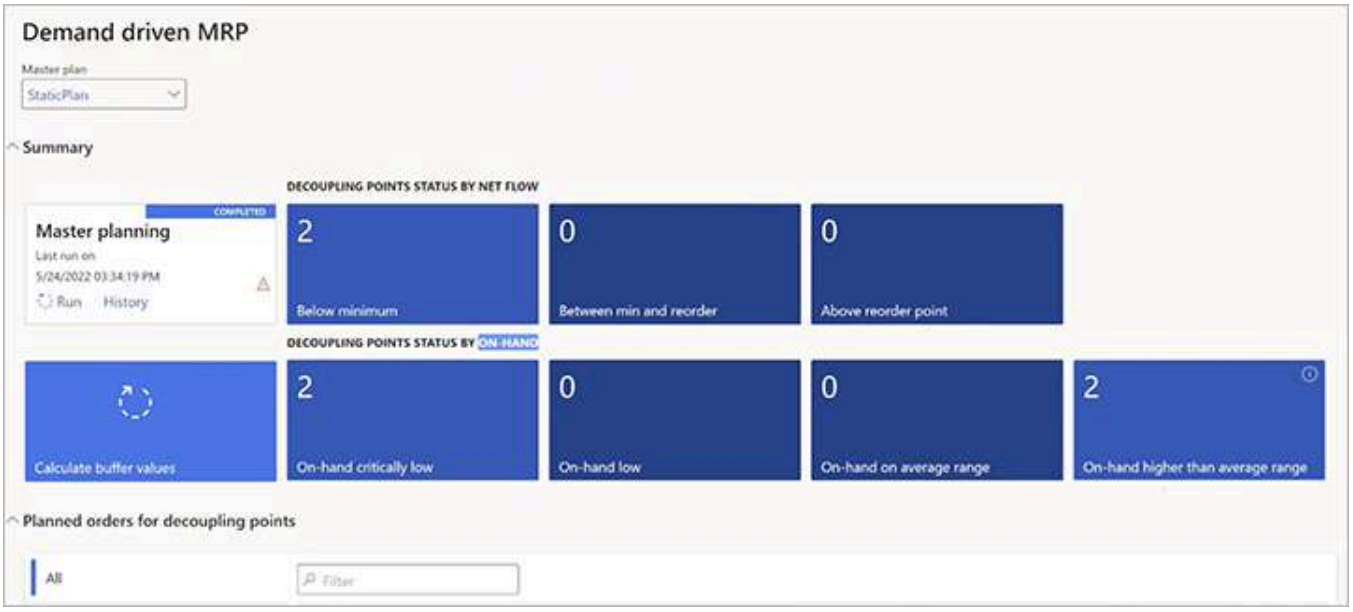
> **Note**
>
> The colors that are used on the **On-hand** tab represent different ranges than the similar colors used on the **Buffer values** tab.

6. To view how your buffer values changed over time, and how they compare to on-hand and net-flow levels, select the **Buffer values** tab.



Track the status and planned orders for all decoupling points

The **Demand driven MRP** workspace provides several tools, together with key performance indicators (KPIs) and overviews of the status of your decoupling point items and related planned orders. To open it, go to **Master planning** > **Workspaces** > **Demand driven MRP**.



Get overviews of decoupling points and planned orders

In addition to the **Demand driven MRP** workspace, Supply Chain Management provides several pages where you can view information about your DDMRP setup, decoupling points, and planned orders. Some of these pages also provide convenient buttons on the Action Pane that let you manage buffers, run master planning, and open other related views.

- To view decoupling point status by net flow level, go to **Master planning** > **Master planning** > **DDMRP** > **Decoupling points status by net flow**.
- To view decoupling point status by on-hand inventory level, go to **Master planning** > **Master planning** > **DDMRP** > **Decoupling points status by on-hand**.
- To view planned orders for decoupling points, go to **Master planning** > **Master planning** > **DDMRP** > **Planned orders for decoupling points**.
- To view decoupled lead times, go to **Master planning** > **Master planning** > **DDMRP** > **Decoupled lead time**.

Clean up decoupling point buffer values

Over time, your system will build up a large amount of historical data that is related to ongoing buffer calculations. This historical data will cause your data volume to increase and can eventually affect the performance of your system. Therefore, we recommend that you occasionally clean up the old decoupling point buffer values.

> **⚠ Warning**
>
> The cleanup job will remove historical buffer value settings and historical on-hand/net-flow information. It isn't reversible.

Follow these steps to clean up your decoupling point buffer values.

1. Go to **Master planning** > **Master planning** > **DDMRP** > **Clean up decoupling point buffer values**.

2. In the **Clean up decoupling point buffer values** dialog box, set the following fields:

    - **Delete records older than (days)** – Specify the age of the youngest records to keep, in days. All decoupling point buffer value records that are older than this value will be deleted.
    - **Master plan** – Select a master plan that includes items that should be affected by this cleanup. The cleanup will apply to all the items in the plan after the **Filter** settings that you specify in this dialog box are applied.

3. To limit the set of records that the batch job should run on, on the **Records to include** FastTab, select **Filter** to open the **Inquiry** dialog box. This dialog box works just as it does for other types of background jobs in Supply Chain Management.

4. On the **Run in the background** FastTab, specify how, when, and how often the cleanup should be done. The fields work just as they do for other types of background jobs in Supply Chain Management.

5. Select **OK** to add the new job to a batch queue for execution.

DDMRP FAQ

Article • 01/06/2023

This topic provides answers to frequently asked questions (FAQ) about Demand Driven Material Requirements Planning (DDMRP) in Microsoft Dynamics 365 Supply Chain Management.

General

Does DDMRP require Planning Optimization?

Yes, DDMRP functionality requires the Planning Optimization Add-in for Dynamics 365 Supply Chain Management. It isn't available for the deprecated master planning engine. For more information about Planning Optimization, see Get started with master planning.

Can priority-based planning be used together with DDMRP?

DDMRP uses priority-based planning functionality to set the priority of planned orders. It calculates the priority of each order by determining the net flow based on the maximum inventory level. Master planning then uses the order priority (instead of the requirement date) to drive supply allocation.

DDMRP seems to be an extension of the min/max coverage code functionality. Are there any scenarios where I might still use min/max functionality instead of DDMRP when I produce or procure stock?

One of the key differences between min/max and DDMRP is that DDMRP doesn't consider all future net requirements when it's determining whether to reorder. DDMRP is run daily and looks only at past-due demand (today's demand) and order spikes to determine whether an order must be placed immediately. By contrast, min/max looks at all demand in the coverage time fence. It will propose planned orders farther in the future, based on when net requirements will deplete inventory below the minimum point.

Can I run the existing material requirements planning (MRP) functionality together with DDMRP (for example, when I use coverage groups)?

Yes, we expect that companies will run some combination of decoupling points and other coverage methods (such as min/max, period, or requirement). Decoupling points should be put at strategic points in the supply chain but probably aren't the best answer for every product. Therefore, it's likely that companies will run DDMRP together with other coverage methods.

Can I simulate DDMRP by using the past two years of data in Supply Chain Management?

Unfortunately not. However, you can easily create an Excel worksheet that contains the formulas, and then use that worksheet to determine what the system would have created as the buffer values.

Can Supply Chain Management analyze whether an item is in the correct coverage group (for example, to test whether the factors that I set up for variability, and so on, will still meet my item consumption)?

No automated functionality for this purpose currently exists in Supply Chain Management. However, you can manually review the performance of your net flow and on-hand inventory by using the buffer values chart. This chart will help you determine whether your actual net flow and on-hand inventory values are in the zones that you expect them to be in.

Is there a data entity for importing usage history from legacy enterprise resource planning (ERP) systems?

Yes, if you come from another system and want to keep your past buffer value history, there's a data entity for updating that history.

Does DDMRP work with Supply Chain Management process manufacturing?

Yes, DDMRP works with any functionality that the deprecated master planning engine works with, provided that you're using Planning Optimization.

Can DDMRP work with projects?

Yes, DDMRP works with any functionality that the deprecated master planning engine works with, provided that you're using Planning Optimization.

Does DDMRP work in an intercompany scenario?

Yes, DDMRP works with any functionality that the deprecated master planning engine works with, provided that you're using Planning Optimization.

The Demand Driven Institute

Is the Demand Driven Institute part of Microsoft?

No, the Demand Driven Institute is a separate organization that developed the DDMRP methodology. Microsoft developed the functionality that supports the DDMRP methodology in Supply Chain Management, and our solution has been certified by the Demand Driven Institute. Learn more at the Demand Driven institute website.

Which Demand Driven Institute certifications are recommended for consulting teams?

The recommended certification for consulting teams is Demand Driven Planner (DDP). This certification includes all the DDMRP material and provides a deep understanding of DDMRP principles, to help consultants successfully explain and implement DDRMP in Supply Chain Management.

Decoupling points

How can I decide where to define decoupling points?

When you're choosing where to put decoupling points in your supply chain, consider the following factors:

- **External variability** – Add buffers to mitigate effects that can arise from supply variability that's out of your control.
- **Inventory leverage and flexibility** – Add buffers to prioritize items that are used as components in multiple products.

- **Critical operation protection** – Add buffers before critical operations or bottlenecks, to ensure that operations don't sit idle because of a lack of raw materials.
- **Customer tolerance time** – Add buffers at stages where customers expect a short lead time for the item.
- **Sales order visibility horizon** – Add buffers at points where you must quickly react to meet new demand.
- **Market potential lead time** – Add buffers at points where you can sell items at a higher price if the lead time is shorter.

Learn more in Inventory positioning.

Are negative and positive days considered for coverage code decoupling points?

No, the DDMRP model doesn't consider negative and positive days.

Decoupling points can be added only at the item coverage level. Should I continue to indicate the coverage group at the item level, so that it can be considered for other locations that aren't specified in the item coverage?

Yes, it's possible that not all locations for a given item must be set up as decoupling points. Therefore, you can choose to have a coverage group for an item that uses min/max, period, requirement, and so on, and then indicate the specific decoupling points on the item coverage page. The settings on the item coverage page override the item-level coverage group.

Is the new coverage code compatible with all product and storage dimensions?

Yes, the *decoupling point* coverage code works with all products and storage dimensions. You must specify all the dimensions for a product that's a decoupling point.

Do I have to create item coverage records for every variant of a product, or can the calculation be run on product masters?

Decoupling points must be set at the product variant level because each variant will have its own demand pattern, and planned orders are generated at the variant level.

Planned order generation with DDMRP

Does DDMRP plan based on forecast values unless qualified demand (orders) for the time frame exceeds the forecast?

DDMRP doesn't use forecasts to generate planned orders. Planned orders are created when the net flow is below the reorder point.

Forecasts are used when the system is set to calculate average daily usage (ADU) based on a *Forward* or *Blended* time period. ADU is one of the factors that affect the buffer values (minimum, reorder point, and maximum). Therefore, it indirectly affects how much you reorder.

How is production scheduling done when a manufactured part uses DDMRP?

Planned production orders are generated and assigned a priority value that's calculated by dividing the net flow by the maximum inventory level. Master planning then uses the order priority (instead of the requirement date) to schedule production.

If I set up a maximum reorder quantity that's lower than the reorder quantity, will DDMRP generate multiple planned orders that have different priority values?

The default order settings are respected when planned orders are created, and the same priority will be assigned to all planned orders.

If different priorities must be assigned to different parts, use planning priority models. Planning priority models let you split a replenishment order into multiple orders that have different priorities. For example, you can assign the highest priority (for example, *10*) to replenish until the minimum, a lower priority (for example, *30*) to replenish until the reorder point, and an even lower priority (for example, *50*) to replenish until the maximum.

In cases where a planned purchase order was generated, how will Supply Chain Management peg the purchase order quantity?

One key concept of DDMRP is that it doesn't use pegging when it generates planned orders. Decoupling points are buffers where supply and demand are decoupled. In other words, there's no specific supply for a demand. Therefore, there's no pegging. All replenishment orders replenish the buffer, which is on-hand inventory.

Lead time and variability factors

Does the variability factor refer to lead time or demand?

The variability factor refers to demand variability (in other words, how much demand fluctuates or how consistent it is).

How can we classify a lead time as long, medium, or short?

Lead time classification differs for every company. You should start by looking at the lead times for all your items, and group them based on whether their lead time is short, medium, or long. After you assign a lead time factor to each item, you can test and adjust the factor to identify the optimal value.

Qualified demand

What is spike demand?

Spikes refer to dates in the future when the total amount of demand exceeds the specified order spike threshold. This situation indicates that the demand for a date exceeds what's considered normal and will be included in the net flow calculation as part of the qualified demand.

How is the order spike threshold determined? Is it calculated or manually defined?

The order spike threshold is manually set on the item coverage record.

Is there a time fence for qualified demand (looking forward)?

The time fence for qualified demand is determined by the coverage time fence setting.

Feedback

Deprecated master planning overview

> **Note**
>
> Although we strongly recommend that you migrate to Planning Optimization as soon as possible for the reasons outlined in this article, you can continue to use the deprecated master planning engine while you prepare to migrate without requesting an exception from Microsoft. For more information about how to do so, see **Continue to use deprecated master planning with existing companies**.

As previously announced, the built-in master planning engine is deprecated. The engine has been deprecated for a long time and receives no meaningful support from Microsoft. Microsoft no longer invests in it (no new features are released).

Planning Optimization is the master planning engine for Supply Chain Management and completely replaces the built-in master planning engine.

> **⚠ Warning**
>
> If you're still using the deprecated master planning engine, you should strongly reconsider doing so. The engine receives no support and has no active development. We strongly encourage you to complete the migration to Planning Optimization as soon as possible so that you can take advantage of the many performance improvements and other new capabilities provided by the new service.

Work with a partner to evaluate and plan the migration to Planning Optimization.

Before you switch to Planning Optimization, evaluate the results of the Planning Optimization fit analysis. Learn more in Planning Optimization fit analysis.

When will the deprecated planning engine be removed?

There's currently no timeline for the full removal of the deprecated master planning engine from Supply Chain Management. Microsoft isn't currently planning to remove it.

> **Important**
>
> If Microsoft decides to remove the deprecated master planning engine, the company will announce those plans at least 12 months before the removal date on the Removed or deprecated features in Dynamics 365 Supply Chain Management page. Monitor that page and the What's new or changed in Dynamics 365 Supply Chain Management page for the latest announcements.

Although the deprecated master planning engine isn't being removed right now, it's important to understand what *deprecated* means in practice:

- **No new features** – Microsoft isn't investing in new capabilities for the deprecated engine.
- **No support** – The deprecated master planning engine has been deprecated for a long time and receives no support from Microsoft. There are no bug fixes, no new features, and no investment in the engine going forward. Customers who continue to use it do so entirely at their own risk.
- **Version restrictions** – Starting in Supply Chain Management version 10.0.41, the deprecated master planning engine is blocked for all new deployments. Existing deployments can continue using it on a per-company basis.

We strongly recommend that you begin planning your migration to Planning Optimization now, even though there's no removal date. Learn more in Migration to Planning Optimization for master planning.

Migration to Planning Optimization for master planning

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

> **Important**
>
> Starting February 2026, new customers can't create projects in Microsoft Dynamics Lifecycle Services for Microsoft Dynamics 365 Finance, Microsoft Dynamics 365 Supply Chain Management, and Microsoft Dynamics 365 Project Operations. New customers should use the Power Platform admin center instead. For more information, see Lifecycle Services project creation freeze.

The built-in master planning engine is deprecated. It's replaced by the Planning Optimization Add-in for Microsoft Dynamics 365 Supply Chain Management. This article provides information about the impact on new and existing deployments. It includes information about required actions.

Planning Optimization enables master planning calculations to occur outside Supply Chain Management and its Azure SQL database. The benefits that are associated with Planning Optimization include improved performance and minimized impact on the SQL database during master planning runs. Because quick planning runs can be done even during office hours, planners can immediately react to demand or parameter changes.

For more information about Planning Optimization, see Master planning system architecture.

Deprecation of the legacy master planning engine

Microsoft deprecated the built-in master planning engine in favor of Planning Optimization. This change affects all cloud environments. On-premises installations aren't affected.

For more information about the deprecated master planning engine, see the announcements in Removed or deprecated features in Dynamics 365 Supply Chain Management.

A deprecated feature is a feature that's no longer in active development and might be removed in a future release. For the deprecated master planning engine, Microsoft won't add new features. Support is provided only for blocking problems (where master planning doesn't create any planned orders and/or continuously fails) and for regressions in the functionality. In March 2023, Microsoft adopted a strict policy against providing support for the deprecated master planning engine, except for blocking problems or regressions. These conditions apply to all customers, including the following types:

- Customers whose needs aren't yet fully supported by Planning Optimization.
- Customers who received an exception so that they can continue to use the deprecated planning engine.
- All on-premises customers.

There's currently no timeline for full removal of the deprecated planning engine from Supply Chain Management. If Microsoft makes plans to remove it, the company announces those plans 12 months before the removal date.

New deployments

Planning Optimization is now the standard master planning engine and you must use it for all new cloud deployments. Starting with Supply Chain Management version 10.0.32, the first time you enable planning processes for any legal entity, the system requires you to install and enable Planning Optimization if you didn't already do so.

Starting in Supply Chain Management version 10.0.41, the deprecated master planning engine is blocked for all new deployments. There's no manual way to enable the deprecated master planning engine for these environments.

Adding a new legal entity to an existing environment

When you add a new legal entity (company) to an existing environment, that company must use Planning Optimization. Starting with Supply Chain Management version 10.0.32, the first time you enable planning processes for any newly added legal entity, the system requires you to install and enable Planning Optimization if you didn't already do so.

You can continue to use the deprecated master planning engine for one or more previously created companies (until you're ready to migrate them) even while using Planning Optimization for the others. For instructions on how to set a company to use the deprecated master planning engine, see Continue to use deprecated master planning with existing companies.

> **Note**
>
> Remember that you must still move each legal entity to Planning Optimization once they're supported.

If you use kanban or are going live very soon and need time to test Planning Optimization

All new deployments and legal entities must use Planning Optimization from the beginning. However, if you've been preparing a new deployment for some time, and the functionality you needed wasn't yet supported by Planning Optimization while you were developing it, you can still go live by using the deprecated master planning engine for that deployment until you have enough time to install and test Planning Optimization on it.

Planning Optimization doesn't yet support kanban, so if you need to use kanban, you can go live by using the deprecated planning engine for now. You should still plan to move to Planning Optimization as soon as kanban is supported.

Existing deployments

Owners of existing cloud-based deployments that depend on master planning must plan to migrate to Planning Optimization. If your implementation depends on functionality that Planning Optimization doesn't currently support, you must request an exception to continue to use the deprecated master planning engine.

Starting in Supply Chain Management version 10.0.32, you can allow some companies (legal entities) to run Planning Optimization while others continue to use the deprecated master planning engine until they're ready to be migrated. Therefore, Microsoft grants exceptions on a per-company basis. The exception only applies to existing companies—starting with version 10.0.32, all new companies that you add to your existing environment must use Planning Optimization. For instructions on how to set a company to use the deprecated master planning engine, see Continue to use deprecated master planning with existing companies.

Migrate companies to Planning Optimization one at a time, as soon as they're supported.

Migration recommendations

Several differences exist between the deprecated master planning engine and Planning Optimization.

For distribution companies, the two planning engines provide very similar feature sets. Based on our experience helping other customers migrate, we recommend that distribution companies enable and test Planning Optimization in a test environment. When testing is successful, enable it in a production environment.

Manufacturing companies might be affected by some of the minor architectural differences that exist between Planning Optimization and the deprecated planning engine. Based on our experience helping other customers migrate, set up a test environment and proceed in the following way:

1. Create two testing plans, one for Planning Optimization and the other for the deprecated planning engine. Use the same settings for both plans.
2. While the deprecated planning engine is enabled, run the plan that you created for it.
3. Enable Planning Optimization, and run the plan that you created for it.
4. For each plan, export the planned orders to an Excel file.
5. For each plan, sum the planned order quantities for each of several regular periods (for example, every month).
6. Compare the quantities for each plan to make sure that the result is the same (or very similar). Some variation can be expected for orders that occur at the start or end of a period.
7. If your test is successful, continue testing on the test environment.
8. If all of your tests are successful, enable Planning Optimization in your production system.

Exception process for version 10.0.32 and later

As of Supply Chain Management version 10.0.32, the process of evaluating your system and moving to Planning Optimization is fully automated. The system analyzes your setup and automatically shows you the correct instructions for your situation and for each company (legal entity). The following subsections provide details about the possible cases.

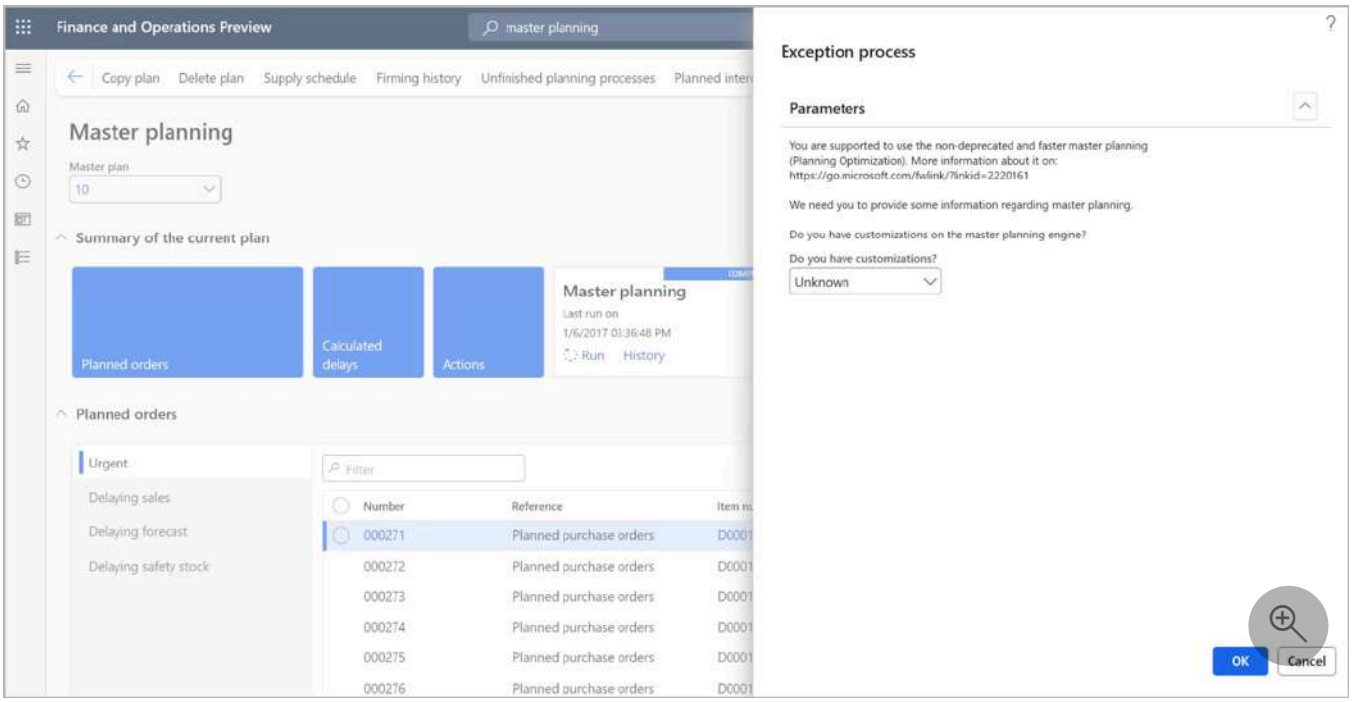
Deployments where Planning Optimization supports all required features

If the system detects that all the relevant features you're using are supported by Planning Optimization, but you're still running the deprecated planning engine, it prompts you to migrate. The next time that you manually run master planning, the system shows the following message:

> You can use the non-deprecated and faster master planning (Planning Optimization).
>
> We need you to provide some information regarding master planning.

> Do you have customizations on the master planning engine?

The following screenshot shows how the message looks.



If you didn't customize the master planning engine for this deployment, you must migrate to Planning Optimization. If you need more time to test and migrate, select the time that you need. The system automatically applies an exception for the selected time.

If you do have customizations, you must move them to the existing extensibility point. Learn more in Planning Optimization extensibility.

Deployments requiring features not yet supported by Planning Optimization

If the system detects that you're using features that aren't supported by Planning Optimization, it shows the following message the next time that you manually run master planning:

> You are not supported yet to use the non-deprecated master planning (Planning Optimization). We expect to be supporting you in the coming future. When you are supported, you will be asked to move to Planning Optimization. If you have customizations on the master planning engine, you can already start evaluating them and preparing to move them to the Planning Optimization extensibility point.

This message informs you that you should start planning to move to Planning Optimization as soon as it supports the features that you're using. Therefore, you should evaluate any customizations that you made to the deprecated planning engine, plan to move them to the

existing extensibility point (see Planning Optimization extensibility), and take other actions to prepare for the migration (for example, by contacting your Microsoft partner or consultant).

For information about which features are already supported and estimates about when each feature will become available for Planning Optimization, see Planning Optimization fit analysis.

If you already received an exception, it remains in place until Planning Optimization supports the features that you require.

Environments that don't support Planning Optimization

Regardless of the features that you're using, to use Planning Optimization, you must be running Supply Chain Management version 10.0.7 or later in a tier 2 or higher high-availability environment that's Microsoft Dynamics Lifecycle Services–enabled. The environment must **not** be a OneBox environment. If you try to install the add-in in a OneBox environment, the installation doesn't complete, so you must cancel it.

If your environment doesn't support Planning Optimization, you receive the following message:

> You can only run deprecated master planning in this environment. If you would like to get an environment that supports non-deprecated planning (Planning Optimization) please follow the instructions: Get started with master planning

If you're a Microsoft partner or independent software vendor (ISV), you can get a nonproduction environment that supports Planning Optimization at a reduced price. It includes Microsoft business applications and demo data. These environments are available only to partners and ISVs. They can be used only on partner tenants, never on customer tenants. Use the environment that you get to learn how Planning Optimization works, test your solutions while you're using it, and deliver end-to-end customer demos. To request a license, go to the partner sandbox request page.

Frequently asked questions about migration

What impact does Planning Optimization have on current planning users?

Users still work in the same module and use the same pages to initiate planning and review planned orders. The only visible difference is that the processing window shows **Run Planning Optimization**.

If I'm running classic planning in a batch job, do I have to update this job when I enable Planning Optimization?

Yes, you must set up a new batch job to run Planning Optimization instead of classic master planning.

If I'm running deprecated planning in some companies and Planning Optimization in others, can I use intercompany master planning?

Yes. Although the intercompany master planning page isn't supported, you can achieve the same effect by scheduling sequential batch jobs to run planning for the different companies in their desired order. Use the Planning Optimization batch job for the companies that are running Planning Optimization (*Planning Optimization* task) and the deprecated engine for the others (*Master planning* task).

To use intercompany master planning for different companies that use Planning Optimization, the process is the same: schedule Planning Optimization tasks as batch jobs the run sequentially.

How much will my performance improve when I move to Planning Optimization?

There's no specific rule about how much your performance improves. In general, companies that run with large datasets and are already experiencing performance problems with deprecated master planning see the biggest improvement. The best way to find out is to test Planning Optimization.

Does it cost extra to use Planning Optimization?

No, it's included in your Supply Chain Management license. There are no extra costs.

Can I run Planning Optimization in a Government Community Cloud (GCC) environment?

Yes, Planning Optimization is supported in Government Community Cloud (GCC) environments now that GCC is compatible with the Microsoft Dynamics Lifecycle Services microservices framework.

Can I run Planning Optimization in a tier-1 environment?

No, Planning Optimization runs through a Lifecycle Services add-in that you can install only in tier-2 or higher environments.

What data center does Planning Optimization run on?

Planning Optimization runs on the same data center as your Supply Chain Management environment.

I'm a partner, and I want to demo or test Planning Optimization. How can I do that?

For partners and independent software vendors (ISVs), Microsoft offers a special license for accessing tier-2 environments. For details, see [ISV] Request License.

I'm going live with version 10.0.32 or higher, but Planning Optimization doesn't yet have all the features I need. Can I go live by using the deprecated planning engine for now?

Yes. When you start using the planning features, the system asks you to install and enable Planning Optimization because this requirement has been mandatory since Supply Chain Management version 10.0.32. However, if one or more of your companies isn't yet ready to use Planning Optimization, you can exclude them from running Planning Optimization by going to the **Planning Optimization parameters** page. For instructions, see Continue to use deprecated master planning with existing companies.

How do I request an exception to continue using the deprecated planning engine on version 10.0.32 or higher?

The system automatically gives you an opportunity to request an exception. Fill out the dialogs when prompted. The exception is applied automatically in the background.

Why do I get an error message when running the deprecated master planning engine?

You might sometimes get an error message when running the deprecated master planning engine. It indicates that you must move to Planning Optimization and provides the following information:

> The built-in master planning engine is deprecated. This means that it is not supported (unless a blocking issue) and it will no longer be invested in. It's being replaced by the Planning Optimization Add-in for Microsoft Dynamics 365 Supply Chain Management.

For information about how to migrate to Planning Optimization, see the earlier sections of this article.

You can continue using the deprecated master planning engine for one or more of your companies if necessary. For instructions, see Continue to use deprecated master planning with existing companies.

If you see this error while running on a sandbox and you'd like to remove it, follow the instructions provided in Can I use the deprecated master planning engine on my sandbox environment?

Can I use the deprecated master planning engine on my sandbox environment?

Yes. Even if you receive the error message described in the answer to the previous question on a sandbox environment, the deprecated master planning engine still runs successfully. However, if the error message disturbs you, you can disable it on an IaaS (not Service Fabric) sandbox environment by running the following query on your database:

SQL

```
-- Insert or update an enabled flight:
DECLARE @flightName NVARCHAR(100) = 'ReqPlanningOptimizationExceptionToggle';
IF NOT EXISTS (SELECT TOP 1 1 FROM SysFlighting WHERE flightName = @flightName)
    INSERT INTO SYSFLIGHTING(FLIGHTNAME,ENABLED, FLIGHTSERVICEID,PARTITION)
    SELECT @flightName, 1, 12719367,RECID FROM DBO.[PARTITIONS];
ELSE
    UPDATE SysFlighting SET enabled = 1, flightServiceId = 12719367 WHERE
flightName = @flightName;
```

My environment is on-premises. Do I need an exception to continue using the deprecated master planning engine?

No. An exception isn't required for on-premises environments. You can continue to use the deprecated master planning engine. Your environment admin is informed if any action is required.

We use planned production orders, but I'm concerned about what will happen when we upgrade to version 10.0.16. Should I take any action?

You shouldn't be concerned. You can continue to use the deprecated master planning engine in version 10.0.16. However, evaluate whether migration to Planning Optimization can start with the current functionality, and stay informed about new functionality.

I'm getting an error message when running master planning. Is master planning blocked?

If you're running version 10.0.16 or later, you might receive the following error message when you run master planning:

> You receive this error message because the deprecated master planning engine was used for scenarios supported by Planning Optimization. You should migrate to Planning Optimization now, as the built-in master planning engine has been deprecated. Note that this master planning run did complete successfully.
>
> In case your migration has strong dependencies on pending features, an exception to continued usage of the deprecated master planning engine can be requested.
>
> Please complete the following questionnaire to get started and if relevant request exception from migration to Planning Optimization.

Master planning isn't blocked. Your master planning run was successfully completed, and you can use the result in the usual way. However, to avoid receiving this error message during future master planning runs, you must either migrate to Planning Optimization immediately or request an exception by using the link in the error message.

Last updated on 03/26/2026

Continue to use deprecated master planning with existing companies

> **Note**
>
> This article applies to **existing deployments** where one or more companies (legal entities) already use the deprecated master planning engine. If you're setting up a new deployment or a new tenant, Planning Optimization is the required engine starting with Supply Chain Management version 10.0.41. For more information, see Migration to Planning Optimization for master planning.

Starting in Supply Chain Management version 10.0.41, the deprecated master planning engine is blocked for all new legal entities (companies) added to existing deployments. There's no manual way to enable the deprecated master planning engine for these companies. However, existing companies can continue to use the deprecated master planning engine until they're ready to migrate.

> **Important**
>
> The deprecated master planning engine is only available to existing companies that already use it. Existing companies that use the deprecated engine aren't affected when you upgrade to a new version of Supply Chain Management. However, any new companies added to the deployment must use Planning Optimization.

Companies where planning processes are disabled

Starting with release 10.0.32, you must install the Planning Optimization Add-in before you can enable planning processes, even if you plan to continue using the deprecated master planning engine. If the company where you want to use deprecated master planning has planning processes disabled, follow the steps in this section to enable them.

When you try to set **Disable all planning processes** to *No* on the **Master planning parameters** page without the Planning Optimization Add-in installed, you receive one of the following error messages:

> To enable all planning processes, first follow the instructions provided in Get started with master planning. Then return to this page and enable the parameter.

or

> All planning processes are disabled. Please enable planning processes to continue.

To resolve this error and enable planning processes, follow these steps:

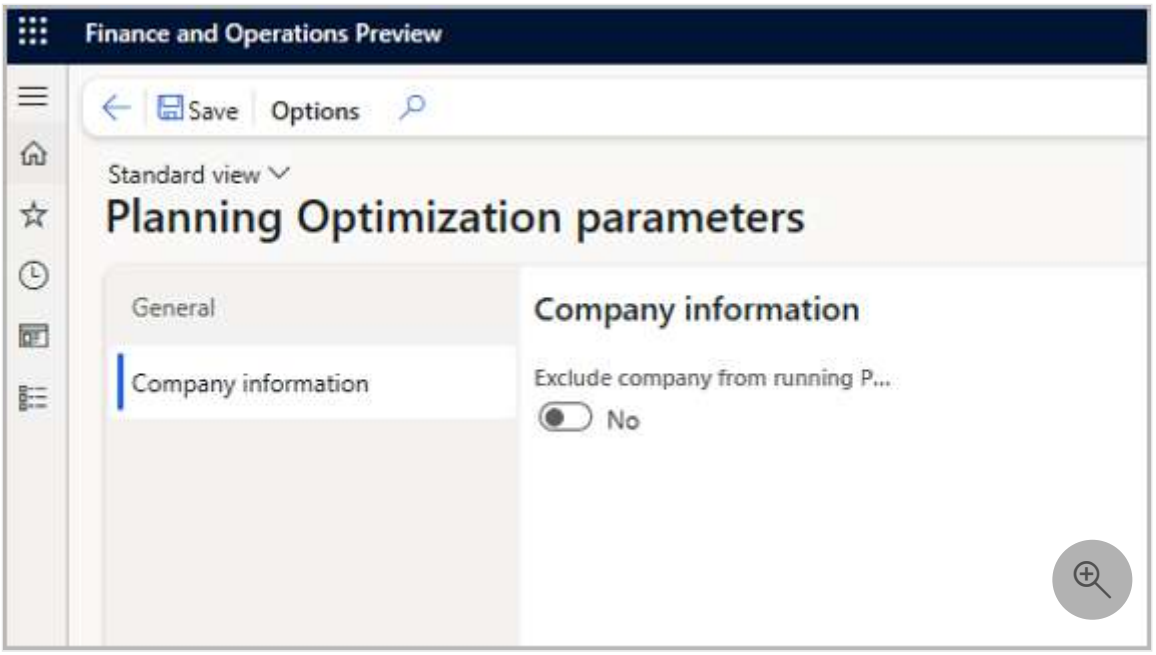
1. Make sure Planning Optimization is installed and enabled as described in Get started with master planning. This step is mandatory starting with release 10.0.32, even if you don't intend to use Planning Optimization.
2. Make sure Planning Optimization is enabled on the **Planning Optimization parameters** page.
3. Enable planning processes for the relevant company by setting **Disable all planning processes** to *No*, on the **Master planning parameters** page.

> **Note**
>
> Starting in Supply Chain Management version 10.0.41, the deprecated master planning engine is blocked for all new legal entities (companies) added to existing deployments. If you're setting up a new company, you must use Planning Optimization. To continue using the deprecated engine for existing companies, see the next section.

Exclude companies from using Planning Optimization and continue to use deprecated master planning

Follow these steps to set a company to continue to use the deprecated master planning engine on an environment that is otherwise enabled to use Planning Optimization:

1. Use the company picker to choose the company (legal entity) that you want to set up.
2. Go to **Master planning** > **Setup** > **Planning Optimization parameters**.
3. Open the **Company information** tab.



4. Set **Exclude company from running Planning Optimization** to one of the following values

    - *Yes* – Use the deprecated master planning engine for this company.
    - *No* – Use Planning Optimization for this company.

5. Select **Save** on the Action Pane.

6. Repeat this procedure for each company you want to set up.

> ⓘ **Note**
>
> If the **Company information** tab appears blank and the **Exclude company from running Planning Optimization** toggle is greyed out, this behavior is expected. The tab and toggle are only relevant for companies that have been granted an exception to use the deprecated master planning engine. Starting from Supply Chain Management version 10.0.41, Planning Optimization is the standard engine for all new deployments and legal entities. Companies that aren't enabled for the deprecated engine don't need this configuration, so the tab remains empty by design. Learn more in Migration to Planning Optimization for master planning.

Unsupported features and exceptions

If your company requires features that aren't yet supported by Planning Optimization, you can continue to use the deprecated engine for the affected companies. Supply Chain Management includes an automated exception process that evaluates your system and shows appropriate

instructions for each legal entity. Learn more about the exception process and the features supported by Planning Optimization in Migration to Planning Optimization for master planning.

Parameters not used by Planning Optimization

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article lists the parameters that Planning Optimization doesn't currently consider during its operation. The planning service might skip a parameter because, for example, it doesn't yet support related functionality. Alternatively, functional changes might make the parameter obsolete.

The following sections list the parameters that Planning Optimization doesn't use on specific pages. They also explain why each parameter isn't used.

Master planning parameters page

Planning Optimization doesn't use the following parameters or options on the **Master planning parameters** page:

- **General** tab:
  - **Current forecast plan** – Planning Optimization doesn't consider this parameter. Instead, create a master plan that specifies a forecast model.
  - **Copy the complete and updated static master plan to the dynamic master plan** – Planning Optimization doesn't support this option. You can run each plan independently, but results aren't copied between them.
  - **Start time for calculated delays** – Planning Optimization doesn't support this option.
  - **Use dynamic negative days** – Planning Optimization always uses the *Dynamic negative days* approach.
  - **Today's date calendar** – Planning Optimization doesn't support this option. Planning Optimization always uses current time rounded to the next whole hour.
  - **Use of cache** – Planning Optimization doesn't consider this parameter because it manages performance and scaling.

- **Number of tasks in helper task bundle** – Planning Optimization doesn't consider this parameter because it manages performance and scaling.
- **Pre-processing: Automatically filter by items with direct demand** – Planning Optimization doesn't support this option.
- **Post-processing: Automatically filter by items with direct demand** – Planning Optimization doesn't support this option.
- **Number of threads** – Planning Optimization doesn't consider this parameter because it manages performance and scaling.
- **Planning process timeout in minutes** – In Planning Optimization, there's a fixed timeout of 1 hour.
- **Scheduling start time** – Planning Optimization doesn't consider this parameter. With Planning Optimization, an explosion run is a run of the plan for the selected items.

- **Planned orders** tab:
  - **Receipt time** – Planning Optimization doesn't support this option. The receipt time exactly matches the demand time in Planning Optimization.

- **Number sequences** tab:
  - **Master scheduling planned order number** – Planning Optimization uses its own proprietary number sequence for all generated planned order numbers, and there's no method available for modifying this number sequence. The system ignores this parameter entirely. Learn more about how Planning Optimization handles number sequences in Differences between Planning Optimization and the deprecated master planning engine.

Coverage groups page

Planning Optimization doesn't use the following parameters or options on the **Coverage groups** page:

- **Other** FastTab:
  - **Freeze time fence (days)** – Freeze time fence is supported in Supply Chain Management version 10.0.40 and later. To use it, turn on the feature named *Freezing time fence for Planning optimization* in feature management.
  - **Forecast plan time fence** – Planning Optimization doesn't support forecast plans. However, it does consider this value when consuming forecast data within a master plan.

- **Delays** FastTab:

- **Calculated delays** – Planning Optimization doesn't consider this parameter because it always calculates delays for the coverage group.
- **Calculate delays time fence (days)** – Planning Optimization doesn't consider this parameter because it calculates delays for the **Coverage time fence (days)**.

Item coverage page

Planning Optimization doesn't use the following parameters or options on the **Item coverage** page:

- **General** tab:
  - **Planned order type** – Planning Optimization supports all order types, including kanban. To use kanban, enable the *Lean manufacturing for Planning Optimization* feature in feature management. This is a preview feature in Supply Chain Management version 10.0.45 and is generally available as of version 10.0.46.
  - **Freeze time fence (days)** – Freeze time fence is supported in Supply Chain Management version 10.0.40 and later. To use it, turn on the feature named *Freezing time fence for Planning optimization* in feature management.
  - **Fulfill minimum** – Planning Optimization doesn't support the *Today's date*, *First issue*, and *Coverage time fence* options. It always uses the *Today's date + procurement time* option.
  - **Minimum periods** – Planning Optimization doesn't support this parameter.

Master plans page

Planning Optimization doesn't use the following parameters or options on the **Master plans** page:

- **General** FastTab:
  - **Include continuity plan** – Planning Optimization doesn't support this parameter.
  - **Capacity time fence for bottleneck resources** – Planning Optimization doesn't support this parameter because customers didn't use it.
  - **Planned orders** – Planning Optimization uses its own proprietary number sequences that you can't modify.
  - **Session** – Planning Optimization uses its own proprietary number sequences that you can't modify.
  - **Continuity plan** – Planning Optimization doesn't support this parameter.

- **Time fences in days** FastTab:

- **Freeze** – Freeze time fence is supported in Supply Chain Management version 10.0.40 and later. To use it, turn on the *Freezing time fence for Planning optimization* feature in feature management.
- **Continuity plan** – Planning Optimization doesn't support this parameter.
- **Calculated delays** – Planning Optimization doesn't consider this parameter. Calculated delays are created for the **coverage time fence (days)**.

- **Calculated delays** FastTab:
  - **Ensure that the planned orders are not created prior to the master planning run date** – Planning Optimization doesn't support this parameter. Planning Optimization never creates planned orders in the past.
  - **Add the calculated delay to the requirement date** (in the **Planned kanban** section) – To use kanban, enable the *Lean manufacturing for Planning Optimization* feature in feature management. This is a preview feature in Supply Chain Management version 10.0.45 and is generally available as of version 10.0.46.

- **Action message** FastTab:
  - **Update postponed date as requirement date** – Planning Optimization discontinued this parameter.

Scheduling parameters page

Planning Optimization doesn't use the following parameters or options on the **Scheduling parameters** page:

- **Schedule timeout enabled** – In Planning Optimization, schedule timeout is always enabled.
- **Maximum scheduling time per sequence** – Planning Optimization doesn't support this parameter.
- **Schedule optimization timeout enabled** – Planning Optimization doesn't support this parameter.
- **Optimization attempts timeout** – Planning Optimization doesn't support this parameter.
- **Keep production unit** – Planning Optimization doesn't support this parameter.
- **Keep warehouse from resource** – Planning Optimization doesn't support this parameter.

Differences between Planning Optimization and the deprecated master planning engine

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you transition from the deprecated built-in master planning engine to Planning Optimization, you might notice differences in planned orders, quantities, and dates. Use this article and the related resources to identify whether an issue you're experiencing is due to an expected difference, an unsupported feature, or a parameter change.

Identify the type of issue

Use the following table to find the right resource for your situation:

Expand table

Issue	Resource
Planning Optimization shows different planned order results, dates, quantities, or behavior	Expected differences (this article)
A feature doesn't work or is missing in Planning Optimization	Planning Optimization fit analysis
Date or time calculations produce different results	Date and time parameters used by Planning Optimization
A master planning parameter seems to have no effect	Parameters not used by Planning Optimization
You have questions about when the deprecated engine will be removed	Deprecated master planning overview
You need guidance on the full migration process	Migration to Planning Optimization

Expected differences

The following table lists specific differences between Planning Optimization and the deprecated master planning engine that aren't listed on the **Planning Optimization fit analysis** page.

Expand table

Feature	How Planning Optimization differs from deprecated master planning
Forecasts for today's date	Planning Optimization doesn't consider forecasts for today's date, though the deprecated master planning engine considered them.
Filtered production runs	For details, see Production planning - Filters.
Forecast planning	Forecast planning isn't supported. Use master planning where a forecast model is assigned to the master plan.
Number sequences for planned orders	Number sequences for planned orders aren't supported. Planning Optimization uses its own proprietary number sequence for all generated planned order numbers, and there's no method available for modifying this number sequence. The **Master scheduling planned order number** setting on the **Number sequences** tab of the **Master planning parameters** page has no effect when you use Planning Optimization. The planned order number normally shows 14 digits, but the sequence is actually built on 20 characters, with 6 digits allocated for the planning run count and 10 for the planned orders count.
Plan copy, plan delete, and plan version cleanup	Under **Master planning** > **Master planning** > **Maintain plans** in the navigation pane, the following items are disabled: • Plan copy • Delete plan • Plan version cleanup Plan version cleanup is automatic with Planning Optimization, so you don't need to do it manually.
Return orders	Planning Optimization doesn't consider return orders.
Scheduling related features	For details, see Scheduling with infinite capacity.
Safety stock fulfillment	Planning Optimization always uses the *Today's date + procurement time* option for the **Fulfill minimum** field on the **Item coverage** page. This choice helps prevent unwanted planned orders and other issues. If the procurement time isn't included for safety stock, planned orders that are created for low on-hand inventory are always delayed because of the lead time. Learn more in Safety stock fulfillment with the deprecated master planning engine.
Safety stock pegging and net requirements	The *Safety stock* requirement type isn't included and isn't displayed on the **Net requirements** page. Safety stock doesn't represent demand and doesn't have a requirement date associated with it. Instead, it sets a constraint on how much inventory must be present at all times. However, the **Minimum** field value is still

Feature	How Planning Optimization differs from deprecated master planning
	taken into account when calculating planned orders during master planning. Inspect the **Accumulated quantity** column on the **Net requirements** page to see that this value was considered. Because the pegging is different, different actions might be suggested. Learn more in Safety stock fulfillment with the deprecated master planning engine.
Transport calendars	The value in the **Transport calendar** column on the **Modes of delivery** page is ignored.
Min/max coverage code with no values	With the deprecated master planning engine, when you use a min/max coverage code where no minimum or maximum values are set, the planning engine treats the coverage code as a requirement and creates one order for each requirement. With Planning Optimization, the system creates one order per day to cover the full amount for that day.
Net requirements and manually created planned orders	With the deprecated master planning engine, manually created supply orders for an item automatically appear among the net requirements for that item. For example, when you create a purchase order from a sales order, the purchase order appears on the **Net requirements** page without requiring any prior actions. This behavior occurs because the deprecated master planning engine logs inventory transactions in the `inventLogTTS` table and shows changes on the **Net requirements** page for dynamic plans. However, with Planning Optimization, manually created orders don't appear among the net requirements of an item until you run Planning Optimization (using a plan that includes the item), or until you select **Update** > **Master planning** on the Action Pane on the **Net requirements** page, which runs master planning for the item. For more information about how to work with the **Net requirements** page, see Net requirements and pegging information.
Net requirements and any changes to supply or demand	With the deprecated master planning engine, any changes to supply or demand for an item automatically appear among the net requirements for that item. For example, when you increase the quantity of a planned order, the purchase order appears on the **Net requirements** page without requiring any prior actions. This behavior occurs because the deprecated master planning engine logs inventory transactions in the `inventLogTTS` table and shows changes on the **Net requirements** page for dynamic plans. However, with Planning Optimization, any changes don't appear among the net requirements of an item until you run Planning Optimization (using a plan that includes the item), or until you select **Update** > **Master planning** on the Action Pane on the **Net requirements** page, which runs master planning for the item. Learn more about how to work with the **Net requirements** page in Net requirements and pegging information.
Resource assignment	When working with infinite capacity, the deprecated master planning engine assigns all planned orders to the same resource on a given resource group. Planning Optimization improves on this behavior by selecting resources at random so different production orders can use different resources. If you want to use the same resource for all planned orders, specify that resource in the route.
Extended data types	Planning Optimization doesn't support changes to the precision of EDTs. This

Feature	How Planning Optimization differs from deprecated master planning
(EDTs)	process isn't officially supported and isn't guaranteed to work.
Safety stock fulfillment	Planning Optimization always uses a **Fulfill minimum** of *Today's date + procurement time*. This choice prepares the system to use a simplified planning setup in the future, and provides an actionable result. If the procurement time isn't included for safety stock, planned orders that are created for low on-hand inventory are always delayed because of the lead time. This behavior can cause significant noise and unwanted planned orders. The best practice is to change the setting to use *Today's date + procurement time*. Update master data to avoid warnings. Learn more in Safety stock fulfillment with the deprecated master planning engine.
Purchase order fulfillment	When fulfilling a purchase order, the system always applies a lead time and never disregards it, even if the **Add delay to calculated requirement date** parameter is set to *No*. This behavior differs from that of the deprecated master planning engine, which would set an unfeasible date in this case. For example, if today is March 1, 2024, lead time is 30 days, and **Add delay to calculated requirement date** is set to *No*, the deprecated engine creates a purchase order with date March 1, 2024, while Planning Optimization creates it with date April 1, 2024 (today plus the 30-day lead time).
Copy static to dynamic plan	Planning Optimization doesn't copy static plans to dynamic plans, regardless of the setting on the **Master planning parameters** page. In general, this operation is less relevant because of the speed and complete regeneration that Planning Optimization provides. If you use two or more plans, trigger master planning for each plan.
Negative days	Planning Optimization always uses dynamic negative days, regardless of the setting of **Use dynamic negative days** on the **Master planning parameters**. The **Use dynamic negative days** setting on the **Master planning parameters** page has no effect on this behavior. For more information on negative days, see Delay tolerance (negative days)
Today's date calendar	Planning Optimization doesn't consider the **Today's date calendar** setting on the **Master planning parameters** page. Planning Optimization always uses the current time rounded to the next whole hour. In the deprecated master planning engine, this setting defined the start of a freezing time fence. However, the system still uses the **Today's date calendar** parameter to determine whether a manually created production order is scheduled within the freezing time fence, even when you're using Planning Optimization.
Planned orders in the past	Planning Optimization never plans orders in the past, regardless of the **Requested date** setting. If you set a **Requested date** that's in the past, the system keeps your setting, but sets the **Required date** to *Today*.
Definition/meaning of safety stock	In Planning Optimization, safety stock isn't actual demand. For each coverage group, you can specify how strictly the system should peg safety stock as demand against the planned order that's created for it. (Learn more in Safety stock pegging options.) Coverage groups that use strict safety stock pegging work just like all

Feature	How Planning Optimization differs from deprecated master planning
	groups in the deprecated engine where the **Fulfill minimum** field is set to *Today's date + procurement time*. In the deprecated master planning engine, safety stock is demand, the same as other demand types. You can specify when safety stock will be fulfilled.
When safety stock is fulfilled	In Planning Optimization, safety stock is always fulfilled on *today's date + procurement time*, regardless of the item coverage setting. In the deprecated master planning engine, item coverage settings include a **Fulfill minimum** field that defines when the safety stock must be fulfilled. (Learn more in Safety stock fulfillment with the deprecated master planning engine.)
Forecast plan time fence	When deciding which demand and supply forecast entries to take into consideration, Planning Optimization always takes the lower of the following two values: *coverage time fence* or *forecast plan time fence*. The deprecated planning engine always uses the *forecast plan time fence*. Planning Optimization therefore guarantees that the supply covers all demand forecast entries that are included in a plan.
Issue margin	When the issue margin can be met, Planning Optimization applies its value to the *receipt requirement date*, not the *issue requirement date*; if the margin can't be met, Planning Optimization pushes the issue requirement date forward. The deprecated planning engine always adjusts the *issue requirement date* by the value of the issue margin. Planning Optimization therefore treats the issue margin more correctly, as a shipping-time buffer that affects how far in advance receipt is required. Learn more in Safety margins.
Vendor calendar lead time	Planning Optimization doesn't consider closed days from the vendor's calendar when calculating lead times for delivery dates. It only considers the coverage group calendar when calculating lead times. Learn more in Calendar matrix for Planning Optimization.
Zero positive days	Setting positive days to one in Planning Optimization provides the same behavior as setting positive days to zero in the deprecated master planning engine.
Planning with negative on-hand quantities	If the system shows a negative aggregate on-hand quantity, Planning Optimization treats it as quantity 0 (zero) to help avoid over supply. Learn more in Planning with negative on-hand quantities. The deprecated master planning engine instead replenished the negative quantity.
Firming manual planned production orders	When firming planned production orders that were created manually, Planning Optimization doesn't automatically trigger the explosion of items. You must manually trigger item explosions as needed.
CTP with lean manufacturing	The *event* kanban rule replenishment strategy with event type *sales event* set to *Automatic with CTP* doesn't automatically generate and add kanbans to the schedule for sales order order lines that use the *CTP* delivery date control method. Instead, replenish through a planning kanban and apply auto-firming.

Planning Optimization fit analysis

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Planning Optimization fit analysis helps you identify where the result might differ between the deprecated master planning engine and Planning Optimization. The system runs this analysis based on your current setup and data.

You should analyze the result from the Planning Optimization fit analysis as part of the migration process. The scope of Planning Optimization isn't equal to the deprecated master planning engine functionality. Work with your partner and read the documentation to prepare for the migration.

> **Note**
>
> - The Planning Optimization fit analysis can't identify some inconsistencies. For more information, see Differences between classic master planning and Planning Optimization.
> - If the analysis finds inconsistencies, you can still use Planning Optimization. The results of the fit analysis just show places where the planning service doesn't honor your current setup. In other words, they show places where some processes might be ignored or aren't supported.

Run Planning Optimization fit analysis

To run the Planning Optimization fit analysis and view the results, follow these steps:

1. Select a company (legal entity) from the company picker in the navigation bar.
2. Go to **Master planning** > **Setup** > **Planning Optimization fit analysis**.
3. On the Action Pane, select **Run analysis**.
4. The system runs the analysis and then shows the results. For each result that shown, consult the table later in this article to see whether that feature is currently supported for Planning Optimization and, if it isn't yet supported, when support is expected to become

available. If no issues exist for your selected company, the result list is blank, and you receive a "No issues found" message.

5. Repeat this procedure for each company in your organization.

Possible results from the fit analysis

The following table shows the various results that can appear after a fit analysis. Number signs (#) are replaced with a number that indicates the number of records that have the listed issue.

> **Important**
>
> For features that aren't yet supported, the following table provides an availability estimate based on the current roadmap. These estimates are subject to change without notice.

Expand table

Feature	Listed issue	Explanation	Expected availability
Actions	Coverage groups with Actions calculation enabled	This feature is now supported.	Supported
Base calendars	Calendars using base calendar	This feature is now supported.	Supported
Batch disposition codes	Non-nettable batch disposition masters	This feature is now supported. Learn more in Use batch disposition codes to mark batches as available or unavailable	Supported
Capable to promise (CTP)	Default order settings with delivery date control set to CTP	In Supply Chain Management 10.0.28 and newer, a process called *CTP for Planning Optimization* makes confirmed ship and receipt dates available after the dynamic plan runs. For older versions of Supply Chain Management, the legacy CTP setting is ignored when Planning Optimization is enabled.	Supported
Firming	Coverage groups with auto firming time fence set	In version 10.0.7 and later, firming is supported as a separate firming batch job after master planning is completed. Auto firming for Planning Optimization is based on the order date (start date), not the requirement date (end date). This behavior ensures that firming of planned orders occurs in due time, without	Supported

Improve master planning performance

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains the various options that can help you improve the performance of master planning or troubleshoot issues. It includes information about parameters and settings, as well as recommended configurations and actions. Also included is a summary of all the important parameters that you should consider when you have long-running master planning jobs.

This article is intended for system admins or IT users who have the capability to troubleshoot. It's also intended for production or supply planners because it includes information about parameters that are related to business planning requirements.

Parameters related to master planning performance

Various parameters influence the running time of master planning and should be considered.

Number of threads

The **Number of threads** parameter lets you adjust the master scheduling process to help improve performance on the specific data set. This parameter specifies the total number of threads used to run master planning. It causes parallelization of the master planning run, which helps decrease the running time.

Set the **Number of threads** parameter in the **Master planning run** dialog box. To open this dialog box, go to **Master planning** > **Master planning** > **Run** > **Master planning**, or select **Run** in the **Master planning** workspace. To determine the best value for this parameter, use a trial-and-error process. However, you can use the following formulas to calculate an initial value:

- **If your industry is manufacturing:** (Number of threads) = (Number of planned orders ÷ 1,000)
- **Otherwise:** (Number of threads) = (Number of items ÷ 1,000)

The number of helpers used during master planning must be less than or equal to the maximum number of threads that the batch server allows. If the number of helpers exceeds the number of threads on the batch server, the extra threads don't do any work.

> **Note**
>
> Setting the **Number of threads** parameter to **0** (zero) increases the master planning running time. Therefore, always set a value that's more than 0.

Number of tasks in helper task bundle

Change the **Number of tasks in task bundle** setting (that is, the bundle size) to potentially decrease the running time. This setting controls the number of items that a single helper plans together.

Set the **Number of tasks in task bundle** parameter in the **Performance** section on the **General** tab of the **Master planning parameters** page (**Master planning** > **Setup** > **Master planning parameters**). The best value for this parameter depends on your data. Therefore, start with a value of **1**, and then use a trial-and-error process to determine the best value for your setup.

In general, increase the number of tasks when the number of items is very large (in the hundreds of thousands). Otherwise, decrease the number of tasks. For the following specific industries, consider these recommendations:

- In the retail and distribution industries where there are many independent items, use many helpers because there's no dependency between items.
- In the manufacturing industry where there are many bills of materials (BOMs) and shared subcomponents, use fewer helpers because dependencies between items might cause waiting times.

> **Tip**
>
> If you have performance issues, reduce the **Number of helpers in task bundle** setting to **1**. Then, start the trial-and-error process to find the best value for your setup. In general, performance issues occur when one item takes longer to process than the remaining items. In this case, you see that two subsequent tasks that have a status of **Coverage** in the master planning run take significantly different amounts of time to run. In extreme cases, this

difference might be as much as 30 minutes. You can infer the amount of time that tasks take to run by looking at the duration of each task.

Use of cache

The **Use of cache** parameter lets you adjust the master scheduling process to help it perform better on the specific data set. For example, you can adjust it to achieve the following results:

- If more caching is done, more data is collected in memory. The expectation is that the data can be used again later. If the data is in memory, you might save some database requests. However, if more caching is done, memory requirements increase.
- If less caching is done, the same data might have to be fetched from the database more often. Additionally, Application Object Server (AOS) stores little data in memory throughout the process.

It's difficult to predict which option is better because each case depends not only on the data but also on the hardware. For example, because less caching causes additional load on the database server, it probably isn't a good idea to use that option if your database server is already overloaded.

Set the **Use of cache** parameter in the **Performance** section on the **General** tab of the **Master planning parameters** page (**Master planning** > **Setup** > **Master planning parameters**). The effectiveness of caching depends heavily on the customer data. For example, if cached data is never needed, you just waste memory if you store data until the end of the scheduling process. In this case, if you configure less caching, performance might increase because AOS requires less memory and server resources are freed up for other tasks.

> **Tip**
>
> In general, set the **Use of cache** parameter to **Maximum**, because the parameter is intended as a performance enhancing feature. Set the parameter to **Minimum** if you run on-premises and have limited memory (approximately 2 gigabytes [GB]).

Number of orders in firming bundle

The **Number of orders in firming bundle** parameter specifies the total number of orders that each thread or batch processes at a time. It causes parallelization of the auto-firming process.

Set the **Number of orders in firming bundle** parameter in the **Performance** section on the **General** tab of the **Master planning parameters** page (**Master planning** > **Setup** > **Master planning parameters**). Parallelization of the auto-firming process is based on the orders that must be processed together. For example, if this parameter is set to **50**, each thread or batch task picks up 50 orders at a time and processes them together. Use a trial-and-error process to find the best value. However, you can use the following formula to calculate an initial value:

(Number of orders per bundle) = (Number of demand items ÷ Number of threads)

> **Note**
>
> If you set the **Number of orders in firming bundle** parameter to **0**, the auto-firming process isn't parallelized. The whole process runs on a single batch task and has a cumulative running time. Therefore, the running time of your master planning increases. For this reason, set this parameter to a value that is more than **0**.

Time fences

Time fences specify how far in the future master planning must calculate requirements. The larger the time fence is, the longer it takes master planning to run. Therefore, set the time fences according to your business requirements. For more information about time fences, see Master plans overview.

Actions

Among the time fences, you can also find the **Action message** parameter. The calculation of action messages causes a longer running time for master planning. If you don't regularly analyze and apply action messages (daily, weekly, and so on), consider turning off the calculation during the master planning run. To turn off the calculation, on the **Master plans** page (**Master planning** > **Setup** > **Plans** > **Master plans**), set the **Action message** time fence to **0**. Also make sure that the **Action message** setting is turned off for all the coverage groups.

Futures

The calculation of futures causes a longer running time for master planning. If you aren't planning BOMs, or if delays don't have to be propagated from supply to demand during planning, consider turning off futures calculations during master planning. To turn off the

calculations, set the **Futures** time fence to **0** for the master plan that you're running. Also make sure that the **Futures** setting is turned off for all the coverage groups.

One heavy routine at a time

When you schedule master planning, don't schedule any other batch job at the same time. Be especially careful that you don't schedule any other heavy routines, such as inventory close, at the same time.

Review the session log

The system can collect extra information about the tasks that run during master planning. To have the system collect this information, turn on the **Track processing time** setting in the **Master planning run** dialog box. The information that the system collects can help you find bottlenecks in the run. For example, when the **Number of tasks in helper task bundle** parameter is set to **1**, you can identify the item that has the longest running time. You can also compare the running times for the various threads that have a status of **Coverage** and compare the duration for each task.

To review the master planning runs of your system, follow one of these steps:

- In the **Master planning** workspace, select a master plan in the drop-down field. On the **Master planning** tile, select **History**. Select a job, select **Inquiries** on the FastTab, and then select **Process task duration**.
- On the **Master plans** page, select a plan in the left pane. Select **History** on the FastTab. Select a job, select **Inquiries** on the FastTab, and then select **Process task duration**.

When you review the session log, consider the following points:

- **Update** shouldn't take a long time (in general, it should take up to 30 minutes), but it's single-threaded.
- **Copy plan** shouldn't take a long time (it should take about one minute).
- **Auto firming** usually takes about 30 minutes. However, it can take up to multiple hours, depending on the number of orders and the complexity of the items.
- **Auto firming** should take less time than **Coverage**.
- **Coverage** should take the longest time relative to the rest.
- **Action** and **Future message** can take a long time, depending on the data and the number of BOMs.

Filtering of items

Filters applied in the **Master planning run** dialog box affect the duration of the master planning run. Go to **Master planning** > **Master planning** > **Run** > **Master planning**, or select **Run** in the **Master planning** workspace. To exclude items from the run, filter by the lifecycle state of the item (not by item numbers). When you filter by lifecycle state, the update process takes less time than when you filter by item numbers.

Automatically filter by items with direct demand

To improve the master planning run time, you can choose to only include items with direct demand. You can use this filter only for a complete master planning run with no other filters applied in the **Records to include** field. A master planning run with filters ignores the **Automatically filter by items with direct demand** setting.

You can find the **Automatically filter by items with direct demand** field on the **Master planning parameters** page. Use it with both pre-processing and post-processing settings.

Pre-processing

The **Pre-processing: Automatically filter by items with direct demand** parameter ensures that the pre-processing phase of master planning only includes items that fulfill at least one of the following conditions:

- The item has an expected receipt or issue, such as a purchase order, sales order, quote, transfer order, or production order.
- The item has item coverage with safety stock (minimum on-hand inventory).
- Forecast demand after today exists for the item.
- Forecast supply after today exists for the item.
- The item includes any continuity lines from the call center module yet to be created.

> **Note**
>
> An item that has physically available on-hand inventory doesn't show a requirement transaction because there's no demand for the item.

Post-processing

The **Post-processing: Automatically filter by items with direct demand** option is only relevant if you set **BOM version requirement** in your coverage groups. Otherwise, you don't need to enable the parameter.

Before the coverage step starts, there's a pre-coverage step during which items with the coverage setting **BOM version requirement** enabled are reprocessed. This step ensures that items from the required BOM version are planned. Items that are considered to have demand during pre-processing no longer have any demand and therefore should be excluded from the planning run.

Performance checklist summary

- **Number of threads** – Set to a value that's more than **0** (zero).
- **Number of tasks in helper task bundle** – Set to a value that's more than **0** (zero). (Use the formulas that are given earlier in this article.)
- **Use of cache** – Set to **Maximum** unless your system is low on memory.
- **Number of orders in firming bundle** – Set to a value that's more than **0** (zero). (Use the formula that is given earlier in this article.)
- **Time fences** – Adjust to your business needs.
- **Actions and futures** – Disable actions and future if you don't use them.
- **One heavy routine at a time** – Don't run master planning together with any other heavy routine.
- **Review the session log.**
- **Filtering of items** – Use the lifecycle state to exclude items from the master planning run. (Don't use the item numbers.)

Set up master plans for the deprecated planning engine

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes various important strategies and parameters that are used to set up master plans when you are using the deprecated planning engine. It includes an overview of the types of plans that are used by master planning and explains which plan strategy you should use, depending on your business requirements. It also describes the main parameters that affect the plan and explains how those parameters influence the planned orders that are suggested.

Types of master plans

The deprecated master planning engine uses two types of plans: static and dynamic. Each type is designed for a different use. For the best performance, we recommend that you use the appropriate plan for your scenario. You can configure master plans on the **Master plans** page.

- **Static plan** – The master planning calculation uses the current data to generate a net requirements plan. This plan remains unchanged until the next time that you run master planning or manually change the plan. This is an operating plan that various company personnel, such as a purchaser or production planner, can use to base their decisions on and perform their daily activities.
- **Dynamic plan** – This plan starts with the same net requirements plan that was generated by master planning. However, you can update the dynamic plan every time that the master data changes. This could be when you create a new sales order, for example. This enables you to monitor the changing order network and item availability without disturbing the static plan that others are using for their work processes.

A company may choose to work with just a dynamic plan or it may use both static and dynamic plans. In addition, you can configure any master plan to reflect a particular strategy or address an issue. Examples are as follows:

- Set higher inventory levels to guarantee against stockouts.
- Set longer safety margins to protect against unreliable vendors.

You can also set up the starting dynamic plan so that it is updated with the new requirements plan every time that you run master planning. You can specify these settings on the **Master planning parameters** page.

Static plan

The static plan remains unchanged, regardless of any changes in the supply and demand, until the next time that master planning is run.

The static plan is used to approve and firm the orders that are suggested. It's an operating plan that various company personnel (such as a purchaser or production planner) can base their decisions on and use to perform their daily tasks and activities.

The static plan also supports regeneration. A totally new optimized plan is calculated every time that master planning is run, and existing orders that haven't been approved are deleted.

Dynamic plan

The dynamic plan usually starts as a copy of the static plan, but it can be updated every time that master data changes. For example, if the data changes, a new sales order is created.

The dynamic plan is used for ad-hoc planning. It lets the company monitor the changing order network and item availability without disturbing the static plan that other people are using for their work processes. It's especially used for capable to promise (CTP). The dynamic plan is the default plan when net requirements are opened from order pages (such as sales order, purchase order, or production order pages).

The dynamic plan uses net change. Therefore, it helps guarantee a faster running time.

Strategies for using master plans

You can use either one plan or two plans in master planning. The strategy that you use depends on your business requirements.

One-plan strategy

For the one-plan strategy, you use the same master plan for the static plan and the dynamic plan. This strategy is used for make-to-stock scenarios, where you don't usually have to simulate a plan that fulfills an order.

The one-plan strategy is typically used in retail and distribution industries, or where sales delivery dates are confirmed based on service level agreements (SLAs) or lead times. For the

plan, delivery date control can be used without CTP.

If you must do a simulation, the plan can be run again for the items that require the simulation. The planned orders that order simulations produce are usually firmed.

Two-plan strategy

For the two-plan strategy, you use a static plan and a different dynamic plan. The two-plan strategy is typically used for configure-to-order and make-to-order scenarios, where you must do sales order simulations and calculate exact delivery dates for sales orders, but the calculations must not affect everyday operations. These simulations are always done in the dynamic plan. The two-plan strategy is useful in the automotive and original equipment manufacturer (OEM) industries, for example.

For the two-plan strategy, delivery date control CTP can be used. When CTP is used, it automatically triggers the run in the dynamic plan.

Setting up the plans

You can create plans on the **Master plans** page (**Master planning** > **Setup** > **Plans** > **Master plans**).

You can specify which plans will be used for the static plan and the dynamic plan by setting the **Current static master plan** and **Current dynamic master plan** fields on the **Master planning parameters** page (**Master planning** > **Setup** > **Master planning parameters**). To use a one-plan strategy, select the same plan in the **Current static master plan** and **Current dynamic master plan** fields.

Types of planning methods

Three calculation methods can be used to run master planning: regeneration and net change. Each method produces a different plan when it's run.

You specify the planning method in the **Master planning run** dialog box. To open this dialog box, go to **Master planning** > **Master planning** > **Run** > **Master planning**, or select **Run** in the **Master planning** workspace.

Regeneration

The regeneration planning method deletes existing planned orders, unless they are firmed. It generates new planned orders, based on all the requirements. Regeneration is the only

planning method that is available for static plans.

- Changes in supply are considered. These changes include changes in the forecast.
- This method respects the **Period** coverage code.
- This method supports product substitution functionality (PI).

Net change

The net change planning method generates planned orders to cover the requirements that have been created or changed since the last master planning run. Changes in supply aren't considered when this method is run. The system doesn't consider any new supplies, and previously created planned orders aren't deleted if they are no longer required. The net change planning method runs faster than the regeneration method. It's available only for dynamic plans.

- Action dates and futures are updated for all requirements.
- This method doesn't respect the **Period** coverage code.
- This method doesn't fulfill the forecast, even if it's selected on the plan.
- This method doesn't support product substitution functionality (PI).

Net change minimized

The net change minimized planning method generates planned orders to cover only the requirements that have been created or changed since the last master planning scheduling run. For this method, unlike the net change method, action dates and future dates are updated only for new or changed requirements. This planning method is available only for dynamic plans.

Scheduling methods, time fences, positive days, and negative days

Other aspects of setting up master plans (including Scheduling methods, time fences, positive days, and negative days) work the same way when using the deprecated planning engine as they do when using Planning Optimization. For more information about these topics, see Master plans overview.

Create an intercompany plan

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure shows how to create an intercompany plan. The demo data company used to create this procedure is USMF.

Set up an intercompany planning group

1. Go to **Master planning** > **Setup** > **Intercompany planning groups**.
2. Use the Quick Filter to find records. For example, filter on the Name field with a value of '10'.
3. In the list, mark the selected row.
4. Select **Delete**. This step is necessary in order to shorten the intercompany planning run. Intercompany planning will run master planning in all the companies in a planning group, starting from the lowest scheduling sequence.
5. Select **Yes**.
6. Close the page.

Create an intercompany master plan

1. Go to **Master planning** > **Workspaces** > **Master planning**.
2. Select **Intercompany master planning**.
3. In the **Intercompany planning group** field, select the drop-down button to open the lookup.
4. In the list, select the link in the selected row. Select intercompany planning group 10.
5. In the **Number of intercompany planning iterations** field, enter '2'. Intercompany planning group 10 has two members. In order to propagate the delays from the source company (USMF) to the customer company (DEMF), you will need to run intercompany in both companies two times. The first iteration will propagate the demand and identify the delays in the source company (USMF). The second iteration will propagate the delays from USMF to DEMF.
6. In the **First iteration** field, select 'Regeneration'.
7. In the **Subsequent iterations** field, select 'Regeneration'.

8. In the **Number of threads** field, enter a number. This represents the number of parallel threads used for planning.
9. Select **OK**.

View the result of the plan

1. In the **Plan** field, select the drop-down button to open the lookup.
2. In the list, select the link in the selected row. Select the link for StaticPlan. You need to be in company USMF.
3. Select **Planned orders**.

Last updated on 06/17/2025

View outbound planned intercompany demand

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This procedure shows how to view all the planned orders that will be fulfilled by an intercompany vendor. The demo data company used to create this procedure is DEMF.

1. Select **Master planning**.
2. In the **Plan** field, enter or select a value.
    - In the **Plan** field, select plan *10*.
3. Select *Run*.
4. In the **Number of threads** field, enter a number.
    - This represents the number of parallel threads to be used for master planning.
5. Select **OK**.
    - This may take a while.
6. Select **Planned intercompany demand**.
7. Select **Outbound planned intercompany demand**.
    - This page provides an overview of all the planned demand that will be fulfilled by an internal supply chain vendor.
8. Expand the **Upstream demand details** section.
    - In this section, you can see the details about how the demand will be fulfilled. You may need to wait for master planning to be run in the supply company before you can see additional information here.

Monitor a master planning run

10/03/2025

Use a Gantt chart to visualize master planning progress

From the **View master planning progress** page, you can view details of historical master planning runs as a Gantt chart. This functionality can help you understand the time that is spent on the various phases of master planning. For a current active planning job, the **View master planning progress** page can be used to track progress and view the estimated remaining time.

Use the Master plan progress visualization feature

The **View master planning progress** page can display both historical planning jobs and active planning jobs.

To view historical planning jobs, there are two options.

1. Go to **Master planning** > **Setup** > **Plans** > **Master plans**, and then, on the Action Pane, select **History**. With the desired job selected, select **Inquiries**, and then select **View progress**
2. Go to **Master planning** > **Workspaces** > **Master planning**, on the Master planning tile click **History**. With the desired job selected, select **Inquiries**, and then select **View progress**

To view active planning jobs, there are two options.

1. Go to **Master planning** > **Workspaces** > **Master planning**, on the Action Pane, select **Unfinished planning process**. With the desired job selected, select **Inquiries**, and then select **View progress**.
2. Go to **Master planning** > **Workspaces** > **Master planning**, on the Master planning tile click **View progress**. With the desired job selected, select **Inquiries**, and then select **View progress**

Note you can view active jobs only when a planning job is processing.

Analyze a master planning job

In the Gantt chart, you can expand each of the following planning processes to view additional details about the time that is spent:

- Initializing
- Deleting and inserting data
- Coverage planning
- Delays
- Action messages
- Finalization
- Auto-firming

The Gantt chart is a useful tool if you want to view the impact of using action messages.

Navigation in the Gantt chart

- To expand the selected group and show the details, select the plus sign (**+**) in the tree view.
- To collapse the selected group, select the minus sign (**–**) in the tree view.
- You can use your keyboard for navigation. Use the **Up arrow** and **Down arrow** keys to move between rows. Use the **Right arrow** and **Left arrow** keys to expand and collapse groups.
- To open or close all levels in the Gantt chart, select **Expand all** or **Collapse all**.
- To view the related processing time, hover over a task. (Tasks are the lowest level in the Gantt chart.)

View an additional master planning run to compare jobs

By selecting a master planning job on field **Show additional master planning run**, you can view an additional master planning run in the Gantt chart and compare the two jobs.

BOM-level display

Bill of materials (BOM) levels are shown differently for coverage planning, delays, actions, and firming.

- **Coverage planning** – BOM levels are shown as expected. They are calculated from the top down.

  Example: BOM level 0, 1, 2

- **Delays** – BOM levels are shown as the coverage planning BOM levels multiplied by –1. (In other words, they have a negative sign.)

Example: BOM level –2, –1, 0

- **Action message** – BOM levels are shown as expected. They are calculated from the top down.

  Example: BOM level 0, 1, 2

- **Auto-firming** – BOM levels are shown as 999 minus the coverage planning BOM level.

  Example: BOM level 999, 998, 997

The following table summarizes the behavior.

Expand table

BOM level that is shown	End item	Subcomponent	Raw material
Coverage planning	0	1	2
Delays	0	–1	–2
Action message	0	1	2
Auto-firming	999	998	997

Visualize progress

If you view a master planning job that is currently running, progress is shown through colors in the Gantt chart. The following colors apply to the blue theme. For other color themes, the colors will differ.

- **Dark blue** – Completed planning tasks.
- **Orange** – The task that is currently in progress.
- **Light blue** – The estimate for remaining tasks.

The color is shown only on the lowest level in the Gantt chart. Select **Expand all** to view all tasks in the master planning job. The estimate of remaining tasks is based on historical master planning jobs.

Run master planning and track processing time

1. On the default dashboard, select **Master planning**.
2. In the **Plan** field, enter or select a value.
3. Select **Run**.
4. Set the **Track processing time** option to **Yes**.

5. In the **Number of threads** field, enter a number.
6. On the **Records to include** FastTab, select **Filter**.
7. In the grid, select the row where the **Field** field is set to **Item number**.
8. In the **Criteria** field, enter a value.
9. Select **OK**.

Net requirements and pegging information with the deprecated master planning engine

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

When you run master planning, it's important that you understand its output, how existing supply covers the demand, and why specific supply was generated. You can use the **Net requirements** page to better understand the calculated requirements that master planning produces.

The **Net requirements** page shows the net requirements that are calculated for the product during master planning. It also shows the coverage settings that were applied during the master planning run, a breakdown of the requirement totals by transaction type, and pegging information.

The **Net requirements** page behaves slightly differently based on whether you're using Planning Optimization or the deprecated master planning engine. For more information about this difference, see Differences between Planning Optimization and the deprecated master planning engine

For more information about how to work with this page, see Net requirements and pegging information.

Safety stock fulfillment with the deprecated master planning engine

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how safety stock functionality differs when you use the deprecated master planning engine compared to when you use Planning Optimization. For more information about safety stock, including information that applies to both planning engines, see Safety stock fulfillment for items.

Differences in safety stock functionality

The following table summarizes the differences in safety stock functionality between the deprecated master planning engine and Planning Optimization.

Expand table

	Planning Optimization	Deprecated master planning engine
Meaning of safety stock	Safety stock ensures that the accumulated on-hand inventory is always above the minimum value that's defined in the item coverage settings for each item. Safety stock isn't actual demand. Demand is prioritized over the safety stock.	Safety stock is a demand just like other types of demand. You can choose when safety stock will be fulfilled.
When safety stock is fulfilled	Safety stock is always fulfilled on *Today's date* + *Procurement time*, regardless of the setting for the item coverage.	On the **Item coverage** page for an item, on the **General** tab, the **Fulfill minimum** field defines when the safety stock must be fulfilled. The options are *Today's date*, *Today's date*

	Planning Optimization	Deprecated master planning engine
		+ procurement time, *First issue*, and *Coverage time fence*.
Safety stock pegging and net requirements	The *Safety stock* requirement type isn't included and isn't shown on the **Net requirements** page. Safety stock doesn't represent demand, and no requirement date is associated with it. Instead, it sets a constraint on the amount of inventory that must be present at all times. However, the value of the **Minimum** field is still considered when planned orders are calculated during master planning. We recommend that you inspect the **Accumulated quantity** column on the **Net requirements** page to confirm that this value was considered. Because the pegging differs, different actions might be suggested.	Safety stock is a demand type, similar to a sales order line, forecast line, or bill of materials (BOM) line. Master planning always fulfills it on the date that's specified in the **Fulfill minimum** field. In some cases, safety stock might take precedence over actual demand fulfillment.

> ⓘ Note
>
> When strict safety stock pegging is enabled, the system ignores pegging priority for safety stock planned orders. This condition can result in unreliable net requirements pegging and the creation of unwanted planned orders. Learn more in Safety stock pegging options.

Safety stock fulfillment date options

The deprecated master planning engine respects the value of the **Fulfill minimum** field on the **General** tab of the **Item coverage** page. This field lets you select the date or the period during which the inventory level must meet the quantity that you specified in the **Minimum** field. The **Fulfill minimum** field is available when you select **Period**, **Requirement**, or **Min/Max** in the **Coverage code** list.

If you use minimum keys, set the **Minimum periods** option to *Yes* to fulfill the minimum inventory level for all the periods that are set up in the minimum key. If you set the option to *No*, the minimum inventory is fulfilled for the current period only.

The following scenario shows how the **Fulfill minimum** setting works and how the values differ.

> ⓘ Note
>
> For all the illustrations in this article, the x-axis represents inventory, the y-axis represents days, the bars represent the inventory level, and the arrows represent transactions, such as

sales order lines, purchase order lines, or planned orders.

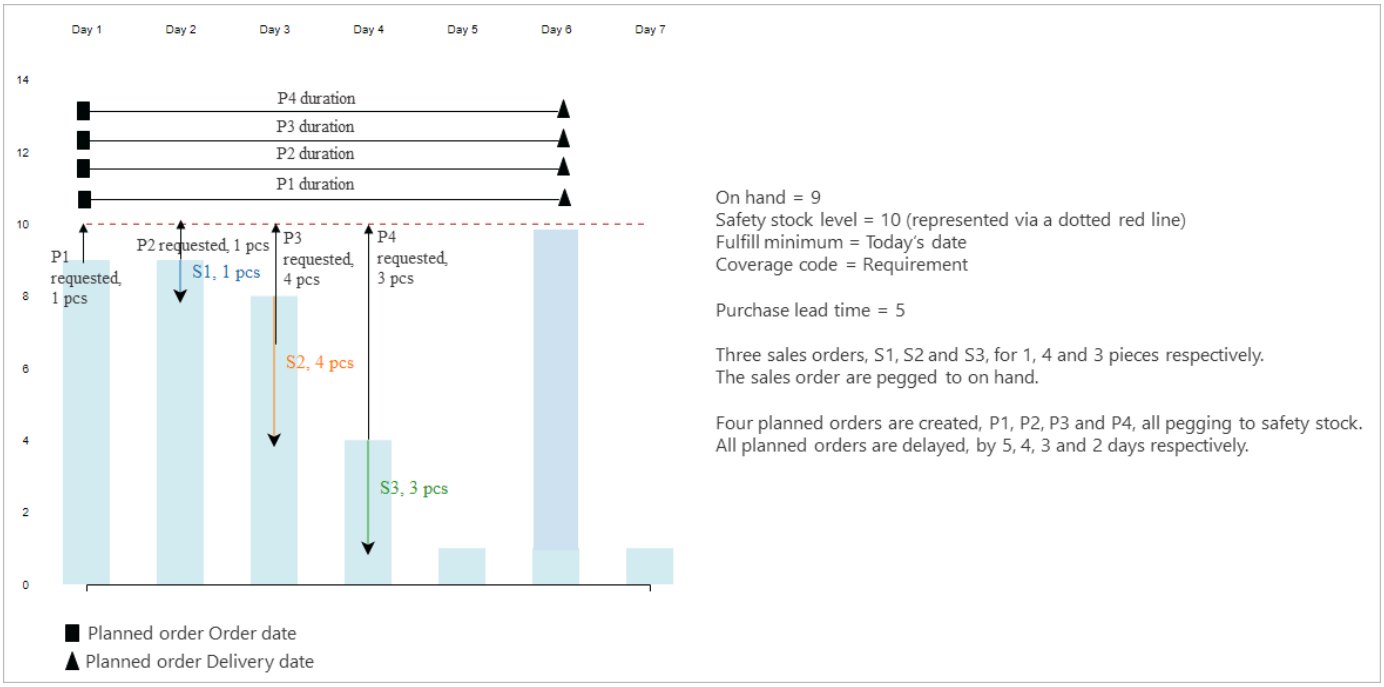
The **Fulfill minimum** field can have the following values:

- *Today's date*
- *Today's date + procurement time*
- *First issue*
- *Coverage time fence*

The following subsections describe how each value works.

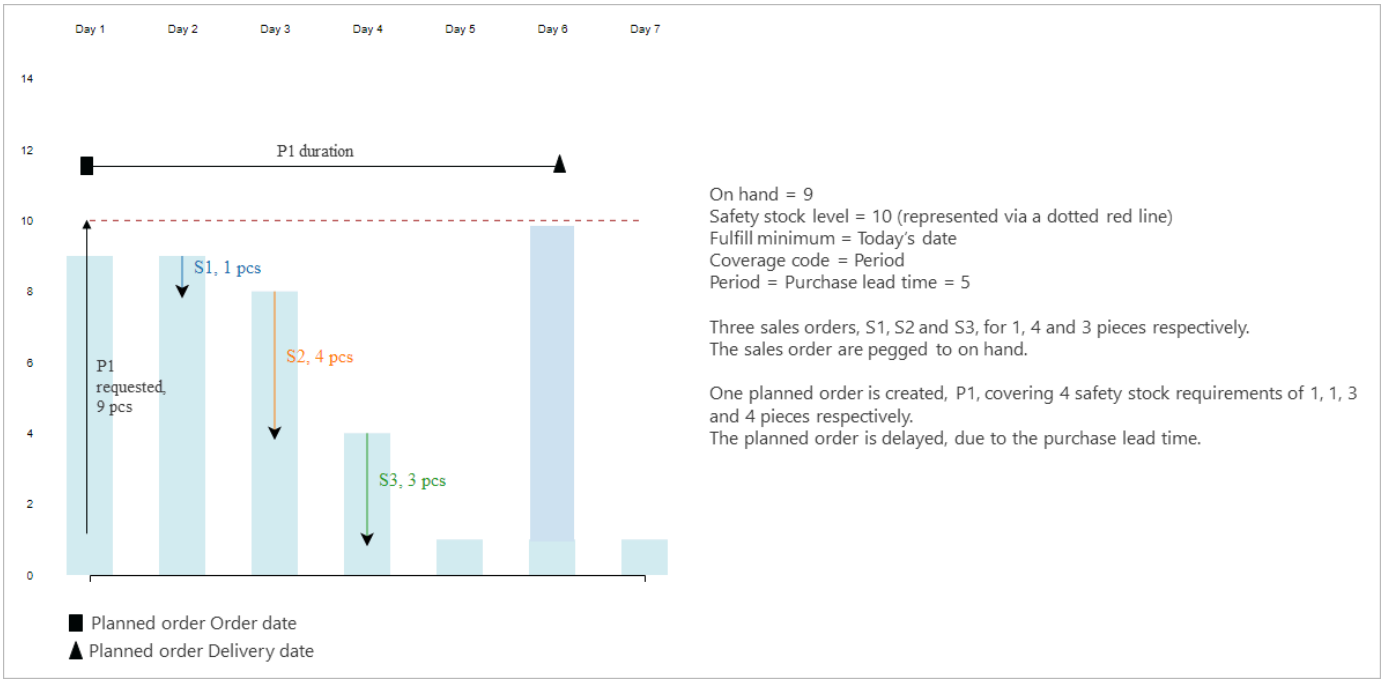
Today's date

The specified minimum quantity is met on the date when master planning runs. The system tries to fulfill the safety stock limit as soon as possible, even though the attempt might be unrealistic because of the lead time.

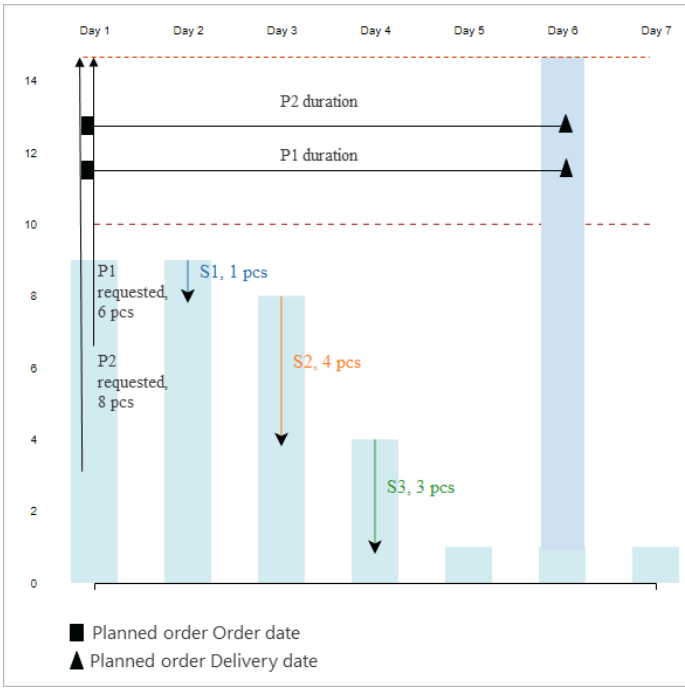


Planned order P1 is created for today's date to bring the available inventory above the safety stock level on this date. The sales order lines S1 through S3 continue to lower the inventory level. Master planning generates planned orders P2 through P4 to bring the inventory level back to the safety limit after each sales order requirement.

When you use the **Requirement** coverage code, the system creates multiple planned orders. Always use either **Period** or **Min/Max** coverage for items and materials that are in frequent demand. In that way, the replenishment is bundled. The following illustration shows an example for the **Period** coverage code.



The following illustration shows an example for the **Min/Max** coverage code.



On hand = 9
Safety stock level = 10 (represented via a dotted red line)
Fulfill minimum = Today's date
Coverage code = Min./Max.
Maximum level = 15

Three sales orders, S1, S2 and S3, for 1, 4 and 3 pieces respectively.
The sales order are pegged to on hand.

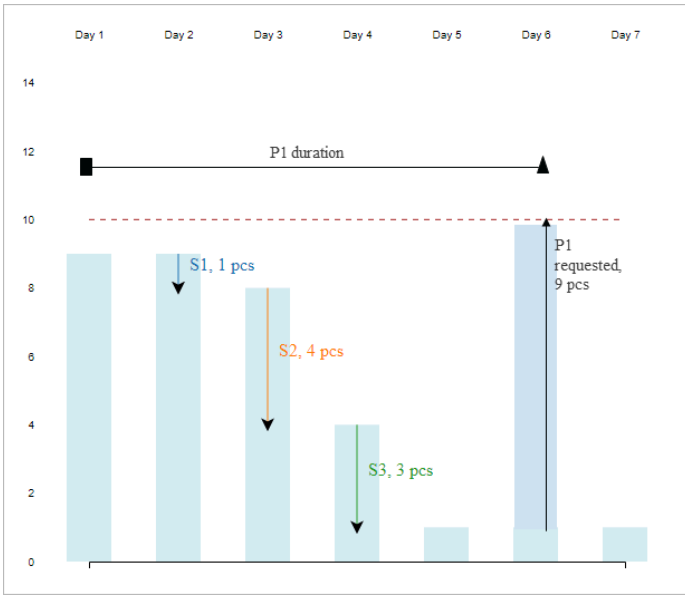
Two planned orders are created, P1 and P2.
P1 is for 6 pcs and is requested on Day 1, because the current on hand is below the safety limit.
P2 is for 8 pcs and is also requested on Day 1, due to the sales orders that are coming in and that would bring the inventory below the safety limit.
Both planned orders are delayed, due to the purchase lead time.

Today's date + procurement time

The specified minimum quantity is met on the date when master planning runs, plus the purchase or production lead time. This time includes any safety margins. If the item carries a trade agreement, and you select the **Find trade agreements** checkbox on the **Master planning parameters** page, the delivery lead time from the trade agreement isn't considered. Instead, lead times are taken from either the item coverage settings or the item.

This fulfillment mode creates plans that have fewer delays and fewer planned orders, regardless of the coverage group that's set up on the item.

The following illustration shows the outcome of the plan if the coverage code is **Requirement** or **Period**.



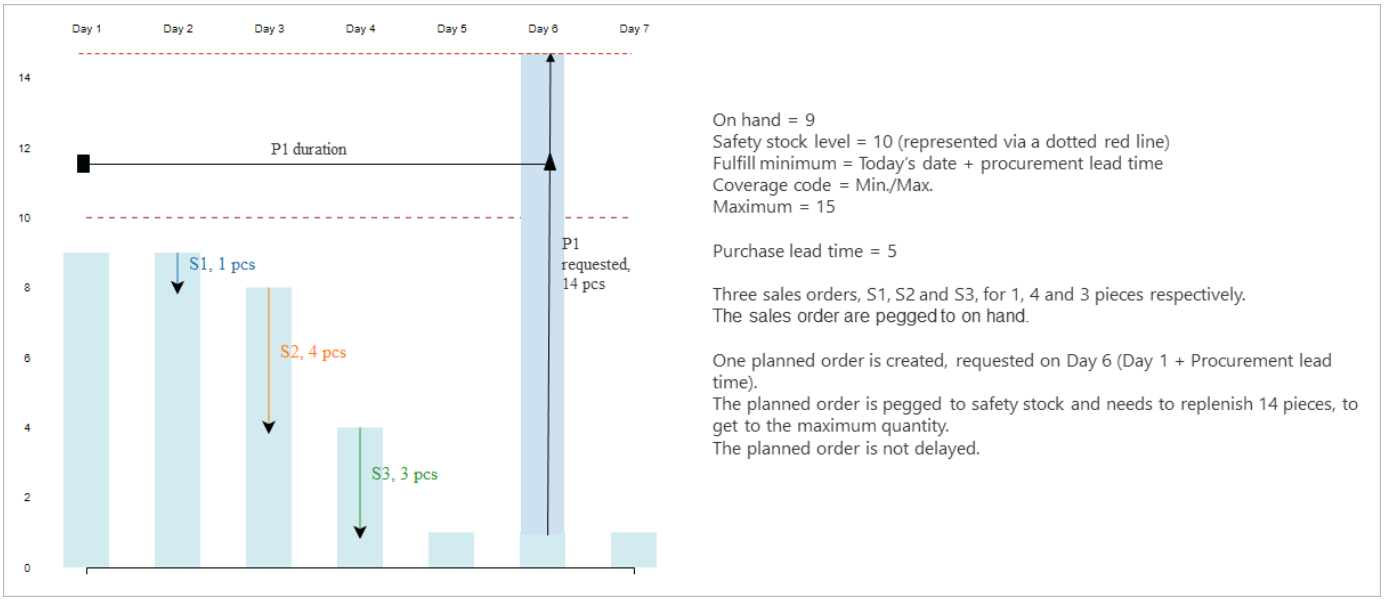
On hand = 9
Safety stock level = 10 (represented via a dotted red line)
Fulfill minimum = Today's date + procurement lead time
Coverage code = Requirement or Period (Period = 5)

Purchase lead time = 5

Three sales orders, S1, S2 and S3, for 1, 4 and 3 pieces respectively.
The sales order are pegged to on hand.

One planned order is created, requested on Day 6 (Day 1 + Procurement lead time).
The planned order is pegged to safety stock and needs to replenish 9 pieces.
The planned order is not delayed.

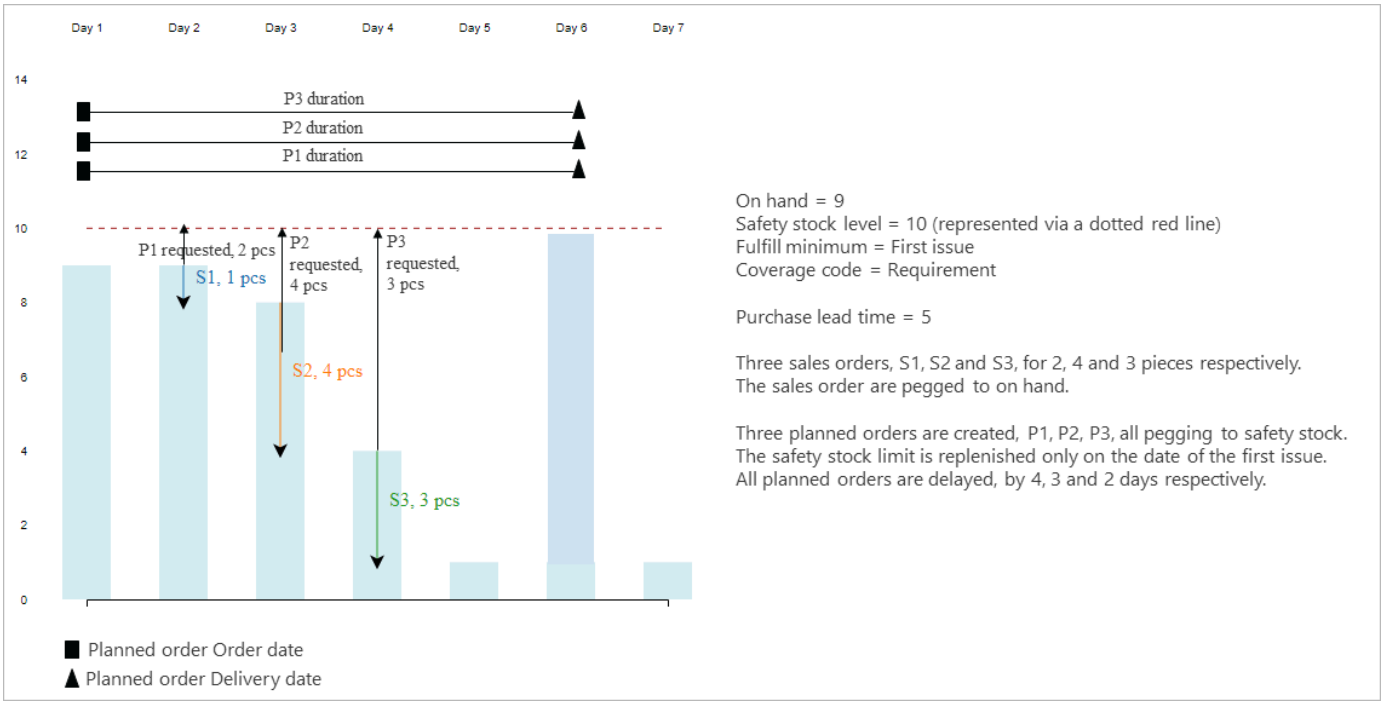
The following illustration shows the outcome of the plan if the coverage code is **Min/Max**.



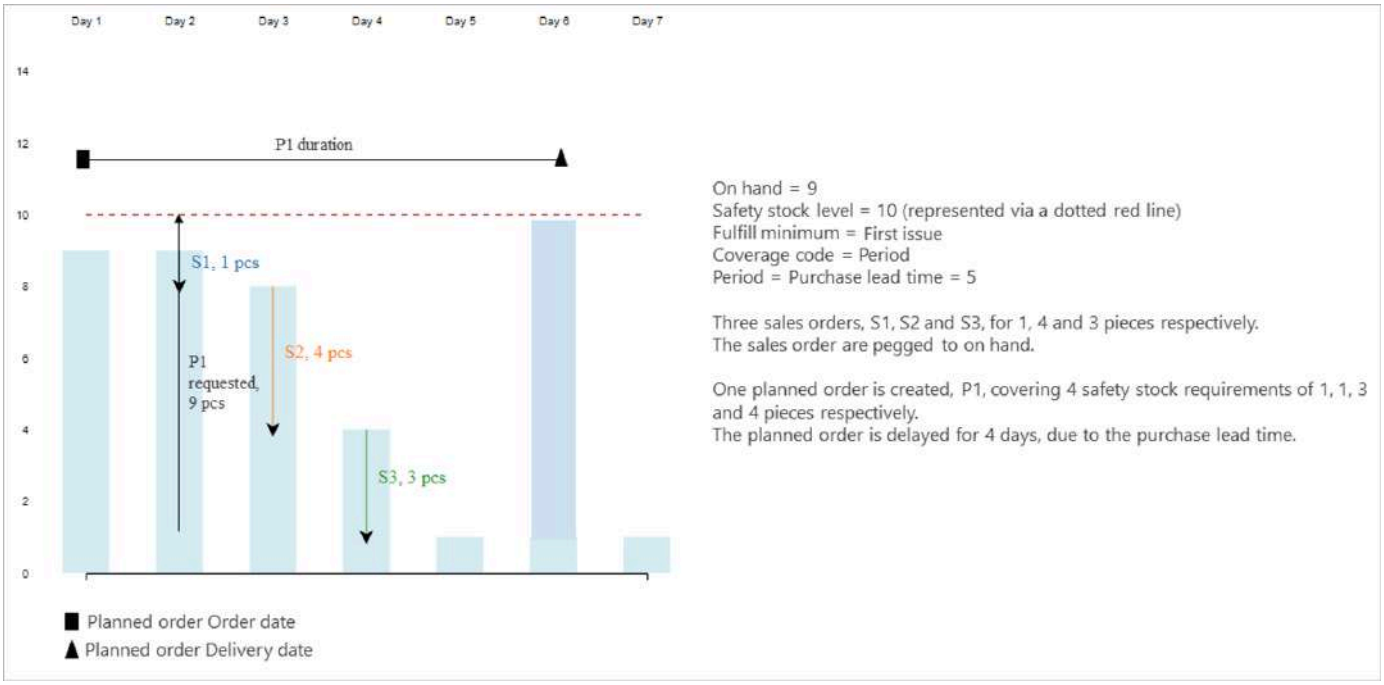
First issue

The specified minimum quantity is met on the date when the available inventory goes below the minimum level. Even if the available inventory is below the minimum level on the date when master planning runs, this fulfillment mode doesn't try to cover it until the next requirement comes in.

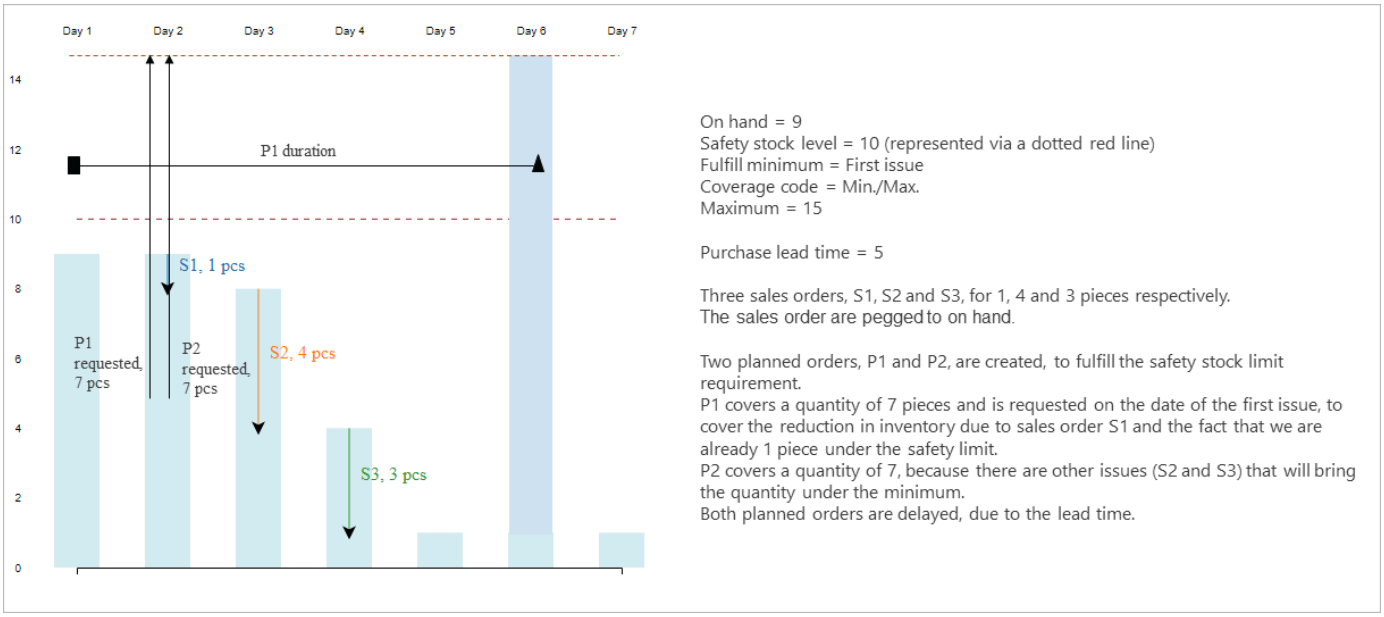
The following illustration shows an example for the **Requirement** coverage code.



The following illustration shows an example for the **Period** coverage code.

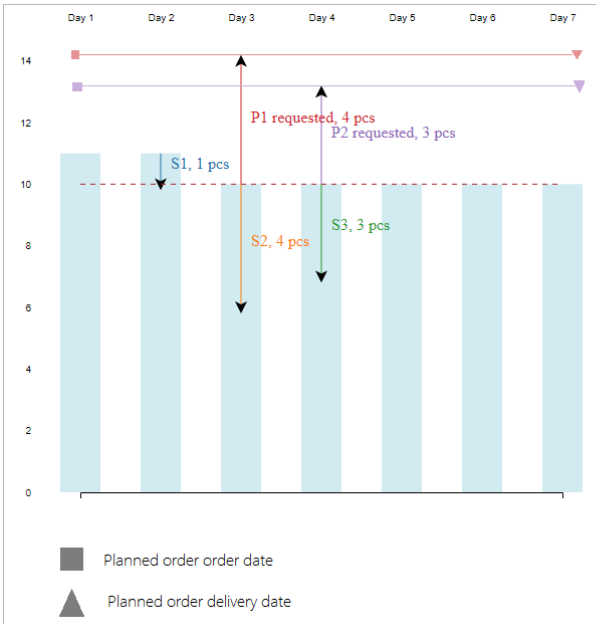


The following illustration shows an example for the **Min/Max** coverage code.



On the date when master planning runs, if the available inventory is already under the safety stock limit, both the **Today's date** fulfillment mode and the **Today's date + procurement time** fulfillment mode trigger the replenishment immediately. However, the **First issue** fulfillment mode waits until there's another issue transaction for the item, such as a sales order and BOM line requirement. It then triggers the replenishment on the date of that transaction.

On the date when master planning runs, if the available inventory isn't under the safety stock limit, the **Today's date** and **First issue** fulfillment modes provide the same result, as shown in the following illustration.



Coverage code = Requirement
Safety stock = 10
On hand = 11
Fulfill minimum = First issue

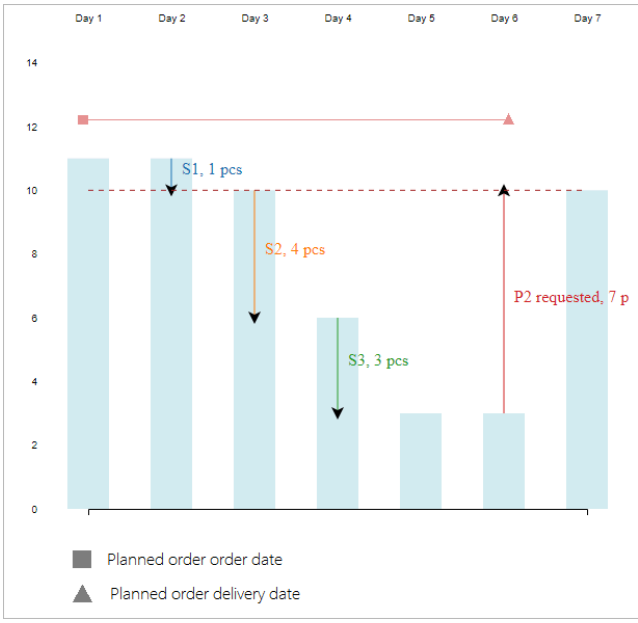
Purchase lead time = 5

Given three sales orders, S1, S2 and S3, master planning will create two planned orders, P1 and P2, as follows:

P1
Quantity = 4
Requested date = Day 3
Order date = Day 1
Delivery date = Day 1 + purchase lead time
Pegging to safety stock requirement, coverage quantity 4
Delay date = Day1 + purchase lead time
Delay = 3 days
Requirement date = Delay date (per plan setup)

P2
Quantity = 3
Requested date = Day 4
Order date = Day 1
Delivery date = Day 1 + purchase lead time
Pegging to safety stock requirement, coverage quantity 3
Delay date = Day 1 + purchase lead time
Delay = 2 days
Requirement date = Delay date (per plan setup)

On the date when master planning runs, if the available inventory isn't under the safety stock limit, the **Today's date + procurement time** fulfillment mode provides the following result, because it postpones the fulfillment until the end of the procurement lead time.



Coverage code = Requirement
Safety stock = 10
On hand = 11
Fulfill minimum = Today's date + procurement time

Purchase lead time = 5

Given three sales orders, S1, S2 and S3, master planning will create one planned order, P2, as follows:

P2
Quantity = 7
Requested date = Day 1 + purchase lead time
Order date = Day 1
Delivery date = Day 1 + purchase lead time
Pegging to safety stock, covered quantity = 7
There are no delays

The sales orders are ll pegged to on hand.

Coverage time fence

The specified minimum quantity is met during the period that's specified by the **Coverage time fence** field. This option is useful when master planning doesn't allow available inventory to be used for real orders, such as sales or transfers, because it's trying to maintain the safety level. However, in a future release, this mode of replenishment won't be needed, and this option will be deprecated.

Create a material plan for co products

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The production planner plans the material requirements for items that are formula co-products. The demo data company used to create this procedure is USP2.

Create requirement for a co-product

1. Go to **Sales and marketing** > **Workspaces** > **Sales order processing and inquiry**.
2. Select **New**.
3. Select **Sales order**.
4. In the **Customer account** field, type a value.
    - Example: US-001
5. Select **OK**.
6. In the **Item number** field, type a value.
    - Example: P6003
7. In the **Quantity** field, enter a number.
    - Example: 50000
8. Select **Save**.

Create a material plan for co-products

1. Close the page.
2. Close the page.
3. Select **Master planning**.
4. In the **Plan** field, select the drop-down button to open the lookup.
5. In the list, select the link in the selected row.
    - Example: MasterPlan

6. Select **Run**.
7. Expand or collapse the **Records to include** section.
8. Select **Filter**.
9. In the list, select the row for **Field** = *Item number*.
10. In the **Criteria** field, type a value.

    - Example: P6003

11. Select **OK**.
12. Select **OK**.
13. Select **Planned orders**.
14. Use the Quick Filter to find records. For example, filter on the **Item number** field with a value of 'P6000'.

    - Filter by the formula item that has as co-product of the item that you created a sales order for.

15. In the list, mark the selected row.

    - Select any of the rows returned by the filter.

16. In the list, select the link in the selected row.
17. Expand the **Pegging** section.
18. In the list, select the link in the selected row.

    - The planned order is pegged to the sales order for the co-product.

19. Close the page.

Create a second requirement for a co-product

1. Go to **Sales and marketing** > **Workspaces** > **Sales order processing and inquiry**.
2. Select **New**.
3. Select **Sales order**.
4. In the **Customer account** field, type a value.

    - Example: US-001

5. Select **OK**.
6. In the **Item number** field, type a value.

    - Example: P6003

7. In the **Quantity** field, enter a number.

- Example: 50000

8. Select **Save**.

Create a second material plan for co-products

1. In the **Plan** field, select the drop-down button to open the lookup.
2. In the list, select the link in the selected row.

    - Example: MasterPlan

3. Select **Run**.
4. Expand or collapse the **Records to include** section.
5. Select **Filter**.
6. In the list, select the row for **Field** = *Item number*.
7. In the *Criteria* field, type a value.

    - Example: P6003

8. Select **OK**.
9. Select **OK**.
10. Select **Planned orders**.
11. Use the Quick Filter to find records. For example, filter on the **Item number** field with a value of 'P6000'.

    - Filter by the formula item that has as co-product of the item that you created a sales order for.

12. In the list, mark the selected row.

    - Select any of the rows returned by the filter.

13. In the list, select the link in the selected row.
14. Expand or collapse the **Pegging** section.
15. In the list, select the link in the selected row.

    - The planned order is pegged to the sales order for the co-product.

16. Close the page.
17. Select **Master planning**.
18. Go to **Master planning** > **Setup** > **Master planning parameters**.
19. Select *No* in the **Disable all planning processes** field.
20. Close the page.

Cancel a job that was created using the deprecated master planning engine

06/17/2025

There are multiple options for canceling a job that was created using the deprecated master planning engine. For example, you might want to cancel a master planning job if it was started by mistake or is running longer than expected and you want to end it.

The best way to cancel a planning job is from the **Unfinished planning processes** page. Alternative options from the **Batch jobs** and **Batch jobs enhanced** pages should only be used if canceling the master planning job from the **Unfinished planning processes** page didn't complete within a few minutes.

Preferred cancel option

Cancel master planning job from the Unfinished planning processes page

1. Go to **Master planning** > **Inquiries and reports** > **Master planning** > **Unfinished planning processes**.
2. Select the line with the planning process that you want to cancel.
3. Select **Cancel**.

Additional cancel options

These should only be used if canceling the master planning job from the **Unfinished planning processes** page didn't complete within a few minutes.

Delete master planning job from the Batch jobs page

1. Go to **System administration** > **Inquiries** > **Batch jobs**.
2. Select the line with the planning job that you want to delete.
3. Select **Delete**.

Abort master planning job task from the Batch jobs enhanced page

1. Go to **System administration** > **Inquiries** > **Batch jobs**.

2. If the job ID isn't shown in the list, select **Switch to enhanced form**, otherwise proceed with the next step.
3. Open the batch job. Select the **Job ID** for the batch job with tasks that you want to end.
4. In **Batch tasks**, select the tasks to end.
5. Select **Change status**, choose **Canceling** and select **OK**.
6. On the **Batch tasks** FastTab, select **Abort**.

Demand planning home page

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Inaccurate forecasts and demand plans can lead to lost revenue and inefficiency in the supply chain. However, forecasts that are infused with intelligence lead to more accurate and effective demand plans. You can measure the direct impact in improved revenue and fewer stockouts. Operating expenses go down in supply chains that require fewer fire drills.

Demand planning in Microsoft Dynamics 365 Supply Chain Management is Microsoft's next-generation collaborative demand planning solution. This app is powered by best-in-class forecasting algorithms and models, and offers immersive user experiences, intelligent reports, and analytics. It empowers organizations to build an agile, resilient, and sustainable demand planning practice that's fueled by intelligence and collaboration.

Demand planning provides the following capabilities:

- **A no-code approach** to demand modeling and planning configuration. Flexible building blocks enable the vast majority (over 85 percent) of demand planners who aren't data scientists to do what-if planning and analyze, optimize, and compare scenarios in minutes.
- **Seamless, on-the-fly aggregation and disaggregation**. Planners can edit forecasts at the corporate or product group level, and then zoom in and instantly see the impact at the regional and stock-keeping unit (SKU) levels.
- **Improved forecast accuracy** with automatic AI parameter tuning to help ensure accurate forecasting and preprocessing. External signals enable superior forecast accuracy by considering promotions or stockouts.
- **Disruption readiness** with interactive and fast what-if analysis. Version history enables tracking, evaluating forecast changes, and using the lessons learned to improve the decision making process.
- **Effective collaboration throughout the planning cycle**. This capability is enabled through Microsoft Teams in-context communication, in-product commenting, and restorable

versions of forecast values throughout the planning process.

- **Increased agility through integrated planning and execution flow** with native integration with Supply Chain Management, customizable worksheets, and exception-based planning.

The demand planning process

Demand planning provides functionality for the complete demand planning process. This process has the following steps:

1. **Import data** – Import your historical data, products, sites, warehouses, prices, and other information into the app.

   https://learn-video.azurefd.net/vod/player?id=62832cd0-1bd9-456b-9dd1-3dc33a101b0b&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Fdemand-planning%2Fdemand-planning-home-page

2. **Create transformation** – Transform imported data from tables into time series by identifying data columns, choosing time buckets, and shifting dates. For example, you can shift historical data from last year to next year so that you can use it as a basis for the forecast. Alternatively, you can apply multiplications or combine data from different systems.

3. **Create forecasts** – Use different forecasting models (including your own Azure Machine Learning model) to create a forecast, or let AI determine which forecast model works best.

   https://learn-video.azurefd.net/vod/player?id=9d178a98-0a58-4765-9885-b73ee2ad17ef&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Fdemand-planning%2Fdemand-planning-home-page

4. **Review and adjust forecast** – Work on the forecast, adjust values, and get different perspectives about how pricing, weather, promotional events, and other factors might affect the forecast. Collaborate to reach the most accurate forecast.

   https://learn-video.azurefd.net/vod/player?id=14bf0230-5088-49c6-9b14-685f322f2376&locale=en-us&embedUrl=%2Fdynamics365%2Fsupply-chain%2Fdemand-planning%2Fdemand-planning-home-page

5. **Export data** – After your forecast is done, you can export it to any external system that can consume forecasts.

Deep dive video

For a deep dive into the capabilities of Demand planning, watch the following video on YouTube: Deep dive into Demand Planning for Supply Chain Management | Dynamics 365 TechTalk.

Licensing

To use Demand planning in a production environment, each relevant user must have a license for it. Learn more in Demand planning license requirements.

Last updated on 07/01/2026

What's new or changed in Demand planning

This article lists new features, fixes, improvements, and known issues for each released version of Demand planning in Microsoft Dynamics 365 Supply Chain Management.

Version 1.4

New features introduced in version 1.4

Demand planning version 1.4 introduces the following new features:

- **Best fit model - version 4** – The *Best fit model - version 4* forecasting algorithm introduces symmetric mean absolute percentage error (SMAPE) as the new metric for selecting between forecast models. This metric improves model selection for products with periods where no historical sales occurred.
- **Forecast calculation accuracy analysis** – The new calculation accuracy page for forecast time series improves on the explainability display previously available in the forecast profile job run history. For each planning object in the forecast, it shows which demand forecasting algorithm was used and the resulting SMAPE value. New data visualizations include model distribution and an average SMAPE indicator that responds to filters. It improves the overall user experience and provides deeper insights.
- **Detailed forecast explainability** – The calculation accuracy page also lets you drill down into individual planning objects (such as product and store) for an even more detailed explainability view. Here, you can see historical data alongside each calculated forecast and get a natural-language explanation of the factors driving it.
- **View forecast with full component breakdown** – View each forecast across the full horizon with a detailed component breakdown. Demand planning splits each forecast into *baseline*, *signals impact*, and *manual adjustments* to provide clearer insight into manual changes and the influence of signals.
- **Signals and fill missing values** – New **Fill missing value** options make it easier to create continuous data signals based on input originating from external sources, including Supply Chain Management and third parties. New options include *Forward fill*, *Backward fill*, and *Interpolation*. Learn more in Signal fill strategies.
- **New calculation options for transformations** – Previously, Demand planning provided a single calculation method for data transformations: Summarize. This version adds several

new options, including *Average*, *Max*, *Min*, and *Last value*, which can be better suited for signals such as inflation, prices, or weather. Learn more in Aggregation methods.

- **Engineering enhancements for upcoming Dataverse storage alignment** – This release includes behind-the-scenes enhancements that prepare the app to support Dataverse storage for timeseries data. As a result of these preparations, both new installations and updates to version 1.4 might require significantly more processing time than previous versions.

New fixes and improvements in version 1.4

Demand planning no longer resets unsaved edits to their start value when you double-click on other cells.

Version 1.2

New features introduced in version 1.2

This release improves data consumption management by allowing you to delete obsolete time series versions or entire time series that you no longer need. The system provides an overview of dependencies between time series, time series versions, and the profiles that use them, so you can easily see what you need to clean up to allow a time series or version to be deleted. Learn more in Clean up time series data.

New fixes and improvements in version 1.2

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- Added a new API that you can use to export time series programmatically. Learn more in Export data using custom APIs.
- Improved performance when exporting forecasts to Supply Chain Management. This improvement is made possible by a new index introduced in Supply Chain Management version 10.0.48.
- Improved forecast calculation performance.

Version 1.1

New features introduced in version 1.1

This version of Demand planning enhances basic forecast calculations by adding two new features:

- The new *Best fit model - version 3 (preview)* forecast algorithm now includes the *Croston's method* forecasting model. It's designed specifically for intermittent demand, which is demand data with many zero-demand periods and occasional non-zero demands. Learn more in Croston's method forecasting (preview).
- Forecasting with signals by using the *XGBoost* forecast model now supports up to five signals. Learn more in Forecast with signals (preview).

New fixes and improvements in version 1.1

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- Improved performance when exporting forecast to Supply Chain Management with data aggregation.
- Improved forecast calculation performance.

Version 1.0.0.3424

New feature introduced in version 1.0.0.3424

This version of Demand planning enhances basic forecast calculations by adding two new features:

- The new *Best fit model - version 2 (preview)* forecast algorithm now applies naive forecasting when an input time series contains a low number of data points. This approach helps improve statistics forecasting results when input data is limited, such as for newly added products. Learn more at Naive forecasting.
- Time freeze can now preserve all manual forecast adjustments. This option ensures that all manually adjusted cell values remain at the adjusted value even after you recalculate an existing forecast. No freeze rules are required. Learn more at Limit automatic time series updates with time freezes.

New fixes and improvements in version 1.0.0.3424

This version of Demand planning includes the following fixes and improvements:

- Increased stability.

- Improvements to Generative insights.
- Improved forecast calculation performance.

Version 1.0.0.3336

New feature introduced in version 1.0.0.3336

This version of Demand planning enhances the *Copilot grid cursor* feature so that it now shows the impact of the signal input separately from the baseline for a selected forecasted cell. Learn more in Copilot grid cursor.

New fixes and improvements in version 1.0.0.3336

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- Auto-detect seasonality is improved to account for certain data compositions.
- Forecast calculations now respect the decimal precision set in the forecast profile.
- Improved the performance of forecast calculations.

Version 1.0.0.2999

New feature introduced in version 1.0.0.2999

This version of Demand planning marks the public preview of *Generative insights*, which offers detailed insights calculated using AI models. The production-ready preview supports two metrics: *seasonality* and *signal correlation*. The system clusters forecast data based on distinct patterns found for each metric. For each cluster, the system provides insights such as its relative size and confidence level. You can also choose the major contributor across various dimensions in the forecast. Learn more in Generative insights for Demand planning (production-ready preview).

New fixes and improvements in version 1.0.0.2999

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- Improvements in demo data. Features like row level security, time fence, and time freeze now work seamlessly when using demo data.

Version 1.0.0.2794

New features introduced in version 1.0.0.2794

This version of Demand planning adds several new features, as described in the following subsections.

Copilot grid cursor

The *Copilot grid cursor* offers detailed insights into a selected cell's value, including its original value, manual adjustments, and full adjustment history. User comments are also shown, to help make the changes easier to understand. Learn more in Copilot grid cursor.

New operator in rules: Select all

To improve efficiency and make queries easier to formulate, Demand planning now provides a *select all* operator. The new operator is available in the following policies: *time fence*, *time freeze*, and *row level access*. Learn more in Using the select all operator.

Multiple rules for time freezes

Demand planning now lets you assign multiple time freeze rules to *Forecast* and *Forecast with signals* steps. Each rule can have a different time freeze horizon. In this way, updates to a continuous forecast calculation are prevented during the selected periods. Learn more in Limit automatic time series updates with time freezes.

New fixes and improvements in version 1.0.0.2794

This version of Demand planning includes the following fixes and improvements:

- Increased stability
- New demo data with seasonal clusters

Version 1.0.0.2502

New features introduced in version 1.0.0.2502

This version of Demand planning adds several new features, as described in the following subsections.

Autodetection of seasonality patterns is now available for all forecast algorithms (preview)

Automatic detection of seasonality patterns was introduced in Demand planning version 1.0.01700, but it was previously available only for the ARIMA forecast algorithm. In this version, it's now available for all forecast algorithms.

Time freeze rules

Time freeze rules let demand planning managers establish policies that prevent forecast calculations from recalculating and overwriting manual adjustments in an existing forecast during a specified date range. Time freeze rules are based on the dimensions that are available in each forecast, and they're easy to maintain. Learn more in Limit automatic time series updates with time freezes.

Generative insights into seasonality patterns (production-ready preview)

Generative insights provide AI-generated insights into your data. The initial preview of the feature provides generative insights into your seasonality patterns. Visual displays make it easy for planners to understand seasonality data and make business decisions based on it. Information is clustered (grouped) according to the detected seasonality patterns. For each cluster, generative insights provide a confidence score and describe the seasonality pattern in natural language. The system also indicates the proportion of planning items that follow the pattern. Learn more in Generative insights for Demand planning (production-ready preview).

Simplified security role dependencies

The *Basic user* security role no longer needs to be applied to all users of Demand planning. Instead, Demand planning now incorporates all privileges from the *App Opener* security role into the *Demand planning contributor* and *Demand planning manager* security roles. Learn more in Security roles and row-level security in Demand planning.

New fixes and improvements in version 1.0.0.2502

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- New demo data that includes seasonal clusters.

Version 1.0.0.1700

New features introduced in version 1.0.01700

This version of Demand planning adds several new features, as described in the following subsections.

Select input for forecasts and calculations at the model level

In previous versions of Demand planning, you set the input time series used by forecast and calculation profiles at the *profile* level. This version makes the setting part of the *model* configuration, which improves usability while adding flexibility to your model designs (including the ability to add a signal input). As before, each forecast or calculation model starts with an *Input* step, but now it includes a setting where you choose the time series to use as input for the model. You can also choose a time series version and add filters based on dates and dimensions, such as products and locations. As with all steps, access these settings by opening the **Actions** menu (ellipsis button) on the card. Learn more in Design calculation models and Design forecast models.

Apply input filters in calculation models

You can now filter the input used in calculation models. Create filters based on dates and dimensions, such as products and locations. You could already apply filters in forecast models. Learn more in Design calculation models.

Analyze demand plans with Copilot

Copilot cursor prompts in Demand planning let you explore specific data points or data ranges in a forecast or time series. Each prompt presents a set of predefined questions that you can ask Copilot, which then returns insights into notable shifts, trends, anomalies, or deviations across multiple dimensions. Copilot replies using natural-language summaries and visuals, which make it easy for you to digest the information and use it to make informed decisions. Learn more in Analyze demand plans with Copilot.

Forecast with signals (preview)

One way to improve the accuracy of a forecast is to include input signal data beyond just historical sales. This version of Demand planning adds a new *Signal* step, which lets planners include any signal, such as inflation or weather data, as input to their forecast models. The current release supports up to one signal, though support for more signals might be added in a future release. The new *Forecast with signals* step lets you combine the signal input and main input to create the forecast. In the current version, *Forecast with signals* always uses the XGBoost demand

forecasting algorithm, but support for other algorithms might be added in a future release. Learn more in Forecast with signals.

Autodetect seasonality patterns (preview)

Seasonality patterns typically vary for different products and different locations, so using forecast models that try to apply the same pattern everywhere can result in inaccurate forecasts. This version of Demand planning adds an algorithm that automatically detects seasonality patterns for each combination of location and product and applies the result to its forecast calculations to help improve forecast accuracy. Automatic seasonality detection is only available when you use the ARIMA forecast algorithm. Learn more in Design forecast models.

New fixes and improvements in version 1.0.0.1700

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- Improved forecast error messages.
- Improved the *best fit model* forecasting algorithm for datasets that contain low inventories of phased-out products.

Version 1.0.0.1281

New feature introduced in version 1.0.0.1281

This version adds support for *time fences*, which allow demand planning managers to establish policies that prevent planners from editing certain date ranges of a forecast. Time fences are both flexible and simple to maintain. Managers create time fence rules based on the dimensions available in each plan. For example, a single product could be set up with different time fences for each store or geographical location. Time fence rules can also apply based on each user's role. For example, a role-based time fence rule could allow managers to edit a forecast in a period that can't be edited by planners. Learn more in Limit manual time series edits with time fences.

New fixes and improvements in version 1.0.0.1281

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- Improved forecast error messages.

Version 1.0.0.1232

New features introduced in version 1.0.0.1232

Forecast calculation job-run records now provide an **Explainability** tab, which lists each combination of dimensions (such as item variant, warehouse location, and so on) the forecast was calculated for. For each combination, it shows the forecast algorithm that was used and the mean average percentage error (MAPE) for the calculation. A lower MAPE value indicates greater accuracy. Learn more in Work with forecast profiles.

New fixes and improvements in version 1.0.0.1232

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- Transformation jobs that include the **Country/Region** column are now processed correctly. Previously, these jobs failed with an error.
- Improved the **Microsoft finance and operations apps** export data provider.
- Improved error messages shown during transformation, calculation, forecast, export, and import operations.
- Improved translation coverage in supported languages.

Version 1.0.0.1182

New features introduced in version 1.0.0.1182

The Microsoft Dynamics 365 Finance and Operations data provider now lets you choose which legal entities to import from. This feature applies to all data entities that contain a data area ID, including custom-built data entities. Learn more in Import data into Demand planning.

New fixes and improvements in version 1.0.0.1182

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- Improved the ARIMA forecast model. The model now provides better error messages if it fails due to a data error.
- Improved the best fit forecast model. Calculations now succeed provided at least one of the models provides a result.

- Each organization instance can now run up to five forecasts in parallel. Newly created forecasts run in parallel only if all existing forecast jobs already started (in the *Executing* state). If one or more existing forecast jobs are still waiting to start (in the *Created* state) when a new forecast is created, then all forecasts execute sequentially.

Version 1.0.0.1132

New features introduced in version 1.0.0.1132

This version of Demand planning focuses on quality and stability improvements and doesn't include any new features.

New fixes and improvements in version 1.0.0.1132

This version of Demand planning includes the following fixes and improvements:

- Increased stability.
- Fixed an issue with data transformations that caused zero values to appear in output.
- Improved the *best fit* forecast model.

Version 1.0.0.1067

Version 1.0.0.1067 is the first general availability (GA) release of Demand planning in Microsoft Dynamics 365 Supply Chain Management.

Last updated on 08/18/2026

Demand planning license requirements

To use Demand planning in Microsoft Dynamics 365 Supply Chain Management in a production environment, each relevant user must have a license for it.

- For an overview of Supply Chain Management and Demand planning licensing plans and prices, see Supply Chain Management pricing.
- For complete licensing details for all Dynamics 365 products, including Supply Chain Management and Demand planning, see the Dynamics 365 Licensing Guide.
- For links to licensing and pricing details for all Dynamics 365 applications, see the Dynamics 365 pricing overview.

After purchasing the required licenses, an administrator must assign one to each user that needs it. For details about how to assign licenses to users, see Assign licenses and Assign or unassign licenses for users in the Microsoft 365 admin center.

Last updated on 07/01/2026

Install, enable, and set up Demand planning

This article describes how to install, enable, and set up Demand planning in Microsoft Dynamics 365 Supply Chain Management. It explains how to use Power Platform admin center to install Demand planning in your tenant and set up the feature in Supply Chain Management.

Prerequisites

To use Demand planning with Supply Chain Management, you must be running one of the following versions of Supply Chain Management:

- Supply Chain Management version 10.0.36, build 10.0.1695.83 or later
- Supply Chain Management version 10.0.37, build 10.0.1725.60 or later
- Supply Chain Management version 10.0.38 (any build) or later

To use Demand planning in a production environment, each relevant user must have a license for it. Learn more in Demand planning license requirements.

> **Important**
>
> **Demand planning no longer supports Supply Chain Management *Cloud hosted* environments.**
>
> As of February 28, 2024, Demand planning no longer supports Supply Chain Management environments of the *Cloud hosted* type. After that date, you can't import, export, or sync data between Demand planning and Supply Chain Management environments of this type.
>
> If you're running a Supply Chain Management *Cloud hosted* environment and want to continue to use Demand planning, you must either switch to a Supply Chain Management environment of the *Tier-2* type or higher, or set up a unified development environment. You must then create new import and export profiles in Demand planning and configure them to connect to your new Supply Chain Management environment.

Install Demand planning in Power Platform admin center

> **Important**

You must install Demand planning on the same tenant as your Supply Chain Management environment to ensure that the built-in import and export profiles can be used to import and export data.

Due to a current technical limitation, you can't install Demand planning on your tenant's default environment.

Follow these steps to install Demand planning in Power Platform admin center.

1. Sign in to Power Platform admin center.
2. Select **Resources** > **Dynamics 365 apps** on the left navigation pane.
3. Search for and select the app named *Dynamics 365 Demand Planning Application*.
4. Select **Install** on the top toolbar.
5. Select an environment, review the packages that will be installed, and select the **I agree to the terms of service** checkbox.
6. Select **Install**.

Enable and configure Demand planning in Supply Chain Management

Follow these steps to enable and configure Demand planning in Supply Chain Management.

1. In the **Feature management** workspace, turn on the *Demand Planning* feature. (As of Supply Chain Management version 10.0.40, it's turned on by default.)

2. Go to **System administration** > **Setup** > **Demand planning app parameters**.

3. On the **General** tab, in the **Demand planning app URL** field, enter the URL where Demand planning is installed.

4. Go to **Master Planning** > **Setup** > **Master planning parameters**.

5. On the **Number sequences** tab, in the grid, find the row where the **Reference** field is set to *Demand forecast sequence number*. Then select the link in the **Number sequence** column for that row.

6. On the details page for the selected number sequence, on the **Performance** FastTab, set the following field:

    - **Preallocation** – Set this option to *Yes*.
    - **Quantity of numbers** – Set the value to *500*.

7. On the Action Pane, select **Save**.

8. You must now refresh the data entity list in Supply Chain Management to ensure that data imports and exports between Supply Chain Management and Demand planning work correctly. Follow these steps:
   a. Go to **System administration** > **Workspaces** > **Data management**.
   b. Select the **Framework parameters** tile.
   c. Open the **Entity settings** tab.
   d. Select **Refresh entity list**.

Last updated on 07/01/2026

Clean up staging data

08/18/2025

When you import data from Demand planning into Supply Chain Management, the data is stored in staging tables in the Supply Chain Management database. After the import is complete, the staging data is no longer needed, so it's deleted automatically. However, if an import operation fails, its staging data is typically left behind in the staging table, which might eventually grow to be very large and therefore reduce database performance and add to data storage charges. To mitigate this problem, you can periodically clean up the staging data tables. The cleanup process deletes all data from the staging tables that is older than a specified number of days.

Manually clean up staging data

You can manually clean up the staging data tables at any time by following these steps:

1. Sign in to Supply Chain Management.
2. Go to **System administration** > **Periodic tasks** > **Setup** > **Demand planning app parameters**.
3. Open the **Periodic tasks** tab.
4. In the **Delete data from jobs executed before** field, enter the newest date for which you want to keep staging data. All data that is older than this date will be deleted.
5. Select **Run clean up job**.

Automatically clean up staging data periodically

To automatically clean up staging data periodically, you can set up a batch job that runs the cleanup process once a month. To do this, follow these steps:

1. Sign in to Supply Chain Management.
2. Go to **System administration** > **Periodic tasks** > **Setup** > **Demand planning app parameters**.
3. Open the **General** tab.
4. Set **Clean up staging data** to *Yes*.

Security roles and row-level security in Demand planning

07/30/2025

This article describes how to set up users, security roles, and access rules for Demand planning. It explains how to configure security roles and duties in Supply Chain Management and how to assign security roles for accessing the app and its various features on Power Platform. It also explains how to set up row-level security within Demand planning.

Configure security roles and duties in Supply Chain Management

Demand planning features in Supply Chain Management are available only to users who have the required security roles and related duties. When you enable Demand planning in Supply Chain Management, the feature adds a privilege named *Demand planning informational tile*. This privilege grants users access to a button that opens Demand planning from the home page of Supply Chain Management. The privilege is added to the out-of-box roles and duties that are listed in the following table.

Expand table

Role name	Duty
Production planner	Maintain forecasts
Production planner	Maintain firming of planned orders
Production manager	Enable forecast process
Production planner	Maintain forecast planning
Production planner	Maintain demand forecasts
Sales manager	Maintain demand forecast
Production manager	Enable the demand planning process

If you're using custom roles in Supply Chain Management, you must manually assign the *Demand planning informational tile* privilege to them as needed after you enable Demand planning in Supply Chain Management.

Assign security roles for accessing Demand planning on Power Platform

When you install Demand planning on Power Platform, it creates and updates several security roles to control access to its various features. To be able to access Demand planning, users must sign in a Power Platform user account that has the security roles for the features they need.

The following security roles are used by Demand planning. Some of them are standard for Power Platform, while others are specific to Demand planning.

- **Demand Planning Contributor**
  - This role is added when you install Demand planning.
  - Grants access to Demand planing.
  - View worksheets (see shared worksheets and save their own views).
  - Controlled by row-level access and can edit data they have access to.
  - Collaborate using Microsoft Teams and in-app comments.

- **Demand Planning Manager**
  - This role is added when you install Demand planning.
  - Grants access to Demand planning and all features that are available to the *Demand Planning Contributor* role.
  - Configure demand planning (role-level security, time fences, worksheets).
  - View and create planning data (forecasts and calculations).
  - View and create tables and import data from excel.
  - View and create transformations.
  - View and create worksheets.
  - Export plans when they're ready to share with Supply Chain Management.

- **Basic User**
  - This is a standard security role that's included with Power Platform.
  - This role isn't required to access Demand planning, nor does it grant access to Demand planning.
  - For users that also have the *Demand Planning Manager* and/or *Demand Planning Contributor* roles, the *Basic User* role adds the following privileges in Demand planning:
    - Export any data table to Microsoft Excel using buttons in the Demand planning user interface.
    - Access core business tables such as accounts, contacts, and so on.

- **System Administrator**
  - This is a standard security role that's included with Power Platform.

    - Grants access to Demand planning and all features that are available to the *Demand Planning Manager*, *Demand Planning Contributor*, and *Basic User* roles.
    - Grants access to admin features within Demand planning.
    - Install the app, add users, assign roles, manage teams, and so on.
    - View, create, and manage tables, relations, and data.
    - Create and manage imports and exports.
    - View and create transformations based on requests from the demand planning manager.
    - Monitor jobs (imports, calculations, forecasts, transformations, and exports).

- **Demand Planning Service Role**
    - This role is added when you install Demand planning.
    - An internal role required by Demand planning, which uses this role for internal operations.
    - You should never assign this role to a human user.

Use the Power Platform admin center to set up user accounts and assign security roles to them as needed. For more instructions, see Assign a security role to a user.

Set up row-level security for accessing data within Demand planning

Users who have the *Demand Planning Contributor* role (but not *Demand Planning Manager* or *System Administrator*) can access Demand planning, but they can only view and edit data that they're granted access to. You control this access using *row-level security*, which is set up in Demand planning. For example, a user might only be granted access to the specific products or product families they manage; or they might be restricted to only viewing data for a specific site or warehouse. By default, demand planning contributors can't see any data until they're granted access to it by a row-level access rule.

To set up row-level security, follow these steps:

1. Sign in to Demand planning using a system admin account.
2. On the navigation pane, select **Configuration** > **Row level access**.
3. Do one of the following steps:

    - To add a new row-level access rule, select **New** from the top toolbar. This launches a setup wizard, where each page of the wizard maps to a tab in the edit dialog.
    - To edit an existing row-level access rule, select the rule in the list, and then select **Edit** from the grid toolbar.

4. On the **Create rule** tab or wizard page, make the following settings.

- **Name** – Enter a name for the rule.
- **Description** – Enter a description for the rule.

5. On the **Conditions** tab or wizard page, set up the logic for which data tables and columns the rule grants access to. Use the buttons to add or remove conditions as needed. The following logic applies.

    - Each condition line is based on a data table and column, which you select in the **Table** and **Column** fields. The values in the column are compared to the values that you enter in the **Value** field. The **Operator** field determines how the comparison is made. For example, you can select *equals*, *greater than*, or *less than*. There is also a *Select all* operator, which matches all values in the column (in which chase the **Value** field is disabled); learn more in Using the select all operator.
    - If you have more than one condition line, then the lines are combined with an AND operator, which means that users will only have access to data rows where all of the condition lines are true.
    - You can select more than one value in the **Value** field for each condition. These values are combined with an OR operator, which means that the condition line evaluates to true for data rows where any of the values are true.

6. On the **Users** tab or wizard page, add each user for whom the current row level access rule applies. If you assign the same user to multiple rules, then the user will have access to data rows that are granted by any of the rules (an OR operator is applies across rules).
7. On the **Activation** tab or wizard page, set **Activation** to *Active* or *Inactive*, as needed. Only active rules take effect, but you might set a rule to inactive if you're still working on it or if you want to temporarily disable it without deleting it.

Convert a Demand planning environment from sandbox to production

Article • 03/21/2025

You can convert a Demand planning environment from sandbox to production. You might want to do this conversion if, for example, you use a sandbox environment to set up models and check integrations before you use them with production data.

Conversion process

The process for converting a Demand planning environment from sandbox to production is the same as the process for converting an environment for any other Microsoft Power Platform–based application. Follow the instructions in Change environment type.

Special considerations

Although the process for environment conversion is the same for every Microsoft Power Platform–based application, conversion of a Demand planning environment involves some special considerations, as described in the following subsections.

Remove sandbox connections

After you convert a Demand planning environment from sandbox to production, the environment can no longer connect to its sandbox sources of data. (Those sources include the previous instance of Dynamics 365 Supply Chain Management and Power Query tables.) This behavior makes sense from a security standpoint, because it prevents accidental leakage of production data. However, one result is that some of your configurations, such as import or export profiles, no longer work as you expect. Therefore, you should delete all existing import and export profiles before you convert the environment to production. Then re-create them after the conversion is completed. Configure the new profiles so that they point to production sources of data.

To delete import and export profiles, follow these steps.

1. Go to **Data management** > **Import** or **Data management** > **Export**.
2. Select the profile to delete.

3. Select **Delete**.

Learn more about how to create new profiles in the following articles:

- **Import profiles:** Import data into Demand planning
- **Export profiles:** Export and download data

Consider removing test data

After you convert a Demand planning environment from sandbox to production, you will probably start to use production data. To avoid mixing test data and production data, consider going through tables and time series, and deleting any that contain test data.

To delete tables and time series, follow these steps.

1. Go to **Data management** > **Tables and data** or **Planning data** > **All**.
2. Select the table or time series to delete.
3. Select **Delete**.

> ⓘ **Note**
>
> The system might block you from deleting some tables or time series (for example, if a time series is used as an input in a forecast or calculation profile). In this case, read the error messages that you receive to learn how to address the issue. For example, you might first have to delete dependent records.

Review user access roles

After you convert a Demand planning environment from sandbox to production, the environment uses production data and generates production forecasts. Therefore, you should review who can access Demand planning, and what kind of data they can view or edit. Learn more in the following articles:

- **Security roles and row-level security:** Security roles and row-level security in Demand planning
- **Time fence functionality:** Limit time series edits with time fences

View and customize tables for holding imported data

Article • 02/21/2024

Data that's imported into Demand planning must be loaded into tables that are set with the fields and relations that are required to accommodate the incoming data. Demand planning includes a set of predefined tables that support the most useful standard data that you'll probably want to import from Microsoft Dynamics 365 Supply Chain Management. If you've customized your tables in Supply Chain Management, you can use the tools that are provided to reproduce the custom fields. You can also create new custom tables to store data from Supply Chain Management and other sources.

View tables

To view the full list of tables that are available to Demand planning, select **Data management** > **Tables and data** on the navigation pane. The tables are listed by name.

- The **Name** column shows the name of each table. Select a table name to view and edit details about that table, including column definitions, relationships, and data.
- The **Is System** column indicates whether each table is a standard table that's provided by the system or a custom table that was added by a user. It shows one of the following values:
  - *Yes* – The table is a system table. You can't delete these tables.
  - *No* – The table is a custom table that was added by a user. You can delete these tables if you no longer need them.

> **Note**
>
> Tables that hold prices aren't marked as systems tables.

Standard tables

Demand planning includes a set of predefined *system tables* that support the most useful standard data that you'll probably want to import from Supply Chain Management. Most system tables represent important data that's imported from Supply Chain Management. However, many of these tables are slightly modified in Demand

planning through minor name changes and the addition of extra columns. This section lists these important tables and explains how they're modified in Demand planning.

Site Location table

Sites and warehouses are implemented as a hierarchy. The site is the parent, and each site can have one or more warehouses. This concept is inherited from Supply Chain Management.

To import sites from Supply Chain Management, export an Excel file from the **Sites V2** data entity in Supply Chain Management, and then import that file into Demand planning.

In the current release, only one-level relations are supported in transformations. Therefore, the **Site location** table and its data can't be used in transformations. Site ID values can still be obtained from the **Warehouse Location** table.

Warehouse Location table

The **Location** table from Supply Chain Management is renamed **Warehouse Location** in Demand planning. Local columns that are named **Operation Site ID** and **Site Location ID** have been added to the **Warehouse Location** table in Demand planning. These extra columns let you generate forecasts based on the warehouse and/or site location ID.

You can derive site IDs by applying a warehouse location ID to the historical demand.

Customer Accounts table

Customer Accounts is a new table that lets you import customers and related details such as the customer group and address information (for example, country/region). This table also lets you generate forecasts based on the customer, the customer group, and/or the customer's country/region.

Legal Entity table

The **Legal Entity** table stores information about legal entities and related details. Usually, you'll import this data from Supply Chain Management.

This table lets you generate forecasts across legal entities. It also lets you slice forecasts according to the owning legal entity.

> **Note**
>
> When you export forecasts back into Supply Chain Management so that they can be used in supply planning, you must include the **Legal Entity ID** column, because supply planning is performed per legal entity in Supply Chain Management.

Product table

The **Product** table stores product information and related details. Usually, you'll import this data from Supply Chain Management.

The **Product** table supports both *Product* and *Service* product types.

You can forecast on products and product variants as a hierarchy. In this way, you can get an aggregate of product variants.

You can add columns for color ID, size ID, style ID, and configuration ID to the forecast. In this way, you can slice the forecast across products variants. For example, you can forecast demand for all silver LCD TVs across sizes.

Historical Demand table

The **Historical Demand** table stores information about historical demand in the form of orders. Each order includes a buyer and a seller, to cater to both external sales and intercompany trade. An order can also be internal. (In this case, the buyer and the seller are the same.) Usually, you'll import this data from Supply Chain Management.

The **Historical Demand** table includes an **Order Type** column that classifies the origin of the demand (*Sales*, *Transfer*, or *Production*). Sales returns are classified as sales that have a negative quantity.

Create or edit a table and its columns and relationships

You can create your own non-system tables, or you can extend system tables by adding extra non-system columns. Custom tables and columns can be used in Demand planning just as system tables and columns can. For example, you can add important signals, such as weather data, inflation statistics, or other macroeconomic data.

To create or edit a table, follow these steps.

1. On the navigation pane, select **Data management** > **Tables and data**.

2. Follow one of these steps:

    - To add a new non-system table, select **New** on the Action Pane.
    - To edit an existing table, select the link for it in the **Name** column.
    - To delete one or more existing non-system tables, select the checkbox next to the name of each table, and then select **Delete** on the Action Pane.

3. On the **General** tab, set the following fields:

    - **Name** – For new tables, enter the table name. For existing tables, this field is read-only.
    - **Owner** – Select the owner of the table (user account, master data manager, or a similar role).
    - **Key** – Specify one or more columns whose combined values will uniquely identify each row in the table. If you're creating a new table, you can't set this field until you add the columns that you'll use as keys. This limitation is important because it helps prevent duplicate records from being created at each import.

4. On the Action Pane, select **Save**.

5. On the **Columns** tab, you can view the name, data type, and system status of each column. Use the buttons on the toolbar to add new columns or delete existing non-system columns. Each column must have a **Name** value and a **Data Type** value.

    > ⓘ **Note**
    >
    > To transform a table and its data into a time series, the table must include at least three columns:
    >
    > - One *timestamp* column (*DateTime* data type)
    > - One *measure* column (*Decimal* or *Integer* data type)
    > - One *dimension* column (*String* data type)

6. If you didn't specify key columns in step 3, go back to the **General** tab, and specify them.

7. Select the **Relationships** tab.

Relationships between tables let you construct a data model that's suitable for your organization's needs. As for tables and columns, predefined system relationships are required. Therefore, the **Is System** field is set to *Yes* for them. You can also add custom relationships as you require. (Set the **Is System** field to *No* for these custom relationships.) System relationships can't be deleted or changed.

Each relationship links two tables together. This link lets you match related information that's stored in different tables. Only columns from related tables can be selected in transformations. You can set up both *many-to-one* (n:1) and *many-to-many* (n:n) relationships. For *many-to-many* relationships, the system shows the first matching record.

Relationships are currently *directional*. Therefore, it's important that you pay attention to which table is the "from" table and which is the "to" table. Often, the "from" table is a transactional table such as **Historical Demand**.

8. To add a new relationship, select **New Relationship** on the toolbar, and then set the following fields in the **Quick Create: Relationship** dialog box:

    - **From Table** – This table is the current table. It's usually a table that holds transaction data.
    - **From Column** – Select the field in the "from" table that holds values that should be matched in the related table.
    - **To Table** – Select the target table that contains the data that you want to relate to.
    - **To Column** – Select the field in the "to" table that holds data values that should be matched to the value that's found in the "from" column.

9. Select **Save and Close**.

    By default, all relationships are active. Therefore, columns from related tables can be selected in transformations. You can change the activation status of a relationship or completely delete the relationship. Select the relationship on the **Relationship** tab, and then select the appropriate button on the toolbar.

10. On the **Data** tab, inspect the data that your table contains.

11. Select **Save** on the Action Pane to save your changes.

Delete all records in a table

As required, you can delete all the records from a selected table but keep the table schema and its relationships. This approach can be useful if you must correct data that

was incorrectly imported.

To delete all the records in a table, follow these steps.

1. On the navigation pane, select **Data management** > **Tables and data**.
2. In the **Name** column, select the name of the target table.
3. On the Action Pane, select **Delete Data**.
4. Select **OK** to confirm the deletion.

Import data from Supply Chain Management

You can easily import data from Supply Chain Management into the standard tables by using the Finance and Operations connector. By default, all system (standard) entities are selected, and their fields are automatically mapped.

You can edit any relationship, unmap fields, or add custom field mappings as you require. Before you can import a custom field, you must add it in the standard table.

When you create an import job, an export data project for the required data entities is created in Supply Chain Management.

Security configuration for custom entities

To allow data to be read from custom entities, you must configure their security settings in Dynamics 365 Supply Chain Management. To do so, follow these steps:

1. Go to **System Administration** > **Security** > **Security Configuration**.
2. Open the **Privileges** tab.
3. Select **Create new** from the toolbar.
4. In the dialog, add a **Name** for your new privilege, and then select **OK**.
5. Your new privilege is added to the list and selected. In the middle column, select **Entities**.
6. On the toolbar, select **Add references**.
7. In the dialog, find and select your custom entity. Select the access properties you want to grant and then select **OK**.
8. In the middle column, select **Duties**.
9. On the toolbar, select **Add references**.

10. In the dialog, find and select the duty named *View Document entity data for data management* or *Create data management project and details using entity*. Choose the duty based on the level of access you require.

    - *View Document entity data for data management* is commonly associated with entities used in the Data Management Framework in Supply Chain Management. It's typically assigned to the role *Data management migration user*, which is a subordinate role to *Demand planning app role*.
    - *Create data management project and details using entity* is part of the *Demand planning app role* role. *Demand planning app role* is assigned to *DemandPlanAppUser*, which is a user role often employed for integrating the Demand Planning Service with Supply Chain Management.

11. Select **OK** to add the selected duty to your new privilege.

12. Open the **Unpublished objects** tab. On the toolbar, select **Publish all**.

Import data into Demand planning

You can import data from a range of sources and file types. For example, you can import data directly from Microsoft Dynamics 365 Supply Chain Management or by importing text files in Excel or comma-separated values (CSV) format. You can also import data that's stored in an Azure data lake. Before you import the data into Demand planning, you can use Power Query to transform it as you require.

Demand planning lets you build a collection of *import profiles*. Each profile imports data from a specific external source into one or more specific tables in Demand planning.

Typically, a manager or system administrator creates the initial collection of required profiles. Forecasters and other users can then run the profiles to update the data as they require.

In addition, you can use the standard user interface (UI) to import your custom data entities into custom tables or add custom fields that you've extended in the standard tables. No developer is required.

View and run existing data import profiles

You only need to import data as often as the relevant data changes in the external systems. Some profiles require occasional runs, whereas others require almost every time that a user works with the app.

To update your data by running an existing data import profile, follow these steps:

1. On the navigation pane, select **Data management** > **Import**.
2. Find the profile for the type of import that you want to run, and select the link for it in the **Name** column.

   The details page for the selected profile appears. It contains the following tabs:

   - **Summary** – This tab provides basic information about the profile. You can edit the name and description to make the profile easier to identify and work with.
   - **Configure provider** – This tab lets you view and edit the settings that are specific to the data provider that the profile uses. For information about how to work with the settings on this tab, see the Create and manage data import profiles section.

- **Run schedule** – This tab lets you set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.
- **Jobs** – This tab shows a list of every run of the profile. It includes date information, the job status, the provider that was used, the table that was updated, and the number of records that were imported. Links to more information are provided.

3. To run the profile, select **Run** on the Action Pane. This command adds a new row to the grid on the **Jobs** tab. There, you can follow the status of the new import. The page isn't automatically refreshed. To update the status information, you must select **Refresh** on the grid toolbar.

Create and manage data import profiles

Each time your organization needs to run a new type of data import, a manager or admin must create a new data import profile. After the profile is created, it becomes available to users, who can run it as often as they require.

Each data import profile uses a *data provider* that's optimized to import data from a specific type of external data source or file type. The following types of data providers are currently available:

- **Power Query providers** – Each of these providers imports from a specific type of file (CSV, Excel, or Azure data lake storage) through Power Query. Therefore, you can transform and map the data for the relevant table in Demand planning.
- **Microsoft finance and operations apps provider** – This provider connects directly to Supply Chain Management (or another finance and operations app) and imports data that one or more data entities provide into the relevant tables in Demand planning.

Create an import profile for importing directly from Supply Chain Management

To import directly from Supply Chain Management (and other finance and operations apps), create an import profile that uses the *Microsoft finance and operations apps* data provider.

1. On the navigation pane, select **Data management** > **Import**.
2. On the Action Pane, select **New**.
3. On **Select data provider**, select the **Microsoft finance and operations apps** tile.
4. A setup wizard opens. On **Get started**, enter a name and description for the new profile. Then select **Next**.

5. On **Configure connection**, in the **Connection URL** field, enter the URL of your Supply Chain Management environment. Then select **Next**.
6. The **Entity selection** page lets you map **Source** data entities from Supply Chain Management to **Target** tables in Demand planning. It initially lists all of the mappings that the solution supports out of the box. You can edit the list, remap fields, and add more mappings as needed. You can make the following settings:

    - For each listed **Source** entity that you want to import, set **Synchronize** to *Yes*. If you set **Synchronize** to *No*, the profile ignores that entity when it runs.
    - To delete all data from a listed **Target** table each time the profile runs, set **Delete data** to *Yes*.
    - Source entities that include company-specific data provide a drop-down dialog box in the **Company** column. To limit the import to only include data from one or more specific companies (data entities), select those companies. This feature supports all data entities that contain a *Data area ID* field, including custom-built data entities. If none of the listed source entities include company-specific data, the **Company** column is hidden.
    - To view or edit the field mappings for any listed entity, select that entity and then select **Edit** from the toolbar. Then use the **Add mapping** dialog to map source entity fields to target table fields.
    - To add an unlisted entity, select **Add** from the toolbar. Use the **Add mapping** dialog to identify the **Source** entity and **Target** table. Then map the required source entity fields to their matching target table fields. The target table and fields must already exist in Demand planning (learn more in View and customize tables for holding imported data).

7. Select **Next**.
8. On **Set run schedule**, you can choose to set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.
9. Select **Next**.
10. On **Review and finish**, review the summary of settings that you configured, and then select **Review and finish** to create the new profile.
11. You're returned to the **Active Import Data Profiles** page, which now shows the new profile in the list. The profile is now available, but it didn't yet run. To run it, follow the instructions in the View and run existing data import profiles section.

Create an import profile for importing data through Power Query

To import data from a text or workbook file exported from an external system, create an import profile that uses one of the *Power Query* data providers. Use the provider that matches the format of the exported file. The procedure is the same for all providers.

1. On the navigation pane, select **Data management** > **Import**.
2. On the Action Pane, select **New**.
3. On **Select data provider**, under **Power Query providers**, select the tile that matches the format of the exported file that you want to import.
4. A setup wizard opens. On **Get started**, enter a name and description for the new profile. Then select **Next**.
5. On **Select target table**, in the **Select table** field, select the name of the table in Demand planning that you want to import data into. Then select **Next**.
6. On **Configure provider**, select the file that you want to import and then send to Power Query, where you can transform the data and map columns from the source document to the selected Demand planning table. Power Query provides the connection, transformation, and mapping features. The procedure varies slightly, depending on the Power Query provider that you're using:
    - **Excel** – For information about how to select the target file, connect to Power Query, and work with data, see Excel in the Power Query documentation.
    - **CSV** – For information about how to select the target file, connect to Power Query, and work with data, see Text/CSV in the Power Query documentation.
        - **Datalake** – For information about how to select the target file, connect to Power Query, and work with data, see Datalake in the Power Query documentation. Set up the data lake as described in Datalake setup.
7. When you finish transforming and mapping your data by using Power Query, select **Next**.
8. On **Refresh settings**, select or clear the **Delete all data for the chosen table before import** checkbox to specify what should happen to the data that's currently in the target table in Demand planning:

- *Selected* – Delete all the data that's currently in the target table. Use this option if, for example, the incoming data includes all the required records that are already in your table, and you don't select a key field for the table. This option ensures that you don't have any duplicate records, but it also deletes all the data that's currently in the target table.
- *Cleared* – Keep all the data that's currently in the target table. Use this option if, for example, the incoming data is an incremental export that contains only new records, and you selected key fields for the table. Incoming records that have key field values that match existing records update those records, whereas incoming records that have unique key field values create new records. If you don't configure and map your key fields correctly, this option might create duplicate records.

9. Select **Next**.

10. On **Set run schedule**, you can choose to set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.

11. Select **Next**.

12. On **Review and finish**, review the summary of settings that you configured, and then select **Review and finish** to create the new profile.

13. You're returned to the **Active Import Data Profiles** page, which now shows the new profile in the list. The profile is now available, but it didn't yet run. To run it, follow the instructions in the View and run existing data import profiles section.

Troubleshoot data import issues

To troubleshoot data import issues in Demand planning, see the Demand Planning Import Profile Troubleshooting Guide.

Last updated on 08/20/2026

Transform data

Transformations let you transform the imported data in a selected table into time series. You can then use the time series to create a forecast, do a comparison to a forecast, or do calculations. For example, you might want to shift the historical demand time from last year by 12 months, so that it can be used as the basis for next year's forecast. Alternatively, you might want to combine daily historical demand data into monthly buckets, because you run planning on a monthly basis.

Demand planning lets you build a collection of *transformation profiles*. Each profile transforms data from a specific data table that's already set up in the app into a time series that you can analyze by using the app.

Each transformation profile takes a selected main table as its input. That main table can have other tables that are related to it.

- The main table typically represents historical demand, such as sales orders.
- The main table must include a *timestamp* column. This column will become the x-axis of the output time series and typically represents the order date or delivery date.
- The main table must also include a *measure* column. This column will become the y-axis of the output time series and typically represents units that are sold.
- Either the main table or one of its related tables must include at least one dimension column. Often, you'll select more than one dimension, so that you can analyze the data in multiple ways. For example, if you're looking at T-shirts, you might include columns for the color, size, style, and warehouse dimensions. You can then view the output time series to see, for example, the historical demand for red, extra-large T-shirts that are sold from the Chicago warehouse. You can also compare that demand with the overall sales of all T-shirts from all warehouses.

Typically, a manager or system administrator creates the initial collection of required profiles. Forecasters and other users can then run the profiles to update the time series as they require.

View and run existing transformation profiles

You have to run a transformation profile only as often as you import new data into the relevant tables. Some profiles must be run only occasionally, whereas others must be run almost every time that a user works with the app.

To update your time series by running an existing transformation profile, follow these steps:

1. On the navigation pane, select **Operations** > **Transformations**.
2. Find the profile for the type of transformation that you want to run, and select the link for it in the **Name** column.

   The details page for the selected profile appears. It contains the following tabs:

   - **Summary** – This tab provides basic information about the profile. You can edit the name and/or description to make the profile easier to identify and work with. Although you can also change the owner and adjust the time bucket, you typically shouldn't change these details for existing profiles. For information about how to work with the settings on this tab, see the Create and manage transformation profiles section.
   - **Transformations** – This tab shows details about the transformation that the profile will process. For information about how to work with the settings on this tab, see the Create and manage transformation profiles section.
   - **Run schedule** – This tab lets you set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.
   - **Jobs** – This tab shows a list of every run of the profile. It includes date information, the job status, and the time series that was updated. Select a link in the **Time Series** column to open the time series.

3. To run the profile, select **Run** on the Action Pane. This command adds a new row to the grid on the **Jobs** tab. There, you can follow the status of the new transformation. The page isn't automatically refreshed. To update the status information, you must select **Refresh** on the grid toolbar.

Create and manage transformation profiles

Each time that your organization requires a new type of data transformation, a manager or admin must create a new transformation profile. After the profile is created, it becomes available to users, who can run it as often as they require.

To create or edit a transformation profile, follow these steps:

1. On the navigation pane, select **Operations** > **Transformations**.
2. On the Action Pane, select **New**.
3. A setup wizard is opened. On the **Get started** page, set the following fields:

- **Name** – Enter a name for the new profile.
- **Description** – Enter a short description of the profile.
- **Owner** – Select the user account that owns the profile.
- **Time Bucket** – Specify the time span to group source records by in the time series that this profile generates as output: *Daily*, *Weekly*, or *Monthly*. The shorter the time bucket, the more data points there are on the x-axis. Select the time bucket that gives the required level of granularity.
- **Precision** – Specify the rounding precision for the output values. For example, select *0.01* to keep two decimal places. The default value is *0.01*.
- **Aggregation Method** – Select how the profile combines multiple source records that have the same dimension values and belong to the same time bucket. The default method is *Sum*. Learn more about the options available here and how they work in Aggregation methods.

4. Select **Next**.

5. On the **Configure transformation** page, select a table, and then map the columns of that table and its related tables to transform the data into a timeline.

   - The grid has a row for each column that the transformation generates as output.
   - You can use the buttons on the toolbar to add columns to the grid, remove selected columns from the grid, or completely reset the grid.
   - You can select only one main table at a time. To change the main table, you must reset the grid.

6. To select the main table, and/or add or remove columns for the main table and related tables, select **Add column** on the toolbar.

7. In the **Add columns to your transformation** dialog box, if no main table has been selected yet, select one in the **Tables** field. (If you have to change the main table, you must first reset the whole transformation by selecting **Reset**.)

8. To add a data column to the transformation, select a table in the left column of the dialog box. Then, in the middle column, select the name of the data column in that table that you want to add. For information about how the different types of columns are used, see the beginning of this article.

   - Under **Timestamp**, you must select exactly one column. This column will become the x-axis of the output time series and typically comes from the main table.

- Under **Measure**, you select exactly one column. This column will become the y-axis of the output time series and typically comes from the main table.
- Under **Dimension**, you must select at least one dimension column. Dimensions provide interactive parameters that let you choose which values to view in the output time series. These columns can come from the main table and/or any related tables.

> ⓘ **Note**
>
> The order that you add the dimension columns in defines how the output time series aggregates the data.

Each time that you add a data column, it's added to the list in the right column of the dialog box. Therefore, you can view your previous selections while you explore the different tables. Under **Dimension**, the order reflects the order that you selected the dimensions in.

9. When you've finished selecting data columns, select **OK**.
10. Select **Next**.
11. On the **Set run schedule** page, you can choose to set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.
12. Select **Next**.
13. On the **Review and finish** page, review the summary of settings that you've configured, and then select **Review and finish** to create the new profile.
14. The profile is now saved, but it hasn't yet run. If you're ready to create a time series now, select **Run** on the Action Pane.

Aggregation methods

Each transformation profile has an **Aggregation method** setting that determines how the profile combines multiple source records that have the same dimension values and belong to the same time bucket. It groups the relevant records in each bucket and applies the selected aggregation method to the measure column to produce one output value for the group. The profile applies its **Precision** setting after it calculates the value.

For example, suppose that the following records belong to the same product dimension and monthly time bucket:

Expand table

Date	Measure value
January 1	40
January 10	20
January 20	80
January 28	60

The following table shows the result of each aggregation method.

Expand table

Aggregation method	How the output value is calculated	Result in the example	Common use
Sum	Adds all measure values in the bucket.	200	Additive values, such as units sold or ordered.
Minimum	Uses the smallest measure value in the bucket.	20	The lowest value recorded during a period.
Maximum	Uses the largest measure value in the bucket.	80	The highest or peak value recorded during a period.
Average	Calculates the arithmetic mean of the measure values in the bucket.	50	Rates, prices, or measurements where a total wouldn't be meaningful.
First	Uses the measure value from the record with the earliest timestamp in the bucket.	40	The opening value or balance for a period.
Last	Uses the measure value from the record with the latest timestamp in the bucket.	60	The closing value or balance for a period.
Count	Counts the source records in the bucket. The measure values aren't used in the calculation.	4	The number of transactions, orders, or events.

Note

Sum is the default method and preserves the behavior of transformation profiles that were created before other aggregation methods were available. *First* and *Last* are based on the timestamp of each record, not the order in which records were imported or displayed.

Work with calculation profiles

Demand planning in Microsoft Dynamics 365 Supply Chain Management lets you build a collection of *calculation profiles*. Each profile takes one or more existing time series as input, and applies a set of predefined calculations to generate a new time series as output.

Here are some examples of purposes that you might use calculations for:

- Increase all forecasts by 10 percent.
- Combine two forecasts, so that the result is the average of the two.
- Remove outliers from the forecast by removing some values that are completely out of range.

Typically, a manager or system administrator creates the initial collection of required profiles. Forecasters and other users can then run the profiles to generate new calculated time series as they require.

View and run existing calculation profiles

You have to run a calculation profile only as often as you import new data into the relevant tables. Some profiles must be run only occasionally, whereas others must be run almost every time that a user works with the app.

To generate a new calculated time series by running an existing calculation profile, follow these steps:

1. On the navigation pane, select **Operations** > **Calculations**.

2. Find the profile for the type of calculation that you want to run, and select the link for it in the **Name** column.

   The details page for the selected profile appears. It contains the following tabs:

   - **Summary** – This tab provides basic information about the profile. You can edit the name and/or description to make the profile easier to identify and work with.
   - **Calculation model** – This tab shows the calculation that the profile does. It uses a flowchart of interconnected steps. Each step does a specific type of operation and has settings that let you define how that operation works. For information about how to

work with the settings on this tab, see the Create and manage calculation profiles section.

- **Run schedule** – This tab lets you set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.
- **Jobs** – This tab shows a list of every run of the profile. It includes date information, the job status, and the time series that was generated. Select a link in the **Time Series** column to open the time series.

3. To run the profile, select **Run** on the Action Pane.

4. In the dialog box that appears, set the **Output option** field to one of the following values to define the output of the job:

   - *Create a new time series* – The job will create a new time series. If you select this value, enter a name for the new series in the **Time series name** field.
   - *Use an existing time series* – The job will overwrite an existing series or create a new version of it. If you select this value, use the fields that are provided to select the target series, specify whether you want to overwrite the existing version or create a new version, and, if you want to create a new version, specify the name of the new version.

5. Select **Save and close**.

6. The new job is added to the grid on the **Jobs** tab. There, you can follow the status of the new calculation. To update the status information, select **Refresh** on the grid toolbar.

Create and manage calculation profiles

Each time that your organization requires a new type of calculation, a manager or admin must create a new calculation profile. After the profile is created, it becomes available to users, who can run it as often as they require.

To create or edit a calculation profile, follow these steps:

1. On the navigation pane, select **Operations** > **Calculations**.

2. On the Action Pane, select **New**.

3. A setup wizard is opened. On the **Get started** page, set the following fields:

   - **Name** – Enter a name for the new profile.
   - **Description** – Enter a short description of the profile.
   - **Owner** – Select the user account that owns the profile.

- **Precision** – Specify number of decimal places that the profile should show for calculation results and output.
- **Category** – Select the category of the output time series (*Forecast*, *Demand*, *Financials*, or *Miscellaneous*). The category affects the location of the output time series under the **Planning data** heading on the navigation pane.

4. Select **Next**.

5. On the **Select and configure calculation model** page, you can select a calculation model preset to use with your current profile. Browse the presets that are listed under **Available model presets** to preview the calculation that each preset does. You can configure settings and customize the calculation model as you require after you save the profile. Therefore, select the preset that's closest to what you're looking for, and then select **Next**. For information about how to configure settings and customize the calculation model that a profile uses, and how to create new presets, see Design calculation models.

6. On the **Set run schedule** page, you can choose to set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.

7. Select **Next**.

8. On the **Review and finish** page, review the summary of settings that you've configured, and then select **Review and finish** to create the new profile.

9. Your profile is now saved, but it hasn't yet run. If you're ready to run the calculation now, select **Run** on the Action Pane.

Design calculation models

Article • 01/10/2025

Calculation models let you arrange and configure steps to define the calculation that's done by a calculation profile. Each model presents a flowchart that graphically represents the calculation that the model does.

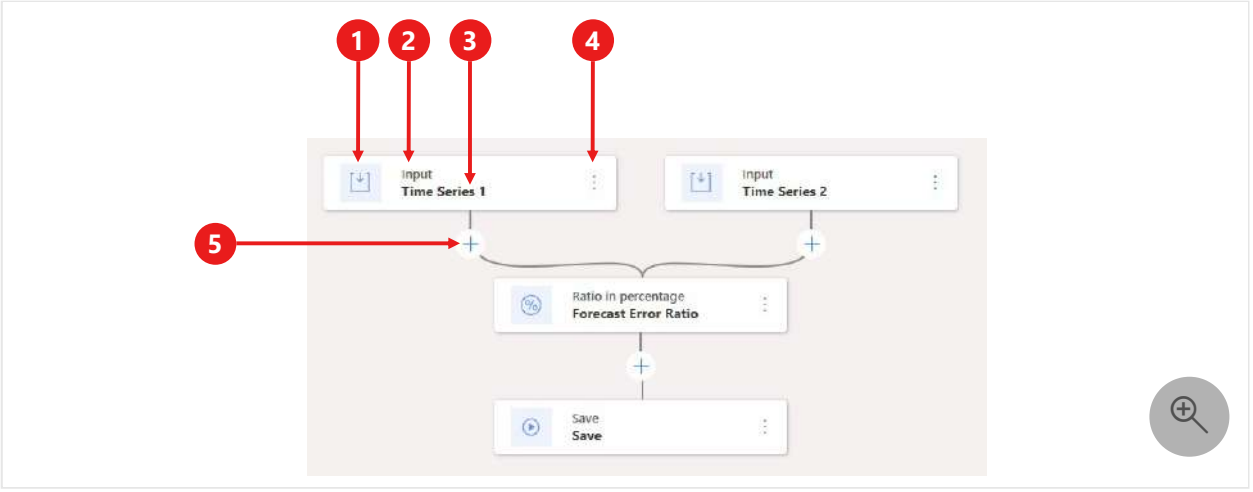
Create and customize a calculation model

To create and customize a calculation model, you must first open an existing calculation profile. (Learn more in Work with calculation profiles.) You can then fully customize the model that the selected profile uses by adding, removing, and arranging steps, and configuring settings for each of them.

Follow these steps to create and customize a calculation model.

1. On the navigation pane, select **Operations** > **Calculations**.
2. Select the calculation profile that you want to create or customize a calculation model for.
3. On the **Calculation Model** tab, there will always be at least one step (of the *Input* type) at the top of the flow chart. The model is processed from top to bottom, and the last step must be a step of the *Save** type. Add, remove, and arrange steps as you require, and configure settings for each of them. For guidelines, see the illustration after this procedure.
4. When you've finished designing your calculation model, select the **Validate** button in the upper-right corner. The system runs a few tests to validate that your model will work, and then provides feedback. Fix any issues that the validation test reports.
5. Continue to work until your model is ready. Then, on the Action Pane, select **Save**.
6. If you want to save your calculation model as a preset, so that it's available when you and other users create a new calculation profile, select the **Save as model template** button in the upper-right corner.

The following illustration highlights the information and controls that are available for steps in a calculation model.



Legend:

1. **Step icon** – A symbol that represents the role of the step.

2. **Step type** – The type of step. This text usually describes the type of calculation or other action that the step represents.

3. **Step name** – The name that's applied to the step. Usually, you can manually enter this text in each step's settings. However, some types of steps have a predefined value here.

4. **Step actions** – Open a menu of actions that you can take on the step. Although some of these actions are specific to the step type, many are common to all steps. If any actions appear dimmed, they can't be used because of the step's current position or for some other contextual reason. Here are some common actions that are available:

    - **Settings** – Open a dialog box where you can configure settings for the step.
    - **Remove** – Remove the step.
    - **Move Up** and **Move Down** – Reposition the step in the flowchart.
    - **Set to 'Pass Through'** – Temporarily disable a currently enabled step without deleting it or its settings.
    - **Unset 'Pass Through'** – Reenable a currently disabled step.
    - **Connect with** – For steps that support multiple inputs, specify the second input. The first input is automatically set based on where you put the step.

5. **Add a step** – Add a new step at the selected location. (If you insert a new *Input* step, that step will always be put at the top of a new flow, not at the button location.)

Calculation step types

This section describes the purpose of each type of calculation step. It also explains how to use and configure each type.

Input steps

Each *Input* step represents a time series that provides input to the calculation model.

Input steps have the following options that you can set:

- **Time series** – The time series that is added by the step. When you first set up an *Input* step, the **Configure step** dialog box provides a button that lets you select the time series to add. After you add a time series, the dialog box shows the name of the time series and provides an **Edit** button that lets you change the time series. It also provides a **Filter** button that lets you set up filtering criteria based on fixed dates, relative dates, and/or field values.
- **Time series version** – If the selected time series includes more than one version, you can select a specific version. By default, the latest (current) version is used.

Arithmetic operator steps

Arithmetic operator steps do a calculation that combines values from two input time series. You might use this type of step, for example, to calculate the expected margins of a forecast by subtracting the cost of goods sold (COGS) from the expected revenue.

Arithmetic operator steps implement the following calculation:

f(x) = a(x) <*operator*> b(x)

In this formula, <*operator*> is one of the following arithmetic operators: +, -, *, or /.

You can use this type of step only if your calculation model has at least two input time series in parallel branches. The first series is at the top of the branch where you create the step. The second series must start with an *Input* step. It can have any number of steps in it, but it must still be open. (In other words, it must not end with a *Save* step.) To specify the second series, open the step's **Action** menu, and select **Connect with**. The flowchart is then updated so that it shows the two branches combining at the *Arithmetic operator* step.

Arithmetic operator steps have the following fields that you can set:

- **Step name** – The specific name of the step. This name is also shown in the flowchart.
- **Description** – A short description of the step.

- **Created by** – The user who created the step.
- **Value 1** – The first series in the calculation (*a(x)*), which is on the left side of the operator. Select *Input 1* or *Input 2*.
- **Operator** – The operator that's applied between the first series (**Value 1**) and the second series (**Value 2**). Select whether to add (+), subtract (-), multiply (*), or divide (/).
- **Value 2** – The second series in the calculation (*b(x)*), which is on the right side of the operator. Select *Input 1* or *Input 2*.

Constant arithmetic operator steps

Constant arithmetic operator steps do a calculation that applies a constant arithmetic operation to each value in an input time series.

Constant arithmetic operator steps implement the following calculation:

f(x) = a(x) <*operator*> C

In this formula:

- <*Operator*> is one of the following arithmetic operators: +, -, *, or /.
- *C* is a constant value.

Constant arithmetic operator steps have the following fields that you can set:

- **Step name** – The specific name of the step. This name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Operator** – The operator that's applied. Select whether to add (+), subtract (-), multiply (*), or divide (/).
- **Constant** – The constant value that's applied to each time series value by using the selected operator.

Date offset steps

Date offset steps shift the input time series by a fixed value along the x-axis. You might use this type of step, for example, to shift last year's demand one year forward, so that you can compare it to next year's forecast by overlaying the time-shifted demand graph on the forecast graph.

Date offset steps implement the following calculation:

$f(x) = a(x - t)$

In this formula, *t* is an integer that represents the number of days, months, or years.

Date offset steps have the following fields that you can set:

- **Step name** – The specific name of the step. The name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Time value** – The amount of time to shift the input time series forward by. The amount is in the unit that's specified in the **Time unit** field.
- **Time unit** – The unit that applies to the time value.

Logical operator steps

Logical operator steps test whether a value exceeds a constant (threshold) at each point along a time series. As output, it returns a *1* for true and a *0* (zero) for false. You might use this type of step, for example, to evaluate when the forecast error is above a specific threshold in either direction, so that you can focus on important products.

Logical operator steps implement the following calculation:

$f(x) = ABS[a(x)]$ <*operator*> C

In this formula:

- <*Operator*> is one of the following logical operators: >, >=, <, or <=.
- *C* is a constant.
- *ABS* is optional. If it's enabled, the absolute value (that is, the distance from zero) is used instead of the literal value.

Logical operator steps have the following fields that you can set:

- **Step name** – The specific name of the step. The name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Apply ABS** – Set this option to *Yes* to use the absolute value (distance from zero) of the input series. Set it to *No* to use the literal value (including +/- signs) of the input series.
- **Operator** – The logical operator that's applied for the comparison against the constant value.
- **Constant** – The constant value to compare against the input time series.

Merge steps

Merge steps merge two time series into a new time series by applying the selected merge logic. You can merge the time series by minimum value, maximum value, average, or sum. You might use this type of step, for example, to calculate a merged result of two forecast methods.

You can use this type of step only if your calculation model has at least two input time series in parallel branches. The first series is at the top of the branch where you create the step. The second series must start with an *Input* step. It can have any number of steps in it, but it must still be open. (In other words, it must not end with a *Save* step.) To specify the second series, open the step's **Action** menu, and select **Connect with**. The flowchart is then updated so that it shows the two branches combining at the *Merge* step.

Merge steps have just one field that you can set: **Merge policy**. Select one of the following values:

- *Min value* – Take the lowest of the two input values.
- *Max value* – Take the largest of the two input values.
- *Average* – Calculate the average of the two input values.
- *Sum* – Add the two input values together.

Monetary value steps

Monetary value steps convert a forecast or historical demand time series that's based on sales units into a series of monetary values that are based on a selected price list. The calculation first tries to match the cost or price from a primary price list. It then tries a fallback price list if one is selected. You might use this type of step, for example, to convert a forecast (quantity) into expected revenue (monetary value).

Monetary value steps implement the following calculation:

$f(x) = a(x) \times \text{Price(product-ID)}$

Monetary value steps have the following fields that you can set:

- **Step name** – The specific name of the step. The name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Primary price list** – Select the primary data table that contains your price list. The list includes all the tables that are currently defined for use with Demand planning.

(Learn more in Set up tables.) The price list must include columns for product IDs and prices.
- **Fallback price list** – If the system can't find a matching price in the primary price list, it checks any price list that you select here.

Phase in/out steps

Phase in/out steps modify the values of a data column in a time series to simulate the gradual phasing in of a new element (such as a new product or warehouse) or phasing out of an old element. The phase in/out calculation lasts for a specific period and uses values that are drawn from the same time series (from either the same data column that is being adjusted or another data column that represents a similar element).

Phase in/out steps have the following fields that you can set:

- **Step name** – The specific name of the step. This name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Rule group** – The name of the rule group that defines the calculation that the step does.

For more information about phase in/out functionality, including details about how to set up your phase in/out rule groups, see Use phase in/out functionality to simulate planned changes.

Ratio in percentage steps

Ratio in percentage steps calculate a ratio in percentage, based on two input time series. You might use this type of step, for example, to calculate the error percentage of a previous forecast, based on a historical demand and forecast time series.

Ratio in percentage steps implement the following calculation:

$$f(x) = \Sigma \{[a(x) - b(x)] \div a(x)\} \times 100\ \%$$

You can use this type of step only if your calculation model has at least two input time series in parallel branches. The first series is at the top of the branch where you create the step. The second series must start with an *Input* step. It can have any number of steps in it, but it must still be open. (In other words, it must not end with a *Save* step). To specify the second series, open the step's **Action** menu, and select **Connect with**. The flowchart is then updated so that it shows the two branches combining at the *Ratio in percentage* step.

Ratio in percentage steps have the following fields that you can set:

- **Step name** – The specific name of the step. This name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Value 1** – The first series in the calculation (*a(x)*). Select *Input 1* or *Input 2*.
- **Value 2** – The second series in the calculation (*b(x)*). Select *Input 1* or *Input 2*.

Save steps

Save steps save the result of the calculation model as a new or updated series. All calculation models must end with a single *Save* step.

The calculated series will be saved according to the settings that you configure each time that you run a calculation job as described in Work with calculation profiles.

Work with forecast profiles

Demand planning lets you build a collection of *forecast profiles*. Each profile takes an existing time series as input, prepares the data, and then runs forecasting algorithms to create a new time series that predicts demand over a coming period.

Typically, a manager or system administrator creates the initial collection of required profiles. Forecasters and other users can then run the profiles to generate new calculated time series as they require.

View and run existing forecast profiles

To generate a new forecast by running an existing forecast profile, follow these steps:

1. On the navigation pane, select **Operations** > **Forecast profiles**.

2. Find the profile for the type of forecast that you want to run, and select the link for it in the **Name** column.

   The details page for the selected profile appears. It contains the following tabs:

   - **Summary** – This tab provides basic information about the profile. You can edit the name and/or description to make the profile easier to identify and work with.
   - **Horizon and time buckets** – This tab shows the granularity (bucket size) that the forecast will be made at (daily, weekly, or monthly) and the number of buckets that will be included in the forecast. You can modify the selections as you require. For information about how to work with the settings on this tab, see the Create and manage forecast profiles section.
   - **Forecast model** – This tab shows the forecast calculation that the profile does. It uses a flowchart of interconnected steps. Each step does a specific type of operation and has settings that let you define how that operation works. For information about how to work with the settings on this tab, see the Create and manage forecast profiles section.
   - **Run schedule** – This tab lets you set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.
   - **Jobs** – This tab shows a list of every run of the profile. It includes date information, the job status, and the time series that was generated. Select a link in the **Time Series** column to open the time series.

3. To run the profile, select **Run** on the Action Pane.

4. In the dialog box that appears, set the **Output option** field to one of the following values to define the output of the job:

    - *Create a new time series* – The job will create a new time series. If you select this value, enter a name for the new series in the **Time series name** field.
    - *Use an existing time series* – The job will overwrite an existing series or create a new version of it. If you select this value, use the fields that are provided to select the target series, specify whether you want to overwrite the existing version or create a new version, and, if you want to create a new version, specify the name of the new version.

5. Select **Save and close**.

6. The new job is added to the grid on the **Jobs** tab. There, you can follow the status of the new calculation. To update the status information, select **Refresh** on the grid toolbar.

Review forecast job run history

Each time you run a forecast profile, the system creates a record of the job run. To review the details of a job run, follow these steps:

1. On the navigation pane, select **Operations** > **Forecast profiles**.

2. Select the forecast profile that you want to inspect.

3. Open the **Jobs** tab, which shows a grid with a row for each time the profile ran.

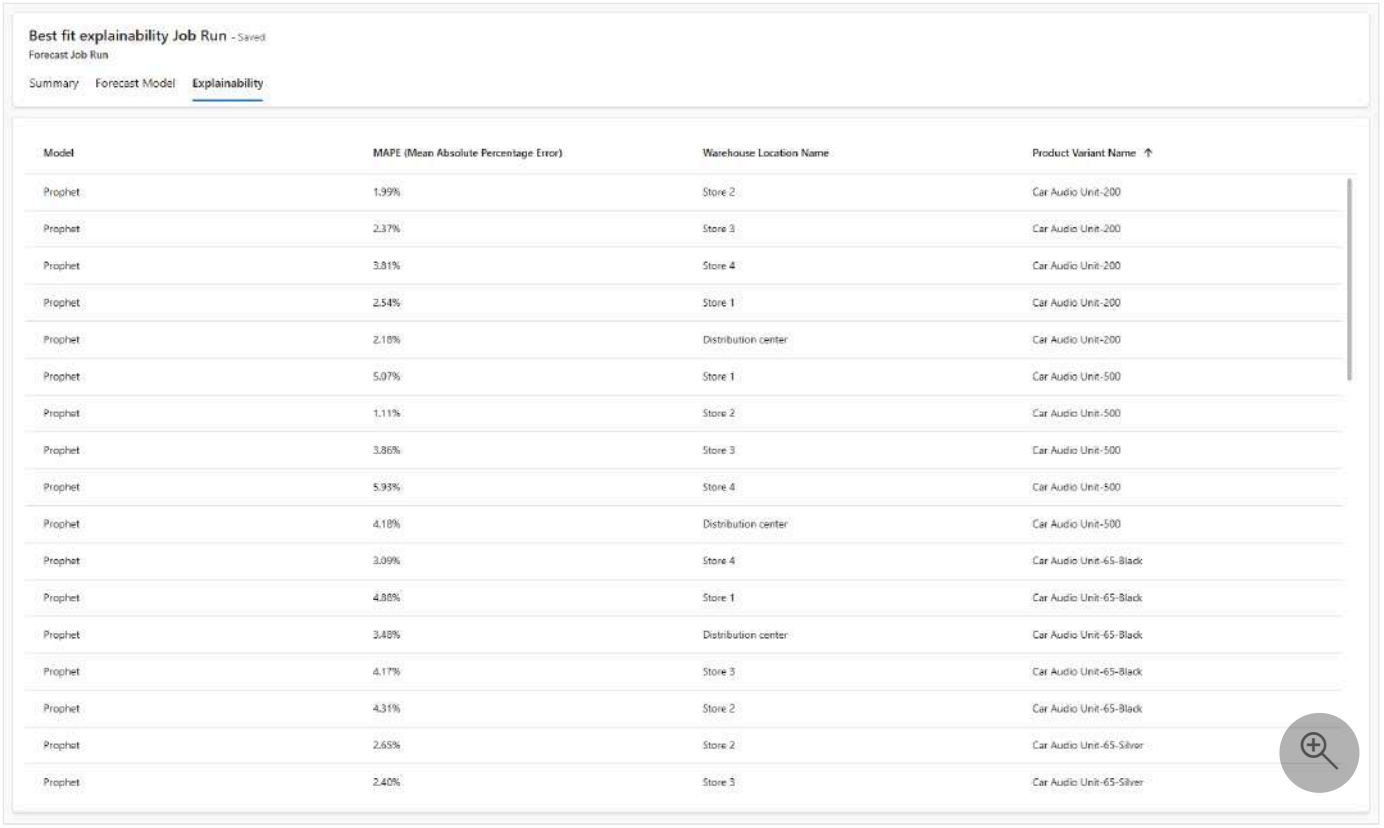
4. Find the job run that you want to inspect and select the link in the **Job run name** column for that run.

5. On the **Forecast job run** page, browse through the following tabs to review the details of the job run:

    - **Summary** – This tab provides basic information about the job run, including who ran it, when it was run, and a link to the time series that was generated or updated. You can also see the job status and any error messages that occurred.
    - **Forecast model** – This tab shows the forecast model run by the job.
    - **Explainability** – This tab lists each combination of dimensions (such as item variant, warehouse location, and so on) that the forecast was calculated for. For each combination, it shows the demand forecasting algorithm that was used and the mean average percentage error (MAPE) for the calculation. A lower MAPE value indicates

greater accuracy. You can sort the grid by selecting the column heading you want to sort by. To resize, filter, or search in a column, select the menu button on the appropriate column heading.

The following image shows an example of the **Explainability** tab of the **Forecast job run** page. This job ran using the *best fit* forecast algorithm, which calculates results for each of the standard demand forecasting algorithms and then picks the one with the lowest MAPE for each row. This is why forecasts for the same product variant (such as *Car Audio Unit-200*) used varying algorithms depending on which warehouse was analyzed.



Create and manage forecast profiles

Each time that your organization requires a new type of forecast, a manager or admin must create a new forecast profile. After the profile is created, it becomes available to users, who can run it as often as they require.

To create or edit a forecast profile, follow these steps:

1. On the navigation pane, select **Operations** > **Forecast profiles**.

2. On the Action Pane, select **New**.

3. A setup wizard is opened. On the **Get started** page, set the following fields:

- **Name** – Enter a name for the new profile.
- **Description** – Enter a short description of the profile.
- **Owner** – Select the user account that owns the profile.
- **Precision** – Specify number of decimal places that the profile should show for calculation results and output.
- **Category** – Select the category of the output time series (*Forecast*, *Demand*, *Financials*, or *Miscellaneous*). The category affects the location of the output time series under the **Planning data** heading on the navigation pane.

4. Select **Next**.

5. On the **Set horizon and time buckets** page, set the following fields:

   - **Time bucket** – Select the granularity (bucket size) that the forecast should be made at (daily, weekly, or monthly).
   - **Horizon in time buckets** – Enter the number of buckets to include in the forecast.

6. Select **Next**.

7. On the **Select a forecasting model preset** page, select a forecast model preset to use with your current profile. Browse the presets that are listed under **Available model presets** to preview the forecast that each preset makes. You can configure settings and customize the forecast model as you require after you save the profile. Therefore, select the preset that's closest to what you're looking for, and then select **Next**. For information about how to configure settings and customize the forecast model that a profile uses, and how to create new presets, see Design forecast models.

8. On the **Set run schedule** page, you can choose to set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.

9. Select **Next**.

10. On the **Review and finish** page, review the summary of settings that you've configured, and then select **Review and finish** to create the new profile.

11. The profile is now saved, but it hasn't yet run. If you're ready to run the forecast now, select **Run** on the Action Pane.

Last updated on 12/30/2025

Design forecast models

Forecast models let you arrange and configure steps to define the forecast that a forecast profile makes. Each model presents a flowchart that graphically represents the calculation that the model does.

For a presentation about how forecast models and outlier removal methods work in Demand planning, watch the following video on YouTube (starting at 16:53): Deep dive into Demand Planning for Supply Chain Management | Dynamics 365 TechTalk.

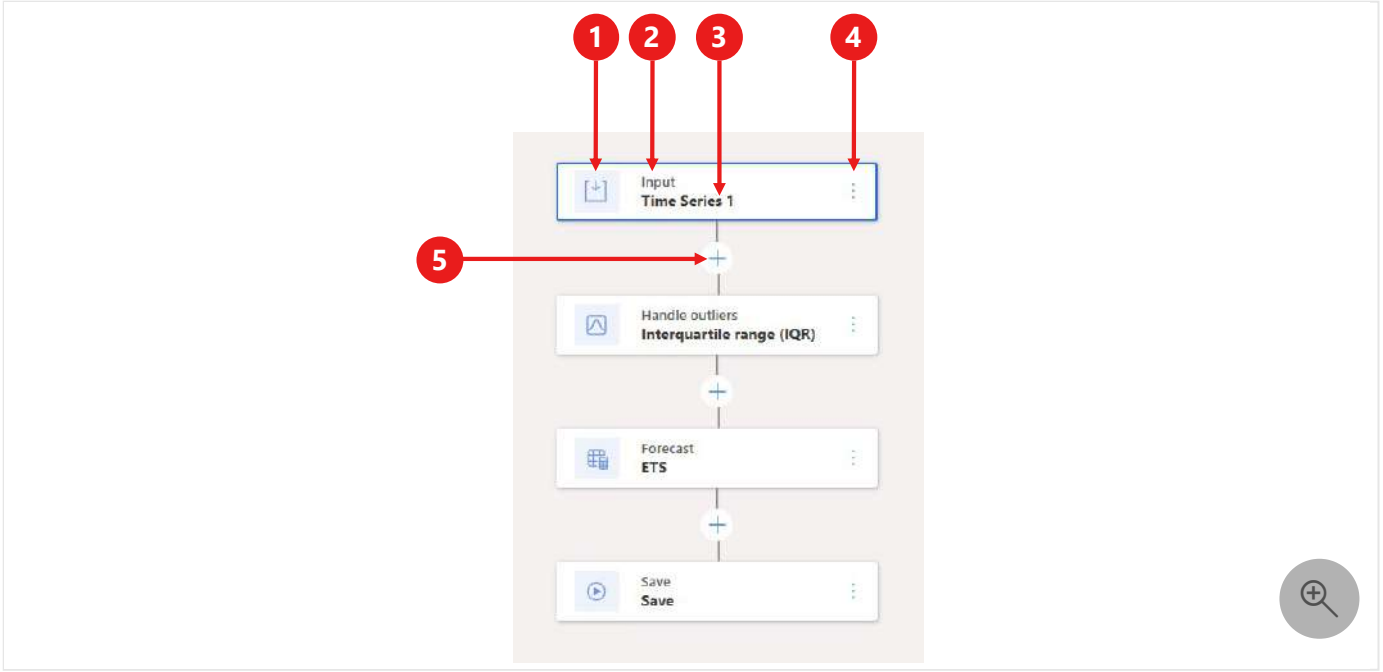
Create and customize a forecast model

To create and customize a forecast model, you must first open an existing forecast profile. (Learn more in Work with forecast profiles.) You can then fully customize the model that the selected profile uses by adding, removing, and arranging steps, and configuring settings for each of them.

Follow these steps to create and customize a forecast model.

1. On the navigation pane, select **Operations** > **Forecast profiles**.
2. Select the forecast profile that you want to create or customize a forecast model for.
3. On the **Forecast model** tab, there's always at least one step of the *Input* type at the top of the flow chart. The model is processed from top to bottom, and the last step must be a step of the *Save* type. Add, remove, and arrange steps as you require, and configure settings for each of them. The illustration after this procedure provides guidelines.
4. After you finish designing your forecast model, select the **Validate** button in the upper-right corner. The system runs a few tests to validate that your model will work, and then provides feedback. Fix any issues that the validation test reports.
5. Continue to work until your model is ready. Then, on the Action Pane, select **Save**.
6. If you want to save your forecast model as a preset, so that it's available when you and other users create a new forecast profile, select the **Save as model template** button in the upper-right corner.

The following illustration shows the information and controls that are available for steps in a forecast model.



Legend:

1. **Step symbol** – A representation of the purpose of the step.
2. **Step type** – The type of step. This text usually describes the type of roles, calculations, or other actions that the step represents.
3. **Step name** – The name that is applied to the step. Sometimes, you can manually enter this text in the step's settings. However, it usually indicates the value of one of the settings that were configured for the step.
4. **Step actions** – Open a menu of actions that you can take on the step. Although some of these actions are specific to the step type, most are common to all steps. If any actions appear dimmed, they can't be used because of the step's current position or for some other contextual reason. Here are some common actions that are available:
    - **Settings** – Open a dialog box where you can configure settings for the step.
    - **Remove** – Remove the step.
    - **Move Up** and **Move Down** – Reposition the step in the flowchart.
    - **Set to 'Pass Through'** – Temporarily disable a currently enabled step without deleting it or its settings.
    - **Unset 'Pass Through'** – Reenable a currently disabled step.
    - **Connect with** – For steps that support multiple inputs, specify the second input. The first input is automatically set based on where you put the step.
5. **Add a step** – Add a new step at the selected location.

Forecast step types

This section describes the purpose of each type of forecast step. It also explains how to use and configure each type.

Input steps

Input steps represent a time series that provides input to the forecast model. All forecast models must start with an *Input* step.

Input steps have the following settings:

- **Step name** – The specific name of the step. This name automatically matches the name of the time series.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Time series** – The time series that is added by the step. When you first set up an *Input* step, the **Configure step** dialog box provides a button that lets you select the time series to add. After you add a time series, the dialog box shows the name of the time series and provides an **Edit** button that lets you change the time series. It also provides a **Filter** button that lets you set up filtering criteria based on fixed dates, relative dates, and/or field values.
- **Time series version** – If the selected time series includes more than one version, you can select a specific version. By default, the latest (current) version is used.
- **Fill missing values** – Specify whether the system should fill in placeholder values for time buckets if the input doesn't provide values. In most cases, you should enable this feature, because it helps produce better forecasts.
- **Fill missing values strategy** – Select the strategy that the system should use to enter values in empty time buckets. In the current version, the only available strategy is *Zeros*. In this strategy, the system sets all missing values to *0* (zero).

Signal steps (preview)

[This section is prerelease documentation and is subject to change.]

Signal steps represent additional time series that can be combined with the primary time series that the *Input* step provides. For example, the primary input that the *Input* step provides might represent historical sales. A *Signal* step might then provide input that represents inflation or weather data.

When you add a *Signal* step, the system automatically creates a parallel branch in your model and puts the step at the top of that branch. The initial branch always has an *Input* step at the top of it. Each branch can include any number of steps, but you must eventually combine the branches by using a *Forecast with signals* step.

Learn more in Forecast with signals (preview).

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Signal step settings

Signal steps have the following settings:

- **Step name** – The specific name of the step. This name automatically matches the name of the time series.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Time series** – The time series that is added by the step. When you first set up a *Signal* step, the **Configure step** dialog box provides a button that lets you select the time series to add. After you add a time series, the dialog box shows the name of the time series and provides an **Edit** button that lets you change the time series. It also provides a **Filter** button that lets you set up filtering criteria based on fixed dates, relative dates, and/or field values.
- **Time series version** – If the selected time series includes more than one version, you can select a specific version. By default, the latest (current) version is used.
- **Fill missing values** – Specify whether the system should fill in placeholder values for time buckets if the input doesn't provide values. In most cases, you should enable this feature, because it helps produce better forecasts. In the current version, all missing values are set to *0* (zero).
- **Fill missing values strategy** – Select the strategy that the system should use to enter values in empty time buckets. The next section describes the options available here and how they work.

Signal fill strategies

When the forecast is generated, Demand planning prepares each signal so that it has one value for each time bucket through the end of the forecast period. If a signal has no row for a time bucket, the system adds a temporary value according to the **Fill missing values strategy** setting on the *Signal* step.

A missing value in this context means that a row is absent for a specific time bucket and combination of dimensions. For example, if a monthly signal has rows for January and March for the same product and warehouse, but no row for February, then February is a missing time bucket. This feature doesn't replace a blank value in a row that already exists.

The system fills missing values separately for each combination of dimensions. The filled values are used only for the current forecast run. The source signal time series isn't changed.

The following table describes the available strategies for filling missing values, how they work, and when to use them:

Expand table

Strategy	How missing time buckets are filled	Example use
Zeros	Enter 0 (zero). This strategy is the default.	Use when a missing bucket means that no signal activity occurred, such as no promotion.
Forward fill	Repeat the previous known value until a new value is available.	Use when the latest known value remains in effect, such as a price or rate.
Backward fill	Use the next known value for earlier missing buckets. If no later value is available, repeat the last known value.	Use when the next observation best represents the preceding gap.
Linear interpolation	Calculate evenly spaced values between the previous and next known values. If no later value is available, repeat the last known value. Linear interpolation treats each time bucket as one equal step; for example, each month is one step even though calendar months have different numbers of days.	Use for a continuous signal that normally changes gradually, such as temperature or an economic index.

> **Note**

The available strategies depend on the version of Demand planning you're using. Earlier versions provide only the *Zeros* strategy.

For example, suppose that a monthly signal has a value of 10 in January, no row in February, a value of 30 in March, and no row in April. The forecast period ends in April, and no later signal value is available. Each strategy prepares the signal as follows:

Expand table

Strategy	January	February	March	April
Zeros	10	0	30	0
Forward fill	10	10	30	30
Backward fill	10	30	30	30
Linear interpolation	10	20	30	30

The system applies the following rules when it fills a signal:

- Filling starts with the first available value for each combination of dimensions. The system doesn't add values before that point.
- Filling continues through the end of the forecast period. Therefore, the stored signal doesn't need to contain a row for every time bucket or an explicit row at the end of the forecast horizon.
- Every combination of shared dimension values in the primary input must appear at least once in each signal. The system can't create an entirely missing combination of signal dimensions, and the forecast fails if a required combination has no signal data.
- Each signal must contain at least one value on or before the end of the forecast period. If the entire signal starts after the forecast period ends, the forecast fails.
- *Backward fill* and *Linear interpolation* can use the next known signal value even if that value occurs after the end of the forecast period. The later value helps calculate missing values through the forecast end date, but isn't included beyond the forecast horizon.

Handle outliers steps

Handle outliers steps identify and compensate for outlier data points in the input. These data points are considered anomalies that should be ignored or smoothed out to prevent them from throwing off the forecast calculation.

Settings for Handle outlier steps

Handle outliers steps have the following settings:

- **Step name** – The specific name of the step. This name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Handle outliers** – Select one of the following options. Learn more about these options in the How the handle outliers options work section.
  - *Interquartile range (IQR)*
  - *Seasonal and trend decomposition using Loess (STL)*
- **Interquartile range multiplier** – This field is available only when the **Handle outliers** field is set to *IQR*. It affects the number of data points that are removed as outliers. Learn more about this setting in the How the handle outliers options work section.
- **Correction methods** – This field is available only when the **Handle outliers** field is set to *IQR*. It affects how outliers are replaced in the data after they're removed. The available options are *Median smoothing* and *Mean smoothing*.
- **Select seasonality detection setting** – This field is available only when the **Handle outliers** field is set to *STL*. It influences the size of the window that is used for locally estimated scatterplot smoothing (LOESS) when the seasonal component is estimated. Learn more about this setting in the Seasonality in forecasts section.

How to choose the method for handling outliers

The following table provides examples that will help you choose which method to use to handle outliers in your time series data, based on your scenario.

Expand table

Scenario	IQR	STL
Data with seasonal or trend patterns	Not recommended	Recommended
Robust handling of outliers	Recommended	Not recommended
Sensitivity to extreme values	Recommended	Recommended

How the handle outliers options work

Interquartile range

The *interquartile range* (IQR) is the range between the first quartile (Q1) and the third quartile (Q3). It measures the spread of the middle 50% of the data. Any data outside the IQR is identified as an outlier that should be smoothed out later. The IQR method applies the following formula to identify outliers:

IQR = Q3 − Q1

Key:

- *Q1* – A representation of the twenty-fifth percentile (that is, the value that 25% of the data lies below).
- *Q3* – A representation of the seventy-fifth percentile (that is, the value that 75% of the data lies below).

When you use the IQR method to handle outliers, you must set an **Interquartile range multiplier** value. This value affects the number of data points that are removed as outliers. It's calculated in the following way:

- Lower bound = Q1 − (Multiplier × IQR)
- Upper bound = Q3 + (Multiplier × IQR)

A *high* multiplier increases the range within which data points are considered non-outliers. High multipliers lead to softer boundaries and include more points. Therefore, the result is less sensitive to variations in the time series.

A *low* multiplier decreases the range within which data points are considered non-outliers. Low multipliers lead to stricter boundaries and remove more data points. Therefore, the result is more sensitive to variations in the time series.

When you use the IQR method to handle outliers, you must also set a **Correction method** value. This value affects how outliers are replaced in the data after they're removed. The available options are *Median smoothing* and *Mean smoothing*.

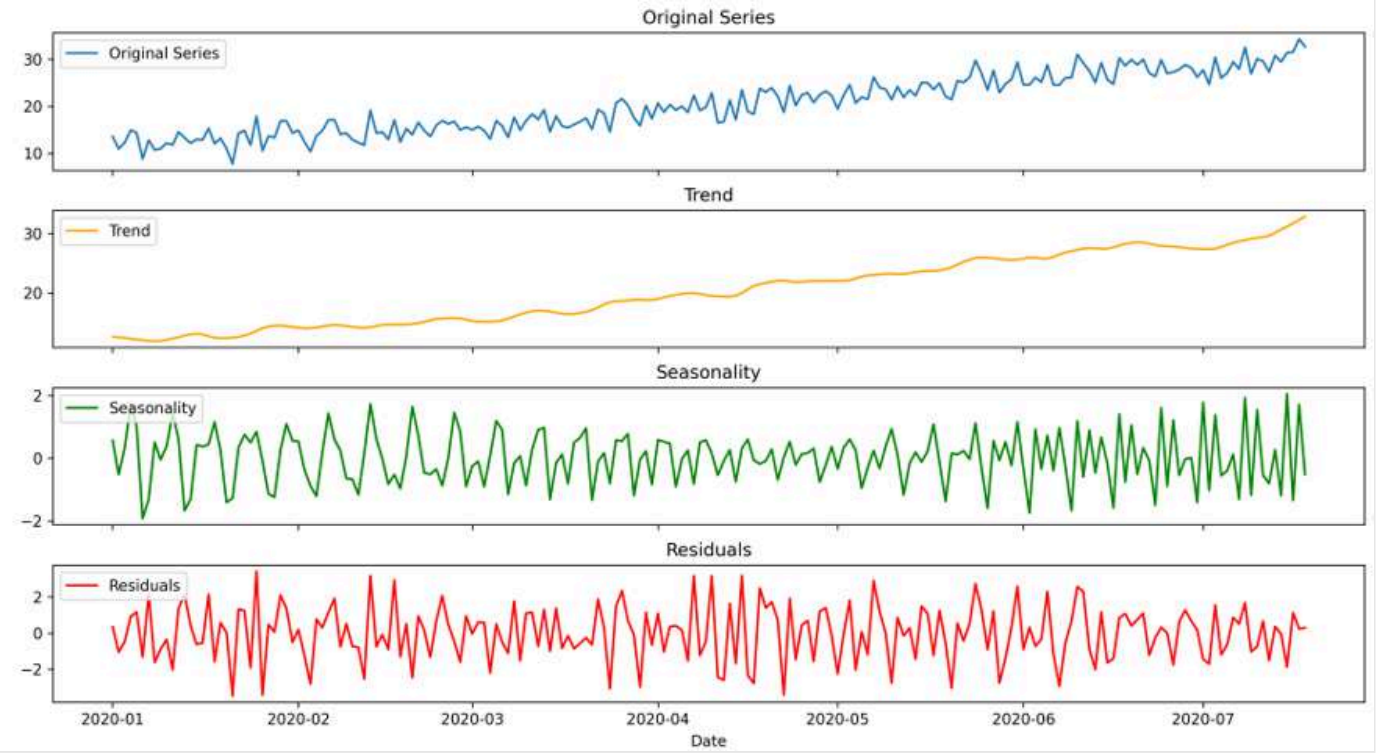
Seasonal and trend decomposition using LOESS

Seasonal and trend decomposition using LOESS (STL) starts by decomposing the time series into three components:

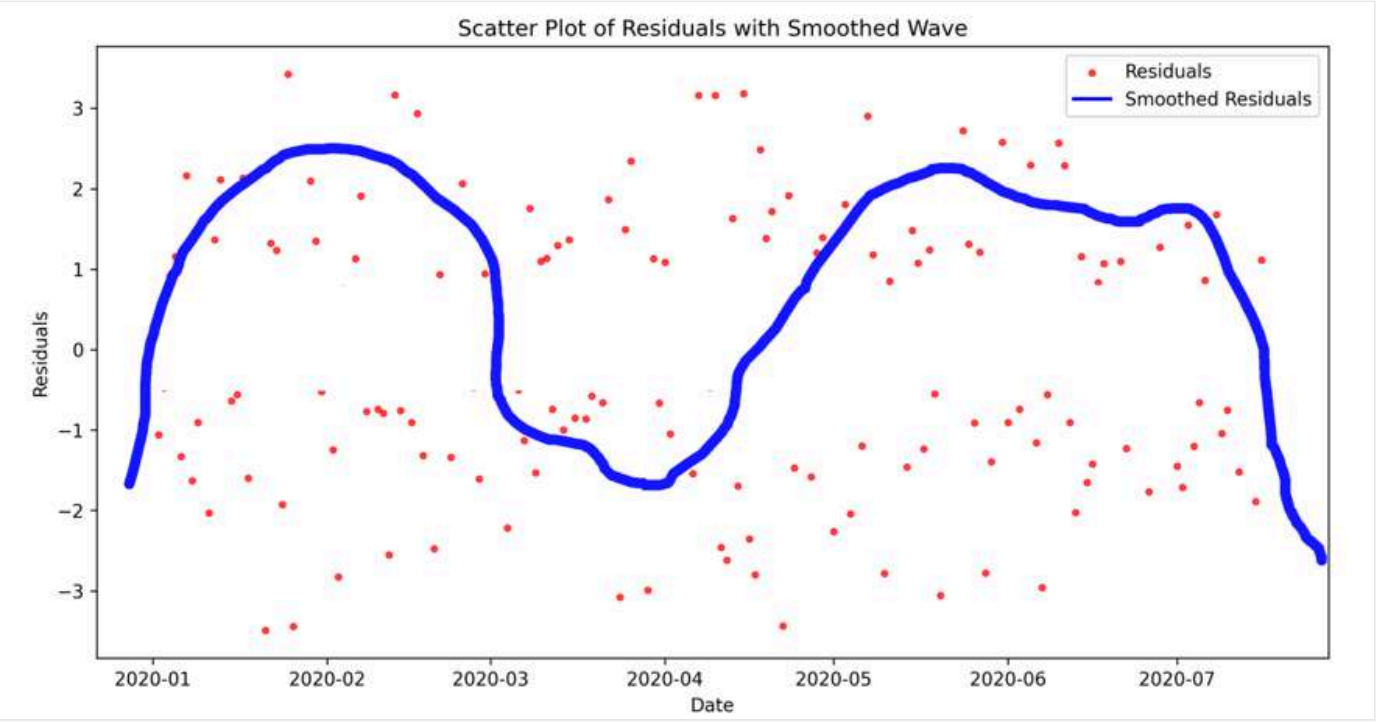
- *Trend* – The overall trend in the data.

- *Seasonality* – Regular and predictable patterns that are driven by factors such as weather, holidays, or economic cycles.
- *Residuals* – The time series after trend and seasonality are removed.

The following illustration shows examples of an original time series, the trend that is decomposed from the time series, the seasonality spikes that are found in the time series, and the residuals after the trend and seasonality are removed.



After STL decomposes the time series, it tries to smooth out the outliers by using LOESS. LOESS is a generalization of the moving average and polynomial regression. It tries to fit a chart through scattered data points and therefore smooth out the residuals, as shown in the following illustration.



After STL calculates the mean and standard deviation, it uses them to eliminate the outliers and mitigate anomalies.

Finally, STL reintroduces the seasonality and trend to the newly smoothed residual.

When you use the STL method to handle outliers, you must also set the **Select seasonality detection setting** option. This setting influences the size of the period (in time buckets) that is used when the seasonality component is estimated. It helps divide the data into segments to ensure that the algorithm correctly extracts repeating patterns. Learn more in Seasonality in forecasts.

Forecast steps

Forecast steps apply a selected forecast algorithm to the input time series to create a forecast time series.

Forecast steps have the following settings:

- **Step name** – The specific name of the step. This name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Model type** – Select the forecast algorithm to use. Learn about each of the available algorithms in Demand forecasting algorithms. The following algorithms are available:
  - *Best fit model - version 1*

- *Best fit model - version 2 (preview)*
- *Best fit model - version 3 (preview)*
- *ARIMA* (auto regressive integrated moving average)
- *ETS* (error, trend, seasonality)
- *Prophet*

- **Select seasonality detection setting** – Choose how the forecast should identify seasonality patterns. Seasonality refers to a pattern of demand that fluctuates according to a regular, recurring schedule. Learn more about seasonality, seasonality auto detection, and seasonality hints in the Seasonality in forecasts section.

- **Enable time freeze** – Select this check box if you want to enable time freeze functionality for the forecasts created by this step. Then select one of the following options:
  - **Freeze manual adjustments** – Select this option to prevent the system from automatically updating any time series cells that have been manually adjusted by a user.
  - **Use time freeze rules** – Select this option to apply one or more time freeze rules to the forecasts created by this step. Then use the **Time freeze rules** field to search for and select the relevant time freeze rules. Time freeze rules are defined as logical expressions and prevent the system from automatically updating time series cells that match that expression. For example, you could create a time freeze rule that lasts two months and applies to product ID *K0001* in color *Red*. Learn more about how to work with time freeze rules at Limit automatic time series updates with time freezes.

Forecast with signals steps (preview)

[This section is prerelease documentation and is subject to change.]

Forecast with signals steps generate a forecast based on multiple input time series. Learn more about forecasting with signals in Forecast with signals (preview).

Forecast with signals steps always use the XGBoost demand forecasting algorithm. Learn about this algorithm in Demand forecasting algorithms.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to **supplemental terms of use**, and are

available before an official release so that customers can get early access and provide feedback.

You can use this type of step only if your forecast model has at least two parallel branches: one that starts with an *Input* step and up to five others that start with a *Signal* step. The first branch is the one where you create the step. To specify a second branch, open the **Action** menu for the *Forecast with signals* step, select **Connect with**, and then select the step to connect to. The flowchart is then updated so that it shows the branches combining at the *Forecast with signals* step. You can add up to five signal branches.

Forecast with signals steps have the following settings:

- **Step name** – The specific name of the step. This name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Model type** – Select the forecast algorithm to use. In the current version, only the *XGBoost* algorithm is available.
- **Enable time freeze** – Select this check box if you want to enable time freeze functionality for the forecasts created by this step. Then select one of the following options:
  - **Freeze manual adjustments** – Select this option to prevent the system from automatically updating any time series cells that have been manually adjusted by a user.
  - **Use time freeze rules** – Select this option to apply one or more time freeze rules to the forecasts created by this step. Then use the **Time freeze rules** field to search for and select the relevant time freeze rules. Time freeze rules are defined as logical expressions and prevent the system from automatically updating time series cells that match that expression. For example, you could create a time freeze rule that lasts two months and applies to product ID *K0001* in color *Red*. Learn more about how to work with time freeze rules at Limit automatic time series updates with time freezes.

Finance and operations steps

You might already be using custom Azure Machine Learning algorithms that you created for use with the legacy Supply Chain Management forecasting functionality, as described in Demand forecasting overview. To use them with Demand planning, you must set up the connection to Azure and then add the forecast calculation to your forecast model using a *Finance and operations* step instead of a *Forecast* step.

Learn how to set up Demand planning to connect to and use your Azure Machine Learning forecast algorithms in Use your own custom Azure Machine Learning algorithms in Demand

planning.

Custom steps

It's possible for you to design your own custom Microsoft Azure Machine Learning algorithms for demand forecasting, even if you've never used them with Dynamics 365 Supply Chain Management before. To use them with Demand planning, you must set up the connection to Azure and then add the forecast calculation to your forecast model using a *Custom* step instead of a *Forecast* step.

Learn how to set up Demand planning to connect to and use your Azure Machine Learning forecast algorithms in Use your own custom Azure Machine Learning algorithms in Demand planning.

Phase in/out steps

Phase in/out steps modify the values of a data column in a time series to simulate the gradual process of phasing in a new element or phasing out an old element. For example, a *Phase in/out* step might simulate the process of phasing in a new product or warehouse. The phase in/out calculation lasts for a specific period and uses values that are drawn from the same time series. (The values come from either the same data column that is being adjusted or another data column that represents a similar element.)

Phase in/out steps have the following settings:

- **Step name** – The specific name of the step. This name is also shown in the flowchart.
- **Description** – A short description of the step.
- **Created by** – The user who created the step.
- **Rule group** – The name of the rule group that defines the calculation that the step does.

When you set up your forecast model, the position of the *Phase in/out* step affects the calculation result.

- To apply the phase in/out calculation to the historical sales numbers, put the *Phase in/out* step before the *Forecast* step, as shown on the left side of the following illustration.
- To apply the phase in/out calculation to the forecasted result, put the *Phase in/out* step after the *Forecast* step, as shown on the right side of the illustration.

Learn more about phase in/out functionality, including details about how to set up your phase in/out rule groups, in Use phase in/out functionality to simulate planned changes.

Save steps

Save steps save the result of the forecast model as a new or updated series. All forecast models must end with a single *Save* step.

The forecast time series is saved according to the settings that you configure each time that you run a forecast job. Learn more in Work with forecast profiles.

Seasonality in forecasts

Seasonality refers to regular and predictable patterns in a time series that occur at fixed intervals because of recurring events or influences. These patterns are often driven by factors such as weather, holidays, or economic cycles. Examples include increased retail sales every December because of holiday shopping or higher electricity demand during summer months because of air conditioning.

Demand planning identifies and compensates for seasonality patterns both when it handles outliers (in a *Handle outliers* step that is set to use STL) and when it generates a forecast (in any *Forecast* step).

Forecast with signals steps (which use the XGBoost algorithm) detect seasonality patterns by analyzing the time series, but they use a different approach than is used by *Forecast* and *Handle outliers* steps and don't provide any related settings.

How seasonality differs from cycles

Although both seasonality and cycles involve repeating patterns, there are key differences, as summarized in the following table.

Expand table

Aspect	Seasonality	Cycles
Frequency	Fixed, regular intervals (such as daily, weekly, or yearly)	Variable, often irregular, and influenced by external factors
Duration	Short-term and predictable (such as seasonal sales)	Long-term and unpredictable (such as business cycles)
Cause	Calendar-based events or natural patterns	Economic, social, or structural forces
Examples	Summer travel peaks or holiday shopping trends	Economic recession cycles or stock market booms and busts

Autodetect seasonality patterns (preview)

[This section is prerelease documentation and is subject to change.]

Automatic seasonality detection uses an algorithm that finds seasonality patterns for each combination of a location and a product, and applies the result to forecast calculations. Seasonality patterns typically vary for different products and different locations. Therefore, auto detection often works better than applying the same pattern everywhere.

To set a *Forecast* or *Handle outliers* step to use seasonality auto detection, edit the step's settings, and then set **Select seasonality detection setting** to *Auto detection*.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are

available before an official release so that customers can get early access and provide feedback.

Detect seasonality using a hint

The system can detect seasonality by using a *seasonality hint* that you choose. This option works best when you know the seasonality pattern in advance. The **Seasonality hint** setting influences the size of the period (in time buckets) that is used in the identification of seasonality patterns. It helps divide the data into segments to ensure that the algorithm correctly extracts repeating patterns. For example, if you notice a weekly seasonality pattern where most customers shop on Saturdays, and you're using buckets in days, enter *7* as the **Seasonality hint** value.

A well-defined seasonal period captures the true periodicity of the data. It enables the algorithm to successfully isolate the seasonality. As a result, the trend and residuals are more interpretable. By contrast, an incorrect seasonal period leads to poor seasonal extraction. As a result, trend and residual components are inaccurate.

If the seasonal period that you use is too short (that is, shorter than the actual cycle), you risk encountering the following issues:

- **Missed patterns** – Important parts of the seasonal pattern might be excluded, so that seasonality extraction is incomplete.
- **Trend contamination** – Some seasonal variations might be mistaken for the trend component, so that the trend estimation is distorted.
- **Residual issues** – Residuals might show unexplained periodicity. This situation indicates that the algorithm failed to capture seasonality correctly.

For example, you use a seasonal period of *6 months* for yearly retail sales data. In this case, only part of the yearly cycle is captured. As a result, critical holiday season peaks might be missing.

If the seasonal period that you use is too long (that is, longer than the actual cycle), you risk encountering the following issues:

- **Overfitting** – Noise or random fluctuations might be falsely interpreted as seasonality.
- **Distorted decomposition** – Artificially long seasonal cycles might obscure the true trend or residual components.
- **Increased complexity** – The model might become unnecessarily complex and therefore harder to interpret and validate.

For example, you use a seasonal period of *24 months* for data that has an annual cycle. The result is overfitting, where small irregularities in the data are treated as seasonal patterns.

To set a *Forecast* or *Handle outliers* step to use a seasonality hint, edit the step's settings, and set **Select seasonality detection setting** to *Detection using hint*. Then, enter the number of time buckets in the **Seasonality hint (in periods of time buckets)** field.

Forecast with signals (preview)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

[This article is prerelease documentation and is subject to change.]

One way to improve the accuracy of a forecast is to include input signal data beyond just historical sales. You can add signals in your forecast models by including a *Signal* step. This type of step lets you include any signal as input data. You can then use the new *Forecast with signals* step to combine the signal input and main input to create the forecast.

This article explains how to set up a forecast model that includes both a primary input (such as historical sales) and up to five signal inputs (such as inflation or weather data).

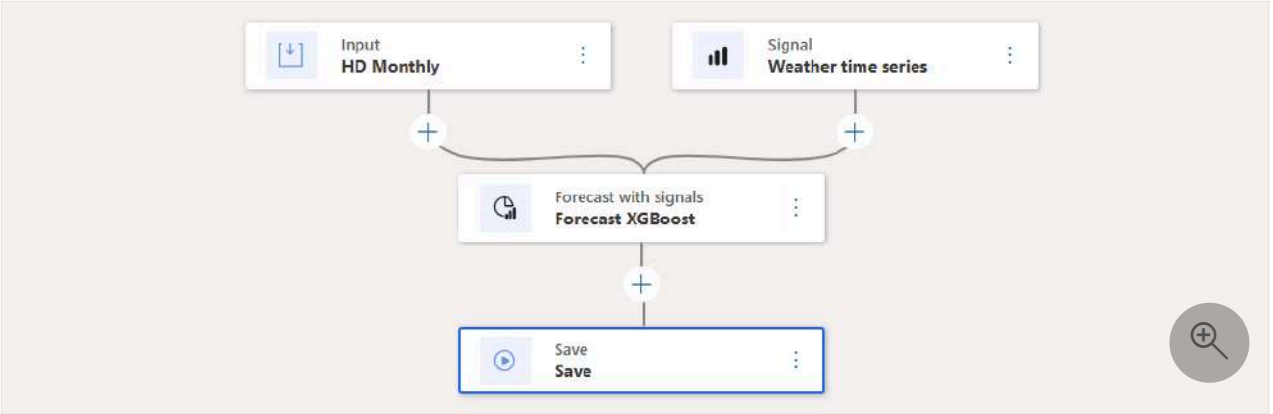
> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Set up a forecast model that includes both input and signals

Follow these steps to set up a forecast that includes both input and up to five signal inputs.

1. Create a new forecast profile as described in Create and manage forecast profiles.
2. On the **Select a forecasting model preset** page, select *None*.
3. After you create and save the profile, on the **Forecast model** tab, set up your model in the following way. (Learn more in Design forecast models.)
   a. Use an *Input* step to set up your primary time series.
   b. Add a *Signal* step to set up a signal time series in a parallel branch.

c. Add other steps as required to condition the data in each branch.
d. Add a *Forecast with signals* step to combine the branches.
e. Complete the model by adding a *Save* step.



4. On the Action Pane, select **Save**.

Align input and signal time series

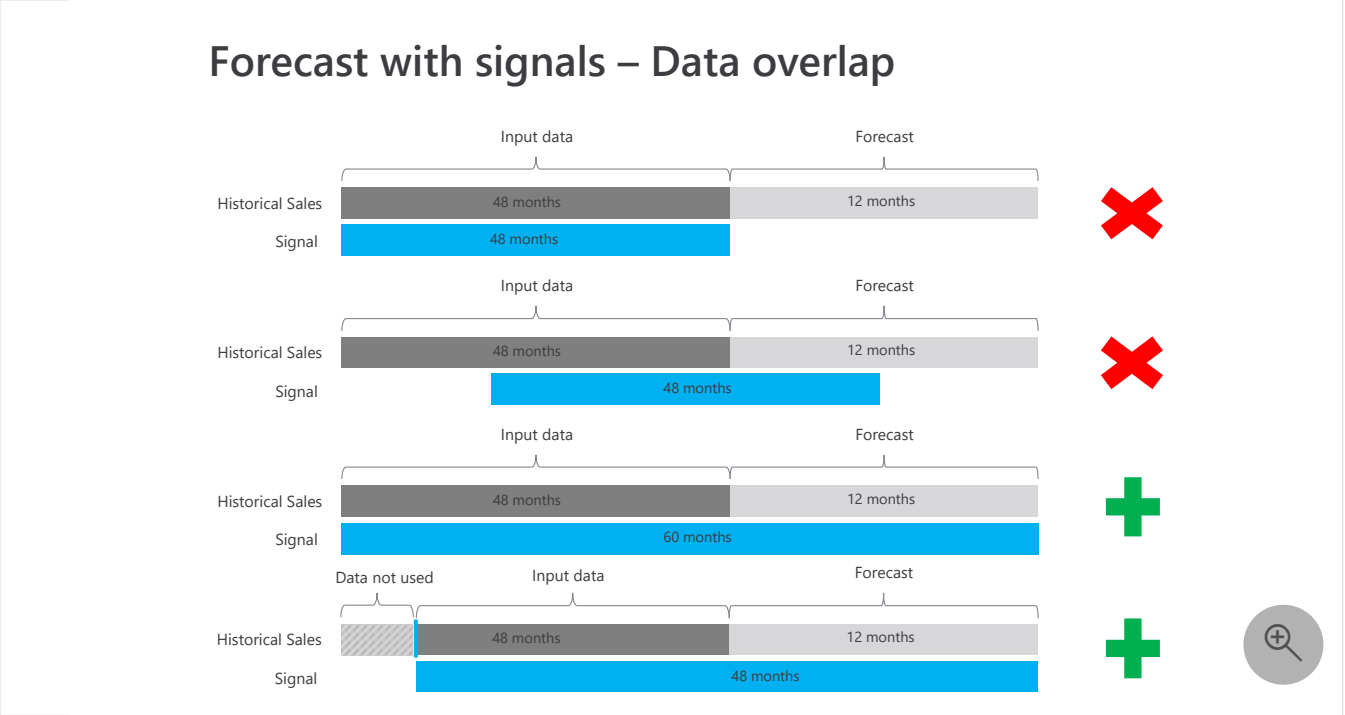
To calculate a forecast with signals, the input and signal time series must be aligned. This means that they must have compatible time bucket sizes, dimensions, and time spans.

Time span requirements

The time span of the signal time series must cover all of the historical input data that you want to consider and extend to the end of the forecast time horizon. If the input time series extends further into the past than the signal time series, then the forecast calculation will ignore all input data that is older than the oldest signal data. If the forecast time horizon extends further into the future than the signal time series, then the forecast will fail and you'll see an error message.

The following illustration provides examples of successful and unsuccessful time span alignments.

- The first example won't work because the signal time series doesn't include any data for the forecast horizon.
- The second example won't work because the signal time series doesn't include enough data to cover the full forecast horizon.
- The third example is perfectly aligned.
- The fourth example works, but the forecast will ignore the input data that is older than the oldest signal data.



Dimension requirements

The input and signal time series must have compatible dimensions. For example, if the input time series has dimensions for *Country* and *Month*, then the signal time series must also have *Country* and *Month* dimensions. The system uses these dimensions to align the two time series. If the dimensions don't match, the forecast calculation will fail and you'll see an error message.

The following illustration provides examples of successful and unsuccessful dimension alignments.

- The first example won't work because the signal time series has a *Country* dimension, but the input time series doesn't.
- The second example works because both time series include dimensions for both the *Country* and the *Month*.

Forecast with signals – Dimension matching

Historical Sales:

Product	Month	Quantity
Product A	Jan	10
Product A	Feb	12

Signal:

Country	Month	Inflation%
USA	Jan	5.00
USA	Feb	5.50

Dimension match

Product	Country	Month	Quantity
Product A	USA	Jan	10
Product A	USA	Feb	12

Country	Month	Inflation%
USA	Jan	5.00
USA	Feb	5.50

Demand forecasting algorithms

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Demand planning in Microsoft Dynamics 365 Supply Chain Management includes four popular demand forecasting algorithms: *auto-ARIMA*, *ETS*, *Prophet*, and *XGBoost*.

- Auto-ARIMA works well with *stationary data*. Stationary data is data that has a constant mean, constant standard deviation, and no seasonality.
- Error, trend, and seasonality (ETS) works well if your business case is simple and the data has various patterns, such as linear or exponential trends, *or* if you want the forecast to give more weight to the most recent data.
- Prophet works best with complex, real-world data.
- eXtreme Gradient Boosting (XGBoost) can generate a forecast based on multiple inputs.

In addition, Demand planning provides a *best fit model* algorithm, which automatically selects the best of the available algorithms for each product and dimension combination. Demand planning also lets you develop and use your own custom algorithms.

In Demand planning, you choose a forecast algorithm when you place and configure a *Forecast* or *Forecast with signals* step in a forecast model. You then use that forecast model in a forecast profile to generate a forecast.

This article describes how each algorithm works and its suitability for different types of historical demand data.

When to use each forecasting algorithm

The demand forecasting algorithm that you use depends on the specific characteristics of your historical data. The following table shows which single-input forecasting algorithms are best suited to each of several different business scenarios. XGBoost is excluded from this table, because it's always used for multi-input forecasting. For most other scenarios, use the best fit

model algorithm, because it automatically selects the correct forecasting algorithm for each product and dimension combination.

Expand table

Scenario	Auto-ARIMA	ETS	Prophet
Simple business case	Acceptable	Recommended	Acceptable
The time series has a different (linear/exponential) trend and several seasonality types.	Not recommended	Recommended	Recommended
The time series shows a clear linear trend.	Recommended	Recommended	Acceptable
Data is stationary.	Recommended	Not recommended	Acceptable
Data is nonstationary.	Not recommended	Acceptable	Recommended
Quick forecasting is required.	Not recommended	Recommended	Acceptable
Forecasting is focused on a recent period.	Acceptable	Recommended	Acceptable

Best fit model algorithm

The best fit model algorithm automatically determines which of the other available single-input algorithms (auto-ARIMA, ETS, or Prophet) best fits your data for each product and dimension combination. In this way, you can use different models for different products. In most cases, use the best fit model, because it combines the strengths of all the other standard models. The following example shows how.

Example of how the best fit model algorithm works

For this example, you have historical demand time series data that includes the following dimension combinations.

Expand table

Product	Store
A	1
A	2

Product	Store
B	1
B	2

When you run a forecast calculation by using the Prophet model, you get the following results. In this example, the system always uses the Prophet model, regardless of the calculated mean absolute percentage error (MAPE) for each product and dimension combination.

Expand table

Product	Store	Forecast model	MAPE
A	1	Prophet	0.12
A	2	Prophet	0.56
B	1	Prophet	0.65
B	2	Prophet	0.09

When you run a forecast calculation by using the ETS model, you get the following results. In this example, the system always uses the ETS model, regardless of the calculated MAPE for each product and dimension combination.

Expand table

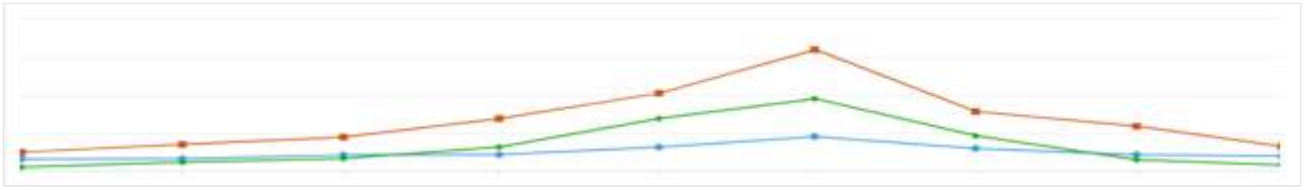
Product	Store	Forecast model	MAPE
A	1	ETS	0.18
A	2	ETS	0.15
B	1	ETS	0.21
B	2	ETS	0.31

When you run a forecast calculation by using the best fit model, the system optimizes the model selection for each product and dimension combination. The selection changes based on patterns that are found in the historical sales data.

Expand table

Product	Store	Prophet MAPE	Auto-ARIMA MAPE	ETS MAPE	Best fit forecast model	Best fit MAPE
A	1	0.12	0.34	0.18	Prophet	0.12
A	2	0.56	0.23	0.15	ETS	0.15
B	1	0.65	0.09	0.21	Auto-ARIMA	0.09
B	2	0.10	0.27	0.31	Prophet	0.10

The following chart shows the overall sales forecast across all dimensions (all products in all stores) over the next nine months, found by using three different forecast models. The green line represents the best fit model. Because the best fit model selects the best forecast model for each product and dimension combination, it avoids the outliers that can occur if a single model is used for all dimension combinations. As a result, the overall best fit forecast resembles an average of the single-model forecasts.



Legend:

- **Red** – Prophet only.
- **Blue** – ETS only.
- **Green** – Best fit.

Best fit model versions

The best fit model algorithm is available in several versions, as described in the following table. Usually, you should use the newest version that's available. However, to ensure that all of your existing forecast models continue to work, the older versions remain available and supported until further notice. To use one of these algorithms, select the appropriate version in the configuration settings for the *Forecast* step in your forecast model.

Expand table

Name	Version required	Description
Best fit model - version 1	Demand planning version 1.0.0.1067 or higher	Works as described in this section

Name	Version required	Description
Best fit model - version 2 (preview)	Demand planning version 1.0.0.3424 or higher	Same as version 1, but with the following changes: • Adds support for Naive forecasting as a way to handle low-data scenarios. • Data used for training and testing models is limited to values from before the forecast start date.
Best fit model - version 3 (preview)	Demand planning version 1.1.0.4 or higher	Same as version 2, but adds support for the Croston's method for forecasting based on intermittent demand (which is demand data with many zero-demand periods and occasional non-zero demands).

> **Important**
>
> - *Best fit model - version 2* and *Best fit model - version 3* are preview features.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to **supplemental terms of use**. They're available before an official release so that customers can get early access and provide feedback.

Auto-ARIMA: The time traveler's delight

The auto-ARIMA algorithm is like a time machine. It takes you on a journey through past demand patterns so that you can make informed predictions about the future.

Auto-ARIMA uses a technique that's known as ARIMA. The name ARIMA is an abbreviation for the three key components that the technique combines:

- *AR* is short for "auto regressive." This component regresses the time series on its own previous values. It captures the influence of past values on the current value.
- *I* is short for "integrated." This component, which is also known as *differencing*, is a step that the model takes to morph a nonstationary time series into stationary data.
- *MA* is short for "moving average." This component accounts for past forecast errors and improves the model's accuracy by smoothing out the noise.

Therefore, the ARIMA technique combines autoregression and moving averages after it differences the data. The final prediction combines the influence of past values and the adjustments from past errors.

The auto-ARIMA algorithm automatically identifies the best combination of the three components to create a forecast model that suits your data. It follows these steps to generate forecasts:

1. Run differencing on the data if it isn't stationary.
2. Find correlation between lagged data points.
3. Calculate moving average error.

Auto-ARIMA works especially well with time series data that shows a stable pattern over time, such as seasonal fluctuations or trends. If your historical demand follows a reasonably consistent path, you might prefer to use auto-ARIMA as your forecasting method.

Auto-ARIMA algorithm equations

Auto regressive calculation

The AR component uses the following equation:

$$Y(t) = c + \phi 1Y(t-1) + \phi 2Y(t-2) + \ldots + \phi pY(t-p) + \epsilon(t)$$

Key:

- *Y(t)* – The value at time *t*.
- *c* – A constant.
- *ϕ1, ϕ2, … ϕp* – Coefficients of the model.
- *ϵ(t)* – The white noise error term.

Moving average calculation

The MA component uses the following equation:

$$Y(t) = c + \epsilon(t) + \Theta 1\epsilon(t-1) + \Theta 2\epsilon(t-2) + \ldots + \Theta q\epsilon(t-q)$$

Key:

- *Y(t)* – The value at time *t*.
- *c* – A constant.
- *ϵ(t), ϵ(t−1), … ϵ(t−q)* – Error terms at time *t*, *t*−1, … *t*−*q*.
- *Θ1, Θ2, … Θq* – Coefficients of the model.

ARIMA calculation

The auto-ARIMA algorithm combines the AR and MA components by using the following equation:

ARIMA = AR + MA (after differencing the time series)

ETS: The shape-shifter

ETS is a versatile demand forecasting algorithm that adapts to the shape of your data. It changes its approach based on the characteristics of your historical demand. Therefore, it's suitable for a wide range of scenarios.

The name ETS is an abbreviation for the three essential components that the algorithm decomposes the time series data into:

- *E* is short for "error." This component captures the random noise or irregular fluctuations.
- *T* is short for "trend." This component represents the overall direction of the data over time: increasing, decreasing, or constant.
- *S* is short for "seasonality." This component reflects repetitive patterns or cycles in the data (for example, yearly or monthly).

By understanding and modeling these components, ETS generates forecasts that capture the underlying patterns in your data.

ETS forecasts future data points by applying varying weights to different observations. More recent data points carry more weight than older ones. ETS can also decompose the time series into error, trend, and seasonality components. (The error comes from noise and fluctuations in the time series.) ETS uses the seasonal period parameter that you set as a seasonal index, estimates the trend in the upcoming horizon, and tries multiple values to determine what fits. Finally, it forecasts the error and combines it with the estimated trend and seasonality components.

Demand planning in Supply Chain Management determines which "flavor" of ETS is most suitable for each time series and applies it accordingly.

Here's a step-by-step explanation of the algorithm:

1. **Decompose components.** Break down the time series into the three components: error (E), trend (T), and seasonality (S).

2. **Select models for the components.** Each component follows an *additive* model:

   ETS(A,A,A) – Additive error, additive trend, additive seasonality.

3. **Specify the initial states.** Calculate initial values for the *level*, *trend*, and *seasonality* states of the model to start the recursive update process. The *level* is the baseline forecast, which the model updates as it trains.

4. **Update the states.** As new data points arrive, update the states of the model (*level*, *trend*, and *seasonality*) by using weighted smoothing equations.

5. **Forecast.** Predict future values by combining the most recent estimates of the *level*, *trend*, and *seasonality*.

ETS algorithm equation

The ETS algorithm uses the following equation:

$F(t+1) = \alpha A(t) + [1-\alpha]F(t)$

Key:

- *F(t+1)* – The forecasted value.
- *F(t)* – The previous forecasted value.
- *A(t)* – The actual historical value.
- α – A smoothing constant ($0 \leq \alpha \leq 1$).

Prophet: The visionary forecasting guru

Facebook's research team developed Prophet. It's a modern and flexible forecasting algorithm that can handle the challenges of real-world data. It's especially effective at handling missing values, outliers, and complex patterns. It performs best with seasonal data, accounts for holidays during forecasting, and doesn't need much preprocessing.

Prophet works by decomposing the time series data into several components, such as trend, seasonality, and holidays, and then fitting a model to each component. This approach enables Prophet to accurately capture the nuances in your data and produce reliable forecasts. Prophet is ideal for businesses that have irregular demand patterns or frequent outliers. It's also ideal for businesses that are affected by special events such as holidays or promotions.

The Prophet algorithm follows these steps to generate forecasts:

1. Decompose the time series into trend, seasonality, and holiday components.
2. Detect and handle change points for trend shifts.
3. Use Fourier series for seasonal patterns.

4. Add holiday regressors for irregular events.
5. Fit the model parameters by using Bayesian optimization.
6. Generate predictions and uncertainty intervals.

Prophet algorithm equation

The Prophet algorithm uses the following equation:

$y(t) = g(t) + s(t) + h(t) + \epsilon(t)$

Key:

- *g(t)* – A value that captures the nonperiodic trend changes over time. The algorithm calculates this value by using a piecewise linear trend equation.
- *s(t)* – A value that represents recurring seasonality patterns, such as daily, weekly, or yearly patterns. The algorithm models this value by using Fourier series.
- *h(t)* – A value that accounts for known, irregular effects caused by holidays or special events. The algorithm treats these effects as additional regressors, which provide flexibility in modeling special events.
- *ϵ(t)* – Random noise or unexplained variability.

XGBoost

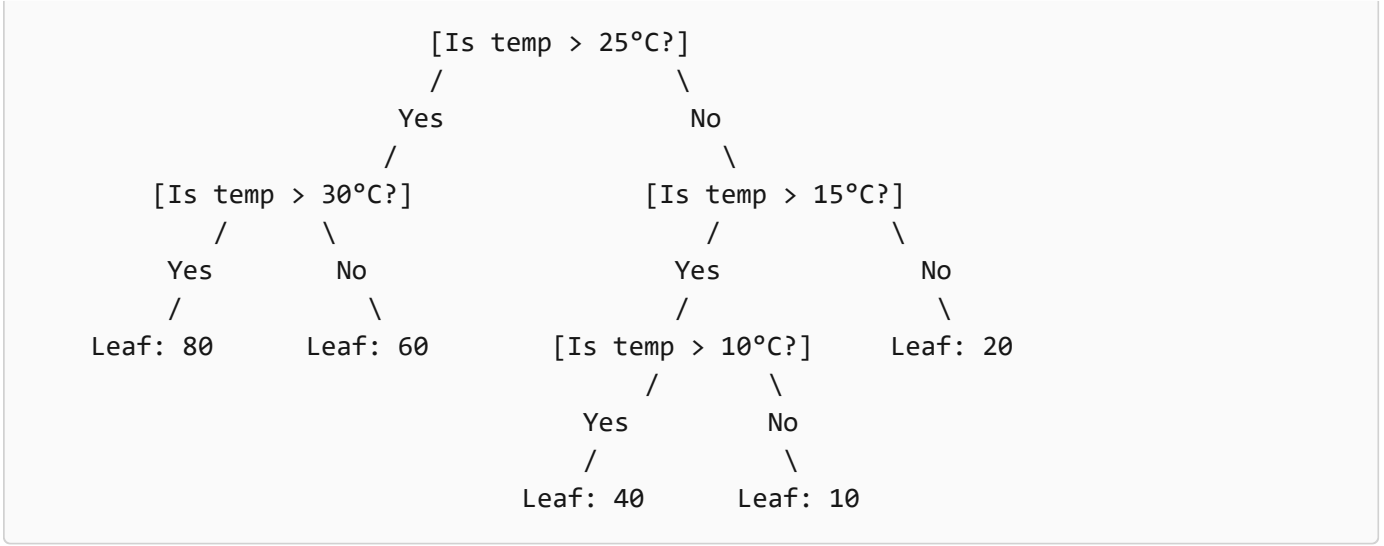
Unlike the other algorithms described in this article, eXtreme Gradient Boosting (XGBoost) generates a forecast based on multiple inputs. It's currently the only algorithm you can use with the *Forecast with signals* forecast model step in Demand planning. In addition, only that type of step supports it. Learn more about how to set up forecast models that use XGBoost and signals input in Forecast with signals.

XGBoost is a highly efficient and scalable implementation of gradient boosting. It builds an ensemble of decision trees to make predictions. The following subsections break down each of the components.

Decision trees

A *decision tree* is a machine learning model that splits data into subsets based on signal values (also known as *dimensions* or *features*) and forms a tree-like structure. The following example shows sales based on weather data.

```
plaintext
```



This decision tree progresses in the following way:

1. **Root node** – The tree splits based on whether the temperature exceeds 25°C:
    - *Yes* – Go to the left subtree.
    - *No* – Go to the right subtree.
2. **Left subtree (temp > 25°C)** – The tree further splits based on whether the temperature exceeds 30°C:
    - *Yes* – Predict *80* sales.
    - *No* – Predict *60* sales.
3. **Right subtree (temp ≤ 25°C)** – The tree splits based on whether the temperature exceeds 15°C:
    - *Yes* – The tree further splits based on whether the temperature exceeds 10°C:
        - *Yes* – Predict *40* sales.
        - *No* – Predict *10* sales.
    - *No* – Predict *20* sales.

Ensemble learning

Ensemble learning is a machine learning approach that combines multiple models (often called *weak learners*) to make predictions. The combined output of many models is often more accurate and robust than any single model.

One type of ensemble learning is known as *boosting*. In this approach, models are built sequentially, and each model corrects the errors of the previous one.

Gradient boosting

Gradient boosting is a powerful machine learning technique that you can use for both regression (which is the case here) and classification problems. It builds an ensemble of weak models (typically decision trees) sequentially, and each model focuses on reducing the errors (*residuals*) that the previous models made.

Gradient boosting effectively captures complex relationships between signals (also known as *exogenous variables*) and the input data (also known as the *target variable*). It also provides better predictive performance than other methods.

How the XGBoost algorithm works

XGBoost is a highly efficient and scalable implementation of gradient boosting. It builds an ensemble of decision trees to make predictions. Here's a step-by-step explanation of how it works:

1. Initialize predictions.

    - **Task** – Start by predicting a base value for all instances.
    - **Purpose** – The base value is typically the mean of the target variable for regression or the log odds for classification.

2. Calculate residuals (gradients).

    - **Task** – Compute the residuals or gradients, which represent the difference between the predicted and actual values.
    - **Purpose** – These residuals serve as the error signal that the model tries to minimize.

3. Fit a decision tree.

    - **Task** – Train a new decision tree by using the residuals (gradients) as the target values.
    - **Purpose** – The tree predicts adjustments to the previous model's predictions.
    - **Key details**
        - XGBoost uses a greedy algorithm to split the data.
        - Splits are selected based on the gain in the objective function, which is regularized to avoid overfitting.

4. Regularize tree growth.

- **Task** – Apply constraints to prevent overfitting.
- **Purpose** – Regularization helps generalize the model and maintain performance on unseen data.
- **Techniques**
  - *Tree depth* – Limit the maximum depth of trees.
  - *Leaf weights* – Penalize overly complex trees by adding regularization terms.
  - *Minimum split gain* – Allow a split only if a minimum improvement occurs in the loss function.

5. Update predictions.

- **Task** – Adjust predictions by adding the outputs of the new tree.
- **Purpose** – This step reduces the error progressively.

6. Repeat the process.

- **Task** – Repeat steps 2 through 5 to sequentially add more trees.
- **Purpose** – Each tree reduces the residuals and therefore gradually improves the model.
- **Stopping criteria**
  - A fixed number of trees are implemented in the algorithm of the Demand planning app.
  - There's no significant improvement in the loss function (*convergence*).

7. Combine trees for the final prediction.

- **Task** – Aggregate the outputs of all trees to produce the final prediction.
- **Purpose** – Each tree contributes to the final result. Therefore, an ensemble effect is created.

Custom Azure Machine Learning algorithm

If you have a custom Azure Machine Learning algorithm that you want to use with your forecasting models, you can use it in Demand planning.

Naive forecasting (preview)

[This article is prerelease documentation and is subject to change.]

Forecasting models are useful for creating accurate forecasts when they have access to large amounts of data. However, in many cases, such data isn't available, leading to inaccurate results like overstocking or understocking. Naive forecasting is a method for handling small datasets that ensures forecasts are predictable and tied to historical data.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

The idea behind naive forecasting

Models and data

Forecasting models use the training data you provide, and their ability to make useful predictions usually increases as the training dataset size grows. However, sometimes you can't provide enough data. For example, new products typically have only a few data points available to train a model. When that happens, regular forecasting models don't have enough information to identify trends and seasonality patterns in the data, which can lead to inaccurate forecasts.

Consequences of insufficient data on models

When there's not enough data to train a model, the model's behavior can be difficult to predict. Sometimes, the model stops trying to find the right approach and instead selects a constant value as its output, usually the last encountered value or zero. In other cases, the model might identify and extend a trend based on limited data, resulting in forecasts that differ significantly from historical data. These inaccurate forecasts might result in overstocking or understocking.

Naive forecasting as a fallback option

When confronted with unpredictable outcomes, demand planning can use naive forecasting as a fallback approach. Demand planning applies this method when the available data doesn't meet the requirements for standard forecasting models. Naive forecasting uses straightforward rules to produce approximate forecasts, reducing the uncertainty that arises from using regular models trained on limited datasets. Naive forecasting is only a fallback, not a replacement for regular forecasting models. Using naive forecasting within a dimension combination indicates that the data you provided might be insufficient.

Conditions and thresholds for using naive forecasting

Naive forecasting applies when both of the following conditions are met:

1. You must use the *Best fit model - version 2 (preview)* (or newer) forecasting algorithm. Naive forecasting isn't available for other forecast algorithms or as a separate algorithm.
2. Your dataset size is below the defined threshold, with no seasonality automatically detected. The following rules apply:

    - If auto seasonality detection is on but no seasonality pattern is detected, Demand planning uses a threshold of 14 days, 12 weeks, or 12 months (depending on the size of the time buckets in your input time series). If the number of data points is less than double the threshold, it's considered low data, and naive forecasting applies.
    - If auto seasonality detection is on and a seasonality pattern is detected, Demand planning applies a regular forecasting model.
    - If auto seasonality detection is off, Demand planning uses the seasonality hint you provide instead of applying naive forecasting.

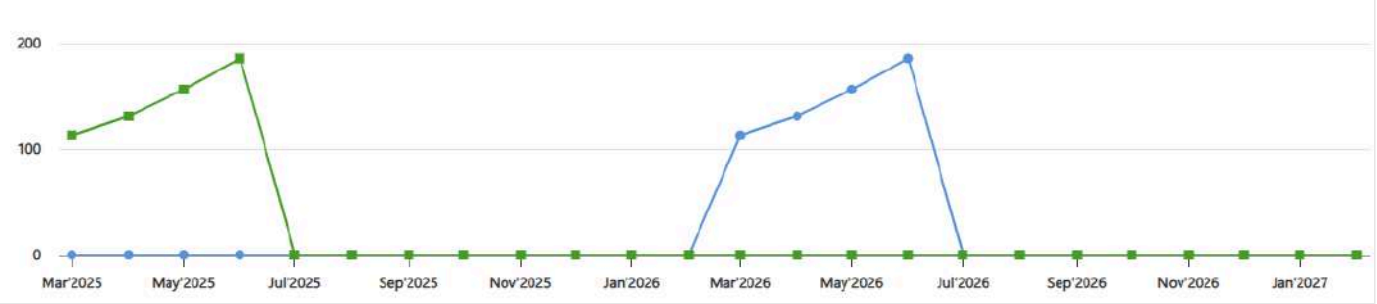
How naive forecasting works

The behavior of the naive forecasting algorithm depends on the size of the input data and the threshold that triggers it. The algorithm uses one of three methods, as described in the following subsections.

Copy and fill with zeros

The *copy and fill with zeros* method is used when the input dataset size is less than half of the threshold. Because only a small amount of data is available, naive forecasting copies the provided data and fills the remaining data points with zeros up to the threshold. This data is then repeated until predictions for all requested dates are found.

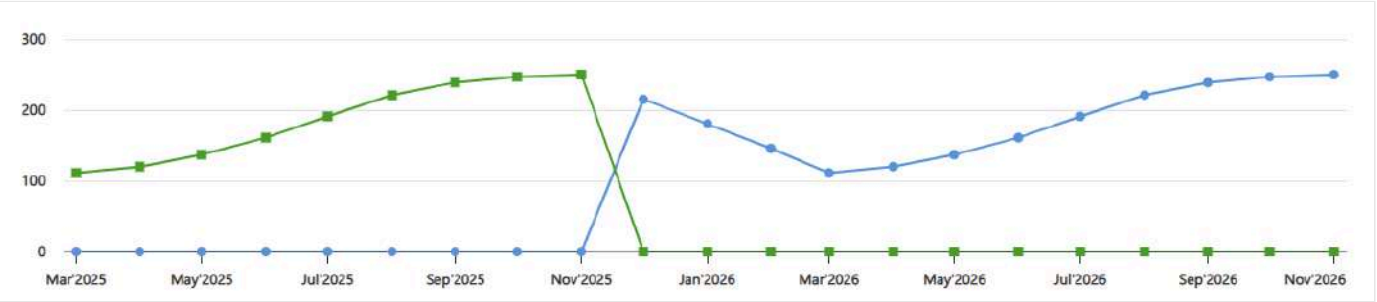
The following image shows an example of the *copy and fill with zeros* method. Input data appears in green, and forecasted data appears in blue. Because there are only 4 input data points, and the threshold is 12, the algorithm applies the *copy and fill with zeros* method, which results in the input values for March to June 2025 being copied to March to June 2026, with zero values inserted in between.



Copy and linear interpolation

When the input dataset size is more than half the threshold but still less than the threshold, naive forecasting uses the *copy and linear interpolation* method. This method fills gaps in the data by using linear interpolation between the first and last data points, ensuring that filled data is closer to copied data compared to the *copy and fill with zeros* method.

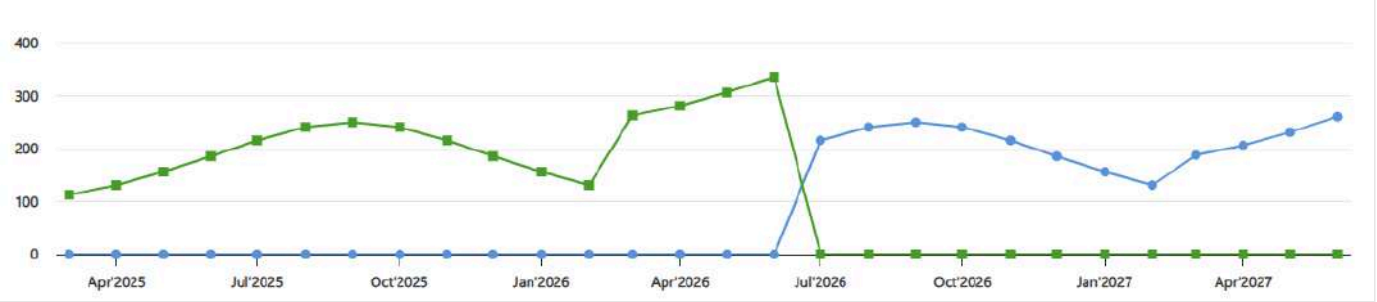
The following image shows an example of the *copy and linear interpolation* method. Input data is shown in green and forecasted data is shown in blue. Because there are 8 input data points, and the threshold is 12, the algorithm applies the *copy and linear interpolation* method, which results in the input values for March–June 2025 being copied to March–June 2026, with linearly interpolated values inserted in between.



Averaged copy

When the input dataset is larger than the threshold but smaller than double the threshold, naive forecasting uses the *averaged copy* method. This method takes an average of values seen before and after the threshold and then uses these values to calculate predictions. This method ensures that calculated values reflect changes in the data and follow the seasonality determined by the threshold.

The following image shows an example of the *averaged copy* method. Input data is shown in green and forecasted data is shown in blue. Because there are 16 input data points, and the threshold is 12, the algorithm applies the *averaged copy* method, which results in the input values for July 2025 to February 2026 being copied to July 2026 to February 2027, with values for March to June 2027 being an average of values for March to June 2025 and March to June 2026.



Limitations and caveats

When you use naive forecasting, the following limitations and caveats apply:

- Naive forecasting isn't a forecasting model but a fallback method for low-data scenarios. Check the explainability tables for your forecast jobs to see which planning objects use the naive method, and consider improving the input data quality where possible.
- Naive forecasting assumes seasonality of the data based on a manual hint or predetermined thresholds. If there's a mismatch between the assumed seasonality and the actual seasonality of the data (for example, if the time series has different seasonality or no seasonality at all), naive forecasting might lead to suboptimal results.
- Zero values are considered when determining whether to use naive forecasting. For planning objects with data that extends far into the past (compared with the rest of the time series), naive forecasting isn't used. To find out how naive forecasting works on this type of data, consider changing the forecast start date to be closer to where data is present. Be careful, because this approach also impacts the accuracy of other models as it limits their training data.

Croston's method forecasting (preview)

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

[This article is prerelease documentation and is subject to change.]

Forecasting models are useful for creating accurate forecasts when they have access to large amounts of data. However, in some cases, such data isn't available, leading to inaccurate results that can cause overstocking or understocking. *Croston's method* is a forecasting algorithm designed specifically for *intermittent demand*, which is demand data that includes many zero-demand periods with occasional nonzero demands.

> **Important**
>
> - This is a preview feature.
> - Preview features aren't meant for production use and might have restricted functionality. These features are subject to supplemental terms of use, and are available before an official release so that customers can get early access and provide feedback.

Models and data

Forecasting models typically rely on consistent, detailed historical data. As the dataset grows, models become better at identifying trends, seasonality, and patterns, which improves forecast accuracy. However, for some products, the data behaves differently; there are long stretches with no demand at all, followed by occasional spikes. In these cases, regular forecasting models might misinterpret the data and produce misleading predictions.

Challenges with intermittent demand

Standard models struggle when the data includes many zero-demand periods. They might overreact to small changes, forecast zero across the board, or attempt to create a trend where

none exists. These inaccurate outputs can lead to poor inventory decisions, such as overstocking low-usage items or understocking critical spare parts.

Croston's method as a fallback option

As with naive forecasting, Croston's method is a fallback option. Demand planning applies this method when the available data doesn't meet the requirements for standard forecasting models. When the system chooses to use Croston's method within a dimension combination, it indicates that the data you provided might be insufficient.

Conditions and thresholds for using Croston's method

Croston's method forecasting applies when all of the following conditions are met:

- You're using the *Best fit model - version 3 (preview)* (or newer) forecasting algorithm. Croston's method isn't available for other forecast algorithms or as a separate algorithm.
- Your dataset doesn't fulfill the conditions for using the naive forecasting algorithm.
- Your dataset doesn't have a clear seasonal pattern.
- Over 80% of values in the input time series are equal to zero.

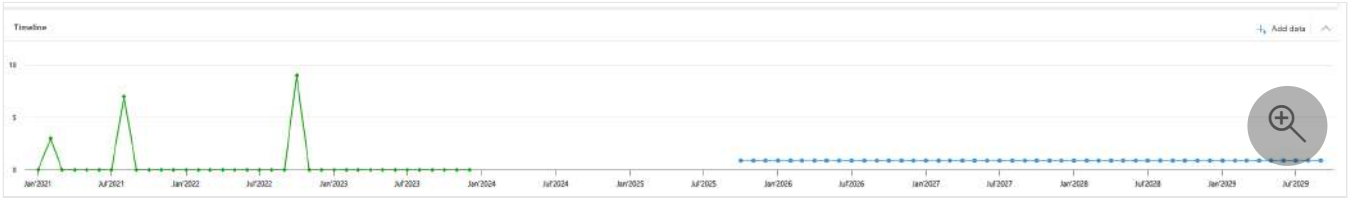
How Croston's method works

Croston's method doesn't try to guess exactly *when* the next demand will happen. Instead, it provides a steady, average forecast over time that reflects:

- How frequently the item is needed.
- How large the average demand is when it occurs.

The forecast stays stable and realistic, without reacting to random fluctuations or zero-demand periods. This approach gives planners a clearer view of what to expect over time.

The following image shows an example time series where Croston's method is a suitable forecasting algorithm.



In this example, the demand history (green line) shows that most periods have zero orders, with occasional spikes that don't follow a pattern. This example is a typical case where Croston's method is appropriate. Instead of chasing the noise, Croston's method produces a flat forecast line (the blue line), which reflects the average demand and its frequency weighted toward recent data.

Limitations and caveats

When you use Croston's method, the following limitations and caveats apply:

- Croston's method isn't a forecasting model that you can choose. The system uses it as a fallback for datasets when most data points are zero. Check the explainability tables for your forecast jobs to see which planning objects use Croston's method and consider improving the input data quality where possible.
- Adding a seasonal hint prevents the best fit algorithm from selecting Croston's method, forcing it to choose an alternative.
- The method predicts only the average interval between demands—not *when* the next demand will occur—and doesn't provide a probability distribution of sizes. Instead, it produces a flat line for a stable, realistic forecast.
- The model gives more weight to recent demand activity, allowing the forecast to better reflect current usage volume.

Use your own custom Azure Machine Learning algorithms in Demand planning

08/18/2025

In addition to the standard forecasting algorithms provided with Demand planning, you can also create your own custom algorithms and use them in your Demand planning forecast models. To do so, you must create and publish your algorithms using Microsoft Azure Machine Learning, set up a connection from Demand planning to Azure, and place one of the following types of steps to your forecast models as needed (instead of using the standard *Forecast* step):

- *Custom* step – Lets you use custom algorithms that you've created using Azure Machine Learning. Use the *Custom* step with custom algorithms that you haven't used with the legacy Supply Chain Management forecasting functionality. This type of step communicates with Azure through a *batch* endpoint and allows you to pass any custom parameters your algorithm requires, though no preconfigured parameters are set up by default.
- *Finance and operations* step – Lets you use custom Azure Machine Learning algorithms that you created for use with the legacy Supply Chain Management forecasting functionality, as described in Demand forecasting overview. This type of step communicates with Azure through a *pipeline* endpoint and is preconfigured to pass the parameters supported by legacy Supply Chain Management forecasting functionality.

This article describes the setup that is required to enable Demand planning to connect to your Azure Machine Learning workspace, including how to set up your Azure Machine Learning workspace, how to connect to that workspace in Demand planning, and how to set up your forecast models to run your custom algorithms.

Download sample code and other resources

To download sample code and other resources that demonstrate how to use custom Azure Machine Learning algorithms in Demand planning, go to the Custom-ML-in-DemandPlanning repository on GitHub. It provides insights into how to read input data, handle standard and custom parameters, and generate output that aligns with the application's consumption requirements. The repository consists of a readme file, a scoring script, and demonstrative videos.

Set up your Azure Machine Learning resources

You must develop your custom forecast algorithms to run in Azure Machine Learning and then set up Azure to make them available to Supply Chain Management. The following subsections explain how. If you've already been using your custom Azure Machine Learning algorithms with the legacy Supply Chain Management forecasting functionality, then these elements might already be set up. In that case, you can skip to the section Connect to the Azure Machine Learning service from Demand planning.

Set up a new Microsoft Entra application

Follow the steps in this section to create a new Microsoft Entra application in your Azure Machine Learning workspace. This resource in the Azure portal holds your algorithms. The Microsoft Entra application is an enterprise application that enables Demand planning to connect to your Azure Machine Learning algorithms. Learn more about how to set up a Microsoft Entra application in Register an application.

1. Sign in to the Azure portal by using an account that has at least *Cloud Application Administrator* privileges.
2. Register a new Microsoft Entra application as described in Create a Microsoft Entra application and service principal that can access resources.
3. Follow the on-screen instructions to complete the wizard. Use the default settings.
4. In the **Certificates & secrets** section of the new Microsoft Entra application, create a secret for the application as described in Add a client secret.
5. Make a note of the application ID and its secret. You'll need these details later.

Grant access for the new Microsoft Entra application to the Azure Machine Learning workspace and Azure Machine Learning workspace storage account

Follow these steps to allow your new Microsoft Entra application to access the Azure Machine Learning workspace.

1. In the Azure portal, go to the resource group that contains your Azure Machine Learning workspace.
2. On the left navigation pane, select **Access control**.
3. On the **Role assignments** tab, select **Add** to add a new role assignment.
4. On the **Privileged administrator roles** tab, select *Contributor*.
5. Select **Next**.
6. Select the **User, group, or service principal** option.
7. Select **Select members**. Use the filter on the menu on the right to find the name of the Microsoft Entra application that you created, and then select it.
8. The application now appears in the **Members** list. Select **Next**.

9. On the **Review + assign** tab, select **Next**.

Follow these steps to allow your new Microsoft Entra application to access the storage account that Azure Machine Learning workspace is connected to.

1. In the Azure portal, go to the resource group that contains your storage account (the storage account that your Azure Machine Learning workspace is using).
2. On the left navigation pane, select **Access control**.
3. On the **Role assignments** tab, select **Add** to add a new role assignment.
4. On the **Job function roles** tab, select *Storage account contributor* and *Storage blob data contributor*. To find these roles quickly, enter *storage contributor* into the **Search** field.
5. Select **Next**.
6. Select the **User, group, or service principal** option.
7. Select **Select members**. Use the filter on the menu on the right to find the name of the Microsoft Entra application that you created, and then select it.
8. The application now appears in the **Members** list. Select **Next**.
9. On the **Review + assign** tab, select **Next**.

The application is now listed in the **All** section of the **Role assignments** tab on both the Azure Machine Learning workspace and the storage account.

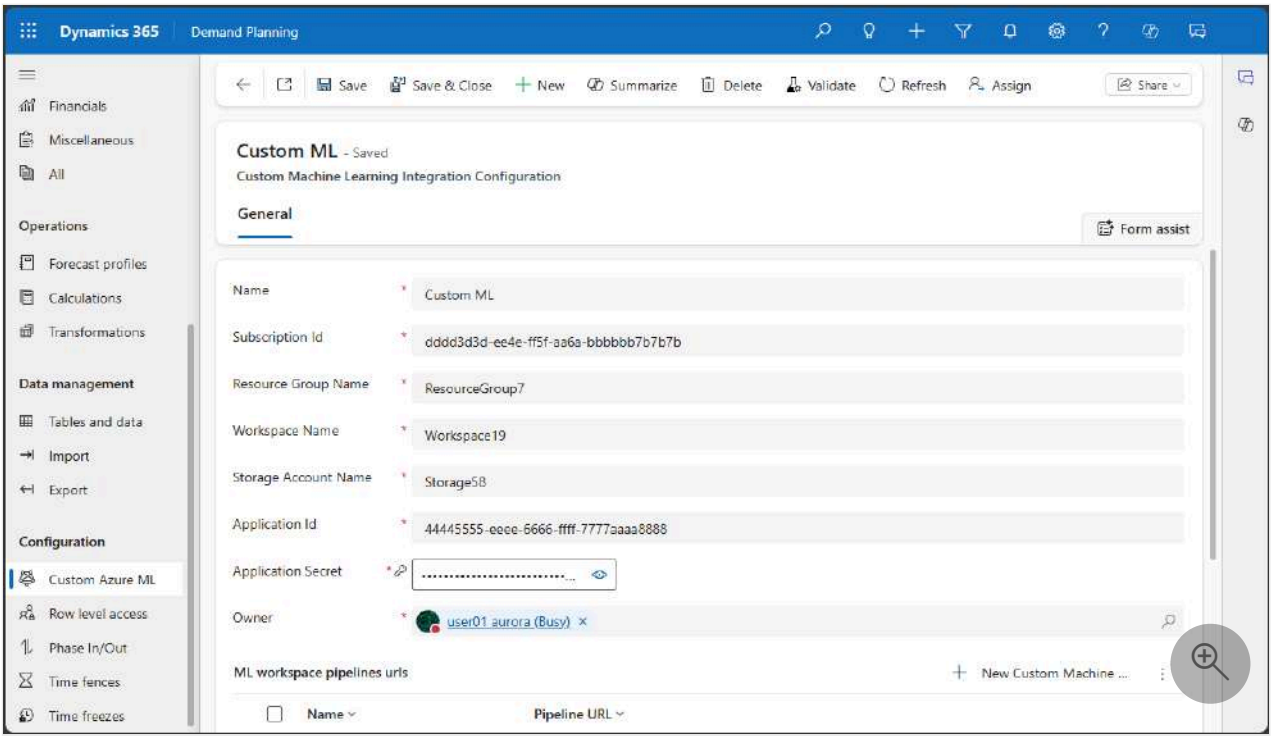
Connect to the Azure Machine Learning service from Demand planning

Follow these steps to set up the Azure Machine Learning service connection in Demand planning.

1. Sign in to Demand planning.

2. On the left navigation pane, select **Custom Azure ML**.

3. In the toolbar, select **New** to create a new connection.



4. Make the following settings for the new connection:

    - **Name** – Enter a name for the connection.
    - **Subscription ID** – Enter the ID for your Azure subscription.
    - **Resource group name** – Enter the name of the resource group that contains your Azure Machine Learning workspace.
    - **Workspace name** – Enter the name of your Azure Machine Learning workspace.
    - **Storage Account Name** – Enter the name of the Azure storage account that you specified when you ran the setup wizard in your Azure workspace.
    - **Application ID** – Enter the application ID of the Microsoft Entra application that you created. This value is used to authorize API requests to the Azure Machine Learning service.
    - **Application secret** – Enter the service principal application secret for the Microsoft Entra application that you created. This value is used to acquire the access token for the security principal that you created to perform authorized operations against Azure Storage and the Azure Machine Language workspace.

5. On the Action Pane, select **Save**.

6. On the **ML workspace pipelines URLs** FastTab, add a row for each Azure Machine Learning endpoint that you want to make available to Demand planning. Each endpoint requires a unique **Name** (which is only used internally in Demand planning) and a **Pipeline URL**, which is the full URL that Demand planning must use to access the endpoint.

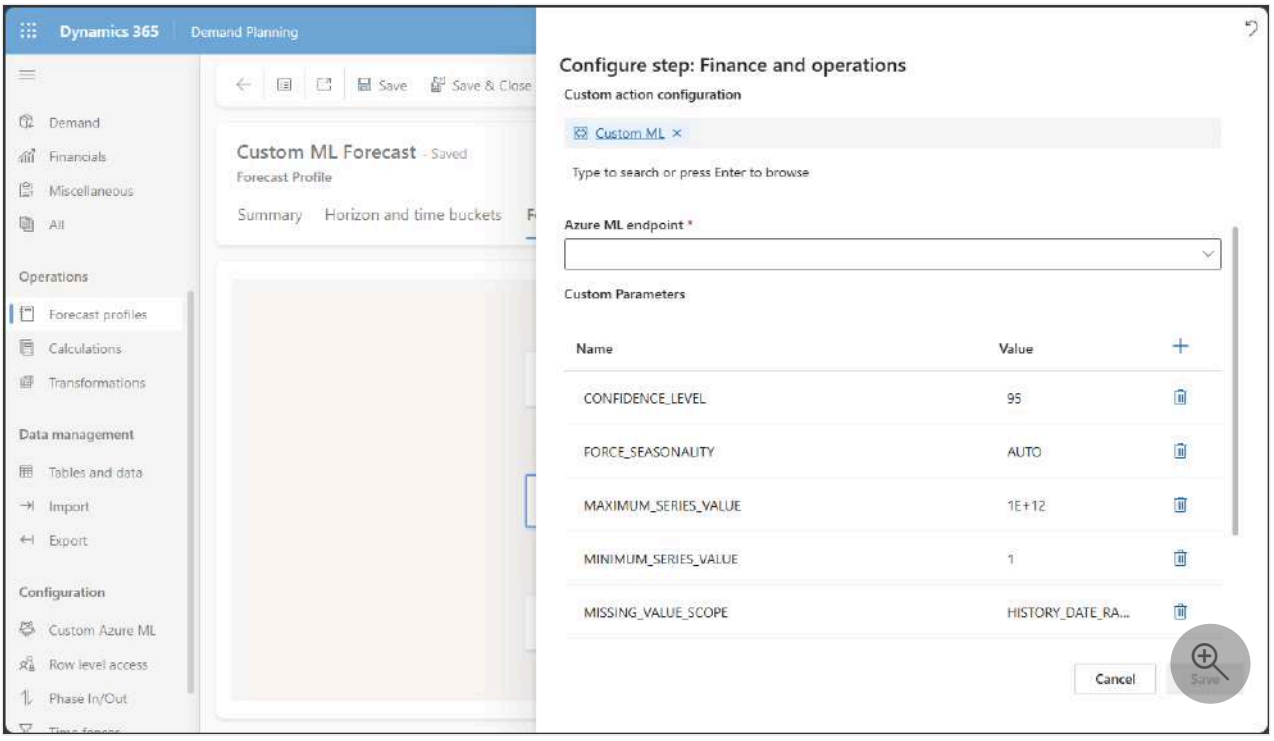
    - For *Finance and operations* steps, these must be Azure Machine Learning *pipeline* endpoints.

- For *Custom* steps, these must be Azure Machine Learning *batch* endpoints. Learn more in Batch endpoints.

Set up a forecast model that uses a custom Azure Machine Learning algorithm

Follow these steps to set up a forecast model that uses a custom Azure Machine Learning algorithm. This procedure applies both to new custom algorithms and to custom algorithms that you previously used with Supply Chain Management; the only difference is the type of forecast step you should use in your model (*Custom* or *Finance and operations*).

1. Create a new forecast profile as described in Create and manage forecast profiles.
2. On the **Select a forecasting model preset** page, select *None*.
3. After you've created and saved the profile, select the **Forecast model** tab. (Learn more in Design forecast models.)
4. Set up your model. Add a *Finance and operations* or *Custom* step in the position where you want to run your algorithm.
    - Use a *Custom* step if you want to connect to an Azure Machine Learning algorithm that you haven't used with the legacy Supply Chain Management forecasting functionality.
    - Use a *Finance and operations* step if you want to connect to an Azure Machine Learning algorithm that you created for use with the legacy Supply Chain Management forecasting functionality.
5. Open the **Actions** menu for the *Finance and operations* or *Custom* step and then select **Settings**.



6. In the **Configure step** dialog, make the following settings for the step:

   - **Step name** – Enter a name for the step.
   - **Description** – Enter a description for the step.
   - **Custom action configuration** – Select the Custom Azure ML profile that you created to connect to your Azure Machine Learning resource.
   - **Azure ML endpoint** – Select the Azure Machine Learning endpoint that triggers the machine learning algorithm that you want to use. The available endpoints must be defined as part of the Custom Azure ML profile that you created.
   - **Custom parameters** – If you've designed your Azure Machine Learning forecast algorithm to accept input parameters, then add them as key/value pairs here as required.
     - For *Custom* steps, no default parameters are provided. You must manually add each one that you require following the specifications of your algorithm.
     - For *Finance and operations* steps, a collection of default parameter names are provided, so all you need to do is adjust the values as needed. These are the parameters used by the legacy Supply Chain Management forecasting functionality. For details about how to use these settings, see Default parameters and values for demand forecasting models.

> **⊗ Caution**
>
> You must only include parameters that your forecast algorithm is designed to accept. If you include parameters that your algorithm doesn't recognize, the forecast will fail when it runs.

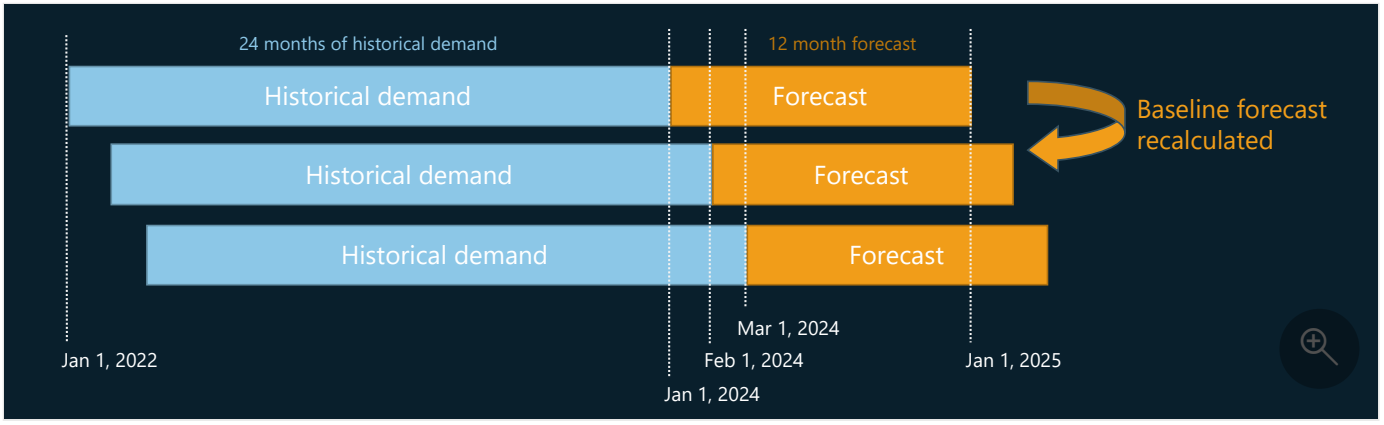
7. Select **Save** to close the dialog.

8. Complete the model by adding a *Save* step.

Rolling forecasts

Rolling forecasts let you establish a regular schedule that your time series follow to automatically update and extend their forecast horizon based on the latest data and assumptions. Rolling forecasts help align the demand planning process with the changing business environment. They also help improve the accuracy and reliability of the forecasts.

The following illustration shows an example of a rolling forecast that recurs on the first of each month.



> **Note**
>
> On a continuous basis, when a forecast is fully recalculated, its baseline forecast is also automatically recalculated. Edits that were made during the previous period aren't kept.

How to use rolling forecasts

After you set up a rolling forecast, you can view different versions of the same time series to compare the historical demand, the current forecast, and the previous forecast. You can also modify, review, and edit the forecast as you require. Rolling forecasts automatically update and extend the forecast horizon each time that they run.

Rolling forecasts can help you monitor the performance of your demand planning process, identify and address issues by collaborating on a forecast, and adjust your plans accordingly. They can also help you communicate and collaborate with other stakeholders (such as sales, marketing, and finance), and align your demand planning with the strategic goals of your organization.

Set up rolling forecasts

You can fully automate a rolling forecast by scheduling each of its processes (importing data, running a transformation, running a calculation, running a forecast, and exporting the forecast).

To schedule a process, follow these steps:

1. Go to one of the following pages, depending on the type of process that you want to schedule:

    - **Data management** > **Import**
    - **Data management** > **Export**
    - **Operations** > **Forecast profile**
    - **Operations** > **Calculations**
    - **Operations** > **Transformations**

2. Select the profile that you want to schedule, or create a new profile.

    - If you're creating a new profile, work through the creation wizard in the usual way. When you reach the **Set run schedule** page of the wizard, you can set up a schedule by configuring the settings that are described in the rest of this procedure. However, to fully automate most types of processes, you must have an existing time series. Therefore, we recommend that you manually run the profile for the first time to create the required time series. Then edit the profile to set up the schedule by using that time series.
    - If you're editing an existing profile, select the **Run Schedule** tab.

3. Set the **Run schedule** field to one of the following values:

    - **None** – The process isn't scheduled to run automatically. You must manually run it.
    - **Recurring** – The process is triggered at a specific date and time, according to the configured schedule (daily, weekly, or monthly).

4. In the **Set run date recurrence** section, define when and how often the process should run, and set the start and end dates that it should run during.

5. In the **Output settings** section, follow one of these steps to specify how you want to save the output of the process:

    - To create a new time series after each run, set the **Save output as** field to *Create new time series*. Then, in the **Time series name** field, enter a base name for the new time

series. In the **Append to name** field, select a dynamic suffix to add to the base name, so that each time series has a unique name. You can use the run date, the run month, or the run month and year as the suffix.

- To add a new version to an existing time series after each run, set the **Save output as** field to *New version of the same time series*. Then set the **Use existing time series** field to the target time series. (The target time series must already exist.) We recommend that you also select the **Save current as a version before overwriting** checkbox to maintain the traceability of the whole process and ensure that the system doesn't accidentally overwrite any version work that's in progress. For more information about how time series versions work, see Time series, worksheets, and planning data.

Use phase in/out functionality to simulate planned changes

Article • 01/10/2025

Phase in/out functionality lets you set up forecasts and calculations that simulate changes that you plan to make. Here are some examples:

- Phase out a product that's no longer popular or that's leaving the market.
- Phase in a new product.
- Replace an older product with a new, similar one.
- Open a new store or warehouse that should be similar to an existing one.

To apply calculations of this type, add a *Phase in/out* step to the relevant calculation model or forecast model. The *Phase in/out* step uses a *phase in/out rule group* to modify a selected data column based on values that are found in the same column or another column of the time series. Each phase in/out rule group defines selection criteria that identify input and output columns, a period to apply the calculation during, and a scaling factor to apply during that period.

Example: Phase in a new product that replaces an existing product

You're introducing a new product (Speaker V2) that replaces a similar existing product (Speaker V1). You expect that customers will increasingly choose the new speaker. However, you also expect that the total number of speakers that are sold each month will remain about the same as last year and follow a familiar seasonal sales pattern. Therefore, you add the following phase in/out calculations to next year's forecast:

- For the first six months of next year, you'll offer Speaker V2 at a premium price. Therefore, you predict that the quantity of Speaker V2 that you sell will be 40 percent of the quantity of Speaker V1 that you sold during the same month last year. Speaker V1 will make up the difference, and you'll sell 60 percent of the quantity that you sold last year.
- After six months, you'll slightly lower the price of Speaker V2. Therefore, for the last half of next year, you predict that the quantity of Speaker V2 that you sell will be 75 percent of the quantity of Speaker V1 that you sold last year. The quantity of Speaker V1 that you sell will be 25 percent of the quantity that you sold last year.
- After a year, you expect that sales of Speaker V2 will completely replace sales of Speaker V1.

To add this calculation to a forecast model, you set up a phase in/out rule group that has the following rules:

- **Phase in rule 1** – This rule applies from January through June. For each month, select the forecast quantity based on last year's sales of Speaker V1, multiply it by 40 percent, and add the result to the forecast quantity for Speaker V2. (The forecast quantity for Speaker V2 is currently 0 [zero], because it's a new product.)
- **Phase out rule 1** – This rule applies from January through June. For each month, select the forecast quantity based on last year's sales of Speaker V1, multiply it by 60 percent, and set the result as the new forecast quantity for Speaker V1.
- **Phase in rule 2** – This rule applies from July through December. For each month, select the forecast quantity based on last year's sales of Speaker V1, multiply it by 75 percent, and add the result to the forecast quantity for Speaker V2.
- **Phase out rule 2** – This rule applies from July through December. For each month, select the forecast quantity based on last year's sales of Speaker V1, multiply it by 25 percent, and set the result as the new forecast quantity for Speaker V1.

The following table shows an example of forecasted sales before the phase in and phase out calculations are applied.

Expand table

Product	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Speaker V1	100	100	100	100	100	100	100	100	100	100	100	100

The following table shows an example of forecasted sales after the phase in and phase out calculations are applied.

Expand table

Product	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Speaker V1	60	60	60	60	60	60	25	25	25	25	25	25
Speaker V2	40	40	40	40	40	40	75	75	75	75	75	75

Manage phase in/out rule groups

Use phase in/out rule groups to define the phase in/out calculations that are applied in your forecast and calculation models. To create, view, or edit a rule group, follow these steps.

1. On the navigation pane, select **Configuration** > **Phase in/out**.

2. Follow one of these steps:

    - To create a new rule group, select **New** on the Action Pane. A wizard guides you through the steps for creating the group.
    - To view or edit an existing rule group, select the link for it in the **Name** column of the grid to open its details page.

3. The details page and wizard pages provide nearly identical fields that you can set:

    - **Name** – Enter a name for the rule group.
    - **Description** – Enter a short description of the rule group.
    - **Owner** – Select the user account that owns the rule group. (This field is available only in the wizard.)
    - **Active** – Set this option to *Yes* or *No*. Only active rules groups can be assigned to the phase in/out steps of your forecast or calculation models.
    - **Rules** – Use the fields on this tab to define the phase in/out calculations that the group does. For information about how to use these fields, see the next section.

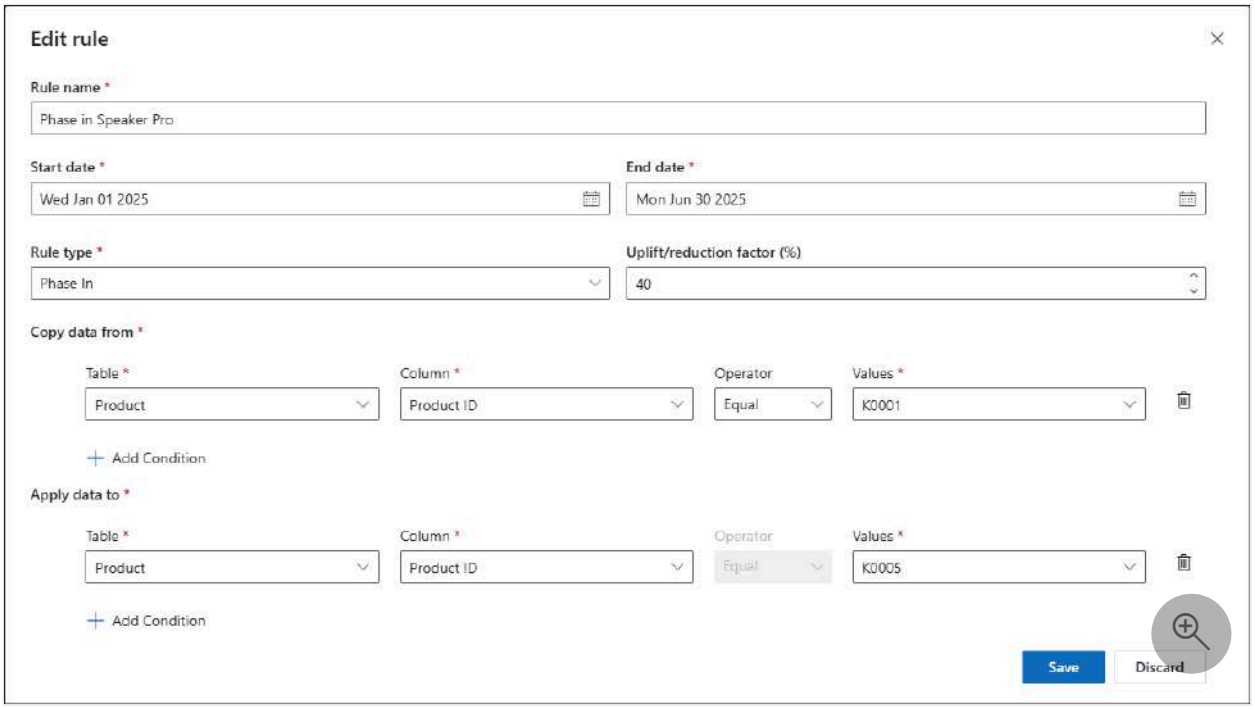
4. Follow one of these steps:

    - If you're creating a new group, select **Review and finish** on the last wizard page to save your rule group and open its details page.
    - If you're editing an existing group, save your settings by selecting **Save** or **Save & close** on the Action Pane.

Set up rules

Each rule group must have at least one rule and might have several rules. You set up rules on the **Rules** tab of either the details page or the **Add rules** page of the new group wizard. The process is the same in both places.

Use the buttons on the toolbar to add, remove, and edit rules. You can include as many rules as you need for each group. Each time that you add or edit a rule, the **Edit rule** dialog box appears.



In the **Edit rule** dialog box, set the following fields for each rule:

- **Rule name** – Enter a name for the rule. Choose a name that makes the rule easy to identify in the rule list.
- **Start date** – Enter the first date when the rule should apply.
- **End date** – Enter the last date when the rule should apply. For a phase in rule, data will stop being copied on this date. (By this date, you should have actual sales data to base your forecasts on.) For a phase out rule, time series values will fall to 0 (zero) on this date unless another phase out rule applies immediately after this rule.
- **Rule type** – Select one of the following values to specify the type of rule:
  - *Phase in* – The rule takes a value from the data column that you identify in the **Copy data from** section, multiplies it by the **Uplift/reduction factor (%)** value, and adds the result to the data column that you identify in the **Apply data to** section.
  - *Phase out* – The rule takes a value from the data column that you identify in the **Copy data from** section, multiplies it by the **Uplift/reduction factor (%)** value, and sets the result as the new value for the same data column that you identify in the **Copy data from** section.
- **Uplift/reduction factor (%)** – Specify a factor (as a percentage) to apply to the input time series values.
- **Copy data from** – Use this section to specify criteria for selecting input values for the calculation. You can use the **Add condition** button to add as many rows as you

need. The data tables that are listed are the data tables that are defined in Demand planning. (Learn more in View and customize tables for holding imported data.) You typically use this section to identify a product from the product table that you want to phase in or out.

- **Apply data to** – This section applies only to phase in rules. (Phase out rules always apply to the same data columns that are identified in the **Copy data from** section.) Specify criteria for selecting the data column that the phase in rule applies to. You typically use this section to identify a new product that you're phasing in. You can use the **Add condition** button to add as many rows as you need.

Assign rule groups to phase in/out steps

After you finish setting up your rule groups, you can use them by putting *Phase in/out* steps at the appropriate positions in your calculation models and forecast models. Learn more in Design calculation models and Design forecast models.

Time series, worksheets, and planning data

08/18/2025

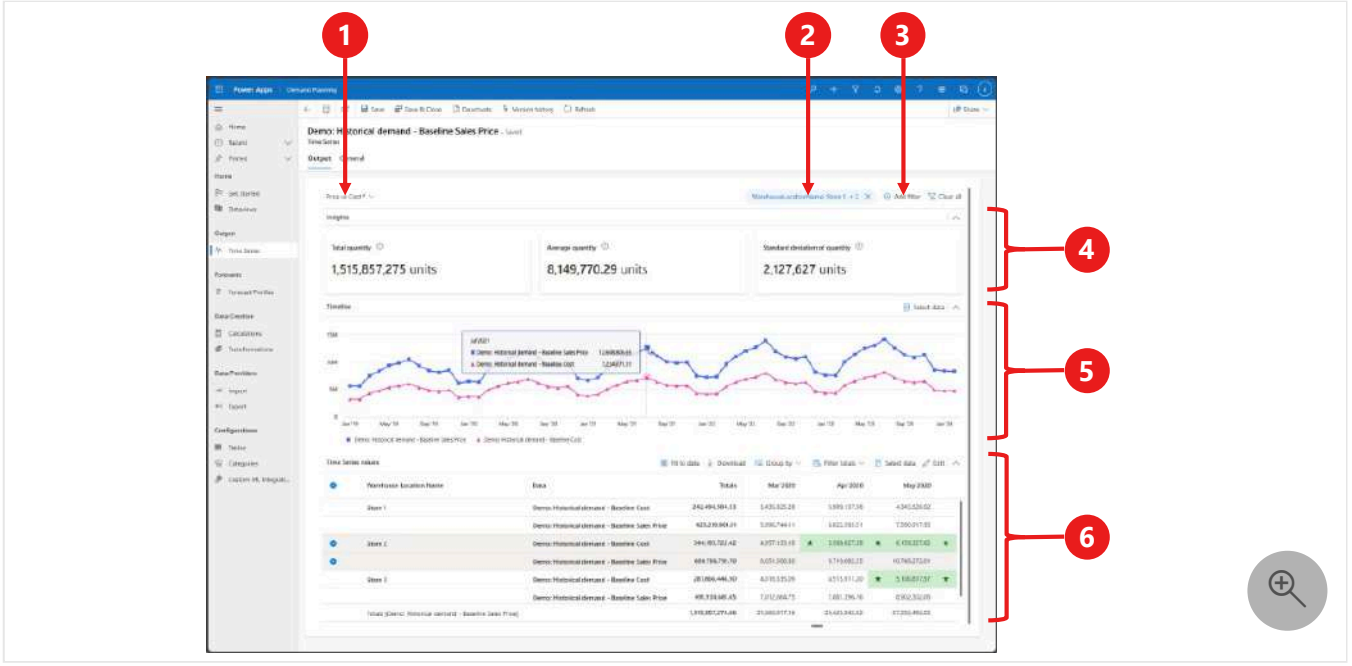
Time series, worksheets, and planning data represent the output from forecasts, calculations, and transformations in daily, weekly, or monthly time buckets.

- *Time series* is a term that describes the type of data that forecasts, calculations, and transformations consume and create. Each time series is a collection of data values that are plotted against a series at regular time intervals. Both planning data and worksheets contain time series data.
- *Planning data* is the processed and categorized output that forecasts, calculations, and transformations create. Demand planning presents planning data by using both a chart and a grid of values. It also provides tools for organizing, analyzing, editing, combining, and presenting this data. Every planning data record is categorized as containing *Forecast*, *Demand*, *Financials*, or *Miscellaneous* data, based on how it was created.
- *Worksheets* let you view, modify, and combine various types, versions, and views of planning data. You can create and switch between any number of worksheets for each planning data record. You can also share worksheets with other users or keep them private for yourself.

Explore planning data and worksheets

To view all your planning data, on the navigation pane, select **Planning data** > **All**. Alternatively, select an appropriate planning data category under **Planning data**. To view shared worksheets, on the navigation pane, select **Home** > **Worksheets**.

To open a worksheet or planning data record, select its name in the **Name** column. The following illustration highlights the features on the **Output** tab of the time series details page.



Legend:

1. **Create and select worksheets** – You can use this menu to save the current view (including all filters, overlaid series, and other selections) as a worksheet in the current planning data record. If you've already saved one or more worksheets, you can use this menu to load them. Each worksheet that's created from this menu is also listed on the **Worksheets** page (available at **Home** > **Worksheets** on the navigation pane). Each worksheet has a share setting that lets you share it with other users or keep it private to yourself. You can also use this menu to delete worksheets.

2. **Current filters** – If you've applied any filters to the data, they're listed next to the **Add filter** button as colored blocks. You can remove any listed filter by selecting its **Close** button (**X**).

3. **Add filter** – Open a menu where you can choose to filter the time series by any combination of date or dimension values. This filtering affects the key performance indicators (KPIs) that are shown on the **Insights** FastTab, the chart that's shown on the **Timeline** FastTab, and the values that are available on the **Time series values** FastTab. Filters that you add from here are added to the current filters list (2).

4. **Insights** – This FastTab shows KPIs for the current time series, including total quantity, average quantity, and standard deviation of quantity. These values reflect the filter settings.

5. **Timeline chart** – This chart is a graphical representation of the selected time series. It provides the following capabilities:

    - **The chart reflects time series filters.** Chart values are consistent with the filter settings that are configured at the top of the page.

- **The chart reflects row selections.** Chart values reflect any rows that are selected on the **Time series values** FastTab.
- **View precise data values.** You can view precise data values at any point by hovering your mouse pointer over the chart.
- **Set chart options.** You can adjust chart options (such as color, style, and grid options) by using the **Select data** button.
- **Overlay another time series.** You can overlay another time series for comparison by using the **Select data** button. In this illustration, a second time series (pink) is overlaid on the current time series (blue).

6. **Time series values** – This FastTab shows tabular data for the selected time series. The following features and toolbar buttons are available:

    - **Row selection** – Select a row to see only that row reflected in the timeline chart. To select multiple rows, select the **Shift** key while you tap or click. A blue check mark indicates each row that's selected. Select the check mark to clear the selection of a row. Select the check mark at the top of the table to clear the selection of all rows.
    - **Add a cell comment** – Enter a comment for the selected cell. The comment is saved with the time series and can be viewed by other users. Cells that have comments show a comment symbol (purple speech bubble). To view the comment for a cell, select the comment symbol (or use the Copilot grid cursor).
    - **Fit to data** – Adjust the width of visible columns to ensure that the data isn't clipped.
    - **Downloads** – Download the data as a comma-separated values (CSV) file where the current filter and group options are applied.
    - **Group by** – Select which of the available dimensions to use to group the data. For example, if you have dimensions for warehouses and product variants, you can group by both warehouse and variant (to show each warehouse, with each product variant listed under it), group by variant only (to show the variants but not the warehouses), or group by warehouse only (to show the warehouses but not the variants). Totals values are aggregated to match the group selection.
    - **Filter totals** – Set up a logical expression to filter the selection of rows that are shown in the table. For example, you can view only rows that have totals above 100,000 units. This setting doesn't affect the chart or KPIs.
    - **Select data** – Add another time series to the chart and/or data table, so that you can compare them. This button opens the same dialog box that the **Select data** button above the chart opens. Therefore, you can also adjust chart options (such as color, style, and grid options).
    - **Edit** – Edit values directly in the data table. If an edited value is aggregated because of the **Group by** settings, the value of your edit will be divided proportionally among the aggregated data rows. If a cell shows a lock symbol, it's currently locked

by a time fence and therefore can't be edited. Learn more about time fences in Limit manual time series edits with time fences.

Select the **General** tab of the time series details page to view and adjust the following basic settings. Many of these settings affect the way that the time series is shown on the list page.

- **Name** – The name of the time series.
- **Description** – A short description of the time series.
- **Category** – The category of the time series. This setting controls which navigation entry, in addition to **All**, the time series is listed in under **Planning data** on the navigation pane. Select the **Search** button (magnifying glass symbol) to select a category.
- **Time buckets** – The time buckets that are used by the time series (daily, monthly, or yearly).
- **Allow manual edits** – A value that indicates whether the series allows users to manually edit data values by using the data table.

> **Tip**
>
> In addition to the features described in this article, time series also provide *generative insights* and a *Copilot grid cursor*, each of which help you analyze and explore time series data with the help of AI. Learn more in Generative insights for Demand planning (production ready preview) and Copilot grid cursor.

Customize time series chart and data table layouts

Demand planning provides many options that help you analyze your time series. For example, you can customize the chart layout (such as style, color, and size), overlay the chart or data table with another time series so that you can easily make comparisons, and assign logic to highlight specific cells in the data table so that they stand out.

To configure these options, open a time series, and then select **Select data** on either the **Timeline** FastTab or the **Time series values** FastTab. The **Select data** dialog box appears.

To add a new time series to the chart and/or data table, select **Add**. You're prompted to select an existing time series. The time series that you select is then added as a new row in the **Select data** dialog box. To remove a time series from the chart and data table, select its **Close** box on the right side of the row. The top row of the **Select data** dialog box lists the current time series. You can customize this time series, but you can't remove it.

The row for each time series that's listed in the **Select data** dialog box provides the following information and options:

- **Name** – The name of the time series.
- **Version** – For time series that have more than one version, select the version to use.
- **Description** – A short description of the time series.
- **Show in chart** – Enable this option for each time series that you want to include in the chart.
- **Chart styling** – Select the **Customize** link in this column to open a dialog box where you can customize the way that the selected row appears in the chart. You can select whether the series is presented as a line or a series of bars, and you can select the color. You can also add a secondary axis. A secondary axis is useful if the selected series use very different values (for example, when you compare sales in the millions of units against prices in the hundreds of dollars). If you add a secondary axis, a new set of values is shown on the right side of the chart to indicate the scale of the second time series.
- **Show in grid** – Enable this option for each time series that you want to include in the data table.
- **Grid formatting** – Select the **Customize** link in this column to open a dialog box where you can specify logic to highlight cells in the data table. You can highlight cells for the selected series according to either their own values or values from another time series for the same time bucket. (If you want to compare the selected series to another series, set the **Use values from another time series** option to *Yes*, and then specify a series and version.) You can add as many rules as you need. For each rule, specify the logic (for example, find values that are less than 4,000,000) and the style (color and symbol) that are applied to cells that match that rule.

After you've spent time customizing and formatting your time series, you'll probably want to save your settings as a new data view that you can return to later. To save the current settings as a data view, select **Save as new dataview** on the dropdown menu in the upper left of the page. (Learn more in the Explore time series section.) You can save as many data views as you need for each time series.

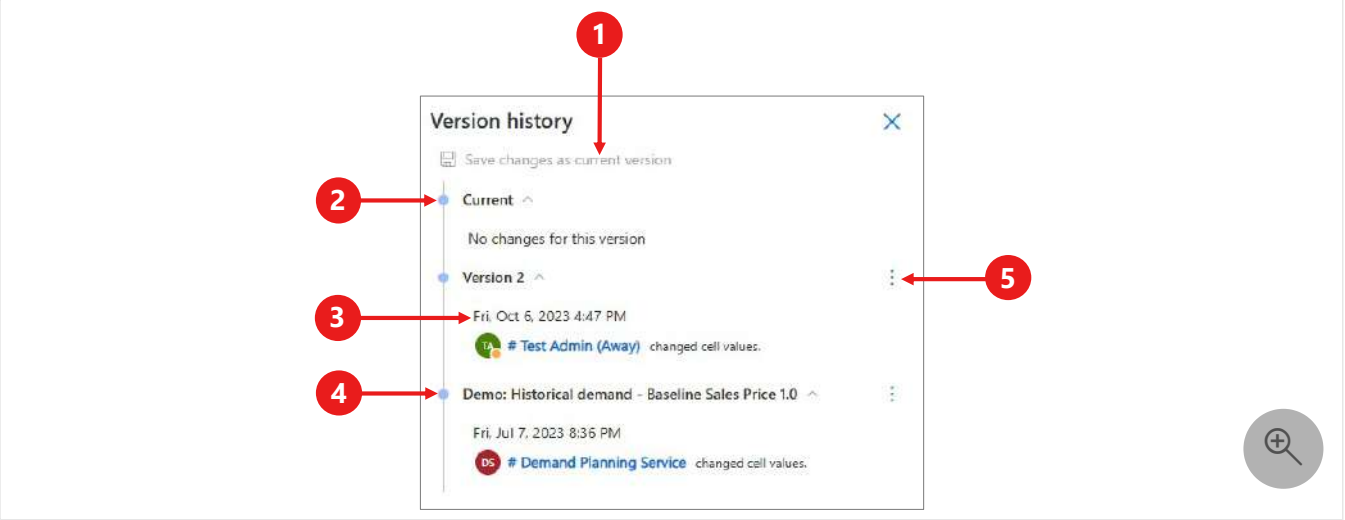
Time series versions, version control, and change log

Demand planning lets you edit cell values directly. Therefore, you can modify the underlying data for any time series. Each time that you edit cell values, the change is noted in the change log, where all users can see when the change was made and who made it. At any time, you can save the edits that you've made so far (since the last version) as a new version and provide a name for it. You can view any version by selecting it in the version history, and you can restore any previous version to the current version.

Sometimes, when you're selecting a time series, you can select which version to use. For example, when you use **Select data** to overlay one time series on the current time series, you can choose which version to use. You can even overlay a previous version of the same time series to quickly see what changed between versions.

To view the change log and version history for a time series, open the time series, and then select **Version history** on the Action Pane. The **Version history** pane that appears shows a log entry for each relevant edit event. Log entries are grouped under the version that they apply to.

The following illustration highlights the features of the **Version history** pane.



Legend:

1. **Save changes as current version** – Save a new version that includes all the changes that have been made since the last saved version. When you select this button, you're prompted to provide a name for the version.

2. **Time series version** – Each saved version shows its version name next to a blue dot on the timeline. Select a version to view it in the chart and data table. You can collapse or expand each version to hide or view the log of edits that were made to create that version. The top version is always the current version. This version might include edits that have been made since the last saved version.

3. **Change log entry** – Change log entries are nested below the version where they were made. Each entry shows the date and time when the change was made, and the user who made it.

4. **Initial version** – The initial version and its change log entry represent the time series creation event. It's always saved as a version. Therefore, you can easily view or restore it as you require.

5. **Version edit button** – Open a menu where you can select any of the following actions:

- **Rename** – Enter a new name for the version.
- **Restore** – Make the selected version the current version.
- **Deactivate** – Deactivate the selected version. The values of newer versions aren't affected. Deactivated versions aren't shown in version selectors.
- **Activate** – Reactivate an inactive version.

Commenting and collaboration

You can add comments to a time series to communicate with other users. For example, you can explain why you chose to edit specific time series values or how to understand a saved data view. Users can also reply to each other's comments, edit or delete comments, and mark comment threads as resolved.

To view and work with comments, open a time series, and select the **Comments** button in the Action Pane at the top of the page. The commenting pane that appears shows all the comments that have been made so far for the current series. From here, you can perform the following actions:

- Select **New** to add a new comment.
- For exiting comments, select the **More thread actions** button ··· to open a menu where you can choose to edit or delete the selected comment or mark the selected thread as resolved.
- Reply to an existing comment by entering text in its **Reply** field.

As mentioned previously, you can also add comments to specific cells in the data table. To do this, select a cell and select the **Add a cell comment** button in the toolbar above the data grid. Cells that have comments show a comment symbol (purple speech bubble). To view the comment for a cell, select its comment symbol (or use the Copilot grid cursor). When you select the **Comments** button in the Action Pane at the top of the page, you'll see both the overall time series comments and all cell-specific comments.

Copilot grid cursor

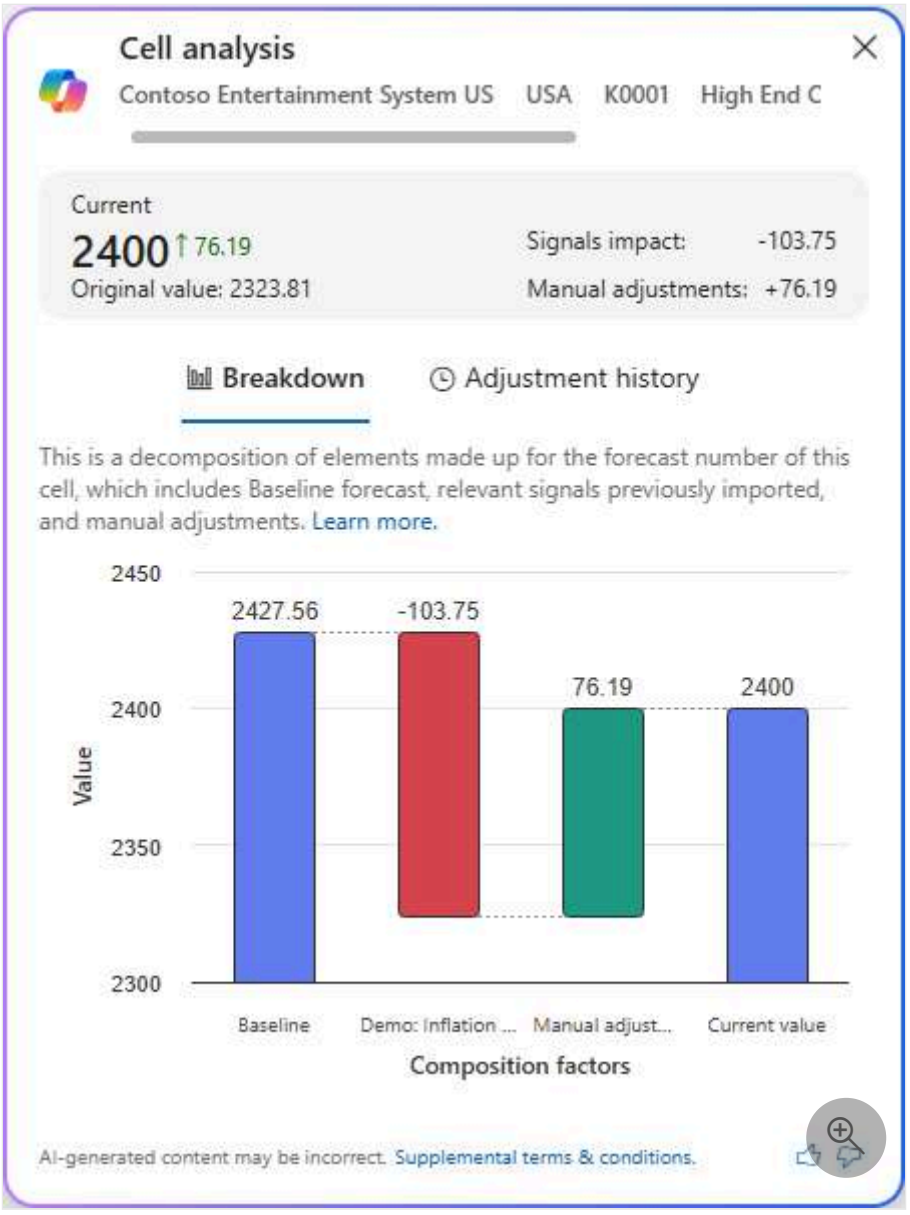
09/09/2025

The *Copilot grid cursor* offers detailed insights into a selected time-series cell's value, including its original value, manual adjustments, and full adjustment history. User comments are also shown, to help make the changes easier to understand.

To use the Copilot grid cursor, follow these steps:

1. Open the time series that you want to analyze. For example, on the navigation pane, select **Planning data** > **Forecasts**, and then select the time series.
2. In the **Time series values section**, find and select the cell that you want to analyze. After you select the cell, the Copilot grid cursor icon appears to the right of the cell and points to it.

3. Select the Copilot grid cursor icon to open the **Cell analysis** dialog for your selected cell.



4. Use the following features of the **Cell analysis** dialog to analyze the selected cell:

    - **Summary** – At the top of the dialog, you can see a summary of the cell's value and its history.
    - **Breakdown** – Select this button to see a graph that shows how the cell's value has been adjusted over time. The previous screenshot shows an example that indicates (from left to right) the baseline value (primary input), the signal impact, manual adjustments, and the current final value of a selected cell.
    - **Adjustment history** – Select this button to see a timeline that lists each time the cell was edited. To read the comments associated with a listed event, select the **Show details** button for the relevant row.

5. When you're done exploring the cell history, select the **Close** button in the upper-right corner of the dialog.

Generative insights for Demand planning (production-ready preview)

[This article is prerelease documentation and is subject to change.]

Generative insights offers detailed insights calculated using AI models. It currently supports two metrics: *seasonality* and *signal correlation*. The system clusters forecast data based on distinct patterns found for each metric.

Visual displays make it easy for planners to understand time series data and make business decisions based on it. Information is clustered (grouped) according to the detected patterns. For each cluster, generative insights provides a confidence score and describes the pattern in natural language. The system also indicates the proportion of planning items that follow the pattern.

> **Important**
>
> - This is a production-ready preview feature.
> - Production-ready previews are subject to supplemental terms of use.

To view generative insights, follow these steps:

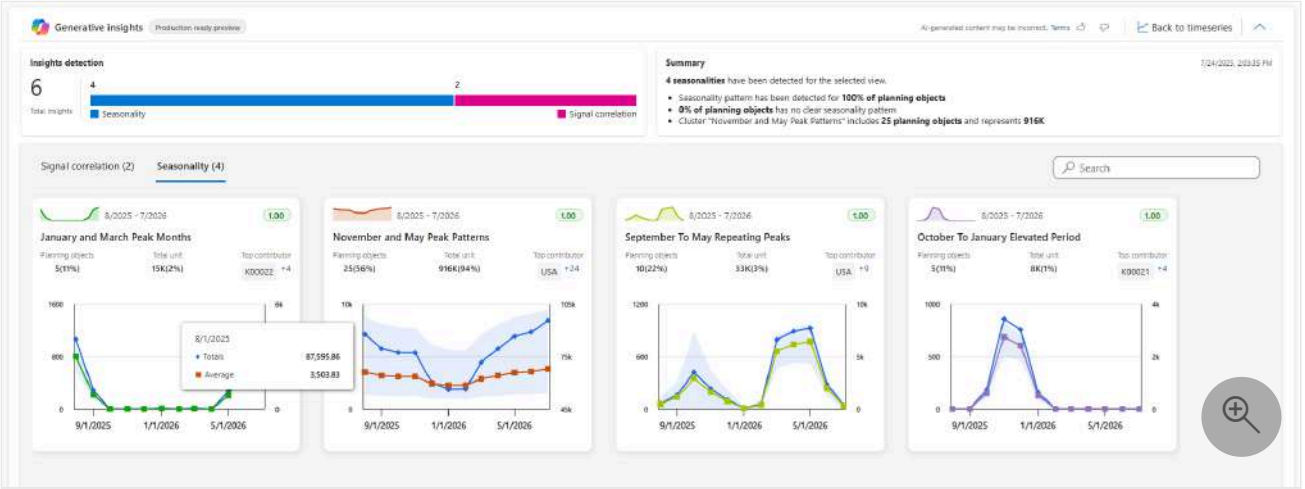
1. Open the time series that you want to analyze. For example, on the navigation pane, select **Planning data** > **Forecasts**, and then select a time series.
2. The **Generative insights** section appears near the top of the page. Do one of the following steps:
    - If you've never generated insights for the current time series, then select the **Generate insights** button available here. The system then runs the AI model to generate insights for the current time series. The process might take a few minutes, depending on the size of the time series.
    - If you have generated insights for the current time series, then summarized results are already shown. There's also a **Regenerate** button to regenerate the insights, which is useful if you've updated the time series since the last time you generated insights for it.

3. When insights are available, they are summarized in the **Generative insights** section (you might need to expand the section to see them). There are two tiles here:

    - **Insights detection** – Shows how many of each type of insight was detected in the time series.
    - **Summary** – Summarizes the insights that were detected.

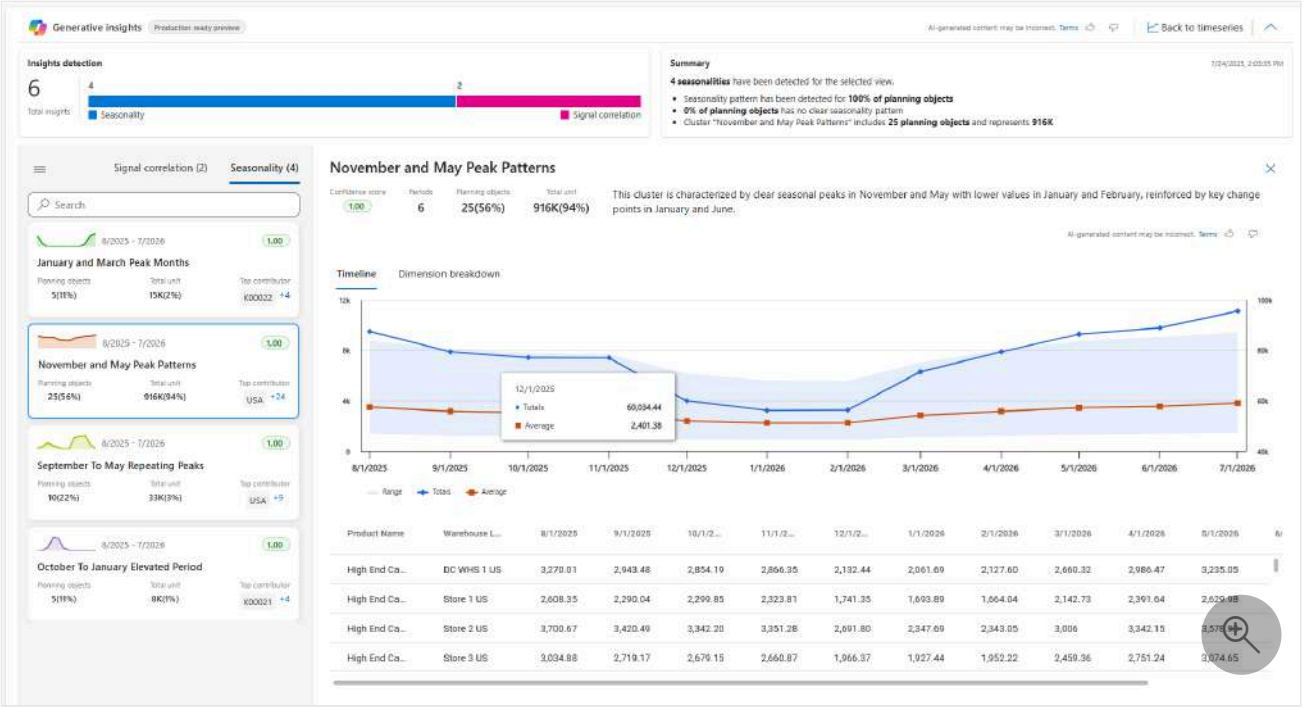
4. In the **Insight detection** tile, select **View insights** to see the details. Depending on what was detected, the system shows one or more of the following:

    - Several graphs of relevant data, with tabs that organize the data by insight type (**Signal correlation** and **Seasonality**). Select a tab to view insights of the indicated type.
    - A confidence score that indicates how confident the system is about each detected insight.
    - Various relevant KPI values for each insight.
    - A description of each insight, which is written in natural language. This description typically explains the detected pattern and its significance.



5. Select a graph on the **Signal correlation** or **Seasonality** tab to view even more details about it.

    - Some detailed graphs provide both a timeline view and data grid. Hover the mouse pointer to read timeline values. Select a row in the grid to add that row to the graph.
    - Some detailed graphs provide a dimension breakdown that lets you review the major contributors to the detected insights. For example, you can see which products or locations contributed most to the detected seasonality or signal correlation.



6. When you're done exploring the insights, select **Back to time series** to return to the time series.

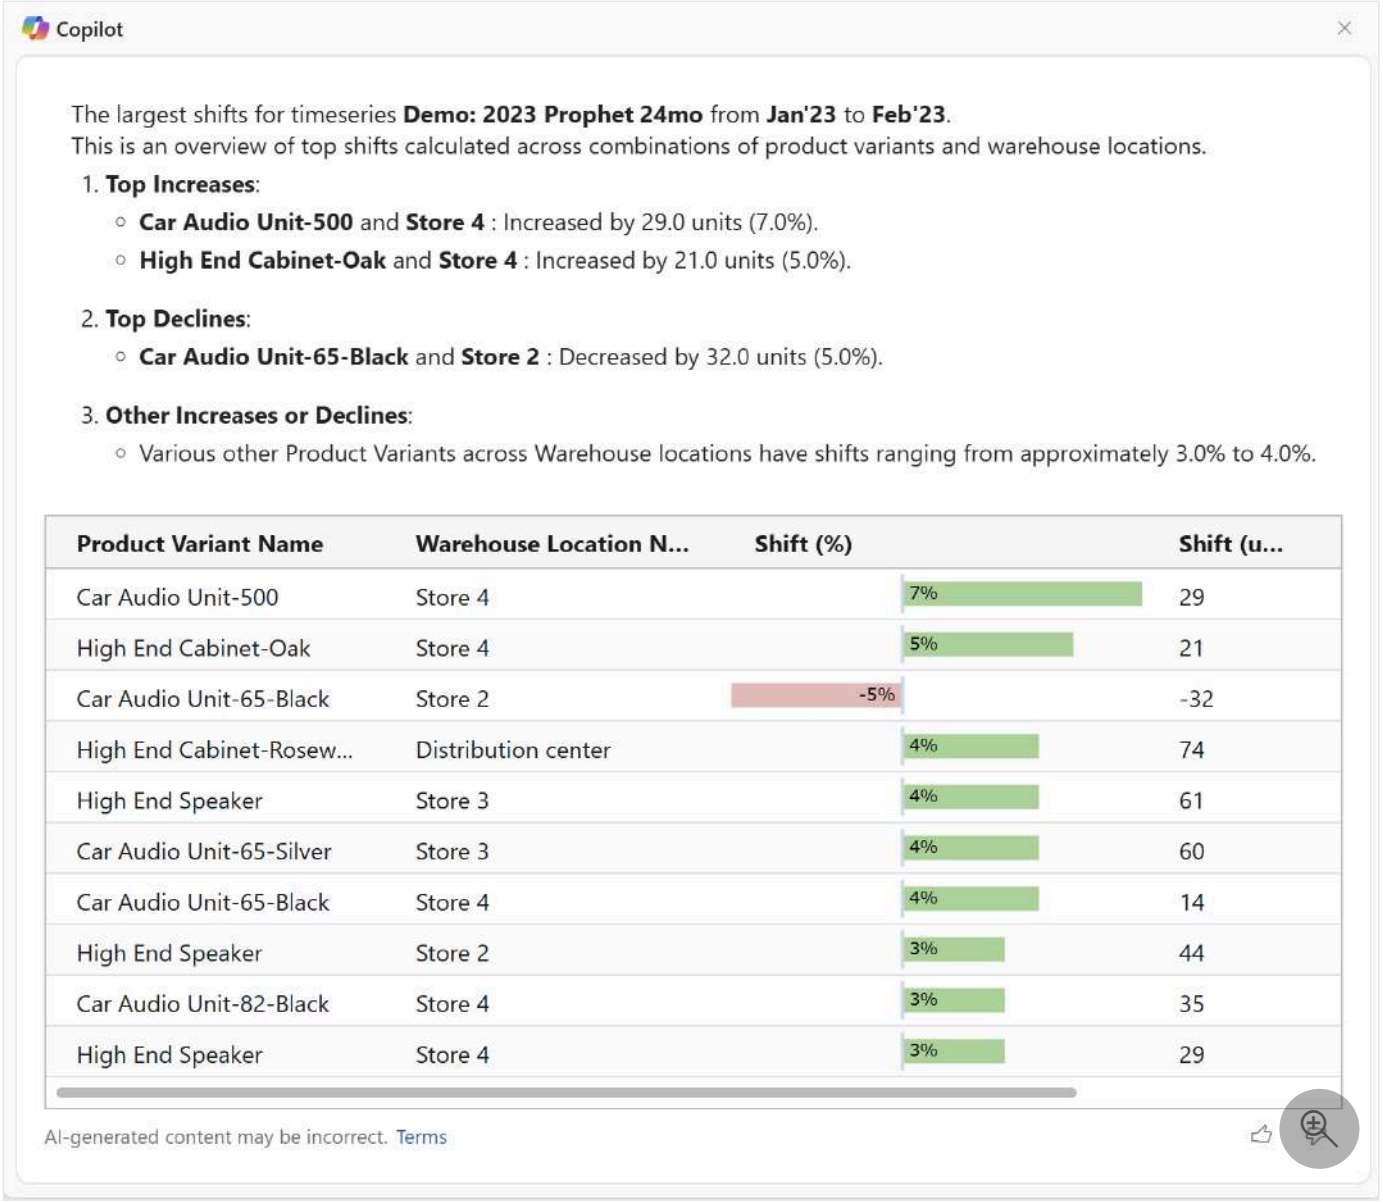
Analyze demand plans with Copilot

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Demand planning in Microsoft Dynamics 365 Supply Chain Management lets you use Copilot to analyze your demand plans. You can select from a set of predefined questions. The app then provides answers in real time by using natural language.

By using Copilot, you can quickly gain valuable insights across multiple dimensions. You can use these insights to improve operational efficiency, increase profitability, and improve customer satisfaction.

For example, a demand planner is interested in learning the most significant factors that contributed to a notable shift between two consecutive periods. The planner opens the relevant worksheet, selects a point of interest on the chart, and then selects a predefined question to ask Copilot. Copilot's response might resemble the following example.



Prerequisites

To use Copilot to analyze demand plans, you must be running the general availability (GA) version of Demand planning in Microsoft Dynamics 365 Supply Chain Management.

Country/region availability and language support

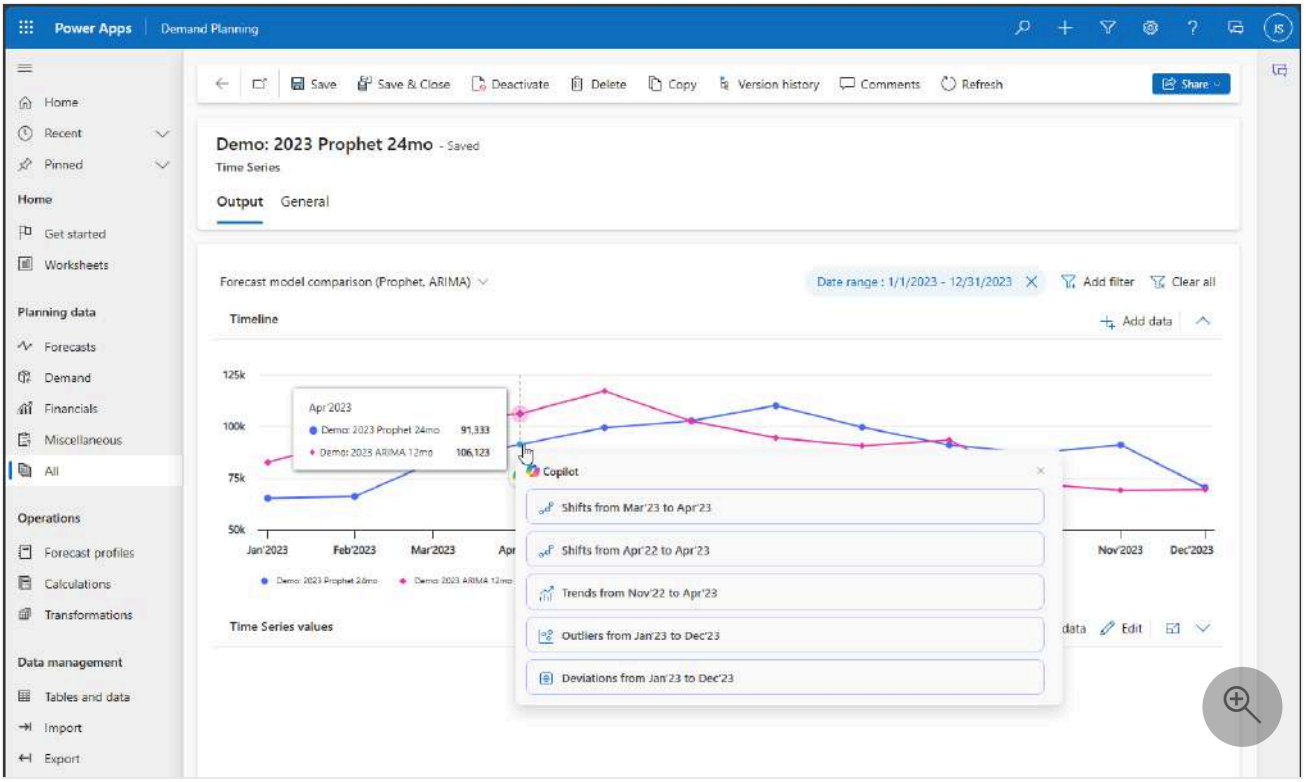
The *Analyze demand plans with Copilot* feature is available in all regions.

As of January 2025, the *Analyze demand plans with Copilot* feature is available in all languages supported by Demand planning.

Ask Copilot to analyze your data

To ask Copilot to analyze your data, follow these steps:

1. On the navigation pane, select **Worksheets**.
2. Open the worksheet that you want to analyze.
3. In the **Timeline** section, on the chart, select the point that represents the period that you want to analyze.
4. The **Copilot** menu shows one or more questions that you can ask about the selected point. Select the question that you want to ask. (For more information about the types of questions that can be shown, see the next section.)



5. Copilot analyzes the data and provides its answer.

Chat with Copilot

The following table provides a quick reference to the predefined questions that you can select on the **Copilot** menu.

Expand table

Example question	Description
Shifts from Apr '24 to May '24	Compare two consecutive periods in the same year. The length of the period (day, week, or month) depends on the setup of the time series in your worksheet. The example question that's shown here indicates that you selected a point that

Example question	Description
	represents the one-month period of May 2024. Copilot will compare that period to the previous one-month period (April 2024).
Shifts from May '23 to May '24	Compare a selected period to the same period one year earlier. The length of the period (day, week, or month) depends on the setup of the time series in your worksheet. The example question that's shown here indicates that you selected a point that represents the one-month period of May 2024. Copilot will compare that period to the one-month period of May 2023.
Trends from Nov '23 to Apr '24	Identify trends that occurred over the previous six time periods. The length of the period (day, week, or month) depends on the setup of the time series in your worksheet. The example question that's shown here indicates that you selected a point that represents the one-month period of April 2024. Copilot will analyze data across all available dimensions for the previous six months (November 2023 to April 2024) and highlight the most significant trends.
Outliers from Jan '24 to Dec '24	Analyze the full calendar year that includes the selected point and apply *interquartile range* (IQR) methodology to identify outlying values that occurred during that year. The example question that's shown here indicates that you selected a point that represents a period from 2024. Copilot will analyze data across all available dimensions to find outliers that occurred in the selected time series during the calendar year 2024.
Deviations from Jan '24 to Dec '24	Compare the selected time series to a second time series to identify the largest deviations that occurred between them during the selected calendar year. On choosing this question, Copilot asks you to choose a second time series included in the same worksheet. This question is only available if you're working with a worksheet that includes at least two time series. Copilot applies *mean average percentage error* (MAPE) methodology to identify the largest deviations occurring between the two selected time series over the selected calendar year.

Turn the Analyze demand plans with Copilot feature on or off

The *Analyze demand plans with Copilot* feature is on by default. Follow these steps to turn the feature on or off for your system. A system administrator of the environment must complete this procedure.

1. Sign in to the Power Apps maker portal.
2. Use the selector in the upper right of the page to select the environment where you want to turn the feature on or off.

3. Go to **Solutions**.
4. In the *Default Solution* row, select the link in the **Default name** column.
5. In the **Objects** list, select **Settings**.
6. In the *Copilot for demand planning* row, select the link in the **Display name** column.
7. In the **Edit Copilot for demand planning** dialog box, in the **Setting environment value** section, select **Add existing value**.
8. In the dropdown list, select *Yes* to enable the feature for the current environment, or select *No* to disable it.
9. Select **Save**.

Limit manual time series edits with time fences

08/18/2025

Time fences let demand planning managers define rules that prevent users from *manually* editing time series values that are associated with a specified time span. They ensure that agreed-upon plans remain intact and unchanged during specified periods. Time fences are similar to time freezes, which are used to prevent the system from *automatically* editing certain existing time series values when you use rolling forecasts or when you manually rerun a forecast to update an existing time series. However, time fences only prevent *manual* updates.

For example, users might be prevented from editing specific time series values that fall within the current month. However, they can still edit values for the previous month or the next month. Every time fence uses the bucket size of the time series to establish a time span that starts in the current period and extends a fixed number of periods into the future.

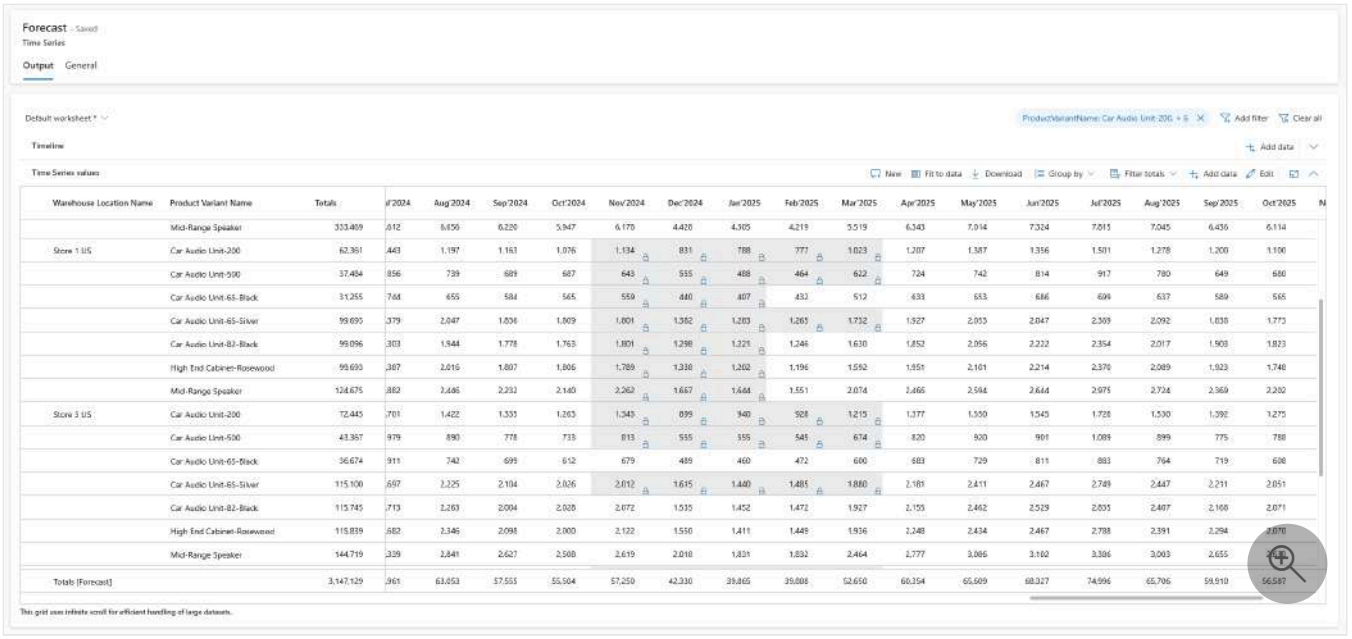
Time fences are defined as logical expressions and apply to all time series cells where the expression is true. For example, you could create a time fence that lasts two months and applies to product ID *K0001* in color *Red* for all time series that use *Monthly* time buckets.

Time fences are both flexible and easy to maintain. Managers create time fence rules based on the dimensions that are available in each plan. For example, a single product can be set up so that different time fences apply to each store or geographical location. Time fence rules can also apply based on each user's role. For example, a role-based time fence rule might allow managers to edit a forecast in a period that planners can't edit.

Time fence example

The following screenshot shows an example of a time series where two time fences apply. The time fences are represented by cells that show a lock symbol. This symbol indicates that the cells are locked. Therefore, the current user can't edit the values in them. However, the user can still edit the values in all unlocked cells. The following time fences apply here:

- Warehouse location name (**Warehouse location**) = *Store 1 US*; Time bucket = *Monthly*; Size = *Current period + 2 Time buckets*
- Product variant name (**Product**) = *Car Audio Unit-200, Car Audio Unit-500, Car Audio 65-Silver*; Time bucket = *Monthly*; Size = *Current period + 4 time buckets*



Manage time fences

To view, create, edit, or delete a time fence, follow these steps.

1. On the navigation pane, select **Configuration** > **Time fences**.

   The **Active time fence rules** page shows a list of active time fences. For each time fence, you can review the name, conditions, role, and other settings.

2. Follow one or more of these steps as required:

   - To create a new time fence, select **New** on the Action Pane.
   - To edit an existing time fence, select the link in the **Name** column.
   - To delete a time fence, select the row for it, and then, on the Action Pane, select **Delete**.
   - To view and edit inactive time fences, select the **Active time fence rules** heading, and then select **Inactive time fence rules** in the dropdown list.

3. If you chose to edit a time fence in the previous step, a tabbed window appears. If you choose to create a new time freeze, then a wizard launches, which offers similar settings. On the **Summary** edit tab (or **Get started** wizard page), set the following fields:

   - **Name** – Enter a name for the time fence.
   - **Description** – Enter a short description of the time fence.
   - **Owner** – Select the user account that owns the time fence record.
   - **Active** – Select whether the time fence should be active. (This option is only shown on the **Summary** edit tab. In the wizard, you can set this field on the **Review and finish** page.)

4. On the **Conditions** edit tab (or **Add conditions** wizard page), define the conditions under which the time fence applies. Use the **Add condition** and **Delete** (trashcan) buttons to add or remove rows as required. The rows are combined by using an *AND* operator. Therefore, the time fence locks only cells where the condition in *every* row is true. For each row, set the following fields:

    - **Table** – Select the data table that provides the cell value to compare.
    - **Column** – For the selected table, select the column that provides the cell value to compare.
    - **Operator** – Select the logic to apply to test the cell value against the row value. For example, select *equals*, *greater than*, or *less than*. There is also a *Select all* operator, which matches all values in the column; learn more in Using the select all operator.
    - **Value** – Enter a comma-separated list of values to compare the cell value to. You can either select among available values in a dropdown list or enter custom values. If you specify more than one value, the values are combined by using an *OR* operator. Therefore, the condition in the row is true for every time series cell that matches any one of the specified values. The **Value** field is disabled when you use the *Select all* operator.

5. On the **Time fence horizon** edit tab or wizard page, define the time span that the time fence applies to. The time span always starts in the time bucket that includes the current date. It then extends a fixed number of time buckets into the future. Set the following fields:

    - **Time buckets** – Specify the size of the time buckets that you want to use to define the time span. The time fence applies only to time series that also use this time bucket size. The system doesn't convert between time bucket sizes. For example, if you select *Monthly* here, your rule doesn't apply to time series that use *Weekly* time buckets (even though a month is about four weeks long).
    - **Current period +** – Specify the total number of time buckets, after the current one, to include in the time fence. The time fence always applies to the current time bucket. Therefore, if you want to include only the current time bucket in the time fence, set this field to *0* (zero). To include only the current time bucket and the next one, set this field to *1*.

    The **Example** area shows the time fence that results from your settings on this page.

6. On the **Role** edit tab (or **Select roles** wizard page), select the user security roles that the time fence applies to.

7. On the **Review and finish** wizard page (which isn't shown when you edit an existing time fence), review the settings that you made in the previous steps and set the **Active** option as needed. If everything looks correct, select **Review and Finish** to create the time fence.

Using the select all operator

To improve efficiency and make queries easier to formulate, Demand planning provides a *select all* operator for creating rules for time fences, time freezes, and row level access. The *Select all* operator matches all values in a selected column and doesn't require a value to compare to.

The following table provides an example that shows how the *select all* operator can be used in a time fence rule. As a result of the rules, all products except *Product A* have a two-month time fence. *Product A* has a three-month time fence.

Expand table

Conditions				**Ruling**			
Table	**Column**	**Operator**	**Value**	**Time bucket**	**Time bucket size**	**Role**	**Status**
Product	Product name	Select all	Not applicable	Monthly	2 months	All	Active
Product	Product name	Equals	Product A	Monthly	3 months	All	Active

Overlapping time fences

In situations where time fences overlap, the more specific condition applies. Here are some examples:

- A time fence for *all users* prevents a specific cell from being edited, but the time fence for the *manager* user role allows the cell to be edited. In this case, a user who has the *manager* role is allowed to edit the cell.
- A time fence of four months is set for *all products*, but a time fence of two months is set for *product 00001*. In this case, the time fence for *product 0001* is two months, but is four months for all other products that don't have more specific rules defined for them.

Limit automatic time series updates with time freezes

09/09/2025

Time freezes let planners define rules that prevent the system from automatically updating selected cells in existing time series when a forecast gets recalculated (such as when you use rolling forecasts or when you manually rerun a forecast to update an existing time series). Time freezes are similar to time fences, which are used to prevent users from *manually* editing certain time series values. However, time freezes only prevent *automated* updates that would otherwise occur when you rerun a forecast; users can still edit those values manually in the time series.

Unlike time fences (which apply to all time series that match the time fence logic), you must explicitly configure each relevant *Forecast* and *Forecast with signals* step to use the time freezes that should apply to it. You can assign any number of time freezes to each step, and you can also assign no time freezes at all. If you don't assign any time freezes to a step, then the step won't use any time freeze rules.

For example, the system might be prevented from updating specific forecast values that fall within the next three months. However, the system can still update values for the previous month or for four months from now. Time freezes use the bucket size of the time series to establish a time span that starts in the current period and extends a fixed number of periods into the future.

There are two types of time freezes:

- **Time freeze rules** – Time freeze rules are defined as logical expressions. For example, you could create a time freeze rule that lasts two months and applies to product ID *K0001* in color *Red*. The rule would then apply for all *Forecast* and *Forecast with signals* steps that have that time freeze assigned.
- **Freeze manual adjustments** – This type of time freeze is a simple on/off setting that you can enable for each *Forecast* and *Forecast with signals* step. When it's enabled, the system prevents automatic updates to any time series cells that have been manually adjusted by a user. No rules are required.

Manage time freeze rules

To view, create, edit, or delete a time freeze rule, follow these steps.

1. On the navigation pane, select **Configuration** > **Time freezes**.

The **Active time freeze rules** page shows a list of active rules. For each rule, you can review the name, conditions, and other settings.

2. Follow one or more of these steps as required:

   - To create a new time freeze rule, select **New** on the Action Pane.
   - To edit an existing time freeze rule, select the link in the **Name** column.
   - To delete a time freeze rule, select the row for it, and then, on the Action Pane, select **Delete**.
   - To view and edit deactivated time freeze rules, select the **Active time freeze rules** heading, and then select **Inactive time freeze rules** in the dropdown list. Other views are also available here, including views for viewing only daily, monthly, or weekly time freeze rules.

3. If you chose to edit a time freeze rule in the previous step, a tabbed window appears. If you choose to create a new time freeze, then a wizard launches, which offers similar settings. On the **Summary** edit tab (or **Get started** wizard page), set the following fields:

   - **Name** – Enter a name for the rule.
   - **Description** – Enter a short description of the rule.
   - **Owner** – Select the user account that owns the time freeze rule record.
   - **Active** – Select whether the rule should be active. Inactive rules have no effect, even when explicitly assigned to step. (This option is only shown on the **Summary** edit tab. In the wizard, you can set this option on the **Review and finish** page.)

4. On the **Conditions** edit tab (or **Add conditions** wizard page), define the conditions under which the rule applies. Use the **Add condition** and **Delete** (trashcan) buttons to add or remove rows as required. The rows are combined by using an *AND* operator. Therefore, the rule locks only cells where the condition in *every* row is true. For each row, set the following fields:

   - **Table** – Select the data table that provides the cell value to compare.
   - **Column** – For the selected table, select the column that provides the cell value to compare.
   - **Operator** – Select the logic to apply to test the cell value against the row value. For example, select *equals*, *greater than*, or *less than*. There's also a *Select all* operator, which matches all values in the column (learn more in Using the select all operator).
   - **Value** – Enter a comma-separated list of values to compare the cell value to. You can either select among available values in a dropdown list or enter custom values. If you specify more than one value, the values are combined by using an *OR* operator. Therefore, the condition in the row is true for every time series cell that matches any one of the specified values. The **Value** field is disabled when you use the *Select all* operator.

5. On the **Time freeze horizon** edit tab or wizard page, define the time span that the time freeze rule applies to. The time span always starts in the time bucket that includes the current date. It then extends a fixed number of time buckets into the future. Set the following fields:

    - **Time buckets** – Specify the size of the time buckets that you want to use to define the time span. The time freeze rule can only be used with forecast profiles that also use this time bucket size. The system doesn't convert between time bucket sizes. For example, if you select *Monthly* here, your rule won't be available to forecast models in profiles that use *Weekly* time buckets (even though a month is about four weeks long).
    - **Current period +** – Specify the total number of time buckets, after the current one, to include in the time freeze rule. The rule always applies to the current time bucket. Therefore, if you want to include only the current time bucket in the rule, set this field to *0* (zero). To include only the current time bucket and the next one, set this field to *1*.

    The **Example** area shows the time freeze rule that results from your settings on this page.

6. On the **Review and finish** wizard page (which isn't shown when you edit an existing rule), review the settings that you made in the previous steps and set the **Active** option as needed. If everything looks correct, select **Review and Finish** to create the rule.

Add a time freeze rule to a forecast profile

As mentioned, you must explicitly configure each relevant *Forecast* and *Forecast with signals* step to use the time freeze rules that should apply to it. To do this, follow these steps:

1. Create the time freeze records that you want to use, as described in the previous sections of this article.
2. Create or open a relevant forecast profile as described in Work with forecast profiles.
3. On the **Forecast model** tab, crate or select the step that you want to add a time freeze rule to. The step must be a *Forecast* or *Forecast with signals* step. (Learn more in Design forecast models.) If you're editing an existing step, open the **Actions** menu for the step and then select **Settings**.
4. In the Freeze values section, select the **Enable time freeze** check box.
5. Select the **Use time freeze** rules radio button.
6. Use the **Time freeze rules** field to search for and select the time freeze rules that you want to apply to the step.

Freeze manual adjustments for a selected forecast profile

To prevent the system from automatically updating any time series cells that have been manually adjusted by a user, use the following procedure. You don't need to create any time freeze rules to use this feature.

1. Create or open a relevant forecast profile as described in Work with forecast profiles.
2. On the **Forecast model** tab, crate or select the step that you want to add a time freeze rule to. The step must be a *Forecast* or *Forecast with signals* step. (Learn more in Design forecast models.) If you're editing an existing step, open the **Actions** menu for the step and then select **Settings**.
3. In the Freeze values section, select the **Enable time freeze** check box.
4. Select the **Freeze manual adjustments** rules radio button.

Clean up time series data

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Almost every operation that changes a time series in Demand planning—such as running a transformation, calculation, or forecast—creates a new version. This version history is valuable, but over time, unused versions and entire time series that you no longer need accumulate and consume storage.

The *data cleanup* feature lets you review everything that's stored and permanently delete the versions and time series you no longer need. The feature shows you exactly what you're removing, including its size and anything that still references it, so you can make informed decisions before deleting.

> **Important**
>
> Deletion is permanent and can't be undone. Always review the details shown in the confirmation dialog before proceeding.

Required security role

Only users with the *Demand planning manager* role can access data cleanup. This restriction ensures that only authorized users can permanently remove data.

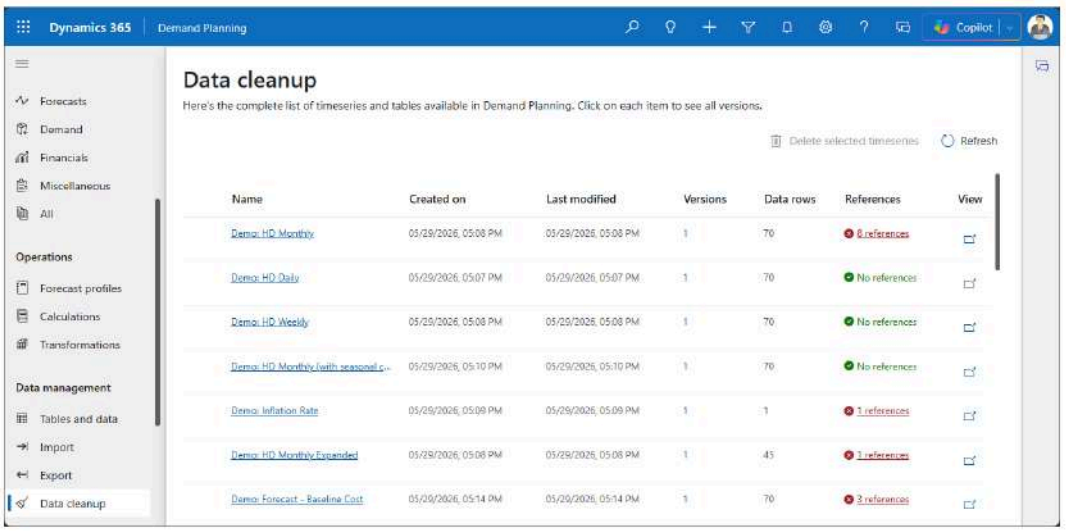
Open the data cleanup page

To review and clean up time series data, open the Demand planning app, go to the navigation pane, and select **Data management** > **Data cleanup**.

The **Data cleanup** page shows a list of all time series in the system. For each time series, you can see the number of versions, the number of data rows, and whether any references to the time

series or its versions still exist.

- Select a time series name to see its versions.
- Select the link in the **References** column to open a list of profiles that are using the time series as input.
- Select the link in the **View** column to open the time series itself.

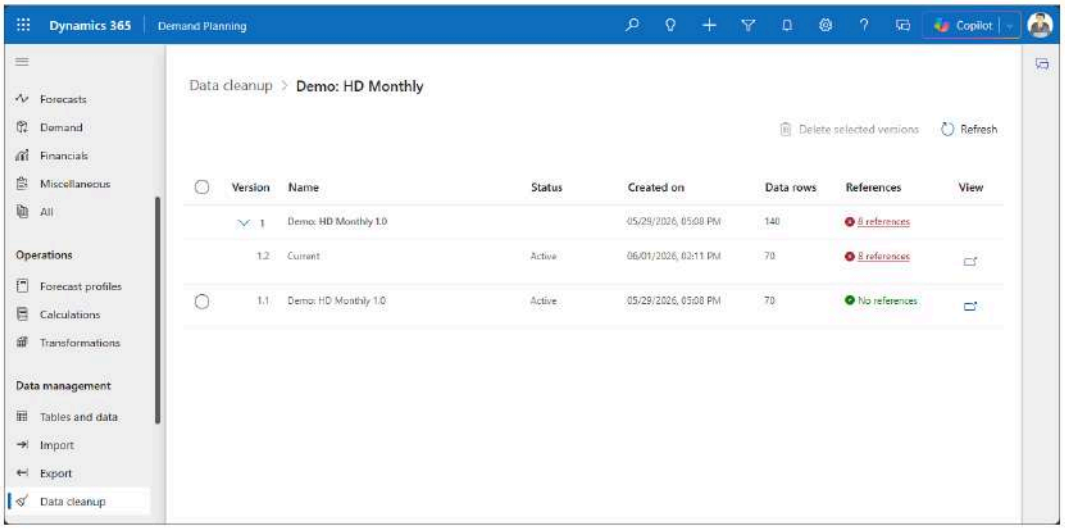


View time series versions

To view the versions of a time series, open the the **Data cleanup** page and select the link in the **Name** column for the target time series.

The versions view shows a list of all major and minor versions of the selected time series, along with details such as their status, creation date, number of data rows, and references.

- The newest versions appear first. The version currently in use is named *Current*.
- Expand or collapse major versions to show or hide their minor versions.
- Select the link in the **References** column to open a list of profiles that use the time series version as input.
- Select the link in the **View** column to open the version itself.



Understand time series versions

Versions are organized in two levels:

- **Major versions** – Created by a job or action such as a transformation, calculation, forecast, revert, or copy. They're numbered sequentially (1, 2, 3, and so on).
- **Minor versions** – Individual data versions within a major version. They're numbered hierarchically (1.1, 1.2, and so on). Users name minor versions and they typically represent saved edits of the major version.

Learn more about how to create and manage versions in Time series, worksheets, and planning data.

Understand version statuses

Each version listed on the version view of the **Data cleanup** page shows one of the following status values:

- *Active* – The version exists normally and is available for use.
- *Marked for deletion* – You confirmed the deletion of this version. A background cleanup process will soon remove the version. This is a normal intermediate state, not an error.
- *Failed deletion* – A cleanup attempt didn't finish, typically because of a temporary issue. The system retries these automatically, so a version might briefly show this status before the retry succeeds.

Understand references

When you use a time series or time series version as input for a calculation or forecast profile, the system creates a reference between the time series and the profile. To preserve data integrity, the

system doesn't allow you to delete a time series or version that is referenced by a profile. You must remove all references to a time series or version before you can delete it. The **Data cleanup** page shows the number of references for each version and provides tools for viewing and removing them, as described later in this article.

Delete time series versions

To delete one or more versions of a time series, follow these steps:

1. On the navigation pane, select **Data management** > **Data cleanup**.
2. Find the time series that has the versions you want to delete and select the link in the **Name** column to open the versions view for that time series.
3. Find a version you want to delete and check the **References** column for that time series version. If it shows that references exist, do the following steps:

    - Select the link in the **References** column to open a dialog that lists the profiles that use your target time series version.
    - Open each listed profile and either delete it or change its settings to use a different input.
    - When you've removed all references, close the dialog to return to the **Data cleanup** page.

4. Repeat the previous step as needed for each version you want to delete.
5. In the versions view, select the check box for each version you want to delete. Selecting a major version automatically selects all of its eligible minor versions, and clearing it clears them. You can't select the *Current* version or any version that has references.
6. On the toolbar, select **Delete selected versions**.
7. You're asked to confirm the deletion. Select **Confirm** to proceed, or **Cancel** to back out.

> ⓘ **Note**
>
> Deleting versions of a time series also affects worksheets that include them. If the deleted version is the main version for a worksheet, the system also deletes the worksheet. If a deleted version isn't the main version, then the system just deletes its reference from the worksheet, which means that the worksheet still appears but without the deleted version.

Delete an entire time series

To delete one or more complete time series, including all of their versions and data, follow these steps.

1. On the navigation pane, select **Data management** > **Data cleanup**.
2. Find the time series you want to delete.
3. Check the **References** column for your selected time series. If it shows that references exist, do the following steps:

    - Select the link in the **References** column to open a dialog that lists the profiles that use your target time series.
    - Open each listed profile and either delete it or change its settings to use a different input.
    - When you've removed all references, close the dialog to return to the **Data cleanup** page.

4. For your target time series, select the checkbox in the left column.
5. On the toolbar, select **Delete selected timeseries**.
6. You're asked to confirm the deletion. Select **Confirm** to proceed, or **Cancel** to back out.

> ⓘ **Note**
>
> Deleting time series also affects worksheets that include them. If the deleted time series is the main time series for a worksheet, the system also deletes the worksheet. If a deleted time series isn't the main time series, then the system just deletes its reference from the worksheet, which means that the worksheet still appears but without the deleted time series.

Export and download data

Article • 01/10/2025

When you've finished creating, analyzing, and editing a forecast, you can export it back to Microsoft Dynamics 365 Supply Chain Management. Alternatively, you can download the data as a comma-separated values (CSV) file that can be viewed in Excel.

Export to Supply Chain Management

View and run existing data export profiles to export to Supply Chain Management

Demand planning lets you build a collection of *export profiles*. Each Supply Chain Management export profile exports data to a specific Supply Chain Management instance. Typically, a manager or system administrator creates the initial collection of required profiles. Forecasters and other users can then run the profiles to export as they require.

To run an existing data export profile, follow these steps.

1. On the navigation pane, select **Data management** > **Export**.
2. Find the profile for the type of export that you want to run, and select the link for it in the **Name** column.

   The details page for the selected profile appears. Supply Chain Management export profiles contain the following tabs:

   - **Get started** – This tab provides basic information about the profile. You can edit the name and/or description to make the profile easier to identify and work with.
   - **Map columns** – This tab shows how the selected profile maps columns in Demand planning to columns in the target system. You can edit the mappings from here as you require.
   - **Define data export rules** – This tab shows any export rules that have been defined for the profile. You can edit the settings from here as you require.
   - **Run schedule** – This tab lets you set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.
   - **Jobs** – This tab shows a list of every run of the profile.

3. To run the profile, select **Run** on the Action Pane. This command adds a new row to the grid on the **Jobs** tab. There, you can follow the status of the new export. The page isn't automatically refreshed. To update the status information, you must select **Refresh** on the grid toolbar.

Create and manage profiles for export to Supply Chain Management

Each time that your organization has to run a new type of data export, a manager or admin must create a new data export profile. After the profile is created, it becomes available to users, who can run it as often as they require. Each profile exports to either Supply Chain Management or a CSV file, depending on how you set it up. This section describes how to create a profile that exports to your selected Supply Chain Management instance.

1. On the navigation pane, select **Data management** > **Export**.
2. On the Action Pane, select **New**.
3. On the **Select data provider** page, select the **Microsoft finance and operations apps** tile.
4. A setup wizard is opened. On the **Get started** page, enter a name and description for the new profile. Then select **Next**.
5. On the **Configure data provider** page, in the **Connection URL** field, enter the URL of your Supply Chain Management environment. Then select **Next**.
6. On the **Select output data** page, select the time series to export to Supply Chain Management. You must select exactly one time series.

    - The **Available** tab shows a list of available time series. Select the time series to export in the grid, and then select **Include data source** on the toolbar. By default, the most recent version of the selected time series is exported. However, you can select older versions on the **Included** tab.

    - The **Included** tab shows the time series that's selected for export.
        - If more than one version of the time series is available, select the version that you want to use in the **Output version** field.
        - To remove a time series, select it, and then select **Remove** on the toolbar.
        - To set up one or more filter rules to apply to the exported data, select **Filter data source** on the toolbar.

7. When you've finished selecting and setting up the time series to export, select **Next**.

8. On the **Map columns** page, use the dropdown lists to map each column in the selected time series to the appropriate column in the target Supply Chain Management data entity. When you've finished, select **Next**.

9. On the **Define data export rules** page, specify the target company (legal entity) and forecast model ID to export the data to. You can select **All** to export all the data to the same company and forecast model, or you can select **Custom** to set up rules for splitting the export between different forecast models.

10. Select **Next**.

11. On the **Set run schedule** page, you can choose to set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.

12. Select **Next**.

13. On the **Review and finish** page, review the summary of settings that you've configured, and then select **Review and finish** to create the new profile.

14. The profile is now available, but it hasn't yet run. To run it, follow the instructions in the View and run existing data export profiles to export to Supply Chain Management section.

Export to a CSV file

Download a time series values grid as a CSV file

You can download the **Time series values** grid from any selected time series as a CSV file. The CSV file presents the data just as it's presented in the **Time series values** grid for the time series. In other words, it has a row for each combination of dimensions and a column for each dimension, the grand total value, and the value for each available date.

If you require a file that has a row for each date instead, you should create a CSV export profile and run it as described in the Create and manage profiles for export to CSV section. This type of CSV file might be more useful for importing data into other systems.

To export the **Time series values** grid from any selected time series to a CSV file, follow these steps.

1. Open the time series that you want to export from.
2. On the **Time series values** FastTab, select **Download** on the toolbar.

The file is saved as a CSV file in your local download folder.

View and run existing data export profiles to export to CSV

Demand planning lets you build a collection of *export profiles*. Each CSV export profile exports data from a selected time series to a CSV file that's saved on your local computer. The CSV file includes a row for each date and columns for the date, value, and each dimension.

Typically, a manager or system administrator creates the initial collection of required profiles. Forecasters and other users can then run the profiles to export as they require.

To run an existing data export profile, follow these steps.

1. On the navigation pane, select **Data management** > **Export**.

2. Find the profile for the type of export that you want to run, and select the link for it in the **Name** column.

   The details page for the selected profile appears. CSV export profiles contain the following tabs:

   - **Get started** – This tab provides basic information about the profile. You can edit the name and/or description to make the profile easier to identify and work with.
   - **Run schedule** – This tab lets you set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.
   - **Jobs** – This tab shows a list of every run of the profile.

3. To run the profile, select **Run** on the Action Pane. This command adds a new row to the grid on the **Jobs** tab. There, you can follow the status of the new export. The page isn't automatically refreshed. To update the status information, you must select **Refresh** on the grid toolbar.

4. When the job is finished, select **Download** on the Action Pane to download the data as a CSV file and save it in your local download folder.

Create and manage profiles for export to CSV

Each time that your organization has to run a new type of data export, a manager or admin must create a new data export profile. After the profile is created, it becomes available to users, who can run it as often as they require. Each profile exports to either Supply Chain Management or a CSV file, depending on how you set it up. This section describes how to create a profile that exports to CSV.

1. On the navigation pane, select **Data management** > **Export**.
2. On the Action Pane, select **New**.
3. On the **Select data provider** page, select the **CSV** tile.
4. A setup wizard is opened. On the **Get started** page, enter a name and description for the new profile. Then select **Next**.
5. On the **Configure data provider** page, in the **Connection URL** field, enter the URL of your Supply Chain Management environment. Then select **Next**.
6. On the **Select output data** page, select the time series to export to CSV. You must select exactly one time series.
    - The **Available** tab shows a list of available time series. Select the time series to export in the grid, and then select **Include data source** on the toolbar. By default, the most recent version of the selected time series is exported. However, you can select older versions on the **Included** tab.
    - The **Included** tab shows the time series that's selected for export.
        - If more than one version of the time series is available, select the version that you want to use in the **Output version** field.
        - To remove a time series, select it, and then select **Remove** on the toolbar.
        - To set up one or more filter rules to apply to the exported data, select **Filter data source** on the toolbar.
7. When you've finished selecting and setting up the time series to export, select **Next**.
8. On the **Set run schedule** page, you can set up a schedule for the profile to run automatically. For details about this functionality and how to configure it, see Rolling forecasts.
9. Select **Next**.

10. On the **Review and finish** page, review the summary of settings that you've configured, and then select **Review and finish** to create the new profile.

11. The profile is now available, but it hasn't yet run. To run it, follow the instructions in the View and run existing data export profiles to export to CSV section.

Improve performance by clearing unneeded staging data

If you're experiencing performance issues, it might help to clear staging data from the *Forecast Sales Import Entity* entity in Supply Chain Management. To do this, take one of the following actions:

- Manually clear the staging data as needed.
- Set up an automatic cleanup process to clear the staging data on a regular basis.

Export data using custom APIs

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Overview

You can programmatically export Demand planning data (forecasts and time series) to external systems using Dataverse custom API actions. This approach enables you to automate export workflows without needing to manually interact with the Demand planning interface. The custom APIs support retrieving exported data as comma-separated values (CSV) files through secure shared access signature (SAS) URLs.

Dataverse custom API actions provide the public interface for export operations. You can call them using:

- **Dataverse Web API** – OData HTTP requests for external applications and services
- **Power Platform tools** – Native integration with Power Automate, custom connectors, and Dataverse plugins

> **Note**
>
> This article describes programmatic export using Dataverse custom APIs. Learn how to export data using the Demand planning interface in Export and download data.

Prerequisites

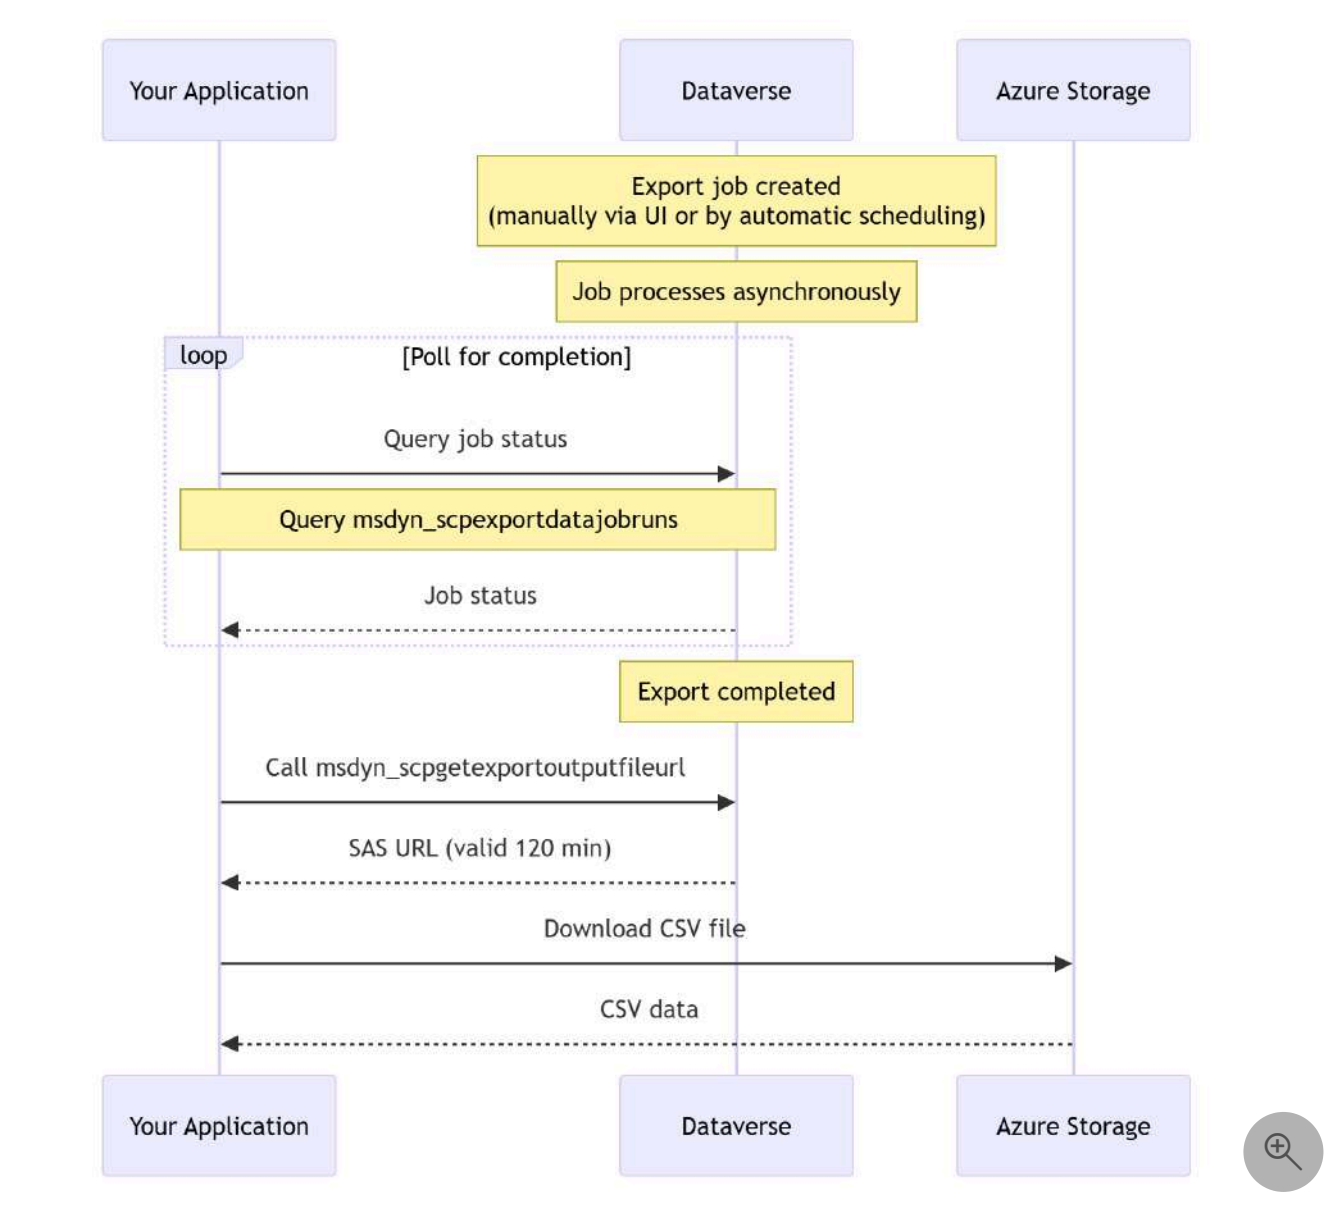
Before you use the export custom APIs, make sure you have:

- An export profile configured in Demand planning. Learn how to create export profiles in Export and download data.
- Access to the Dataverse environment for your Demand planning instance.

> **Tip**
>
> To find your export profile ID, open the export profile in the Demand planning interface and copy the GUID from the browser URL. Alternatively, query the `msdyn_scpexportdataprofile` entity using the Dataverse Web API to retrieve profile IDs programmatically.

Export data programmatically

The following diagram shows the workflow for exporting data using Dataverse custom APIs:



To export Demand planning data using Dataverse custom APIs, follow these steps:

1. **Create an export job** – Create an export job using the Demand planning interface. You can create jobs manually or configure scheduled jobs within the Demand planning

application. The job creation process runs asynchronously, so the export job is created immediately and then processes in the background.

2. **Monitor job status** – Poll the Dataverse **Export Job Run** entity (`msdyn_scpexportdatajobruns`) to track job progress. Query the entity using Dataverse Web API OData queries to check the `msdyn_jobrunstatus` field. Learn more in Monitor job status.

3. **Retrieve the file URL** – When the job status shows as completed (status value 192350002), call the `msdyn_scpgetexportoutputfileurl` custom API action to retrieve a SAS URL for downloading the exported file. The URL is valid for 120 minutes. Learn more in Power Platform integration.

4. **Download the file** – Use the returned SAS URL to download the CSV file. The file contains your exported Demand planning data in the format described in the Export file format section.

Monitor job status

After scheduling an export job, monitor its progress by querying the Dataverse **Export Job Run** entity. Export jobs run asynchronously, so you need to poll for status updates until the job completes.

Entity details

Query the following Dataverse entity to check export job status:

Expand table

Property	Value
Entity name	`msdyn_scpexportdatajobrun`
Display name	Export Job Run

The following table lists the key fields in the `msdyn_scpexportdatajobrun` entity that are relevant for monitoring export jobs:

Expand table

Field name	Description
`msdyn_jobrunstatus`	Current job status (see status values in the next section)
`msdyn_name`	Job name provided when scheduling
`msdyn_starttime`	Job start timestamp
`msdyn_endtime`	Job completion timestamp
`msdyn_errormessage`	Error details if the job failed
`_msdyn_profile_value`	Associated export profile ID (lookup field)

Job status values

The `msdyn_jobrunstatus` field uses the following integer values:

Expand table

Status	Value	Description
Created	192350000	Job is created but not started yet
Executing	192350001	Job is currently running
Completed	192350002	Job finished successfully
Failed	192350003	Job encountered an error
Canceling	192350004	Job cancellation in progress
Canceled	192350005	Job was cancelled

Query examples

Use Dataverse Web API OData queries to retrieve job status. The base query pattern is:

OData

```
GET [Organization URI]/api/data/v9.2/msdyn_scpexportdatajobruns?$filter={filter expression}&$select={columns}
```

The following examples show common query patterns for monitoring export jobs.

Filter by completed status:

OData

```
GET [Organization URI]/api/data/v9.2/msdyn_scpexportdatajobruns?
$filter=msdyn_jobrunstatus eq 192350002&$select=msdyn_name,msdyn_endtime
```

Filter by export profile:

OData

```
GET [Organization URI]/api/data/v9.2/msdyn_scpexportdatajobruns?
$filter=_msdyn_profile_value eq 11111111-1111-1111-1111-
111111111111&$select=msdyn_name,msdyn_jobrunstatus
```

Combine multiple filters:

OData

```
GET [Organization URI]/api/data/v9.2/msdyn_scpexportdatajobruns?
$filter=msdyn_jobrunstatus eq 192350002 and _msdyn_profile_value eq 11111111-1111-
1111-1111-111111111111
```

> **Note**
>
> When calling Dataverse Web API endpoints, authenticate by using one of the supported methods. Options include OAuth tokens, Azure managed identities, Azure DefaultAzureCredential, or service principal authentication. For detailed guidance on authentication options and implementation, see Authenticate with Microsoft Dataverse web services.

> **Tip**
>
> For Dataverse-native integrations, you can also use the `msdyn_scpgetexportoutputfileurl` custom API action to retrieve the output file URL directly from Dataverse.

For more information about Dataverse Web API queries, see Query data using the Web API.

Power Platform integration

For Power Platform scenarios such as Power Automate flows, custom connectors, or Dataverse plugins, use Dataverse custom API actions. These actions provide native integration with the Power Platform ecosystem.

Available custom API actions

The following custom API action is available for export operations:

Expand table

Action name	Description	Use case
`msdyn_scpgetexportoutputfileurl`	Retrieves the SAS URL for a completed export file	Downloading exported data in Power Automate flows or custom code

Use the custom API action

The `msdyn_scpgetexportoutputfileurl` action retrieves a SAS URL for downloading the exported CSV file from a completed export job.

The following table lists the input parameters required to call the `msdyn_scpgetexportoutputfileurl` custom API action:

Expand table

Parameter name	Type	Required	Description
`msdyn_exportprofileid`	String (GUID)	Yes	The ID of the export profile

The following table describes the output returned by the `msdyn_scpgetexportoutputfileurl` custom API action:

Expand table

Property name	Type	Description
`output`	String	The SAS URL for downloading the exported CSV file (valid for 120 minutes)

Use the `msdyn_scpgetexportoutputfileurl` custom API action in the following scenarios:

- **Power Automate flows** – Use the *Perform an unbound action* step to call the custom API action natively.
- **Custom connectors** – Invoke the custom API action through Dataverse connectors.
- **External applications** – Call the custom API action via Dataverse Web API (OData HTTP requests).
- **Dataverse plugins** – Execute the custom API action from within plugin code.

Example: Power Automate flow

To retrieve an export file URL in Power Automate:

1. Add the *Perform an unbound action* step.
2. Select the action name `msdyn_scpgetexportoutputfileurl`.
3. Enter the export profile ID as `msdyn_exportprofileid`.
4. Use the `output` property to download the file or pass the URL to subsequent steps.

> **Note**
>
> The custom API action requires Dataverse authentication and appropriate permissions. Make sure your application or Power Platform connection has access to the Dataverse organization where Demand planning is deployed.

For more information about using custom API actions in Power Platform, see Use custom APIs.

Walkthrough: Automatically download exports to SharePoint

This walkthrough shows how to create a Power Automate flow that automatically downloads completed export files to a SharePoint folder. The flow monitors export job completions and retrieves the CSV file by using the custom API action.

Scenario

When an export job completes in Demand planning, the flow automatically:

1. Detects the completed job
2. Retrieves the export file URL by using the custom API action
3. Downloads the CSV file
4. Saves it to a designated SharePoint folder

Scenario prerequisites

To implement this scenario, you need the following prerequisites:

- Access to Power Automate with a Dataverse connection
- SharePoint site and folder for storing export files
- Export profile configured in Demand planning

Create the flow

To create the flow, follow these steps:

1. **Add trigger** – Use the *When a row is added, modified or deleted* trigger

    - Set **Change type** – Added, Modified, or Deleted
    - Set **Table name** – Export Data Job Runs (`msdyn_scpexportdatajobruns`)
    - Set **Filter rows** – `msdyn_jobrunstatus eq 192350002` (filters for completed jobs only)
    - Optional: Add `_msdyn_profile_value eq {your-profile-guid}` to filter for specific export profiles

2. **Get export file URL** – Add the *Perform an unbound action in selected environment* step

    - Set **Environment** – Your Dataverse environment
    - Set **Action name** – `msdyn_scpgetexportoutputfileurl`
    - Set **msdyn_exportprofileid** – The known export profile ID, or use the profile ID from the trigger output

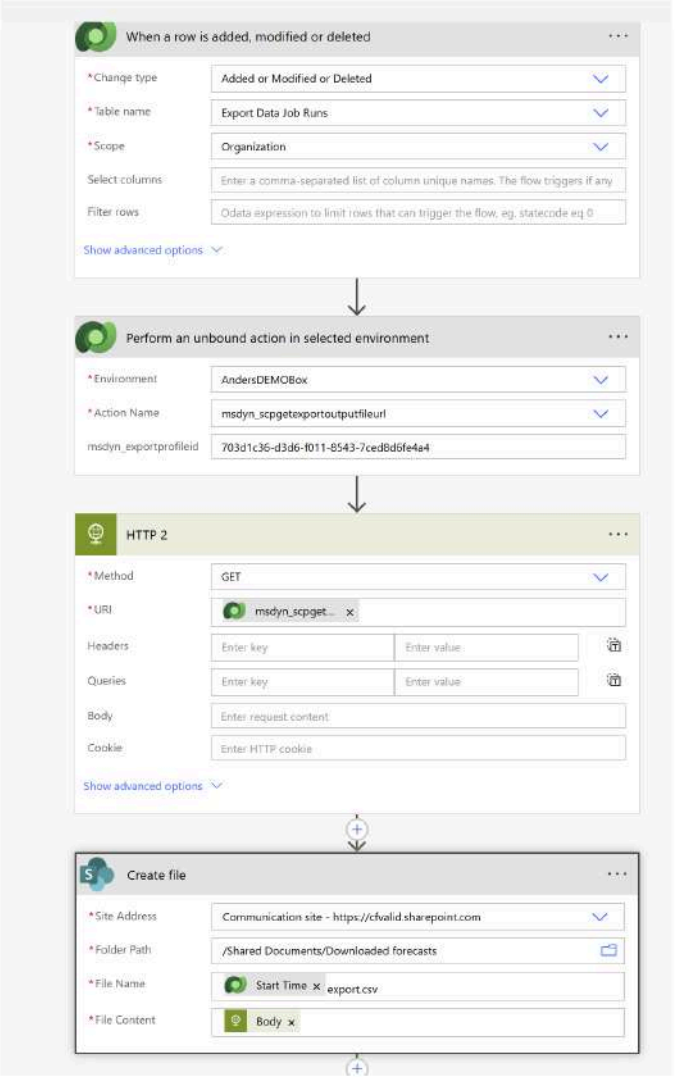
3. **Download file** – Add the *HTTP 2* action

    - Set **Method** – GET
    - Set **URI** – Use the `output` from the previous step (the SAS URL)

4. **Save to SharePoint** – Add the *Create file* action (SharePoint)

    - Set **Site address** – Your SharePoint site
    - Set **Folder path** – Your target folder
    - Set **File name** – Use the job name from trigger or create a naming pattern
    - Set **File content** – Use the body output from the HTTP download step

The following image shows the final created flow:



> **Tip**
>
> To download exports from multiple profiles, remove the profile filter from the trigger. The flow processes all completed export jobs. You can add condition logic to route files to different SharePoint folders based on the profile ID.

Export file format

The exported files use a standard comma-separated values (CSV) format with configurable columns.

CSV structure

Exported files have the following standard columns:

- **Time** – Timestamp of the data point (format configurable via organization settings)
- **Value** – The numeric value (forecast, demand, and so on)

- **Dimension columns** – Additional columns based on the time series dimensions (such as Product, Location, Customer)

Here's an example of CSV file content:

```csv
Time,Value,Product,Location
2024-01-01,1500.50,PROD001,WH-EAST
2024-01-02,1623.75,PROD001,WH-EAST
2024-01-01,892.25,PROD002,WH-WEST
2024-01-02,945.00,PROD002,WH-WEST
```

File storage

Files are stored as follows:

- **Location** – Azure Data Lake Storage Gen2
- **Path** – `ExportFiles/{exportProfileId}.csv`
- **Format** – UTF-8 encoded CSV
- **Access** – SAS URL valid for 120 minutes (2 hours)

Best practices

Follow these best practices to ensure successful exports:

- **SAS URL expiration** – The SAS URL expires after 120 minutes. Download the file promptly or request a new URL if needed.
- **Job naming** – Use descriptive job names that include context (such as date range and purpose) for easier tracking and auditing.
- **Export profile management** – Configure export profiles in advance with appropriate filters, date ranges, and dimension selections.
- **Error handling** – Implement retry logic for transient failures and proper error handling for authentication and authorization issues when calling Dataverse custom APIs.
- **File size** – Be mindful of large exports. Consider filtering data by date range or dimensions to manage file sizes.

Error responses

When an error occurs calling Dataverse custom APIs, the API returns standard Dataverse error responses. For details on error handling, see Web API error handling.

Here are some common error scenarios you might encounter when calling the export custom API action:

- **401 Unauthorized** – Authentication token is missing, expired, or invalid.
- **403 Forbidden** – The authenticated user lacks permissions to access the Dataverse organization or execute custom API actions.
- **404 Not Found** – The specified export profile or export file doesn't exist.
- **400 Bad Request** – Invalid request parameters exist, such as malformed GUIDs or missing required fields.

Data classification

> **Important**
>
> Exported data might contain customer content and system metadata. The `msdyn_scpgetexportoutputfileurl` custom API action returns SAS URLs to access customer content. Make sure you follow appropriate data handling and storage practices according to your organization's security policies.

Office integration overview

Article • 01/03/2025

Applies to these Dynamics 365 apps:
Commerce, Finance, Supply Chain Management

This article reviews Microsoft Office integration concepts and features. The integration depends on several technologies:

- Working in Microsoft Azure
- Working with Microsoft Entra ID
- Running a web client in multiple browsers

The Microsoft Office integration capabilities provide users with a productive environment that helps them get the job done by using Office products.

Excel Data Connector add-in

Microsoft Excel can change and quickly analyze data. The Excel Data Connector app interacts with Excel workbooks and OData services that are created for publicly exposed data entities. The Excel Data Connector add-in enables Excel to become a seamless part of the user experience. The Excel Data Connector add-in is built by using the Office Web add-ins framework. The add-in runs in a task pane. Office Web Add-ins are web applications that run inside an embedded Microsoft Edge browser window.

Dynamics AX 2012 architecture vs. Finance and operations architecture

There are several differences between versions. For both, we built lightweight add-ins that run in Excel and use services to connect to the application.

Dynamics AX 2012

Excel > VSTO (.NET) Add-in > Windows Communication foundation (WCF) > Authentication through Active Directory (AD) > AIF SOAP services on the AOS > AX Services and Tables > AX query engine > Database

Finance and operations

Excel > Office Web Add-in (JS + HTML) > JavaScript OData API (Olingo) > Authentication through Microsoft Entra ID (Microsoft Entra ID) > AX OData services on the AOS > AX Entities > AX LINQ provider > AX Database

Office Add-in explained

The Excel Data Connector app is located in a task pane on the right side of a workbook. The following table describes the parts of the add-in.

Expand table

Name	Description
Add-in primary title	The title of the add-in that is provided to the Office Web Add-ins framework.
Add-in secondary title	The title of the add-in that is provided by the add-in.
Source name	The label of the entity that provides data for the selected data table. You can hover over the label to see the corresponding name.
Field name	The label of the field that provides data for the selected data table column. You can hover over the label to see the corresponding name and type.
Refresh button	Refresh the data in the workbook.
Publish button	Publish the data changes in the workbook.
Design button	Open the design-time experience.
Status bar	The status bar provides brief temporary information alerts. Information that is appears in the status bar also appears in the **Messages** dialog box.
Options button	Open the **Options** dialog box.
Messages button	Open the **Messages** dialog box, which displays the information messages, warnings, and errors that the program provides to the user. A number sometimes appears next to the **Messages** button to provide a count of the warnings or errors that the user might be interested in.
Excel data table containing data	The filter and sort controls in the columns headers can be used on this data. The filters must be removed before data changes are published.
Office Web Add-ins menu	The Office Web Add-ins menu button provides several standard links. The most important of the links is used to reload the add-in. When the add-in is reloaded, it updates all the data for the workbook that is contained in tables that are associated with the add-in.

Authentication

OData sits on the same authentication stack as the server. The add-in uses OAuth to facilitate authentication.

Lookups and drop-down lists

When you click in a table cell, any lookup, enumeration drop-down list, or date picker that is associated with that cell will be shown inside the add-in, underneath the source and field information. Any value that you select inside the add-in is put into the currently selected table cell.

Adding and deleting records

To add a record, either start typing in a row directly below a table, or use the Tab key to tab away from the last cell of the last row in the table. To delete a record, select the row label (1, 2, 3, and so on), and then delete all the cells in that row. To publish the changes, select **Publish**. The **Messages** dialog box shows how many records were added, edited, and deleted.

Workbook Designer

You can use the **Workbook Designer** page to design an editable custom export workbook that contains an entity and a set of fields. To open the **Workbook Designer** (**ExportToExcelWorkbookDesigner**) page, select **Common** > **Common** > **Office Integration** > **Excel workbook designer**. Before you can publish data edits, all the key fields of the entity must be in the Excel table. Key fields have a key symbol next to them. To successfully create or update a record, it must have all the mandatory fields in the Excel table. Mandatory fields have an asterisk (*) next to them.

To retrieve the resulting workbook, select **Create workbook** in the app bar.

Click **View related form** to see the data that the entity exposes. This button is only enabled for entities that have a **FormRef** property value.

Document management

Document management supports saving record attachments in Azure Blob storage and SharePoint Online. Database storage is deprecated. Azure Blob storage is equivalent to storage in the database since documents can only be accessed through the application and it provides the added benefit of providing storage that doesn't negatively affect the

performance of the database. Azure blob storage is the default and works immediately. SharePoint storage will work immediately if you have an O365 license since we auto-discover the SharePoint tenant e.g. a user on the TenantA.onmicrosoft.com O365/Microsoft Entra tenant gets TenantA.sharepoint.com as the SharePoint site. If document management has been turned off by the user, turn it on by selecting **Options** > **General** > **Miscellaneous** and setting **Document handling active** to **Yes**.

On any page that has data, an **Attach** button is available in the upper-right corner.

The **Attachments** page provides a view of the attachments (documents) that are associated with the record that was selected on the previous page. You can add new attachments to the record by selecting the **New** button (+) in the app bar. For the **File** and **Image** document types, you will be prompted to provide the associated file.

Document preview

A preview for supported file types is provided on the **Preview** FastTab. Basic document types, such as PNG images and text files, are supported by default. Office document types, such as Microsoft Word, Excel, and PowerPoint files, must use a production Office Web Apps Server, which might not be available in a OneBox configuration.

Frequently asked questions

Office Licensing

What Microsoft 365 licenses are available?

There are lots of Microsoft 365 license options. You should select the license that makes sense for your organization.

After purchasing a Microsoft 365 license, what needs to be done to set up SharePoint storage for attachments?

Open the Document Parameters form and ensure that the SharePoint server has been automatically discovered and set. Now open or create a Document Type, set the Document Type's location to "SharePoint" and select the folder that the files should be stored in.

Office integration tutorial

Applies to these Dynamics 365 apps:
Commerce, Finance, Human Resources, Supply Chain Management

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

In this tutorial, you will use and build Office integration experiences that involve Excel, Word, document management, and email.

Overview

In this tutorial, you will use and build Microsoft Office integration experiences that involve Microsoft Excel, Microsoft Word, the document management capabilities of finance and operations apps, and email. You will see how Excel and Word use data entities as an entry point into the system, how Excel can become a core part of the user experience, and how Excel and Word can be used for ad-hoc lightweight reporting. You will also see how files can be stored and shared by using the document management and email capabilities.

Key concepts

- **Entities and OData** – You will use the Microsoft Dynamics Excel Data Connector App (Excel App) to create, read, update, and delete. The connector uses OData services that are created for any entity that is left in the default state of "public" (**DataEntity.Public**=**Yes**).
- **Apps for Office** – The Excel App is built by using the Apps for Office framework (which is also known as the Office Web API). The Excel App is web-based, and therefore shares technology with the client and will run inside both on-premises Excel instances and Microsoft Excel Online (Microsoft 365). The app runs inside Excel in a task pane.
- **Microsoft Office 2016** – The Excel and Word Apps use advances in the Apps for Office framework that were introduced in Office 2016. Therefore, Office 2016 is required in order to run the Excel and Word Apps.
- **Authentication** – The Excel and Word apps run in a browser window inside Excel and Word. For details about which browser will be used for your configuration, see Browsers used by Office Add-ins. The specified browser is used even if the user is running the client

in an InPrivate browsing session in Microsoft Edge, or in a different browser such as Google Chrome. Authentication is facilitated by OAuth, and the user can select accounts and sign in within the app. The browser will first try to automatically sign the user in, so if you aren't signed in as the correct user or if you have trouble signing in, you might need to force a sign-out from the app by using the sign-out link. After signing out, try to sign in again to the app.

- **Excel App** – In addition to facilitating refresh and publish data operations, the Excel App also provides source and field information, lookups, filtering, error messaging, and a design experience for adding or removing fields, table columns, or labels from entity data sources.

Setup

Load the Fleet data set

During this tutorial, we will mainly use forms, entities, and data in the Fleet Management model. Therefore, we must first load the Fleet data set.

1. Go to **Fleet Management** > **Setup** > **Fleet setup**.
2. Select **Create**.

Static Export to Excel experiences

Static Export to Excel

Static Export to Excel provides a quick mechanism for getting data into grids on a page. The standard mechanism for triggering Export to Excel is the **Open in Microsoft Office** menu. Static Export to Excel is also available via a shortcut menu on the grid.

1. Go to **Fleet Management** > **Customers** > **Customer**.
2. Select **Open in Microsoft Office** > **Export to Excel** > **Customers**.
3. Download and open the workbook that is generated. Note that the columns in the workbook match the columns in the grid.
4. Select ("mark") the first two rows by clicking in the left edge of the row, below the "Select all" check mark.
5. Right-click the grid header to open the shortcut menu. Note that both **Export all rows** and **Export marked rows** are available as commands.
6. Select **Export marked rows**. Note that the columns in the workbook match the columns in the grid, and that the rows that are exported match the rows that you marked.

Modify the static Export to Excel experience

You can suppress the static Export to Excel mechanism for a grid or change the label that appears on the **Open in Microsoft Office** menu.

1. Start Visual Studio. Make sure that it's running as an administrator.
2. Select **View** > **Application Explorer** (or press Ctrl+E, Ctrl+E).
3. Go to **AOT** > **User Interface** > **Forms** > **FMCustomer**.
4. Right-click **FMCustomer**, and then click **Add to new project**.
5. In Solution Explorer, double-click the **FMCustomer** form to open the designer view.
6. Select **FMCustomerDesignTab(Tab)TabPageGrid(TabPage)MainGrid(Grid)**.
7. In the **Properties** window, find the **Export Label** property.
8. Set the **Export Label** property to **Fleet Customers**.
9. Save the form. If you're asked whether you want to overwrite the existing form or save it as a new form, click **Overwrite**.
10. Build the solution (press Ctrl+Shift+B).
11. In the browser, go to **Fleet Management** > **Customers** > **Customer**.
12. Select **Open in Microsoft Office**. Note that the **Customers** option has changed to **Fleet Customers**.

Generated Open in Excel experiences

Generated Open in Excel

Generated Open in Excel options are automatically added to forms when the system finds data entities that have the same root data source as the form. The workbook that is generated will contain a single table data source where the data from that entity is loaded. The Open in Excel experiences are listed on the **Open in Microsoft Office** menu. (When an entity has the same root data source as a form, it's added as an option in the **Open in Excel** section of the **Open in Microsoft Office** menu. This option is referred to as a “generated” option.)

1. Go to **Fleet Management** > **Customers** > **Customer**.
2. Select **Open in Microsoft Office** > **Open in Excel** > **Fleet Management Customers (unfiltered)**.
3. Download and open the workbook that is generated. This workbook contains the Excel Data Connector App, a binding to the **Fleet Management Customer** entity, and a pointer to the server that the workbook was generated from.
4. Select **Enable editing** to enable the Excel Data Connector App to load. Customer data is read from the OData service on the server and added to the table.
5. In the browser on the **Customer** page, click **Edit** (or press F2), and change the email address of one of the customers.

6. In the Excel App, click **Refresh**. Note that the new email address is shown in Excel.
7. In Excel, change the email address of one of the customers.
8. In the Excel App, click **Publish**.
9. In the browser, click **Refresh** in the upper right of the page (or press Shift+F5). Note that the new email address is shown on the **Customer** page.
10. In Excel, click the **Settings** (gear) button in the lower-right corner of the Excel App. You can use the dialog box that appears to adjust the settings in the current workbook. Note that the **Server URL** value matches the start of the URL that is shown in the browser. Also note that the data refresh and data publish operations are listed.
11. Select **Cancel** to close the **Settings** dialog box.
12. Select the **Message Center** (flag) button in the lower-right corner of the Excel App. The message center dialog box that appears provides information about what is occurring in the Excel App.

Add and remove table columns from an existing table data source in the Excel App

The Excel App has a design experience that lets users add and edit bindings to entity data sources and labels. To add and remove fields from an existing binding, you use the edit experience that is outlined in the following steps.

1. Get a workbook that has an existing table data source:
   a. Go to **Fleet Management** > **Customers** > **Customer**.
   b. Select **Open in Microsoft Office** > **Open in Excel** > **Fleet Management Customers (unfiltered)**.
   c. Download and open the workbook that is generated. This workbook contains the Excel Data Connector App, a binding to the Fleet Management Customer entity, and a pointer to the server that the workbook was generated from.
   d. Select **Enable editing** to enable the Excel Data Connector App to load. Customer data is read from the OData service on the server and added to the table.

2. Open the data source for editing:
   a. In Excel, in the Excel App, click **Design**. A list of table and field data sources appears.
   b. Select the **Edit** (pencil) button next to the existing table data source. The data source details are shown.

3. Remove fields. In the **Selected** list, double-click a field. Alternatively, click a field, and then click **Remove**. To select multiple fields, keep the Ctrl key held down while you click them. To select all fields, press Ctrl+A.

4. Add fields. In the **Available** list, double-click a field. Alternatively, click a field, and then click **Add**. To select multiple fields, keep the Ctrl key held down while you click them. To

select all fields, press Ctrl+A.

5. Change the field order. In the **Selected** list, click a field, and then click **Up** or **Down**.
6. Change a field label. In the **Selected** list, click a field, and then click in the **Column label** field below the list. You can change the label to either a static string or a label identifier that will be translated to the active language (for example, **@SYS129977**).
7. Apply the changes that you made to data source fields:
   a. Select **Update** to return to the data source list.
   b. Select **Refresh** to make sure that any new fields are filled with data.

Change an automatically generated Open in Excel experience

The automatically generated Open in Excel experiences that are created for entities have a single table binding. The list of fields that are added to that table binding is defined by the **AutoReport** field group if the table binding contains fields. Otherwise, the key and mandatory fields for the entity are automatically added. The order of fields in the **AutoReport** group determines the order of fields in the table binding.

1. Start Visual Studio. Make sure that it's running as an administrator.
2. Select **View** > **Application Explorer** (or press Ctrl+E, Ctrl+E).
3. Go to **AOT** > **Data Model** > **Data Entities** > **FMCustomerEntity**.
4. Right-click **FMCustomerEntity**, and then click **Add to project**.
5. Expand **FMCustomerEntity** > **Field Groups** > **AutoReport**.
6. Reverse the order of the **First name** and **Last name** fields by clicking the **Last name** field and moving it up (press Alt+Up arrow key).
7. Save the entity. If you're asked whether you want to overwrite the existing entity or save it as a new entity, click **Overwrite**.
8. Build the solution (press Ctrl+Shift+B).
9. In the browser, go to **Fleet Management** > **Customers** > **Customer**.
10. Select **Open in Microsoft Office** > **Open in Excel** > **Fleet Management Customers**.
11. Open the workbook that is generated.
12. Select **Enable editing** to enable the Excel Data Connector App to load. Note that the **Last name** column appears before the **First name** column.

Open in Excel Online

The Excel App is built by using a new Apps for Office framework. This framework provides a JavaScript-based web application programming interface (API) that enables apps to communicate with Office applications. The biggest advantage of this new framework is that

apps can run in on-premises Excel instances (Win32), Excel Online (Microsoft 365), and Excel on the Apple iPad. They will also be able to run in other Excel apps in the future.

1. Go to **Fleet Management** > **Customers** > **Customer**.
2. Select **Open in Microsoft Office** > **Open in Excel** > **Fleet Management Customers**.
3. Select **SharePoint**.
4. Browse to the desired Microsoft SharePoint folder.
5. Select **Save**. The default behavior is to open the file after it's saved. Note that the workbook opens in Excel Online. In Excel Online, capabilities of the Excel App, such as refresh and publish, and the design experience, should work just as they work in on-premises Excel instances.

Template Open in Excel experiences

Template Open in Excel

Template options resemble the generated Open in Excel options. They are automatically added to forms when the system finds templates that have the same first data source as the root data source in the form. A workbook template can have multiple data sources. It can also have unbound content. The Open in Excel experiences are listed on the **Open in Microsoft Office** menu. The **Excel workbook designer** page provides an easy way to get a generated Open in Excel experience for an entity. It also provides a mechanism getting a blank workbook that contains just the Excel App and a pointer to the server.

1. Go to **Common** > **Common** > **Office integration** > **Excel workbook designer**.
2. Select the **FleetCustomer** entity.
3. Add all fields in the list of available fields to the list of selected fields.
4. Select **Create workbook**.
5. Open the workbook that is generated. This workbook contains the Excel Data Connector App, a binding to the **Fleet Management Customer** entity, and a pointer to the server that the workbook was generated from.
6. Select **Enable editing** to enable the Excel Data Connector App to load. Customer data is read from the OData service on the server and added to the table.
7. Insert a blank row above the table, and enter **Fleet Customers** as the title.
8. Rename the worksheet **FleetCustomers**.
9. Rearrange some of the fields in the table. Select **Design** to open the design experience.
10. Next to the **FleetCustomer** data source, there are buttons for editing and deleting the data source. Select **Edit** to see the field list.
11. Select fields, and move them as you require. Set the order for the first three fields to **FirstName**, **LastName**, and **DriverLicense**.

12. Select **Update**. Note that the field order is changed.
13. Select **Done**.
14. Select the **Settings** (gear) button.
15. Select **Clear binding data** so that the workbook contains no bound data.
16. Select **OK**.
17. Save the workbook as **FleetCustomersBasic.xlsx**.
18. In the browser, go to **Common** > **Common** > **Office integration** > **Document templates**.
19. Select **New**.
20. Browse to the file that you just saved.
21. Select **OK**. The template is added as a line in the templates table.
22. In the **FleetCustomersBasic** row, clear the **Apply current record filter** check box, so that an unfiltered list of customers will be loaded after the template is opened.
23. Change the **Template display name** value to **Fleet Customers Basic**.
24. Go to **Fleet Management** > **Customers** > **Customer**.
25. Select **Open in Microsoft Office**. Note that **Fleet Customers Basic** is now an option in the **Open in Excel** section. Select that option.
26. Open the workbook that is generated.
27. Select **Enable editing** to enable the Excel Data Connector App to load. Customer data is read from the OData service on the server and added to the table binding that you created.

Register a template as a system-defined template

Templates that are registered as system-defined templates are loaded at deployment. This behavior is useful for independent software vendors (ISVs) and partners that want to package templates together with other model artifacts.

1. Start Visual Studio by opening the previously created project where the model is set to **Fleet Management**, or create a new project.

2. Right-click the project, and then click **Add** > **New item**.

3. Select the **Resource** item type.

4. Set the name to **FleetCustomersBasicTemplate**.

5. Make sure that the FleetCustomersBasic.xlsx file is closed.

6. Select **Add**.

7. Select the **FleetCustomersBasic.xlsx** file. Note that the resource is added to the project.

8. Select **View** > **Application Explorer** (or press Ctrl+E, Ctrl+E).

9. Go to **AOT** > **Classes** > **Code** > **FMTemplateRegistrations**.
10. Right-click **FMTemplateRegistrations**, and then click **Add to project**.
11. Open **FMTemplateRegistrations**. The FMTemplateRegistrations.xpp code file should be shown.
12. Copy one of the existing lines, and change it by providing the template name, resource name, description, display name, and **Apply current record filter** and **List in Open in Office menu** values. The display name is the text that appears as an Open in Excel option. The description appears when the user holds the pointer over that item. The display name and description can be either labels or static strings. The code should resemble the following example.

    X++

    ```
    this.addTemplate(
        OfficeAppApplicationType::Excel,
        resourceStr(FleetCustomersBasicTemplate),
        resourceStr(FleetCustomersBasicTemplate),
        "Template for fleet customers", "Fleet customers basic", NoYes::No,
    NoYes::Yes);
    ```

13. Save the code. If you're asked whether you want to overwrite the existing code or save it as a new file, click **Overwrite**.
14. Build the solution (press Ctrl+Shift+B).
15. Verify that the change was successful. In the browser, go to **Common** > **Common** > **Office integration** > **Document templates**.
16. Select **Reload system templates**.
17. Select **Yes** to confirm that you want to reload the system templates.
18. Verify that the new system-defined template is loaded, and that the template name is **FleetCustomersBasicTemplate**.

Journal Entry in Excel experience powered by a template

1. Go to **General ledger** > **Journal entries** > **General journals**.
2. Make sure that you're in company **USMF**.
3. Create a new journal by clicking **New**.
4. Set the name to **GenJrn**.
5. Select **Open lines in Excel**.

6. Open the workbook that is generated, and enable editing as required. Note that header fields are filled with data.
7. Enter a new line, and set the **MainAccount** field to **110110**. Enter a description, a currency, and a debit amount. Note that lookups are provided for the company and currency fields, because those relationships are defined for this entity.
8. Select **Publish**. Note that the line is updated with the current date and a debit amount of 0 (zero).
9. In the browser, click **Lines**. Note that line that you entered in Excel is shown.

Lookups in Excel experiences

Lookups in the Excel App

To facilitate data entry, the Excel App provides lookups and data assistance. Date fields provide a date picker, enumeration (enum) fields provide an enum list, and relationships provide a relationship lookup.

1. Go to **Fleet Management** > **Rentals** > **Rental**.
2. Select **Open in Microsoft Office** > **Open in Excel** > **Fleet Management Rentals**.
3. Open the workbook that is generated.
4. Select **Enable editing** to enable the Excel Data Connector App to load and read in data.
5. Select a **Drivers license** value. Note that a relationship lookup now appears in the Excel App and shows a list of customers. Because relationship lookups are in their first generation, no filtering or sorting is currently supported.
6. Select another customer in the lookup, and note that the **Drivers license** value changes. Because this field is part of the key, click the original **Drivers license** value to reset it. Note that the **Drivers license**, **First name**, and **Last name** fields form a multi-part key, but the Excel App doesn't immediately change all parts of the multi-part key.
7. Select a **Start date** value. Note that a date picker now appears in the Excel App.
8. Select another date to change the **Start date** value.
9. Select **Design**, and edit the FleetRental data source by adding the **Status** field as a column in the table binding.
10. When you've finished adding the **Status** column, click a **Status** value. Note that an enum list now appears in the Excel App.
11. While focus is in the **Status** column, move up and down the list of rentals to see how quickly the enum list changes to reflect the current value. The whole enum list is shown, so that the user can quickly see all the available values.
12. Select a different **Status** value to see how an enum value can be changed by using a single click.

Create a relationship lookup

When relationships exist between entities, a relationship lookup is shown.

1. Start Visual Studio by opening the previously created project where the model is set to **Fleet Management**, or create a new project.
2. Select **View** > **Application Explorer** (or press Ctrl+E, Ctrl+E).
3. Go to **AOT** > **Data Model** > **Tables** > **FMCustGroup**.
4. Right-click, and then click **Open designer**.
5. In the designer, right-click **FMCustGroup**, and then click **Add-ins** > **Create data entity**. Artifacts are added to the project.
6. Open the designer view for **FMCustGroupEntity**.
7. In the property sheet for **FMCustGroupEntity**, set **Public Collection Name** to **FleetCustomerGroups** and **Public Entity Name** to **FleetCustomerGroup**.
8. Add the **CustGroup** and **Description** fields to the **AutoLookup** field group.
9. If **FMCustomerEntity** isn't already in the project, add it.
10. Open the designer view for **FMCustomerEntity**.
11. Right-click **Relations**, and then click **New** > **Relation**.
12. On the new relation, set **Name** to **CustomerGroup**, **Cardinality** to **ZeroMore**, **RelatedDataEntity** to **FMCustGroupEntity**, **RelatedDataEntityCardinality** to **ZeroOne**, **RelationshipType** to **Association**, **Role** to **CustomerGroupSource**, and **RelatedDataEntityRole** to **CustomerGroupTarget**.
13. Build the solution (press Ctrl+Shift+B).
14. Verify that the change was successful. In the browser, go to **Fleet Management** > **Customers** > **Customer**.
15. Select **Open in Microsoft Office** > **Open in Excel** > **Fleet Management Customers**.
16. Open the workbook that is generated.
17. Select a **Customer group** value.
18. Change the **Customer group** value for a customer.
19. Publish the change.
20. Change the value back, and publish that change.

Create a custom lookup

You can create custom lookups to show data options when an enum or relationship isn't sufficient. The main use case is when data must be retrieved from an external service and presented in real time.

1. Start Visual Studio by opening the previously created project where the model is set to **Fleet Management**, or create a new project.

2. Open the designer view for **FMCustomerEntity**.

3. Right-click **Methods**, and then click **New Method**.

4. Add the **lookup_Country** code from the following example.

```
X++
```

```
  public class FMCustomerEntity extends common
{
    [SysODataAction("FMCustomerEntityCountryCustomLookup", false), //Name in
$metadata
    SysODataCollection("_fields", Types::String), //Types in context
    SysODataFieldLookup(fieldStr(FMCustomerEntity, Country))] //Name of field
    public static str lookup_Country(Array _fields)
    {
        OfficeAppCustomLookupListResult result = new
OfficeAppCustomLookupListResult();

        result.items().value(1, "US");
        result.items().value(2, "AU");
        result.items().value(3, "FR");
        result.items().value(4, "GR");
        result.items().value(5, "NZ");

        return result.serialize();
    }
  }
```

5. Save the code. If you're asked whether you want to overwrite the existing code or save is as a new file, click **Overwrite**.

6. Build the solution (press Ctrl+Shift+B).

7. Verify that the change was successful. In the browser, go to **Fleet Management** > **Customers** > **Customer**.

8. Select **Open in Microsoft Office** > **Open in Excel** > **Fleet Management Customers**.

9. Open the workbook that is generated.

10. Select a **Country/region** value.

11. Change the **Country/region** value for a customer.

12. Publish the change.

13. Change the value back, and publish that change.

Export to Word experiences

Export to Word

Export to Word experiences can be used for lightweight reporting. They are powered by pre-built templates. The Export to Word experiences are listed on the **Open in Microsoft Office** menu. Let's look at an example experience that has been created for Fleet Management Customers.

1. Go to **Fleet Management** > **Customers** > **Customer**.
2. Select **Open in Microsoft Office** > **Export to Word** > **Customer information Fleet Management Customers (unfiltered)**.
3. Download and open the document that is generated. The document contains data from the record that is currently selected.

Create a Word template

The Microsoft Dynamics App for Office can be run in Word to enable the creation of templates that can then be used for document generation.

1. Create a blank document
   a. Go to **Common** > **Common** > **Excel workbook designer**.
   b. Select **Create blank document**.
   c. Download and open the document that is generated.

2. Sign in to the app:
   a. Select **Sign In**. The Microsoft Entra sign-in screen should provide a list of credentials. If you encounter an error, force a sign-out (by using the sign-out link), and then sign in again.
   b. Select the appropriate account, or click **Use another account**.
   c. Enter the credentials for that environment, and then click **Sign in**.

3. Follow one of these steps:

   - Add a fields data source:
     a. In the app, click **Design**.
     b. Select **Add fields**.
     c. Select **FleetCustomer**.
     d. Select **Next** to go to the field selection page.
     e. In the document, add a title and/or some blank lines at the top of the document.
     f. In the app, in the **Available** list, select the **FirstName** field.
     g. Select **Add label** to add a content control that references the "First name" label.
     h. In the document, click to put focus into the document, click again to put focus at the end of the label, and then press the Right arrow key until the cursor is outside

the content control (the control box will disappear).
    i. Add a separator, such as space+hyphen+space (" - ") or space+colon+space (" : ").
    j. In the app, click **Add value** to add a content control that references the **FirstName** field.
    k. Repeat the process for the **LastName** field label and value.
    l. Continue to add fields as desired.
- Add a table data source:
    a. In the app, click **Design**.
    b. Select **Add table**.
    c. Select **FleetCustomer**.
    d. Select **Next** to go to the field selection page.
    e. In the document, add a title and/or some blank lines at the top of the document.
    f. In the app, in the **Available fields** list, add the **FirstName**, **LastName**, and **City** fields.
    g. Select **Done**.

4. In Word, save the template document.

Create a Word template and use it for document generation

After you've built a Word template, you can upload it to create an Export to Word experience.

1. Upload a template:
    a. Go to **Common** > **Common** > **Office integration** > **Document templates**. Alternatively, search for the page.
    b. Select **New**.
    c. Select **Browse**.
    d. In the dialog box, select a previously created template, and then click **Open**. Note that the Root data entity is obtained from the template and appears near the bottom of the dialog box.
    e. Select **OK**.
    f. Scroll down the list of templates to confirm that the template was added.
    g. Optional: If the template should not be filtered to the user's current record, clear the **Apply current record filter** check box.
    h. Optional: If the template should not be filtered to the user's current company, clear the **Apply company filter** check box.

2. Use the uploaded template for document generation:
    a. Go to a page that shares the same root data source as the template's root data entity. For **FleetCustomer** (**FMCustomerEntity**), that page is **Fleet Management** > **Customers** > **Customer**.

b. Select **Open in Microsoft Office** > **Export to Word**, and click the template.
c. Download and open the document that is generated.

Document Management and SharePoint experiences

Add a SharePoint document type

The Document Management subsystem can be used to attach files to records. Most non-executable file types are supported as attachments. A document preview is provided for Office document files and PDFs. Administrators create document types to indicate where attachments should be stored. When administrators use SharePoint as the storage location, they must provide a specific folder that the files should be put in. Security of that SharePoint folder is a separate administration responsibility.

1. Go to **Organization administration** > **Document management** > **Document management parameters**.
2. Select **SharePoint**.
3. Make sure that the **Default SharePoint server** field is set to a default value for the tenant, such as **contosoax7.sharepoint.com**.
4. Select **Test SharePoint connection**. Note a successful connection.
5. Select **Save**.
6. Go to **Organization administration** > **Document management** > **Document types**.
7. Select **New**.
8. Set **Type** to **SharePointDoc**.
9. Set **Name** to **SharePointDoc**.
10. Set **Location** to **SharePoint**.
11. Select the **Edit** (pencil) button next to the **SharePoint Address** field.
12. On the left side of the dialog box, select a site. For the contosoax7 tenant, select **ContosoAX Team Site**.
13. On the right side of the dialog box, select a folder. For the contosoax7 tenant, select **ContosoAX Team Site** > **Documents** > **OfficeIntegration** > **Attachments**.
14. Select **OK**.
15. Select **Save**.
16. Select the **Browse** (globe) button next to the **SharePoint Address** field. Note that a new browser tab that shows the selected folder appears.
17. Use Windows Explorer to create a Word document in the Documents folder, and enter a few words in the document.
18. In the browser, go to **Fleet Management** > **Customers** > **Customer**.

19. Put focus on the first customer, and then click the **Attach** (paperclip) button in the upper-right corner of the page.
20. Select **New** > **SharePointDoc**.
21. Select **Browse**, and select the Word document that you created.
22. Expand the **Preview** FastTab to see a preview of the Word document.
23. Expand the **Attachment** FastTab to see the file location of the Word document.
24. In the browser, use the previously opened tab that shows the SharePoint folder to double-check that the file has been placed appropriately.

Email experiences

Send mail via a local mail client

Email workflows that are enabled via the SysEmail framework can generate email messages (.eml files) that contain attachments. You can then send these messages via Microsoft Outlook or another email client.

1. Go to **Accounts receivable** > **Customers** > **All customers**.
2. Select **US-008 Sparrow Retail**.
3. Select **Collect** > **Customer balances** > **Collections** to open the **Collections** page.
4. Select **Communicate** > **Email** > **Statements to contact**.
5. Select **OK** to accept the default values in the dialog box.
6. If you're prompted for the mail option to use, clear the **Do not ask again** check box (you can change this option from the user options page), select **Use an email app, such as Outlook**, and then click **OK**.
7. If you're running the browser on your laptop, open the email (.eml) file that is generated. If you're running the browser on the VM, copy the file to your laptop, and open it there.
8. Note the email address in the **To** field and the generated workbook attachment.

Send mail via SMTP

Email workflows that are enabled via the SysEmail framework can also be created in a simple email dialog box and then sent via Simple Mail Transfer Protocol (SMTP).

1. Go to **System administration** > **Setup** > **Email** > **Email parameters**.
2. Select **SMTP settings**.
3. Set the **Outgoing mail server** to the desired SMTP server:
    - For Microsoft 365 production (including *.onmicrosoft.com accounts): smtp.office365.com (Find this setting via outlook.office.com, at **Settings** > **Mail** >

POP and IMAP.)
- For Outlook/Hotmail: smtp-mail.outlook.com

4. Set the user name and password to an appropriate email account and password.
5. Leave **SSLRequired** turned on, and leave **SMTP port number** set to **587**.
6. Select **Save**.
7. In the browser, go to **Accounts receivable** > **Customers** > **All customers**.
8. Select **US-008 Sparrow Retail**.
9. Select **Collect** > **Customer balances** > **Collections** to open the **Collections** page.
10. Select **Communicate** > **Email** > **Statements to contact**.
11. Select **OK** to accept the default values in the dialog box.
12. If you're prompted for the mail option to use, select **Use the Microsoft Dynamics 365 Finance email client**, and then click **OK**.
13. To receive the test message, change the To address to your email address.
14. Enter a subject and body for the message.
15. Select **Send**. The message should be delivered in one to five minutes. Note that the message will appear to be sent from the email account that is set on the **Email parameters** page. If that email account is given "Send As" (or "Send email from this mailbox") permissions for the From address that is used in the **Send email** dialog box, messages will appear to come from that address.
    - You can configure "Send As" permissions in the Microsoft 365 admin center (portal.office.com/Admin), at **Users** > **Active users** > **User** > **Edit mailbox permissions** > **Send email from this mailbox**. For more information, see Enable sending email from another user's mailbox in Microsoft 365.
    - Before users can send email messages, "Send As" permissions for each user email account in the client must be given to the email account that is set on the **Email parameters** page. For more information, see How to set up a multifunction device or application to send email using Microsoft 365.
16. Email that is sent directly from the server, without user interaction, is sent via a batch process and requires that the **Email distributor batch** process be started. Follow these steps to start the process:
    a. Go to **System administration** > **Periodic tasks** > **Email processing** > **Batch**.
    b. Turn on **Batch processing**.

View and update entity data with Excel

Summarize this article for me

Applies to these Dynamics 365 apps:
Commerce, Finance, Supply Chain Management

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to open entity data in Microsoft Excel, and then view, update, and edit the data by using the Microsoft Dynamics Excel add-in. To open entity data, you can start from either Excel or finance and operations apps.

By opening entity data in Excel, you can quickly and easily view and edit the data by using the Excel add-in. This add-in requires Microsoft Excel 2016 or later.

> **Note**
>
> If your Microsoft Entra ID (Azure AD) tenant is configured to use Active Directory Federation Services (AD FS), you must make sure that the May 2016 update for Office is applied, so that the Excel add-in can correctly sign you in.

To learn more about how to use the Excel add-in, watch the short Create an Excel template for header and line patterns video.

Open entity data in Excel when you start from a finance and operations app

1. On a page in a finance and operations app, select **Open in Microsoft Office**.

   If the root data source (table) for the page is the same as the root data source for any entities, default **Open in Excel** options are generated for the page. You can find **Open in Excel** options on frequently used pages, such as **All vendors** and **All customers**.

2. Select an **Open in Excel** option, and open the workbook that is generated. This workbook has binding information for the entity, a pointer to your environment, and a pointer to

the Excel add-in.

3. In Excel, select **Enable editing** to enable the Excel add-in to run. The Excel add-in runs in a pane on the right side of the Excel window.

4. If you're running the Excel add-in for the first time, select **Trust this Add-in**.

5. If you're prompted to sign in, select **Sign in**, and then sign in by using the same credentials that you used to sign in to the finance and operations app. The Excel add-in uses a previous sign-in context from the browser and automatically signs you in, if it can. (For information about the browser that is used based on the operating system, see Browsers used by Office add-ins. To ensure that sign-in was successful, verify the user name in the upper-right corner of the Excel add-in.

The Excel add-in automatically reads the data for the entity that you selected. The workbook contains no data until the Excel add-in reads it in.

Open entity data in Excel when you start from Excel

1. In Excel, on the **Insert** tab, in the **Add-ins** group, select **Store** to open the Office Store.

2. In the Office Store, search on the keyword **Dynamics**, and then select **Add** next to **Microsoft Dynamics Office Add-in** (the Excel add-in).

3. If you're running the Excel add-in for the first time, select **Trust this Add-in** to enable the Excel add-in to run. The Excel add-in runs in a pane on the right side of the Excel window.

4. Select **Add server information** to open the **Options** pane.

5. In your browser, copy the URL of your target finance and operations app instance, paste it into the **Server URL** field, and then delete everything after the host name. The resulting URL should have only the host name.

   For example, if the URL is `https://xxx.dynamics.com/?cmp=usmf&mi=CustTableListPage`, delete everything except `https://xxx.dynamics.com`.

6. Select **OK**, and then select **Yes** to confirm the change. The Excel add-in restarts and loads metadata.

   The **Design** button is now available. If the Excel add-in has a **Load applets** link, you likely aren't signed in as the correct user. For more information on addressing this issue, see the Load applets troubleshooting entry.

7. Select **Design**. The Excel add-in retrieves entity metadata.
8. Select **Add table**. A list of entities appears. The entities are listed in "Name - Label" format.
9. Select an entity in the list, such as **Customer - Customers**, and then select **Next**.
10. To add a field from the **Available fields** list to the **Selected fields** list, select the field, and then select **Add**. Alternatively, double-click the field in the **Available fields** list.
11. After you finish adding fields to the **Selected fields** list, make sure that the cursor is in the correct place in the worksheet (for example, cell A1), and then select **Done**. Then select **Done** to exit the designer.
12. Select **Refresh** to pull in a set of data.

View and update entity data in Excel

After the Excel add-in reads entity data into the workbook, you can update the data at any time by selecting **Refresh** in the Excel add-in.

Edit entity data in Excel

You can change entity data as needed and then publish it back to finance and operations apps by selecting **Publish** in the Excel add-in. To edit a record, select a cell in the worksheet, and then change the cell value. To add a new record, follow one of these steps:

- Click anywhere in the data sources table, and then select **New** in the Excel add-in.
- Click anywhere in the last row of the data sources table, and then press the Tab key until the cursor moves out of the last column of that row and a new row is created.
- Click anywhere in the row immediately below the data sources table, and start to enter data in a cell. When you move the focus out of that cell, the table expands to include the new row.
- For field bindings of header records, select one of the fields, and then select **New** in the Excel add-in.

You can create a new record only if the worksheet binds all the key and mandatory fields, or if default values are filled in by using the filter condition.

To delete a record, follow one of these steps:

- Right-click the row number next to the worksheet row that you want to delete, and then select **Delete**.

- Right-click anywhere in the worksheet row that you want to delete, and then select **Delete** > **Table Rows**.

If you add data sources as related data sources, the header publishes before the lines. If dependencies exist between other data sources, you might need to change the default publishing order. To change the publishing order, in the Excel add-in, select the **Options** button (the gear symbol). On the **Data Connector** FastTab, select **Configure publish order**.

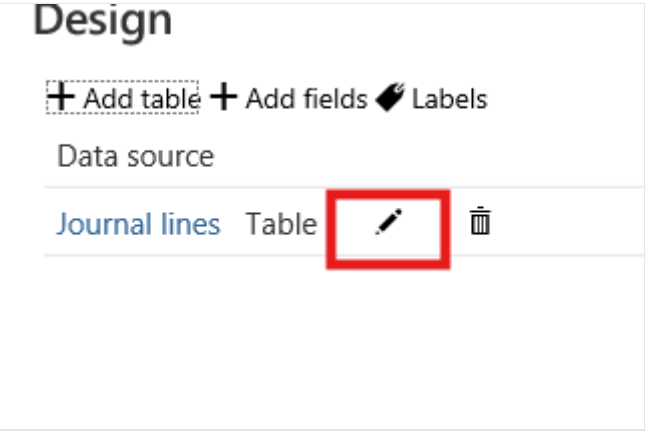
Add or remove columns

Use the designer to adjust the columns that the worksheet automatically adds.

> **Note**
>
> If the **Design** button doesn't appear below the **Filter** button in the Excel add-in, you must enable the data source designer. Select the **Options** button (the gear symbol), and then select the **Enable design** check box.

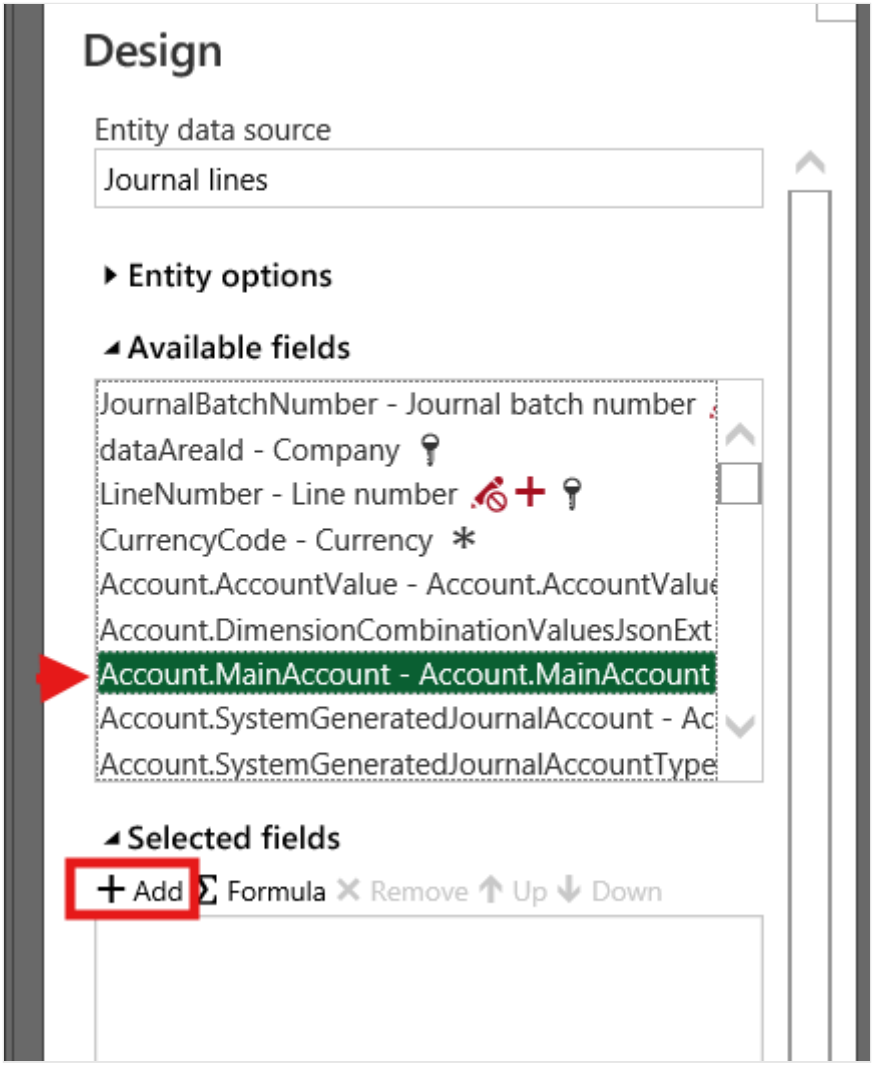
1. In the Excel add-in, select **Design**. All the data sources are listed.

1. Next to the data source, select the **Edit** button (the pencil symbol).



1. In the **Selected fields** list, adjust the list of fields as you require:

    - To add a field from the **Available fields** list to the **Selected fields** list, select the field, and then select **Add**. Alternatively, double-click the field in the **Available fields** list.
    - To remove a field from the **Selected fields** list, select the field, and then select **Remove**. Alternatively, double-click the field.
    - To change the order of fields in the **Selected fields** list, select a field, and then select **Up** or **Down**.



1. To apply your changes to the data source, select **Update**. Then select **Done** to exit the designer.
2. If you added a field (column), select **Refresh** to pull in an updated set of data.

Change the publish batch size

When users publish changes to data records by using the Excel add-in, the updates are submitted in batches. The default and maximum publish batch size is 100 rows. However, the **Allow configuration of the publish batch size in the Excel add-in** feature gives you flexibility in lowering the publish batch size, especially if you see time outs when attempting to publish updates from Excel.

System administrators can specify a system-wide limit on the publish batch size for "Open in Excel" workbooks by setting the **Publish batch limit** field in the **App parameters** section of the **Office app parameters** page.

You can also change the publish batch size for an individual workbook by using the Excel add-in.

1. Open the workbook in Excel.
2. Select the **Option** (gear) button in the upper right of the Excel add-in.
3. Set the **Publish batch size** field as desired. The value that you set must be less than the system-wide publish batch limit.
4. Select **OK**.
5. Save the workbook. If you don't save the workbook after you make changes to the add-in settings, those changes don't persist when the workbook is reopened.

Excel workbook template authors can use the same procedure to set the publish batch size for templates before they upload them into the system.

Copy environment data

The data that is read into the workbook from one environment can be copied to another environment. However, you can't just change the connection URL, because the data cache in the workbook will continue to treat the data as existing data. Instead, you must use the Copy Environment Data functionality to publish the data to a new environment as new data.

1. Select the **Options** button (the gear symbol). On the **Data Connector** FastTab, select **Copy Environment Data**.

2. Enter the server URL for the new environment.

3. Select **OK**, and then select **Yes** to confirm the action. The Excel add-in restarts and connects to the new environment. The existing data in the workbook is treated as new data.

4. After the Excel add-in restarts, a message box states that the workbook is in Environment copy mode.

5. To copy the data into the new environment as new data, select **Publish**. To cancel the environment copy operation and review the existing data in the new environment, select **Refresh**.

Troubleshooting

There are a few issues that can be resolved through some easy steps.

- **The "Load applets" link appears** – For more information about this problem, see Load applets.
- **You receive a "Forbidden" message** – If you receive a "Forbidden" message while the Excel add-in is loading metadata, the account that is signed in to the Excel add-in doesn't have permission to use the targeted service, instance, or database. To resolve this problem, verify that the correct user name appears in the upper-right corner of the Excel add-in. If an incorrect user name appears, select it, sign out, and then sign back in.
- **A blank webpage appears over Excel** – If a blank webpage opens during the sign-in process, the account requires AD FS, but the version of Excel that is running the Excel add-in isn't recent enough to load the sign-in dialog box. To resolve this problem, update the version of Excel that you're using. To update the version of Excel when you're in an enterprise that is on the deferred channel, use the Office deployment tool to move from the deferred channel to the current channel.
- **You receive a timeout while you publish data changes** – If you receive timeout messages while you're trying to publish data changes to an entity, consider reducing the publish batch size for the affected workbook. Entities that trigger larger amounts of logic on record changes might require updates to be sent in smaller batches to help prevent timeouts.

Open in Excel experiences FAQ

Article • 01/23/2025

Applies to these Dynamics 365 apps:
Commerce, Finance, Human Resources, Supply Chain Management

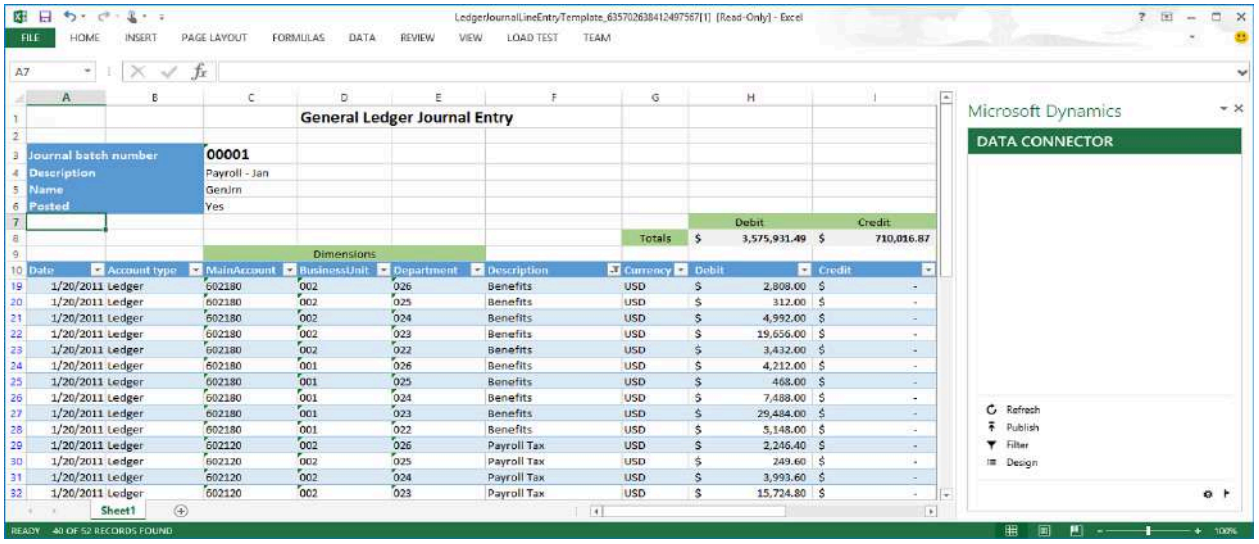
Learn about creating Open in Office experiences for Excel and Word.

What are Open in Excel experiences?

Open in Excel experiences are:

- Based on entities and the OData services that they create.
- Dynamically-generated or based on a pre-defined template.
- Editable and refreshable via the Excel Add-in.

The following image shows the **Excel Add-in** being used for Journal entry.



Where are the Open in Excel experiences?

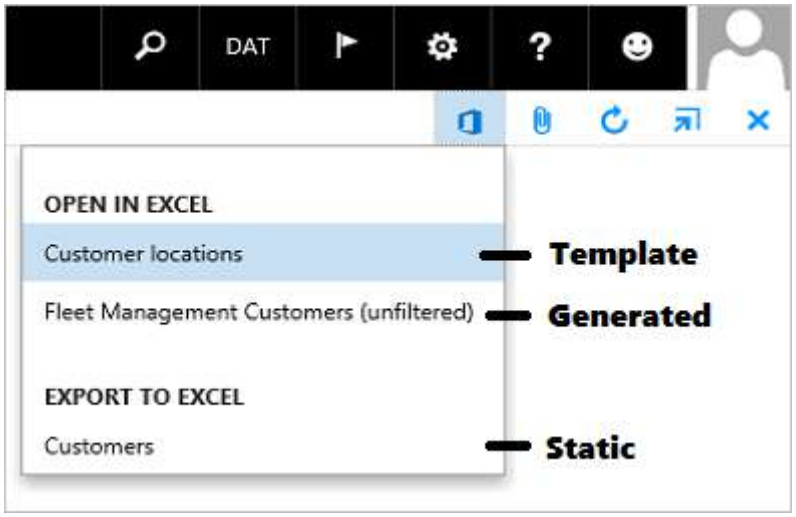
Open in Excel experiences are found under in the Open in Excel section of the Open in Microsoft Office menu, but an explicit button can be added for these experiences.

What's the difference between Export to Excel and Open in Excel?

The Export to Excel options and experiences are both found in the Open in Microsoft Office menu:

- The Export to Excel options are static exports of grid data. Each one corresponds to a visible grid. All the grid data for the current filter is placed into a workbook.
- The Open in Excel experiences utilize the Excel Add-in to facilitate refresh and publish.

The following image shows the **Open in Microsoft Office** menu on the **Fleet Customers** form with a template **Open in Excel** option, a generated **Open in Excel** option, and a static **Export to Excel** option.



When will an entity show as an Open in Excel option?

When an entity has the same root datasource (table) as a form, it will be added as an option in the Open in Excel section of the Open in Microsoft Office menu. This is referred to as a "generated" option.

> ⓘ Note
>
> The user must have security access to the underyling entity for that option to appear in the Open in Excel menu. See Security and data entities for more details.

What fields will be shown in the workbook?

The default fields that will be added into the workbook are the key and mandatory fields of the entity. If a different set of fields should be provided by default, then those fields can be added into the **AutoReport field group** on the entity. The following image shows the Visual Studio view of the AutoReport field group for the FMCustomerEntity.

What fields will be shown when an entity is the target of a lookup?

When a relationship is defined between two entities, if the identifier for one entity is shown on the other entity, then the fields that will be shown in that lookup are either the key fields, or the fields in the **AutoLookup field group** if it isn't empty. Relationship lookups aren't currently supported, but they will eventually display in the app in a similar way to the enumeration lookups.

What should be done to make an entity ready for use in Excel?

Define the AutoReport and AutoLookup field groups and test them using the Excel App design experience.

Why does an automatically added entity option have “(unfiltered)” after the entity name?

Currently, a filter isn't added to these options, hence the term “(unfiltered)”. In the future, an attempt will be made to apply the filter from the form to these options. For example, if a list of Customers was filtered to just Customers in the state of California, then, in the future, the entity will be scanned for the state field and if it's found then a filter would be added automatically.

How can an entity be added as an Open in Excel option on a form that doesn’t share the same root datasource?

A generated Open in Excel option can be added on any form by implementing the OfficeIGeneratedWorkbookCustomExporter interface. When adding a generated option programmatically, the set of fields can be explicitly specified. For more information, see Modifying the Open in Office menu through interfaces.

What are the region-specific considerations for defining entities?

The Open in Excel generated experiences can be made region-specific by adding region-specific fields into the AutoLookup group. These region-specific fields will then be included in the generated workbook.

How can I create a custom lookup for an entity field in Excel?

A custom lookup can be shown for an Entity field.

- Name - The method needs to have a name that is “lookup_<fieldname>” e.g. a field “MyField” could have a lookup method “lookup_MyField”.
- Attributes – Attributes need to be added to the method:
  - SysODataActionAttribute(str <name>, Boolean <isInstanceMethod>)
  - SysODataCollectionAttribute(str <name>, Types <type>, “Value”)
- Return – The method should return a list of strings.

Example

X++

```
public class ExportToExcel_SimpleEntity extends common
{
    [SysODataActionAttribute("Lookup_StringLookupField", true),
    SysODataCollectionAttribute("return", Types::String, "Value")]
    public List lookup_StringLookupField()
    {
        List lookupList = new List(Types::String);
        const int items = 5;

        for (int item = 0; item < items; item++)
        {
            lookupList.addEnd(strfmt('%1 - %2 (%3)', this.StringField,
this.IntField, item));
        }

        return lookupList;
    }
}
```

How does the app get injected into a workbook to start building a template?

The Excel Add-in is injected into a workbook when a generated Open in Excel experience is triggered or when a workbook is created using the **Common** > **Common**

> **Office integration** > **Excel workbook designer** form.

- The **Create workbook** button will add the selected entity and fields, a pointer to the server, and the app into a workbook.
- The **Create blank workbook** button adds a pointer to the server and the app into a workbook.
- The **View related** form will navigate to the form relating to the currently selected entity to more easily review the effect of data changes made in Excel.
- The **Get entity record count** button will show the record count for the currently selected entity. The Excel Add-in will handle large sets of data within the memory limits of a user's machine. By default, the Excel Add-in has a data governor that restricts the data size to one million cells but, depending on the performance abilities of the user's machine, this can usually be extended to around 2.5 million cells.

After obtaining a workbook containing the Excel Add-in, additional datasources can be added using the **Design** button. Currently, datasources can't be removed.

When will a template show as an Open in Excel option?

When a template listed in the **Common** > **Common** > **Office integration** > **Document templates** form (DocuTemplate) has ShowInOpenInOfficeMenu set to Yes and has the same root datasource (table) as the current form, it will be added as an option in the Open in Excel section of the Open in Microsoft Office menu.

Will a filter be added to the template?

In the **Document Templates** form, the standard filter for “current record” can be turned on and off. If the filter is on, when the template is invoked as an Open in Excel option, then a filter for the current record will be added to the workbook. The filter will be the key fields and their values.

How can templates be defined in metadata and code and loaded automatically?

When adding a template into the **Document Templates** form, it's added for that instance and is referred to as a “user-defined” template. Templates can also be defined in metadata and code and loaded automatically, thus making them “system-defined”

templates. To create a system-defined template using metadata and code, you need to do the following:

- Define the template.
- Create a new resource in a project.
- Define a new class that extends the DocuTemplateRegistrationBase class and add an implementation of the registerTemplates method.

The LedgerJournalLineEntryTemplateRegistration and FMTemplateRegistrations classes are good examples of template registrations defined in code. The LedgerJournalLineEntryTemplate and FMTemplateCustomersWithLocations resources are the corresponding templates stored in metadata as resources. When a template has a registration class, it will be loaded when the **Reload system templates** button is clicked in the **Document Templates** form.

How do templates get loaded into a fresh deployment?

To load system defined templates, click the **Reload system templates** button in the **Common** > **Common** > **Office integration** > **Document templates** form.

How do I decide if I should create a template?

A template is an artifact that needs to be maintained and versioned. If you can avoid defining a template without sacrificing much from the user experience, then you probably should use a template. Create a template if:

- You need additional content or formatting in the template.
- You want to combine multiple entities/datasources in the same workbook.

Don’t create a template if:

- You can just specify a set of fields to show in a table binding.

What are the region-specific considerations for templates?

When creating a template for an entity that has region-specific fields, you should leave those region-specific fields out of the template, otherwise all users will see the region-specific fields. Templates should cater to the majority of users by default and region-

specific users can add those fields using the easy-to-use design experience of the Excel Add-in. The region-specific fields and columns can be added by users as needed. That template can be either saved to local computer for reuse by a single user or uploaded via the Document Templates form for reuse by any user of that instance. A couple of other considerations:

- If a region has a region-specific entity, then a region-specific template could be created.
- If a region is important enough, then you could define a region-specific template as well as a region-generic template.

How do I add an explicit button for a template Open in Excel option?

An explicit button can be added for Open in Excel experiences. The label shown on the button should usually be "Open target in Excel" where target is the name of the target data like "lines" or "catalog". The code behind such a button will:

- Obtain the template to be used.
- Add a filter.
- Pass the template to the user.

An example of this code can be found on the **LedgerJournalTable** form (**General ledger** > **Journals** > **General journal**) in the **Clicked** method on the **OpenLinesInExcel** button.

X++

```
[Control("Button")]
class OpenLinesInExcel
{

    /// <summary>
    /// Opens the current journal in Excel for line entry and editing
    /// </summary>
    public void clicked()
    {
        super();

        const str templateName =
resourceStr(LedgerJournalLineEntryTemplate);
                DocuTemplate template =
DocuTemplate::findTemplate(OfficeAppApplicationType::Excel, templateName);

        // Ensure the template was present
        if (template && template.TemplateID == templateName)
        {
```

```
            Map filtersToApply = new Map(Types::String, Types::String);

            // Create lines filter
            ExportToExcelFilterBuilder filterBuilder = new
ExportToExcelFilterBuilder(tablestr(LedgerJournalLineEntity));
            str filterString =
filterBuilder.areEqual(fieldstr(LedgerJournalLineEntity,
JournalBatchNumber), LedgerJournalTable.JournalNum);
            filtersToApply.insert(tablestr(LedgerJournalLineEntity),
filterString);

            // Create header filter
            filterBuilder = new
ExportToExcelFilterBuilder(tablestr(LedgerJournalHeaderEntity));
            filterString =
filterBuilder.areEqual(fieldstr(LedgerJournalHeaderEntity,
JournalBatchNumber), LedgerJournalTable.JournalNum);
            filtersToApply.insert(tablestr(LedgerJournalHeaderEntity),
filterString);

            // Generate the workbook using the template and filters
            DocuTemplateRender renderer = new DocuTemplateRender();
            str documentUrl = renderer.renderTemplateToStorage(template,
filtersToApply);

            // Pass the workbook to the user
            if (documentUrl)
            {
                Browser b = new Browser();
                b.navigate(documentUrl, false, false);
            }
            else
            {

error(strFmt("@ApplicationFoundation:DocuTemplateGenerationFailed",
templateName));
            }
        }
        else
        {
            warning(strFmt("@ApplicationFoundation:DocuTemplateNotFound",
templateName));
        }
    }

}
```

To programmatically add generated and template Open in Excel options, Open in Excel options can be added by implementing the ExportToExcelIGeneratedCustomExport and ExportToExcelITemplateCustomExport interfaces. This allows the addition of options to forms where the entity or template doesn't have the same table as the root datasource. An example of when you would use this capability is on forms without a datasource,

potentially containing only a collection of form parts. The following example adds generated and template Open in Excel options programmatically to the **FMRental** form.

X++

```
[Form]
public class FMRental extends FormRun implements
ExportToExcelIGeneratedCustomExport, ExportToExcelITemplateCustomExport
{
...

    public List getExportOptions()
    {
        List exportOptions = new List(Types::Class);

        ExportToExcelExportOption exportOption =
ExportToExcelExportOption::construct(ExportToExcelExportType::CustomGenerate
d, int2str(1));
        exportOption.setDisplayNameWithDataEntity(tablestr(FMRentalEntity));
        exportOptions.addEnd(exportOption);

        ExportToExcelExportOption exportOption2 =
ExportToExcelExportOption::construct(ExportToExcelExportType::CustomTemplate
, int2str(2));
        exportOption2.displayName("Analyze rentals");
        exportOptions.addEnd(exportOption2);

        return exportOptions;
    }

    public ExportToExcelDataEntityContext
getDataEntityContext(ExportToExcelExportOption _exportOption)
    {
        ExportToExcelDataEntityContext context = null;

        if (_exportOption.id() == int2str(1))
        {
            context =
ExportToExcelDataEntityContext::construct(tablestr(FMRentalEntity),
tablefieldgroupstr(FMRentalEntity, AutoReport));
        }

        return context;
    }

    public System.IO.Stream getTemplate(ExportToExcelExportOption
_exportOption)
    {
        System.IO.Stream stream = null;

        if (_exportOption.id() == int2str(2))
        {
            stream =
Microsoft.Dynamics.Ax.Xpp.MetadataSupport::GetResourceContentStream(resource
```

```
str(FMRentalEditableExportTemplate));
        }

        return stream;
    }

    public void updateTemplateSettings(ExportToExcelExportOption
_exportOption,
Microsoft.Dynamics.Platform.Integration.Office.ExportToExcelHelper.SettingsE
ditor _settingsEditor)
    {
    }
...
```

How do I add a filter for a programmatically-added template Open in Excel option?

A template Open in Excel option can be programmatically added by implementing the ExportToExcelITemplateCustomExport interface and providing a template in the getTemplate method. A filter for that option can be programmatically added by using the ExportToExcelFilterBuilder API in the updateTemplateSettings method.

X++

```
public void updateTemplateSettings(ExportToExcelExportOption _exportOption,
Microsoft.Dynamics.Platform.Integration.Office.ExportToExcelHelper.SettingsE
ditor _settingsEditor)

{

_settingsEditor.SetFilterExpression(tableStr(RetailTmpBulkProductAttributeVa
lueEntity), element.getExportToExcelFilterExpression());

DictDataEntity dictDataEntity = new
DictDataEntity(tableNum(RetailTmpBulkProductAttributeValueEntity));

_settingsEditor.SetFilterExpressionByPublicName(dictDataEntity.publicEntityN
ame(), element.getExportToExcelFilterExpression());

}
```

After a filter has been added programmatically, the resulting filter can be viewed in the Excel Add-in using the **Filter** button.

How do I enable relationship lookups in Excel?

To enable relationship lookups in the Excel Data Connector, you must ensure that the following metadata is set.

- The Role and Related Data Entity Role defined on the relationship need to be unique among all relationships on both the source and target entity. Also, the relation role properties must be unique across all entities. This is particularly important for relationships involving entities with many relationships, such as DimensionCombinationEntity. If you're not seeing an expected lookup, try changing the role names to the following format:
    - **Role**: [this entity's public name] + [target entity's public name] + [target entity field] + "Source"
    - **Related Data Entity Role**: [this entity's public name] + [target entity's public name] + [target entity field] + "Target"
    - The Cardinality and Related Data Entity Cardinality need to be set appropriately.
    - At least one constraint must be added to the relationship. With the exception of dimension relationships, which are a special case, the properties constrained must both be public.

How can I enable users to create new header records as well as lines in a workbook?

To enable creation of header records and related lines, the header data source must be added as a set of "fields" and the lines data source must be added as a related table. This pattern can work well for document data entry scenarios such as Journal entry.

To learn more about header records and related lines, watch the short Create an Excel template for header and line patterns in Dynamics 365 Finance video.

To design a workbook with header fields and a lines table that enables header creation:

1. In the Excel Add-in, click **Design** to open the Designer. Select **Add fields** to add a header data source.
2. Select the header fields that you want to use. Be sure to include all the key fields or the **New** button won't be enabled.
3. For all of the string header value fields, manually apply "Text" format for that cell using **Excel ribbon** > **Home tab** > **Number group** > **set "Number"** in the format drop-down menu. If the Text format isn't manually set on a string field and there's a string value with leading zeros like "00045", then Excel will automatically change it to "45" and an error will be shown like: "*Unable to change the value of*

PurchaseOrderHeader's PurchaseOrderNumber field as it's a key field". Currently, the API doesn't allow for automatically applying the text formatting on individual cells (versus table columns).

4. In the Designer, on the header data source, click the **Add related table** button represented by a double plus icon.
5. Select the line fields that you want to use.

Here's an example of a header data source with a related table data source.

- PurchaseOrderHeader (Fields)
  - dataAreaId
  - PurchaseOrderNumber
  - PurchaseOrderName
  - OrderVendorAccountNumber
- PurchaseOrderLine (Table - related)
  - LineNumber
  - ItemNumber
  - LineDescription
  - OrderedPurchaseQuantity
  - LineAmount

To use a header and lines workbook to create a new header and lines, follow these steps:

1. In the workbook, move the focus to a cell with a header value.
2. In the Excel Add-in, click **New**.
3. Enter header values and lines as needed.
4. Select **Publish**.

How can fields be added, removed, or moved within an existing template workbook?

Fields can be added into an existing template workbook by editing the workbook stored in **Document Templates**.

1. Get the original template workbook.
   a. Open the **Document Templates** form.
   b. Find the existing template workbook.
   c. Download the workbook.
   d. Open the workbook and enable editing so that the Excel Add-in runs.
2. Make changes to the template.
   a. In the Excel Add-in, select **Design**.

b. Click the **Edit** button (pencil icon) next to the datasource that you want to add a field into.
c. Add fields by moving them from the **Available fields** list into the **Selected fields** list. Double-clicking a field will move it. Remove fields by moving them from the **Selected fields** list into the **Available fields** list.Move fields using the **Up** and **Down** buttons.
d. After changes are complete, select **Update**, select **Yes** to confirm, and then select **Done** to exit the Designer (if appropriate, select **Refresh** to verify that the data is correctly populated).
e. Clear the data from the template before upload by clicking **Options** (gear icon), expand the **Data Connector** section, then click the **Clear binding data** button.
f. Use **Save As** to store the template somewhere temporarily.

3. Upload the changed template.
   a. Return to the **Document Templates** form and upload the changed template.
   b. Click **New** and browse to find the changed template.
   c. Select the saved template file and click **Open**.
   d. In the **Upload template** dialog box, remove the underscore and trailing random number from the name For example, "CustInvoiceJournalTemplate_636564840743000567" becomes "CustInvoiceJournalTemplate".
   e. A confirmation dialog box should show that "A template with this name already exists...", click **Yes** to confirm replacement of the previous template. Note that if this confirmation isn't shown, then the template name is different and it's being uploaded as a new template.
4. Open the form that the template is used on and use the changed template.

Troubleshooting

If you aren't seeing an expected lookup, validate relationship metadata by checking the metadata feed available at [YourSiteURL]/data/$metadata. Search the $metadat feed for the public name of your entity to find its EntityType element, then make sure there's a child NavigationProperty element with a name equal to the Role value of the relationship. If the navigation property exists, it will be used by the Excel Data Connector to show a relationship lookup. Lookups aren't shown under the following conditions:

- All of the entity's key fields are included as constraints in the relationship.
- The selected field is a key and the selected record isn't new.
- The authenticated user does not have permission to access the entity targeted by the lookup.

How do dimensions work?

The easiest way to set up dimension metadata on data entities is to use the data entity creation wizard, which will automatically create the private relationships and public display value fields exactly as the dimensions framework needs them. If you want to customize your dimensions setup, see Add dimensions to Excel templates. Lookups, are only generated automatically for non-ledger dimensions. Custom dimensions aren't supported currently. If you want to enable lookups for ledger dimensions (MainAccount, Department, CostCenter, etc.), see Add dimensions to Excel templates for guidance on creating relationships on DimensionCombationEntity and DimensionSetEntity fields. When those relationships are present, relationship lookups will be displayed in the Excel Data Connector. The Excel Data Connector supports two types of dimension data entry: editing the display value directly or editing each attribute of the display value in a separate column. If both the display value column and the individual attribute columns are bound, they can both be edited and published separately. If both the display value and an individual attribute are edited in the same row, the individual attribute change overrides the display value change.

How do I create formula table columns?

If a formula is needed in a table, then add a formula column. When in the field selection page for a table binding, click the **Formula** button above the Selected fields list to add a new formula column. The label and value for the formula are entered in the fields immediately below the Selected fields list. After adding a new formula column, leave the value empty and click **Update**. After the field has been added to the table, use standard Excel capabilities to create a formula, then copy the formula and paste it into the formula column value field. When defining a formula, make sure there's more than one row in the table, otherwise the formula that Excel provides may be for ALL rows instead of THAT row. To specify just the current row, the at sign (@) is needed. For example, sum of four columns for all rows "=SUM(Table1[[ColumnA]:[ColumnD]])" versus sum of four columns for the current row "=SUM(Table1[@[ColumnA]:[ColumnD]])".

Known issues

Error triggered when selecting custom Excel templates

This issue occurs when the user selects an Excel template from an **Open in Excel** button and receives the following error: `Record for Id {guid} not found`

The error occurs when a custom Excel template can't be found. One scenario that could cause this error is moving the finance and operations database between environments, but not copying the Excel templates.

To resolve this issue, delete the database entry for the template from the **Document templates** page (**Common** > **Common** > **Office integration** > **Document templates**) and then reload the template.

Refresh doesn’t automatically occur in old templates

The ability to control “refresh on open” was added as a setting. To add this to the default behavior, existing templates and workbooks need to have the **Refresh on open** check box selected in **Options** > **Data Connector** > **Refresh Options**.

Error finding entity

The reference to entities changed from using the Private Entity Name (DataEntity.Name) to Public Entity Name (DataEntity.PublicEntityName). If the public and private names for an entity were different and that entity was used in an Excel template or workbook, then this will cause the following error to be displayed in the Excel App: “Error Finding Entity. Details: Entity "<DataEntity.Name>" not found”.

To resolve this, change the binding information in the affected template so that it points to DataEntity.PublicEntityName instead of DataEntity.Name.

1. For the DataEntity.Name that needs to be replaced, determine the DataEntity.PublicEntityName, for example replace FMCustomerEntity with FleetCustomer.
2. Find the affected template.
3. Change the file extension on the template from .xlsx to .zip.
4. The file to be changed will be one of the webextension*.xml files in the xlwebextensions directory, such as 2015-05-25-FleetCustomersWithLocations.zipxlwebextensionswebextension2.xml.
5. Open the file to ensure that you have the correct location.
6. Find the DataEntity.Name, such as FMCustomerEntity.
7. Extract the zip file.
8. Open the webextension xml file.
9. Replace the DataEntity.Name with the corresponding DataEntity.PublicEntityName.
10. Save the webextension .xml file changes.
11. Rename the old zip file, for example, add “.old” to the name.

12. Create a new zip file of all the previously extracted content. This usually involves highlighting the content inside the archive/zip folder and creating a zipped folder using that content.
13. Verify that the zip file has the “_rels”, “docProps”, and “xl” folders in the root of the zip file.
14. Rename the zip file as needed, for example rename the file 2015-05-25-FleetCustomersWithLocations.zip.
15. Change the zip file extension to .xlsx.
16. Re-publish the workbook .xlsx file, if needed.

Add templates to the Open lines in Excel menu

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article describes how you can promote a template to the **Open lines in Excel** menu that is available on journal pages.

Some of the most frequently used templates are the journal templates. You can promote these journal templates so they appear on the **Open lines in Excel** menu by default. However, when you add a new template to the system, you must promote it so it's available on both the **Open in Office** menu and the **Open lines in Excel** menu. To promote a new template, follow these steps:

1. Create a Microsoft Excel template, and save it locally. For more information, see Create Open in Excel experiences.

2. In Microsoft Visual Studio, create a new project for a model that has a reference to the ApplicationSuite model.

3. Create a new class, implement the **LedgerIJournalExcelTemplate** interface, and extend **DocuTemplateRegistrationBase**. Your implementation (supported journal type, and so on) defines the context that your template will be available as an option for in the Open in Excel experience. This example uses LedgerJournalHeaderEntity and LedgerJournalLineEntity, but you're not limited to these entities. You can define your own entities, as long as they follow the journal header/line entity pattern. Here's an example from the **LedgerDailyJournalExcelTemplate** class.

   X++

   ```
   using Microsoft.Dynamics.Platform.Integration.Office;
   public class TestNewTemplate extends DocuTemplateRegistrationBase implements
   LedgerIJournalExcelTemplate
   {
       private const DocuTemplateName ExcelTemplateName =
   resourceStr(TestNewTemplate);
       private const EntityName LineEntityName =
   tableStr(LedgerJournalLineEntity);
   ```

```
    private const FieldName LineEntityJournalNum =
fieldStr(LedgerJournalLineEntity, JournalBatchNumber);
    private const FieldName LineEntityDataAreaId =
fieldStr(LedgerJournalLineEntity, dataAreaId);
    private const FieldName HeaderEntityName =
tableStr(LedgerJournalHeaderEntity);
    private const FieldName HeaderEntityJournalNum =
fieldStr(LedgerJournalHeaderEntity, JournalBatchNumber);
    private const FieldName HeaderEntityDataAreaId =
fieldStr(LedgerJournalHeaderEntity, dataAreaId);
    /// <summary>
    /// A boolean value which indicates whether the journal type is supported
for the Excel template.
    /// </summary>
    /// <param name = "_ledgerJournalType">The ledger journal type.</param>
    /// <returns>True if the journal type is supported; otherwise, false.
</returns>
    public boolean isJournalTypeSupported(LedgerJournalType
_ledgerJournalType)
    {
        return _ledgerJournalType == LedgerJournalType::Daily;
    }
    /// <summary>
    /// Gets the document template name.
    /// </summary>
    /// <returns>The document template name</returns>
    public DocuTemplateName documentTemplateName()
    {
        return ExcelTemplateName;
    }
    /// <summary>
    /// Gets a collection of the supported account types for the entity.
    /// </summary>
    /// <returns>A collection of <c>LedgerJournalACType</c> values.</returns>
    public Set supportedAccountTypes()
    {
        Set accountTypeSet = new Set(Types::Integer);
        accountTypeSet.add(LedgerJournalACType::Ledger);
        return accountTypeSet;
    }
    /// <summary>
    /// Gets a collection of the supported offset account types for the
entity.
    /// </summary>
    /// <returns>A collection of <c>LedgerJournalACType</c> values.</returns>
    public Set supportedOffsetAccountTypes()
    {
        Set offsetAccountTypeSet = new Set(Types::Integer);
        offsetAccountTypeSet.add(LedgerJournalACType::Ledger);
        return offsetAccountTypeSet;
    }
    /// <summary>
    /// Validates the journal is valid for the template.
    /// </summary>
    /// <param name = "_ledgerJournalTable">The <c>LedgerJournalTable</c>
```

```
record.</param>
    /// <returns>True if the journal is valid for the template; otherwise,
false.</returns>
    public boolean validateJournalForTemplate(LedgerJournalTable
_ledgerJournalTable)
    {
        return
LedgerJournalExcelTemplate::validateJournalForTemplate(_ledgerJournalTable,
this);
    }
    public void registerTemplates()
    {
        this.addTemplate(
            OfficeAppApplicationType::Excel,
            ExcelTemplateName,
            ExcelTemplateName,
            'Test new template',
            'Test new template',
            NoYes::No,
            NoYes::No,
            NoYes::No);
    }
    /// <summary>
    /// The resource name of the header entity.
    /// </summary>
    /// <returns>The resource name of the header entity.</returns>
    public EntityName headerEntityName()
    {
        return HeaderEntityName;
    }
    /// <summary>
    /// The resource name of the line entity.
    /// </summary>
    /// <returns>The resource name of the line entity.</returns>
    public EntityName lineEntityName()
    {
        return LineEntityName;
    }
    /// <summary>
    /// The field name for the header journal batch number.
    /// </summary>
    /// <returns>The field name for the header journal batch number.</returns>
    public FieldName headerJournalBatchNumberFieldName()
    {
        return HeaderEntityJournalNum;
    }
    /// <summary>
    /// The field name for the header data area.
    /// </summary>
    /// <returns>The field name for the header data area.</returns>
    public FieldName headerDataAreaFieldName()
    {
        return HeaderEntityDataAreaId;
    }
    /// <summary>
```

```
    /// The field name for the line journal batch number.
    /// </summary>
    /// <returns>The field name for the line journal batch number.</returns>
    public FieldName lineJournalBatchNumberFieldName()
    {
        return LineEntityJournalNum;
    }
    /// <summary>
    /// The field name for the line data area.
    /// </summary>
    /// <returns>The field name for the line data area.</returns>
    public FieldName lineDataAreaFieldName()
    {
        return LineEntityDataAreaId;
    }
    /// <summary>
    /// Append additional filter to the default filtering behavior.
    /// </summary>
    /// <returns>The original filter with new filter(s) appended; Otherwise,
the original filter</returns>
    public FilterCollectionNode appendHeaderEntityFilters(FilterCollectionNode
_headerFilter, ExportToExcelFilterTreeBuilder _headerFilterBuilder)
    {
        return _headerFilter;
    }
    /// <summary>
    /// Append additional filter to the default filtering behavior.
    /// </summary>
    /// <returns>The original filter with new filter(s) appended; Otherwise,
the original filter</returns>
    public FilterCollectionNode appendLineEntityFilters(FilterCollectionNode
_lineFilter, ExportToExcelFilterTreeBuilder _lineFilterBuilder)
    {
        FilterCollectionNode lineFilter = _lineFilterBuilder.and(
            _lineFilterBuilder.areEqual(fieldStr(LedgerJournalLineEntity,
AccountType), LedgerJournalACType::Ledger),
            _lineFilterBuilder.areEqual(fieldStr(LedgerJournalLineEntity,
OffsetAccountType), LedgerJournalACType::Ledger));
        return _lineFilterBuilder.and(_lineFilter, lineFilter);
    }
}
```

4. Build the project/model that has the new resources. You should have one new resource and one new class.

5. In the client, go to **Common** > **Common** > **Office integration** > **Document templates** > **Reload system templates**. You see the new template in the list. If you open the journal page that you added the template to, you also see that template on the **Open lines in Excel** menu.

Customize the Open in Microsoft Office menu

Article • 12/31/2024

Applies to these Dynamics 365 apps:
Commerce, Finance, Supply Chain Management

Most pages include an Open in Microsoft Office menu. This topics provides information about the Open in Office menu, and explains how customize it by adding, removing, and changing options.

Overview

The **Open in Microsoft Office** menu button (**Open in Office** menu) is a system-defined button that appears on pages. The **Open in Office** menu contains menu items that let you export data to various Office products, such as Microsoft Excel and Microsoft Word. The following table describes the menu items on the **Open in Office** menu.

Expand table

Menu item	Description
Export to Excel	The data is exported to an Excel workbook. The workbook contains no references back to finance and operations, and the data can't be refreshed.
Export to Word	The data is exported to a Word document. The document contains no references back to finance and operations, and the data can't be refreshed.
Open in Excel	A workbook is created that contains the Microsoft Dynamics Office add-in. The workbook contains a reference back to finance and operations, and the data can be refreshed, updated, and published from the Data Connector that is hosted in the add-in.

How menu items are added to the Open in Office menu

The export options are added to the **Open in Office** menu in the following manner:

1. In the **Export to Excel** group, a menu item is added for each visible grid.

2. For each root data source on the page, the set of data entities that have the same root data source is determined. For each of these data entities, the following menu items are added:

    - In the **Open in Excel** group, a menu item is added for a default export of the data entity.
    - In the **Open in Excel** group, a menu item is added for each Document Template record of the **Excel** type that has the same root data entity and is marked for inclusion on the **Open in Office** menu.
    - In the **Export to Word** group, a menu item is added for each Document Template record of the **Word** type that has the same root data entity and is marked for inclusion on the **Open in Office** menu.

Default exports

The **Open in Office** menu provides a default export for each data entity. This export includes all the fields in the **AutoReport** group on the data entity. If **SaveDataPerCompany** is set to **Yes** for the data entity, a filter is applied to limit the data to the current company.

Document templates

Document templates can be added from the **Document templates** page. Several fields that are associated with each Document Template record control the behavior of that template on the **Open in Office** menu.

Expand table

Field	Description
Root data entity	The root data entity of the template. The root data entity is used to determine which pages the template can be included on.
List in Office menu	If this field is selected, the template will be included on the **Open in Office** menu on applicable pages. (The applicable pages depend on the root data entity).
Apply record filter	If this field is selected, the data will be filtered, based on the record that is currently selected on the page.
Apply company filter	If this field is selected, the data will be filtered, based on the current company.

Trimmed template columns and fields

For Excel templates that are included on the **Open in Office** menu, columns and fields will be trimmed from the workbook, based on the configuration keys that are applied to the system and the applicable country/region context. If a configuration key is associated with a column or field in the workbook, the column or field will be removed if the configuration key is disabled. If a set of country/region codes is associated with the column or field in the workbook, the column or field will be removed if the country/region code isn't in scope.

Open in Office menu customization

There are several methods for customizing the content that appears on the **Open in Office** menu on a given page. For example, you can customize the content statically through metadata properties on model element and code attributes. However, customization via code gives you the finest level of control. In code, you can either implement one or more interfaces on a page, or use extensions and event subscriptions. The following sections describe the customization scenarios that are most often used.

Modifying the Open in Office menu through interfaces

If you must modify a page that you own, interfaces are the most appropriate customization method, because they give access to all private members of the page and allow for deeper customization. You can apply the following interfaces to the code for a page.

Expand table

Interface	Description
OfficeIMenuCustomizer	Use this interface to modify the set of data entities that is considered for a page and add custom menu items.
OfficeIGeneratedWorkbookCustomExporter	Use this interface to do a custom export of a workbook that is generated at run time.
OfficeITemplateCustomExporter	Use this interface to do a custom export that is based on a Document Template record.

Modifying the Open in Office menu through extensions and event subscriptions

If you must modify a page that you don't own, you should avoid using interfaces, because that approach will require over-layering. Instead, you should do the customization through extensions and event subscriptions. To use this approach, implement an extension class that subscribes to the **OnIntializing** event of the page that you're customizing. From this event handler, get the **OfficeFormRunHelper** for the page, and subscribe to its **OfficeMenuInitializing** event. The following example shows sample code for this approach.

X++

```
public static class MyForm_Extension
{
    [FormEventHandler(formStr(MyForm), FormEventType::Initializing)]
    public static void
ExportToExcel_DataEntityCustom_OnInitializing(xFormRun sender, FormEventArgs
e)
    {
        FormRun formRun = sender as FormRun;
        if (formRun)
        {
            OfficeFormRunHelper officeHelper = formRun.officeHelper();
            if (officeHelper)
            {
                officeHelper.OfficeMenuInitializing +=
eventhandler(MyForm_Extension::officeMenuInitializingHandler);
            }
        }
    }
    private static void officeMenuInitializingHandler(FormRun _formRun,
OfficeMenuEventArgs _eventArgs)
    {
        // Modify the OfficeMenuOptions available on the
OfficeMenuEventArgs.menuOptions() as necessary.
    }
}
```

Office menu best practices

Avoid APIs that could initialize the metadata cache during form load

The following classes could initialize the metadata cache, which can be extremely time consuming. For this reason, these classes should never be used in methods that are executed during form load (such as `init()` and `run()`), as this can cause a form to take a long time to load.

- ExportToExcelMetadataCache
- ExportToExcelDataEntityContext
- OfficeDataEntityExportMenuItem
- ExportToExcelDataEntityHelper
- ExportToExcelFilterTreeBuilder

Typical customization scenarios

The following examples assume that the **_menuOptions** variable contains the **OfficeMenuOptions** instance that you're customizing.

Modifying the set of data entities that is considered for a page

Many of the menu items on the **Open in Office** menu are added automatically, based on the data entities that are considered for the page. However, in some cases, the algorithm that is used to determine the set of data entities might not determine the correct set. To modify the set of data entities that is considered for the page, you can use the **OfficeMenuOptions** that is available from either the **OfficeIMenuCustomizer.customizeMenuOptions** method or the **OfficeFormRunHelper.OfficeMenuInitializing** delegate.

> ⚠ **Warning**
>
> Do not use this code in form init() or run(). This can negatively impact form load speed, especially upon system reboot.

X++

```
// Add an entity to the list
OfficeMenuDataEntityOptions entityOptions  =
OfficeMenuDataEntityOptions::construct(tableStr(MyEntity));
_menuOptions.dataEntityOptions().addEnd(entityOptions);
// Remove an entity from the list
ListIterator dataEntityOptionsIterator = new
ListIterator(_menuOptions.dataEntityOptions());
while (dataEntityOptionsIterator.more())
{
    OfficeMenuDataEntityOptions dataEntityOptions =
dataEntityOptionsIterator.value();
    if (dataEntityOptions.dataEntityName() == tableStr(MyOtherEntity))
    {
        dataEntityOptionsIterator.delete();
    }
```

```
    else
    {
        dataEntityOptionsIterator.next();
    }
}
```

Specifying the default data entity–related options that are included

The **OfficeMenuDataEntityOptions** class lets you specify whether to include a menu item for a default export or a menu item that is related to a document template.

X++

```
// Find the entity options if they were included by default.
OfficeMenuDataEntityOptions entityOptions =
_menuOptions.getOptionsForEntity(tableStr(MyEntity));
if (!entityOptions)
{
    // The entity options were not included. Add them.
    entityOptions =
OfficeMenuDataEntityOptions::construct(tableStr(MyEntity);
    _menuOptions.dataEntityOptions().addEnd(entityOptions);
}
entityOptions.includeDefault(false); // Don't include the default export
menu item.
entityOptions.includeTemplates(false); // Don’t include Document Template
related menu items.
```

Adding a custom export menu item – Generating a workbook

To explicitly add a menu item, you must add it to the **OfficeMenuOptions.customMenuItems()** list. To add a menu item that corresponds to a workbook that is generated at run time, use an **OfficeGeneratedExportMenuItem**.

X++

```
OfficeGeneratedExportMenuItem menuItem =
OfficeGeneratedExportMenuItem::construct(tableStr(MyEntity),
"MyCustomGeneratedExportId");
menuItem.setDisplayNameWithDataEntity();
_menuOptions.customMenuItems().addEnd(menuItem);
```

To define what is actually exported, use an **ExportToExcelDataEntityContext**. The method for specifying the **ExportToExcelDataEntityContext** depends on whether you're using interfaces or extensions and event subscriptions to customize the **Open in Office** menu.

Using interfaces

If you're using interfaces, you must implement the **OfficeIGeneratedWorkbookCustomExporter.getDataEntityContext()** method.

```
X++
```

```
public ExportToExcelDataEntityContext
getDataEntityContext(OfficeGeneratedExportMenuItem _menuItem)
{
    ExportToExcelDataEntityContext context = null;
    if (_menuItem.id() == "MyCustomGeneratedExportId")
    {
        context =
ExportToExcelDataEntityContext::construct(tableStr(MyEntity),
tableFieldGroupStr(MyEntity, MyFieldGroup);
    }
    return context;
}
```

Using extensions and event subscriptions

If you're using extensions and event subscriptions, the **OfficeGeneratedExportMenuItem.getDataEntityContext** delegate should be subscribed to before you add the menu item to the **OfficeMenuOptions.customMenuItems()** list. The code for the event handler should resemble the preceding code for the interface. The following example shows how to do the event subscription.

```
X++
```

```
menuItem.getDataEntityContext +=
eventhandler(MyForm_Extension::getDataEntityContextHandler);
```

Adding a custom export menu item – Specifying a document template

To explicitly add a menu item, you must add it to the **OfficeMenuOptions.customMenuItems()** list. To add a menu item that corresponds to a

Document Template record, use an **OfficeTemplateExportMenuItem**.

```
X++
```

```
OfficeTemplateExportMenuItem menuItem =
OfficeTemplateExportMenuItem::construct(OfficeAppApplicationType::Excel,
"MyTemplateId", "MyCustomTemplateExportId");
_menuOptions.customMenuItems().addEnd(menuItem);
```

To modify the template at run time, you can supply a set of initial filters. These filters will replace any filters in the template for the specified data entities. Additionally, you can modify filters and specify many settings by using **WorkbookSettingsManager**. The following sections show examples.

Using interfaces

If you're using interfaces, you must implement the **OfficeITemplateCustomExporter.getInitialTemplateFilters()** and **OfficeITemplateCustomExporter.updateTemplateSettings()** methods.

```
X++
```

```
public Map getInitialTemplateFilters(OfficeTemplateExportMenuItem _menuItem)
{
    Map initialFilters = new Map(Types::String, Types::Class);
    if (_menuItem.id() == "MyCustomTemplateExportId")
    {
        // Add an initial filter.
        ExportToExcelFilterTreeBuilder bldr = new
ExportToExcelFilterTreeBuilder(_menuItem.dataEntityName());
        FilterNode filter = // create the filter…
        initialFilters.insert(_menuItem.dataEntityName(), filter);
    }
    return initialFilters;
}
public void updateTemplateSettings(OfficeTemplateExportMenuItem _menuItem,
Microsoft.Dynamics.Platform.Integration.Office.SettingsManager
_settingsManager)
{
    if (_menuItem.id() == "MyCustomTemplateExportId")
    {
        // Set a new filter.
        ExportToExcelFilterTreeBuilder bldr = new
ExportToExcelFilterTreeBuilder(_menuItem.dataEntityName());
        FilterNode filter = // create the filter…
        Excel.WorkbookSettingsManager workbookSettingsManager =
_settingsManager as Excel.WorkbookSettingsManager;

workbookSettingsManager.SetEntityFilter(entityMetadata.PublicEntityName,
```

```
filter);
        // Adjust settings.
        DataConnectorAppletSettings settings =
settingsManager.DataConnectorSettings;
        DataConnectorAppletUserOptions options = settings.DataOptions;
        options.RefreshOnOpen = true;
        options.EnableDesign = false;
        workbookSettingsManager.DataConnectorSettings = settings;
    }
}
```

Using extensions and event subscriptions

If you're using extensions and event subscriptions, the **OfficeTemplateExportMenuItem.getInitialTemplateFilters** and **OfficeTemplateExportMenuItem.updateTemplateSettings** delegates should be subscribed to before you add the menu item to the **OfficeMenuOptions.customMenuItems()** list. The code for the event handlers should resemble the preceding code for the interface. The following example shows how to do the event subscription.

```
X++
```

```
menuItem.getInitialTemplateFilters +=
eventhandler(MyForm_Extension::getInitialTemplateFiltersHander);
menuItem.updateTemplateSettings +=
eventhandler(MyForm_Extension::updateTemplateSettingsHandler);
```

Additional customizations

The following customizations let you modify the contents of the **Open in Office** menu for a page without using interfaces or extensions and event handlers.

Removing an Export to Excel menu item for a grid

On the **Open in Office** menu, the **Export to Excel** group will contain a menu item for each visible grid. To remove a grid from the **Open in Office** menu, set the **ExportAllowed** metadata property on the grid to **No**. After you make this change, users won't be able to export the grid by using the shortcut menu for the grid.

Renaming an Export to Excel menu item for a grid

To rename the **Export to Excel** menu item that is related to a grid, set the **ExportLabel** metadata property on the grid to the appropriate label.

Removing all menu items for a data entity from all pages

Integration scenarios require that some data entities be publicly available via the OData Service. However, it isn't always appropriate that these data entities appear on the **Open in Office** menu by default. In this scenario, you can add the **OfficeMenuOmit** code attribute to the entity declaration.

```
X++
```

```
[OfficeMenuOmit]
public class MyEntity extends common
{
    // Entity code…
}
```

After you make this change, by default, the entity won't appear on the **Open in Office** menu on pages that have a matching root data source. However, if the entity should be added to a specific page, you can use other customization mechanisms to add it.

Adding a menu item button to a page that corresponds to an Open in Office menu entry

Sometimes, it's appropriate that the Action Pane of a page have a menu item button that corresponds to a custom menu item on the **Open in Office** menu. In this case, you can model a menu item button that has the following properties:

- **Menu Item Type: Action**
- **Menu Item Name: ExportToExcelExportForm**
- **Parameters:** The ID of the menu item

Then, a mouse click of this menu item button is equivalent to a mouse click of the corresponding menu item on the **Open in Office** menu.

>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The behavior of the email subsystem is influenced by a combination of administrator configuration, user configuration, and user choices. This article is divided into sections for administrators and users to make it easy to find relevant information.

Both administrators and users set the behavior of the email subsystem.

[Administrator] Email parameters page

Email configuration for the environment

On the **Email parameters** page, administrators can configure the high-level email behavior for the environment from the **Configuration** tab.

Expand table

Field	Description
Batch email provider	Specifies which email provider will be used to send emails that are sent by processes in a batch or non-interactive manner. The Microsoft Graph and Exchange providers will use the account that's associated with the batch process. Note: Microsoft Graph is available in Dynamics 365 Finance version 10.0.38 and later.
Attachment size limit	Specifies the maximum size of a single email that can be sent via the email subsystem.
Email expiration in days	Specifies the number of days before the status of an unsent message is set to **Expired**. A value of **0** means that the default period of 30 days is in effect.

The **Email history** section serves two purposes. First, it provides an entry point to the **Email history** page, where administrators can review all sent emails and also any errors that prevented an email from being sent. Second, it lets you configure how long email history is maintained. By default, the last 30 days of email history are retained. You can adjust this period

by changing the value of the **Number of days to retain email history** field to a non-zero number. If you set the value to **0** (zero), the default number and behavior are used.

The **Email throttling** section enables non-interactive email providers (such as the batch email provider) to adhere to a per-minute sending limit. This feature can help prevent some errors if the system tries to send more emails than the provider allows. Specifically, if an email can't originally be sent because the per-minute sending limit has been reached, the send attempt for the email will be deferred for up to one minute. After ten deferrals, the system will try to send the email regardless. You can remove the per-minute sending limit from a provider by resetting the **per-minute email sending limit** field to **0**. The sending limits for the Office 365 SMTP email provider is automatically set according to the Exchange Online sending limits. Manual configuration is required for all other email providers.

> **Note**
>
> Use of the **Email throttling** feature isn't recommended for the Microsoft Graph and Exchange email providers, because they have their own throttling mechanisms. Therefore, you should ensure that the **per-minute email sending limit** field is set to **0** for both those providers.

Send email with Microsoft Graph

For customers who use Office 365, Microsoft Graph is the recommended email provider for Dynamics 365 finance and operations apps. This email provider replaces the deprecated Exchange email provider.

You must have the following permissions to set up the Microsoft Graph integration:

- You must be a system administrator in the application to link the Dynamics 365 finance and operations environment to Microsoft Graph.
- You must be an administrator for your Microsoft Entra ID account. If you aren't the administrator, an administrative user must perform the first part of the configuration for you.

One-time registration process

To create an app, follow these steps:

1. Sign in to the Azure portal by using an Azure tenant admin account.

   > **Note**

> The user who completes this procedure must have Admin rights for the tenant to register applications.

2. Go to **Microsoft Entra ID** > **App registrations** > **New application**.

3. Enter the following values:

   - **Name** – Enter the name of your app.
   - **Supported account types** – Enter only accounts that are directly in this organization (single tenant).

4. Select **Register**.

5. Make a note of the **Application (client) ID** value. You will use this value to connect to the Microsoft Graph service from your finance and operations environment.

   > ⓘ **Important**
   >
   > Be sure to capture the **Application (client) ID** value before you continue.

6. To add permissions, follow these steps:

   a. Select **Manage** > **API permissions** > **Add a permission** > **Microsoft APIs** > **Microsoft Graph**.

   b. Select **Application permissions**, and enable **Mail.Send**.

      > ⓘ **Note**
      >
      > By default, the app should include the **User.Read** delegated permission for Microsoft Graph. If that permission is missing, you must add it from the delegated permissions.

   c. Select **Add permissions**.

   d. Select **Grant admin consent for** to allow emails to be sent.

7. To create a client secret, follow these steps:
   a. Select **Manage** > **Certificates and secrets**.
   b. On the **Client secrets** tab, select **New client secret**.
   c. Enter a value in the **Description** and **Expires** fields, and then select **Add**.
   d. Make a note of the **Secret value** value. You will use this value to connect to the Microsoft Graph service from your Dynamics 365 finance and operations

environments.

> **Important**
>
> Be sure to capture the **Secret value** value before you continue.

Restrict mailboxes

Administrators can modify mailbox access. For more information, see Limiting application permissions to mailboxes.

Configure Microsoft Graph in Dynamics 365 finance and operations apps

1. In Dynamics 365 finance and operations apps, open the **Email parameters** page.
2. On the **Microsoft Graph settings** tab, in the **Application ID** field, enter the **Application ID** value that you captured when you created the new app in the previous procedure.
3. In the **Application secret** field, enter the **Secret value** value that you captured when you created a client secret in the previous procedure.
4. Select **Save**.

Exchange email provider (Deprecated)

On the **Email parameters** page, an administrator can select **Exchange** as an interactive email provider and as the Batch email provider. This mail provider will use the current user's Exchange Online account to send emails. When it's used as the Batch email provider, the batch account will be used. No additional configuration is required.

If troubleshooting is required, ensure that it's possible to sign in to the current user's account, and that emails can be sent from that account to the intended recipients.

Note that the Exchange mail provider has the following limitations:

- It isn't supported for external users, because those users won't have Exchange accounts on the system tenant.
- It's available only in Microsoft-managed environments.

Send email by using SMTP

On the **Email parameters** page, note the following settings on the **SMTP settings** tab.

Server information

Expand table

Field	Description
Outgoing mail server	The host name of the desired Simple Mail Transfer Protocol (SMTP) server. For Microsoft 365 production (including *.onmicrosoft.com accounts), use smtp.office365.com. (You can find this setting at outlook.office.com at **Settings** > **Mail** > **POP and IMAP**.) For Outlook/Hotmail, use smtp-mail.outlook.com.
SMTP port number	Typically, the port number should be set to 587 for secure transport.
SSL required	Determines whether secure transport is used. Typically, this is **Yes**, except for internal or troubleshooting scenarios.

> **Note**
>
> If you are running into issues from too many emails being sent in a short period of time, it is recommended to utilize the **Email throttling** feature mentioned in the **Configuration tab** section above. If that doesn't resolve the issue, you may consider adding the appropriate IP addresses from the outbound IP safe list to your DNS SPF record authorizing Dynamics 365 finance and operations to send emails from your domain. For more information, see Outbound IP safe list.

Authentication

Expand table

Field	Description
Authentication required	Determines whether a user name and password are needed to send emails.
User name and **Password**	If authentication is required, specify the appropriate mail account to send email from. All users need to provide the SMTP account **Send As** and **Send On Behalf Of** permissions to enable the ability to send SMTP mail. You can configure Send As permissions in the Microsoft 365 admin center (portal.office.com/Admin) at **Users** > **Active users** > **User** > **Edit mailbox permissions** > **Send email from this mailbox**. For more information, see Enable sending email from another user's mailbox in Microsoft 365.

> **Note**

Finance and operations apps don't support multifactor authentication or Modern auth (OAuth 2.0) for SMTP. The Microsoft Graph email provider can be used if a more modern integration is desired. Administrators might have to re-enable Basic authentication to allow for SMTP AUTH. For more information, see Enable or disable SMTP AUTH. Note that the deprecation of Basic authentication for Exchange online only impacts the use of Office 365 SMTP servers. Other SMTP servers that still support basic authentication won't be impacted by this Office 365 deprecation.

[Administrator] Email distributor batch process

Email that is sent directly from the server, without user interaction, via SMTP is sent by the **Email distributor batch** process. That batch process must be started to process the email queue. To start the process, open the **Email distributor batch** pane (**System administration** > **Periodic tasks** > **Email processing** > **Batch**) and turn on **Batch processing**.

If the Microsoft Graph or Exchange provider is used, then the user account associated with the batch process (usually admin) will be the sender.

[Administrator] User email

The default **send from** address for each user is pulled from the **Email** field on the **Users** page (**System administration** > **Users** > **Users**). Administrators can override this **send from** default if needed using the **Sender email** field on the **Options** page.

[User] Email provider selection section on the Options page

The **Options** page can be opened via **Settings** > **User options**. The **Email provider selection** section is on the **Account** tab.

Expand table

Field	Description
Email provider ID	Allows the user to select the email provider that should be used when sending an email. Selecting an option here is the equivalent of selecting **Do not ask again** in the **How would you like to send email** dialog box. Selecting the blank option **Prompt for which email provider to use** will cause the **How would you like to send email** dialog box to display when an email is going to be sent.

Field	Description
Sender email	Allows the administrator to provide an email address override for the user in the **From** field of the email. By default, the email alias that is associated with the user account is used as the **From** field in new emails, but this user option email address will override that. When sending email via SMTP, the user needs to have appropriate **Send As** and **Send On Behalf Of** permissions configured in Exchange or on the SMTP server. **NOTE:** You can configure **Send As** and **Send On Behalf Of** permissions in the Microsoft 365 admin center (portal.office.com/Admin) at **Users** > **Active users** > **User** > **Edit mailbox permissions** > **Send email from this mailbox**. For more information, see Enable sending email from another user's mailbox in Microsoft 365.

[User] How would you like to send email dialog box (optional)

When an email is going to be sent, the user will see the **How would you like to send email** dialog box that will list the available options for sending email.

Expand table

Field	Description
Use an email app, such as Outlook	Provides the user with a generated email (.eml) file.
Use Exchange email server	Uses the Exchange Online server associated with the tenant. The **Exchange** mail provider is currently not supported outside the public cloud, including on-premises environments.
Use the system email client	Opens the **Send email** composition dialog box and then sends the resulting email via SMTP.
Do not ask again	If this field is not selected, the next time an email is sent the most recently selected option will be used and the dialog box will not open.

[User] Send email dialog box (optional)

The **Send email** dialog box is opened to allow the user to edit the contents of the email that will be sent. Some of the following fields will be pre-populated in this window.

Expand table

Field	Description
From	Populated from the **Email** field on the **Options** page.
To, **Cc**, **Bcc**, **Subject**, and **Body**	Populated with values specified by the process that initiated the sending of the email. These fields can be edited as needed by the user.
Attachments list	May be populated with attachments specified by the process that initiated the sending of the email. This list can be edited as needed by the user.

When the email is ready to be sent, the **Send** button will cause the email to be sent via SMTP.

Usage scenarios to verify if email is configured correctly

Send mail via a local mail client

Email workflows that are enabled via the SysEmail framework can generate email messages (.eml files) that contain attachments. You can then send these messages via Microsoft Outlook or another email client.

1. In Microsoft Edge, navigate to **Accounts receivable** > **Customers** > **All customers**.
2. Select **US-008 Sparrow Retail**.
3. Click **Collect** > **Customer balances** > **Collections** to open the **Collections** page.
4. Click **Communicate** > **Email** > **Statements to contact**.
5. Click **OK** to accept the default values in the dialog box.
6. If you're prompted for the mail option to use, clear the **Do not ask again** check box (you can change this option from the **User options** page), select **Use an email app, such as Outlook**, and then click **OK**.
7. If you're using Microsoft Edge on your computer, open the email (.eml) file that is generated. If you're using Microsoft Edge on the VM, copy the file to your computer, and open it there.
8. Note the email address in the **To** field and the generated workbook attachment.

Send mail via SMTP

Email workflows that are enabled via the SysEmail framework can also be created in a simple email dialog box and then sent via Simple Mail Transfer Protocol (SMTP).

1. Go to the **Email parameters** page.
2. Click **SMTP settings**.

3. Set the **Outgoing mail server** to the desired SMTP server:

    - For Microsoft 365 production (including *.onmicrosoft.com accounts) use smtp.office365.com. (Find this setting via outlook.office.com, at **Settings** > **Mail** > **POP and IMAP**.)
    - For Outlook/Hotmail use smtp-mail.outlook.com.

4. Set the user name and password to an appropriate email account and password.
5. Leave **SSLRequired** turned on, and leave **SMTP port number** set to **587**.
6. Click **Save**.
7. In Microsoft Edge, navigate to **Accounts receivable** > **Customers** > **All customers**.
8. Select **US-008 Sparrow Retail**.
9. Click **Collect** > **Customer balances** > **Collections** to open the **Collections** page.
10. Click **Communicate** > **Email** > **Statements to contact**.
11. Click **OK** to accept the default values in the dialog box.
12. If you're prompted for the mail option to use, select **Use the Microsoft Dynamics 365 Finance email client**, and then click **OK**.
13. To receive the test message, change the **To address** to your email address.

    Ensure that the account specified in the SMTP settings is able to **Send As** and **Send On Behalf Of** your email account. The easiest way to ensure this is to use your email account in the SMTP settings.

14. Enter a subject and body for the message.
15. Click **Send**. The message should be delivered in one to five minutes.

[Administrator] Workflow email notifications

Workflow email configuration is a collection of related settings that work in conjunction.

Workflow email notification setup

1. Verify email settings:
    a. Go to **System administration** > **Setup** > **Email** > **Email parameters**.
    b. Verify that SMTP is enabled.

c. Set the SMTP mail server settings.

2. Verify that the email batch process is running:

   a. Go to **System administration** > **Periodic tasks** > **Email processing** > **Email distributor batch**.

   b. Enable the **Batch processing** option.

   c. Optionally, adjust the recurrence of the email process:
      i. Select **No end date** to adjust all recurrences of the email batch process.
      ii. Adjust the count.
      iii. Adjust to run every minute if needed.

3. Verify workflow notification system email templates:
   a. Go to **System administration** > **Setup** > **Email** > **System email templates** (for system-wide templates).
   b. Verify that the **Sender email** field is set and valid.

4. Verify workflow notification organization email templates:
   a. Go to **Organization administration** > **Setup** > **Organization email templates** (for organization-specific templates).
   b. Verify that the **Sender email** field is set and valid.

5. Verify that the user can receive email notifications:

   a. Go to **Settings** > **User options**.

   b. Go to the **Account** tab.
      i. Set the **Email provider ID** (for example, SMTP).
      ii. Optionally, set a **Sender email** override if the default **send from** address should not be used for the current user.

   c. Navigate to the **Workflow** tab. Set the option to send notifications in email to **Yes**.

6. Verify that the workflow system will send email notifications:

   For each workflow that should have a notification, open the workflow properties in the workflow editor.

   a. Click **Basic settings**. Adjust the email template for the workflow notifications.

   b. Click **Notifications**.
      i. Enable the events for which a user should be notified.
      ii. Set the recipient of the workflow notification for each event notification that is enabled.

c. On a workflow approval element for which a user should be notified:
   i. Go to **Properties**.
   ii. Enable the events for which a user should be notified.
   iii. Set the recipient of the workflow notification for each event notification that is enabled.

Workflow email notification testing

The testing for email notifications is to simply trigger the notification and then check for it.

1. Submit a workflow that has been set up for email notifications.
2. Check the workflow history to make sure that a workflow work item was assigned to the expected user.
3. Check the status of the pending email notification in **System administration** > **Periodic tasks** > **Email processing** > **Batch email sending status**.

   If the email fails to be sent, make sure that the SMTP mail account can be opened.
4. Check for the email notification in the appropriate inbox.

Troubleshooting

Common issues with sending email

There are some standard processes that can help you troubleshoot the configuration of email settings.

Expand table

Verify email settings, and send a test email.	1. Go to **System administration** > **Setup** > **Email** > **Email parameters**. 1. Verify that SMTP is enabled. 1. Verify the settings of the SMTP mail server. 1. Sign in to the SMTP account in a separate window to make sure that the account and password are correct. 1. Send a test email by going to **System administration** > **Setup** > **Email** > **Email parameters** > **Test email**.
Verify that the email batch process is running.	1. Go to **System administration** > **Periodic tasks** > **Email processing** > **Batch**. 1. Make sure that the **Batch processing** option is set to **Yes**. 1. Review the recurrence of the email process: 1. Select **No end date** to adjust all recurrences of the email batch process. 1. Adjust the count as needed.

Review the status of batch emails.	1. Go to **System administration** > **Periodic tasks** > **Email processing** > **Batch email sending status**. 1. Verify that emails are being sent from the correct account. If the account is incorrect, you must adjust settings such as user options, system templates, or organization templates, as needed. 1. Verify that all email user accounts have been granted **Send As** permission for the configured SMTP account (see Verify that all email accounts have appropriate Send As permissions later in this table).
Review any errors on the Email history page.	1. Go to **System administration** > **Setup** > **Email** > **Email history**. The **Email history** page lets administrators review all sent emails and also any errors that prevented an email from being sent. It shows both interactive and non-interactive/batch emails. 1. For any emails where the **Email status** value is **Failed**, review the error message on the **Failure details** tab, and determine whether corrective actions should be taken. Some of these errors are covered later in this article.
Verify that all email accounts have appropriate Send as permissions.	In the Microsoft 365 admin center, verify that all user mail accounts that will be used to send emails have **Send As** and **Send On Behalf Of** permissions for the configured SMTP account. For more information, see Give mailbox permissions to another user in Microsoft 365.
Verify user mailboxes.	Consider signing in to the affected (or all) user mailboxes to verify that they are valid and can be accessed by using sign-in.

Specific Microsoft Graph/Exchange email issues

- **"(401) Unauthorized" or "(403) Forbidden" error when email is sent via Exchange**

Expand table

Explanation	This issue might indicate an invalid or incorrectly set up mailbox in Office 365.
Fix	To fix this issue, make sure that the specified user exists in Office 365 and has appropriate permissions. To find the affected users, follow these steps: 1. Open the **Email history** page. 1. Add a filter for **Failed** emails to the **Email status** field. 1. Make a note of the value in the **Email sender** field. This field shows the user that Exchange is indicating isn't a valid or correctly permissioned user in Office 365.

- **"(404) Not found" error when email is sent via Exchange**

Expand table

Explanation	This issue indicates that no mailbox exists for the user account in Exchange.
Fix	To fix this issue, make sure that the specified user exists in Office 365 and has appropriate permissions, or use alternate user accounts that have valid Exchange mailboxes. To find the affected users, follow these steps: 1. Open the **Email history** page. 1. Add a filter for **Failed** emails to the **Email status** field. 1. Make a note of the value in the **Email sender** field. This field shows the user that doesn't have a mailbox in Exchange.

Specific SMTP email issues

If you continue to experience issues when email is sent via SMTP, you may be running into one of the specific errors below. If not, consider entering the SMTP account information in a tool such as SMTPer.net to verify that the SMTP server and account are valid and working correctly.

- **SMTP emails fail to be sent with "Recipient addresses in single label domains not accepted"**

Expand table

Explanation	An email failed to be sent because a recipient is using a single-label domain, but Office 365 doesn't support single-label domains. Single-label domains are Domain Name System (DNS) names that don't contain a suffix such as .com, .corp, .net, or .org. For example, contoso is a single-label domain. However, contoso.com, contoso.net, and contoso.local aren't single-label domains.
Fix	Specify alternate addresses for email recipients that aren't single-label domains.

- **SMTP emails fail to be sent with "Mailbox full"**

Expand table

Explanation	An email failed to be sent because at least one recipient's mailbox is full. For more information, see Error (554 5.2.2 mailbox full) when sending email to mail-enabled public folders in Office 365.
Fix	Use an alternate address for the recipient, or contact the recipient by using alternate means before you try again.

- **SMTP emails fail to be sent with "Authentication unsuccessful, the request did not meet the criteria to be authenticated successfully"**

Expand table

Explanation	An email failed to be sent because additional criteria are required to successfully authenticate the SMTP user account. These additional criteria might be required because multifactor authentication (MFA) is configured. However, finance and operations apps don't currently support MFA.
Fix	Adjust the user account configuration as appropriate in Office 365 before you try again. For more information, see Fix issues with printers, scanners, and LOB applications that send email using Microsoft 365 or Office 365.

- **SMTP emails fail to be sent with "Authentication unsuccessful, SmtpClientAuthentication is disabled for the Mailbox"**

Expand table

Explanation	An email failed to be sent because SMTP client authentication is disabled for the SMTP user account.
Fix	Enable SMTP client authentication for the user account in Office 365 before you try again. For more information, see Enable or disable authenticated client SMTP submission.

- **SMTP emails fail to be sent with "If your SMTP server doesn't support authentication, please clear the SMTP user name and password"**

Expand table

Explanation	This issue is related to migration from the .NET SMTP mail client (which is now obsolete) to MailKit per Microsoft recommendations. This migration causes a change in the way that SMTP user names and passwords are handled in situations where the mail server didn't support authentication. Previously, if an SMTP user name was provided, but the server didn't support authentication, the .NET SMTP mail client ignored the provided user name and password, and continued without authentication. This behavior led some customers to incorrectly believe that they were using an authenticated mail server. In MailKit, authentication is required if a user name is provided. This requirement will trigger an error for mail servers that don't support authentication, and emails will fail to be sent.

Fix	The user must go to the **Email parameters** page (**System administration** > **Setup** > **Email**) and clear the **User name** and **Password** fields on the **SMTP settings** tab.

- **SMTP emails fail to be sent with an "5.7.57 SMTP" error, or an indication that either you aren't authenticated or authentication is required**

Expand table

Explanation	The mail server is indicating that the SMTP user credentials aren't valid.
Fix	Verify that the SMTP user credentials are correct.

- **SMTP emails fail to be sent with "Microsoft.Dynamics.Ax.Xpp.Security.CryptoEncryptionException: Encryption error occurred with exception"**

Expand table

Explanation	The SMTP password is encrypted by using a key that is specific to a single environment. This error typically occurs when the password can no longer be decrypted after database migration between environments.
Fix	Clear and reenter the SMTP password on the **SMTP settings** tab of the **Email parameters** page.

- **SMTP emails fail to be sent with "Client does not have permissions to send as this sender"**

Expand table

Explanation	This issue is usually caused by incorrect setup of the **Send As** permissions for the email account.
Fix	Ensure that the email account has appropriate **Send As** permissions. For more information, see Verify that all email accounts have appropriate Send As permissions earlier in this article.

Frequently asked questions

Where do workflow email templates come from?

The email templates will be sourced from either system email templates or organization email templates depending on whether the workflow is a system-level (not company specific) or organization-level (company specific) workflow.

What email limits apply when using Microsoft Graph, Exchange, or SMTP?

The system communicates with Microsoft Graph, Exchange, or an SMTP server like a typical email client, so standard behavior and limits apply. For example, standard Exchange Online receiving and sending limits apply.

Sending emails

The SysMailer framework is a new, extensible way to send email. It replaces all previous application programming interfaces (APIs) for mail, such as CDO.Messaging (SysMailer), MAPI (SysINetMail), and Outlook COM (SmmOutlookEmail). Those older mail APIs don't work correctly in finance and operations applications. By taking advantage of the SysPlugin framework and several .NET technologies, SysMailer provides a configurable experience for users and enables the application consumers to remain agnostic to the email option that users use to send email.

The SysMailer framework consists of a factory class that you use to retrieve an email provider, a set of email providers that send messages, a message builder that builds the messages, and the forms that are related to configuring and interacting with the email providers. To consume the SysMailer framework, an application developer primarily uses the **SysMailerFactory** and **SysMailerMessageBuilder** classes. The email provider factory is used to retrieve interactive or non-interactive email providers, so that you can send multiple messages at the same time, or so that you can send a message directly. The email providers expect the messages that they send to be encapsulated in .NET **System.Net.Mail.MailMessage** objects. Use the message builder class to build the .NET object that you pass to the email provider.

Scenarios

This article describes three scenarios:

- Sending an interactive message
- Sending a non-interactive (batch) message

- Sending multiple non-interactive (batch) messages

Sending an interactive message

The following example is taken from the **CustCollectionsEmail** class. It demonstrates multiple features of the framework, such as the ability to chain message builder calls, conditionally set the sender address ("from" address), and add attachments.

X++

```
using (System.IO.Stream attachmentStream = this.generateAttachment())
{
    var messageBuilder = new SysMailerMessageBuilder();
    messageBuilder.addTo(context.parmEmailAddress())
    .setSubject(emailSubject)
    .setBody(SysEmailMessage::stringExpand(emailBody,
    SysEmailTable::htmlEncodeParameters(templateTokens)));
    if (emailSenderAddr)
    {
        messageBuilder.setFrom(emailSenderAddr, emailSenderName);
    }
    else if (custParameters.CollectionsOMTeam)
    {
        var collectionsEmail =
OMTeam::find(custParameters.CollectionsOMTeam).primaryEmail();
        if (strLen(collectionsEmail) > 0)
        {
            messageBuilder.setFrom(collectionsEmail);
        }
    }
    if (attachmentStream != null)
    {
        messageBuilder.addAttachment(
            attachmentStream,
            strFmt('%1%2', strReplace(DateTimeUtil::toStr(DateTimeUtil::utcNow()),
':', ''), '.xlsx'));
    }
    SysMailerFactory::sendInteractive(messageBuilder.getMessage());
}
```

Sending a non-interactive (batch) message

The following example is taken from the **VendRequestCompanyWorkflowManager** class. It shows how you can send a single message non-interactively.

X++

```
// The vendor <vendor name> has been approved and has been added to the vendor
master.
```

```
messageText = strFmt("@SYS134393",
DirPartyTable::findRec(vendRequestCompany.VendParty).Name);
// Request
var messageBuilder = new SysMailerMessageBuilder();
messageBuilder.setFrom(senderEmail)
    .addTo(recipientEmail)
    .setSubject("@SYS130372")
    .setBody(messageText);
SysMailerFactory::sendNonInteractive(messageBuilder.getMessage());
```

Sending multiple non-interactive (batch) messages

The following example is taken from the **UserAdAddManager** class. It shows how you can get an instance of a batch email provider before you iterate over a list of emails to send.

X++

```
var mail = SysMailerFactory::getNonInteractiveMailer();
var messageBuilder = new SysMailerMessageBuilder();
for (i = 1; i <= conLen(_notifyCon); i++)
{
    notifyEmailsStr = conPeek(_notifyCon, i);
    select firstonly RecId, Email from sysUser where sysUser.Id == notifyEmailsStr;
    if (sysUser.RecId && sysUser.Email != '')
    {
        messageBuilder.reset()
            .setFrom(_emailFrom)
            .addTo(sysUser.Email)
            .setSubject("@SYS129183")
            .setBody(errorStr);
        mail.sendNonInteractive(messageBuilder.getMessage());
        delete_from tmpUserErrorNotification;
    }
}
```

Important considerations

- When you send messages to an email provider, you need a sender address ("from" address). When you send messages non-interactively, you need a receiver address ("to" address). If you don't meet these conditions, the framework throws an exception. If you call **getMessage** on the message builder before you call **setFrom**, the builder tries to set the sender address to the current user's email address or network alias.

- When you send messages, how the sender address ("from" address) is used depends on the provider:
    - **EML provider:** The sender address is removed from the message before the message is opened in the user's email client. Therefore, the email client can set the sender

address to the default account that is configured for sending mail.
    - **SMTP provider:** You must configure the Simple Mail Transfer Protocol (SMTP) server to allow messages to be sent by using the sender address. In other words, the SMTP server must allow the impersonation of emails that are sent from it. Otherwise, the SMTP server might prevent the messages from being sent, flag them as spam, and so on.

- When you send messages, the framework returns a Boolean value that indicates whether the operation to send the message was successful. However, it doesn't report any messages to the Action Center when the operation is successful. You decide whether messages are shown in the Action Center.

- By default, the body of all messages that you send is in rich-text (HTML) format. If an application scenario requires that plain text be used to maintain newline spacing, you can pass **false** to the optional **_isHtml** parameter of the **setBody** method on the message builder.

Adding a new email provider

You can add email providers by using the pluggable framework. When you use the factory class and interfaces, new email providers immediately become available for use across all relevant application scenarios. You can find examples of email providers in the existing provider implementations, SysMailerEML and SysMailerSMTP, and also in an existing tutorial implementation, Tutorial_SysMailerMailTo. The following examples are excerpts from the implementation of the SysMailerEML email provider.

To implement an email provider, create an implementation class that has the following properties:

- The class must have the appropriate **Export** attributes.
- The class must implement the base **SysIMailer** methods, **getId** and **getDescription**.
- The class must implement the **SysImailerInteractive** interface, the **SysIMailerNonInteractive** interface, or both interfaces.

Specify attributes for the implementation class

First, specify attributes for the implementation class. The class must have two attributes:

- **ExportAttribute** – The framework uses this attribute to discover the plug-in. The attribute specifies that the plug-in is an implementation of **SysIMailer** and therefore part of the

SysMailer framework.

- **ExportMetadataAttribute** – The framework uses this attribute to find specific instances of a plug-in that have specific metadata. The attribute specifies the ID of the email provider, so that a single provider can be discovered quickly. **No two email providers should ever have the same ID.**

X++

```
using System.IO;
using System.Net.Mail;
using System.Text.RegularExpressions;
#define.SysMailerEML_ID('EML')
/// <summary>
/// The <c>SysMailerEML</c> class is an interactive email provider implementation
that sends messages by generating
/// an EML file, uploading it to Azure temporary blob storage, and then redirecting
the user's browser to
/// the file to save or open for sending using their default email client.
/// </summary>
// This is a framework class. Customizing this class may cause problems with future
upgrades to the software.
[System.ComponentModel.Composition.ExportAttribute(identifierStr(Dynamics.AX.Applic
ation.SysIMailer)),
System.ComponentModel.Composition.ExportMetadataAttribute(extendedTypeStr(SysMailer
Id), #SysMailerEML_ID)]
public class SysMailerEML implements SysIMailerInteractive
{
```

Implement the SysIMailer interface

The **SysIMailer** interface includes identifiable information about an email provider, regardless of the capabilities of the email provider itself. To implement this interface, you must create two methods:

- **getId** – This method returns the same ID that you specify in the **ExportMetadataAttribute** attribute.
- **getDescription** – This method returns a non-technical description that indicates how the email is sent.

X++

```
public SysMailerId getId()
{
    return #SysMailerEML_ID;
}
public SysMailerDescription getDescription()
{
```

```
    // Use an email app, such as Outlook
    return "@ApplicationFoundation:EmailProviderEMLDescription";
}
```

Implement a combination of the SysIMailerInteractive and SysIMailerNonInteractive interfaces

The **SysIMailerInteractive** and **SysIMailerNonInteractive** interfaces are very simple. They implement the **sendInteractive** and **sendNonInteractive** methods, respectively. An email provider might implement one or both methods, depending on its capabilities. Each method that you implement takes a .NET **System.Net.Mail.MailMessage** object that you use to construct and send the email.

X++

```
public boolean sendInteractive(System.Net.Mail.MailMessage _message)
{
    using (var emlStream = this.generateEmlFile(_message))
    {
        Dynamics.AX.Application.File::SendFileToUser(emlStream, 'message.eml');
    }
    return true;
}
```

The **System.Net.Mail.MailMessage** object contains a large amount of advanced functionality that's related to MIME messages. You can build a relatively complex message object and pass it to an email provider. If there's specific functionality that an email provider doesn't support, the email provider is expected to handle the functionality actively (by modifying the message), passively (by making an internal call to another email provider), or not at all (by throwing an error).

Migration from Microsoft Dynamics AX 2012 to finance and operations applications

Migration involves using the **SysMailerMessageBuilder** object to build a message and then using the **SysMailerFactory** to send it, as outlined in the examples in this article.

Office integration FAQ

09/23/2025

Applies to these Dynamics 365 apps:
Commerce, Finance, Human Resources, Supply Chain Management

This article provides answers to frequently asked questions about the capabilities of the Microsoft Office integration. The questions and issues that are discussed range across user, administration, and development scenarios.

Frequently asked questions

What platforms do the Office add-ins support?

The Microsoft Excel add-in and Microsoft Word Add-in are built by using the Office Web/JavaScript add-in framework. This framework was originally released for Microsoft Office 2013 but received significant updates in Microsoft Office 2016. For more information, see Office Add-in host and platform availability. The Excel add-in requires ExcelAPI 1.2. Therefore, use the Office Add-in host and platform availability matrix to determine which platforms support the Excel add-in. For many users, the phrase "Excel 2016 with the latest updates" is sufficient.

Are the Office Add-ins safe?

In an age of malware, full connectivity, and compliance risks, nothing is completely secure. However, the web add-ins, like other websites, are basically a web application that interacts with the Office client products via a limited application programming interface (API). For more information, see Office add-ins platform overview

Does the Excel add-in support Office for Mac?

No. The Office JavaScript (JS) APIs work differently in Apple Safari and Microsoft Edge/Internet Explorer, especially in respect to authentication. For details about platform support for the Office JS APIs, see Office Add-in host and platform availability.

What version of Office is required for the Excel add-in to support AD FS?

For more information, see the "Troubleshooting issue" section later in this article.

How can I force an update of Office?

If your Office build isn't updated, you might be on the deferred track (Overview of update channels for Microsoft 365 Apps). In this case, you can use the Office Deployment Tool to move to the Current channel or sign up for the Office Insider program to help guarantee that you have the latest updates. The easiest method is to use the Office Deployment Tool to switch to the current channel. In this case, the latest updates are installed immediately.

Why can't you tell me what version of Office or Excel a particular issue is fixed in?

Office has many releases. These releases receive updates at different times and have different version numbers that don't correspond. Some frequently used Office versions and update methods are Click to Run (C2R) Current channel, C2R Deferred, C2R First Update Deferred, Office Insider Fast, Office Insider Slow, and MSI/MSO (install from DVD). For more information about Office versions, see the Release information for updates to Microsoft 365 Apps page.

Why am I having trouble signing into the Excel add-in?

The browser used to authenticate the Excel add-in (or any Office add-in) is dependent on the Office and operation system versions. For more information about the specific browser used to sign in for your configuration, see Browsers used by Office add-ins. By default, the Excel add-in picks up stored credentials from the browser, and the browser provides the current Microsoft Windows credentials if there are no stored credentials. Make sure that you're using the correct credentials to sign in. In the Excel add-in, explicitly sign out, and then sign in to ensure that the correct credentials are used.

The Excel add-in seems to be slow when it publishes records. How can I learn more about what is occurring?

Most of the work that the Excel add-in does should occur on the server. To learn where the time is being spent, you can use Fiddler (a free download) to make sure that the Excel Add-in works as you expect.

The Excel add-in sends the published records as a request. When those records are processed, the response is sent back from the server. The Excel add-in then creates another message that contains the next set of records to publish, and sends that request. Five to 10 seconds of processing time in the Excel add-in should be required between the previous response from the server and the next request to the server.

To check processing time in the Excel add-in versus the server/service, follow these steps.

1. Start Fiddler.
2. Publish a few records to test the process.
3. Make sure that you can view that request and response in Fiddler (make sure that HTTPS traffic is being decrypted).
4. Publish a larger number of records.
5. In Fiddler, watch the time that is required from a request to its response, and from a response to the next request.
    - If the time from a request to its response is large, the bottleneck is the server/service.
    - If the time from a response to the next request is large, the bottleneck is the Excel add-in (that is, the client).

Is Export to Excel the best way to get data out of the system?

The best way for end users to get data out of the system is to use the Excel add-in. The add-in relies on the Open Data Protocol (OData) service to retrieve data and takes advantage of the security that data entities provide. The import and export capabilities in the Data management framework (DMF) and Data import/export framework (DIXF) can also be used. However, DMF and DIXF are often limited to administrators. Additionally, you might consider exploring the available reporting and analytic features in the product.

When the previously mentioned options can't be used, you might consider the Export to Excel functionality, which can be useful for retrieving data from calculated columns (display methods), columns that have formatted values, and data from temporary tables. Because the export process uses the data from the active form to retrieve data, Export to Excel returns the data exactly as it's shown in the grid. Additionally, it only returns the data that matches the current set of filters.

Export to Excel does have its own set of limitations. First, this mechanism takes more time to export than the options that go through the OData service, and the time to export can be significant for larger exports. Secondly, the export of data to Excel is a memory-intensive process that can cause out-of-memory errors to occur and servers to stop responding, especially if the organization increases the export row limit beyond the default value. Export to Excel isn't intended for auditing purposes. When very large datasets must be exported from the system, data management is recommended.

> ⚠ **Warning**

Although organizations can increase the default Export to Excel row limit (50,000 records), we **strongly recommend** that you **not** raise this limit above 100,000 records. Depending on the characteristics of the environment and the specific grid that is being exported, even that limit might be too high and might cause memory issues.

Because an export from Excel can take some time, it's recommended that the export is done with the Chrome or Edge browsers, with the automatic download option enabled. The automatic download option ensures that the browser downloads the file as soon as the export is complete to ensure that the download link is used within the 15-minute time limit.

Why is the Publish button in the Excel add-in unavailable?

Hover over the **Publish** button to get more information as to why publishing currently isn't supported. Typically when this occurs, it's because all key and required fields must be present to publish data back to the entity, in which case you should open the designer and make sure all the key fields are bound.

Why are the Excel add-in, the Word add-in, and the Open in Excel options only available when the Internet is available?

All environments including on-premises, the Excel and Word add-ins, and the libraries they use, are loaded from multiple Internet locations and only run when the Internet is available. For on-premises environments, when the Internet isn't available, the Open in Excel options are hidden because the Excel Add-in doesn't run without access to the Content Delivery Network (CDN) that houses the Excel add-in.

Can the Excel add-in and Word add-in be made available to users using centralized deployment?

Yes, centralized deployment is supported. For more information, see Centralized Deployment.

To use Centralized Deployment, on the **App parameters** tab on the **Office App Parameters** page change the **App ID**, **Store**, and **Store Type**:

- **App ID**: 61bcc63f-b860-4280-8280-3e4fb5ea7726
- **Store**: EXCatalog
- **Store Type**: Centralized Deployment

In case a change back to Office Store is needed, the standard values are:

- **App ID**: WA104379629

- **Store**: en-US
- **Store Type**: Office Store

> ⓘ Note
>
> - **Name**, **Version**, and **Notes** are values that provide information but they aren't needed to run the Excel add-in.
> - These same values are also used for the Word add-in when it's run from the Document Templates form.

If you encounter issues with centralized deployment for some users, it could be one of these problems:

- One or more users are members in a group that is more restrictive than others
- The user referenced is on a different Microsoft 365 account (such as a personal account)

What is the cell limit for the Excel add-in?

The default Excel add-in cell limit is about half the limit of what the Excel Add-in can handle on a reasonably fast machine. The speed of the machine is the limitation. If problems are encountered, then the cell limit should be reduced and/or the filter should be adjusted to reduce the data set. A common workaround is to use a filter to manage the data in smaller pieces instead of all at once.

How do I make an entity available in the Excel add-in and/or as an Open in Excel option?

If the entity is marked as “IsPublic=Yes” and has unique PublicEntityName and PublicCollectionName values, then it will be available via the OData service. Check that there aren’t any existing entities with the same PublicEntityName and PublicCollectionName values by looking at the $metadata feed for the environment (preferably in Google Chrome): https://*SomeFullEnvironmentURL*.dynamics.com/data/$metadata

Why are date and time values in UTC in the Excel add-in?

The Excel add-In, Data Management Framework, and Power BI reporting are all designed to interact with data directly on the database level. Because there's no client to adjust Date and Time data to the time zone of the user, all Date and Time values are in UTC.

Troubleshooting issues

Issue: The Excel add-in loads, but instead of showing data, it displays "Load applets" in the task pane

Issue: The Excel add-in loads, but instead of showing data, it displays "Load applets" in the task pane.

Explanation: This issue usually occurs due to one of the following reasons:

- Incorrect sign in
- Add-in registration data hasn't been initialized in the environment
- OData issues

Fix:

- **Incorrect sign in**: The most likely cause of this issue is that the user is signed in as the wrong user. This can happen if the user has multiple accounts and the browser uses the wrong user context. Before trying any other fix, you should sign out of the add-in using the user menu in the upper-right corner and then sign back in to the add-in. If the issue persists, ensure registration data is properly initialized, as noted in the following fix.
- **Registration data not initialized**: If the issue wasn't addressed by signing back in to the add-in, another potential cause is that the environment doesn't yet have the add-in data initialized. To check this, the admin can navigate to the **Office app parameters** page. For each of the **App parameters**, **Registered applets**, and **Registered resources** tabs on that page, verify that there's data populated in each tab. If any tab has an empty grid, select the appropriate **Initialize** button on that tab.
- **OData issue**: If the issue persists after attempting the previous two fixes, then the final cause of this issue could be that the OData service, through which the add-in communicates with finance and operations, is unable to return the registration data to the add-in. Without that data, the add-in fails to load applets. At this stage, you need to contact Microsoft Support with information from the **Application correlation ID** from the Excel add-in with the failed session. You can find this field under **Options**.

Issue: During sign-in to the Excel add-in, users receive an error message saying they "can't access the application '2bc50526-cdc3-4e36-a970-c284c34cbd6e' in that tenant"

Issue: During sign in to the Excel add-in, a user receives an error similar to the following:

- "Microsoft EntraSTS50020: User account 'XXX' from identity provider 'https://sts.windows.net/XXX' doesn't exist in tenant 'XXX' and can't access the application '2bc50526-cdc3-4e36-a970-c284c34cbd6e'(Microsoft Business Office Add-in) in that tenant."
- "Selected user account doesn't exist in tenant 'XXX' and can't access the application '2bc50526-cdc3-4e36-a970-c284c34cbd6e' in that tenant."

Explanation: This issue is caused by a change made to Microsoft Entra ID in April 2021 in regard to external users. Because this change wasn't made to the finance and operations apps, it can affect customers on any version of the platform or application.

Fix: All external users need to be invited to the tenant through Microsoft Entra ID. For more information, see Invite users with Microsoft Entra B2B collaboration.

[Fixed] Issue: During sign-in to the Excel add-in, I receive the following error message: "Microsoft EntraSTS65001: The user or administrator hasn't consented to use the application with ID XYZ"

Issue: During sign in to the Excel add-in, you receive the following error message: "Microsoft EntraSTS65001: The user or administrator hasn't consented to use the application with ID XYZ."

Explanation: Typically, this issue occurs because Microsoft Entra ID can't find the Microsoft Entra application that represents the Excel add-in. That issue occurs because, during the configuration of Microsoft Power BI, a Microsoft Entra application was added that has the App ID URI set to the environment URL.

Fix: Make sure that no Microsoft Entra apps have the App ID URI set to the environment URL. App ID URIs should be fabricated, unique URIs, such as `https://contosoAXPowerBI`.

[Fixed] Issue: During sign-in to the Excel add-in, I receive the following error message: "Microsoft EntraSTS50001: The application named ABC wasn't found in the tenant named XYZ"

Issue: During sign-in to the Excel add-in, you receive the following error message: "Microsoft EntraSTS50001: The application named ABC wasn't found in the tenant named XYZ."

Explanation: This issue probably occurs because an error in the deployment system caused the environment to get a URL that wasn't added to the configured list of service principals for the tenant.

Fix: File a support issue for your environment, so that the problem can be investigated and the configuration can be adjusted.

[Fixed] Issue: After the Excel add-in starts and updates data, I receive the following error message: "An error occurred while writing to the data cache"

Issue: After the Excel add-in starts and updates data, you receive the following error message: "An error occurred while writing to the data cache." The details of the error state, "The argument is invalid or missing or has an incorrect format."

Explanation: You receive this error message if the client is open in Internet Explorer, and the user clicks **Open** immediately after selecting the **Open in Excel** option. The way that Internet Explorer handles temporary Internet files causes an issue in Excel. This issue, in turn, causes API calls to fail.

Workaround: The recommendation is to use Microsoft Edge or another modern browser. These browsers tend to save files to a Downloads folder by default, which mitigates the issue. If you're using Internet Explorer, which is now deprecated, when you open a workbook, select **Save** first, and then select **Open**. The file will then be opened from your Downloads folder.

Long-term fix: We are working with the Office team to understand this issue so that it can be fixed in Excel.

Issue: VPN users see a blank authentication screen when trying to sign into the Excel add-in

Issue: Users using a virtual private network (VPN) aren't able to sign in to the add-in because the authentication dialog appears blank or is missing text.

Fix: The issue must be solved from the customer side, as the VPN software or browser settings when running under VPN are preventing their machines from retrieving resources and/or interpreting those resources correctly.

Here are some common solutions to VPN issues:

- Verify that the user has access to the locations listed in: Issue: The Excel Add-in doesn't correctly run or enable sign-in.
- Verify that your browser isn't set to "Display intranet sites in Compatibility view" for Microsoft Edge (or Internet Explorer 11). This can be configured by organization policy.
- Have the affected user compare their VPN and Edge/IE browser settings with other users who aren't impacted.

[Fixed] Issue: The Excel add-in doesn't correctly run or enable sign-in

Issue: When users try to sign into the Excel add-in, a blank authentication dialog box appears, or an error message is shown instead of the authentication page. The user can't sign in.

Explanation: The Excel add-in relies on the Office Web JS Add-in platform and uses Microsoft Entra ID authentication. If a proxy is used, several URLs must be accessible for users to run and sign in to the Excel Add-in. Additionally, if AD FS is used, the AD FS URL must use HTTPS.

Solution: Because this issue is a customer-specific network issue, it requires a customer-specific resolution. If AD FS is used, make sure that the AD FS URL uses HTTPS. Additionally, make sure that all the following URLs are accessible from the user's computer.

The following URLs are accessed for loading.

- `https://az689774.vo.msecnd.net:443`
- `https://az689774.vo.msecnd.net`
- `https://appsforoffice.microsoft.com:443`
- `https://appsforoffice.microsoft.com`
- `https://secure.aadcdn.microsoftonline-p.com:443`
- `https://secure.aadcdn.microsoftonline-p.com`
- `https://az416426.vo.msecnd.net:443`
- `https://az416426.vo.msecnd.net`
- `https://telemetryservice.firstpartyapps.oaspapps.com:443`
- `https://telemetryservice.firstpartyapps.oaspapps.com`
- `https://nexus.officeapps.live.com:443`
- `https://nexus.officeapps.live.com`
- `https://browser.pipe.aria.microsoft.com:443`
- `https://browser.pipe.aria.microsoft.com`
- `http://schemas.microsoft.com`

The following URLs are accessed for authentication.

- `https://login.windows.net:443`
- `https://login.windows.net`
- `https://login.microsoftonline.com:443`
- `https://login.microsoftonline.com`

Alternate solution: If the user is running an older version of Windows 10 (earlier than version 1909), consider upgrading Windows 10 to version 1909 or later. Version 1909 may need KB5003635. For more information, see May 2021 resolved issues.

Issue: The Excel add-in needs an explicit sign out after encountering a Microsoft EntraSTS50058 "silent sign in failed" error

Issue: When users try to sign in to the Excel add-in after some period of inactivity, the user encounters the Microsoft EntraSTS50058 "silent sign in failed" error and is forced to sign out before signing back in.

Explanation: The Excel add-in uses Microsoft Entra ID authentication. When authentication occurs, a token is created for the user. That token has an expiration period. After the token has expired, a Microsoft EntraSTS50058 error occurs indicating that "silent sign in failed".

Solution: The user needs to sign out and sign back in. We will improve this behavior in the future by automatically signing the user out to enable faster sign in.

Issue: When trying to use a document template with Open in Excel a "Record for id GUID not found" error displays

Issue: The "Record for id GUID not found" error can display when copying a database from one environment to another.

Explanation: Copying the database is problematic for document templates, record attachments, and other files that are stored in Azure blob storage. When the database is copied from one environment to another, the files aren't copied along with the records, so the files that the application tries to access aren't found.

Solution: For document templates, the solution is to identify the templates that are needed and load a copy of those template files into the target environment.

Office integration

Office integration tutorial

Configuring Power BI integration

Organization administration home page

This article points to content that helps power users and administrators configure the system to work smoothly and effectively for your organization and business.

Much of the content listed here applies to features in the **Organizational administration** module. However, you can perform a couple of tasks, such as creating and using a record template, in any module to help your organization run more efficiently.

Number sequences

Use number sequences to generate readable, unique identifiers for master data records and transaction records that require identifiers. A master data record or transaction record that requires an identifier is a *reference*. Before you can create new records for a reference, you must set up a number sequence and associate it with the reference.

- Number sequences overview
- Set up number sequences using a wizard (Task guide)
- Set up number sequences on an individual basis (Task guide)

Organizations

An organization is a group of people who work together to carry out a business process or achieve a goal. Organizational hierarchies represent the relationships between the organizations that make up your business.

Before you set up organizations and organization hierarchies, plan how your business is modeled. The organization model has a significant effect on implementation and business processes.

- Organizations and organizational hierarchies overview
- Plan your organizational hierarchy
- Create an organization hierarchy (Task guide)
- Create a legal entity (Task guide)
- Create an operating unit (Task guide)

Address books

The global address book is a centralized repository for master data that you must store for all internal and external persons and organizations that your company interacts with. The data associated with party records includes the party's name, address, and contact information.

After you create the global address book, you can create more address books as you require, such as a separate address book for each company in your organization or for each line of business.

- Global address book overview
- Plan for the global address book and other address books
- Configure the global address book
- Address books FAQ

Workflow

Workflow is a system that you can use to create individual workflows or business processes. When you create a workflow, you specify how a document flows or moves through the system by showing who must complete a task, make a decision, or approve a document.

- Workflow system overview
- Workflow elements
- Actions in workflow approval processes
- Create workflows overview

Electronic signatures

An electronic signature confirms the identity of a person who is about to start or approve a computing process. In some industries, an electronic signature is as legally binding as a handwritten signature. Electronic signatures are a regulations compliance requirement for several regulated industries, such as pharmaceuticals, food and beverage, and aerospace and defense.

You can use electronic signatures for critical business processes. Some processes have built-in electronic signature capabilities. You can also create custom signature requirements for any database table and field.

- Electronic signatures overview
- Set up electronic signatures (Task guide)

Case management

By planning, tracking, and analyzing cases, you can develop efficient resolutions that you can use for similar issues. For example, when customer service representatives or Human Resources generalists create cases, they can find information in knowledge articles to help them work with or resolve a case more efficiently.

- Case management overview
- Plan case category security, case processes, and case categories

Record templates

Record templates can help you create records more quickly. You can create a record template so that you don't have to enter field values that you use often for each new record.

- Record templates overview
- Create a record template to facilitate data entry (Task guide)
- Use record template to create a new record (Task guide)

General organization administration

- Change the banner or logo (Task guide)
- Configure document management
- Configure and send email
- Date/time data and time zones

Number sequences overview

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use number sequences to generate readable, unique identifiers for master data records and transaction records that need identifiers. A master data record or transaction record that needs an identifier is called a *reference*.

Before you can create new records for a reference, set up a number sequence and associate it with the reference. Use the pages in **Organization administration** to set up number sequences. If you need module-specific settings, use the parameters page in a module to specify number sequences for the references in that module. For example, in **Accounts receivable** and **Accounts payable**, you can set up number sequence groups to allocate specific number sequences to specific customers or vendors.

When you set up a number sequence, specify a scope to define which organization uses the number sequence. The scope can be **Shared**, **Company**, **Legal entity**, or **Operating unit**. You can combine **Legal entity** and **Company** scopes with **Fiscal calendar period** to create even more specific number sequences.

Number sequence formats consist of segments. Number sequences with a scope other than **Shared** can contain segments that correspond to the scope. For example, a number sequence with a scope of **Legal entity** can contain a legal entity segment. By including a scope segment in the number sequence format, you can identify the scope of a particular record by looking at its number.

In addition to segments that correspond to scopes, number sequence formats can contain **Constant** and **Alphanumeric segments**. A **Constant** segment contains a set of letters, numbers, or symbols that doesn't change. An **Alphanumeric** segment contains a set of letters or numbers that increment each time you use a number. Use a number sign (#) to represent incrementing numbers and an ampersand (&) to represent incrementing letters. For example, the format #####_2017 creates the sequence 00001_2017, 00002_2017, and so on.

Number sequence examples

The following examples show how to use segments to create number sequence formats. In particular, the examples demonstrate the effects of using scope segments.

Expense report numbers

In the following example, you set up expense report numbers for the legal entity that is titled **CS**.

- **Area:** Travel and expense
- **Reference:** Expense report number
- **Scope:** Legal entity
- **Legal entity:** CS

Expand table

Segments	Segment type	Value
Segment 1	Legal entity	CS
Segment 2	Constant	-EXPENSE-
Segment 3	Alphanumeric	####

Example of formatted number: CS-EXPENSE-0039

You can set up a similar number sequence format for other legal entities. For example, for a legal entity that is named **RW**, if you change only the value of the legal entity segment, the formatted number is RW-EXPENSE-0039. You can also change the whole number sequence format for other legal entities. For example, you can omit the legal entity scope segment to create a formatted number such as Exp-0001.

Sales order numbers

In the following example, you set up sales order numbers for the company ID **CEU**.

- **Area:** Sales
- **Reference:** Sales order
- **Scope:** Company
- **Company:** CEU

Expand table

Segments	Segment type	Value
Segment 1	Constant	SO-
Segment 2	Alphanumeric	####

Example of formatted number: SO-0029

Even though the format doesn't include a scope segment, numbering restarts for each company ID. If you use the same format for all company IDs, each company uses the same numbers. For example, sales order number SO-0029 is used in each company. You can also change the whole number sequence format for other company IDs.

Purchase requisition numbers

In the following example, purchase requisition numbers are organization-wide.

- **Area:** Purchase
- **Reference:** Purchase requisition
- **Scope:** Shared

Expand table

Segments	Segment type	Value
Segment 1	Constant	Req
Segment 2	Alphanumeric	####

Example of formatted number: Req0052

Because the scope is **Shared**, the number sequence format is used across the organization. You can't set up different number sequence formats for different parts of the organization.

Performance considerations for number sequences

Consider the following information about how the configuration of number sequences can affect system performance before you set up number sequences.

Continuous and noncontinuous number sequences

Number sequences can be continuous or noncontinuous. A continuous number sequence doesn't skip any numbers, but you might not use the numbers sequentially. You use numbers

from a noncontinuous number sequence sequentially, but the number sequence might skip numbers.

- Continuous Number Sequence (CNS)
  - Doesn't skip any numbers
  - You might not use numbers sequentially
  - Example: If a user cancels a transaction, the system generates a number but later recycles (reuses) it
- Noncontinuous Number Sequence (Non-CNS)
  - Might skip numbers
  - You use numbers sequentially (based on caching)
  - Example: If a user cancels a transaction, the system generates a number but doesn't use it

> **Note**
>
> The **Enable continuous number sequence performance improvements** feature provides enterprise readiness with continuous number sequences, which was challenging in finance and operations apps. The feature is in public preview in version 10.0.34, and generally available in version 10.0.36.
>
> This feature improves performance with continuous number sequences by preallocating a number in the sequence for each request. By default, the system allocates five numbers in a sequence, but you can adjust this value. If there's an unexpected termination of any number, the clean-up job is improved.

For continuous and noncontinuous number sequences, you can enable **Preallocation** on the **Performance** FastTab of the **Number sequences** page. When you specify a quantity of numbers to preallocate, the system selects those numbers and stores them in memory for noncontinuous number sequences and in the database for continuous number sequences.

If you use a noncontinuous number sequence, you can enable **Preallocation** on the **Performance** FastTab of the **Number sequences** page. When you specify a quantity of numbers to preallocate, the system selects those numbers and stores them in memory. The system requests new numbers from the database only after it uses the preallocated quantity.

Unless there's a regulatory or legal compliance requirement that you use continuous number sequences, use noncontinuous number sequences.

Automatic cleanup of number sequences

If an application error, crash, or other unexpected failure occurs, the system tries to automatically recycle numbers for continuous number sequences. You can run the cleanup process manually or automatically to recover lost numbers.

Carefully consider server usage when you plan the cleanup process. Perform the cleanup as a batch job during nonpeak hours.

Set up number sequences on an individual basis

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

This article explains how to set up number sequences on an individual basis. Use number sequences to generate readable, unique identifiers for master data records and transaction records that need them. A master data or transaction record that needs an identifier is called a reference. Before you can create new records for a reference, you must set up a number sequence and associate it with the reference. You can set up all required number sequences at the same time by using the **Set up number sequences** wizard, or you can create or modify individual number sequences by using the **Number sequences** page.

1. Go to **Navigation pane** > **Modules** > **Organization administration** > **Number sequences** > **Number sequences**.
2. Select **Number sequence**.
3. In the **Number sequence code** field, enter a value.
4. In the **Name** field, enter a value.
5. On the **Scope parameters** FastTab, select a scope for the number sequence and select scope values from the drop-down list. The scope defines which organizations use the number sequence. In addition, number sequences that have a scope other than **Shared** can have segments that correspond to their scope. For example, a number sequence with a scope of **Legal entity** can have a legal entity segment. For more information about scopes, see Number sequence overview.
6. Expand the **Segments** section.

    - Define the format for the number sequence by adding, removing, and rearranging segments.
    - Number sequences of all scopes can contain *Constant segments* and *Alphanumeric segments*. Constant segments contain a set of alphanumeric characters that don't change. Use this segment type to add a hyphen or other separators between number sequence segments. Alphanumeric segments contain a combination of number signs (#) and ampersands (&). These characters represent letters and

numbers that increment each time you use a number from the sequence. Use a number sign (#) to indicate incrementing numbers and an ampersand (&) to indicate incrementing letters. For example, the format `#####_2014` creates the sequence `00001_2014`, `00002_2014`, and so on. At least one alphanumeric segment must be present. Scope segments, such as company or legal entity, aren't required. However, if you don't include scope segments in the format, the system still generates numbers for the selected reference per scope.

7. Expand the **References** section. Select the document type or record to assign this number sequence to. This step is optional for sequences that you define for special application usage patterns. In these scenarios, the system generates a new number by using the value of a number sequence code or ID, without using a reference. An example of a special application usage pattern is a voucher series that is used for specific journal names. However, don't use such patterns.
8. Expand the **General** section. On the General FastTab, specify whether the number sequence is manual, and continuous or non-continuous. In addition, enter the lowest and highest numbers that can be used in the number sequence. Don't change a non-continuous number sequence to a continuous number sequence. The number sequence won't be truly continuous. This change might also cause duplicate key violations in the database. In addition, continuous number sequences have a larger effect on performance.
9. Select **Save**.

Set up number sequences by using a wizard

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Number sequences generate readable, unique identifiers for master data records and transaction records that need them. A master data or transaction record that needs an identifier is called a reference. Before you can create new records for a reference, you need to set up a number sequence and associate it with the reference. This article explains how to set up all required number sequences at the same time by using a wizard. The demo data company used to create this procedure is USMF.

1. Go to **Navigation** > **Modules** > **Organization administration** > **Number sequences** > **Number sequences**.
2. Select **Generate**.
3. Select **Next**.
    - On this page, you can modify the identification code, the lowest value, and the highest value. You can also specify whether the number sequence must be continuous.
    - Don't select the **Continuous** option if you need to preallocate numbers for the number sequence. To add a scope segment to the format of a number sequence, select the format in the list, and then select **Include scope in format**. To remove a scope segment from the format of a number sequence, select the format in the list, and then select **Remove scope from format**. To exclude a number sequence from automatic generation, select the number sequence in the list, and then select **Delete**.
4. Select **Next**.
5. Select **Finish**.

Configure number sequences for warehouse flows

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The *Number sequence extensions* feature adds a new configuration page for setting up number sequences. It enables flexible configuration of GS1-regulated IDs, including GS1 prefixes and check digits (modulo 10), and enforces a length limit on existing number sequences.

Standard number sequence segments aren't suitable for GS1 implementation, because no check digit is calculated, and the company's GS1 prefix must be updated manually.

This feature adds the following functionality:

- Bill of lading (BOL) IDs can be generated in advance.
- A unique number sequence can be generated for serial shipping container code (SSCC) numbers.
- GS1-compliant number sequences can be created for BOL and SSCC numbers. The feature adds out-of-box support for license plate IDs, container IDs, wave label IDs, and BOL IDs.
- Configuration of license plate ID numbers is flexible. For example, you can include or exclude application identifiers (AI), such as leading zeros (00).

This functionality makes it more efficient to support labeling of cartons and to adjust new numbers that are generated by the system.

Set up the feature

To set up number sequence extensions in your system, follow these steps:

1. Go to **Warehouse management** > **Setup** > **Warehouse management parameters**.
2. On the **General** tab, in the **GS1 company prefix** field, and enter your company's GS1 prefix. This value will affect all number sequences where the GS1 prefix is included as a segment.

3. If you want to generate BOL numbers for wave labels, on the **Reports** tab, select the **Generate BOL number when printing wave labels** checkbox.

   > ⓘ **Note**
   >
   > This checkbox is available only if the functionality for wave label printing is turned on.

4. Go to **Warehouse management** > **Setup** > **Number sequence extensions**

5. On the Action Pane, select **Create default setup**. A GS1-compliant BOL number sequence and three types of SSCC number sequences are created. All these number sequences take the length of your company's GS1 prefix into account.

   For more information about how to customize these default number sequences and/or add new sequences, see the next section. You can also remove any of these sequences if you don't need them.

6. Go back to **Warehouse management** > **Setup** > **Warehouse management parameters**.

7. On the **Number sequences** tab, select a relevant number sequence extension to use to generate numbers for your license plate IDs, wave label IDs, container IDs (in this case, select the appropriate **SSCC-18 number** sequence), and/or BOL IDs (in this case, select the **BOL** sequence). By default, number sequence extensions are supported only for these four types of IDs.

The next time that a new number is generated for one of these number sequences, the new logic will be used.

> ⓘ **Note**
>
> If you don't select a number sequence extension for license plate IDs, the current rules for generating license plate IDs will be used. Otherwise, your selected number sequence will be used. The other IDs will use a plain number sequence until you apply a number sequence extension for them.

Create and edit number sequences

In the previous section, you generated a default set of number sequences. This section explains how each number sequence is defined. It also explains how to create custom sequences, and how to edit the default or custom sequences.

To create and edit number sequences, follow these steps:

1. Go to **Warehouse management** > **Setup** > **Number sequence extensions**.
2. On the Action Pane, select **New**.
3. In the **Number sequence extension** field, enter a name for the new sequence. In the **Description** field, enter a description.
4. On the **Segments** FastTab, use the buttons on the toolbar to assemble your numbering format by adding, deleting, and arranging segments. In the **Segment** field for each row, assign a segment type to define the purpose and content of that segment. The following table describes the types of segments that are available.

Expand table

Segment type	Description
Constant	This segment type adds the same constant text for each generated number in the sequence. In the **Value** field, enter the required text. The **Length** field is automatically updated to the length of the text that you entered in the **Value** field.
Number sequence	In the **Value** field, enter a number sign (#) for each character that should be shown in the generated sequence. The number sequence itself might generate longer numbers, but only the right-most characters will be shown. The **Length** field is automatically updated to the number of number signs that you entered in the **Value** field. To comply with GS1 requirements for SSCC-18 numbers, make sure that the length of this segment is 16 minus the length of your GS1 prefix.
GS1 prefix	This segment type adds the value that is set in the **GS1 company prefix** field on the **Warehouse management parameters** page. The **Value** field shows the value that is set on the **Warehouse management parameters** page, and the **Length** field shows the number of characters in the value. Both the **Value** field and the **Length** field are read-only.
Application identifier	In the **Value** field, enter an application identifier, as specified by the relevant bar code data policy for this type of number sequence. For example, enter *00* for SSCC or *420* for BOL. The **Length** field is automatically updated to the length of the identifier that you entered in the **Value** field.
Packing type	For items that can be clearly identified, this segment type adds a field value from the relevant unit sequence group (from the **Unit sequence groups** page). (This behavior matches the existing logic for license plate IDs.) For license plates that include multiple stock keeping units (SKUs), this segment type adds *0* (zero) by default. For this segment type, the **Value** field is always set to *P*, and the **Length** field is always set to *1*.

Segment type	Description
Check digit	This segment type adds a check digit, which is a modulo 10 calculation. (This behavior matches the existing logic for license plate IDs.) For this segment type, the **Value** field is always set to a caret (^), and the **Length** field is always set to *1*.

5. To view an example of your final number format, inspect the **Format** field at the bottom of the **Segments** FastTab.

Organizations and organizational hierarchies overview

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

An organization is a group of people who work together to carry out a business process or achieve a goal. Organizational hierarchies show the relationships between the organizations that make up your business.

Organizations

You can define the following types of internal organizations: legal entities, operating units, and teams.

All internal organizations are types of the **Party** entity. Therefore, these organizations use the address book to store address and contact information. A party, which can be either a person or an organization, can belong to one or more address books.

Legal entities

A legal entity is an organization that has a registered or legislated legal structure. Legal entities can enter into legal contracts and must prepare statements that report on their performance.

A company is a type of legal entity. Currently, companies are the only kind of legal entity that you can create, and every legal entity is associated with a company ID. This association exists because some functional areas in the program use a company ID, or DataAreaId, in their data models. In these functional areas, companies are used as a boundary for data security. Users can access data only for the company that they're currently signed in to.

Operating units

An operating unit is an organization that divides the control of economic resources and operational processes in a business. People in an operating unit have a duty to maximize the use of scarce resources, improve processes, and account for their performance.

The types of operating units include cost centers, business units, value streams, departments, and commerce channels. The following table provides more information about each type of operating unit.

Expand table

Operating unit type	Description	Purpose
Cost center	An operating unit in which managers are accountable for budgeted and actual expenditures.	Used for the management and operational control of business processes that span legal entities.
Business unit	A semi-autonomous operating unit that is created to meet strategic business objectives.	Used for financial reporting that is based on industries or product lines that the organization serves independently of legal entities.
Value stream	An operating unit that controls one or more production flows.	Commonly used in lean manufacturing to control the activities and flows that are required to supply a product or service to consumers.
Department	An operating unit that represents a category or functional part of an organization that performs a specific task, such as sales or accounting.	Used to report on functional areas. A department might have profit and loss responsibility, and might consist of a group of cost centers.
Retail channel	An operating unit that represents a brick-and-mortar store, an online store, or call center.	Used for the management and operational control of one or more stores within or across legal entities.

Establishments

> **Note**
>
> **Availability**: Establishments support in Dynamics 365 Finance is available starting with version **10.0.48**. **Establishments** functionality in Finance is controlled by **Feature management**. To use **Establishments** in business documents and enable establishment-level **Registration ID** validation and immutable storage on invoices, enable the **Establishment and Registration ID governance on invoices** feature. When the feature is turned off,

establishment-specific behavior (such as establishment selection, defaulting, and validation on invoices) isn't applied.

In Finance, an establishment represents an operational unit of a legal entity that carries out economic activity on a stable basis and might require its own regulatory identifiers, such as registration numbers used on invoices and regulatory reports.

You model establishments by using existing **Operating units**, combined with an **Organizational hierarchy** assigned with *Enterprise establishment structure* **Organizational hierarchy purpose**, to support invoicing and compliance scenarios.

A single legal entity can have one or multiple establishments, while remaining the sole legal and accounting entity. All establishments share the same legal identity of the company but might have distinct operational identities for invoicing and regulatory purposes.

Use **Operating units** to represent **Establishments** when a business requires:

- Identification of the issuing or receiving unit on invoices
- Separate regulatory identifiers per operational location
- Consistent establishment assignment across customer, vendor, project invoices

The system treats only **Operating units** that you explicitly include in a dedicated **Organizational hierarchy** assigned with **Enterprise establishment structure** purpose as **Establishments**. You can select these establishments in the **Establishment** field in the following documents where you can post an invoice:

- Free text invoices
- Sales orders
- Purchase orders
- Vendor invoices
- Pending vendor invoices
- Project invoice proposals
- Intercompany customer invoices
- General journals

Associate **Establishments** with inventory **Sites** (**Inventory management** > **Setup** > **Inventory breakdown** > **Sites**) to support transactional defaulting.

When you link an inventory **Site** to an **Establishment**, the system can derive the issuing or receiving establishment of the legal entity for customer, vendor, or project invoice that reference

that site. This association ensures consistent establishment identification across business documents that result in invoice posting.

Associate **Establishments** with **Financial dimension values** to support transactional defaulting. When a **Financial dimension value** linked to an **Operating unit** included into an **Organizational hierarchy** assigned with **Enterprise establishment structure** purpose, is used on a business document, the system can derive and default the applicable **Establishments** for customer, vendor, or project invoices created from that document. This association complements site-based defaulting and helps ensure consistent establishment identification across invoice-generating processes.

Teams

A team is an organization in which the members share a common responsibility, interest, or objective. Teams can't be used in organizational hierarchies.

Organizational hierarchies

Set up organizational hierarchies to view and report on your business from different perspectives. For example, you can set up a hierarchy of legal entities for tax, legal, or statutory reporting. Set up a hierarchy that is based on operating units to report financial information that isn't legally required, but that is used for internal control. For example, you can create a purchasing hierarchy to control purchasing policies, rules, and business processes.

> **Note**
>
> After an operating unit is added to a hierarchy, the operating unit can't be deleted.

Each hierarchy is assigned to a purpose. The purpose of a hierarchy determines the types of organizations that can be included in the hierarchy. The purpose also determines which application scenarios a hierarchy can be used in.

Organizations in a hierarchy can share parameters, policies, and transactions. An organization can inherit or override the parameters of its parent organization. However, shared master data, such as products and address books, applies to the whole organization and can't be overridden for individual organizations. Creating organizations and hierarchies requires careful planning. Learn more in Plan your organizational hierarchy.

Establishment hierarchy

> **Note**
>
> **Availability**: Establishments support in Finance is available starting with version **10.0.48**. **Establishments** functionality in Finance is controlled by **Feature management**. To use **Establishments** in business documents and enable establishment-level **Registration ID** validation and immutable storage on invoices, enable the **Establishment and Registration ID governance on invoices** feature. When the feature is turned off, establishment-specific behavior (such as establishment selection, defaulting, and validation on invoices) isn't applied.

Organizational hierarchies can be used to define which **Operating units** represent valid **Establishments** within a legal entity.

To support establishment scenarios, Finance introduces a dedicated organization hierarchy purpose: **Enterprise establishment structure**. This hierarchy purpose determines which operating units are considered establishments and participate in **Registration ID** validation and immutability on documents such as invoices.

Using Organizational Hierarchies in Financial Reporting

Organizational Hierarchies can be selected as a **Tree type** option in Financial Reporting. Financial reporting selects the current effective hierarch as noted by hierarchy.

Plan your organizational hierarchy

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Before you set up organizations and organization hierarchies, plan how your business will be modeled. The organization model significantly affects the implementation and business processes.

Organizational hierarchies represent the relationships between the organizations that make up a business. Therefore, the most important consideration when you model organizations is the structure of your business. Define organization structures based on feedback from executives and senior managers from functional areas, such as finance and accounting, human resources, operations, purchasing, and sales and marketing.

When you plan hierarchies, consider the relationship between the organizational hierarchy and financial dimensions. You can set up multiple organizational hierarchies to represent different views of your business. By using financial dimensions, you can create reports based on these views. Work with your partner to create hierarchies that address both organizational and statutory reporting needs.

> **Note**
>
> Although you can use financial dimensions to represent legal entities without creating the legal entities, financial dimensions aren't designed to address the operational or business needs of legal entities. The interunit accounting functionality is designed to address only the accounting entries that are created by each transaction.

> **Important**
>
> You shouldn't decide how to model organizations based only on the information in this article. This documentation is a guide. You can work with your partner for additional

guidance. Your partner has gained experience in various industries and across the customer base.

Decide whether to model internal organizations as legal entities or operating units

You must have at least one legal entity to represent your business. A legal entity can enter legal contracts and is required to prepare financial statements that report on its performance.

Use legal entities for transactional business or for consolidation. This structure means that a legal entity in finance and operations doesn't necessarily represent a real entity in your business. For example, a company that participates in transactions can own subsidiary legal entities. In this scenario, a legal entity is required for transactions, and a virtual legal entity is required to consolidate the results and balances of the subsidiary legal entities.

Internal organizations in your business, such as regional offices, can be represented as additional legal entities, or as operating units of the main legal entity. An operating unit isn't required to be a legally defined organization. Operating units are used to control economic resources and operational processes in the business. For example, departments and cost centers are operating units.

Some functionality works differently depending on whether the organization is a legal entity or an operating unit. Carefully consider the functionality described in the following section as you make your decision.

Master data

If you model the organization as a legal entity

Some master data, such as customers, payment terms, tax authorities, and site-specific stock ordering, must be set up for each legal entity. Some master data, such as users, products, and most human resources data, is shared among all legal entities.

If you model the organization as an operating unit

Master data is shared among operating units.

Module parameters

If you model the organization as a legal entity

Set module parameters, such as Accounts receivable, Accounts payable, and Cash and bank management, per legal entity. Because the module setup for legal entities is separate, each subsidiary can comply with local statutory requirements and business practices. For example, a professional services legal entity and a manufacturing legal entity can have different module parameters even though they report to the same parent company.

If you model the organization as an operating unit

Module parameters are shared among operating units.

Data security

If you model the organization as a legal entity

Most data is automatically secured by company ID. A company ID is a unique identifier for the data that is associated with a legal entity. A company can be associated with only one legal entity, and a legal entity can be associated with only one company. Users can access data only for the companies that they have access to. You don't need to customize to secure data by company ID.

If you model the organization as an operating unit

Data can be secured per operating unit by creating customized data security policies. Data security policies are used to limit access to data. For example, assume that a user is allowed to create purchase orders only in a particular operating unit. Data security policies can be created to prevent the user from accessing purchase order data from any other operating unit. The volume of transactions and the number of security policies can affect performance. When you design security policies, keep performance in mind.

Ledgers

If you model the organization as a legal entity

Each legal entity requires a ledger that provides a chart of accounts, accounting currency, reporting currency, and fiscal calendar. A balance sheet can be created only for a legal entity. Main accounts, dimensions, account structures, charts of accounts, and account rules can be used by more than one legal entity.

If you model the organization as an operating unit

An operating unit can't have its own ledger information. If your internal organizations don't require unique ledgers, model them as operating units. Set up ledger information for the parent legal entity in the hierarchy. You can create income statements for operating units within a legal entity or for the parent legal entity.

Fiscal calendars

If you model the organization as a legal entity

Each legal entity has its own fiscal calendar. If your internal organizations use different fiscal years and fiscal calendars, model the organizations as legal entities.

If you model the organization as an operating unit

Operating units must share a fiscal calendar. If your internal organizations can use the same fiscal years and fiscal calendars, model the organizations as operating units.

Consolidation

If you model the organization as a legal entity

You must consolidate the financial results for regional offices into a single, consolidated company to prepare financial statements.

If you model the organization as an operating unit

Consolidation isn't required, because data is already shared among operating units.

Centralized payments

If you model the organization as a legal entity

Set up centralized payments so you can pay invoices for all child legal entities to or from a single parent legal entity.

If you model the organization as an operating unit

You don't need centralized payments because you record all invoices in a single legal entity.

Intercompany transactions

If you model the organization as a legal entity

You can apply intercompany sales orders, purchase orders, payments, or receipts to one another. You don't need to use journal vouchers. You can view intercompany transactions at the subledger level, such as Accounts receivable and Accounts payable. The following examples illustrate how the system handles intercompany transactions.

Example 1: Headquarters provides services to regional offices and must charge the costs of those services to the regional offices

If you model the regional office as a legal entity, you have the following options:

- Headquarters creates a journal entry to cross-charge the regional office for the expense. The transactions can't be aged.
- Headquarters sends a purchase order for the services to the regional office. A sales order is automatically created in the legal entity for the regional office, with intercompany subledger transactions.

Example 2: Headquarters procures and pays for service that is delivered to a regional office

If you model the regional office as a legal entity, you have the following options:

- The invoice and payment follow the regulatory requirements of headquarters. Headquarters can create a journal entry to cross-charge the regional office for the expense. The transactions can't be aged.
- The invoice and payment follow the regulatory requirements of headquarters. Headquarters can create an intercompany subledger transaction.

If you model the organization as an operating unit

Intercompany transactions among operating units are supported only through journal vouchers. An operating unit can't issue or receive a purchase order, sales order, or invoice from another operating unit in the same legal entity. You can't view intercompany transactions at the subledger level (Accounts receivable, Accounts payable). The following examples illustrate how intercompany transactions are handled.

Example 1: Headquarters provides services to regional offices and must charge the costs of those services to the regional offices

If you model the regional office as an operating unit, headquarters enters an expense transaction and codes it to the regional office.

Example 2: Headquarters procures and pays for service that is delivered to a regional office

If you model the regional office as an operating unit, the invoice and payment follow the regulatory requirements of headquarters. The invoice can be coded to the regional office. On the income statement, use a balancing financial dimension to report costs for the regional office.

Local tax requirements

If you model the organization as a legal entity

A legal entity is subject to the tax laws of the tax authority in the country/region where the legal entity is registered. For example, a legal entity that is registered in Denmark is subject to Danish tax laws and regulations. A legal entity can belong to only one country/region. The country/region that you select for the primary address of the legal entity controls the country/region-specific features that are available to that legal entity. For example, if the primary address of the legal entity is in Denmark, features that are related to Danish tax laws and regulations become available. Therefore, if your organizations are in different countries/regions and require different local tax options, you must set up the organizations as separate legal entities.

If you model the organization as an operating unit

Operating units use the country context of the parent legal entity. Operating units in the same legal entity can't have different country/region-specific requirements. If your organizations are in the same country/region and use the same tax options, you can set them up as operating units.

Statutory reporting for a country/region

If you model the organization as a legal entity

For countries/regions that are supported, most statutory reports can be created.

> **Note**
>
> A posting layer in the general ledger allows you to make adjusting entries to a parent company that uses a different accounting standard than the child company. For example, for a company that uses generally accepted accounting practices in the United Kingdom (UK GAAP), you can make adjusting entries in the posting layer. These entries can be

consolidated into a parent company that uses generally accepted accounting principles (GAAP) in the United States. The adjusting entries don't affect UK GAAP reporting.

If you model the organization as an operating unit

Statutory reports must be created by using another application. You must ensure that data is captured in finance and operations apps to support the requirements of each operating unit, where they differ from the requirements of headquarters.

Currency

If you model the organization as a legal entity

If your organizations must use different functional currencies, you must model the organizations as legal entities. Functional currencies are set up per legal entity. However, you can enter transactions in multiple currencies.

If you model the organization as an operating unit

If your organizations can use a single functional currency, you can model the organizations as operating units. Operating units must share a functional currency. However, you can enter transactions and create reports in multiple currencies.

Year-end closing

If you model the organization as a legal entity

Model the organizations as legal entities if laws and accounting practices differ among the countries or regions where your organizations are located. Each legal entity has its own year-end procedures.

If you model the organization as an operating unit

Model the organizations as operating units if laws and accounting practices are the same among the countries or regions where your organizations are located. All operating units must use the same year-end closing procedure.

Number sequences

If you model the organization as a legal entity

Set up number sequences for some references per legal entity. Share some number sequences.

If you model the organization as an operating unit

Number sequences for some references can be set up per operating unit. Some number sequences can be shared.

Products

If you model the organization as a legal entity

Product definitions are shared, and they must be released to individual legal entities before they can be included in transactions. Each legal entity has its own set of released products that can be included in transaction documents. If your internal organizations must use different sets of products, you must model the organizations as legal entities.

> **Note**
>
> Even though product definitions are shared, in each legal entity where a product has been released, you can specify different sales, purchase, and stocking parameters for the item at each inventory site.

If you model the organization as an operating unit

All operating units share the same set of products. If your internal organizations can share the same set of products, you can model the organizations as operating units.

Inquiry and reporting

If you model the organization as a legal entity

You must manually change companies to enter transactions and perform inquiries in multiple legal entities. Because of data security boundaries, consolidated inquiry and reporting can be resource intensive and time-consuming.

If you model the organization as an operating unit

You don't need to change companies to access data from multiple operating units. Consolidated inquiry and reporting and individual regional inquiry is easier and faster.

Multi-company processing for hierarchical legal entity selection

To enable users who have access to multiple companies to execute transactions, generate reports, and perform inquiries across legal entities, assign the **Multi-company processing** purpose to one or more organization hierarchies. This capability was introduced in Dynamics 365 Finance version 10.0.44. Starting with Dynamics 365 Finance version 10.0.47, the feature is enabled by default.

To enable the feature manually, follow these steps:

1. Go to **Feature management**.
2. Enable the **Multi-company purpose** feature.

The feature activates a hierarchical parent-child legal entity selection experience, replacing the previous flat multiselection company picker. This enhancement provides a more scalable and structured approach for cross-company operations and improves usability for organizations managing complex legal entity structures.

You can search, sort, and select multiple legal entities in:

- General ledger
  - Currency revaluation
  - Year-end close
- Fixed assets
  - Fixed assets depreciation proposal
- Asset leasing
  - Asset leasing batch journal creation
- Cash and bank
  - Currency revaluation
- Accounts payable
  - Pending vendor invoice
  - Vendor invoice automation
  - Payment workspace (Vendor)
  - Global transaction
- Accounts receivable
  - Payment workspace (Customer)
  - Global transaction
  - Payment workspace

Best practices for modeling organizations and hierarchies

Consider the following best practices when you implement an organization hierarchy:

- Create a department to model the intersection between a legal entity and a business unit. You can then roll up data from a department to a legal entity for statutory reporting, and from a department to a business unit for internal reporting. Departments can serve as profit centers. If you use departments, you don't have to use legal entities and business units as dimensions in the account structure. You can use just departments as a dimension. However, you must use both cost centers and departments as dimensions in the account structure if cost centers are used only as cost accumulators, and departments are used for revenue recognition.
- Model multiple hierarchies for operating units if you have complex requirements for reporting profit and loss.
- In a single legal entity, don't model multiple hierarchies for the same hierarchy purpose.
- Don't create a hierarchy for every purpose. Usually, you can use one hierarchy for multiple purposes. For example, one hierarchy of operating units can be assigned to all policy-related purposes.
- Create balanced hierarchies. In a hierarchy, all nodes that are the same distance from the root node are defined as a level. In a balanced hierarchy, only one type of operating unit can occur at each level, and the distance from the root node to each level is consistent. If there are intermediate levels between a department and a legal entity or a business unit, placeholder organizations may be required to create a balanced hierarchy.
- Don't model a separate hierarchy of operating units if the structure for legal entities is also your operating structure. A mixed hierarchy of legal entities and operating units may serve both purposes.
- Before you model major restructuring scenarios, use the hierarchy's effective dates to perform an impact analysis and a validation test.
- Use draft mode to change a hierarchy before you publish a new version in a production environment.
- Limit the number of people who have permissions to add or remove organizations from a hierarchy in a production environment. A smaller number reduces the chance that costly mistakes can occur and corrections must be made.

Create an organization hierarchy

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use the following procedure to create an organizational hierarchy. You can use organizational hierarchies to view and report on your business from various perspectives. For example, you can set up one hierarchy for tax, legal, or statutory reporting. You can then set up another hierarchy to report financial information that isn't legally required, but that is used for internal reporting.

Starting with Dynamics 365 Finance version 10.0.48, organization hierarchies can also be used to model Establishments. Establishments represent operational units of a legal entity that may require their own regulatory identifiers on invoices. Establishments are modeled using existing operating units and are identified through a dedicated organization hierarchy purpose, **Enterprise establishment structure**. This hierarchy determines which operating units are treated as establishments in invoicing, while the legal entity remains the single legal and accounting entity.

Before you create an organizational hierarchy, you must create organizations. For more information, see the "Create a legal entity" or "Create an operating unit" tasks. You can also create departments and teams.

The demo data company used to create this procedure is USMF.

Create a hierarchy

1. Go to **Navigation pane** > **Modules** > **Organization administration** > **Organizations** > **Organization hierarchies**.
2. On the **Action pane**, select **New**.
3. In the **Name** field, enter a value.
4. In the **Purpose** section, select **Assign purpose**.
5. In the list, find and select the desired record. Select a purpose to assign to your organization hierarchy.

6. In the **Assigned hierarchies** section, select **Add**.
7. In the list, select the row. Find the hierarchy you just created.
8. Select **OK**.

Add organizations to the hierarchy

1. In the list, find and select the desired record. Select your hierarchy.
2. In the **Assigned hierarchies** section, select **View hierarchy**.

    - Add organizations, as necessary.
    - To add an organization, select **Edit** and then **Insert** to add the organization. When you're done making changes, you can **Save** a draft and/or **Publish** the changes.

A legal entity is an organization that a legal authority identifies through registration. Legal entities can enter into contracts and must prepare statements that report on their performance. The following procedure explains how to create a legal entity. The demo data company used to create this procedure is USMF.

1. Go to **Organization administration** > **Organizations** > **Legal entities**.
2. Select **New**.
3. In the **Name** field, enter a value.
4. In the **Company** field, enter a value.
5. In the **Country/region** field, enter or select a value.
6. Select **OK**. In the **General** section, provide the following general information about the legal entity: Enter a search name, if a search name is required. A search name is an alternate name that you can use to search for this legal entity. Select whether this legal entity is being used as a consolidation company or an elimination company.
7. Expand the **Addresses** section. In the **Addresses** section, select **Edit** to enter address information, such as the street name and number, postal code, and city.
8. Expand the **Contact information** section and enter information about methods of communication, such as email addresses, URLs, and telephone numbers.
9. Expand the **Statutory reporting** section and enter the registration numbers that are used for statutory reporting.
10. Expand the **Registration numbers** section and enter any information required by the legal entity.
11. Expand the **Bank account information** section and enter bank accounts and routing numbers for the legal entity.
12. Expand the **Foreign trade and logistics** section and enter shipping information for the legal entity.
13. Expand the **Number sequences** section and view the number sequences that are associated with the legal entity.
14. Expand the **Images** section and view or change the logo and dashboard image that are associated with the legal entity.

15. Expand the **Tax registration** section and enter the registration numbers that are used to report to tax authorities.
16. Expand the **Tax 1099** section and enter 1099 information for the legal entity.
17. Select **Save**.

Create an operating unit

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

An operating unit is an organization that is used to divide the control of economic resources and operational processes in a business. People in an operating unit have a duty to maximize the use of scarce resources, improve processes, and account for their performance. The types of operating units include cost centers, business units, departments, and value streams.

Starting with Dynamics 365 Finance version 10.0.48, operating units can be used to represent Establishments. An establishment represents an operational unit of a legal entity that carries out economic activity and may require its own regulatory identifiers on business documents, such as invoices. Establishments are modeled by using existing operating units and identified through an organization hierarchy that's assigned the **Enterprise establishment structure** purpose. Only operating units that are included in such a hierarchy are treated as establishments. The legal entity remains the single legal and accounting entity, while establishments are used for operational and regulatory purposes.

Use the following procedure to create an operating unit. The demo data company used to create this procedure is USMF.

1. Go to **Navigation pane** > **Modules** > **Organization administration** > **Organizations** > **Operating units**.
2. Select **New** to open the dialog.
3. Find and select the desired record. Select the type of operating unit you want to create.
4. Select the link in the selected row.
5. In the **Name** field, enter a value.

    - Expand the **General** section, if necessary.
    - Provide general information about the operating unit, such as an identification number, DUNS number, and manager.
    - Expand the **Addresses** section, if necessary.

- Enter address information, such as the street name and number, postal code, and city. Select **Add** to enter a new address record, or select **Edit** to modify an existing address record.
- Expand the **Contact information** section, if necessary.
- Enter information about methods of communication, such as email addresses, URLs, and telephone numbers. To enter a new communication record, select **New**. To modify an existing communication record, select **More options** > **Advanced**.

6. Optionally, change the **Operating unit number** as needed. This number is a unique identifier for the corresponding **Party** record and can't be the same as any other operating unit.
7. Select **Save**.

Global address book overview

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

The global address book is a centralized repository for master data that you must store for all internal and external persons and organizations that your company interacts with. The data associated with party records includes the party's name, address, and contact information. Other details vary, depending on whether the party is a person or an organization. You assign each party record to a party, and each party can be associated with one or more party roles in a company. Party roles include customer, prospect, worker, user, vendor, competitor, applicant, and contact. For example, the organization party First Up Consultants, can be associated with customer, business relation, and vendor roles in the CEE company, and can also be associated with the vendor role in the CEU company. Here are some of the benefits of this shared data:

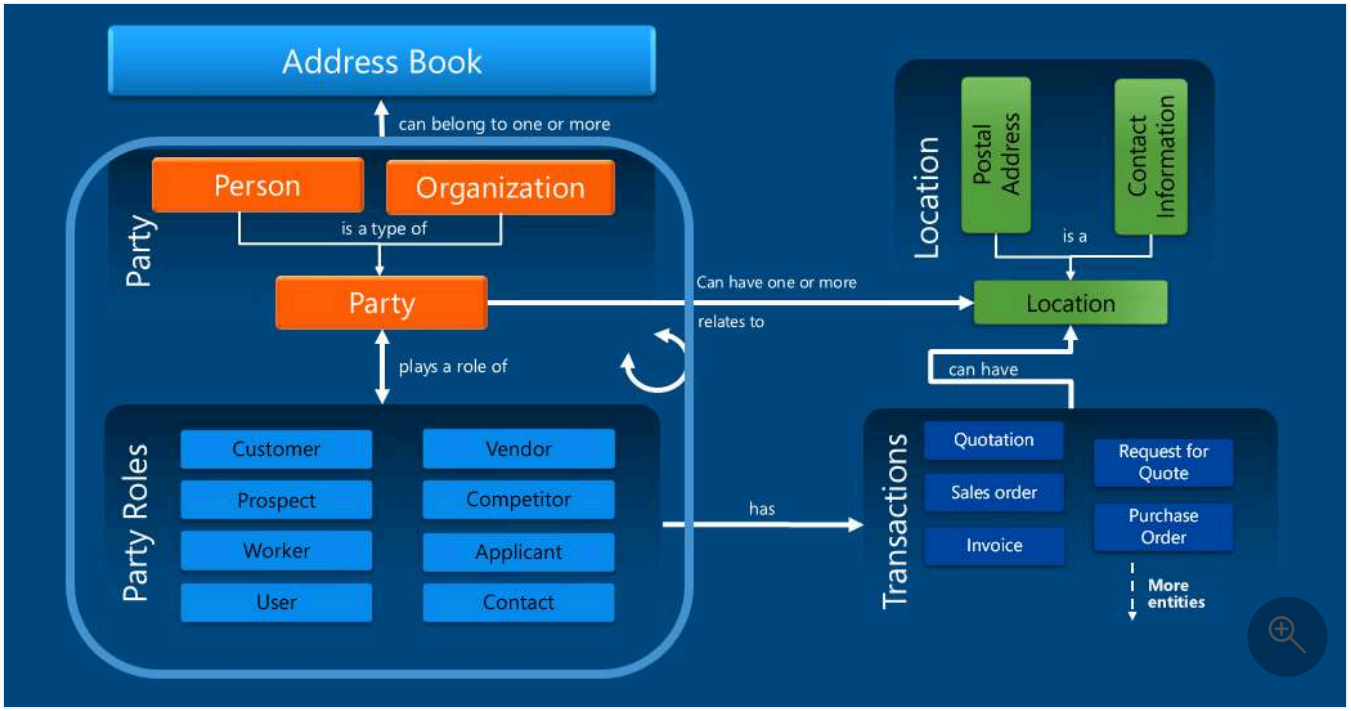
- The data shows the relationships that people and organizations have with other areas of the company. The relationship between two organizations changes when one organization has multiple roles, such as vendor and customer. Communication between the two organizations also changes. There might be special agreements that you can negotiate to encourage a closer partnership with the other organization.
- Setup and maintenance are easier. For example, when an address changes, you need to update the address in only one place. All the other associated records are updated automatically.

You can't delete any party in the global address book that's a legal entity. The **Delete** button is unavailable for these parties.

How the global address book works

The following illustration shows how party records, party roles, locations, and transactions interact and relate to an address book. As the illustration shows, a party record can belong to one or more address books. Each party record can store one or more locations, or addresses, and is assigned a party role. The role that is assigned to the party record can have specific transactions types associated with it. The following sections provide more information about party roles, locations, and transaction types. The following image is a graphical representation

of the ways that parties, party roles, locations, and transactions interact in relation to the global address book.



Party roles

You refer to roles that are associated with party records as party roles. You can assign several party roles to both party types, person and organization. Here are the definitions for each party role:

- **Customer** – Individuals, companies, or other entities who purchase goods and services that are produced by other individuals, companies, or entities.
- **Prospect** – A party that might provide a service or benefit to a legal entity.
- **Worker** – A person who assumes the role of an employee or a contractor, and who is paid in exchange for services.
- **User** – A person who is a user of the system.
- **Vendor** – A party that supplies products to one or more legal entities in exchange for payment.
- **Competitor** – A person or organization that provides goods or services that are similar to the goods or services that your business provides.
- **Applicant** – A person who makes a formal written or electronic request to work for or fill an open position in an organization.
- **Contact** – A person, either inside or outside your organization, that you create an entry for. In this entry, you can save information such as the person's street and email addresses, telephone and fax numbers, and webpage URLs.

Creating new party records

Enter party records in the global address book in two ways:

- **Create a party record when you don't know the role** – Create a party record in the global address book when you don't know the role type (for example, you don't know whether the party is a customer or an opportunity). You can select the role type later.
- **Create a party record when you know the role** – If you know the role type for the party, create a record on the appropriate page for that type. For example, if the party is a customer, create a record on the **Customer** page. When you create and save a record by using the page for the party's role type, you automatically create the record in the global address book.

Party roles and transactions

For transactions that are a part of the business processes, multiple parties might be associated with each transaction. An example is a customer that you need to reference on project quotations.

Parties locations, addresses, and contact information

Each party record's addresses, locations, and contact information are shared across all the party roles that are associated with that party. Therefore, when you change any of this information, all other associated records are updated accordingly.

Locations and transactions

When you include a party role in a transaction, you can access the location, address, or contact information of the party when you enter transaction details.

Plan for the global address book and other address books

This article describes the considerations and decisions that you must make during the planning process before you set up and configure the global address book and any additional address books. Some of the decisions require that you confirm the decisions made for other areas of the product, such as the organization hierarchy.

Global address book

Before you begin to work with the global address book, determine the default values for it. Use these default values for any additional address books that you create.

Decisions

- What sequence should names be displayed in for party records of the **Person** type? For example, one sequence is last name, middle name, first name.
- Should the system delete party records from the address book when the system deletes the role record? For example, if the system deletes a customer record, should the system also delete the party record?
- When a user creates a new record, should the system notify the user if a duplicate record is found in the global address book?
- Should the Data Universal Numbering System (DUNS) number be included in a party record's information?
- If the system includes the DUNS number in a party record, should the system check the uniqueness of the number?
- When a user creates a party record in the global address book, do you want a default party type, person, or organization?
- Which user roles should have access to the private addresses and contact information of party records?

Additional address books

After you create the global address book, you can create additional address books as you require, such as a separate address book for each company in your organization or for each line of business. For example, Fabrikam is an international organization that has multiple companies and

multiple lines of business. Fabrikam plans to create an address book for each line of business. For lines of business that occur in more than one location, such as the pneumatic tools business, Fabrikam plans to create an address book for each location. Chris, the IT manager at Fabrikam, created the following list of address books that are required. This list also describes the party records that each address book must include.

- **Public Sector Contracts (PubSC)** – Party records for all parties that are involved in the public sector contracts that Fabrikam holds.
- **Private Sector Contracts (PriSC)** – Party records for all parties that are involved in the private sector contracts that Fabrikam holds.
- **Electronic Tools (ET)** – Party records for all parties that are involved in the purchase or sale of electronic tools, or that otherwise interact with the electronic tools that are provided by or purchased for Fabrikam in the Fabrikam-Japan company.
- **Pneumatic Tools (PTJPN)** – Party records for all parties that are involved in the purchase or sale of pneumatic tools, or that otherwise interact with the pneumatic tools that are provided by or purchased for Fabrikam in the Fabrikam-Japan company.
- **Pneumatic Tools (PTUSA)** – Party records for all parties that are involved in the purchase or sale of pneumatic tools, or that otherwise interact with the pneumatic tools that are provided by or purchased for Fabrikam in the Fabrikam-US company.

Decision:

- How many additional address books will you create?

Configure the global address book

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use this procedure to set the default values and security policies for the global address book.

The demo data company used to create this task is USMF. This task is intended for the Planning and configuration team.

1. In the navigation pane, go to **Modules** > **Organization administration** > **Global address book** > **Global address book parameters**.
2. In the **Name sequence** field, select how names should be shown.
3. In **Delete parties with no roles**, select whether to delete parties that don't have an assigned role.
4. In **Use duplicate check**, select whether to check for duplicate records.
5. In **Display DUNS number on addresses**, select whether to display the DUNS number on addresses.
6. In **Check for unique DUNS number**, select whether to check for unique DUNS numbers.
7. In the **Party** field, select an option.
8. In the **Customer** field, select an option.
9. In the **Vendor** field, select an option.
10. In the **Prospect** field, select an option.
11. In the **Competitor** field, select an option.
12. Select the **Private location security** tab.
13. In the list, find and select the desired record. Press the **Shift** key to select multiple roles to add to the **Selected roles** pane, and then select the arrow to add the selected roles.
14. Select **Save**.

Address setup

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Global regions where your organization operates might have different address format types. You must be able to adjust to the appropriate address format when a postal address is shown for each region. You can use the **Address setup** page to set up the postal address formats that are required for your organization.

Define address parameters

The **Parameters** tab of the **Address setup** page defines which fields must be validated when addresses are created. You can select options to require validation for **ZIP/postal code**, **District**, and **City** values.

If the option that corresponds to a field isn't selected, no validation is done for that field when new addresses are created in the global address book. In this case, the field is a free-text field where users can enter any value. If the option that corresponds to a field is selected, validation is done for that field when new addresses are created in the global address book. In this case, the value that is entered in the field must have been previously created in the address setup.

For example, the **City** option is selected in the **Validate on creating addresses** section. In this case, when a new address is created in the global address book, the **City** value for the new address must be selected in the list of cities that is set up in the **City** section of the **Address setup** page.

Set up address formats

You can set up address component information and formatting on the **Address format** tab. As you enter address information for a selected address type, the **Preview** field in the upper-right pane shows how the address will appear.

1. On the **Address setup** page, on the **Address format** tab, select **New** to add a new address format type.

2. Enter the name of the address format type and a brief description. For example, you might enter **NO** in the **Address format** field and **Norway** in the **Description** field.

3. In the lower pane, select **New** to configure a new address component for the address format type that is selected in the upper pane.

4. In the **Address application object** field, select the first object that must appear when an address in this format is shown. For example, select **Street**.

5. In the **Separator** field, enter the character that is used to separate this object from the next object when an address in this format is shown. For example, enter a comma (**,**).

6. Set the following checkboxes as appropriate:

    - **New line** – Select this checkbox if the object should appear on a new line.
    - **Data entry only** – Select this checkbox if the object should be shown only when the address is entered. If this checkbox is selected, the object won't be shown when the address is printed.
    - **Not active** – Select this checkbox if the object should not be used in an address of the selected format type.
    - **Expand** – Select this checkbox to show the full name of the country/region, state/province, or county instead of the code when the address is printed.
    - **Special** – Select this checkbox if the field value contains the character that you specified as a separator.

Set up country/region information

Use the **Country/region** tab to define the country/region information for the address setup.

1. On the **Address setup** page, on the **Country/region** tab, select **New** to create a new line.
2. Enter the country/region code, a short name for country/region, and the full name. For example, enter **DEU**, **Germany**, and **Federal Republic of Germany**, respectively.
3. In the **Address format** field, select an address format to use for the country/region. The address formats that are defined on the **Address format** tab of the page are available for selection.
4. In the **Time zone** field, select the time zone of the country/region.
5. Enter the International Organization for Standardization (ISO) code for the country/region.
6. In the **BACEN code**, **IOR facility ID**, and **Code by OKSM** fields, enter values if they are required for your financial, purchasing, or sales transactions. Also select whether the country/region is a member of the customs union.

7. To enable only valid five-digit or nine-digit ZIP/postal codes, select the **Use ZIP + 4 postal code validation rules** option.

Set up state/province information

Use the **State/province** tab to define the state/province information for the address setup.

1. On the **Address setup** page, on the **State/province** tab, in the **Country/region** filter, select the country/region that you're adding the state/province information to.
2. Select **New** to create a new line.
3. Enter the state/province code and the name of the state/province.
4. Select the time zone for the state/province.
5. Enter the IT state code for the state/province, and any additional codes that are required for transactional information.
6. To define the state/province as the default state/province for the selected country/region, select the **Default state/province** option. The default state/province will be entered by default in state/province fields when a new county or city record is created.

Set up county information

Use the following procedure to add county information to any existing countries/regions or states/provinces.

1. On the **Address setup** page, on the **County** tab, select **New** to create a new line.
2. In the **Country/region** field, select the country/region where the county is located.
3. In the **State or province** field, select the state/province where the county is located.
4. Enter the name of the county and a brief description.

Set up city information

Use the following procedure to add city information to any existing countries/regions or states/provinces.

1. On the **Address setup** page, on the **City** tab, select **New** to create a new line.
2. In the **Country/region** field, select the country/region that you're adding the city information to.
3. Enter the name of the city and a brief description.
4. Select the state/province or county where the city is located.

Set up district information

1. On the **Address setup** page, on the **District** tab, use the filters to select the country/region, state/province, county, and city, as appropriate, where the district is located.
2. Select **New** to create a new line.
3. Enter the name of the district and a brief description.

Set up ZIP/postal code information

1. On the **Address setup** page, on the **ZIP/postal codes** tab, use the filter to select the country/region for the ZIP/postal code.
2. Select **New** to create a new line.
3. Enter the ZIP/postal code, and select the corresponding city.
4. Enter the street name that the ZIP/postal code applies to.
5. Enter the lowest and highest street numbers that use the ZIP/postal code, and enter the number types. For example, the ZIP/postal code might apply only to odd-numbered street addresses.
6. Select the state/province, county, district, and time zone for the ZIP/postal code.

Address books FAQ

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

How do I check for duplicate records?

You can check for duplicate records directly from the **Global address book** list page. On the Action Pane, on the **Party** tab, in the **Maintain** group, select **Check for duplicates**. Then select the values to include in the check for duplicates.

Can I bulk add or delete party records from an address book?

Yes, you can add multiple party records to an address book and also remove multiple party records.

- To add multiple party records to an address book, on the **Global address book** list page, select the parties in the list. Then, on the Action Pane, on the **Party** tab, in the **Maintain** group, select **Assign parties**. Select the address books to add the selected party records to, and then select **OK**. All the selected party records are added to the address books that you selected.
- To remove multiple party records from an address book, on the **Global address book** list page, select the parties in the list. Then, on the Action Pane, on the **Party** tab, in the **Maintain** group, select **Remove parties**. Select the address books to remove the parties from, and then select **OK**. All the selected party records are removed from the address books that you selected.

Can I delete historical addresses?

As of Microsoft Dynamics 365 Finance version 10.0.32, an administrator can use the following procedure to enable the advanced address maintenance feature so that historical addresses can be deleted.

1. Go to **Feature Management** > **Check for updates**.
2. Search for **Advanced address maintenance**. Advanced address maintenance is disabled by default.
3. Select **Enable**.

After the **Advanced address maintenance** feature is enabled by an administrator, follow these steps to delete historical addresses.

1. Open the **Global address book** list page.
2. Select the party record to remove historical addresses for.
3. On the **Addresses** tab, select **More options** > **Advanced**.
4. On the **History** tab, select one or more addresses.
5. Select **Delete** to delete the selected addresses.

If an address that you're trying to delete is linked to another record, you receive an error message.

Alternatively, you can set up a SysOperation framework batch job to delete multiple historical addresses.

1. Go to **Organization administration** > **Periodic** > **Delete deactivated addresses**.
2. Select **OK**.

You're notified whether the batch job succeeded or failed.

You can also delete inactive postal addresses through the Microsoft Office add-in.

1. Open the **Global address book** list page.
2. Select the party record to remove historical addresses for.
3. On the **Addresses** tab, select **More options** > **Advanced**.
4. Select the Microsoft Office logo in the upper-right corner.
5. Select **Inactive Logistics Postal Address**.
6. Sign in to the add-in by using your credentials. You can use the add-in to delete only inactive addresses.

> ⓘ **Note**
>
> You can't use this procedure to update records or insert new records. For example, if you try to update the **ValidFrom** date, the record will be deleted instead.

Can I change the party type of a record, or do I have to delete the old record and create a new

one?

Occasionally, you might have to change the party type of a record from person to organization or from organization to person. For example, Nancy is a member of the sales team for Fabrikam U.K. At a trade show in London, Nancy meets six new prospects, and creates a prospect party record for each prospect. When Nancy saves the records, each record is also created in the global address book. Fabrikam has set the default party type to organization, but two of the new prospects should have a record type of person. Therefore, on returning from the trade show, Nancy must change the party type of the two prospect records. To change a party record from one party type to another, you must first create a new party record of the correct type in the global address book. You then associate the old party record with this new record. After you have made the new party association, delete the original party record that has the incorrect record type.

How do I change the name or address of a party record?

You can update the name of a party record, and the addresses that are associated with that record, at any time.

- To update the name of a party record, open the party record, and then, on the Action Pane, select **Edit**. On the **General** FastTab, enter the new name for the party, and then save the record.
- To update an address for a party record, open the party record, and then, on the **Addresses** FastTab, select the address to update. Select **Edit**, and then, on the **Edit address** page, make the required changes to the address or address parameters.

Can I merge two or more party records into one record?

Occasionally, you might want to merge two or more party records into a single record. This can occur if you create one or more duplicate party records, either on purpose or unintentionally. When you merge party records, you select one record to keep. The information from the other records is then merged into this record. For example, you discover that information about Fabrikam is stored in three party records: A, B, and C. You decide to keep party record A. Therefore, the information that is stored in party records B and C will be merged into party record A. There are some situations where you can't merge party records:

- You can't merge party records that are associated with the same party role, such as customer or vendor, in the same legal entity. For example, party A is associated with a

customer in legal entity 123, and party B is associated with a different customer in legal entity 123. These party records can't be merged, because if they were merged, the merged party record would be associated with multiple customers in the same legal entity, and this isn't allowed. However, the records can be merged if party B is associated with a vendor in legal entity 123 or with a customer in a different legal entity.
- You can't merge internal party organization records in the same legal entity, team, or operating unit.

Should I create a party record in the global address book or in another place, such as the Customer or Vendor page?

You can enter party records either in the global address book or on the appropriate entity page. When you add a record in one location, the same record is always added in the other location. For example, if you add a party record for a customer in the global address book, the record is also added on the **Customer** page. Likewise, if you add a party record for a customer on the **Customer** page, the record is also added in the global address book. Use the following guidelines to decide where you should enter new party records:

- **Creating a party record when you don't know the entity type** – If you must create a party record but don't know the entity type (for example, you don't know whether the entity is a customer or an opportunity), create the record in the global address book. You can select the entity type later.
- **Creating a party record when you know the entity type** – If you know the entity type for the party, you can create a record on the applicable page for that type. For example, create a record for a customer on the **Customer** page. When you create and save a record by using the appropriate entity page, the record is automatically created in the global address book.

Can I translate address information for party records?

You can set up translations of address information, so that the information appears in your user language (system language) in your program, but in another language on documents such as sales orders. You can enter translations for country/region names, address purposes, and name sequences. For example, your system language is Danish, and you create a sales order for a customer in France. In this case, you can view the customer record in Danish in the program but display the address information in French on the printed sales order. When you set up translations, you should enter a translation for every item in the list. Any item that you don't

enter a translation for will appear in the system language. For example, your system language is Danish, and you send a document to a customer in Spain. If you haven't entered Spanish (ESP) translations for the address information, that information will appear in Danish both in the program and on the printed document.

After I import addresses, why can't I edit the records?

When you import addresses, there is a field that is named **IsLocationOwner**. This field indicates whether the party that is associated with the location (address) is the owner of the address. If the party is the owner of the address, the address can be edited when the party is used in the global address book or from the master record page (such as the customer, vendor, or worker). If the party isn't the owner of the address, the record can't be edited.

When you import addresses, the **IsLocationOwner** field should be set to **Yes** if you want the address to be editable by using the associated party. If this field is incorrectly imported, the location owner can be updated in the global address book.

For more information about how to change the location owner of an imported address, see Managing location owners.

If the party type is Legal entity or Team, will the global address book synchronize the customer record?

No, the global address book won't synchronize the customer. Because Customer's V3 mapping supports only the **Person** party type for contacts and **Organization** party type for accounts, the record doesn't reach Dataverse, and no errors are displayed. A separate party record of the **Person** or **Organization** types must be created.

> **Note**
>
> Data can't be deleted using excel due to dependency on the platform. Users can remove addresses using the **Manage addresses** page.

Configure address books

Summarize this article for me

> **Note**
>
> Community interest groups have now moved from Yammer to Microsoft Viva Engage. To join a Viva Engage community and take part in the latest discussions, fill out the Request access to Finance and Operations Viva Engage Community form and choose the community you want to join.

Use this procedure and the decisions you made when planning the configuration of the global address book and additional address books to set up additional address books for your organization.

The demo data company used to create this task is USMF.

Configure address books

1. In the **Navigation pane**, go to **Modules** > **Organization administration** > **Global address book** > **Address books**.
2. Select **New**.
3. Enter a value in the **Name** field.
4. Enter a value in the **Description** field.
5. Select **Save**.
6. In the list, find and select the record you want.
7. Select the arrow to add the selected available teams to the address book.
8. Select **Save**.

This article describes the workflow system.

What is workflow?

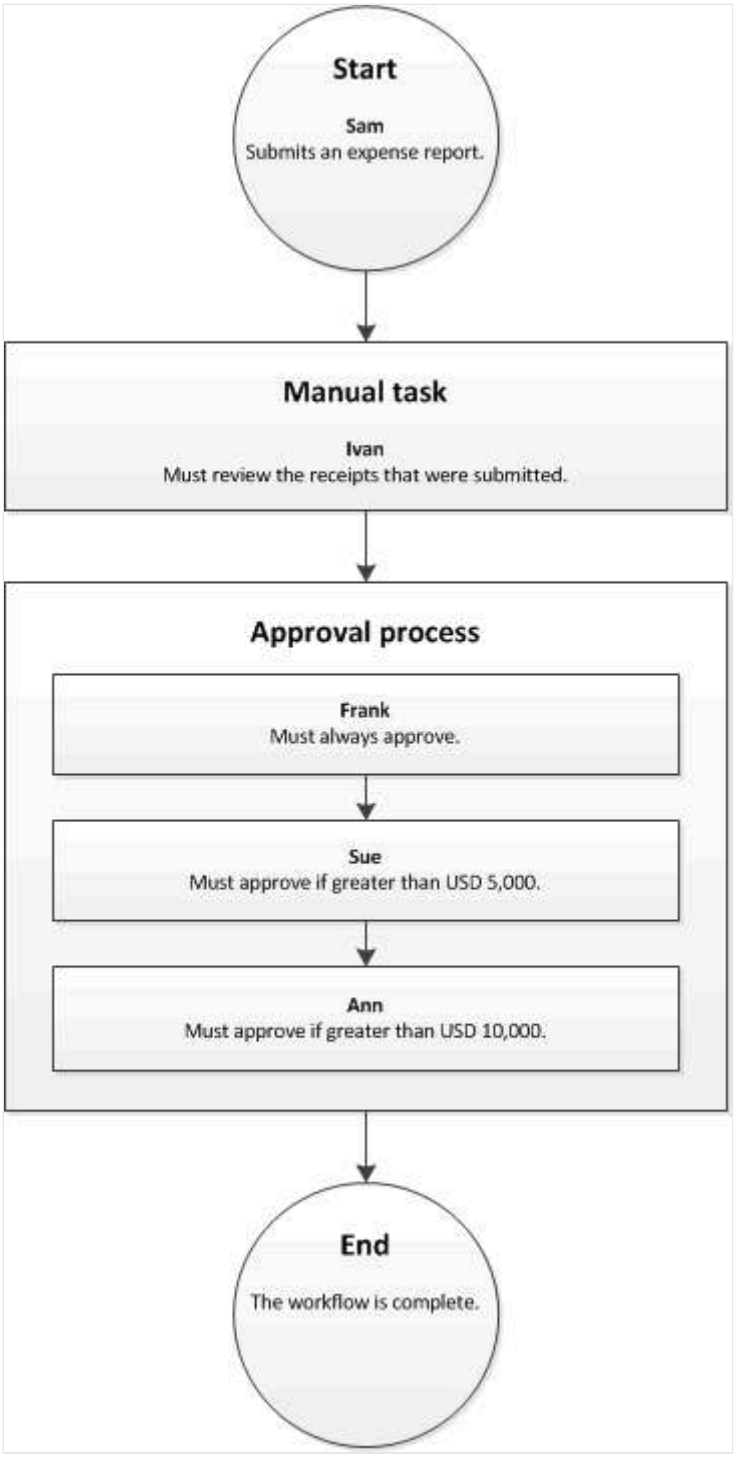
You can define the term *workflow* in two ways: as a system and as a business process.

Workflow is a system

Workflow is a system that runs on the Application Object Server (AOS). The workflow system provides functionality that you can use to create individual workflows, or business processes.

Workflow is a business process

A workflow represents a business process. It defines how a document flows, or moves, through the system by showing who must complete a task, make a decision, or approve a document. For example, the following illustration shows a workflow for expense reports.



To better understand this workflow, suppose that Sam submits an expense report for USD 7,000. In this scenario, Ivan must review the receipts that Sam submitted. Then Frank and Sue must approve the expense report. Now suppose that Sam submits an expense report for USD 11,000. In this scenario, Ivan must review the receipts, and Frank, Sue, and Ann must approve the expense report.

Benefits of using the workflow system

Use the workflow system in your organization to get these benefits:

- **Consistent processes** – Define how to process specific documents, such as purchase requisitions and expense reports. By using the workflow system, you ensure that documents are processed and approved in a consistent and efficient manner.
- **Process visibility** – Track the status, history, and performance metrics of workflow instances. This information helps you determine whether you need to make changes to the workflow to improve efficiency.
- **Centralized work list** – View a centralized work list that displays the workflow tasks and approvals assigned to you.

Workflow system architecture

This article describes the architecture of the workflow system.

The workflow infrastructure consists of two components that AOS hosts: the X++ workflow runtime and the managed workflow runtime.

The X++ workflow runtime consists of the following components:

- Workflow runtime application programming interface (API)
- A messaging batch job
- A message queue

Either the messaging batch job or the workflow runtime API can invoke the application code, if it's required. The X++ workflow runtime compiles into the Common Intermediate Language (CIL) of the Microsoft .NET Framework.

The managed workflow runtime consists of the Windows Workflow Foundation and finance and operations apps extensions.

Logically, the workflow infrastructure is an extension and is transparent to users. Physically, AOS hosts both the X++ workflow and the managed workflow runtimes. The workflow infrastructure uses batch processing on AOS and .NET Interop to integrate both subsystems, and to pass messages from one subsystem to the other. The X++ code that runs in the batch processor compiles to .NET CIL. The batch processing runs in the .NET common language runtime (CLR).
